If the width or height of a destination rectangle is greater than or equal to 32 pixels, the function uses the 32-by-32 pixel icon with the appropriate bit depth for the display device. If the destination rectangle is less than 32 by 32 pixels and greater than 16 pixels wide or 12 pixels high, the function uses the 16-by-16 pixel icon with the appropriate bit depth. If the destination rectangle's height is less than or equal to 12 pixels or its width is less than or equal to 16 pixels, the function uses the 12-by-16 pixel icon with the appropriate bit depth. (Typically, only the Finder and Standard File Package use 12-by-16 pixel icons.)

The destination rectangle passed in the `theRect` parameter must be exactly 32 by 32 pixels, 16 by 16 pixels, or 12 by 16 pixels for the function to draw the icon without stretching it. If the destination rectangle is not one of these standard sizes, the function expands or shrinks the icon to fit.

align

Specifies how the function should align the icon within the rectangle. For example, you can specify that the function center the icon within the rectangle or align it at one side or the other. See "Icon Alignment Constants" (page 1307) for a description of the values you can use here.

transform

Specifies how the function should modify the appearance of the icon. See "Icon Transformation Constants" (page 1309) for a description of the values you can use here.

If you don't specify a label constant in this parameter, the function displays the icon using the default label for that icon suite. When you create an icon suite using the `GetIconSuite` (page 1257) function or the `NewIconSuite` (page 1273) function, these functions set the default label for the suite to none. To set a new default label for an icon suite, use the `SetSuiteLabel` (page 1300) function.

theIconSuite

A handle to the icon suite from which the function gets the icon to draw. You can get a handle to an icon suite using the `GetIconSuite` or `NewIconSuite` functions.

Return Value

A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Special Considerations

This function may move or purge memory blocks in the application heap. For that reason, your application should not call it at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In
`Icons.h`

PlotSICNHandle

Draws a small icon of resource type `'SICN'` to which you have a handle. (Deprecated in Mac OS X v10.5. Use Icon Services instead.)

```
OSErr PlotSICNHandle (
   const Rect *theRect,
   IconAlignmentType align,
   IconTransformType transform,
   Handle theSICN
);
```

Parameters

theRect
A pointer to the rectangle in which to draw the icon, specified in local coordinates of the current graphics port.

align
Specifies how the function should align the icon within the rectangle. See "Icon Alignment Constants" (page 1307) for a description of the values you can use in this parameter.

transform
Specifies how the function should modify the appearance of the icon. See "Icon Transformation Constants" (page 1309) for a description of the values you can use in this parameter.

theSICN
A handle to the icon to draw. You can obtain a handle to the icon using `GetResource` or other Resource Manager functions.

Return Value
A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Discussion
Only `'SICN'` resources with a single member—or with two members, the second of which is a mask for the first—plot correctly.

Special Considerations

This function may move or purge memory blocks in the application heap. For that reason, your application should not call it at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Icons.h`

PtInIconID

Determines whether a specified point is within an icon. (Deprecated in Mac OS X v10.5. Use Icon Services instead.)

```
Boolean PtInIconID (
   Point testPt,
   const Rect *iconRect,
   IconAlignmentType align,
   SInt16 iconID
);
```

Parameters

testPt

The point to be tested, specified in local coordinates of the current graphics port. A point is considered to be within an icon if the point is within the icon's mask.

iconRect

A pointer to the rectangle in which the icon appears, specified in local coordinates of the current graphics port. The function determines, from the size of the rectangle specified in this parameter, which icon mask from the given icon family to test the point against. The rectangle which you specify here should be the same rectangle that you last used to draw the icon. The function then uses the location of this rectangle (and the alignment of the icon in the rectangle) to determine whether the specified point is within the icon.

align

Specifies how the icon against which to hit-test is aligned within the rectangle specified by the `iconRect` parameter. The alignment which you specify here should be the same alignment that you last used to draw the icon. See "Icon Alignment Constants" (page 1307) for a description of the values you can use in this parameter.

iconID

A resource ID for an icon family. In general, you should specify your icon resources as purgeable.

Return Value

`TRUE` if the point is in the icon and `FALSE` if it is not.

Special Considerations

This function may move or purge memory blocks in the application heap. For that reason, your application should not call it at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Icons.h`

PtInIconMethod

Determines whether a specified point is within an icon obtained with the aid of your icon getter callback function. (Deprecated in Mac OS X v10.5. Use Icon Services instead.)

```
Boolean PtInIconMethod (
   Point testPt,
   const Rect *iconRect,
   IconAlignmentType align,
   IconGetterUPP theMethod,
   void *yourDataPtr
);
```

Parameters

testPt

The point to be tested, specified in local coordinates of the current graphics port. A point is considered to be within an icon if the point is within the icon's mask.

iconRect

A pointer to the rectangle in which the icon appears, specified in local coordinates of the current graphics port. The rectangle which you specify here should be the same rectangle that you last used to draw the icon.

align

Specifies how the icon against which to hit-test is aligned within the rectangle specified by the `iconRect` parameter. The alignment which you specify here should be the same alignment that you last used to draw the icon. See "Icon Alignment Constants" (page 1307) for a description of the values you can use in this parameter.

theMethod

A universal procedure pointer to your icon getter callback function. `PtInIconMethod` passes to your icon getter function the type of icon your function should retrieve (either `'ICN#'` or `'ics#'`) and also passes the value specified in the `yourDataPtr` parameter. The `PtInIconMethod` function examines the size of the specified rectangle and requests the appropriate icon from your icon getter function. Your icon getter function should return a handle to the requested icon's data. The `PtInIconMethod` function extracts the mask from the icon data that your icon getter function returns. If your icon getter function returns data that does not correspond to an icon of type `'ICN#'` or type `'ics#'`, `PtInIconMethod` attempts to generate a mask from the returned data.

Your icon getter function can get the icon's data using whatever method is appropriate to your application. For example, your application might maintain its own cache of icons (and pass a pointer to it in the `yourDataPtr` parameter) or use its icon getter function to get an icon from the desktop database.

See the `IconGetterProcPtr` (page 1303) callback for more information on creating an icon getter function.

yourDataPtr

A pointer to data that is passed to your icon getter function.

Return Value

`TRUE` if the point is in the icon and `FALSE` if it is not.

Special Considerations

This function may move or purge memory blocks in the application heap. For that reason, your application should not call it at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In
`Icons.h`

PtInIconRef

Tests whether a specified point falls within an icon's mask. (Deprecated in Mac OS X v10.5. Use `IconRefContainsCGPoint` (page 1262) instead.)

```
Boolean PtInIconRef (
   const Point *testPt,
   const Rect *iconRect,
   IconAlignmentType align,
   IconServicesUsageFlags theIconServicesUsageFlags,
   IconRef theIconRef
);
```

Parameters

testPt
A pointer to the location, specified in local coordinates of the current graphics port, that Icon Services tests to see whether it falls within the mask of the indicated icon.

iconRect
A pointer to the rectangle defining the area that Icon Services uses to determine which icon is hit-tested. Use the same `Rect` value as when the icon was last drawn.

align
A value that specifies how the indicated icon is aligned within the rectangle specified in the `iconRect` parameter. Use the same `IconAlignmentType` value as when the icon was last drawn. for a description of possible return values, see "Icon Alignment Constants" (page 1307).

theIconServicesUsageFlags
Reserved for future use. Pass the `kIconServicesNormalUsageFlag` constant in this parameter.

theIconRef
The icon to be tested.

Return Value
`true` if the point specified in the `testPt` parameter falls within the appropriate icon mask, `false` otherwise.

Discussion
This function is similar to the Icon Utilities function `PtInIconSuite`. The function is useful when you want to determine whether a user has clicked on a particular icon, for example.

Icon Services uses the icon's black-and-white mask for hit-testing, even if you provide a deep mask.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Icons.h`

PtInIconSuite

Determines whether a specified point is within an icon. (Deprecated in Mac OS X v10.5. Use Icon Services instead.)

```
Boolean PtInIconSuite (
   Point testPt,
   const Rect *iconRect,
   IconAlignmentType align,
   IconSuiteRef theIconSuite
);
```

Parameters

testPt

The point to be tested, specified in local coordinates of the current graphics port. A point is considered to be within an icon if the point is within the icon's mask.

iconRect

A pointer to the rectangle in which the icon appears, specified in local coordinates of the current graphics port. The function determines, from the size of the rectangle specified in this parameter, which icon mask (`'ICN#'` or `'ics#'`) from the specified icon suite to test the point against. The function then uses the location of this rectangle (and the location of the icon in the rectangle) to determine whether the given point is within the icon. The rectangle which you specify here should be the same rectangle that you last used to draw the icon.

align

Specifies how the icon against which to hit-test is aligned within the rectangle specified by the `iconRect` parameter. The alignment which you specify here should be the same alignment that you last used to draw the icon. See "Icon Alignment Constants" (page 1307) for a description of the values you can use in this parameter.

theIconSuite

A handle to an icon suite.

Return Value

`TRUE` if the point is in the icon and `FALSE` if it is not.

Special Considerations

This function may move or purge memory blocks in the application heap. For that reason, your application should not call it at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Icons.h`

ReadIconFile

Copies data from a given file into an icon family. (Deprecated in Mac OS X v10.5. Use `ReadIconFromFSRef` (page 1289) instead.)

```
OSErr ReadIconFile (
   const FSSpec *iconFile,
   IconFamilyHandle *iconFamily
);
```

Parameters

iconFile

A pointer to the file specification structure for the source file for icon data.

iconFamily

A handle to an `iconFamily` data structure to be used as the target data structure. Icon Services resizes the handle as needed. For more information on the `IconFamily` data structure, see 'icns'.

Return Value
A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`IconsCore.h`

ReadIconFromFSRef

Reads an icon ('`icns`') file into memory.

```
OSStatus ReadIconFromFSRef (
   const FSRef *ref,
   IconFamilyHandle *iconFamily
);
```

Parameters

ref

A pointer to the `FSRef` for the icon file.

iconFamily

A pointer to the handle for the icon family.

Return Value
A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Availability
Available in Mac OS X v10.1 and later.

Declared In
`IconsCore.h`

RectInIconID

Hit-tests a rectangle against the appropriate icon mask from an icon family for a specified destination rectangle and alignment. (Deprecated in Mac OS X v10.5. Use Icon Services instead.)

```
Boolean RectInIconID (
   const Rect *testRect,
   const Rect *iconRect,
   IconAlignmentType align,
   SInt16 iconID
);
```

Parameters

testRect

A pointer to the rectangle to be tested, specified in local coordinates of the current graphics port.

iconRect

A pointer to the rectangle in which the icon appears, specified in local coordinates of the current graphics port. The rectangle which you specify here should be the same rectangle that you last used to draw the icon. Like the `PtInIconID` (page 1285) function, this function determines, from the size of the rectangle specified in this parameter, which icon mask from the icon family to test the `testRect` parameter against.

align

Specifies how the icon against which to hit-test is aligned within the rectangle specified by `iconRect`. The alignment which you specify here should be the same alignment that you last used to draw the icon. See "Icon Alignment Constants" (page 1307) for a description of the values you can use in this parameter.

iconID

A resource ID for an icon family. In general, you should specify your icon resources as purgeable.

Return Value

`TRUE` if the rectangle intersects the icon and `FALSE` if it doesn't.

Special Considerations

This function may move or purge memory blocks in the application heap. For that reason, your application should not call it at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Icons.h`

RectInIconMethod

Hit-tests a rectangle against an icon obtained by your icon getter callback function for a specified destination rectangle and alignment. (Deprecated in Mac OS X v10.5. Use Icon Services instead.)

```
Boolean RectInIconMethod (
   const Rect *testRect,
   const Rect *iconRect,
   IconAlignmentType align,
   IconGetterUPP theMethod,
   void *yourDataPtr
);
```

Parameters

testRect

A pointer to the rectangle to be tested, specified in local coordinates of the current graphics port.

iconRect

A pointer to the rectangle in which the icon appears, specified in local coordinates of the current graphics port. The rectangle which you specify here should be the same rectangle that you last used to draw the icon.

align

Specifies how the icon against which to hit-test is aligned within the rectangle specified by `iconRect`. The alignment which you specify here should be the same alignment that you last used to draw the icon. See "Icon Alignment Constants" (page 1307) for a description of the values you can use in this parameter.

theMethod

A universal procedure pointer to your icon getter callback function. `RectInIconMethod` passes to your icon getter function the type of the icon your function should retrieve and the value specified in the `yourDataPtr` parameter. The `RectInIconMethod` function examines the size of the rectangle and requests the appropriate icon from your icon getter function—an icon of icon type `'ICN#'` or `'ics#'`. Your icon getter function should return a handle to the data of the requested icon type. The `RectInIconMethod` function extracts the mask from the icon data that your icon getter function returns. If your icon getter function returns data that does not correspond to an icon of type `'ICN#'` or type `'ics#'`, `RectInIconMethod` attempts to generate a mask from the returned data.

Your icon getter function can get the data for the icon and its mask using whatever method is appropriate to your application. For example, your application might maintain its own cache of icons (and pass a pointer to it in the `yourDataPtr` parameter) or use its icon getter function to get an icon from the desktop database.

See the `IconGetterProcPtr` (page 1303) callback for more information on creating an icon getter function.

yourDataPtr

A pointer to data that is passed to your icon getter function.

Return Value

`TRUE` if the rectangle intersects the icon and `FALSE` if it doesn't.

Special Considerations

This function may move or purge memory blocks in the application heap. For that reason, your application should not call it at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Icons.h`

RectInIconRef

Tests whether a specified rectangle falls within an icon's mask. (Deprecated in Mac OS X v10.5. Use `IconRefIntersectsCGRect` (page 1263) instead.)

```
Boolean RectInIconRef (
   const Rect *testRect,
   const Rect *iconRect,
   IconAlignmentType align,
   IconServicesUsageFlags iconServicesUsageFlags,
   IconRef theIconRef
);
```

Parameters

testRect

A pointer to the rectangle, specified in local coordinates of the current graphics port, that Icon Services tests to see whether it falls within the mask of the indicated icon.

iconRect

A pointer to the area that Icon Services uses to determine which icon is hit-tested. Use the same `Rect` value as when the icon was last drawn.

align

A value that specifies how the indicated icon is aligned within the rectangle specified in the `iconRect` parameter. Use the same `IconAlignmentType` value as when the icon was last drawn. for a description of possible return values, see "Icon Alignment Constants" (page 1307).

iconServicesUsageFlags

Reserved for future use. Pass the `kIconServicesNormalUsageFlag` constant in this parameter.

theIconRef

A pointer to a value of type `IconRef` specifying the icon family to use for drawing the requested icon.

Return Value

`true` if the rectangle specified in the `testRect` parameter intersects the appropriate icon mask, `false` otherwise.

Discussion

This function is similar to the Icon Utilities function `RectInIconSuite`. The function is useful when you want to determine whether a user selection intersects a particular icon, for example.

Icon Services uses the icon's black-and-white mask for hit-testing, even if you provide a deep mask.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Icons.h`

RectInIconSuite

Hit-tests a rectangle against the appropriate icon mask from an icon suite for a specified destination rectangle and alignment. (Deprecated in Mac OS X v10.5. Use Icon Services instead.)

```
Boolean RectInIconSuite (
   const Rect *testRect,
   const Rect *iconRect,
   IconAlignmentType align,
   IconSuiteRef theIconSuite
);
```

Parameters

testRect

A pointer to the rectangle to be tested, specified in local coordinates of the current graphics port.

iconRect

A pointer to the rectangle in which the icon appears, specified in local coordinates of the current graphics port. The rectangle which you specify here should be the same rectangle that you last used to draw the icon. Like the `PtInIconSuite` (page 1288) function, this function determines, from the size of the rectangle specified in this parameter, which icon mask from the icon suite specified by `theIconSuite` to test the test rectangle against. For example, if the coordinates of the `iconRect` parameter are (100,100,116,116) and the icon cache contains entries for each icon family member, `RectInIconSuite` uses the icon mask defined by the `'ics#'` entry.

The function then intersects the rectangle specified by `testRect` with the icon mask in the `iconRect` rectangle.

align

Specifies how the icon against which to hit-test is aligned within the rectangle specified by `iconRect`. The alignment which you specify here should be the same alignment that you last used to draw the icon. See "Icon Alignment Constants" (page 1307) for a description of the values you can use in this parameter.

theIconSuite

A handle to an icon suite.

Return Value

`TRUE` if the rectangle intersects the icon and `FALSE` if it doesn't.

Special Considerations

This function may move or purge memory blocks in the application heap. For that reason, your application should not call it at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Icons.h`

RegisterIconRefFromFSRef

Registers an `IconRef` from a `.icns` file and associates it with a creator and type pair.

```
OSStatus RegisterIconRefFromFSRef (
   OSType creator,
   OSType iconType,
   const FSRef *iconFile,
   IconRef *theIconRef
);
```

Parameters

creator

The creator code for the `.icns` file.

iconType

The type code for the `.icns` file.

iconFile

A pointer to the `FSRef` of the `.icns` file.

theIconRef

A pointer to an `IconRef`. On return, this contains the registered `IconRef`.

Return Value
A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Availability
Available in Mac OS X v10.1 and later.

Declared In
`IconsCore.h`

RegisterIconRefFromIconFamily

Adds an `iconFamily`-derived `IconRef` to the Icon Services registry.

```
OSErr RegisterIconRefFromIconFamily (
   OSType creator,
   OSType iconType,
   IconFamilyHandle iconFamily,
   IconRef *theIconRef
);
```

Parameters

creator

The creator code of the desired icon. You can use your application's creator code, for example. Lower-case creator codes are reserved for the System.

iconType

The type code of the desired icon.

iconFamily

A handle to the `iconFamily` data structure to register.

theIconRef

On return, a pointer to the desired icon data.

Return Value
A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Discussion
Consider using the function `RegisterIconRefFromIconFile` (page 1295), since the data registered using the `RegisterIconRefFromIconFamily` function cannot be purged. You are responsible for disposing of the `IconRef` by using the function `ReleaseIconRef` (page 1296).

Calling this function increments the reference count of the `IconRef`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`IconsCore.h`

RegisterIconRefFromIconFile

Adds a file-derived `IconRef` to the Icon Services registry. (Deprecated in Mac OS X v10.5. Use `RegisterIconRefFromFSRef` (page 1293) instead.)

```
OSErr RegisterIconRefFromIconFile (
   OSType creator,
   OSType iconType,
   const FSSpec *iconFile,
   IconRef *theIconRef
);
```

Parameters

creator
The creator code of the icon data you wish to register. You can use your application's creator code, for example. Lower-case creator codes are reserved for the system.

iconType
The type code of the icon data you wish to register.

iconFile
A pointer to the file system specification structure for the file to use as the icon data source.

theIconRef
On return, a pointer to the desired icon data.

Return Value
A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`IconsCore.h`

RegisterIconRefFromResource

Adds a resource-derived `IconRef` to the Icon Services registry. (Deprecated in Mac OS X v10.5. Use `RegisterIconRefFromFSRef` (page 1293) instead.)

```
OSErr RegisterIconRefFromResource (
   OSType creator,
   OSType iconType,
   const FSSpec *resourceFile,
   SInt16 resourceID,
   IconRef *theIconRef
);
```

Parameters

creator

The creator code of the icon data you wish to register. You can use your application's creator code, for example. Lower-case creator codes are reserved for the system.

iconType

The type code of the icon data you wish to register.

resourceFile

A pointer to the file system specification structure for the resource file from which to read the icon data.

resourceID

The resource ID of the icon data to be registered. This value must be non-zero.

You should provide a resource of type `'icns'` if possible. If an `'icns'` resource is not available, Icon Services uses standard icon suite resources, such as `'ICN#'`, instead.

theIconRef

On return, a pointer to the desired icon data.

Return Value

A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Discussion

You can use the `RegisterIconRefFromResource` function to register icons from `'icns'` resources or "classic" custom icon resources (`'ics#'` , `'ICN#'` , etc.). Icon Services searches `'icns'` resources before searching other icon resources.

Calling this function increments the reference count of the `IconRef`.

Remember to call the function `ReleaseIconRef` (page 1296) when you're done with an `IconRef`.

Special Considerations

Before using the recommended replacement function, you need to move the contents of the icon resource into an icon family `.icns` file.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`IconsCore.h`

ReleaseIconRef

Decrements the reference count for an `IconRef`.

```
OSErr ReleaseIconRef (
   IconRef theIconRef
);
```

Parameters

theIconRef

An `IconRef` whose reference count you wish to decrement.

Return Value

A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Discussion

When an `IconRef`'s reference count reaches 0, all memory allocated for the `IconRef` is marked as disposable. Any subsequent attempt to use the `IconRef` returns a result code of - `2580` (`invalidIconRefErr`).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`IconsCore.h`

RemoveIconRefOverride

Restores the original bitmaps of an overridden `IconRef`.

```
OSErr RemoveIconRefOverride (
   IconRef theIconRef
);
```

Parameters

theIconRef

A pointer to a value of type `IconRef` whose bitmaps are to be restored.

Return Value

A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`IconsCore.h`

SetCustomIconsEnabled

Enables or disables custom icons on a specified volume.

```
OSErr SetCustomIconsEnabled (
   SInt16 vRefNum,
   Boolean enableCustomIcons
);
```

Parameters

vRefNum

The volume where custom icons are to be enabled or disabled.

enableCustomIcons
If you pass `true`, custom icons are enabled on the volume specified. Passing `false` disables custom icons on the volume specified.

Return Value
A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Discussion
If you use the `SetCustomIconsEnabled` function to enable or disable custom icons, the setting remains in effect only as long as the specified volume remains mounted during the current session.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`IconsCore.h`

SetIconCacheData

Sets the data associated with an icon cache. (Deprecated in Mac OS X v10.5. Use Icon Services instead.)

```
OSErr SetIconCacheData (
   IconCacheRef theCache,
   void *theData
);
```

Parameters
theCache
A reference to the icon cache whose data is to be set.

theData
A pointer to the data to set.

Return Value
A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Discussion
All the Icon Utilities functions that accept a handle to an icon suite also accept a handle to an icon cache.

Special Considerations

This function may move or purge memory blocks in the application heap. For that reason, your application should not call it at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Icons.h`

SetIconCacheProc

Sets the icon getter callback function associated with an icon cache. (Deprecated in Mac OS X v10.5. Use Icon Services instead.)

```
OSErr SetIconCacheProc (
   IconCacheRef theCache,
   IconGetterUPP theProc
);
```

Parameters

theCache

A reference to the icon cache whose icon getter function is to be set.

theProc

A universal procedure pointer to the icon getter callback function to associate with the specified cache. See the `IconGetterProcPtr` (page 1303) callback for more information on icon getter functions.

Return Value

A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Discussion

All the Icon Utilities functions that accept a handle to an icon suite also accept a handle to an icon cache. An icon cache is like an icon suite except that it also contains a pointer to an icon getter callback function and a pointer to data that can be used as a reference constant. An icon cache typically does not contain handles to the icon resources for all icon family members. Instead, if the icon cache does not contain an entry for a specific type of icon in an icon family, the Icon Utilities functions call your application's icon getter function to retrieve the data for that icon type.

Special Considerations

This function may move or purge memory blocks in the application heap. For that reason, your application should not call it at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Icons.h`

SetIconFamilyData

Provides new raw icon data for an individual element of an icon family.

```
OSErr SetIconFamilyData (
   IconFamilyHandle iconFamily,
   OSType iconType,
   Handle h
);
```

Parameters

iconFamily

A handle to an `iconFamily` data structure to be used as the target.

iconType

The format of the icon data you provide.You may specify one of the icon types (as defined in `IconStorage.h` in the CoreServices/OSServices framework) or `'PICT'` in this parameter. For a thumbnail icon, for example, you specify `kThumbnail32BitData` in this parameter. For a thumbnail mask, you specify `kThumbnail8BitMask`.

h

A handle to the icon data you provide. For a thumbnail icon, the handle contains raw image data in the form of 128x128, four bytes per pixel, RGB data. For a thumbnail mask, the data is in the same format except that it is one byte per pixel.

Return Value
A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Icons.h`

SetSuiteLabel

Specifies the default label associated with an icon suite. (Deprecated in Mac OS X v10.5. Use Icon Services instead.)

```
OSErr SetSuiteLabel (
   IconSuiteRef theSuite,
   SInt16 theLabel
);
```

Parameters

theSuite

A handle to an icon suite.

theLabel

An integer from 1 to 7 that specifies a label for the icon suite, or 0 to set the icon suite's label to none. The default label setting helps to determine which of the label colors shown in the Finder's Label menu is applied to icons of that suite when your application displays them.

You can override the default label setting for a suite by specifying a label in the `transform` parameter of the `PlotIconSuite` (page 1282) function. For example, suppose the color currently set for the third label displayed in the Finder's Label menu is red, and the color for the fourth label is green. If you set the default label for a suite using `SetSuiteLabel(theSuite,3)`, then draw an icon from the same suite using `PlotIconSuite` and specifying `kTransformNone` in the `transform` parameter, the label color red is applied to the icon. However, if you specify `kTransformLabel4` in the `transform` parameter of the `PlotIconSuite` function, the label color green is applied to the icon.

Return Value
A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Special Considerations

This function may move or purge memory blocks in the application heap. For that reason, your application should not call it at interrupt time.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Icons.h`

UnregisterIconRef

Removes the specified icon data from the icon registry.

```
OSErr UnregisterIconRef (
   OSType creator,
   OSType iconType
);
```

Parameters

creator
The creator code of the icon data to be unregistered.

iconType
The type code of the icon data to be unregistered.

Return Value
A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Discussion
The specified icon data is not unregistered until all its users have called the function `ReleaseIconRef` (page 1296).

You should not unregister an icon that you have not registered.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`IconsCore.h`

UpdateIconRef

Forces an update of `IconRef` data.

```
OSErr UpdateIconRef (
   IconRef theIconRef
);
```

Parameters

theIconRef
An `IconRef` to be updated.

Return Value
A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Discussion
This function is useful after you have changed a file or folder's custom icon, for example. Do not call the `UpdateIconRef` function if you have not already obtained an `IconRef` for a particular icon; call the function `GetIconRefFromFile` (page 1251) instead.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`IconsCore.h`

WriteIconFile

Copies data from a given icon family into a file. (Deprecated in Mac OS X v10.5. Use the File Manager instead.)

```
OSErr WriteIconFile (
   IconFamilyHandle iconFamily,
   const FSSpec *iconFile
);
```

Parameters

iconFamily
A handle to an `iconFamily` data structure to be used as a source for icon data. For more information on the `IconFamily` data structure, see 'icns'.

iconFile
A pointer to the file specification structure for the file to use as the target for icon data.

Return Value
A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Special Considerations

Icon Services is designed to read icon data from a file and cache the data, but not to write out icon data. You can use File Manager functions to write your icon data to a file.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`IconsCore.h`

Callbacks

IconActionProcPtr

Defines a pointer to an icon action callback function, which performs an action on a single icon.

```
typedef OSErr (*IconActionProcPtr) (
    ResType theType,
    Handle *theIcon,
    void *yourDataPtr
);
```

If you name your function `MyIconActionProc`, you would declare it like this:

```
OSErr MyIconActionProc (
    ResType theType,
    Handle *theIcon,
    void *yourDataPtr
);
```

Parameters

theType

The resource type of the icon.

theIcon

A pointer to the handle to the icon on which to perform the operation.

yourDataPtr

A pointer to data as specified in the `yourDataPtr` parameter of the `ForEachIconDo` function. When your application calls `ForEachIconDo`, it typically provides in the `yourDataPtr` parameter a value that identifies the action your function should perform.

Return Value

A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Discussion

You can perform operations on every icon in an icon suite by providing a pointer to an icon action function as a parameter to the `ForEachIconDo` (page 1244) function. The `ForEachIconDo` function calls your icon action function for specified icon resource types. Your icon action function should return a result code indicating whether it successfully performed the action on the icon.

Before using your icon action function, you must first create a new universal procedure pointer to it, using the `NewIconActionUPP` (page 1272) function, as shown here:

```
IconActionUPP MyIconActionUPP;
MyIconActionUPP = NewIconActionUPP(&MyIconActionProc)
```

You then pass `MyIconActionUPP` to the `ForEachIconDo` function. When you are finished with your icon action callback function, you should dispose of the universal procedure pointer associated with it:

```
DisposeIconActionUPP(MyIconActionUPP);
```

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Icons.h`

IconGetterProcPtr

Defines a pointer to an icon getter callback function, which retrieves a handle to an icon of the requested type.

```
typedef Handle (*IconGetterProcPtr) (
    ResType theType,
    void *yourDataPtr
);
```

If you name your function `MyIconGetterProc`, you would declare it like this:

```
Handle MyIconGetterProc (
    ResType theType,
    void *yourDataPtr
);
```

Parameters

theType

The resource type of the icon. In general, you should specify your icon resources as purgeable.

yourDataPtr

If your icon getter function was called by an icon cache function, this parameter contains, on return, a pointer to the data associated with the icon cache. Otherwise, this parameter contains the value your application specified in the `yourDataPtr` parameter. For icon caches, you initially set this value when you first create a cache using the `MakeIconCache` (page 1272) function. You can change this value using the `SetIconCacheData` (page 1298) function. The icon getter function can use this data as needed.

Return Value

An icon getter function should return as its function result a handle to the requested icon's data.

Discussion

If you use icon caches, you must provide at least one icon getter function. The `MakeIconCache` function takes a pointer to an icon getter function for use with a new icon cache. Subsequent calls to Icon Utilities functions that use icon types not present in the icon cache use the icon getter function associated with the icon cache to return a handle to the icon data. To get and set an existing icon cache's icon getter function, use the `GetIconCacheProc` (page 1247) and `SetIconCacheProc` (page 1299) functions.

You can also specify an icon getter function for use by the `PlotIconMethod` (page 1280), `IconMethodToRgn` (page 1261), `PtInIconMethod` (page 1285), and `RectInIconMethod` (page 1290) functions. Like Icon Utilities functions that work with icon caches, the icon getter function that you provide as a parameter to `PlotIconMethod` should return a handle to the requested icon's data. Note that the icon getter function that you provide as a parameter to `IconMethodToRgn`, `PtInIconMethod`, and `RectInIconMethod` should also return a handle to the requested icon; these three functions then extract the icon mask from the icon data your icon getter function returns.

Before using your icon getter function, you must first create a new universal procedure pointer to it, using the `NewIconGetterUPP` (page 1273) function, as shown here:

```
IconGetterUPP MyIconGetterUPP;
MyIconGetterUPP = NewIconGetterUPP(&MyIconGetterProc)
```

You can then pass `MyIconGetterUPP` to any of the Icon Utilities functions which use custom icon getter functions. When you are finished with your icon getter callback function, you should dispose of the universal procedure pointer associated with it, using the `DisposeIconGetterUPP` (page 1241) function:

```
DisposeIconGetterUPP(MyIconGetterUPP);
```

Availability

Available in Mac OS X v10.0 and later.

Declared In
`Icons.h`

Data Types

CIcon

Defines a color icon structure.

```
struct CIcon {
    PixMap iconPMap;
    BitMap iconMask;
    BitMap iconBMap;
    Handle iconData;
    SInt16 iconMaskData[1];
};
typedef struct CIcon CIcon;
typedef CIcon * CIconPtr;
```

Fields

`iconPMap`
The pixel map describing the icon. Note that this is a pixel map record, not a handle to a pixel map record.

`iconMask`
A bitmap of the icon's mask.

`iconBMap`
A bitmap of the icon.

`iconData`
A handle to the icon's pixel image.

`iconMaskData`
An array containing the icon's mask data followed by the icon's bitmap data. This is used only when the icon is stored as a resource.

Discussion
The `PlotCIcon` (page 1275), `PlotCIconHandle` (page 1276), `GetCIcon` (page 1244), and `DisposeCIcon` (page 1240) functions all use the `CIconHandle` data type to refer to a color icon structure. A color icon structure contains information about a color icon.

All color icon resources should be marked purgeable. You can use icons of resource type `'cicn'` in menus the same way that you use resources of type `'ICON'`. If a menu item specifies an icon number, the menu definition function first tries to load in a `'cicn'` resource with the specified resource ID. If it doesn't find one, the menu definition function tries to load in an `'ICON'` resource with the same ID. The Dialog Manager also uses a `'cicn'` resource instead of an `'ICON'` resource if it finds one with the same resource ID.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Icons.h`

IconRef

Defines an icon reference.

```
typedef struct OpaqueIconRef * IconRef;
```

Discussion
An `IconRef` is a 32–bit values identifying cached icon data. `IconRef` 0 is invalid.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`IconsCore.h`

IconActionUPP

Defines a universal procedure pointer (UPP) to an icon action callback function.

```
typedef IconActionProcPtr IconActionUPP;
```

Discussion
For more information, see the description of the `IconActionProcPtr` (page 1302) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Icons.h`

IconGetterUPP

Defines a universal procedure pointer to an icon getter callback function.

```
typedef IconGetterProcPtr IconGetterUPP;
```

Discussion
For more information, see the description of the `IconGetterProcPtr` (page 1303) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Icons.h`

IconCacheRef

Defines a reference to an icon cache.

```
typedef Handle IconCacheRef;
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Icons.h`

IconSuiteRef

Defines a reference to an icon suite.

```
typedef Handle IconSuiteRef;
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Icons.h`

Constants

Icon Alignment Constants

Define constants that allow you to specify how to align an icon within its rectangle.

```
enum {
    kAlignNone = 0x00,
    kAlignVerticalCenter = 0x01,
    kAlignTop = 0x02,
    kAlignBottom = 0x03,
    kAlignHorizontalCenter = 0x04,
    kAlignAbsoluteCenter = kAlignVerticalCenter | kAlignHorizontalCenter,
    kAlignCenterTop = kAlignTop | kAlignHorizontalCenter,
    kAlignCenterBottom = kAlignBottom | kAlignHorizontalCenter,
    kAlignLeft = 0x08,
    kAlignCenterLeft = kAlignVerticalCenter | kAlignLeft,
    kAlignTopLeft = kAlignTop | kAlignLeft,
    kAlignBottomLeft = kAlignBottom | kAlignLeft,
    kAlignRight = 0x0C,
    kAlignCenterRight = kAlignVerticalCenter | kAlignRight,
    kAlignTopRight = kAlignTop | kAlignRight,
    kAlignBottomRight = kAlignBottom | kAlignRight
};
typedef SInt16 IconAlignmentType;
```

Constants
`kAlignNone`
Use this value if you do not wish to specify a particular alignment.
Available in Mac OS X v10.0 and later.
Declared in `Icons.h`.

`kAlignVerticalCenter`
Use this value to center the icon vertically within the rectangle.
Available in Mac OS X v10.0 and later.
Declared in `Icons.h`.

`kAlignTop`
Use this value to top align the icon within the rectangle.
Available in Mac OS X v10.0 and later.
Declared in `Icons.h`.

`kAlignBottom`
Use this value to bottom align the icon within the rectangle.
Available in Mac OS X v10.0 and later.
Declared in `Icons.h`.

`kAlignHorizontalCenter`
Use this value to center the icon horizontally within the rectangle.
Available in Mac OS X v10.0 and later.
Declared in `Icons.h`.

`kAlignAbsoluteCenter`
Use this value to center the icon horizontally and vertically within the rectangle.
Available in Mac OS X v10.0 and later.
Declared in `Icons.h`.

`kAlignCenterTop`
Use this value to top align the icon and center it horizontally within the rectangle.
Available in Mac OS X v10.0 and later.
Declared in `Icons.h`.

`kAlignCenterBottom`
Use this value to bottom align the icon and center it horizontally within the rectangle.
Available in Mac OS X v10.0 and later.
Declared in `Icons.h`.

`kAlignLeft`
Use this value to left align the icon within the rectangle.
Available in Mac OS X v10.0 and later.
Declared in `Icons.h`.

`kAlignCenterLeft`
Use this value to left align the icon and center it vertically within the rectangle.
Available in Mac OS X v10.0 and later.
Declared in `Icons.h`.

`kAlignTopLeft`
Use this value to left and top align the icon within the rectangle.
Available in Mac OS X v10.0 and later.
Declared in `Icons.h`.

`kAlignBottomLeft`
Use this value to left and bottom align the icon within the rectangle.

Available in Mac OS X v10.0 and later.

Declared in `Icons.h`.

`kAlignRight`
Use this value to right align the icon within the rectangle.

Available in Mac OS X v10.0 and later.

Declared in `Icons.h`.

`kAlignCenterRight`
Use this value to right align the icon and center it vertically within the rectangle.

Available in Mac OS X v10.0 and later.

Declared in `Icons.h`.

`kAlignTopRight`
Use this value to right and top align the icon within the rectangle.

Available in Mac OS X v10.0 and later.

Declared in `Icons.h`.

`kAlignBottomRight`
Use this value to right and bottom align the icon within the rectangle.

Available in Mac OS X v10.0 and later.

Declared in `Icons.h`.

Discussion
Icon Services and Utilities functions use the `IconAlignmentType` constants to determine how an icon is aligned within its bounding rectangle.

Icon Transformation Constants

Define values that Icon Services uses to report how an icon has been transformed after you call the function `GetIconRefVariant`.

```
enum {
    kTransformNone = 0x00,
    kTransformDisabled = 0x01,
    kTransformOffline = 0x02,
    kTransformOpen = 0x03,
    kTransformLabel1 = 0x0100,
    kTransformLabel2 = 0x0200,
    kTransformLabel3 = 0x0300,
    kTransformLabel4 = 0x0400,
    kTransformLabel5 = 0x0500,
    kTransformLabel6 = 0x0600,
    kTransformLabel7 = 0x0700,
    kTransformSelected = 0x4000,
    kTransformSelectedDisabled = kTransformSelected | kTransformDisabled,
    kTransformSelectedOffline = kTransformSelected | kTransformOffline,
    kTransformSelectedOpen = kTransformSelected | kTransformOpen
};
typedef SInt16 IconTransformType;
```

Discussion
The functions `PlotIconID` (page 1279)`PlotIconMethod` (page 1280), `PlotIconHandle` (page 1278), `PlotCIconHandle` (page 1276), `PlotIconSuite` (page 1282), `LoadIconCache` (page 1270) and `PlotSICNHandle` (page 1284) use these constants to specify how an icon should be modified, if at all, when plotted.

Icon Selector Constants

Describe values that you can use to obtain information about the sizes and depths of icons available in a given icon family.

```
enum {
    kSelectorLarge1Bit = 0x00000001,
    kSelectorLarge4Bit = 0x00000002,
    kSelectorLarge8Bit = 0x00000004,
    kSelectorLarge32Bit = 0x00000008,
    kSelectorLarge8BitMask = 0x00000010,
    kSelectorSmall1Bit = 0x00000100,
    kSelectorSmall4Bit = 0x00000200,
    kSelectorSmall8Bit = 0x00000400,
    kSelectorSmall32Bit = 0x00000800,
    kSelectorSmall8BitMask = 0x00001000,
    kSelectorMini1Bit = 0x00010000,
    kSelectorMini4Bit = 0x00020000,
    kSelectorMini8Bit = 0x00040000,
    kSelectorHuge1Bit = 0x01000000,
    kSelectorHuge4Bit = 0x02000000,
    kSelectorHuge8Bit = 0x04000000,
    kSelectorHuge32Bit = 0x08000000,
    kSelectorHuge8BitMask = 0x10000000,
    kSelectorAllLargeData = 0x000000FF,
    kSelectorAllSmallData = 0x0000FF00,
    kSelectorAllMiniData = 0x00FF0000,
    kSelectorAllHugeData = 0xFF000000,
    kSelectorAll1BitData = kSelectorLarge1Bit | kSelectorSmall1Bit
| kSelectorMini1Bit | kSelectorHuge1Bit,
    kSelectorAll4BitData = kSelectorLarge4Bit | kSelectorSmall4Bit
| kSelectorMini4Bit | kSelectorHuge4Bit,
    kSelectorAll8BitData = kSelectorLarge8Bit | kSelectorSmall8Bit
| kSelectorMini8Bit | kSelectorHuge8Bit,
    kSelectorAll32BitData = kSelectorLarge32Bit | kSelectorSmall32Bit
| kSelectorHuge32Bit,
    kSelectorAllAvailableData = 0xFFFFFFFF
};
typedef UInt32 IconSelectorValue;
```

Constants

`kSelectorLarge1Bit`
Specify to include `'ICN#'` resource.
Available in Mac OS X v10.0 and later.
Declared in `Icons.h`.

`kSelectorLarge4Bit`
Specify to include `'icl4'` resource.
Available in Mac OS X v10.0 and later.
Declared in `Icons.h`.

`kSelectorLarge8Bit`
Specify to include `'icl8'` resource.
Available in Mac OS X v10.0 and later.
Declared in `Icons.h`.

`kSelectorLarge32Bit`
Available in Mac OS X v10.0 and later.
Declared in `Icons.h`.

`kSelectorLarge8BitMask`
Available in Mac OS X v10.0 and later.
Declared in `Icons.h`.

`kSelectorSmall1Bit`
Specify to include `'ics#'` resource.
Available in Mac OS X v10.0 and later.
Declared in `Icons.h`.

`kSelectorSmall4Bit`
Specify to include `'ics4'` resource.
Available in Mac OS X v10.0 and later.
Declared in `Icons.h`.

`kSelectorSmall8Bit`
Specify to include `'ics8'` resource.
Available in Mac OS X v10.0 and later.
Declared in `Icons.h`.

`kSelectorSmall32Bit`
Available in Mac OS X v10.0 and later.
Declared in `Icons.h`.

`kSelectorSmall8BitMask`
Available in Mac OS X v10.0 and later.
Declared in `Icons.h`.

`kSelectorMini1Bit`
Specify to include `'icm#'` resource.
Available in Mac OS X v10.0 and later.
Declared in `Icons.h`.

`kSelectorMini4Bit`
Specify to include `'icm4'` resource.
Available in Mac OS X v10.0 and later.
Declared in `Icons.h`.

`kSelectorMini8Bit`
Specify to include `'icm8'` resource.
Available in Mac OS X v10.0 and later.
Declared in `Icons.h`.

`kSelectorHuge1Bit`
Available in Mac OS X v10.0 and later.
Declared in `Icons.h`.

`kSelectorHuge4Bit`
Available in Mac OS X v10.0 and later.
Declared in `Icons.h`.

`kSelectorHuge8Bit`
Available in Mac OS X v10.0 and later.
Declared in `Icons.h`.

`kSelectorHuge32Bit`
Available in Mac OS X v10.0 and later.
Declared in `Icons.h`.

`kSelectorHuge8BitMask`
Available in Mac OS X v10.0 and later.
Declared in `Icons.h`.

`kSelectorAllLargeData`
Specify to include `'ICN#'`, `'icl4'`, and `'icl8'` resources.
Available in Mac OS X v10.0 and later.
Declared in `Icons.h`.

`kSelectorAllSmallData`
Specify to include `'ics#'`, `'ics4'`, and `'ics8'` resources.
Available in Mac OS X v10.0 and later.
Declared in `Icons.h`.

`kSelectorAllMiniData`
Specify to include `'icm#'`, `'icm4'`, and `'icm8'` resources.
Available in Mac OS X v10.0 and later.
Declared in `Icons.h`.

`kSelectorAllHugeData`
Available in Mac OS X v10.0 and later.
Declared in `Icons.h`.

`kSelectorAll1BitData`
Specify to include `'ICN#'`, `'ics#'`, and `'icm#'` resources.
Available in Mac OS X v10.0 and later.
Declared in `Icons.h`.

`kSelectorAll4BitData`
Specify to include `'icl4'`, `'ics4'`, and `'icm4'` resources.
Available in Mac OS X v10.0 and later.
Declared in `Icons.h`.

`kSelectorAll8BitData`
Specify to include `'icl8'`, `'ics8'`, and `'icm8'` resources.
Available in Mac OS X v10.0 and later.
Declared in `Icons.h`.

`kSelectorAll32BitData`
Available in Mac OS X v10.0 and later.
Declared in `Icons.h`.

`kSelectorAllAvailableData`
Specify to include all resources of given ID.
Available in Mac OS X v10.0 and later.
Declared in `Icons.h`.

Discussion
The functions `GetIconSuite` (page 1257) and `ForEachIconDo` (page 1244) use these constants in the `selector` parameter to specify which members of the family to include in the icon suite.

Catalog Information Bitmask

Defines a minimal bitmask for use with the `GetIconRefFromFileInfo` function.

```
enum {
    kIconServicesCatalogInfoMask =
            (kFSCatInfoNodeID | kFSCatInfoParentDirID | kFSCatInfoVolume
            | kFSCatInfoNodeFlags | kFSCatInfoFinderInfo |
            kFSCatInfoFinderXInfo | kFSCatInfoUserAccess)
};
```

Constants

`kIconServicesCatalogInfoMask`

Use this mask with the File Manager function `FSGetCatalogInfo` before calling `GetIconRefFromFileInfo`.

Available in Mac OS X v10.1 and later.

Declared in `IconsCore.h`.

System Icon Constant

Defines a creator type for all system–defined icons.

```
enum {
    kSystemIconsCreator = 'macs'
};
```

Discussion

You can use the `kSystemIconsCreator` constant to obtain System icons that are not associated with a file, such as the help icon.

Icon Services Usage Flag

```
typedef UInt32 IconServicesUsageFlags;
enum {
    kIconServicesNormalUsageFlag = 0
};
```

Alert Icon Constants

Specify standard alert icons.

```
enum {
    kAlertNoteIcon = 'note',
    kAlertCautionIcon = 'caut',
    kAlertStopIcon = 'stop'
};
```

Discussion

Icon Services defines constants for a number of standard alert icons. You can pass one of these constants in the `iconType` parameter of the function `GetIconRef` (page 1249), for example.

Filesharing Privilege Icon Constants

Identify standard filesharing privilege icons.

```
enum {
    kSharingPrivsNotApplicableIcon = 'shna',
    kSharingPrivsReadOnlyIcon = 'shro',
    kSharingPrivsReadWriteIcon = 'shrw',
    kSharingPrivsUnknownIcon = 'shuk',
    kSharingPrivsWritableIcon = 'writ'
};
```

Discussion
Icon Services defines constants for a number of standard filesharing privilege icons. You can pass one of these constants in the `iconType` parameter of the function `GetIconRef` (page 1249), for example.

Folder Icon Constants

Identify standard folder icons.

```
enum {
    kGenericFolderIcon = 'fldr',
    kDropFolderIcon = 'dbox',
    kMountedFolderIcon = 'mntd',
    kOpenFolderIcon = 'ofld',
    kOwnedFolderIcon = 'ownd',
    kPrivateFolderIcon = 'prvf',
    kSharedFolderIcon = 'shfl'
};
```

Discussion
Icon Services defines constants for a number of standard folder icons. You can pass one of these constants in the `iconType` parameter of the function `GetIconRef` (page 1249), for example.

Internet Icon Constants

Identify standard Internet icons.

```
enum {
    kInternetLocationHTTPIcon = 'ilht',
    kInternetLocationFTPIcon = 'ilft',
    kInternetLocationAppleShareIcon = 'ilaf',
    kInternetLocationAppleTalkZoneIcon = 'ilat',
    kInternetLocationFileIcon = 'ilfi',
    kInternetLocationMailIcon = 'ilma',
    kInternetLocationNewsIcon = 'ilnw',
    kInternetLocationNSLNeighborhoodIcon = 'ilns',
    kInternetLocationGenericIcon = 'ilge'
};
```

Discussion
Icon Services defines constants for a number of standard Internet icons. You can pass one of these constants in the `iconType` parameter of the function `GetIconRef` (page 1249), for example.

Toolbar Icons

Identify standard toolbar icons.

```
enum {
    kToolbarCustomizeIcon = 'tcus',
    kToolbarDeleteIcon = 'tdel',
    kToolbarFavoritesIcon = 'tfav',
    kToolbarHomeIcon = 'thom'
};
```

Miscellaneous Icon Constants

Identify miscellaneous icons.

```
enum {
    kAppleLogoIcon = 'capl',
    kAppleMenuIcon = 'sapl',
    kBackwardArrowIcon = 'baro',
    kFavoriteItemsIcon = 'favr',
    kForwardArrowIcon = 'faro',
    kGridIcon = 'grid',
    kHelpIcon = 'help',
    kKeepArrangedIcon = 'arng',
    kLockedIcon = 'lock',
    kNoFilesIcon = 'nfil',
    kNoFolderIcon = 'nfld',
    kNoWriteIcon = 'nwrt',
    kProtectedApplicationFolderIcon = 'papp',
    kProtectedSystemFolderIcon = 'psys',
    kRecentItemsIcon = 'rcnt',
    kShortcutIcon = 'shrt',
    kSortAscendingIcon = 'asnd',
    kSortDescendingIcon = 'dsnd',
    kUnlockedIcon = 'ulck',
    kConnectToIcon = 'cnct',
    kGenericWindowIcon = 'gwin',
    kQuestionMarkIcon = 'ques',
    kDeleteAliasIcon = 'dali',
    kEjectMediaIcon = 'ejec',
    kBurningIcon = 'burn',
    kRightContainerArrowIcon = 'rcar'
};
```

Discussion
Icon Services defines constants for a number of miscellaneous icons. You can pass one of these constants in the `iconType` parameter of the function `GetIconRef` (page 1249), for example.

Networking Icon Constants

Identify standard networking icons.

```
enum {
    kAppleTalkIcon = 'atlk',
    kAppleTalkZoneIcon = 'atzn',
    kAFPServerIcon = 'afps',
    kFTPServerIcon = 'ftps',
    kHTTPServerIcon = 'https',
    kGenericNetworkIcon = 'gnet',
    kIPFileServerIcon = 'isrv'
};
```

Discussion
Icon Services defines constants for a number of standard networking icons. You can pass one of these constants in the `iconType` parameter of the function `GetIconRef` (page 1249), for example.

Special Folder Icon Constants

Identify special folder icons.

```
enum {
    kAppearanceFolderIcon = 'appr',
    kAppleExtrasFolderIcon = 'aexf',
    kAppleMenuFolderIcon = 'amnu',
    kApplicationsFolderIcon = 'apps',
    kApplicationSupportFolderIcon = 'asup',
    kAssistantsFolderIcon = 'astf',
    kColorSyncFolderIcon = 'prof',
    kContextualMenuItemsFolderIcon = 'cmnu',
    kControlPanelDisabledFolderIcon = 'ctrD',
    kControlPanelFolderIcon = 'ctrl',
    kControlStripModulesFolderIcon = 'sdvf',
    kDocumentsFolderIcon = 'docs',
    kExtensionsDisabledFolderIcon = 'extD',
    kExtensionsFolderIcon = 'extn',
    kFavoritesFolderIcon = 'favs',
    kFontsFolderIcon = 'font',
    kHelpFolderIcon = 'fhlp',
    kInternetFolderIcon = 'intf',
    kInternetPlugInFolderIcon = 'fnet',
    kInternetSearchSitesFolderIcon = 'issf',
    kLocalesFolderIcon = 'floc',
    kMacOSReadMeFolderIcon = 'morf',
    kPublicFolderIcon = 'pubf',
    kPreferencesFolderIcon = 'prff',
    kPrinterDescriptionFolderIcon = 'ppdf',
    kPrinterDriverFolderIcon = 'fprd',
    kPrintMonitorFolderIcon = 'prnt',
    kRecentApplicationsFolderIcon = 'rapp',
    kRecentDocumentsFolderIcon = 'rdoc',
    kRecentServersFolderIcon = 'rsrv',
    kScriptingAdditionsFolderIcon = 'fscr',
    kSharedLibrariesFolderIcon = 'flib',
    kScriptsFolderIcon = 'scrf',
    kShutdownItemsDisabledFolderIcon = 'shdD',
    kShutdownItemsFolderIcon = 'shdf',
    kSpeakableItemsFolder = 'spki',
    kStartupItemsDisabledFolderIcon = 'strD',
    kStartupItemsFolderIcon = 'strt',
    kSystemExtensionDisabledFolderIcon = 'macD',
    kSystemFolderIcon = 'macs',
    kTextEncodingsFolderIcon = 'ftex',
    kUsersFolderIcon = 'usrf',
    kUtilitiesFolderIcon = 'utif',
    kVoicesFolderIcon = 'fvoc'
};
```

Discussion
Icon Services defines constants for a number of special folder icons. You can pass one of these constants in the `iconType` parameter of the function `GetIconRef` (page 1249), for example.

Standard Finder Icon Constants

Identify standard Finder icons.

```
enum {
    kClipboardIcon = 'CLIP',
    kClippingUnknownTypeIcon = 'clpu',
    kClippingPictureTypeIcon = 'clpp',
    kClippingTextTypeIcon = 'clpt',
    kClippingSoundTypeIcon = 'clps',
    kDesktopIcon = 'desk',
    kFinderIcon = 'FNDR',
    kFontSuitcaseIcon = 'FFIL',
    kFullTrashIcon = 'ftrh',
    kGenericApplicationIcon = 'APPL',
    kGenericCDROMIcon = 'cddr',
    kGenericControlPanelIcon = 'APPC',
    kGenericControlStripModuleIcon = 'sdev',
    kGenericComponentIcon = 'thng',
    kGenericDeskAccessoryIcon = 'APPD',
    kGenericDocumentIcon = 'docu',
    kGenericEditionFileIcon = 'edtf',
    kGenericExtensionIcon = 'INIT',
    kGenericFileServerIcon = 'srvr',
    kGenericFontIcon = 'ffil',
    kGenericFontScalerIcon = 'sclr',
    kGenericFloppyIcon = 'flpy',
    kGenericHardDiskIcon = 'hdsk',
    kGenericIDiskIcon = 'idsk',
    kGenericRemovableMediaIcon = 'rmov',
    kGenericMoverObjectIcon = 'movr',
    kGenericPCCardIcon = 'pcmc',
    kGenericPreferencesIcon = 'pref',
    kGenericQueryDocumentIcon = 'qery',
    kGenericRAMDiskIcon = 'ramd',
    kGenericSharedLibaryIcon = 'shlb',
    kGenericStationeryIcon = 'sdoc',
    kGenericSuitcaseIcon = 'suit',
    kGenericURLIcon = 'gurl',
    kGenericWORMIcon = 'worm',
    kInternationalResourcesIcon = 'ifil',
    kKeyboardLayoutIcon = 'kfil',
    kSoundFileIcon = 'sfil',
    kSystemSuitcaseIcon = 'zsys',
    kTrashIcon = 'trsh',
    kTrueTypeFontIcon = 'tfil',
    kTrueTypeFlatFontIcon = 'sfnt',
    kTrueTypeMultiFlatFontIcon = 'ttcf',
    kUserIDiskIcon = 'udsk',
    kUnknownFSObjectIcon = 'unfs',
    kInternationResourcesIcon = kInternationalResourcesIcon
};
```

Discussion
Icon Services defines constants for a number of standard Finder icons. You can pass one of these constants in the `iconType` parameter of the function `GetIconRef` (page 1249), for example.

Standard Icon Badge Constants

Identify standard badges.

```
enum {
    kAppleScriptBadgeIcon = 'scrp',
    kLockedBadgeIcon = 'lbdg',
    kMountedBadgeIcon = 'mbdg',
    kSharedBadgeIcon = 'sbdg',
    kAliasBadgeIcon = 'abdg',
    kAlertCautionBadgeIcon = 'cbdg'
};
```

Discussion
Icon Services defines constants for a number of standard badges. You can pass one of these constants in the `iconType` parameter of the function `GetIconRef` (page 1249), for example.

Users and Groups Icon Constants

Identify icons used in the Users and Groups control panel.

```
enum {
    kUserFolderIcon = 'ufld',
    kWorkgroupFolderIcon = 'wfld',
    kGuestUserIcon = 'gusr',
    kUserIcon = 'user',
    kOwnerIcon = 'susr',
    kGroupIcon = 'grup'
};
```

Discussion
Icon Services defines constants for a number of icons used in the Users and Groups control panel. You can pass one of these constants in the `iconType` parameter of the function `GetIconRef` (page 1249), for example.

genericDocumentIconResource

Use the constants listed in "Standard Icon Resources" instead.

```
enum {
    genericDocumentIconResource = kGenericDocumentIconResource,
    genericStationeryIconResource = kGenericStationeryIconResource,
    genericEditionFileIconResource = kGenericEditionFileIconResource,
    genericApplicationIconResource = kGenericApplicationIconResource,
    genericDeskAccessoryIconResource = kGenericDeskAccessoryIconResource,
    genericFolderIconResource = kGenericFolderIconResource,
    privateFolderIconResource = kPrivateFolderIconResource,
    floppyIconResource = kFloppyIconResource,
    trashIconResource = kTrashIconResource,
    genericRAMDiskIconResource = kGenericRAMDiskIconResource,
    genericCDROMIconResource = kGenericCDROMIconResource,
    desktopIconResource = kDesktopIconResource,
    openFolderIconResource = kOpenFolderIconResource,
    genericHardDiskIconResource = kGenericHardDiskIconResource,
    genericFileServerIconResource = kGenericFileServerIconResource,
    genericSuitcaseIconResource = kGenericSuitcaseIconResource,
    genericMoverObjectIconResource = kGenericMoverObjectIconResource,
    genericPreferencesIconResource = kGenericPreferencesIconResource,
    genericQueryDocumentIconResource = kGenericQueryDocumentIconResource,
    genericExtensionIconResource = kGenericExtensionIconResource,
    systemFolderIconResource = kSystemFolderIconResource,
    appleMenuFolderIconResource = kAppleMenuFolderIconResource
};
```

Standard Icon Resources

Identify standard icon resources.

```
/*Icons for which both icon suites and 'SICN' resources exist*/
enum {
    kGenericDocumentIconResource = -4000,
    kGenericStationeryIconResource = -3985,
    kGenericEditionFileIconResource = -3989,
    kGenericApplicationIconResource = -3996,
    kGenericDeskAccessoryIconResource = -3991,
    kGenericFolderIconResource = -3999,
    kPrivateFolderIconResource = -3994,
    kFloppyIconResource = -3998,
    kTrashIconResource = -3993,
    kGenericRAMDiskIconResource = -3988,
    kGenericCDROMIconResource = -3987
};
/* Icons for which only 'SICN' resources exist*/
enum {
    kDesktopIconResource = -3992,
    kOpenFolderIconResource = -3997,
    kGenericHardDiskIconResource = -3995,
    kGenericFileServerIconResource = -3972,
    kGenericSuitcaseIconResource = -3970,
    kGenericMoverObjectIconResource = -3969
};
/*Icons for which only icon suites exist*/
enum {
    kGenericPreferencesIconResource = -3971,
    kGenericQueryDocumentIconResource = -16506,
    kGenericExtensionIconResource = -16415,
    kSystemFolderIconResource = -3983,
    kHelpIconResource = -20271,
    kAppleMenuFolderIconResource = -3982
};
enum {
    kStartupFolderIconResource = -3981,
    kOwnedFolderIconResource = -3980,
    kDropFolderIconResource = -3979,
    kSharedFolderIconResource = -3978,
    kMountedFolderIconResource = -3977,
    kControlPanelFolderIconResource = -3976,
    kPrintMonitorFolderIconResource = -3975,
    kPreferencesFolderIconResource = -3974,
    kExtensionsFolderIconResource = -3973,
    kFontsFolderIconResource = -3968,
    kFullTrashIconResource = -3984
};
```

startupFolderIconResource

Use the constants described in "Standard Icon Resources" instead.

```
enum {
    startupFolderIconResource = kStartupFolderIconResource,
    ownedFolderIconResource = kOwnedFolderIconResource,
    dropFolderIconResource = kDropFolderIconResource,
    sharedFolderIconResource = kSharedFolderIconResource,
    mountedFolderIconResource = kMountedFolderIconResource,
    controlPanelFolderIconResource = kControlPanelFolderIconResource,
    printMonitorFolderIconResource = kPrintMonitorFolderIconResource,
    preferencesFolderIconResource = kPreferencesFolderIconResource,
    extensionsFolderIconResource = kExtensionsFolderIconResource,
    fontsFolderIconResource = kFontsFolderIconResource,
    fullTrashIconResource = kFullTrashIconResource
};
```

atNone

Use the constants described in "Icon Alignment Constants" instead.

```
enum {
    atNone = kAlignNone,
    atVerticalCenter = kAlignVerticalCenter,
    atTop = kAlignTop,
    atBottom = kAlignBottom,
    atHorizontalCenter = kAlignHorizontalCenter,
    atAbsoluteCenter = kAlignAbsoluteCenter,
    atCenterTop = kAlignCenterTop,
    atCenterBottom = kAlignCenterBottom,
    atLeft = kAlignLeft,
    atCenterLeft = kAlignCenterLeft,
    atTopLeft = kAlignTopLeft,
    atBottomLeft = kAlignBottomLeft,
    atRight = kAlignRight,
    atCenterRight = kAlignCenterRight,
    atTopRight = kAlignTopRight,
    atBottomRight = kAlignBottomRight
};
```

svLarge1Bit

Use the constants described in "Icon Selector Constants" instead.

```
enum {
    svLarge1Bit = kSelectorLarge1Bit,
    svLarge4Bit = kSelectorLarge4Bit,
    svLarge8Bit = kSelectorLarge8Bit,
    svSmall1Bit = kSelectorSmall1Bit,
    svSmall4Bit = kSelectorSmall4Bit,
    svSmall8Bit = kSelectorSmall8Bit,
    svMini1Bit = kSelectorMini1Bit,
    svMini4Bit = kSelectorMini4Bit,
    svMini8Bit = kSelectorMini8Bit,
    svAllLargeData = kSelectorAllLargeData,
    svAllSmallData = kSelectorAllSmallData,
    svAllMiniData = kSelectorAllMiniData,
    svAll1BitData = kSelectorAll1BitData,
    svAll4BitData = kSelectorAll4BitData,
    svAll8BitData = kSelectorAll8BitData,
    svAllAvailableData = kSelectorAllAvailableData
};
```

ttNone

Use the constants described in "Icon Transformation Constants" instead.

```
enum {
    ttNone = kTransformNone,
    ttDisabled = kTransformDisabled,
    ttOffline = kTransformOffline,
    ttOpen = kTransformOpen,
    ttLabel1 = kTransformLabel1,
    ttLabel2 = kTransformLabel2,
    ttLabel3 = kTransformLabel3,
    ttLabel4 = kTransformLabel4,
    ttLabel5 = kTransformLabel5,
    ttLabel6 = kTransformLabel6,
    ttLabel7 = kTransformLabel7,
    ttSelected = kTransformSelected,
    ttSelectedDisabled = kTransformSelectedDisabled,
    ttSelectedOffline = kTransformSelectedOffline,
    ttSelectedOpen = kTransformSelectedOpen
};
```

Result Codes

The table below shows the most common result codes returned by Icon Services and Utilities.

Result Code	Value	Description
`noMaskFoundErr`	-1000	Available in Mac OS X v10.0 and later.
`invalidIconRefErr`	-2580	The `IconRef` is not valid. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
`noSuchIconErr`	-2581	The requested icon could not be found. Available in Mac OS X v10.0 and later.
`noIconDataAvailableErr`	-2582	The necessary icon data is not available. Available in Mac OS X v10.0 and later.

Gestalt Constants

You can check for version and feature availability information by using the Icon Services selectors defined in the Gestalt Manager. For more information, see *Gestalt Manager Reference*.

Language Analysis Manager Reference

Framework: ApplicationServices/ApplicationServices.h
Declared in LanguageAnalysis.h

Overview

The Language Analysis Manager application programming interface (API) is a shared library designed to analyze morphemes in text. It is a general-purpose API that does not rely on languages, algorithms of morpheme analysis, or their applications. Language Analysis Manager is not a framework for creating International-aware applications. To make your applications work correctly with various languages, you can use APIs such as Script Manager and Text Utilities.

The Language Analysis Manager (LAM) provides your application with morphological analysis capability, and is designed to work with a language analysis engine. Using the Language Analysis Manager, your application can manage an analysis engine and create environments and contexts in which morpheme analysis can occur. This version of the Language Analysis Manager works only with a Japanese analysis engine.

Functions by Task

Getting The Library Version

`LALibraryVersion` (page 1335) Deprecated in Mac OS X v10.5
Returns the version of the Language Analysis Manager installed.

Handling Environments

`LACreateCustomEnvironment` (page 1332) Deprecated in Mac OS X v10.5
Creates a new environment with the specified name.

`LADeleteCustomEnvironment` (page 1332) Deprecated in Mac OS X v10.5
Disposes of a reference to a custom language analysis environment.

`LAGetEnvironmentList` (page 1333) Deprecated in Mac OS X v10.5
Obtains a list of the available language analysis environments.

`LAGetEnvironmentName` (page 1334) Deprecated in Mac OS X v10.5
Obtains the name of an environment.

`LAGetEnvironmentRef` (page 1334) Deprecated in Mac OS X v10.5
Obtains the language analysis environment reference associated with an environment name

Opening and Closing Contexts

`LACloseAnalysisContext` (page 1329) Deprecated in Mac OS X v10.5
Closes the specified language analysis context.

`LAOpenAnalysisContext` (page 1338) Deprecated in Mac OS X v10.5
Creates a language analysis context from a specified language analysis environment.

Managing Dictionaries

`LAAddNewWord` (page 1328) Deprecated in Mac OS X v10.5
Adds a new word to a dictionary.

`LACloseDictionary` (page 1330) Deprecated in Mac OS X v10.5
Closes a dictionary in the specified environment.

`LAListAvailableDictionaries` (page 1336) Deprecated in Mac OS X v10.5
Obtains the number of dictionaries available in a specified environment.

`LAOpenDictionary` (page 1339) Deprecated in Mac OS X v10.5
Opens a dictionary for the specified environment.

Analyzing Text

`LAContinuousMorphemeAnalysis` (page 1330) Deprecated in Mac OS X v10.5
Performs a continuous morphological analysis of Unicode text.

`LAGetMorphemes` (page 1335) Deprecated in Mac OS X v10.5
Reads the results of a continuous morpheme analysis.

`LAMorphemeAnalysis` (page 1337) Deprecated in Mac OS X v10.5
Performs a morphological analysis of the specified Unicode text.

`LAResetAnalysis` (page 1339) Deprecated in Mac OS X v10.5
Clears the internal status of the analysis context.

`LAShiftMorphemes` (page 1340) Deprecated in Mac OS X v10.5
Shifts the read out of continuous morpheme analysis.

`LATextToMorphemes` (page 1341) Deprecated in Mac OS X v10.5
Performs a morphological analysis of the specified text.

Functions

LAAddNewWord

Adds a new word to a dictionary. (Deprecated in Mac OS X v10.5.)

```
OSStatus LAAddNewWord (
   LAEnvironmentRef environ,
   const FSSpec *dictionary,
   const AEDesc *dataList
);
```

Parameters

environ

A reference to the language analysis environment for the dictionary you want to modify.

dictionary

The file specification for the dictionary you want to modify.

dataList

A pointer to an `AEDesc` data structure that specifies the word you want to add to the dictionary. See the Apple Event Manager documentation for more information on Apple Event descriptor records.

Return Value
A result code. See "Result Codes" (page 1354).

Availability
Available in CarbonLib 1.0 and later when LanguageAnalysis 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`LanguageAnalysis.h`

LACloseAnalysisContext

Closes the specified language analysis context. (Deprecated in Mac OS X v10.5.)

```
OSStatus LACloseAnalysisContext (
   LAContextRef context
);
```

Parameters

context

A reference to the language analysis context you want to close.

Return Value
A result code. See "Result Codes" (page 1354).

Availability
Available in CarbonLib 1.0 and later when LanguageAnalysis 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`LanguageAnalysis.h`

LACloseDictionary

Closes a dictionary in the specified environment. (Deprecated in Mac OS X v10.5.)

```
OSStatus LACloseDictionary (
   LAEnvironmentRef environ,
   const FSSpec *dictionary
);
```

Parameters

environ

A reference to the language analysis environment for which you want to close a dictionary.

dictionary

The file specification for the dictionary you want to close.

Return Value

A result code. See "Result Codes" (page 1354).

Availability

Available in CarbonLib 1.0 and later when LanguageAnalysis 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`LanguageAnalysis.h`

LAContinuousMorphemeAnalysis

Performs a continuous morphological analysis of Unicode text. (Deprecated in Mac OS X v10.5.)

```
OSStatus LAContinuousMorphemeAnalysis (
   LAContextRef context,
   ConstUniCharArrayPtr text,
   UniCharCount textLength,
   Boolean incrementalText,
   LAMorphemePath *leadingPath,
   LAMorphemePath *trailingPath,
   Boolean *modified
);
```

Parameters

context

A reference to the language analysis context whose text you want to analyze. You can obtain a language analysis context by calling the function `LAOpenAnalysisContext`.

text

A pointer to the Unicode text string you want to analyze.

textLength

The length of the Unicode text string specified in the `text` parameter. This value must specify the number of `UniChar` (double-byte) values in the string.

incrementalText

A Boolean value that indicates the method for passing text. Pass `false` to specify you want the text to be analyzed as a whole and the analysis started. Pass `true` if the text is a continuation of the text currently held by the context, and should be added to the context before undergoing analysis.

leadingPath

A pointer to the morpheme path that specifies the results of analyzing the text just previous to the string specified by the `text` parameter. The Langauage Analysis Manager uses this string to restrict the analyis. For example, if the previous section ends with a noun, the text that follows can begin with a verb. If no valid leading path is available you can pass `NULL` or a "Leading and Trailing Constants" (page 1350)—`kLAFreeEdge` or `kLADefaultEdge`. Pass `kLAFreeEdge` if it is possible for an optional morpheme to come at the start or the end of analysis. Pass `kLADefaultEdge` if you want the analysis is carried out so that the start/end of analysis becomes the start of the sentence/end of sentence or the start of the segment/end of segment. Definitions for start of sentence/end of sentence and start of segment/end of segment depend on the engine.

trailingPath

A pointer to the morpheme path that specifies the results of analyzing the text that follows the string specified by the `text` parameter. When performing a continuous analysis, you must pass the constant `kLAIncompleteEdge` to indicate that the string is not complete. Note that the function `LAGetMorphemes` only returns the results it has completed analyzing, not the analysis of the complete source text. If you want to obtain all of the analysis results up to a point, (if a user expressly indicates a conversion with the space bar in a kana-kanji conversion program, and so forth) then you can pass a value other than `kLAIncompleteEdge`. Then, when you call the function `LAGetMorphemes` you obtain analysis results for that portion of the string that has been analyzed to that point.

modified

On output, `true` if the internal state of the context is changed (new analyzed morphemes are generated); otherwise `false`. When `true` is returned, you should call the function `LAGetMorphemes` and update the display. If modified is specified as `NULL`, values are not returned.

Return Value
A result code. See "Result Codes" (page 1354).

Discussion
The function `LAContinuousMorphemeAnalysis` does not return analysis results, but holds them internally. You can obtain the results by calling the functions `LAGetMorphemes` or `LAShiftMorphemes`. In contrast to the function `LAMorphemeAnalysis` you cannot obtain multiple paths for an analysis done using the function `LAContinuousMorphemeAnalysis`.

You can obtain the same results as calling the function `LAResetAnalysis` by calling `LAContinuousMorphemeAnalysis` with the `text` parameter set to "" and the `incrementalText` parameter set to `false`.

Availability
Available in CarbonLib 1.0 and later when LanguageAnalysis 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`LanguageAnalysis.h`

LACreateCustomEnvironment

Creates a new environment with the specified name. (Deprecated in Mac OS X v10.5.)

```
OSStatus LACreateCustomEnvironment (
   LAEnvironmentRef baseEnvironment,
   ConstStr63Param newEnvironmentName,
   Boolean persistent,
   LAEnvironmentRef *newEnvironment
);
```

Parameters

baseEnvironment

A reference to the language analysis environment that you want to use as the base environment.

newEnvironmentName

The name for the newly-created environment. This name must be unique. If an environment with the same name already exists, the function returns the result code `laEnvironmentExistErr`.

persistent

A Boolean value that specifies whether the environment should be persistent (`true`) or not (`false`). If you pass `true`, the newly-created environment is saved to disk, and it can be referred to at any time subsequently by using the name. If you pass `false`, the newly-created environment can only be used during that session. Additionally, environments created with persistent set to `false` are not returned in the list provided by the function `LAGetEnvironmentList`, so these environments can be used only as private environments. If you create a private environment, you must call the function `LADeleteCustomEnviroment` to dispose of it before you terminate your application.

newEnvironemnt

On output, a reference to the newly-created language analysis environment.

Return Value

A result code. See "Result Codes" (page 1354).

Discussion

If you open or close dictionaries for custom environments, it is possible to create independent environments without interfering with existing environments.

Availability

Available in CarbonLib 1.0 and later when LanguageAnalysis 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`LanguageAnalysis.h`

LADeleteCustomEnvironment

Disposes of a reference to a custom language analysis environment. (Deprecated in Mac OS X v10.5.)

```
OSStatus LADeleteCustomEnvironment (
   LAEnvironmentRef environment
);
```

Parameters

environment

A reference to the language analysis environment you want to dispose of.

Return Value
A result code. See "Result Codes" (page 1354).

Availability
Available in CarbonLib 1.0 and later when LanguageAnalysis 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`LanguageAnalysis.h`

LAGetEnvironmentList

Obtains a list of the available language analysis environments. (Deprecated in Mac OS X v10.5.)

```
OSStatus LAGetEnvironmentList (
   UInt32 maxCount,
   UInt32 *actualCount,
   LAEnvironmentRef environmentList[]
);
```

Parameters

maxCount

The maximum number of environments provided by the system. To determine this value, see the Discussion.

actualCount

On output, the actual number of environments.

environmentList

On output, a list of the available environments. You must allocate a buffer of the appropriate size. If you are uncertain of how much memory to allocate for this array, see the Discussion.

Return Value
A result code. See "Result Codes" (page 1354).

Discussion
Typically, you use the function `LAGetEnvironmentList` by calling it twice, as follows:

1. Pass `0` for the `maxCount` parameter and `NULL` for the `environmentList` parameter.
2. Allocate enough space for an array of the size specified by `actualCount`, then call the function `LAGetEnvironmentList` again. This time, provide a count of the actual number of environments as the `maxCount` parameter, and a pointer to a buffer of the correct size for the `environmentList` parameter. On output, the pointer points to an array of the available environments.

Availability
Available in CarbonLib 1.0 and later when LanguageAnalysis 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`LanguageAnalysis.h`

LAGetEnvironmentName

Obtains the name of an environment. (Deprecated in Mac OS X v10.5.)

```
OSStatus LAGetEnvironmentName (
   LAEnvironmentRef environment,
   Str63 environmentName
);
```

Parameters

environment
A reference to the language analysis environment whose name you want to obtain.

environmentName
On return, the environment name.

Return Value
A result code. See "Result Codes" (page 1354).

Availability
Available in CarbonLib 1.0 and later when LanguageAnalysis 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`LanguageAnalysis.h`

LAGetEnvironmentRef

Obtains the language analysis environment reference associated with an environment name (Deprecated in Mac OS X v10.5.)

```
OSStatus LAGetEnvironmentRef (
   ConstStr63Param targetEnvironmentName,
   LAEnvironmentRef *environment
);
```

Parameters

targetEnvironmentName
The environment name whose language analysis environment reference you want to obtain.

environment
On output, a reference to the language analysis environment associated with the environment name.

Return Value
A result code. See "Result Codes" (page 1354).

Availability
Available in CarbonLib 1.0 and later when LanguageAnalysis 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`LanguageAnalysis.h`

LAGetMorphemes

Reads the results of a continuous morpheme analysis. (Deprecated in Mac OS X v10.5.)

```
OSStatus LAGetMorphemes (
   LAContextRef context,
   LAMorphemePath *result
);
```

Parameters

context

A reference to the language analysis context whose result you want to obtain. You can obtain a language analysis context by calling the function `LAOpenAnalysisContext`.

result

On output, points to the morpheme bundle that contains the results of the analysis. You are responsible for disposing of this structure by calling the Apple Event Manager function `AEDisposeDesc`.

Return Value
A result code. See "Result Codes" (page 1354).

Availability
Available in CarbonLib 1.0 and later when LanguageAnalysis 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`LanguageAnalysis.h`

LALibraryVersion

Returns the version of the Language Analysis Manager installed. (Deprecated in Mac OS X v10.5.)

```
UInt32 LALibraryVersion (
   void
);
```

Return Value
Returns the version of Language Analysis manager that is installed.

Discussion
The function `LALibraryVersion` returns the version of the Language Analysis Manager installed in the same format as `'vers'` resource. That is to say, the version number is returned in BCD (Binary-Coded Decimal) format to higher-place words, while release stage information is returned to lower-place words. For example, version 1.1.1 final release library returns 0x01118000.

Availability
Available in CarbonLib 1.0 and later when LanguageAnalysis 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`LanguageAnalysis.h`

LAListAvailableDictionaries

Obtains the number of dictionaries available in a specified environment. (Deprecated in Mac OS X v10.5.)

```
OSStatus LAListAvailableDictionaries (
   LAEnvironmentRef environ,
   ItemCount maxCount,
   ItemCount *actualCount,
   FSSpec dictionaryList[],
   Boolean opened[]
);
```

Parameters

environ
A reference to the language analysis environment for which you want to obtain a list of available dictionaries.

maxCount
The maximum number of available dictionaries. To determine this value, see the Discussion.

actualCount
On output, the actual number of available dictionaries.

dictionaryList
On output, points to a list of available dictionaries. You must allocate a buffer of the appropriate size. If you are uncertain of how much memory to allocate for this array, see the Discussion.

opened
On output, points to a list of Boolean values that specify whether the available dictionaries are open. This array is parallel to the `dictionaryList` array. A dictionary file whose associated value is `true` is open and `false` if it is not open. You must allocate a buffer of the appropriate size. If you are uncertain of how much memory to allocate for this array, see the Discussion.

Return Value
A result code. See "Result Codes" (page 1354).

Discussion
Typically, you use the function `LAListAvailableDictionaries` by calling it twice, as follows:

1. Pass `0` for the `maxCount` parameter, `NULL` for the `dictionaryList` parameter, and `NULL` for the `opened` parameter.

2. Allocate enough space for arrays of the size specified by `actualCount`, then call the function `LAListAvailableDictionaries` again. This time, provide a count of the actual number of dictionaries as the `maxCount` parameter, and a pointer to buffers of the correct size for the `dictionaryList` and `opened` parameters. On output, `dictionaryList` points to an array of the available dictionaries and `opened` points to an array that specifies whether each dictionary is opened or closed.

Availability
Available in CarbonLib 1.0 and later when LanguageAnalysis 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`LanguageAnalysis.h`

LAMorphemeAnalysis

Performs a morphological analysis of the specified Unicode text. (Deprecated in Mac OS X v10.5.)

```
OSStatus LAMorphemeAnalysis (
   LAContextRef context,
   ConstUniCharArrayPtr text,
   UniCharCount textLength,
   LAMorphemePath *leadingPath,
   LAMorphemePath *trailingPath,
   ItemCount pathCount,
   LAMorphemeBundle *result
);
```

Parameters

context
A reference to the language analysis context whose text you want to analyze. You can obtain a language analysis context by calling the function `LAOpenAnalysisContext`.

text
A pointer to the Unicode text string you want to analyze.

textLength
The length of the Unicode text string specified in the `text` parameter. This value must specify the number of `UniChar` (double-byte) values in the string.

leadingPath
A pointer to the morpheme path that specifies the results of analyzing the text just previous to the string specified by the `text` parameter. The Language Analysis Manager uses this string to restrict the analysis. For example, if the previous section ends with a noun, the text that follows can begin with a verb. If no valid leading path is available you can pass `NULL` or a "Leading and Trailing Constants" (page 1350)—`kLAFreeEdge` or `kLADefaultEdge`. Pass `kLAFreeEdge` if it is possible for an optional morpheme to come at the start or the end of analysis. Pass `kLADefaultEdge` if you want the analysis is carried out so that the start/end of analysis becomes the start of the sentence/end of sentence or the start of the segment/end of segment. Definitions for start of sentence/end of sentence and start of segment/end of segment depend on the engine.

trailingPath

A pointer to the morpheme path that specifies the results of analyzing the text that follows the string specified by the `text` parameter. The Language Analysis Manager uses this string to restrict the analysis. For example, if the following section begins with a verb, the text that precedes it can begin with a noun. If no valid trailing path is available you can pass `NULL` or a "Leading and Trailing Constants" (page 1350)—`kLAFreeEdge` or `kLADefaultEdge`. Pass `kLAFreeEdge` if it is possible for an optional morpheme to come at the start or the end of analysis. Pass `kLADefaultEdge` if you want the analysis is carried out so that the start/end of analysis becomes the start of the sentence/end of sentence or the start of the segment/end of segment. Definitions for start of sentence/end of sentence and start of segment/end of segment depend on the engine.

pathCount

On output, specifies the maximum rank of the returned path.

result

On output, points to the morpheme bundle that contains the results of the analysis. You are responsible for disposing of this structure by calling the Apple Event Manager function `AEDisposeDesc`.

Return Value
A result code. See "Result Codes" (page 1354).

Discussion
If you have previously called the function `LAContinuousMorphemeAnalysis`, and you the call the function `LAMorphemeAnalysis`, the internal state maintained by the function `LAContinuousMorphemeAnalysis` is disposed of. Then, if you call the functions `LAGetMorphemes` and `LAShiftMorphemes` the result code `laNoMoreMorphemeErr` is returned .

Availability
Available in CarbonLib 1.0 and later when LanguageAnalysis 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`LanguageAnalysis.h`

LAOpenAnalysisContext

Creates a language analysis context from a specified language analysis environment. (Deprecated in Mac OS X v10.5.)

```
OSStatus LAOpenAnalysisContext (
   LAEnvironmentRef environ,
   LAContextRef *context
);
```

Parameters

environ

A reference to the language analysis environment for which you want to open a context.

context

On output, a language analysis context derived from the specified language analysis environment.

Return Value
A result code. See "Result Codes" (page 1354).

Availability
Available in CarbonLib 1.0 and later when LanguageAnalysis 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`LanguageAnalysis.h`

LAOpenDictionary

Opens a dictionary for the specified environment. (Deprecated in Mac OS X v10.5.)

```
OSStatus LAOpenDictionary (
   LAEnvironmentRef environ,
   const FSSpec *dictionary
);
```

Parameters

environ
A reference to the language analysis environment for which you want to open the dictionary.

dictionary
The file specification for the dictionary you want to open.

Return Value
A result code. See "Result Codes" (page 1354).

Discussion
The environment makes an appropriate assessment of type of dictionary, user dictionary, option dictionary and so forth, before carrying out necessary operations.

Availability
Available in CarbonLib 1.0 and later when LanguageAnalysis 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`LanguageAnalysis.h`

LAResetAnalysis

Clears the internal status of the analysis context. (Deprecated in Mac OS X v10.5.)

```
OSStatus LAResetAnalysis (
   LAContextRef context
);
```

Parameters

context
A reference to the language analysis context whose analysis you want to reset. You can obtain a language analysis context by calling the function `LAOpenAnalysisContext`.

Return Value
A result code. See "Result Codes" (page 1354).

Discussion
Clear the internal status of analysis context. This is accessed before the continuous analysis by the next LAContinuousMorphemeAnalysis. Accessing LAGetMorphemes and LAShiftMorphemes immediately after this call will fail.

The same result will be achieved even if LAContinuousMorphemeAnalysis is accessed as text = "", incrementalText = false

Availability
Available in CarbonLib 1.0 and later when LanguageAnalysis 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`LanguageAnalysis.h`

LAShiftMorphemes

Shifts the read out of continuous morpheme analysis. (Deprecated in Mac OS X v10.5.)

```
OSStatus LAShiftMorphemes (
   LAContextRef context,
   ItemCount morphemeCount,
   LAMorphemePath *path,
   UniCharCount *shiftedLength
);
```

Parameters

context
A reference to the language analysis context whose read-out you want to shift. You can obtain a language analysis context by calling the function `LAOpenAnalysisContext`.

morphemeCount
The number of morphemes to be shifted. If you pass `kAllMorphemes`, all morphemes which are analized are returned.

path
If you pass `typeNull` a new path is created. If you pass a valid path, the morpheme read out at the end of the path is added. This is handy when this path is to be used as the leading edge the next time `LAContinuousMorphemeAnalysis` is accessed. In both cases, when you are done using the path, you must dispose of it by calling the Apple Event Manager function `AEDispose`.

shiftedLength
A pointer to the input character string length (in `UniChars`) corresponding to the morpheme read out. If you pass `NULL`, it is not returned.

Return Value
A result code. See "Result Codes" (page 1354).

Discussion
When you call the function `LAShiftMorphemes`, the results of the analysis performed by the function `LAContinuousMorphemeAnalysis` are returned from the start to the number of morpheme readout paths specified in the `morphemeCount` parameter . Morphemes which have been read out are deleted from analysis context. For example, if "AABBCC" represents the internal status, after you fetch the morpheme "AA" by calling `LAShiftMorphemes`, the internal status becomes "BBCC".

The results you obtain by calling the funciton `LAShiftMorphemes`, are impacted by the `trailingEdge` parameter of the function `LAContinuousMorphemeAnalysis`. If the value of the `trailingEdge` parameter is `kLAIncompleteEdge`, the function `LAShiftMorphemes` might not return all morphemes and non-converted sections. The analysis engine only returns morphemes with a high degree of certainty. For example, those morphemes which are likely to change if text is added, and `laNoMoreMorphemeErr` is returned in subsequent accesses. If something other than `kLAIncompleteEdge` is passed as the `trailingEdge` parameter, it is possible to fetch morphemes up to the final morpheme. After all morphemes are fetched, the result code `laNoMoreMorphemeErr` is returned to indicate that nothing remains. This is the same as the status returned after calling the function `LAResetAnalysis`.

You can carry out a continuous analysis using the functions `LAContinuousMorphemeAnalysis` and `LAShiftMorphemes` in two ways. The first method leaves as much text as possible within the analysis engine. That is, continue to provide text to the fucntoin `LAContinuousMorphemeAnalysis` until you encounter the result code `laTextOverflowErr` , and call the function `LAShiftMorphemes` once when the error is returned. The second method leaves as little text as possible within the analysis search engine. That is, continue to provide text to the function `LAContinuousMorphemeAnalysis` until `true` is returned to the `modified` parameter. When `true` is returned, call the function `LAShiftMorphemes` with the `morphemeCount` parameter set to `kAllMorphemes`.

Availability
Available in CarbonLib 1.0 and later when LanguageAnalysis 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`LanguageAnalysis.h`

LATextToMorphemes

Performs a morphological analysis of the specified text. (Deprecated in Mac OS X v10.5.)

```
OSStatus LATextToMorphemes (
   LAContextRef context,
   TextEncoding preferedEncoding,
   ByteCount textLength,
   ConstLogicalAddress sourceText,
   ByteCount bufferSize,
   OptionBits convertFlags,
   UInt32 structureVersion,
   ByteCount *acceptedLength,
   LAMorphemesArrayPtr resultBuffer
);
```

Parameters

context

A reference to the language analysis context whose text you want to analyze. You can obtain a language analysis context by calling the function `LAOpenAnalysisContext`.

preferedEncoding

A value of type `TextEncoding` that specifies the encoding of text to use for both input and output. The text and length included in the `results` parameter are adjusted in accordance with the encoding specified here.

textLength

The length, in bytes, of the text you want to analyze.

sourceText

A pointer to the text you want to analyze.

bufferSize

The size of the buffer pointed to by the `resultBuffer` parameter.

convertFlags

An `OptionBits` value that specifies how to proceed with the analysis. Currently the only option you can set is `kLAEndOfSourceTextMask`. If this bit is set, the source text is analyzed to the end, and then results are generated. If this bit is not set, there is a possibility that the end portion of the source text is not yet analyzed when results are available. For example, when a large text file is analyzed it may be preferable to analyze it in chunks, returning results as each chunk is analyzed. You can specify this by passing 0 for the `convertFlags` parameter, advancing the analysis, and the setting `kLAEndOfSourceTextMask` when the whole file has been read.

structureVersion

The current version of `LAMorphemesArrayPtr`. You should pass `kLAMorphemesArrayVersion`.

acceptedLength

On output, the length of the source text that is accepted by the analysis engine.

resultBuffer

On output, a pointer to an array of `LAMorphmesArray` structures that contain the results of the morphological analysis.

Return Value

A result code. See "Result Codes" (page 1354).

Discussion

The function `LATextToMorphemes` analyzes the text specified in `textLength` and `sourceText`, and returns the results to `resultBuffer` in the form of `LAMorphemesArray`. While there are no restrictions on the length of text specified, the length in byte units of `sourceText` received in this call is set to `acceptedLength` at the point where the output buffer becomes full, or until all text provided has been analyzed. In practice, sections currently being analyzed exist within the analysis context, so be aware that the length returned may

not necessarily be the same as the section included in analysis results. This means that if the length of the returned text is shorter than the source text, analysis results are not complete. In this case, fetch the `results`, increment the `sourceText` by the `acceptedLength`, shorten `textLength` by the `acceptedLength`, and repeatedly call `LATextToMorphemes` until all the text is analyzed. The sample code below shows how to analyze text while loading it from a file.

```
while ( fileErr == noErr )
{
    fileErr = ReadFile (readBufferSize, &actualReadSize, readBuffer);
    if ( fileErr == eofErr )
        analyzeOption = kLAEndOfSourceTextMask;
    else
        analyzeOption = 0;
    analyzeLen = actualReadSize;
    analyzeText = readBuffer;
    result->morphemesCount = 0;
    while (analyzeLen || result->morphemesCount)
    {
        err = LATextToMorphemes (context, kTextEncodingMacJapanese,
                        analyzeLen, analyzeText, resultBufferSize,
                        analyzeOption, kLAMorphemesArrayVersion,
                        &acceptedLen, result);
        if (result->morphemesCount > 0 )
        {
                //
                // Retrieve result here...
                //
        }
        analyzeText += acceptedLen; // Increment source text ptr
        analyzeLen -= acceptedLen; // Decrement source text length
         }
}
```

If `kLAEndOfSourceTextMask` is specified and the analysis of all of the source text is done, the context becomes empty. If the analysis is suspended under this or other conditions (including errors), you must call the function `LAResetAnalysis` to clear the context.

Availability
Available in CarbonLib 1.0 and later when LanguageAnalysis 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

LAEnvironmentRef

A reference to an opaque language analysis environment structure.

```
typedef struct OpaqueLAEnvironmentRef * LAEnvironmentRef;
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`LanguageAnalysis.h`

LAHomograph

Defines a data types for a homograph node.

```
typedef AERecord LAHomograph;
```

Discussion
The Apple event record (`AERecord`) is the data type upon which many Language Analysis Manager data types are based. A homograph node is the minimum unit of analysis and is representative of an individual language. Typically a homograph node corresponds to one word obtained from the dictionary.

Homograph nodes include the character string which represents this language, but the content varies according to the type of analysis stipulated in the analysis environment. Depending on the type of environment, additional information may be included for a specific language.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`LanguageAnalysis.h`

LAMorpheme

Defines a data type for a morpheme node.

```
typedef AERecord LAMorpheme;
```

Discussion
The Apple event record (`AERecord`) is the data type upon which many Language Analysis Manager data types are based. Morpheme nodes display the language of a specific part of speech for a particular text character strings, and have corresponding character string range, part of speech and homograph nodes within text character strings as attributes.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`LanguageAnalysis.h`

LAMorphemeBundle

Defines a data type for a morpheme bundle.

```
typedef AERecord LAMorphemeBundle;
```

Discussion
The Apple event record (`AERecord`) is the data type upon which many Language Analysis Manager data types are based. Morpheme bundles are a collection of different solutions to morpheme analysis on one character string. The "different solutions" referred to here means that two solutions have different morpheme delimiters, or the same morpheme delimiters, but the parts of speech are not the same. Morpheme bundles have each of these different solutions in the from of a morpheme path. Morpheme bundles normally have multiple paths in the "most likely" order.

Within morpheme bundles, morpheme paths do not directly include morpheme nodes. Morpheme bundles have a list of morpheme nodes as one of their attributes distinct from the morpheme path, and morpheme paths have an index to that list. In this way, it is possible to share a morpheme node from one or more paths by indirectly indicating the morpheme node. In most cases, multiple paths within one bundle resemble one another to some extent, and multiple paths may be deemed to have the same morpheme node. One morpheme node may include many homograph nodes, making it bigger, so a mechanism such as this which allows sharing is important in maintaining a small data size.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`LanguageAnalysis.h`

LAMorphemePath

Defines a data type for a morpheme path.

```
typedef AERecord LAMorphemePath;
```

Discussion
The Apple event record (`AERecord`) is the data type upon which many Language Analysis Manager data types are based. A morpheme path defines a single solution for the analysis of a morpheme. The path has an individual morphme delmiinter and part of speech.

There are two types of variation of morpheme paths which have a different way of holding the lower-place morpheme nodes, and in some cases they are used for different purposes. One is the morpheme path within the morpheme bundle mentioned earlier, where the path does not directly include morpheme nodes.

The other form is the morpheme path which can be used alone, and in this case, it is more convenient for it to be closed in that unit. If an application changes the operation of a morpheme node, the morpheme node must not be being shared. Therefore, for single morpheme paths, morpheme nodes are directly included in the morpheme path.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`LanguageAnalysis.h`

LAMorphemeRec

Contains results of the analayis of one morpheme.

```
struct LAMorphemeRec {
    ByteCount sourceTextLength;
    LogicalAddress sourceTextPtr;
    ByteCount morphemeTextLength;
    LogicalAddress morphemeTextPtr;
    UInt32 partOfSpeech;
};
typedef struct LAMorphemeRec LAMorphemeRec;
```

Fields

`sourceTextLength`
The length of the source text for this morpheme.

`sourceTextPtr`
A pointer to the source text.

`morphemeTextLength`
The length of the result text for this morpheme.

`morphemeTextPtr`
A pointer to the result text.

`partOfSpeech`
The part of speech of this morpheme.

Discussion
This structure is an entry in the `LAMorphemesArray` data structure.

Availability
Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In
`LanguageAnalysis.h`

LAMorphemesArray

Contains the results of high-level morphological analysis.

```
struct LAMorphemesArray {
    ItemCount morphemesCount;
    ByteCount processedTextLength;
    ByteCount morphemesTextLength;
    LAMorphemeRec morphemes[1];
};
typedef struct LAMorphemesArray LAMorphemesArray;
typedef LAMorphemesArray * LAMorphemesArrayPtr;
```

Fields

`morphemesCount`
The number of morphemes included.

`processedTextLength`
The processed source character length.

`morphemesTextLength`
The overall length of the result string.

`morphemes`
An array of morpheme records.

Discussion
When you perform high-level analysis, you can analyze stream-format text and obtain the results as an array of morpeme information.

`LanguageAnalysis.h`

Constants

File Creator Constants

Specify file creator for dictionary of Apple Japanese access methods.

```
enum {
    kAppleJapaneseDictionarySignature = 'jlan'
};
```

Analysis Engine Keywords

Specify analysis engine keywords for morpheme/homograph information.

```
enum {
    keyAEHomographDicInfo = 'lahd',
    keyAEHomographWeight = 'lahw',
    keyAEHomographAccent = 'laha'
};
```

Analysis Results Constants

Specify the nodes associated with analysis resutls.

```
enum {
    keyAELAMorphemeBundle = 'lmfb',
    keyAELAMorphemePath = 'lmfp',
    keyAELAMorpheme = 'lmfn',
    keyAELAHomograph = 'lmfh'
};
```

Morpheme Key Values

Specify key values used for morpheme/homgraph information.

```
enum {
    keyAEMorphemePartOfSpeechCode = 'lamc',
    keyAEMorphemeTextRange = 'lamt'
};
```

All Morphemes Constant

Specifies to use all morphemes.

```
enum {
    kLAAllMorphemes = 0
};
```

Leading and Trailing Constants

Specify constraints to apply to a string.

```
enum {
    kLADefaultEdge = 0,
    kLAFreeEdge = 1,
    kLAIncompleteEdge = 2
};
```

Converting Mask

Defines a mask for high-level API conversion flags.

```
enum {
    kLAEndOfSourceTextMask = 0x00000001
};
```

Morphemes Array Version

Specifies the version of the array used to hold morpheme analysis results.

```
enum {
    kLAMorphemesArrayVersion = 0
};
```

Conjugation Constants

Specify Japanese conjugations.

```
enum {
    kLASpeechKatsuyouGokan = 0x00000001,
    kLASpeechKatsuyouMizen = 0x00000002,
    kLASpeechKatsuyouRenyou = 0x00000003,
    kLASpeechKatsuyouSyuushi = 0x00000004,
    kLASpeechKatsuyouRentai = 0x00000005,
    kLASpeechKatsuyouKatei = 0x00000006,
    kLASpeechKatsuyouMeirei = 0x00000007
};
```

Parts of Speech Constants

Specify Japanese parts of speech.

```
enum {
    kLASpeechMeishi = 0x00000000,
    kLASpeechFutsuuMeishi = 0x00000000,
    kLASpeechJinmei = 0x00000100,
    kLASpeechJinmeiSei = 0x00000110,
    kLASpeechJinmeiMei = 0x00000120,
    kLASpeechChimei = 0x00000200,
    kLASpeechSetsubiChimei = 0x00000210,
    kLASpeechSoshikimei = 0x00000300,
    kLASpeechKoyuuMeishi = 0x00000400,
    kLASpeechSahenMeishi = 0x00000500,
    kLASpeechKeidouMeishi = 0x00000600,
    kLASpeechRentaishi = 0x00001000,
    kLASpeechFukushi = 0x00002000,
    kLASpeechSetsuzokushi = 0x00003000,
    kLASpeechKandoushi = 0x00004000,
    kLASpeechDoushi = 0x00005000,
    kLASpeechGodanDoushi = 0x00005000,
    kLASpeechKagyouGodan = 0x00005000,
    kLASpeechSagyouGodan = 0x00005010,
    kLASpeechTagyouGodan = 0x00005020,
    kLASpeechNagyouGodan = 0x00005030,
    kLASpeechMagyouGodan = 0x00005040,
    kLASpeechRagyouGodan = 0x00005050,
    kLASpeechWagyouGodan = 0x00005060,
    kLASpeechGagyouGodan = 0x00005070,
    kLASpeechBagyouGodan = 0x00005080,
    kLASpeechIchidanDoushi = 0x00005100,
    kLASpeechKahenDoushi = 0x00005200,
    kLASpeechSahenDoushi = 0x00005300,
    kLASpeechZahenDoushi = 0x00005400,
    kLASpeechKeiyoushi = 0x00006000,
    kLASpeechKeiyoudoushi = 0x00007000,
    kLASpeechSettougo = 0x00008000,
    kLASpeechSuujiSettougo = 0x00008100,
    kLASpeechSetsubigo = 0x00009000,
    kLASpeechJinmeiSetsubigo = 0x00009100,
    kLASpeechChimeiSetsubigo = 0x00009200,
    kLASpeechSoshikimeiSetsubigo = 0x00009300,
    kLASpeechSuujiSetsubigo = 0x00009400,
    kLASpeechMuhinshi = 0x0000A000,
    kLASpeechTankanji = 0x0000A000,
    kLASpeechKigou = 0x0000A100,
    kLASpeechKuten = 0x0000A110,
    kLASpeechTouten = 0x0000A120,
    kLASpeechSuushi = 0x0000A200,
    kLASpeechDokuritsugo = 0x0000A300,
    kLASpeechSeiku = 0x0000A400,
    kLASpeechJodoushi = 0x0000B000,
    kLASpeechJoshi = 0x0000C000
};
```

Parts of Speech Masks

Specify masks for parts of speech.

```
enum {
    kLASpeechRoughClassMask = 0x0000F000,
    kLASpeechMediumClassMask = 0x0000FF00,
    kLASpeechStrictClassMask = 0x0000FFF0,
    kLASpeechKatsuyouMask = 0x0000000F
};
```

Engine Limitations

Specify language analysis engine limitations.

```
enum {
    kMaxInputLengthOfAppleJapaneseEngine = 200
};
```

Analysis Engine Type Definitions

Specify language analysis engine type definitions for morpheme/homograph information.

```
enum {
    typeAEHomographDicInfo = 'lahd',
    typeAEHomographWeight = typeShortInteger,
    typeAEHomographAccent = 'laha'
};
```

Morpheme Types

Specify data types for morphemes.

```
enum {
    typeAEMorphemePartOfSpeechCode = 'lamc',
    typeAEMorphemeTextRange = 'lamt'
};
```

Morpheme Type Analysis Constants

Specify types used in morphological analysis.

```
enum { typeLAMorphemeBundle = typeAERecord, typeLAMorphemePath = typeAERecord,
typeLAMorpheme = typeAEList, typeLAHomograph = typeAEList };
```

Default Environment Names

Specify names for default environments for Japanese analysis.

```
#define kLAJapaneseKanaKanjiEnvironment "\pKanaKanjiConversion"
#define kLAJapaneseMorphemeAnalysisEnvironment
                                "\pJapaneseMorphemeAnalysis"
#define kLAJapaneseTTSEnvironment         "\pJapaneseTextToSpeech"
```

Result Codes

The most common result codes retuned by the Language Analysis Manager are listed in the table below.

Result Code	Value	Description
laTooSmallBufferErr	-6984	The output buffer is too small to store any result. Available in Mac OS X v10.0 and later.
laEnvironmentBusyErr	-6985	The specified environment is used. Available in Mac OS X v10.0 and later.
laEnvironmentNotFoundErr	-6986	The specified environment can't be found. Available in Mac OS X v10.0 and later.
laEnvironmentExistErr	-6987	An environment by the same name already exists. Available in Mac OS X v10.0 and later.
laInvalidPathErr	-6988	The path is not correct. Available in Mac OS X v10.0 and later.
laNoMoreMorphemeErr	-6989	There is nothing to read. Available in Mac OS X v10.0 and later.
laFailAnalysisErr	-6990	The analysis failed. Available in Mac OS X v10.0 and later.
laTextOverFlowErr	-6991	The text is too long. Available in Mac OS X v10.0 and later.
laDictionaryNotOpenedErr	-6992	The dictionary is not opened. Available in Mac OS X v10.0 and later.
laDictionaryUnknownErr	-6993	This dictionary can't be used with this environment. Available in Mac OS X v10.0 and later.
laDictionaryTooManyErr	-6994	There are too many dictionaries. Available in Mac OS X v10.0 and later.
laPropertyValueErr	-6995	Invalid property value. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
laPropertyUnknownErr	-6996	The property is unknown to this environment. Available in Mac OS X v10.0 and later.
laPropertyIsReadOnlyErr	-6997	The property is read only. Available in Mac OS X v10.0 and later.
laPropertyNotFoundErr	-6998	The property can't be found. Available in Mac OS X v10.0 and later.
laPropertyErr	-6999	There is an error in the property. Available in Mac OS X v10.0 and later.
laEngineNotFoundErr	-7000	The engine can't be found. Available in Mac OS X v10.0 and later.

Palette Manager Reference (Not Recommended)

Framework: ApplicationServices/ApplicationServices.h
Declared in Palettes.h

Overview

Important: The Palette Manager is deprecated as of Mac OS X v10.4. There is no replacement.

Prior to Mac OS X, applications could use the Palette Manager to ensure that the best set of colors is available when drawing to displays with limited color capabilities (pixel depth of 8 bits or less). For applications running in Mac OS X, the Palette Manager is no longer relevant because display devices always support direct color (pixel depth of 16 or 32 bits). The palette-based graphics model only works in 256-color (8-bit pseudocolor) modes of operation, which are not supported for the Mac OS X GUI.

There is some support for palettes in Quartz Services; see *Quartz Display Services Reference*.

Functions by Task

Function descriptions are grouped by programming task. For an alphabetical list of functions, see the API index.

Animating Palettes

`AnimateEntry` (page 1361) Deprecated in Mac OS X v10.4
Changes the color of a window's palette entry. (Deprecated. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

`AnimatePalette` (page 1362) Deprecated in Mac OS X v10.4
Changes the colors of a series of palette entries; it is similar to the `AnimateEntry` function, but it acts upon a range of entries. (Deprecated. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

Changing the Pixel Depth for a Video Device

`SetDepth` (page 1382)
Changes the pixel depth of a video device. (Deprecated. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

`HasDepth` (page 1371) Deprecated in Mac OS X v10.4
Determines whether a video device supports a specific pixel depth. (Deprecated. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

Drawing With Color Palettes

`PmBackColor` (page 1376) Deprecated in Mac OS X v10.4
Sets the background color field of the current graphics port to a palette color. (Deprecated. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

`PmForeColor` (page 1376) Deprecated in Mac OS X v10.4
Sets the foreground color field of the current graphics port to a palette color. (Deprecated. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

`RestoreBack` (page 1379) Deprecated in Mac OS X v10.4
Sets the current background color to the color you specify. (Deprecated. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

`RestoreFore` (page 1380) Deprecated in Mac OS X v10.4
Sets the current foreground color to the color you supply. (Deprecated. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

`SaveBack` (page 1381) Deprecated in Mac OS X v10.4
Saves the current background color. (Deprecated. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

`SaveFore` (page 1381) Deprecated in Mac OS X v10.4
Saves the current foreground color. (Deprecated. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

Initializing and Allocating Palettes

`DisposePalette` (page 1365) Deprecated in Mac OS X v10.4
Disposes of a palette. (Deprecated. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

`GetNewPalette` (page 1369) Deprecated in Mac OS X v10.4
Creates and initializes a palette from a `'pltt'` resource. (Deprecated. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

`NewPalette` (page 1373) Deprecated in Mac OS X v10.4
Allocates a new palette from colors in the color table. (Deprecated. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

Initializing the Palette Manager

`InitPalettes` (page 1372) Deprecated in Mac OS X v10.4
Initializes the Palette Manager. (Deprecated. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

`PMgrVersion` (page 1377) Deprecated in Mac OS X v10.4
Determines which version of the Palette Manager is executing; it returns an integer specifying the version number. (Deprecated. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

Interacting With the Window Manager

`ActivatePalette` (page 1360) Deprecated in Mac OS X v10.4
Changes the device color tables and generates window updates as needed to meet the color requirements of your window. (Deprecated. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

`GetPalette` (page 1370) Deprecated in Mac OS X v10.4
Obtains a window's palette. (Deprecated. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

`GetPaletteUpdates` (page 1371) Deprecated in Mac OS X v10.4
Obtains the update attribute of a palette. (Deprecated. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

`NSetPalette` (page 1374) Deprecated in Mac OS X v10.4
Associates a new palette with a window. (Deprecated. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

`SetPalette` (page 1385) Deprecated in Mac OS X v10.4
Associates a palette with a window. (Deprecated. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

`SetPaletteUpdates` (page 1386) Deprecated in Mac OS X v10.4
Sets the update attribute of a palette. (Deprecated. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

Manipulating Palette Entries

`Entry2Index` (page 1366) Deprecated in Mac OS X v10.4
Obtains the index for a specified entry in the current graphics port's palette on the current device. (Deprecated. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

`GetEntryColor` (page 1367) Deprecated in Mac OS X v10.4
Obtains the color of a palette entry. (Deprecated. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

`GetEntryUsage` (page 1367) Deprecated in Mac OS X v10.4
Obtains the usage and tolerance fields of a palette entry. (Deprecated. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

`SetEntryColor` (page 1383) Deprecated in Mac OS X v10.4
Changes the color of a palette entry. (Deprecated. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

`SetEntryUsage` (page 1384) Deprecated in Mac OS X v10.4
Modifies the usage category and tolerance values of a palette entry. (Deprecated. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

Manipulating Palettes and Color Tables

`CopyPalette` (page 1363) Deprecated in Mac OS X v10.4
: Copies entries from one palette to another. (Deprecated. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

`CTab2Palette` (page 1364) Deprecated in Mac OS X v10.4
: Copies the colors of a color table into a palette. (Deprecated. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

`Palette2CTab` (page 1375) Deprecated in Mac OS X v10.4
: Copies the colors of a palette into a color table. (Deprecated. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

`ResizePalette` (page 1378) Deprecated in Mac OS X v10.4
: Changes the size of a palette. (Deprecated. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

`RestoreDeviceClut` (page 1379) Deprecated in Mac OS X v10.4
: Sets the color table of a graphics device to its default state. (Deprecated. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

Miscellaneous

`GetGray` (page 1368) Deprecated in Mac OS X v10.4
: Determines the best intermediate color between two colors on a given graphics device. (Deprecated. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

Functions

ActivatePalette

Changes the device color tables and generates window updates as needed to meet the color requirements of your window. (Deprecated in Mac OS X v10.4. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

Not recommended.

```
void ActivatePalette (
   WindowRef srcWindow
);
```

Parameters

srcWindow
: A pointer to the window for which you want status changes reported.

Discussion

The Window Manager calls `ActivatePalette` when your window's status changes—for example, when your window opens, closes, moves, or becomes frontmost. You need to call the `ActivatePalette` function yourself if you change a palette—for example, by changing a color with the `SetEntryColor` function—and you want the changes to take place immediately, before the Window Manager would do it.

If the window specified in the `srcWindow` parameter is frontmost, `ActivatePalette` examines the information stored in the window's palette and attempts to provide the color environment described therein. It determines a list of devices on which to render the palette by intersecting the port rectangle of the window with each device. If the intersection is not empty and if the device has a color table, then `ActivatePalette` checks to see if the color environment is sufficient. If a change is required, `ActivatePalette` calls QuickDraw to reserve or modify the device's color entries as needed. The `ActivatePalette` function then generates update events for all windows that need color updates.

Calling `ActivatePalette` with an offscreen graphics world has no effect.

Special Considerations

For applications running in Mac OS X, the Palette Manager is no longer relevant because display devices always support direct color (pixel depth of 16 or 32 bits). The palette-based graphics model only works in 256-color (8-bit pseudocolor) modes of operation, which are not supported for the Mac OS X GUI.

There is some support for palettes in Quartz Services; see *Quartz Display Services Reference*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Palettes.h`

AnimateEntry

Changes the color of a window's palette entry. (Deprecated in Mac OS X v10.4. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

Not recommended.

```
void AnimateEntry (
   WindowRef dstWindow,
   short dstEntry,
   const RGBColor *srcRGB
);
```

Parameters

dstWindow
A pointer to the window whose palette color is to be changed.

dstEntry
The palette entry to be changed.

srcRGB
A pointer to the new RGB value.

Discussion
The `AnimateEntry` function changes the RGB value of an animated entry for a window's palette. Each device for which that index has been reserved is immediately modified to contain the new value. This is not considered to be a change to the device's color environment because no other windows should be using the animated entry.

If the palette entry is not an animated color or if the associated indexes are no longer reserved, no animation occurs.

If you have blocked color updates in a window by using `SetPalette` with `cUpdates` set to `FALSE`, you may observe unintentional animation. This occurs when `ActivatePalette` reserves for animation device indexes that are already used in the window. Redrawing the window, which normally is the result of a color update event, removes any animated colors that do not belong to the window.

Special Considerations

For applications running in Mac OS X, the Palette Manager is no longer relevant because display devices always support direct color (pixel depth of 16 or 32 bits). The palette-based graphics model only works in 256-color (8-bit pseudocolor) modes of operation, which are not supported for the Mac OS X GUI.

There is some support for palettes in Quartz Services; see *Quartz Display Services Reference*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Palettes.h`

AnimatePalette

Changes the colors of a series of palette entries; it is similar to the `AnimateEntry` function, but it acts upon a range of entries. (Deprecated in Mac OS X v10.4. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

Not recommended.

```
void AnimatePalette (
    WindowRef dstWindow,
    CTabHandle srcCTab,
    short srcIndex,
    short dstEntry,
    short dstLength
);
```

Parameters

dstWindow
A pointer to the window whose palette colors are to be changed.

srcCTab
A handle to the color table containing the new colors.

srcIndex
The source color table entry at which copying starts.

dstEntry
The palette entry at which copying starts.

dstLength
The number of palette entries to be changed.

Discussion
The `AnimatePalette` function changes the colors of a series of palette entries. Beginning at the index specified by the `srcIndex` parameter (which has a minimum value of 0), the number of entries specified in `dstLength` are copied from the source color table to the destination window's palette, beginning at the entry specified in the `dstEntry` parameter. If the source color table specified in `srcCTab` is not sufficiently large to accommodate the request, `AnimatePalette` modifies as many entries as possible and leaves the remaining entries unchanged.

Special Considerations

For applications running in Mac OS X, the Palette Manager is no longer relevant because display devices always support direct color (pixel depth of 16 or 32 bits). The palette-based graphics model only works in 256-color (8-bit pseudocolor) modes of operation, which are not supported for the Mac OS X GUI.

There is some support for palettes in Quartz Services; see *Quartz Display Services Reference*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Palettes.h`

CopyPalette

Copies entries from one palette to another. (Deprecated in Mac OS X v10.4. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

Not recommended.

```
void CopyPalette (
   PaletteHandle srcPalette,
   PaletteHandle dstPalette,
   short srcEntry,
   short dstEntry,
   short dstLength
);
```

Parameters

srcPalette
A handle to the palette from which colors are copied.

dstPalette
A handle to the palette to which colors are copied.

srcEntry
The source palette entry at which copying starts.

dstEntry
The destination palette entry at which copying starts.

dstLength
The number of destination palette entries to change.

Discussion
The `CopyPalette` function copies entries from the source palette into the destination palette. The copy operation begins at the values specified by the `srcEntry` and `dstEntry` parameters, copying into as many entries as are specified by the `dstLength` parameter. `CopyPalette` resizes the destination palette when the number of entries after the copy operation is greater than it was before the copy operation.

`CopyPalette` does not call `ActivatePalette`, so your application is free to change the palette a number of times without causing a series of intermediate changes to the color environment. Your application should call `ActivatePalette` after completing all palette changes.

If either of the palette handles is `NULL`, `CopyPalette` does nothing.

Special Considerations

For applications running in Mac OS X, the Palette Manager is no longer relevant because display devices always support direct color (pixel depth of 16 or 32 bits). The palette-based graphics model only works in 256-color (8-bit pseudocolor) modes of operation, which are not supported for the Mac OS X GUI.

There is some support for palettes in Quartz Services; see *Quartz Display Services Reference*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Palettes.h`

CTab2Palette

Copies the colors of a color table into a palette. (Deprecated in Mac OS X v10.4. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

Not recommended.

```
void CTab2Palette (
   CTabHandle srcCTab,
   PaletteHandle dstPalette,
   short srcUsage,
   short srcTolerance
);
```

Parameters

srcCTab
A handle to the color table whose colors are to be copied.

dstPalette
The palette to receive the colors.

srcUsage
A usage constant to be assigned the palette entries. Usage constants are described in "Update Constants" (page 1390).

srcTolerance
A tolerance value to be assigned the palette entries.

Discussion
The `CTab2Palette` function copies the fields from an existing color-table structure into an existing palette structure. If the structures are not the same size, then `CTab2Palette` resizes the palette structure to match the number of entries in the color-table structure. If the palette in `dstPalette` has any entries allocated for animation on any screen device, they are relinquished before the new colors are copied. The `srcUsage` and `srcTolerance` parameters are the value that you assign to the new colors.

If you want to use color-table animation, you can use `AnimateEntry` (page 1361) and `AnimatePalette` (page 1362) to change the colors in a palette and on corresponding devices. Changes made to a palette by `CTab2Palette` do not take effect until the next `ActivatePalette` function is performed. If either the color-table handle or the palette handle is `NULL`, `CTab2Palette` does nothing.

Special Considerations

For applications running in Mac OS X, the Palette Manager is no longer relevant because display devices always support direct color (pixel depth of 16 or 32 bits). The palette-based graphics model only works in 256-color (8-bit pseudocolor) modes of operation, which are not supported for the Mac OS X GUI.

There is some support for palettes in Quartz Services; see *Quartz Display Services Reference*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Palettes.h`

DisposePalette

Disposes of a palette. (Deprecated in Mac OS X v10.4. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

Not recommended.

```
void DisposePalette (
   PaletteHandle srcPalette
);
```

Parameters
`srcPalette`
A handle to the palette to be disposed of.

Discussion
If the palette has any entries allocated for animation on any screen device, then `DisposePalette` relinquishes these entries before the palette's memory is released.

If a palette is attached to a window automatically—because the palette resource and the window have the same ID—you do not have to call the `DisposePalette` function to dispose of the function. The Palette Manager and Window Manager dispose of the palette automatically if the palette is replaced or if the window goes away.

However, if you explicitly attach a palette to a window with the `SetPalette` or `NSetPalette` function, your application owns the palette and is responsible for disposing of it. It is possible to attach a single palette to multiple windows; therefore, even when a window goes away and no longer needs a palette, other windows may still need it.

Special Considerations

For applications running in Mac OS X, the Palette Manager is no longer relevant because display devices always support direct color (pixel depth of 16 or 32 bits). The palette-based graphics model only works in 256-color (8-bit pseudocolor) modes of operation, which are not supported for the Mac OS X GUI.

There is some support for palettes in Quartz Services; see *Quartz Display Services Reference*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Palettes.h`

Entry2Index

Obtains the index for a specified entry in the current graphics port's palette on the current device. (Deprecated in Mac OS X v10.4. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

Not recommended.

```
SInt32 Entry2Index (
   short entry
);
```

Parameters

entry
The palette entry whose equivalent device index is to be returned.

Return Value
The index of the given `entry`.

Special Considerations

For applications running in Mac OS X, the Palette Manager is no longer relevant because display devices always support direct color (pixel depth of 16 or 32 bits). The palette-based graphics model only works in 256-color (8-bit pseudocolor) modes of operation, which are not supported for the Mac OS X GUI.

There is some support for palettes in Quartz Services; see *Quartz Display Services Reference*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Palettes.h`

GetEntryColor

Obtains the color of a palette entry. (Deprecated in Mac OS X v10.4. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

Not recommended.

```
void GetEntryColor (
   PaletteHandle srcPalette,
   short srcEntry,
   RGBColor *dstRGB
);
```

Parameters

srcPalette

A handle to the palette to be accessed.

srcEntry

The palette entry whose color is desired.

dstRGB

A pointer to an RGB color structure to receive the palette color.

Discussion

You can modify the entry's color using the `SetEntryColor` (page 1383) function.

Special Considerations

For applications running in Mac OS X, the Palette Manager is no longer relevant because display devices always support direct color (pixel depth of 16 or 32 bits). The palette-based graphics model only works in 256-color (8-bit pseudocolor) modes of operation, which are not supported for the Mac OS X GUI.

There is some support for palettes in Quartz Services; see *Quartz Display Services Reference*.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Palettes.h`

GetEntryUsage

Obtains the usage and tolerance fields of a palette entry. (Deprecated in Mac OS X v10.4. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

Not recommended.

```
void GetEntryUsage (
   PaletteHandle srcPalette,
   short srcEntry,
   short *dstUsage,
   short *dstTolerance
);
```

Parameters

srcPalette

A handle to the palette to be accessed.

srcEntry

The palette entry whose usage and tolerance are desired.

dstUsage

A pointer to the usage value of the palette entry.

dstTolerance

A pointer to the tolerance value of the palette entry.

Discussion

You can modify the entry's usage and tolerance values by using the `SetEntryUsage` (page 1384) function.

Special Considerations

For applications running in Mac OS X, the Palette Manager is no longer relevant because display devices always support direct color (pixel depth of 16 or 32 bits). The palette-based graphics model only works in 256-color (8-bit pseudocolor) modes of operation, which are not supported for the Mac OS X GUI.

There is some support for palettes in Quartz Services; see *Quartz Display Services Reference*.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Palettes.h`

GetGray

Determines the best intermediate color between two colors on a given graphics device. (Deprecated in Mac OS X v10.4. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

```
Boolean GetGray (
   GDHandle device,
   const RGBColor *backGround,
   RGBColor *foreGround
);
```

Parameters

device

A handle to the graphics device for which an intermediate color or gray is needed.

backGround

The `RGBColor` structure for one of the two colors for which you want an intermediate color.

foreGround
On input, the `RGBColor` structure for the other of the two colors; upon completion, the best intermediate color between these two.

Return Value
If no gray is available (or if no distinguishable third color is available), the `foreGround` parameter is unchanged, and the function returns `FALSE`. If at least one gray or intermediate color is available, it is returned in the `foreGround` parameter, and the function returns `TRUE`.

Discussion
The `GetGray` function determines the midpoint values for the red, green, and blue values of the two colors you specify in the `backGround` and `foreGround` parameters.

You can also use `GetGray` to return the best gray. For example, when dimming an object, supply black and white as the two colors, and `GetGray` returns the best available gray that lies between them.

Special Considerations

For applications running in Mac OS X, the Palette Manager is no longer relevant because display devices always support direct color (pixel depth of 16 or 32 bits). The palette-based graphics model only works in 256-color (8-bit pseudocolor) modes of operation, which are not supported for the Mac OS X GUI.

There is some support for palettes in Quartz Services; see *Quartz Display Services Reference*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Palettes.h`

GetNewPalette

Creates and initializes a palette from a `'pltt'` resource. (Deprecated in Mac OS X v10.4. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

Not recommended.

```
PaletteHandle GetNewPalette (
   short PaletteID
);
```

Parameters
PaletteID
The resource ID of the source palette.

Return Value
A handle to the new palette.

Discussion
The `GetNewPalette` function detaches the resource when it creates the new palette, so you do not need to call the `ReleaseResource` function.

If you open a new color window with `GetNewCWindow`, the Window Manager calls `GetNewPalette` automatically, with `paletteID` equal to the window's resource ID. Therefore, if you have created a palette resource with the same ID as a window, the Window Manager and Palette Manager automatically create the palette for you and your application need not call `GetNewPalette` to create the palette.

To attach a palette to a window after creating it, use the `SetPalette` (page 1385) function. To change the entries in a palette after creating it, use the `SetEntryColor` (page 1383) and `SetEntryUsage` (page 1384) functions.

Special Considerations

For applications running in Mac OS X, the Palette Manager is no longer relevant because display devices always support direct color (pixel depth of 16 or 32 bits). The palette-based graphics model only works in 256-color (8-bit pseudocolor) modes of operation, which are not supported for the Mac OS X GUI.

There is some support for palettes in Quartz Services; see *Quartz Display Services Reference*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Palettes.h`

GetPalette

Obtains a window's palette. (Deprecated in Mac OS X v10.4. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

Not recommended.

```
PaletteHandle GetPalette (
   WindowRef srcWindow
);
```

Parameters

`srcWindow`
A pointer to the window for which you want the associated palette.

Return Value
A handle to the palette associated with the window specified in the `srcWindow` parameter or `NULL` if the window has no associated palette or is not a color window.

Discussion
Normally, the `GetPalette` function does not allocate memory, with one exception. When your application calls `GetPalette` to get a copy of the default application palette, the Palette Manager looks at the `AppPalette` global variable. If `AppPalette` is `NULL`, `GetPalette` makes a copy of the default system palette and returns a handle to this copy.

You request the default palette as follows:

myPaletteHndl = GetPalette ((WindowPtr) -1);

Special Considerations

For applications running in Mac OS X, the Palette Manager is no longer relevant because display devices always support direct color (pixel depth of 16 or 32 bits). The palette-based graphics model only works in 256-color (8-bit pseudocolor) modes of operation, which are not supported for the Mac OS X GUI.

There is some support for palettes in Quartz Services; see *Quartz Display Services Reference*.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Palettes.h`

GetPaletteUpdates

Obtains the update attribute of a palette. (Deprecated in Mac OS X v10.4. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

Not recommended.

```
short GetPaletteUpdates (
   PaletteHandle p
);
```

Parameters

p

A handle to the palette.

Return Value

One of the update attributes described in "Update Constants" (page 1390).

Special Considerations

For applications running in Mac OS X, the Palette Manager is no longer relevant because display devices always support direct color (pixel depth of 16 or 32 bits). The palette-based graphics model only works in 256-color (8-bit pseudocolor) modes of operation, which are not supported for the Mac OS X GUI.

There is some support for palettes in Quartz Services; see *Quartz Display Services Reference*.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Palettes.h`

HasDepth

Determines whether a video device supports a specific pixel depth. (Deprecated in Mac OS X v10.4. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

```
short HasDepth (
   GDHandle gd,
   short depth,
   short whichFlags,
   short flags
);
```

Parameters

gd

A handle to the `GDevice` structure of the video device.

depth

The pixel depth for which you're testing.

whichFlags

The `gdDevType` constant, which represents a bit in the `gdFlags` field of the `GDevice` structure. If this bit is set to 0 in the `GDevice` structure, the video device is black and white; if the bit is set to 1, the device supports color.

flags

The value 0 or 1. If you pass 0 in this parameter, the `HasDepth` function tests whether the video device is black and white. If you pass 1 in this parameter, `HasDepth` tests whether the video device supports color.

Return Value

Returns 0 if the device does not support the depth you specify in the `depth` parameter or the display mode you specify in the `flags` parameter. Any other value indicates that the device supports the specified depth and display mode. The function result contains the mode ID that QuickDraw passes to the video driver to set its pixel depth and to specify color or black and white. You can pass this mode ID in the `depth` parameter for the `SetDepth` function to set the graphics device to the pixel depth and display mode for which you tested.

Special Considerations

For applications running in Mac OS X, the Palette Manager is no longer relevant because display devices always support direct color (pixel depth of 16 or 32 bits). The palette-based graphics model only works in 256-color (8-bit pseudocolor) modes of operation, which are not supported for the Mac OS X GUI.

There is some support for palettes in Quartz Services; see *Quartz Display Services Reference*.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Palettes.h`

InitPalettes

Initializes the Palette Manager. (Deprecated in Mac OS X v10.4. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

Not recommended.

```
void InitPalettes (
   void
);
```

Discussion
The `InitPalettes` function searches for devices that support a device color table and initializes an internal data structure for each one. Your application does not have to call `InitPalettes` because the Window Manager's `InitWindows` function calls it automatically.

Special Considerations

For applications running in Mac OS X, the Palette Manager is no longer relevant because display devices always support direct color (pixel depth of 16 or 32 bits). The palette-based graphics model only works in 256-color (8-bit pseudocolor) modes of operation, which are not supported for the Mac OS X GUI.

There is some support for palettes in Quartz Services; see *Quartz Display Services Reference*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Palettes.h`

NewPalette

Allocates a new palette from colors in the color table. (Deprecated in Mac OS X v10.4. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

Not recommended.

```
PaletteHandle NewPalette (
   short entries,
   CTabHandle srcColors,
   short srcUsage,
   short srcTolerance
);
```

Parameters

entries
The number of `ColorInfo` structures to be created in the new palette.

srcColors
A handle to the color table from which the colors are to be obtained. If no color table is provided (`srcColors` = `NULL`), then all colors in the palette are set to black (red, green, and blue equal to $0000).

srcUsage
The usage value to be assigned each `ColorInfo` structure in the palette.

srcTolerance
The tolerance value to be assigned each `ColorInfo` structure in the palette.

Return Value
A handle to the new palette.

Discussion
The `NewPalette` function fills the palette with as many RGB values from the color table as it has or can fit.

To attach a palette to a window after creating it, use the `SetPalette` (page 1385) function. To change the entries in a palette after creating it, use the `SetEntryColor` (page 1383) and `SetEntryUsage` (page 1384) functions.

Special Considerations

For applications running in Mac OS X, the Palette Manager is no longer relevant because display devices always support direct color (pixel depth of 16 or 32 bits). The palette-based graphics model only works in 256-color (8-bit pseudocolor) modes of operation, which are not supported for the Mac OS X GUI.

There is some support for palettes in Quartz Services; see *Quartz Display Services Reference*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Palettes.h`

NSetPalette

Associates a new palette with a window. (Deprecated in Mac OS X v10.4. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

Not recommended.

```
void NSetPalette (
   WindowRef dstWindow,
   PaletteHandle srcPalette,
   short nCUpdates
);
```

Parameters

dstWindow
A pointer to the window to which you want to assign a new palette.

srcPalette
A handle to the palette you want to assign.

nCUpdates
An integer value in which you specify whether the window is to receive updates as a result of various changes to the color environment. See "Update Constants" (page 1390) for a description of the update options.

Discussion
`NSetPalette` changes the palette associated with the window specified in the `dstWindow` parameter to the palette specified by `srcPalette`. `NSetPalette` also records whether the window is to receive updates as a result of changes to its color environment. The update constants, which you pass to the `nCUpdates` parameter, determine when the window is updated.

This function is identical to the `SetPalette` (page 1385) function except that the `nCUpdates` parameter is an integer rather than a Boolean value, so that a variety of conditions can trigger an update event.

Use the SetPalette (page 1385) function if you do not need the flexibility that NSetPalette provides for update events.

Use the GetNewPalette (page 1369) function or the NewPalette (page 1373) function to create a new palette. To dispose of a palette, use the DisposePalette (page 1365) function.

Special Considerations

For applications running in Mac OS X, the Palette Manager is no longer relevant because display devices always support direct color (pixel depth of 16 or 32 bits). The palette-based graphics model only works in 256-color (8-bit pseudocolor) modes of operation, which are not supported for the Mac OS X GUI.

There is some support for palettes in Quartz Services; see *Quartz Display Services Reference*.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

Palettes.h

Palette2CTab

Copies the colors of a palette into a color table. (Deprecated in Mac OS X v10.4. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

Not recommended.

```
void Palette2CTab (
   PaletteHandle srcPalette,
   CTabHandle dstCTab
);
```

Parameters

srcPalette

A handle to the palette whose colors are to be used.

dstCTab

A handle to the color table to receive the colors.

Discussion

The Palette2CTab function copies all of the colors from an existing palette structure into an existing color-table structure. If the structures are not the same size, then Palette2CTab resizes the color-table structure to match the number of entries in the palette structure. If either the palette handle or the color-table handle is NULL, Palette2CTab does nothing.

Special Considerations

For applications running in Mac OS X, the Palette Manager is no longer relevant because display devices always support direct color (pixel depth of 16 or 32 bits). The palette-based graphics model only works in 256-color (8-bit pseudocolor) modes of operation, which are not supported for the Mac OS X GUI.

There is some support for palettes in Quartz Services; see *Quartz Display Services Reference*.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Palettes.h`

PmBackColor

Sets the background color field of the current graphics port to a palette color. (Deprecated in Mac OS X v10.4. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

Not recommended.

```
void PmBackColor (
   short dstEntry
);
```

Parameters

dstEntry

The palette entry whose color is to be used as the background color.

Discussion
The `PmBackColor` function sets the current color graphics port's `rgbBkColor` field to match the color in the entry specified by the `dstEntry` parameter of the palette associated with the current window structure. For courteous and tolerant entries, `PmBackColor` calls the `RGBBackColor` function using the RGB color of the palette entry. For animated colors, `PmBackColor` selects the recorded device index previously reserved for animation (if still present) and installs it in the color graphics port. The `rgbBgColor` field is set to the value from the palette entry. For explicit colors, `PmBackColor` places the value

```
dstEntry modulo (maxIndex +1)
```

into the color graphics port, where `maxIndex` is the largest index available in a device's color table. When multiple devices with different depths are present, `maxIndex` varies appropriately for each device.

Special Considerations

For applications running in Mac OS X, the Palette Manager is no longer relevant because display devices always support direct color (pixel depth of 16 or 32 bits). The palette-based graphics model only works in 256-color (8-bit pseudocolor) modes of operation, which are not supported for the Mac OS X GUI.

There is some support for palettes in Quartz Services; see *Quartz Display Services Reference*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Palettes.h`

PmForeColor

Sets the foreground color field of the current graphics port to a palette color. (Deprecated in Mac OS X v10.4. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

Not recommended.

```
void PmForeColor (
   short dstEntry
);
```

Parameters

dstEntry

The palette entry whose color is to be used as the foreground color.

Discussion

The `PmForeColor` function sets the current color graphics port's `rgbFgColor` field to match the color in the entry specified by the `dstEntry` parameter of the palette associated with the current window structure. For courteous and tolerant entries, `PmForeColor` calls the `RGBForeColor` function using the RGB color of the palette entry. For animated colors, `PmForeColor` selects the recorded device index previously reserved for animation (if still present) and installs it in the color graphics port. The RGB foreground color field is set to the value from the palette entry. For explicit colors, `PmForeColor` places the value

```
dstEntry modulo (maxIndex +1)
```

into the color graphics port, where `maxIndex` is the largest index available in a device's color table. When multiple devices with different depths are present, the value of `maxIndex` varies appropriately for each device.

Special Considerations

For applications running in Mac OS X, the Palette Manager is no longer relevant because display devices always support direct color (pixel depth of 16 or 32 bits). The palette-based graphics model only works in 256-color (8-bit pseudocolor) modes of operation, which are not supported for the Mac OS X GUI.

There is some support for palettes in Quartz Services; see *Quartz Display Services Reference*.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Palettes.h`

PMgrVersion

Determines which version of the Palette Manager is executing; it returns an integer specifying the version number. (Deprecated in Mac OS X v10.4. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

```
short PMgrVersion (
   void
);
```

Return Value

`PMgrVersion` returns $0202 if system software version 7.0 is executing; $0201 if system software version 6.0.5 is executing; and $0200 if the original 32-Bit QuickDraw system extension is executing.

Special Considerations

For applications running in Mac OS X, the Palette Manager is no longer relevant because display devices always support direct color (pixel depth of 16 or 32 bits). The palette-based graphics model only works in 256-color (8-bit pseudocolor) modes of operation, which are not supported for the Mac OS X GUI.

There is some support for palettes in Quartz Services; see *Quartz Display Services Reference*.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Palettes.h`

ResizePalette

Changes the size of a palette. (Deprecated in Mac OS X v10.4. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

Not recommended.

```
void ResizePalette (
    PaletteHandle p,
    short size
);
```

Parameters

p

A handle to the palette to be resized.

size

The number of resulting entries in the palette.

Discussion

The `ResizePalette` function sets the palette specified in `srcPalette` to the number of entries indicated in the `size` parameter. If `ResizePalette` adds entries at the end of the palette, it sets them to `pmCourteous`, with the RGB values set to (0,0,0)—that is, black. If `ResizePalette` deletes entries from the end of the palette, it safely disposes of them.

Special Considerations

For applications running in Mac OS X, the Palette Manager is no longer relevant because display devices always support direct color (pixel depth of 16 or 32 bits). The palette-based graphics model only works in 256-color (8-bit pseudocolor) modes of operation, which are not supported for the Mac OS X GUI.

There is some support for palettes in Quartz Services; see *Quartz Display Services Reference*.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Palettes.h`

RestoreBack

Sets the current background color to the color you specify. (Deprecated in Mac OS X v10.4. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

Not recommended.

```
void RestoreBack (
   const ColorSpec *c
);
```

Parameters

c

A pointer to the `ColorSpec` structure containing the RGB color to be set as the background color. If you specify 0 in the `value` field of the `ColorSpec` structure, the `RestoreBack` function stores the RGB value in the `rgbFgColor` field of the current `CGrafPort` structure. If you specify 1 in the `value` field of the `ColorSpec` structure, the `RestoreBack` function stores the RGB value in the `pmBkColor` field of the `GrafVars` structure.

Special Considerations

For applications running in Mac OS X, the Palette Manager is no longer relevant because display devices always support direct color (pixel depth of 16 or 32 bits). The palette-based graphics model only works in 256-color (8-bit pseudocolor) modes of operation, which are not supported for the Mac OS X GUI.

There is some support for palettes in Quartz Services; see *Quartz Display Services Reference*.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Palettes.h`

RestoreDeviceClut

Sets the color table of a graphics device to its default state. (Deprecated in Mac OS X v10.4. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

Not recommended.

```
void RestoreDeviceClut (
   GDHandle gd
);
```

Parameters

gd

A handle to the `GDevice` structure. Pass `NULL` in the `gdh` parameter to restore all screens.

Discussion

The `RestoreDeviceClut` function changes the color table of the device specified by the `gdh` parameter to its default state. If this process changes any entries, the Palette Manager posts color updates to windows intersecting the device.

You do not need to use this function to restore the Finder's desktop colors, because its colors are automatically restored upon switching from applications that use the Palette Manager. Likewise, you need not worry when switching to another application that uses the Palette Manager. Although colors are not automatically restored in this case, if that application needs a certain set of colors, the Palette Manager provides them the moment that application comes to the front.

The reason to use `RestoreDeviceClut` is that you may be switching to an application that does not use the Palette Manager, in which case that application inherits your palette unless you restore the default color lookup tables for all the available display devices.

Special Considerations

For applications running in Mac OS X, the Palette Manager is no longer relevant because display devices always support direct color (pixel depth of 16 or 32 bits). The palette-based graphics model only works in 256-color (8-bit pseudocolor) modes of operation, which are not supported for the Mac OS X GUI.

There is some support for palettes in Quartz Services; see *Quartz Display Services Reference*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Palettes.h`

RestoreFore

Sets the current foreground color to the color you supply. (Deprecated in Mac OS X v10.4. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

Not recommended.

```
void RestoreFore (
   const ColorSpec *c
);
```

Parameters

c

A pointer to the `ColorSpec` structure containing the RGB color to be set as the foreground color. If you specify 0 in the `value` field of the `ColorSpec` structure, the `RestoreFore` function stores the RGB value in the `rgbFgColor` field of the current `CGrafPort` structure. If you specify 1 in the `value` field of the `ColorSpec` structure, the `RestoreFore` function stores the RGB value in the `pmFgColor` field of the `GrafVars` structure.

Special Considerations

For applications running in Mac OS X, the Palette Manager is no longer relevant because display devices always support direct color (pixel depth of 16 or 32 bits). The palette-based graphics model only works in 256-color (8-bit pseudocolor) modes of operation, which are not supported for the Mac OS X GUI.

There is some support for palettes in Quartz Services; see *Quartz Display Services Reference*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`Palettes.h`

SaveBack

Saves the current background color. (Deprecated in Mac OS X v10.4. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

Not recommended.

```
void SaveBack (
   ColorSpec *c
);
```

Parameters

c

A pointer to the `ColorSpec` structure to receive the current background color. A value of 0 in the `value` field of the `ColorSpec` structure specifies retrieving the RGB color from the `rgbBkColor` field of the `CGrafPort` structure; a value of 1 in the `value` field specifies retrieving the palette entry from the `pmBkColor` field of the `GrafVars` structure.

Special Considerations

For applications running in Mac OS X, the Palette Manager is no longer relevant because display devices always support direct color (pixel depth of 16 or 32 bits). The palette-based graphics model only works in 256-color (8-bit pseudocolor) modes of operation, which are not supported for the Mac OS X GUI.

There is some support for palettes in Quartz Services; see *Quartz Display Services Reference*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Palettes.h`

SaveFore

Saves the current foreground color. (Deprecated in Mac OS X v10.4. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

Not recommended.

```
void SaveFore (
   ColorSpec *c
);
```

Parameters

c

A pointer to the `ColorSpec` structure to hold the current foreground color. A value of 0 in the `value` field of the `ColorSpec` structure specifies retrieving the RGB color from the `rgbFgColor` field of the `CGrafPort` structure; a value of 1 in the `value` field specifies retrieving the palette entry from the `pmFgColor` field of the `GrafVars` structure.On return, `ColorSpec` structure holds the current foreground color. You can save either QuickDraw's foreground color from the `CGrafPort` structure or the Palette Manager's foreground color from the `GrafVars` structure.

Special Considerations

For applications running in Mac OS X, the Palette Manager is no longer relevant because display devices always support direct color (pixel depth of 16 or 32 bits). The palette-based graphics model only works in 256-color (8-bit pseudocolor) modes of operation, which are not supported for the Mac OS X GUI.

There is some support for palettes in Quartz Services; see *Quartz Display Services Reference*.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Palettes.h`

SetDepth

Changes the pixel depth of a video device. (**Deprecated.** There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

```
OSErr SetDepth (
   GDHandle gd,
   short depth,
   short whichFlags,
   short flags
);
```

Parameters

gd

A handle to the `GDevice` structure of the video device whose pixel depth you wish to change.

depth

The mode ID returned by the `HasDepth` (page 1371) function indicating that the video device supports the desired pixel depth. Alternatively, you can pass the desired pixel depth directly in this parameter, although you should use the `HasDepth` function to ensure that the device supports this depth.

whichFlags

The `gdDevType` constant, which represents a bit in the `gdFlags` field of the `GDevice` structure. (If this bit is set to 0 in the `GDevice` structure, the video device is black and white; if the bit is set to 1, the device supports color.

flags

The value 0 or 1. If you pass 0 in this parameter, the `SetDepth` function changes the video device to black and white; if you pass 1 in this parameter, `SetDepth` changes the video device to color.

Return Value
Returns zero if successful, or it returns a nonzero value if it cannot impose the desired depth and display mode on the requested device.

Discussion
The `SetDepth` function does not change the `'scrn'` resource; when the system is restarted, the original depth for this device is restored.

The Monitors control panel is the user interface for changing the pixel depth, color capabilities, and positions of video devices. Since the user can control the capabilities of the video device, your application should be flexible: although it may have a preferred pixel depth, your application should do its best to accommodate less than ideal conditions.

Use `SetDepth` only if your application can run on devices of a particular pixel depth and is unable to adapt to any other depth. Your application should display a dialog box that offers the user a choice between changing to that depth or canceling display of the image before your application uses `SetDepth`. Such a dialog box saves the user the trouble of going to the Monitors control panel before returning to your application.

Special Considerations

For applications running in Mac OS X, the Palette Manager is no longer relevant because display devices always support direct color (pixel depth of 16 or 32 bits). The palette-based graphics model only works in 256-color (8-bit pseudocolor) modes of operation, which are not supported for the Mac OS X GUI.

There is some support for palettes in Quartz Services; see *Quartz Display Services Reference*.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ImageCompression.k.h`

SetEntryColor

Changes the color of a palette entry. (Deprecated in Mac OS X v10.4. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

Not recommended.

```
void SetEntryColor (
   PaletteHandle dstPalette,
   short dstEntry,
   const RGBColor *srcRGB
);
```

Parameters

dstPalette

The palette whose entry color is to be changed.

dstEntry

The palette entry to be changed.

srcRGB
A pointer to the new RGB color value.

Discussion
`SetEntryColor` marks the entry as having changed, but it does not change the color environment. That change occurs upon the next call to `ActivatePalette`. `SetEntryColor` marks modified entries such that the palette is updated, even though no update is required by a change in the color environment.

Special Considerations

For applications running in Mac OS X, the Palette Manager is no longer relevant because display devices always support direct color (pixel depth of 16 or 32 bits). The palette-based graphics model only works in 256-color (8-bit pseudocolor) modes of operation, which are not supported for the Mac OS X GUI.

There is some support for palettes in Quartz Services; see *Quartz Display Services Reference*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Palettes.h`

SetEntryUsage

Modifies the usage category and tolerance values of a palette entry. (Deprecated in Mac OS X v10.4. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

Not recommended.

```
void SetEntryUsage (
   PaletteHandle dstPalette,
   short dstEntry,
   short srcUsage,
   short srcTolerance
);
```

Parameters
dstPalette
A handle to the palette to be modified.
dstEntry
The palette entry.
srcUsage
The new usage value; one or more usage constants.
srcTolerance
The new tolerance value.

Discussion
`SetEntryUsage` marks the entry as having changed, but it does not change the color environment. That change occurs upon the next call to `ActivatePalette`. Modified entries are marked such that the palette is updated even though no update is required by a change in the color environment. If either `srcUsage` or `srcTolerance` is set to $FFFF (–1), the entries are not changed.

This function allows you to easily modify a palette created with `NewPalette` or modified by `CTab2Palette`. For such palettes the `ciUsage` and `ciTolerance` fields of the `ColorInfo` structure are the same because you can designate only one value for each. You typically call `SetEntryUsage` after `NewPalette` or `CTab2Palette` to adjust and customize your palette.

Special Considerations

For applications running in Mac OS X, the Palette Manager is no longer relevant because display devices always support direct color (pixel depth of 16 or 32 bits). The palette-based graphics model only works in 256-color (8-bit pseudocolor) modes of operation, which are not supported for the Mac OS X GUI.

There is some support for palettes in Quartz Services; see *Quartz Display Services Reference*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Palettes.h`

SetPalette

Associates a palette with a window. (Deprecated in Mac OS X v10.4. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

Not recommended.

```
void SetPalette (
   WindowRef dstWindow,
   PaletteHandle srcPalette,
   Boolean cUpdates
);
```

Parameters

dstWindow
A pointer to the window to which you want to assign a new palette.

srcPalette
A handle to the palette you want to assign.

cUpdates
A Boolean value in which your application specifies whether the window is to receive updates as a result of changes to the color environment. Specify `TRUE` if you want the window to be updated, even if the window is not the frontmost window. When a window is the frontmost window, changes to its palette cause it to get an update event regardless of how the `cUpdates` parameter is set.

Discussion
You can use the `NSetPalette` (page 1374) function, which does the same thing as `SetPalette`, when you need greater flexibility in setting criteria for updates. The `nCUpdates` parameter for the `NSetPalette` function includes the option of turning off updates when the window is the frontmost window.

Use the `NSetPalette` function to associate a palette with a window but with additional options as to when an update event is triggered by changes to the color environment.

Use the `GetNewPalette` (page 1369) function or the `NewPalette` (page 1373) function to create a new palette. To dispose of a palette, use the `DisposePalette` (page 1365) function.

Special Considerations

For applications running in Mac OS X, the Palette Manager is no longer relevant because display devices always support direct color (pixel depth of 16 or 32 bits). The palette-based graphics model only works in 256-color (8-bit pseudocolor) modes of operation, which are not supported for the Mac OS X GUI.

There is some support for palettes in Quartz Services; see *Quartz Display Services Reference*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Palettes.h`

SetPaletteUpdates

Sets the update attribute of a palette. (Deprecated in Mac OS X v10.4. There is no replacement; 8-bit graphics mode is not supported by the Mac OS X GUI.)

Not recommended.

```
void SetPaletteUpdates (
   PaletteHandle p,
   short updates
);
```

Parameters

p
A handle to the palette.

updates
One of the update attributes for the `NSetPalette` function. See "Update Constants" (page 1390) for a description of the update attributes.

Special Considerations

For applications running in Mac OS X, the Palette Manager is no longer relevant because display devices always support direct color (pixel depth of 16 or 32 bits). The palette-based graphics model only works in 256-color (8-bit pseudocolor) modes of operation, which are not supported for the Mac OS X GUI.

There is some support for palettes in Quartz Services; see *Quartz Display Services Reference*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Palettes.h`

Data Types

ColorInfo

Specifies color information for each color in a palette.

```
struct ColorInfo {
    RGBColor ciRGB;
    short ciUsage;
    short ciTolerance;
    short ciDataFields[3];
};
typedef struct ColorInfo ColorInfo;
typedef ColorInfo * ColorInfoPtr;
```

Fields

`ciRGB`
: An RGB color value, which is defined by the `RGBColor` structure. It contains three fields that contain integer values for defining, respectively, the red, green, and blue values of the color.

`ciUsage`
: One or more of the usage constants, specifying how this entry is to be used. The `ciUsage` field can contain any of the `Usage Constants` (page 1388).

`ciTolerance`
: An integer expressing the range in RGB space within which the red, green, and blue values must fall to satisfy this entry. A tolerance value of $0000 means that only an exact match is acceptable. Values of $0xxx other than $0000 are reserved and should not be used in applications.

`ciDataFields`
: Private fields.

Discussion

Each color information structure in a palette comprises an RGB color value, information describing how the color is to be used, a tolerance value for colors that need only be approximated, and private fields. You should not create and modify the public fields directly; instead, use Palette Manager functions such as `SetEntryColor` and `SetEntryUsage`.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Palettes.h`

Palette

Represents a set of colors optimized for use on display devices with a limited number of colors.

```
struct Palette {
    short pmEntries;
    short pmDataFields[7];
    ColorInfo pmInfo[1];
};
typedef struct Palette Palette;
typedef Palette * PalettePtr;
```

Fields

`pmEntries`

The number of `ColorInfo` structures in the `pmInfo` array.

`pmDataFields`

Private fields used by the Palette Manager.

`pmInfo`

An array of `ColorInfo` (page 1387) structures.

Discussion

A palette structure contains a header and a collection of color information structures, one for each color in the palette.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Palettes.h`

Constants

Usage Constants

Constants used to determine how the Palette Manager uses a specific palette color.

```
enum {
    pmCourteous = 0,
    pmDithered = 0x0001,
    pmTolerant = 0x0002,
    pmAnimated = 0x0004,
    pmExplicit = 0x0008,
    pmWhite = 0x0010,
    pmBlack = 0x0020,
    pmInhibitG2 = 0x0100,
    pmInhibitC2 = 0x0200,
    pmInhibitG4 = 0x0400,
    pmInhibitC4 = 0x0800,
    pmInhibitG8 = 0x1000,
    pmInhibitC8 = 0x2000
};
```

Constants

`pmCourteous`
The color accepts whatever value the Color Manager determines to be the closest match currently available in the device color table.

Available in Mac OS X v10.0 and later.

Declared in `Palettes.h`.

`pmDithered`
[description forthcoming]

Available in Mac OS X v10.0 and later.

Declared in `Palettes.h`.

`pmTolerant`
The color accepts the Color Manager's choices on an indexed device.

Available in Mac OS X v10.0 and later.

Declared in `Palettes.h`.

`pmAnimated`
The color is used for special color animation effects.

Available in Mac OS X v10.0 and later.

Declared in `Palettes.h`.

`pmExplicit`
The color specifies an index value rather than an RGB color and always generates the corresponding entry from the device's color table.

Available in Mac OS X v10.0 and later.

Declared in `Palettes.h`.

`pmWhite`
Assign color to white on a 1-bit device.

Available in Mac OS X v10.0 and later.

Declared in `Palettes.h`.

`pmBlack`
Assign color to black on a 1-bit device.

Available in Mac OS X v10.0 and later.

Declared in `Palettes.h`.

`pmInhibitG2`
Inhibit on 2-bit grayscale device.
Available in Mac OS X v10.0 and later.
Declared in `Palettes.h`.

`pmInhibitC2`
Inhibit on 2-bit color device.
Available in Mac OS X v10.0 and later.
Declared in `Palettes.h`.

`pmInhibitG4`
Inhibit on 4-bit grayscale device.
Available in Mac OS X v10.0 and later.
Declared in `Palettes.h`.

`pmInhibitC4`
Inhibit on 4-bit color device.
Available in Mac OS X v10.0 and later.
Declared in `Palettes.h`.

`pmInhibitG8`
Inhibit on 8-bit grayscale device.
Available in Mac OS X v10.0 and later.
Declared in `Palettes.h`.

`pmInhibitC8`
Inhibit on 8-bit color device.
Available in Mac OS X v10.0 and later.
Declared in `Palettes.h`.

Discussion
You can logically `AND` these constants in certain combinations to specify the value of `ciUsage` in a `ColorInfo` (page 1387) record.

The inhibit constants are used to indicate that a graphics device should be prevented from displaying the color at specified pixel depths. They are always used in combination with other usage constants.

Update Constants

Constants used to determine whether a window is updated based on various changes to the color environment.

```
enum {
    pmNoUpdates = 0x8000,
    pmBkUpdates = 0xA000,
    pmFgUpdates = 0xC000,
    pmAllUpdates = 0xE000
};
```

Constants

`pmNoUpdates`
Do not update the window when its color environment changes.
Available in Mac OS X v10.0 and later.
Declared in `Palettes.h`.

`pmBkUpdates`
Update the window only when it is not the active window.
Available in Mac OS X v10.0 and later.
Declared in `Palettes.h`.

`pmFgUpdates`
Update the window only when it is the active window.
Available in Mac OS X v10.0 and later.
Declared in `Palettes.h`.

`pmAllUpdates`
Update the window whenever its color environment changes.
Available in Mac OS X v10.0 and later.
Declared in `Palettes.h`.

Discussion

You use these constants in the `nCUpdates` parameter of the `NSetPalette` (page 1374) function and the `updates` parameter of the `SetPaletteUpdates` (page 1386) function.

Pasteboard Manager Reference

Framework:	HIServices/HIServices.h
Declared in	Pasteboard.h
Companion guide	Pasteboard Manager Programming Guide

Overview

The Pasteboard Manager lets you create and manipulate pasteboards, which act as holding containers for data to be transferred from one place to another. Typically you use pasteboards to facilitate copy-and-paste or drag-and-drop operations, but you can use them whenever you need to temporarily store data that will be moved elsewhere.

Note: The Pasteboard Manager supersedes the Scrap Manager and the drag flavor APIs in the Drag Manager, adding greater flexibility in the type and quantity of data to be transferred. Pasteboard Manager pasteboards are also fully compatible with Cocoa pasteboards.

Functions by Task

Creating and Using Pasteboards

`PasteboardCreate` (page 1397)
Creates a reference to the specified global pasteboard.

`PasteboardSynchronize` (page 1402)
Synchronizes the local pasteboard reference to reflect the contents of the global pasteboard.

`PasteboardClear` (page 1394)
Clears the contents of the specified pasteboard.

`PasteboardCopyName` (page 1396)
Gets the name of a pasteboard.

`PasteboardGetItemCount` (page 1398)
Obtains the number of data items in the specified pasteboard.

`PasteboardGetItemIdentifier` (page 1399)
Obtains the item identifier for an item in a pasteboard.

Manipulating Pasteboard Flavor Data

`PasteboardCopyItemFlavors` (page 1395)
Obtains an array of flavors for a specified item in a pasteboard.

`PasteboardGetItemFlavorFlags` (page 1398)
Obtains the flags for a given flavor.

`PasteboardCopyItemFlavorData` (page 1395)
Obtains data from a pasteboard for the desired flavor.

`PasteboardPutItemFlavor` (page 1399)
Adds flavor data or a promise to the specified pasteboard.

`PasteboardSetPromiseKeeper` (page 1402)
Registers the promise keeper callback function for a pasteboard.

`PasteboardCopyPasteLocation` (page 1396)
Determines the location in which to paste promised data.

`PasteboardSetPasteLocation` (page 1401)
Sets the paste location before requesting flavor data.

`PasteboardResolvePromises` (page 1400)
Resolves all promises to a given pasteboard.

Functions

PasteboardClear

Clears the contents of the specified pasteboard.

```
OSStatus PasteboardClear (
   PasteboardRef inPasteboard
);
```

Parameters

inPasteboard
The pasteboard you want to clear.

Return Value
A result code. See "Pasteboard Manager Result Codes" (page 1407).

Discussion
After calling this function, the application owns the pasteboard and can add data to it. You must call `PasteboardClear` before modifying a pasteboard.

Availability
Available in Mac OS X v10.3 and later.

Related Sample Code
CarbonSketch

Declared In
`Pasteboard.h`

PasteboardCopyItemFlavorData

Obtains data from a pasteboard for the desired flavor.

```
OSStatus PasteboardCopyItemFlavorData (
   PasteboardRef inPasteboard,
   PasteboardItemID inItem,
   CFStringRef inFlavorType,
   CFDataRef *outData
);
```

Parameters

inPasteboard
The pasteboard containing the data.

inItem
The identifier for the item whose flavor data you want to obtain.

inFlavorType
The flavor of the data you want to obtain, specified as a uniform type identifier.

outData
On return, `outData` points to the flavor data. You must release this data using `CFRelease` when you are done using it.

Return Value

A result code. See "Pasteboard Manager Result Codes" (page 1407).

Availability

Available in Mac OS X v10.3 and later.

Related Sample Code

CarbonCocoa_PictureCursor
CarbonSketch

Declared In

`Pasteboard.h`

PasteboardCopyItemFlavors

Obtains an array of flavors for a specified item in a pasteboard.

```
OSStatus PasteboardCopyItemFlavors (
   PasteboardRef inPasteboard,
   PasteboardItemID inItem,
   CFArrayRef *outFlavorTypes
);
```

Parameters

inPasteboard
The pasteboard containing the data.

inItem
The identifier for the item whose flavors you want to obtain.

outFlavorTypes
On return, `outFlavorTypes` points to an array of flavors, specified as uniform type identifiers. You must release this array by calling `CFRelease` when you are done using it.

Return Value
A result code. See "Pasteboard Manager Result Codes" (page 1407).

Availability
Available in Mac OS X v10.3 and later.

Related Sample Code
CarbonSketch

Declared In
`Pasteboard.h`

PasteboardCopyName

Gets the name of a pasteboard.

```
OSStatus PasteboardCopyName (
    PasteboardRef inPasteboard,
    CFStringRef *outName
);
```

Parameters

inPasteboard
The pasteboard whose name you want to retrieve.

outName
A pointer to a `CFStringRef` variable allocated by the caller. On return, the string contains the name of the specified pasteboard. The caller is responsible for releasing the string.

Return Value
A result code. See "Pasteboard Manager Result Codes" (page 1407).

Discussion
You can use this function to discover the name of a uniquely-named pasteboard so that other processes may access it.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`Pasteboard.h`

PasteboardCopyPasteLocation

Determines the location in which to paste promised data.

```
OSStatus PasteboardCopyPasteLocation (
   PasteboardRef inPasteboard,
   CFURLRef *outPasteLocation
);
```

Parameters

inPasteboard
The pasteboard whose paste location you want to determine.

outPasteLocation

On return, `outPasteLocation` points to a CFURL indicating the paste location. You must release this URL when you are done with it by calling `CFRelease`.

Return Value
A result code. See "Pasteboard Manager Result Codes" (page 1407).

Discussion
You typically call this function from your promise keeper callback function to determine where to deliver a promised file. It is also used to tell a translation service where to place a translated file.

This function is analogous to the Drag Manager function `GetDropLocation`.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`Pasteboard.h`

PasteboardCreate

Creates a reference to the specified global pasteboard.

```
OSStatus PasteboardCreate (
   CFStringRef inName,
   PasteboardRef *outPasteboard
);
```

Parameters

inName

The name of the pasteboard to reference. To create a new pasteboard, specify a unique name. Pasteboard names should have a reverse DNS-style name to ensure uniqueness. You may also pass one of the following constants:

- `kPasteboardFind` (page 1405) to obtain a reference to the global Find pasteboard
- `kPasteboardClipboard` (page 1405) to obtain a reference to the global Clipboard
- `kPasteboardUniqueName` (page 1405) to ask the Pasteboard Manager to create a new pasteboard with a unique name

outPasteboard

A pointer to a `PasteboardRef` variable allocated by the caller. On return, the variable refers to the pasteboard specified in the *inName* parameter.

When you are finished using the pasteboard, you can call `CFRelease` to release the reference. If you do not release the reference, the pasteboard continues to exist even after your application terminates. A subsequently launched application can find a previously created pasteboard by name and examine the data within it.

Return Value
A result code. See "Pasteboard Manager Result Codes" (page 1407).

Discussion
You can use this function to create a reference to a new or existing pasteboard.

Availability
Available in Mac OS X v10.3 and later.

Related Sample Code
CarbonSketch

Declared In
`Pasteboard.h`

PasteboardGetItemCount

Obtains the number of data items in the specified pasteboard.

```
OSStatus PasteboardGetItemCount (
   PasteboardRef inPasteboard,
   ItemCount *outItemCount
);
```

Parameters

`inPasteboard`
The pasteboard whose items you want to count.

`outItemCount`
On return, `outItemCount` points to the number of items in the pasteboard.

Return Value
A result code. See "Pasteboard Manager Result Codes" (page 1407).

Discussion
You usually call this function before calling `PasteboardGetItemIdentifier` (page 1399).

Availability
Available in Mac OS X v10.3 and later.

Related Sample Code
CarbonSketch

Declared In
`Pasteboard.h`

PasteboardGetItemFlavorFlags

Obtains the flags for a given flavor.

```
OSStatus PasteboardGetItemFlavorFlags (
   PasteboardRef inPasteboard,
   PasteboardItemID inItem,
   CFStringRef inFlavorType,
   PasteboardFlavorFlags *outFlags
);
```

Parameters

`inPasteboard`
The pasteboard containing the data.

`inItem`
The identifier for the item whose flavor flags you want to obtain.

inFlavorType
The flavor whose flags you want to obtain.

outFlags
On return, `outFlags` points to a bit field containing the flavor flags. See "Pasteboard Flavor Flags" (page 1405) for a list of possible values.

Return Value
A result code. See "Pasteboard Manager Result Codes" (page 1407).

Availability
Available in Mac OS X v10.3 and later.

Declared In
`Pasteboard.h`

PasteboardGetItemIdentifier

Obtains the item identifier for an item in a pasteboard.

```
OSStatus PasteboardGetItemIdentifier (
   PasteboardRef inPasteboard,
   CFIndex inIndex,
   PasteboardItemID *outItem
);
```

Parameters

inPasteboard
The pasteboard containing the data.

inIndex
The one-based index number of the data item whose identifier you want to obtain.

outItem
On return, `outItem` points to the item identifier for the data item at index `inIndex`.

Return Value
A result code. See "Pasteboard Manager Result Codes" (page 1407).

Discussion
The item index is one-based to match the convention used by the Drag Manager.

Availability
Available in Mac OS X v10.3 and later.

Related Sample Code
CarbonCocoa_PictureCursor
CarbonSketch

Declared In
`Pasteboard.h`

PasteboardPutItemFlavor

Adds flavor data or a promise to the specified pasteboard.

```
OSStatus PasteboardPutItemFlavor (
   PasteboardRef inPasteboard,
   PasteboardItemID inItem,
   CFStringRef inFlavorType,
   CFDataRef inData,
   PasteboardFlavorFlags inFlags
);
```

Parameters

inPasteboard

The pasteboard to which to add flavor data or a promise.

inItem

The identifier for the item to which to add flavor data or a promise.

inFlavorType

The flavor type of the data or promise you are adding, specified as a uniform type identifier.

inData

The data to add, or a promise to supply the data later. If you pass a CFData object, you may safely release the object when this function returns. To indicate that the data is promised, pass `kPasteboardPromisedData` (page 1407). For more information about promised data, see the Discussion below.

inFlags

A bit field of flags for the specified flavor.

Return Value
A result code. See "Pasteboard Manager Result Codes" (page 1407).

Discussion
If you promise data, you must implement a promise keeper callback to deliver the data when asked for it (see `PasteboardPromiseKeeperProcPtr` (page 1403) for more details). Typically, you store promises instead of the actual data when the data requires a large overhead to generate. You can call this function multiple times to add multiple flavors to a given item. You should add the flavors in your application's order of preference or richness.

Availability
Available in Mac OS X v10.3 and later.

Related Sample Code
CarbonSketch

Declared In
`Pasteboard.h`

PasteboardResolvePromises

Resolves all promises to a given pasteboard.

```
OSStatus PasteboardResolvePromises (
   PasteboardRef inPasteboard
);
```

Parameters

inPasteboard

The pasteboard whose promises your application wants to resolve. If you pass `kPasteboardResolveAllPromises` (page 1407), all the promises for all pasteboards handled by the application are resolved.

Return Value
A result code. See "Pasteboard Manager Result Codes" (page 1407).

Discussion
You should call this function when your application quits or otherwise becomes unavailable.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`Pasteboard.h`

PasteboardSetPasteLocation

Sets the paste location before requesting flavor data.

```
OSStatus PasteboardSetPasteLocation (
   PasteboardRef inPasteboard,
   CFURLRef inPasteLocation
);
```

Parameters

inPasteboard

The pasteboard you want to obtain flavor data from.

inPasteLocation

A Core Foundation URL indicating where to put the data.

Return Value
A result code. See "Pasteboard Manager Result Codes" (page 1407).

Discussion
Applications that receive pasteboard data in the form of a file should call this function before calling `PasteboardCopyItemFlavorData` (page 1395), so the sender knows where to place the promised data. If the requested data was promised by the sender, the sending application calls `PasteboardCopyPasteLocation` (page 1396) to determine where to put it.

If a paste location is not applicable for your application, you don't need to call this function.

This function is analogous to the Drag Manager function `SetDropLocation`.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`Pasteboard.h`

PasteboardSetPromiseKeeper

Registers the promise keeper callback function for a pasteboard.

```
OSStatus PasteboardSetPromiseKeeper (
   PasteboardRef inPasteboard,
   PasteboardPromiseKeeperProcPtr inPromiseKeeper,
   void *inContext
);
```

Parameters

inPasteboard

The pasteboard to assign the promise keeper callback. If you have multiple pasteboards, you can assign multiple callbacks.

inPromiseKeeper

A pointer to your promise keeper callback function. See `PasteboardPromiseKeeperProcPtr` (page 1403) for more information about implementing the callback.

inContext

A pointer to application-defined data. The value you pass in this parameter is passed to your promise keeper callback function when it is called.

Return Value

A result code. See "Pasteboard Manager Result Codes" (page 1407).

Discussion

You must have registered a promise keeper callback function before promising any data on the specified pasteboard.

Availability

Available in Mac OS X v10.3 and later.

Declared In

`Pasteboard.h`

PasteboardSynchronize

Synchronizes the local pasteboard reference to reflect the contents of the global pasteboard.

```
PasteboardSyncFlags PasteboardSynchronize (
   PasteboardRef inPasteboard
);
```

Parameters

inPasteboard

The pasteboard you want to synchronize.

Return Value

A flag indicating what synchronization actions occurred.

Discussion

Calling this function compares the local pasteboard reference with its global pasteboard. If the global pasteboard was modified, it updates the local pasteboard reference to reflect this change. You typically call this function whenever your application becomes active, so that its pasteboard information reflects any changes that occurred while it was in the background. This function has low overhead, so you should call it whenever you suspect a global pasteboard may have been changed.

Availability
Available in Mac OS X v10.3 and later.

CarbonSketch

Declared In
`Pasteboard.h`

Callbacks

PasteboardPromiseKeeperProcPtr

Defines a pointer to a callback function that supplies the actual data promised on the pasteboard.

```
typedef OSStatus (*PasteboardPromiseKeeperProcPtr)
(
PasteboardRef pasteboard,
PasteboardItemID item,
CFStringRef flavorType,
void* context
);
```

You would declare your promise keeper callback function named `MyPromiseKeeper` like this:

```
OSStatus MyPromiseKeeper (
PasteboardRef pasteboard,
PasteboardItemID item,
CFStringRef flavorType,
void* context
);
```

Parameters

pasteboard
The pasteboard whose promise you need to fulfill.

item
The pasteboard item identifier containing the promised flavor.

flavorType
The flavor of the data being requested, specified as a uniform type identifier.

context
The pointer you passed to `PasteboardSetPromiseKeeper` (page 1402) in the `inContext` parameter.

Discussion
When promising any flavor data on a pasteboard using `PasteboardPutItemFlavor` (page 1399), you must implement a callback function to fulfill that promise.

If your application delivers the promised data as a file, your callback should call `PasteboardCopyPasteLocation` (page 1396) to determine where to deliver the requested data and then take the necessary steps to do so.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`Pasteboard.h`

Data Types

PasteboardRef

Defines an opaque type that represents a pasteboard.

```
typedef struct OpaquePasteboardRef *PasteboardRef;
```

Discussion
This is a Core Foundation type. For more information, see *CFType Reference*.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`Pasteboard.h`

PasteboardItemID

Defines a pasteboard item identifier.

```
typedef void* PasteboardItemID;
```

Discussion
You can use any arbitrary (but unique) ID to identify your pasteboard items when placing them on a pasteboard. For example, you may want to identify items by their internal memory address. Only the owning application should interpret its pasteboard item identifiers.

When your application's promise keeper callback function is invoked, it receives a pasteboard item ID, and your application must be able to map that ID to the corresponding promised data.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`Pasteboard.h`

Constants

Pasteboard Name Constants

Define the pasteboard names used when calling `PasteboardCreate` (page 1397).

```
#define kPasteboardClipboard CFSTR("com.apple.pasteboard.clipboard")
#define kPasteboardFind CFSTR("com.apple.pasteboard.find")
#define kPasteboardUniqueName (CFStringRef)NULL
```

Constants

`kPasteboardClipboard`
The global Clipboard (used for copy and paste).

Available in Mac OS X v10.3 and later.

Declared in `Pasteboard.h`.

`kPasteboardFind`
The global Find pasteboard (used for search fields).

Available in Mac OS X v10.3 and later.

Declared in `Pasteboard.h`.

`kPasteboardUniqueName`
A system-declared pasteboard that is guaranteed to be unique. Each time you call `PasteboardCreate` (page 1397) with this constant, you create a different, unique pasteboard.

Available in Mac OS X v10.3 and later.

Declared in `Pasteboard.h`.

Pasteboard Flavor Flags

Indicate useful information associated with pasteboard item flavors.

```
enum {
   kPasteboardFlavorNoFlags = 0,
   kPasteboardFlavorSenderOnly = (1 << 0),
   kPasteboardFlavorSenderTranslated = (1 << 1),
   kPasteboardFlavorNotSaved = (1 << 2),
   kPasteboardFlavorRequestOnly = (1 << 3),
   kPasteboardFlavorSystemTranslated = (1 << 8),
   kPasteboardFlavorPromised = (1 << 9)
};
typedef UInt32 PasteboardFlavorFlags;
```

Constants

`kPasteboardFlavorNoFlags`
No flag information exists for this flavor.

Available in Mac OS X v10.3 and later.

Declared in `Pasteboard.h`.

`kPasteboardFlavorSenderOnly`
Only the process that added this flavor can see it. Typically used to tag proprietary data that can be cut, dragged, or pasted only within the owning application. This flag is identical to the Drag Manager `flavorSenderOnly` flag.

Available in Mac OS X v10.3 and later.

Declared in `Pasteboard.h`.

`kPasteboardFlavorSenderTranslated`
: The sender translated this data in some fashion before adding it to the pasteboard. The Finder cannot store flavor items marked with this flag in clipping files. This flag is identical to the Drag Manager `flavorSenderTranslated` flag.

  Available in Mac OS X v10.3 and later.

  Declared in `Pasteboard.h`.

`kPasteboardFlavorNotSaved`
: The receiver should not save the data provided for this flavor. The data may become stale after a drag, or the flavor may be used only to augment another flavor. For example, an application may add a flavor whose only purpose is to supply additional information (say text style) about another flavor. The Finder cannot store flavor items marked with this flag in clipping files. This flag is identical to the Drag Manager `flavorNotSaved` flag.

  Available in Mac OS X v10.3 and later.

  Declared in `Pasteboard.h`.

`kPasteboardFlavorRequestOnly`
: When the sender sets this flag, this flavor is hidden from calls to `PasteboardCopyItemFlavors` (page 1395). However, you can obtain the flavor flags and data by calling `PasteboardGetItemFlavorFlags` (page 1398) or `PasteboardCopyItemFlavorData` (page 1395). The net result is that applications cannot obtain this flavor unless they are already aware it exists and specifically request it. This functionality can be useful for copying and pasting proprietary data within a suite of applications.

  Available in Mac OS X v10.3 and later.

  Declared in `Pasteboard.h`.

`kPasteboardFlavorSystemTranslated`
: This data flavor is available through the Translation Manager. That is, the Translation Manager must translate the sender's data before the receiver can receive it. This flag is set automatically when appropriate and cannot be set programmatically. The Finder cannot store flavor items marked with this flag in clipping files. This flag is identical to the Drag Manager `flavorSystemTranslated` flag.

  Available in Mac OS X v10.3 and later.

  Declared in `Pasteboard.h`.

`kPasteboardFlavorPromised`
: The data associated with this flavor is not yet on the pasteboard. Typically data is promised to the pasteboard if it requires a lot of overhead to generate. If the receiver requests the data, the sender is notified so it can supply the promised data. This flag is set automatically when appropriate and cannot be set programmatically. This flag is identical to the Drag Manager `flavorDataPromised` flag.

  Available in Mac OS X v10.3 and later.

  Declared in `Pasteboard.h`.

Pasteboard Synchronization Flags

Indicate the pasteboard status after a call to `PasteboardSynchronize` (page 1402).

```
enum {
   kPasteboardModified = (1 << 0),
   kPasteboardClientIsOwner = (1 << 1)
};
typedef UInt32 PasteboardSyncFlags;
```

Constants

`kPasteboardModified`

The pasteboard was modified since the last time the application accessed it, and the local pasteboard has been synchronized to reflect any changes. Your application should check to see what flavors are now available on the pasteboard and update appropriately (for example, enabling the Paste menu item).

Available in Mac OS X v10.3 and later.

Declared in `Pasteboard.h`.

`kPasteboardClientIsOwner`

The application recently cleared the pasteboard and is its current owner. The application can add flavor data to the pasteboard as desired.

Available in Mac OS X v10.3 and later.

Declared in `Pasteboard.h`.

Pasteboard Promise Constants

Define constants related to the use of promised data.

```
#define kPasteboardPromisedData (CFDataRef)NULL
#define kPasteboardResolveAllPromises (PasteboardRef)NULL
```

Constants

`kPasteboardPromisedData`

Indicates a promise that pasteboard data will be supplied later. Used when calling `PasteboardPutItemFlavor` (page 1399).

Available in Mac OS X v10.3 and later.

Declared in `Pasteboard.h`.

`kPasteboardResolveAllPromises`

Indicates that all promises on all global pasteboard resources owned by this application should be resolved. Used when calling `PasteboardResolvePromises` (page 1400).

Available in Mac OS X v10.3 and later.

Declared in `Pasteboard.h`.

Result Codes

The table below lists the most common error codes returned by the Pasteboard Manager.

Result Code	Value	Description
badPasteboardSyncErr	-25130	The pasteboard has been modified and must be synchronized before use. Available in Mac OS X v10.3 and later.
badPasteboardIndexErr	-25131	The specified pasteboard item index does not exist. Available in Mac OS X v10.3 and later.
badPasteboardItemErr	-25132	The item reference does not exist. Available in Mac OS X v10.3 and later.
badPasteboardFlavorErr	-25133	The item flavor does not exist. Available in Mac OS X v10.3 and later.
duplicatePasteboardFlavorErr	-25134	The item flavor already exists. Available in Mac OS X v10.3 and later.
notPasteboardOwnerErr	-25135	The application did not clear the pasteboard before attempting to add flavor data. Available in Mac OS X v10.3 and later.
noPasteboardPromiseKeeperErr	-25136	The application attempted to add promised data without previously registering a promise keeper callback. Available in Mac OS X v10.3 and later.

Picture Utilities Reference (Not Recommended)

Framework: ApplicationServices/ApplicationServices.h

Declared in PictUtils.h

Overview

Important: The Picture Utilities are deprecated as of Mac OS X v10.4. The replacement API for all QuickDraw technologies is Quartz 2D (Core Graphics). See *Quartz Programming Guide for QuickDraw Developers* for strategies to replace QuickDraw code with Quartz 2D..

Because Quartz 2D uses an entirely different approach to graphics than used by QuickDraw, there is no one-to-one correlation between QuickDraw and Quartz 2D functions. However, because Quartz offers many new features and improved performance compared to QuickDraw, it is worthwhile making the effort to convert your graphics code to Quartz.

QuickDraw pictures are sequences of saved drawing commands. Pictures provide a common medium for the sharing of image data.

The Picture Utilities allow your application to gather information about a picture, such as color, fonts, picture comments, and resolution. You can also use the Picture Utilities to gather information about the colors in pixel maps.

Functions by Task

Collecting Picture Information

`DisposePictInfo` (page 1412) Deprecated in Mac OS X v10.4

Disposes of the private data structures allocated by the `NewPictInfo` function. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`GetPictInfo` (page 1414) Deprecated in Mac OS X v10.4

Gathers information about a single picture. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`GetPixMapInfo` (page 1416) Deprecated in Mac OS X v10.4

Gathers color information about a single pixel map or bitmap. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`NewPictInfo` (page 1422) Deprecated in Mac OS X v10.4
Begins collecting pictures, pixel maps, and bitmaps for a survey of pictures. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`RecordPictInfo` (page 1424) Deprecated in Mac OS X v10.4
Adds a picture to an informational survey of multiple pictures. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`RecordPixMapInfo` (page 1424) Deprecated in Mac OS X v10.4
Adds a pixel map or bitmap to an informational survey of multiple pixel maps and bitmaps. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`RetrievePictInfo` (page 1425) Deprecated in Mac OS X v10.4
Returns information about all the pictures, pixel maps, and bitmaps included in a survey. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Using Universal Procedure Pointers

`DisposeCalcColorTableUPP` (page 1411) Deprecated in Mac OS X v10.4
Disposes of a universal procedure pointer (UPP) to a color table calculation callback. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`DisposeDisposeColorPickMethodUPP` (page 1411) Deprecated in Mac OS X v10.4
Disposes of a universal procedure pointer (UPP) to a method disposal callback. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`DisposeInitPickMethodUPP` (page 1412) Deprecated in Mac OS X v10.4
Disposes of a universal procedure pointer (UPP) to a method initialization callback. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`DisposeRecordColorsUPP` (page 1413) Deprecated in Mac OS X v10.4
Disposes of a universal procedure pointer (UPP) to a color recording callback. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`InvokeCalcColorTableUPP` (page 1418) Deprecated in Mac OS X v10.4
Invokes a color table calculation callback, using a universal procedure pointer. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`InvokeDisposeColorPickMethodUPP` (page 1418) Deprecated in Mac OS X v10.4
Invokes a method disposal callback, using a universal procedure pointer. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`InvokeInitPickMethodUPP` (page 1419) Deprecated in Mac OS X v10.4
Invokes a method initialization callback, using a universal procedure pointer. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`InvokeRecordColorsUPP` (page 1419) Deprecated in Mac OS X v10.4
Invokes a color recording callback, using a universal procedure pointer. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`NewCalcColorTableUPP` (page 1420) Deprecated in Mac OS X v10.4
Creates a new universal procedure pointer (UPP) to a color table calculation callback. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`NewDisposeColorPickMethodUPP` (page 1420) Deprecated in Mac OS X v10.4
Creates a new universal procedure pointer (UPP) to a method disposal callback. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`NewInitPickMethodUPP` (page 1421) Deprecated in Mac OS X v10.4
Creates a new universal procedure pointer (UPP) to a method initialization callback. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`NewRecordColorsUPP` (page 1423) Deprecated in Mac OS X v10.4
Creates a new universal procedure pointer (UPP) to a color recording callback. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Functions

DisposeCalcColorTableUPP

Disposes of a universal procedure pointer (UPP) to a color table calculation callback. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void DisposeCalcColorTableUPP (
   CalcColorTableUPP userUPP
);
```

Parameters

userUPP
The universal procedure pointer.

Discussion

For more information, see `CalcColorTableProcPtr` (page 1426).

Special Considerations

Because Quartz 2D uses an entirely different approach to graphics than used by QuickDraw, there is no one-to-one correlation between QuickDraw and Quartz 2D functions. However, because Quartz offers many new features and improved performance compared to QuickDraw, it is worthwhile making the effort to convert your graphics code to Quartz.

Availability

Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In

`PictUtils.h`

DisposeDisposeColorPickMethodUPP

Disposes of a universal procedure pointer (UPP) to a method disposal callback. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void DisposeDisposeColorPickMethodUPP (
   DisposeColorPickMethodUPP userUPP
);
```

Parameters

userUPP
The universal procedure pointer.

Discussion
For more information, see `DisposeColorPickMethodProcPtr` (page 1428).

Special Considerations

Because Quartz 2D uses an entirely different approach to graphics than used by QuickDraw, there is no one-to-one correlation between QuickDraw and Quartz 2D functions. However, because Quartz offers many new features and improved performance compared to QuickDraw, it is worthwhile making the effort to convert your graphics code to Quartz.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`PictUtils.h`

DisposeInitPickMethodUPP

Disposes of a universal procedure pointer (UPP) to a method initialization callback. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void DisposeInitPickMethodUPP (
   InitPickMethodUPP userUPP
);
```

Parameters

userUPP
The universal procedure pointer.

Discussion
For more information, see `InitPickMethodProcPtr` (page 1429).

Special Considerations

Because Quartz 2D uses an entirely different approach to graphics than used by QuickDraw, there is no one-to-one correlation between QuickDraw and Quartz 2D functions. However, because Quartz offers many new features and improved performance compared to QuickDraw, it is worthwhile making the effort to convert your graphics code to Quartz.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`PictUtils.h`

DisposePictInfo

Disposes of the private data structures allocated by the `NewPictInfo` function. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
OSErr DisposePictInfo (
   PictInfoID thePictInfoID
);
```

Parameters

thePictInfoID

The unique identifier returned by `NewPictInfo`.

Return Value

A result code. See "Picture Utilities Result Codes" (page 1441).

Discussion

The `DisposePictInfo` function does not dispose of any of the handles returned to you in a `PictInfo` structure by the `RetrievePictInfo` (page 1425) function. Instead, you can dispose of a `Palette` structure by using the `DisposePalette` function. You can dispose of a `ColorTable` structure by using the `DisposeCTable` function. Dispose of other allocations with the `DisposeHandle` function.

Use this function when you are finished gathering information from a survey of pictures, pixel maps, or bitmaps.

Special Considerations

Because Quartz 2D uses an entirely different approach to graphics than used by QuickDraw, there is no one-to-one correlation between QuickDraw and Quartz 2D functions. However, because Quartz offers many new features and improved performance compared to QuickDraw, it is worthwhile making the effort to convert your graphics code to Quartz.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`PictUtils.h`

DisposeRecordColorsUPP

Disposes of a universal procedure pointer (UPP) to a color recording callback. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void DisposeRecordColorsUPP (
   RecordColorsUPP userUPP
);
```

Parameters

userUPP

The universal procedure pointer.

Discussion

For more information, see `RecordColorsProcPtr` (page 1431).

Special Considerations

Because Quartz 2D uses an entirely different approach to graphics than used by QuickDraw, there is no one-to-one correlation between QuickDraw and Quartz 2D functions. However, because Quartz offers many new features and improved performance compared to QuickDraw, it is worthwhile making the effort to convert your graphics code to Quartz.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`PictUtils.h`

GetPictInfo

Gathers information about a single picture. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
OSErr GetPictInfo (
   PicHandle thePictHandle,
   PictInfo *thePictInfo,
   short verb,
   short colorsRequested,
   short colorPickMethod,
   short version
);
```

Parameters

thePictHandle

A handle to a picture.

thePictInfo

On return, a pointer to a `PictInfo` (page 1434) structure, which holds information about the picture. Initially, all of the fields in the new `PictInfo` structure are set to `NULL`. Relevant fields are set to appropriate values depending on the information you request using the `GetPictInfo` function.

This function collects information from black-and-white pictures and bitmaps, and is supported in System 7 even by computers running only basic QuickDraw. However, when collecting color information on a computer running only basic QuickDraw, the function returns `NULL` instead of a handle to a `Palette` or `ColorTable` structure.

verb

A value indicating what type of information you want `GetPictInfo` to return in the `PictInfo` structure. See "Color Information Type" (page 1440) for a description of the values you can use in this parameter.

You can specify whether you want color information (in a `ColorTable` structure, a `Palette` structure, or both), whether you want picture comment information, and whether you want font information. If you want color information, be sure to use the `colorPickMethod` parameter to specify the method by which to select colors.

Because the Palette Manager adds black and white when creating a `Palette` structure, you can specify the number of colors you want minus 2 in the `colorsRequested` parameter and specify the `suppressBlackAndWhite` constant in the `verb` parameter when gathering colors destined for a `Palette` structure or a screen.

colorsRequested

From 1 to 256, the number of colors you want in the `ColorTable` or `Palette` structure returned via the `PictInfo` structure. If you are not requesting colors (that is, if you pass the `recordComments` or `recordFontInfo` constant in the `verb` parameter), specify 0 in this parameter.

colorPickMethod

The method by which colors are selected for the `ColorTable` or `Palette` structure returned via the `PictInfo` structure. See "Color Selection Method" (page 1440) for a description of the values you can use here.

You can also create your own color-picking method in a resource file of type `'cpmt'` and pass its resource ID in the `colorPickMethod` parameter. The resource ID must be greater than 127.

version

Always set this parameter to 0.

Return Value

A result code. See "Picture Utilities Result Codes" (page 1441).

Discussion

The Picture Utilities provide two color-picking methods: one (specified by the `popularMethod` constant) that gives you the most frequently used colors and one (specified by the `medianMethod` constant) that gives you the widest range of colors. Each has advantages in different situations. For example, suppose the picture of a forest image contains 400 colors, of which 300 are greens, 80 are browns, and the rest are a scattering of golden sunlight effects. If you ask for the 250 most used colors, you will probably receive all greens. If you ask for a range of 250 colors, you will receive an assortment stretching from the greens and golds to the browns, including colors in between that might not actually appear in the image. If you specify the `systemMethod` constant, the Picture Utilities choose the method; currently they always choose `popularMethod`. You can also supply a color-picking method of your own.

If your application uses more than one color-picking method, it should present the user with a choice of which method to use.

When you are finished with the information in the `PictInfo` structure, use the Memory Manager function `DisposeHandle` to dispose of the `PictInfo`, `CommentSpec`, and `FontSpec` structures. Dispose of the `Palette` structure by using the `DisposePalette` function. Dispose of the `ColorTable` structure by using the `DisposeCTable` function.

Special Considerations

Because Quartz 2D uses an entirely different approach to graphics than used by QuickDraw, there is no one-to-one correlation between QuickDraw and Quartz 2D functions. However, because Quartz offers many new features and improved performance compared to QuickDraw, it is worthwhile making the effort to convert your graphics code to Quartz.

When you ask for color information, `GetPictInfo` takes into account only the version 2 and extended version 2 picture opcodes `RGBFgCol`, `RGBBkCol`, `BkPixPat`, `PnPixPat`, `FillPixPat`, `HiliteColor` and pixel map or bitmap data. Each occurrence of these opcodes is treated as 1 pixel, regardless of the number and sizes of the objects drawn with that color. If you need an accurate set of colors from a complex picture, create an image of the picture in an offscreen pixel map, and then call the `GetPixMapInfo` (page 1416) function to obtain color information about that pixel map.

The `GetPictInfo` function returns a bit depth of 1 on QuickTime-compressed `'PICT'` files. However, when QuickTime is installed, QuickTime decompresses and displays the image correctly.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`PictUtils.h`

GetPixMapInfo

Gathers color information about a single pixel map or bitmap. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
OSErr GetPixMapInfo (
   PixMapHandle thePixMapHandle,
   PictInfo *thePictInfo,
   short verb,
   short colorsRequested,
   short colorPickMethod,
   short version
);
```

Parameters

thePixMapHandle

A handle to a pixel map or bitmap.

thePictInfo

On return, a pointer to a `PictInfo` (page 1434) structure, which holds information about a pixel map or bitmap. Initially, all of the fields in a new `PictInfo` structure are set to `NULL`. Relevant fields are set to appropriate values depending on the information you request using the `GetPixMapInfo` function.

This function also collects information from black-and-white pictures and bitmaps, and is supported in System 7 even by computers running only basic QuickDraw. However, when collecting color information on a computer running only basic QuickDraw, this function returns `NULL` instead of a handle to a `Palette` or `ColorTable` structure.

verb

A value indicating whether you want color information returned in a `ColorTable` structure, a `Palette` structure, or both. You can also request that black and white not be included among the returned colors. See "Color Information Type" (page 1440) for a description of the values you can use here.

Because the Palette Manager adds black and white when creating a `Palette` structure, you can specify the number of colors you want minus 2 in the `colorsRequested` parameter and specify the constant `suppressBlackAndWhite` in the `verb` parameter when gathering colors destined for a `Palette` structure or a screen.

colorsRequested

From 1 to 256, the number of colors you want in the `ColorTable` or `Palette` structure returned via the `PictInfo` structure.

colorPickMethod

The method by which colors are selected for the `ColorTable` or `Palette` structure returned via the `PictInfo` structure. See "Color Selection Method" (page 1440) for a description of the values you can use here.

You can also create your own color-picking method in a resource file of type `'cpmt'` and pass its resource ID in the `colorPickMethod` parameter. The resource ID must be greater than 127.

version

Always set this parameter to 0.

Return Value
A result code. See "Picture Utilities Result Codes" (page 1441).

Discussion
The Picture Utilities provide two color-picking methods: one that gives you the most frequently used colors and one that gives you the widest range of colors. If you specify the `systemMethod` constant, the Picture Utilities choose that method. Currently they always choose `popularMethod`. You can also supply a color-picking method of your own.

When you are finished with the information in the `PictInfo` structure, be sure to dispose of it. Use the Memory Manager function `DisposeHandle` to dispose of the `PictInfo` structure. Dispose of the `Palette` structure by using the `DisposePalette` function. Dispose of the `ColorTable` structure by using the `DisposeCTable` function.

Special Considerations

Because Quartz 2D uses an entirely different approach to graphics than used by QuickDraw, there is no one-to-one correlation between QuickDraw and Quartz 2D functions. However, because Quartz offers many new features and improved performance compared to QuickDraw, it is worthwhile making the effort to convert your graphics code to Quartz.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

NewPictInfo

Begins collecting pictures, pixel maps, and bitmaps for a survey of pictures. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
OSErr NewPictInfo (
   PictInfoID *thePictInfoID,
   short verb,
   short colorsRequested,
   short colorPickMethod,
   short version
);
```

Parameters

thePictInfoID

On return, a value that uniquely identifies your collection of pictures, pixel maps, or bitmaps.

verb

A value indicating what type of information you want the `RetrievePictInfo` (page 1425) function to return in a `PictInfo` (page 1434) structure. See "Color Information Type" (page 1440) for a description of the values you can use here.

The constants `recordComments` and `recordFontInfo` and the values they represent have no effect when gathering information about the pixel maps and bitmaps included in your survey.

Because the Palette Manager adds black and white when creating a palette, you can specify the number of colors you want minus 2 in the `colorsRequested` parameter and specify the constant `suppressBlackAndWhite` in the `verb` parameter when gathering colors destined for a `Palette` structure or a screen.

colorsRequested

From 1 to 256, the number of colors you want included in the `ColorTable` or `Palette` structure returned by the `RetrievePictInfo` function via a `PictInfo` structure.

colorPickMethod

The method by which colors are selected for the `ColorTable` or `Palette` structure included in the `PictInfo` structure returned by the `RetrievePictInfo` function. See "Color Selection Method" (page 1440) for a description of the values you can use here.

You can also create your own color-picking method in a resource file of type `'cpmt'` and pass its resource ID in the `colorPickMethod` parameter. The resource ID must be greater than 127.

version

Always set this parameter to 0.

Return Value

A result code. See "Picture Utilities Result Codes" (page 1441).

Discussion

To add the information for a picture to your survey, use the `RecordPictInfo` function. To add the information for a pixel map or a bitmap to your survey, use the `RecordPixMapInfo` (page 1424) function. For each of these functions, identify the survey with the ID number returned by `NewPictInfo`.

Use the `RetrievePictInfo` function to return information about the pictures, pixel maps, and bitmaps in the survey. The `RetrievePictInfo` function returns your requested information in a `PictInfo` structure.

Use the `verb` parameter for `NewPictInfo` to specify whether you want to gather comment or font information for the pictures in the survey. If you want to gather color information, use the `verb` parameter for `NewPictInfo` to specify whether you want this information in a `ColorTable` structure, a `Palette` structure,

or both. The `PictInfo` structure returned by the `RetrievePictInfo` function will then include a handle to a `ColorTable` structure or a `Palette` structure, or handles to both. If you want color information, be sure to use the `colorPickMethod` parameter to specify the method by which to select colors.

The Picture Utilities provide two color-picking methods: one (specified by the `popularMethod` constant) that gives you the most frequently used colors and one (specified by the `medianMethod` constant) that gives you the widest range of colors. If you specify the `systemMethod` constant, the Picture Utilities choose the method; currently they always choose `popularMethod`. You can also supply a color-picking method of your own.

Special Considerations

Because Quartz 2D uses an entirely different approach to graphics than used by QuickDraw, there is no one-to-one correlation between QuickDraw and Quartz 2D functions. However, because Quartz offers many new features and improved performance compared to QuickDraw, it is worthwhile making the effort to convert your graphics code to Quartz.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`PictUtils.h`

NewRecordColorsUPP

Creates a new universal procedure pointer (UPP) to a color recording callback. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
RecordColorsUPP NewRecordColorsUPP (
   RecordColorsProcPtr userRoutine
);
```

Parameters

`userRoutine`
A pointer to your color recording callback. For more information, see `RecordColorsProcPtr` (page 1431).

Return Value
A UPP to the callback.

Special Considerations

Because Quartz 2D uses an entirely different approach to graphics than used by QuickDraw, there is no one-to-one correlation between QuickDraw and Quartz 2D functions. However, because Quartz offers many new features and improved performance compared to QuickDraw, it is worthwhile making the effort to convert your graphics code to Quartz.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`PictUtils.h`

RecordPictInfo

Adds a picture to an informational survey of multiple pictures. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
OSErr RecordPictInfo (
   PictInfoID thePictInfoID,
   PicHandle thePictHandle
);
```

Parameters

thePictInfoID

The ID number—returned by the `NewPictInfo` (page 1422) function—that identifies the survey to which you are adding the picture.

thePictHandle

A handle to the picture being added to the survey.

Return Value

A result code. See "Picture Utilities Result Codes" (page 1441).

Discussion

The `RecordPictInfo` function adds the picture you specify in the parameter `thePictHandle` to the survey of pictures identified by the parameter `thePictInfoID`. Use `RecordPictInfo` repeatedly to add additional pictures to your survey.

After you have collected all of the pictures you need, use the `RetrievePictInfo` (page 1425) function to return information about pictures in the survey.

Special Considerations

Because Quartz 2D uses an entirely different approach to graphics than used by QuickDraw, there is no one-to-one correlation between QuickDraw and Quartz 2D functions. However, because Quartz offers many new features and improved performance compared to QuickDraw, it is worthwhile making the effort to convert your graphics code to Quartz.

When you ask for color information, `RecordPictInfo` takes into account only the version 2 and extended version picture opcodes `RGBFgCol`, `RGBBkCol`, `BkPixPat`, `PnPixPat`, `FillPixPat`, and `HiliteColor`. Each occurrence of these opcodes is treated as 1 pixel, regardless of the number and sizes of the objects drawn with that color. If you need an accurate set of colors from a complex picture, create an image of the picture in an offscreen pixel map, and then call the `GetPixMapInfo` (page 1416) function to obtain color information about that pixel map.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`PictUtils.h`

RecordPixMapInfo

Adds a pixel map or bitmap to an informational survey of multiple pixel maps and bitmaps. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
OSErr RecordPixMapInfo (
   PictInfoID thePictInfoID,
   PixMapHandle thePixMapHandle
);
```

Parameters

thePictInfoID

The ID number—returned by the `NewPictInfo` (page 1422) function—that identifies the survey to which you are adding the pixel map or bitmap.

thePixMapHandle

A handle to a pixel map or bitmap to be added to the survey.

Return Value

A result code. See "Picture Utilities Result Codes" (page 1441).

Discussion

The `RecordPixMapInfo` function adds the pixel map or bitmap you specify in the parameter `thePixMapHandle` to the survey identified by the parameter `thePictInfoID`. Use `RecordPictInfo` repeatedly to add additional pixel maps and bitmaps to your survey.

After you have collected all of the images you need, use the `RetrievePictInfo` (page 1425) function to return information about all the images in the survey.

Special Considerations

Because Quartz 2D uses an entirely different approach to graphics than used by QuickDraw, there is no one-to-one correlation between QuickDraw and Quartz 2D functions. However, because Quartz offers many new features and improved performance compared to QuickDraw, it is worthwhile making the effort to convert your graphics code to Quartz.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`PictUtils.h`

RetrievePictInfo

Returns information about all the pictures, pixel maps, and bitmaps included in a survey. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
OSErr RetrievePictInfo (
   PictInfoID thePictInfoID,
   PictInfo *thePictInfo,
   short colorsRequested
);
```

Parameters

thePictInfoID

The ID number, returned by the `NewPictInfo` (page 1422) function, that identifies the survey of pictures, pixel maps, and bitmaps.

thePictInfo

On return, a pointer to the `PictInfo` (page 1434) structure that holds information about the pictures or images in the survey.

This function also collects information from black-and-white pictures and bitmaps, and is supported in System 7 even by computers running only basic QuickDraw. However, when collecting color information on a computer running only basic QuickDraw, the function returns `NULL` instead of a handle to a `Palette` or `ColorTable` structure.

colorsRequested

From 1 to 256, the number of colors you want returned in the `ColorTable` or `Palette` structure included in the `PictInfo` structure.

Return Value
A result code. See "Picture Utilities Result Codes" (page 1441).

Discussion
After using the `NewPictInfo` function to create a new survey, and then using `RecordPictInfo` to add pictures to your survey and `RecordPixMapInfo` to add pixel maps and bitmaps to your survey, call `RetrievePictInfo`.

When you are finished with the information in the `PictInfo` structure, dispose of the `Palette` structure by using the `DisposePalette` function. Dispose of the `ColorTable` structure with the `DisposeCTable` function. Dispose of other allocations with the `DisposeHandle` function. Use the `DisposePictInfo` function to dispose of the private data structures created by the `NewPictInfo` function.

Special Considerations

Because Quartz 2D uses an entirely different approach to graphics than used by QuickDraw, there is no one-to-one correlation between QuickDraw and Quartz 2D functions. However, because Quartz offers many new features and improved performance compared to QuickDraw, it is worthwhile making the effort to convert your graphics code to Quartz.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`PictUtils.h`

Callbacks

CalcColorTableProcPtr

Defines a pointer to a color table calculation callback. Your color calculation callback selects as many colors as are requested by your application from the color bank for a picture or pixel map and then fills these colors into an array of `ColorSpec` structures.

```
typedef OSErr (*CalcColorTableProcPtr)
(
    UInt32 dataRef,
    SInt16 colorsRequested,
    void * colorBankPtr,
    CSpecArray resultPtr
);
```

If you name your function `MyCalcColorTableProc`, you would declare it like this:

```
OSErr CalcColorTableProcPtr (
    UInt32 dataRef,
    SInt16 colorsRequested,
    void * colorBankPtr,
    CSpecArray resultPtr
);
```

Parameters

dataRef

A handle to any data your method needs. Your application initially creates this handle using the `InitPickMethodProcPtr` (page 1429) function.

colorsRequested

The number of colors requested by your application to be gathered for examination in a `ColorTable` or `Palette` structure.

colorBankPtr

If your `MyInitPickMethodCallback` function returned either the `colorBankIsExactAnd555` or `colorBankIs555` constant, then this parameter contains a pointer to the 5-5-5 histogram that describes all of the colors in the picture, pixel map, or bitmap being examined. (The format of the 5-5-5 histogram is explained in the function description for the `InitPickMethodProcPtr` (page 1429) function.) Your `MyCalcColorTableCallback` function should examine these colors and then, using its own criterion for selecting the colors, fill in an array of `ColorSpec` structures with the number of colors specified in the `colorsRequested` parameter.

If your `MyInitPickMethodCallback` function returned the `colorBankIsCustom` constant, then the value passed in this parameter is invalid. In this case, your `MyCalcColorTableCallback` function should use the custom color bank that your application created (using the `RecordColorsProcPtr` (page 1431) function) for filling in an array of `ColorSpec` structures with the number of colors specified in the `colorsRequested` parameter.

Your `MyCalcColorTableCallback` function should return a pointer to this array of `ColorSpec` structures in the next parameter.

resultPtr

A pointer to the array of `ColorSpec` structures to be filled with the number of colors specified in the `colorsRequested` parameter. The Picture Utilities function that your application initially called places these colors in a `Palette` structure or `ColorTable` structure, as specified by your application.

Return Value

A result code. See "Picture Utilities Result Codes" (page 1441). If `MyCalcColorTableCallback` generates an error, it should return the error as its function result. This error is passed back to the `GetPictInfo`, `GetPixMapInfo`, or `NewPictInfo` function, which in turn passes the error to your application as a function result.

Discussion
Selecting from the color bank created for the picture, bitmap, or pixel map being examined, `MyCalcColorTableCallback` fills an array of `ColorSpec` structures with the number of colors requested in the `colorsRequested` parameter and returns this array in the `resultPtr` parameter.

If more colors are requested than the picture contains, `MyCalcColorTable` fills the remaining entries with black (0000 0000 0000).

The `colorBankPtr` parameter is of type `Ptr` because the data stored in the color bank is of the type specified by your `InitPickMethodProcPtr` (page 1429) function. Thus, if you specified `colorBankIs555` in the `colorBankType` parameter, the color bank would be an array of integers. However, if the Picture Utilities support other data types in the future, the `colorBankPtr` parameter could point to completely different data types.

Always coerce the value passed in the `colorBankPtr` parameter to a pointer to an integer. In the future you may need to coerce this value to a pointer of the type you specify in your `MyInitPickMethodCallback` function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`PictUtils.h`

DisposeColorPickMethodProcPtr

Defines a pointer to a method disposal callback function. Your method disposal function releases the memory for the `'cpmt'` resource allocated by your `MyInitPickMethodCallback` function.

```
typedef OSErr (*DisposeColorPickMethodProcPtr)
(
    UInt32 dataRef
);
```

If you name your function `MyDisposeColorPickMethodProc`, you would declare it like this:

```
OSErr DisposeColorPickMethodProcPtr (
    UInt32 dataRef
);
```

Parameters
`dataRef`
A handle to any data your method needs. Your application initially creates this handle using the `InitPickMethodProcPtr` (page 1429) function.

Return Value
A result code. See "Picture Utilities Result Codes" (page 1441). If your `MyDisposeColorPickMethodCallback` function generates an error, it should return the error as its function result. This error is passed back to the `GetPictInfo`, `GetPixMapInfo`, or `NewPictInfo` function, which in turn passes the error to your application as a function result.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`PictUtils.h`

InitPickMethodProcPtr

Defines a pointer to a method initialization callback function. Your method initialization function specifies the color back and allocates whatever data your color-picking method needs.

```
typedef OSErr (*InitPickMethodProcPtr)
(
    SInt16 colorsRequested,
    UInt32 * dataRef,
    SInt16 * colorBankType
);
```

If you name your function `MyInitPickMethodProc`, you would declare it like this:

```
OSErr InitPickMethodProcPtr (
    SInt16 colorsRequested,
    UInt32 * dataRef,
    SInt16 * colorBankType
);
```

Parameters

colorsRequested

The number of colors requested by your application to be gathered for examination in a `ColorTable` or `Palette` structure.

dataRef

A handle to any data needed by your color-picking method; that is, if your application allocates and uses additional data, it should return a handle to it in this parameter.

colorBankType

The type of color bank your color-picking method uses. Your `MyInitPickMethodCallback` function should return one of three valid color bank types.

Return the `colorBankIs555` constant in this parameter if you want to let the Picture Utilities gather the colors for a picture or a pixel map into a 5-5-5 histogram. When you return the `colorBankIs555` constant, the Picture Utilities call your `MyCalcColorTableCallback` function with a pointer to the color bank (that is, to the 5-5-5 histogram). Your `MyCalcColorTableCallback` function selects whatever colors it needs from this color bank. Then the Picture Utilities function called by your application returns these colors in a `Palette` structure, a `ColorTable` structure, or both, as requested by your application.

Return the `ColorBankIsExactAnd555` constant in this parameter to make the Picture Utilities return exact colors if there are less than 256 unique colors in the picture; otherwise, the Picture Utilities gather the colors for the picture in a 5-5-5 histogram, just as they do when you return the `colorBankIs555` constant. If the picture or pixel map has fewer colors than your application requests when it calls a Picture Utilities function, the Picture Utilities function returns all of the colors contained in the color bank. If the picture or pixel map contains more colors than your application requests, the Picture Utilities call your `MyCalcColorTableCallback` function to select which colors to return.

Return the `colorBankIsCustom` constant in this parameter if you want to implement your own color bank for storing the colors in a picture or a pixel map. For example, because the 5-5-5 histogram that the Picture Utilities provide gathers colors to a resolution of 5 bits per color, your application may want to create a histogram with a resolution of 8 bits per color. When you return the `colorBankIsCustom` constant, the Picture Utilities call your `MyRecordColorsCallback` function to create this color bank. The Picture Utilities also call your `MyCalcColorTableCallback` function to select colors from this color bank.

Return Value
A result code. See "Picture Utilities Result Codes" (page 1441). If `MyInitPickMethodCallback` generates any error, it should return the error as its function result. This error is passed back to the `GetPictInfo`, `GetPixMapInfo`, or `NewPictInfo` function, which in turn passes the error to your application as a function result.

Discussion
Your color-picking method (`'cpmt'`) resource should include a function that specifies its color bank (that is, the structure into which all the colors of a picture, pixel map, or bitmap are gathered) and allocates whatever data your color-picking method needs. Your `MyInitPickMethodCallback` can let the Picture Utilities generate a color bank consisting of a histogram (that is, frequency counts of each color) to a resolution of 5 bits per color. Or, your `MyInitPickMethodCallback` function can specify that your application has its own custom color bank—for example, a histogram to a resolution of 8 bits per color.

The 5-5-5 histogram that the Picture Utilities provide if you return the `ColorBankIs555` or `ColorBankIsExactAnd555` constant in the `colorBankType` parameter is like a reversed `cSpecArray` structure, which is an array of `ColorSpec` structures. This 5-5-5 histogram is an array of 32,768 integers, where the index into the array is the color: 5 bits of red, followed by 5 bits of green, followed by 5 bits of blue. Each entry in the array is the number of colors in the picture that are approximated by the index color for that entry.

For example, suppose there were three instances of the following color in the pixel map:

- Red = %1101 1010 1010 1110
- Green = %0111 1010 1011 0001
- Blue = %0101 1011 0110 1010

This color would be represented by index % 0 11011-01111-01011 (in hexadecimal, $6DEB), and the value in the histogram at this index would be 3, because there are three instances of this color.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`PictUtils.h`

RecordColorsProcPtr

Defines a pointer to a color recording callback function. Your color recording function creates a color bank.

```
typedef OSErr (*RecordColorsProcPtr)
(
    UInt32 dataRef,
    RGBColor * colorsArray,
    SInt32 colorCount,
    SInt32 * uniqueColors
);
```

If you name your function `MyRecordColorsProc`, you would declare it like this:

```
OSErr RecordColorsProcPtr (
    UInt32 dataRef,
    RGBColor * colorsArray,
    SInt32 colorCount,
    SInt32 * uniqueColors
);
```

Parameters

`dataRef`
A handle to any data your function needs. Your application initially creates this handle using the `InitPickMethodProcPtr` (page 1429) function.

`colorsArray`
An array of `RGBColor` structures. Your `MyRecordColorsCallback` function stores the color information for this array of `RGBColor` structures in a data structure of type `RGBColorArray`.

`colorCount`
The number of colors in the array specified in the `colorsArray` parameter.

`uniqueColors`
Upon input, the number of unique colors already added to the array in the `colorsArray` parameter. (The Picture Utilities functions call your `MyRecordColors` function once for every color in the picture, pixel map, or bitmap.) Your `MyRecordColorsCallback` function must calculate the number of unique colors (to the resolution of the color bank) that are added by this call. Your `MyRecordColorsCallback` function should add this amount to the value passed upon input in this parameter and then return the sum in this parameter.

Return Value
A result code. See "Picture Utilities Result Codes" (page 1441). If your `MyRecordColorsCallback` function generates any error, it should return the error as its function result. This error is passed back to the `GetPictInfo`, `GetPixMapInfo`, or `NewPictInfo` function, which in turn passes the error to your application as a function result.

Discussion
`MyRecordColorsCallback` stores each color encountered in a picture or pixel into its own color bank. The Picture Utilities call `MyRecordColorsCallback` only if your `MyInitPickMethodCallback` function returns the constant `colorBankIsCustom` in the `colorBankType` parameter. When you return the `colorBankIsCustom` constant in the `colorBankType` parameter to your `MyInitPickMethodCallback` function, your color-picking method (`'cpmt'`) resource must include a function that creates this color bank; for example, your application may want to create a histogram with a resolution of 8 bits per color.

The Picture Utilities functions call `MyRecordColorsCallback` for all the colors in the picture, pixel map, or bitmap.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`PictUtils.h`

Data Types

CalcColorTableUPP

Defines a universal procedure pointer (UPP) to a color table calculation callback.

```
typedef CalcColorTableProcPtr CalcColorTableUPP;
```

Discussion
For more information, see the description of the callback function `CalcColorTableProcPtr` (page 1426).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`PictUtils.h`

CommentSpec

Contains information about the comments in a picture.

```
struct CommentSpec {
    short count;
    short ID;
};
typedef struct CommentSpec CommentSpec;
typedef CommentSpec * CommentSpecPtr;
typedef CommentSpecPtr * CommentSpecHandle;
```

Fields
`count`
The number of times this kind of picture comment occurs in the picture specified to the `GetPictInfo` function or in all the pictures examined with the `NewPictInfo` function.

`ID`

The value set in the `kind` parameter when the picture comment was created using the function `PicComment`. For a description of this function, see *Inside Mac OS X: Quickdraw Reference*.

Discussion
If you specify the `structureComments` constant in the `verb` parameter to the `GetPictInfo` (page 1414) function or the `NewPictInfo` (page 1422) function, you receive a `PictInfo` (page 1434) structure that includes in its `commentHandle` field a handle to an array of `CommentSpec` structures. The `uniqueComments` field of the `PictInfo` structure indicates the number of `CommentSpec` structures in this array.

When you are finished using the information returned in a `CommentSpec` structure, use the `DisposeHandle` function to dispose of the memory allocated to it.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`PictUtils.h`

DisposeColorPickMethodUPP

Defines a universal procedure pointer (UPP) to a method disposal callback.

```
typedef DisposeColorPickMethodProcPtr DisposeColorPickMethodUPP;
```

Discussion
For more information, see the description of the callback function `DisposeColorPickMethodProcPtr` (page 1428).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`PictUtils.h`

FontSpec

Contains information about the fonts in a picture.

```
struct FontSpec {
    short pictFontID;
    short sysFontID;
    long size[4];
    short style;
    long nameOffset;
};
typedef struct FontSpec FontSpec;
typedef FontSpec * FontSpecPtr;
typedef FontSpecPtr * FontSpecHandle;
```

Fields
`pictFontID`

The ID number of the font as it is stored in the picture.

`sysFontID`
: The number that identifies the resource file (of type `'FOND'`) that specifies the font family. Every font family, has a unique font family ID, in a range of values that determines the script system to which the font family belongs.

`size`
: The point sizes of the fonts in the picture. The field contains 128 bits, in which a bit is set for each point size encountered, from 1 to 127 points. Bit 0 is set if a size larger than 127 is found.

`style`
: The styles for this font family at any of its sizes. The values in this field can also be represented with the `Style` data type.

`nameOffset`
: The offset into the list of font names (indicated by the `fontNamesHandle` field of the `PictInfo` structure) at which the name for this font family is stored. A font name is given to a font family to distinguish it from other font families.

Discussion
If you specify the `recordFontInfo` constant in the `verb` parameter to the `GetPictInfo` function or the `NewPictInfo` function, your application receives a `PictInfo` structure that includes in its `fontHandle` field a handle to an array of `FontSpec` structures. The `uniqueFonts` field of the `PictInfo` structure indicates the number of `FontSpec` structures in this array. (For bitmap fonts, a font is a complete set of glyphs in one size, typeface, and style. For outline fonts, a font is a complete set of glyphs in one typeface and style.)

When you are finished using the information returned in a `FontSpec` structure, you should use the Memory Manager function `DisposeHandle` to dispose of the memory allocated to it.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`PictUtils.h`

InitPickMethodUPP

Defines a universal procedure pointer (UPP) to a method initialization callback.

```
typedef InitPickMethodProcPtr InitPickMethodUPP;
```

Discussion
For more information, see the description of the callback function `InitPickMethodProcPtr` (page 1429).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`PictUtils.h`

PictInfo

Contains information about a picture.

```
struct PictInfo {
    short version;
    long uniqueColors;
    PaletteHandle thePalette;
    CTabHandle theColorTable;
    Fixed hRes;
    Fixed vRes;
    short depth;
    Rect sourceRect;
    long textCount;
    long lineCount;
    long rectCount;
    long rRectCount;
    long ovalCount;
    long arcCount;
    long polyCount;
    long regionCount;
    long bitMapCount;
    long pixMapCount;
    long commentCount;
    long uniqueComments;
    CommentSpecHandle commentHandle;
    long uniqueFonts;
    FontSpecHandle fontHandle;
    Handle fontNamesHandle;
    long reserved1;
    long reserved2;
};
typedef struct PictInfo PictInfo;
typedef PictInfo * PictInfoPtr;
```

Fields

`version`

The version number of the Picture Utilities, currently set to 0.

`uniqueColors`

The number of colors in the picture specified to the `GetPictInfo` function, or the number of colors in the pixel map or bitmap specified to the `GetPixMapInfo` function, or the total number of colors for all the pictures, pixel maps, and bitmaps returned by the `RetrievePictInfo` function. The number of colors returned in this field is limited by the accuracy of the Picture Utilities' color bank for color storage. See `InitPickMethodProcPtr` (page 1429), `RecordColorsProcPtr` (page 1431), `CalcColorTableProcPtr` (page 1426), and `DisposeColorPickMethodProcPtr` (page 1428) for information about the Picture Utility's color bank and about how you can create your own for selecting colors.

`thePalette`

A handle to the resulting `Palette` structure if you specified to the `GetPictInfo`, `GetPixMapInfo`, or `NewPictInfo` function that colors be returned in a `Palette` structure. That `Palette` structure contains either the number of colors you specified to the function or—if there are not that many colors in the pictures, pixel maps, or bitmaps—the number of colors found. Depending on the constant you pass in the `verb` parameter to the function, the `Palette` structure contains either the most used or the widest range of colors in the pictures, pixel maps, and bitmaps. On Macintosh computers running basic QuickDraw only, this field is always returned as `NULL`.

`theColorTable`

A handle to the resulting `ColorTable` structure if you specified to the `GetPictInfo`, `GetPixMapInfo`, or `NewPictInfo` function that colors be returned in a `ColorTable` structure. If the pictures, pixel maps, or bitmaps contain fewer colors found than you specified to the function, the unused entries in the `ColorTable` structure are filled with black. Depending on the constant you pass in the `verb` parameter to the function, the `ColorTable` structure contains either the most used or the widest range of colors in the pictures, pixel maps, and bitmaps. On Macintosh computers running basic QuickDraw only, this field is always returned as `NULL`.

If a picture has more than 256 colors or has pixel depths of 32 bits, then Color QuickDraw translates the colors in the `ColorTable` structure to 16-bit depths. In such a case, the returned colors might have a slight loss of resolution, and the `uniqueColors` field reflects the number of colors distinguishable at that pixel depth.

`hRes`

The horizontal resolution of the current picture, pixel map, or bitmap retrieved by the `GetPictInfo` or `GetPixMapInfo` function or the greatest horizontal resolution from all pictures, pixel maps, and bitmaps retrieved by the `RetrievePictInfo` function.

`vRes`

The vertical resolution of the current picture, pixel map, or bitmap retrieved by the `GetPictInfo` or `GetPixMapInfo` function or the greatest vertical resolution of all pictures, pixel maps, and bitmaps retrieved by the `RetrievePictInfo` function. Although the values of the `hRes` and `vRes` fields are usually the same, they do not have to be.

`depth`

The pixel depth of the picture specified to the `GetPictInfo` function or the pixel map specified to the `GetPixMapInfo` function. When you use the `RetrievePictInfo` function, this field contains the deepest pixel depth of all pictures or pixel maps retrieved by the function.

`sourceRect`

The optimal bounding rectangle for displaying the picture at the resolution indicated by the `hRes` and `vRes` fields. The upper-left corner of the rectangle is always (0,0). Pictures created with the `OpenCPicture` function have the `hRes`, `vRes`, and `sourceRect` fields built into their `Picture` structures. For pictures created by `OpenPicture`, the `hRes` and `vRes` fields are set to 72 dpi, and the source rectangle is calculated using the `picFrame` field of the `Picture` structure for the picture.

`textCount`

The number of text strings in the picture specified to the `GetPictInfo` function, or the total number of text objects in all the pictures retrieved by the `RetrievePictInfo` function. For pixel maps and bitmaps specified to `GetPixMapInfo` or `RetrievePictInfo`, this field is set to 0.

`lineCount`

The number of lines in the picture specified to the `GetPictInfo` function, or the total number of lines in all the pictures retrieved by the `RetrievePictInfo` function. For pixel maps and bitmaps, this field is set to 0.

`rectCount`

The number of rectangles in the picture specified to the `GetPictInfo` function, or the total number of rectangles in all the pictures retrieved by the `RetrievePictInfo` function. For pixel maps and bitmaps, this field is set to 0.

`rRectCount`

The number of rounded rectangles in the picture specified to the `GetPictInfo` function, or the total number of rounded rectangles in all the pictures retrieved by the `RetrievePictInfo` function. For pixel maps and bitmaps, this field is set to 0.

`ovalCount`
: The number of ovals in the picture specified to the `GetPictInfo` function, or the total number of ovals in all the pictures retrieved by the `RetrievePictInfo` function. For pixel maps and bitmaps, this field is set to 0.

`arcCount`
: The number of arcs and wedges in the picture specified to the `GetPictInfo` function, or the total number of arcs and wedges in all the pictures retrieved by the `RetrievePictInfo` function. For pixel maps and bitmaps, this field is set to 0.

`polyCount`
: The number of polygons in the picture specified to the `GetPictInfo` function, or the total number of polygons in all the pictures retrieved by the `RetrievePictInfo` function. For pixel maps and bitmaps, this field is set to 0.

`regionCount`
: The number of regions in the picture specified to the `GetPictInfo` function, or the total number of regions in all the pictures retrieved by the `RetrievePictInfo` function. For pixel maps and bitmaps, this field is set to 0.

`bitMapCount`
: The total number of bitmaps in the survey.

`pixMapCount`
: The total number of pixel maps in the survey.

`commentCount`
: The number of comments in the picture specified to the `GetPictInfo` function, or the total number of comments in all the pictures retrieved by the `RetrievePictInfo` function. This field is valid only if you specified to the `GetPictInfo` or `NewPictInfo` function that comments be returned in a `CommentSpec` structure. For pixel maps and bitmaps, this field is set to 0.

`uniqueComments`
: The number of picture comments that have different IDs in the picture specified to the `GetPictInfo` function, or the total number of picture comments with different IDs in all the pictures retrieved by the `RetrievePictInfo` function. This field is valid only if you specify that comments be returned in a `CommentSpec` (page 1432) structure. For pixel maps and bitmaps, this field is set to 0.

`commentHandle`
: A handle to an array of `CommentSpec` structures. For pixel maps and bitmaps, this field is set to `NULL`. See `CommentSpec` (page 1432).

`uniqueFonts`
: The number of different fonts in the picture specified to the `GetPictInfo` function, or the total number of different fonts in all the pictures retrieved by the `RetrievePictInfo` function. For bitmap fonts, a font is a complete set of glyphs in one size, typeface, and style. For outline fonts, a font is a complete set of glyphs in one typeface and style—for example, 12-point Geneva italic. For outline fonts, a font is a complete set of glyphs in one typeface and style—for example, Geneva italic.

  This field is valid only if you specify that fonts be returned in a `FontSpec` (page 1433) structure. For pixel maps and bitmaps, this field is set to 0.

`fontHandle`
: A handle to a list of `FontSpec` structures. For pixel maps and bitmaps, this field is set to `NULL`.

`fontNamesHandle`
: A handle to the names of the fonts in the picture retrieved by the `GetPictInfo` function or the pictures retrieved by the `RetrievePictInfo` function. The offset to a particular name is stored in the `nameOffset` field of the `FontSpec` structure for that font. A font name is a name given to one font family to distinguish it from other font families.

```
reserved1
reserved2
```

Discussion
When you use the `GetPictInfo` (page 1414) function to collect information about a picture, or when you use the `GetPixMapInfo` (page 1416) function to collect color information about a pixel map or bitmap, the function returns the information in a `PictInfo` structure. When you gather this information for multiple pictures, pixel maps, or bitmaps, the `RetrievePictInfo` (page 1425) function also returns a `PictInfo` structure containing this information.

Initially, all of the fields in a new `PictInfo` structure are set to `NULL`. Relevant fields are set to appropriate values depending on the information you request using the Picture Utilities functions.

When you are finished with this information, be sure to dispose of it. You can dispose of `Palette` structures by using the Palette Manager function, `DisposePalette`. Dispose of `ColorTable` structures by using the QuickDraw function, `DisposeCTable`. Dispose of other allocations with the Memory Manager function, `DisposeHandle`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`PictUtils.h`

PictInfoID

Defines an identifier for a collection of pictures, pixel maps, or bitmaps in an application.

```
typedef long PictInfoID;
```

Discussion
Picture Utilities returns a `PictInfoID` value when you call the function `NewPictInfo` (page 1422). It serves as a unique identifier for a collection of pictures, pixel maps, or bitmaps defined in your application. You use this ID when calling other Picture Utilities functions to manage and survey your collection.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`PictUtils.h`

RecordColorsUPP

Defines a universal procedure pointer (UPP) to a color recording callback.

```
typedef RecordColorsProcPtr RecordColorsUPP;
```

Discussion
For more information, see the description of the callback function `RecordColorsProcPtr` (page 1431).

Availability
Available in Mac OS X v10.0 and later.

Declared In
PictUtils.h

Constants

Color Bank Type

Specifies the type of color bank used in a color-picking method.

```
enum {
    ColorBankIsCustom = -1,
    ColorBankIsExactAnd555 = 0,
    ColorBankIs555 = 1
};
```

Constants

ColorBankIsCustom
: Gathers colors into a custom color bank. Picture Utilities gathers the colors for a picture or a pixel map into a 5-5-5 histogram. When you return the colorBankIs555 constant, the Picture Utilities call your RecordColorsProcPtr (page 1431) function with a pointer to the color bank (that is, to the 5-5-5 histogram). Your CalcColorTableProcPtr function selects whatever colors it needs from this color bank. Then the Picture Utilities function called by your application returns these colors in a Palette structure, a ColorTable structure, or both, as requested by your application.

Available in Mac OS X v10.0 and later.

Declared in PictUtils.h.

ColorBankIsExactAnd555
: Gathers exact colors if there are less than 256 unique colors in picture; otherwise gathers colors for picture in a 5-5-5 histogram. If the picture or pixel map has fewer colors than your application requests when it calls a Picture Utilities function, the Picture Utilities function returns all of the colors contained in the color bank. If the picture or pixel map contains more colors than your application requests, the Picture Utilities call your CalcColorTableProcPtr function to select which colors to return.

Available in Mac OS X v10.0 and later.

Declared in PictUtils.h.

ColorBankIs555
: Gathers colors into a 5-5-5 histogram. Specify colorBankIsCustom constant if you want to implement your own color bank for storing the colors in a picture or a pixel map. For example, because the 5-5-5 histogram that the Picture Utilities provide gathers colors to a resolution of 5 bits per color, your application may want to create a histogram with a resolution of 8 bits per color. When you return the colorBankIsCustom constant, the Picture Utilities call your RecordColorsProcPtr (page 1431) function to create this color bank. The Picture Utilities also call your CalcColorTableProcPtr function to select colors from this color bank.

Available in Mac OS X v10.0 and later.

Declared in PictUtils.h.

Discussion
Your InitPickMethodProcPtr (page 1429) function returns these constants in the colorBankType parameter to indicate the type of color bank used in your color-picking method.

Color Selection Method

Indicates the color selection method used in a `PictInfo` record.

```
enum {
    systemMethod = 0,
    popularMethod = 1,
    medianMethod = 2
};
```

Constants

`systemMethod`
Lets Picture Utilities choose the method. Currently they always choose `popularMethod`.
Available in Mac OS X v10.0 and later.
Declared in `PictUtils.h`.

`popularMethod`
Returns the most frequently used colors.
Available in Mac OS X v10.0 and later.
Declared in `PictUtils.h`.

`medianMethod`
Returns a weighted distribution of colors.
Available in Mac OS X v10.0 and later.
Declared in `PictUtils.h`.

Discussion

These constants are used to indicate the method by which colors are selected for the `ColorTable` or `Palette` structure returned via the `PictInfo` structure, by the functions `NewPictInfo` (page 1422) , `GetPixMapInfo` (page 1416) , or `GetPictInfo` (page 1414).

Color Information Type

Indicates the type of color information returned in a `PictInfo` record.

```
enum {
    returnColorTable = 0x0001,
    returnPalette = 0x0002,
    recordComments = 0x0004,
    recordFontInfo = 0x0008,
    suppressBlackAndWhite = 0x0010
};
```

Constants

`returnColorTable`
Specify to return a Color Table.
Available in Mac OS X v10.0 and later.
Declared in `PictUtils.h`.

`returnPalette`
Specify to return a Palette structure.
Available in Mac OS X v10.0 and later.
Declared in `PictUtils.h`.

`recordComments`
Specify to return comment information.
Available in Mac OS X v10.0 and later.
Declared in `PictUtils.h`.

`recordFontInfo`
Specify to return font information.
Available in Mac OS X v10.0 and later.
Declared in `PictUtils.h`.

`suppressBlackAndWhite`
Don't include black and white with returned colors.
Available in Mac OS X v10.0 and later.
Declared in `PictUtils.h`.

Discussion
These constants are used in the `verb` parameter of the `GetPictInfo` (page 1414) , `GetPixMapInfo` (page 1416) ,and `NewPictInfo` (page 1422) functions to indicate the type of information those functions should return. You can use any or all of these constants or the sum of the integers they represent.

Result Codes

The table below lists the most common result codes returned by Picture Utilities.

Result Code	Value	Description
`pictInfoVersionErr`	-11000	Wrong version of the PictInfo structure. Available in Mac OS X v10.0 and later.
`pictInfoIDErr`	-11001	The internal consistancy check for the PictInfoID is wrong. Available in Mac OS X v10.0 and later.
`pictInfoVerbErr`	-11002	The PictInfo verb is not valid. Available in Mac OS X v10.0 and later.
`cantLoadPickMethodErr`	-11003	Unable to load the custom pick method resource. Available in Mac OS X v10.0 and later.
`colorsRequestedErr`	-11004	The number of colors requested is illegal. Available in Mac OS X v10.0 and later.
`pictureDataErr`	-11005	The picture data is not valid. Available in Mac OS X v10.0 and later.

Process Manager Reference

Framework: Carbon/Carbon.h
Declared in Processes.h

Overview

The Process Manager provides the cooperative multitasking environment for versions of Mac OS that preceded Mac OS X. The Process Manager controls access to shared resources and manages the scheduling and execution of applications.

You can use the Process Manager to control the execution of processes and to get information about processes, including your own. You can use the Process Manager routines to

- control the execution of your application
- get information about processes
- launch other applications

Some Process Manager functions access a `ProcessInfoRec` data structure, which contains fields that are no longer applicable in a preemptively scheduled environment (for example, the `processLocation`, `processFreeMem`, and `processActiveTime` fields). Your application should avoid accessing such fields. Changes to the memory model may also affect certain fields.

Carbon does not support Process Manager functions that deal with control panels or desk accessories.

Functions by Task

Getting Process Information

`CopyProcessName` (page 1445)
Gets a copy of the name of a process.

`GetCurrentProcess` (page 1446)
Gets information about the current process, if any.

`GetFrontProcess` (page 1446)
Gets the process serial number of the front process.

`GetNextProcess` (page 1447)
Gets information about the next process, if any, in the Process Manager's internal list of open processes.

`GetProcessBundleLocation` (page 1447)
Retrieves the file system location of the application bundle (or executable file) associated with a process.

`GetProcessInformation` (page 1448)
Get information about a specific process.

`ProcessInformationCopyDictionary` (page 1452)
Obtains a superset of `GetProcessInformation` in modern data types.

`GetProcessPID` (page 1449)
Obtains the Unix PID from a process serial number.

`GetProcessForPID` (page 1448)
Obtains the process serial number from a Unix PID.

`IsProcessVisible` (page 1450)
Determines the visiblility of the user interface for a process.

`SameProcess` (page 1453)
Determines whether two process serial numbers specify the same process.

Starting and Terminating Processes

`LaunchApplication` (page 1451)
Launches an application.

`ExitToShell` (page 1445)
Terminates an application.

`KillProcess` (page 1450)
Terminates a process with the specified ID.

Modifying Processes

`SetFrontProcess` (page 1454)
Moves a process to the foreground.

`SetFrontProcessWithOptions` (page 1455)
Brings a process to the front of the process list, and activates it.

`ShowHideProcess` (page 1455)
Shows or hides a given process.

`TransformProcessType` (page 1456)
Changes the type of the specified process.

`WakeUpProcess` (page 1456)
Makes a suspended process eligible for CPU time.

Functions

CopyProcessName

Gets a copy of the name of a process.

```
OSStatus CopyProcessName (
   const ProcessSerialNumber *psn,
   CFStringRef *name
);
```

Parameters

PSN

A pointer to a valid process serial number. See `ProcessSerialNumber` (page 1461) for more information.

name

A Core Foundation string that contains the name of the specified process.

Return Value

A result code. See "Process Manager Result Codes" (page 1467).

Discussion

Because the string returned is a Core Foundation string, it can represent a multilingual name, unlike the `processName` field value you obtain using `GetProcessInformation` (page 1448).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Processes.h`

ExitToShell

Terminates an application.

```
void ExitToShell (
   void
);
```

Discussion

In general, you need to call `ExitToShell` only if you want your application to terminate without reaching the end of its main function.

The `ExitToShell` function terminates the calling process. The Process Manager removes your application from the list of open processes and performs any other necessary cleanup operations. In particular, all memory in your application partition and any temporary memory still allocated to your application is released. If necessary, the Application Died Apple event is sent to the process that launched your application.

Availability

Available in Mac OS X v10.0 and later.

Related Sample Code

BSDLLCTest

HideMenuBar

ictbSample
QTCarbonShell
QTMetaData

Declared In
`Processes.h`

GetCurrentProcess

Gets information about the current process, if any.

```
OSErr GetCurrentProcess (
    ProcessSerialNumber * PSN
);
```

Parameters

PSN

On output, a pointer to the process serial number of the current process, that is, the one currently accessing the CPU. This application can be running in either the foreground or the background.

Return Value
A result code. See "Process Manager Result Codes" (page 1467).

Discussion
Applications can use this function to find their own process serial number. Drivers can use this function to find the process serial number of the current process. You can use the returned process serial number in other Process Manager functions.

This function is named `MacGetCurrentProcess` on non Macintosh platforms and `GetCurrentProcess` on Macintosh computers. However, even Macintosh code can use the `MacGetCurrentProcess` name because a macro exists that automatically maps that call to `GetCurrentProcess`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Processes.h`

GetFrontProcess

Gets the process serial number of the front process.

```
OSErr GetFrontProcess (
   ProcessSerialNumber *PSN
);
```

Parameters

PSN

On return, a pointer to the process serial number of the process running in the foreground.

Return Value
A result code. See "Process Manager Result Codes" (page 1467). If no process is running in the foreground, returns `procNotFound`.

Discussion
You can use this function to determine if your process or some other process is in the foreground. You can use the process serial number returned in the `PSN` parameter in other Process Manager functions.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Processes.h`

GetNextProcess

Gets information about the next process, if any, in the Process Manager's internal list of open processes.

```
OSErr GetNextProcess (
   ProcessSerialNumber *PSN
);
```

Parameters

PSN

On input, a pointer to the process serial number of a process. This number should be a valid process serial number returned from `LaunchApplication` (page 1451), `GetFrontProcess` (page 1446), or `GetCurrentProcess` (page 1446), or a process serial number structure containing `kNoProcess`. For details about this structure, see `ProcessSerialNumber` (page 1461). On return, a pointer to the process serial number of the next process, or else `kNoProcess`.

Return Value
A result code. See "Process Manager Result Codes" (page 1467).

Discussion
The Process Manager maintains a list of all open processes. You can derive this list by using repetitive calls to `GetNextProcess`. Begin generating the list by calling `GetNextProcess` and specifying the constant `kNoProcess` in the `PSN` parameter. You can then use the returned process serial number to get the process serial number of the next process. Note that the order of the list of processes is internal to the Process Manager. When the end of the list is reached, `GetNextProcess` returns the constant `kNoProcess` in the `PSN` parameter and the result code `procNotFound`.

You can use the returned process serial number in other Process Manager functions. You can also use this process serial number to specify a target application when your application sends a high-level event.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Processes.h`

GetProcessBundleLocation

Retrieves the file system location of the application bundle (or executable file) associated with a process.

```
OSStatus GetProcessBundleLocation (
   const ProcessSerialNumber *psn,
   FSRef *location
);
```

Parameters

PSN

A pointer to a valid process serial number. See `ProcessSerialNumber` (page 1461) for more information.

location

Return Value
A result code. See "Process Manager Result Codes" (page 1467).

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
QTCarbonShell

Declared In
`Processes.h`

GetProcessForPID

Obtains the process serial number from a Unix PID.

```
OSStatus GetProcessForPID (
   pid_t pid,
   ProcessSerialNumber *psn
);
```

Parameters

pid

The Unix process ID (PID).

psn

On return, `psn` points to the process serial number.

Return Value
A result code. See "Process Manager Result Codes" (page 1467).

Discussion
Note that this call does not make sense for Classic applications, since they all share a single UNIX process ID.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Processes.h`

GetProcessInformation

Get information about a specific process.

```
OSErr GetProcessInformation (
   const ProcessSerialNumber *PSN,
   ProcessInfoRec *info
);
```

Parameters

PSN

A pointer to a valid process serial number. You can pass a process serial number structure containing the constant `kCurrentProcess` to get information about the current process. See `ProcessSerialNumber` (page 1461) for more information.

info

On return, a pointer to a structure containing information about the specified process.

Return Value
A result code. See "Process Manager Result Codes" (page 1467).

Discussion
The information returned in the `info` parameter includes the application's name as it appears in the Application menu, the type and signature of the application, the address of the application partition, the number of bytes in the application partition, the number of free bytes in the application heap, the application that launched the application, the time at which the application was launched, and the location of the application file.

The `GetProcessInformation` function also returns information about the application's `'SIZE'` resource and indicates whether the process is an application or a desk accessory.

You need to specify values for the `processInfoLength`, `processName`, and `processAppSpec` fields of the process information structure. Specify the length of the process information structure in the `processInfoLength` field. If you do not want information returned in the `processName` and `processAppSpec` fields, specify `NULL` for these fields. Otherwise, allocate at least 32 bytes of storage for the string pointed to by the `processName` field and, in the `processAppSpec` field, specify a pointer to an `FSSpec` structure.

The `processName` field may not be what you expect, especially if an application has a localized name. The `processName` field, if not `NULL`, on return will contain the filename part of the executable file of the application. If you want the localized, user-displayable name for an application, call `CopyProcessName` (page 1445).

In Mac OS X, the `processActiveTime` field of the returned structure is always 0, and the `modeCanBackground`, `mode32BitCompatible`, and `modeHighLevelEventAware` fields are always set.

Special Considerations

In most cases, Mac OS X applications should use `ProcessInformationCopyDictionary` (page 1452) instead of this function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Processes.h`

GetProcessPID

Obtains the Unix PID from a process serial number.

```
OSStatus GetProcessPID (
   const ProcessSerialNumber *psn,
   pid_t *pid
);
```

Parameters

psn

A pointer to a valid process serial number. See `ProcessSerialNumber` (page 1461) for more information.

pid

On return, `pid` points to a Unix PID.

Return Value
A result code. See "Process Manager Result Codes" (page 1467).

Discussion
Note that this call does not make sense for Classic applications, since they all share a single UNIX process ID.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Processes.h`

IsProcessVisible

Determines the visiblility of the user interface for a process.

```
Boolean IsProcessVisible (
   const ProcessSerialNumber *psn
);
```

Parameters

PSN

A pointer to a valid process serial number. See `ProcessSerialNumber` (page 1461) for more information.

Return Value
Returns `true` if the user interface is currently visible. Otherwise, returns `false`.

Availability
Available in Mac OS X v10.1 and later.

Declared In
`Processes.h`

KillProcess

Terminates a process with the specified ID.

```
OSErr KillProcess (
   const ProcessSerialNumber *inProcess
);
```

Parameters

inProcess

The serial number of the process you want to terminate. You can also pass a process serial number structure containing the constant `kCurrentProcess` to refer to the current process. See `ProcessSerialNumber` (page 1461) for more information.

Return Value
A result code. See "Process Manager Result Codes" (page 1467).

Discussion
`KillProcess` terminates an process without sending a "quit" Apple event or allowing it any time to save user data or perform cleanup. You should use this function only as a last resort when all other attempts have failed. Even then, there is no guarantee that this call will succeed in killing the application, even if it returns with `noErr`.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`Processes.h`

LaunchApplication

Launches an application.

```
OSErr LaunchApplication (
   LaunchPBPtr LaunchParams
);
```

Parameters

LaunchParams

A pointer to a `LaunchParamBlockRec` (page 1457) specifying information about the application to launch.

Return Value
A result code. See "Process Manager Result Codes" (page 1467).

Discussion
The `LaunchApplication` function launches the application from the specified file and returns the process serial number, preferred partition size, and minimum partition size if the application is successfully launched.

Note that if you launch another application without terminating your application, the launched application is not actually executed until you make a subsequent call to `WaitNextEvent` or `EventAvail`.

Set the `launchContinue` flag in the `launchControlFlags` field of the launch parameter block if you want your application to continue after the specified application is launched. If you do not set this flag, `LaunchApplication` terminates your application after launching the specified application, even if the launch fails.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Processes.h`

ProcessInformationCopyDictionary

Obtains a superset of `GetProcessInformation` in modern data types.

```
CFDictionaryRef ProcessInformationCopyDictionary (
   const ProcessSerialNumber *PSN,
   UInt32 infoToReturn
);
```

Parameters

PSN

A pointer to a valid process serial number. See `ProcessSerialNumber` (page 1461) for more information.

infoToReturn

A bitmask indicating the information to obtain. Pass `kProcessDictionaryIncludeAllInformationMask` for this parameter.

Return Value

An immutable Core Foundation dictionary containing the system information in key-value pairs.

Discussion

You should use this function instead of `GetProcessInformation` (page 1448). Table 41-1 and Table 41-2 show keys you can use to get process attributes in the returned Core Foundation dictionary. All keys in the dictionary are Core Foundation strings. (Note that additional keys exist, but these are for internal use only.) Keys marked with an asterisk (*) may not appear in the dictionary, depending on the application.

Table 41-1 Process information keys

Key	Type	Summary
PSN	`CFNumberRef`	The process serial number. See `ProcessSerialNumber` (page 1461).
Flavor	`CFNumberRef`	A hint as to the type of the application. You shouldn't need to use this key.
Attributes	`CFNumberRef`	Attributes for the process. Useful attributes generally have their own keys.
ParentPSN *	`CFNumberRef`	The process serial number of the application that launched this process.
FileType *	`CFStringRef`	The file type (if any) of the executable.
FileCreator *	`CFStringRef`	The creator type (if any) of the executable.
pid *	`CFNumberRef`	The UNIX PID for this process.
LSBackgroundOnly	`CFBooleanRef`	`kCFBooleanTrue` if the application is a background-only application.

Key	Type	Summary
LSUIElement	`CFBooleanRef`	`kCFBooleanTrue` if the application is an accessibility UIElement.
IsHiddenAttr	`CFBooleanRef`	`kCFBooleanTrue` if the application is currently hidden.
RequiresCarbon	`CFBooleanRef`	`kCFBooleanTrue` if the application's Info.plist file indicates that it is a Carbon application.
LSUIPresentationMode	`CFNumberRef`	The initial user-interface mode for the application. See *Runtime Configuration Guidelines* for a list of possible values.
BundlePath *	`CFStringRef`	The path to the application bundle (if the application is bundled).

Table 41-2 lists additional keys that you should reference by their predefined constants, rather than the actual string names.

Table 41-2 Process information key constants

Key	Type	Summary
`kCFBundleExecutableKey` *	`CFStringRef`	The path to the actual executable file.
`kCFBundleNameKey` *	`CFStringRef`	The application's display name.
`kCFBundleIdentifierKey` *	`CFStringRef`	The application's bundle identifier (if the application is bundled). For example, "com.apple.TextEdit".

Availability
Available in Mac OS X v10.2 and later.

Declared In
`Processes.h`

SameProcess

Determines whether two process serial numbers specify the same process.

```
OSErr SameProcess (
   const ProcessSerialNumber *PSN1,
   const ProcessSerialNumber *PSN2,
   Boolean *result
);
```

Parameters

PSN1

A process serial number.

PSN2

A process serial number.

result

On return, a pointer to a Boolean value which is `TRUE` if the process serial numbers passed in `PSN1` and `PSN2` refer to the same process; otherwise `FALSE`.

Return Value
A result code. See "Process Manager Result Codes" (page 1467).

Discussion
Do not attempt to compare two process serial numbers by any means other than the `SameProcess` function, because the interpretation of the bits in a process serial number is internal to the Process Manager.

The values of `PSN1` and `PSN2` must be valid process serial numbers returned from `LaunchApplication` (page 1451), `GetNextProcess` (page 1447), `GetFrontProcess` (page 1446), `GetCurrentProcess` (page 1446), or a high-level event. You can also pass a process serial number structure containing the constant `kCurrentProcess` to refer to the current process.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Processes.h`

SetFrontProcess

Moves a process to the foreground.

```
OSErr SetFrontProcess (
   const ProcessSerialNumber *PSN
);
```

Parameters

PSN

A pointer to a valid process serial number. You can also pass a process serial number structure containing the constant `kCurrentProcess` to refer to the current process. See `ProcessSerialNumber` (page 1461) for more information.

Return Value
A result code. See "Process Manager Result Codes" (page 1467).

Discussion
The `SetFrontProcess` function moves the specified process to the foreground immediately.

If the specified process serial number is invalid or if the specified process is a background-only application, `SetFrontProcess` returns a nonzero result code and does not change the current foreground process.

Special Considerations

Do not call `SetFrontProcess` at interrupt time.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Processes.h`

SetFrontProcessWithOptions

Brings a process to the front of the process list, and activates it.

```
OSStatus SetFrontProcessWithOptions (
   const ProcessSerialNumber *inProcess,
   OptionBits inOptions
);
```

Parameters

PSN

A pointer to a valid process serial number. You can also pass a process serial number structure containing the constant `kCurrentProcess` to refer to the current process. See `ProcessSerialNumber` (page 1461) for more information.

inOptions

A flag that indicates how process windows should be brought forward—see the discussion below.

Return Value

A result code. See "Process Manager Result Codes" (page 1467).

Discussion

If you pass 0 in the `inOptions` parameter, the process is activated and all process windows are brought forward. This is equivalent to calling `SetFrontProcess` (page 1454). If you pass `kSetFrontProcessFrontWindowOnly`, the process is activated and the frontmost nonfloating window is brought forward.

Availability

Available in Mac OS X v10.2 and later.

Declared In

`Processes.h`

ShowHideProcess

Shows or hides a given process.

```
OSErr ShowHideProcess (
   const ProcessSerialNumber *psn,
   Boolean visible
);
```

Parameters

PSN

A pointer to a valid process serial number. See `ProcessSerialNumber` (page 1461) for more information.

visible

A Boolean value that specifies whether you want to show (`true`) or hide (`false`) the process.

Return Value

A result code. See "Process Manager Result Codes" (page 1467).

Availability

Available in Mac OS X v10.1 and later.

Declared In

`Processes.h`

TransformProcessType

Changes the type of the specified process.

```
OSStatus TransformProcessType (
   const ProcessSerialNumber *psn,
   ProcessApplicationTransformState transformState
);
```

Parameters

PSN

The serial number of the process you want to transform. You can also use the constant `kCurrentProcess` to refer to the current process. See `ProcessSerialNumber` (page 1461) for more information.

transformState

A constant indicating the type of transformation you want. See "Process Transformation Constant" (page 1467). Currently you can pass only `kProcessTransformToForegroundApplication`.

Return Value

A result code. See "Process Manager Result Codes" (page 1467).

Discussion

You can use this call to transform a background-only application into a foreground application. A foreground application appears in the Dock (and in the Force Quit dialog) and contains a menu bar. This function does not cause the application to be brought to the front; you must call `SetFrontProcess` (page 1454) to do so.

Availability

Available in Mac OS X v10.3 and later.

Declared In

`Processes.h`

WakeUpProcess

Makes a suspended process eligible for CPU time.

```
OSErr WakeUpProcess (
   const ProcessSerialNumber *PSN
);
```

Parameters

PSN

The serial number of the process you want to wake up. You can also pass a process serial number structure containing the constant `kCurrentProcess` to refer to the current process. See `ProcessSerialNumber` (page 1461) for more information.

Return Value

A result code. See "Process Manager Result Codes" (page 1467).

Discussion

The `WakeUpProcess` function makes a process suspended by `WaitNextEvent` eligible to receive CPU time. A process is suspended when the value of the `sleep` parameter in the `WaitNextEvent` function is not 0 and no events for that process are pending in the event queue. This process remains suspended until the time specified in the sleep parameter expires or an event becomes available for that process. You can use

`WakeUpProcess` to make the process eligible for execution before the time specified in the `sleep` parameter expires. This function does not change the order of the processes scheduled for execution; it only makes the specified process eligible for execution.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Processes.h`

Data Types

AppParameters

Defines the first high-level event sent to a newly-launched application.

```
struct AppParameters {
    struct {
        UInt16 what;
        UInt32 message;
        UInt32 when;
        Point where;
        UInt16 modifiers;
    } theMsgEvent;
    unsigned long eventRefCon
    unsigned long messageLength
};
typedef struct AppParameters AppParameters;
typedef AppParameters * AppParametersPtr;
```

Discussion
The application parameters structure is used in the `launchAppParameters` field of the launch parameter block, `LaunchParamBlockRec` (page 1457) , whose address is passed to the `LaunchApplication` (page 1451) function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Processes.h`

LaunchParamBlockRec

Defines the required parameters when launching an application.

```
struct LaunchParamBlockRec {
    unsigned long reserved1;
    unsigned short reserved2;
    unsigned short launchBlockID;
    unsigned long launchEPBLength;
    unsigned short launchFileFlags;
    LaunchFlags launchControlFlags;
    FSSpecPtr launchAppSpec;
    ProcessSerialNumber launchProcessSN;
    unsigned long launchPreferredSize;
    unsigned long launchMinimumSize;
    unsigned long launchAvailableSize;
    AppParametersPtr launchAppParameters;
};
typedef struct LaunchParamBlockRec LaunchParamBlockRec;
typedef LaunchParamBlockRec * LaunchPBPtr;
```

Fields

`reserved1`
Reserved.

`reserved2`
Reserved.

`launchBlockID`
A value that indicates whether you are using the fields following it in the launch parameter block. Specify the constant `extendedBlock` if you use the fields that follow it.

`launchEPBLength`
The length of the fields following this field in the launch parameter block. Use the constant `extendedBlockLen` to specify this value.

`launchFileFlags`
The Finder flags for the application file. Set the `launchNoFileFlags` constant in the `launchControlFlags` field if you want the `LaunchApplication` function to extract the Finder flags from the application file and to set the `launchFileFlags` field for you.

`launchControlFlags`
See "Launch Options" (page 1464) for a complete description of these flags.

`launchAppSpec`
A pointer to a file specification structure that gives the location of the application file to launch.

`launchProcessSN`
The process serial number returned to your application if the launch is successful. You can use this process serial number in other Process Manager functions to refer to the launched application.

`launchPreferredSize`
The preferred partition size for the launched application as specified in the launched application's `'SIZE'` resource. `LaunchApplication` sets this field to 0 if an error occurred or if the application is already open.

`launchMinimumSize`
The minimum partition size for the launched application as specified in the launched application's `'SIZE'` resource. `LaunchApplication` sets this field to 0 if an error occurred or if the application is already open.

`launchAvailableSize`
: The maximum partition size that is available for allocation. This value is returned to your application only if the `memFullErr` result code is returned. If the application launch fails because of insufficient memory, you can use this value to determine if there is enough memory available to launch in the minimum size.

`launchAppParameters`
: The first high-level event to send to the launched application. If you set this field to `NULL`, `LaunchApplication` creates and sends the Open Application Apple event to the launched application.

Discussion
You specify a launch parameter block as a parameter to the `LaunchApplication` (page 1451) function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Processes.h`

ProcessInfoRec

Defines the structure of a process information record.

```
struct ProcessInfoRec {
    unsigned long processInfoLength;
    StringPtr processName;
    ProcessSerialNumber processNumber;
    unsigned long processType;
    OSType processSignature;
    unsigned long processMode;
    Ptr processLocation;
    unsigned long processSize;
    unsigned long processFreeMem;
    ProcessSerialNumber processLauncher;
    unsigned long processLaunchDate;
    unsigned long processActiveTime;
    FSSpecPtr processAppSpec;
};
typedef struct ProcessInfoRec ProcessInfoRec;
typedef ProcessInfoRec * ProcessInfoRecPtr;
```

Fields

`processInfoLength`
: The number of bytes in the process information structure. For compatibility, you should specify the length of the structure in this field.

`processName`
: The name of the application. This field contains the name of the application as designated by the user at the time the application was opened. For example, for foreground applications, the `processName` field contains the name as it appears in the Application menu. You must specify `NULL` in the `processName` field if you do not want the application name returned. Otherwise, you should allocate at least 32 bytes of storage for the string pointed to by the `processName` field. Note that the `processName` field specifies the name of the application, whereas the `processAppSpec` field specifies the location of the file.

`processNumber`
: The process serial number.

`processType`
: The file type of the application, generally `'APPL'` for applications and `'appe'` for background-only applications launched at startup.

`processSignature`
: The signature (or creator) of the file containing the application.

`processMode`
: Process mode flags. These flags indicate whether the process is an application or desk accessory. For applications, this field also returns information specified in the application's `'SIZE'` resource. This information is returned as flags.

  On Mac OS X, some flags in `processMode` will not be set as they were on Mac OS 9, even for Classic applications. Mac OS X doesn't support applications which can't be sent into the background, so `modeCanBackground` will always be set. Similarly, Mac OS X applications will always have `mode32BitCompatible` and `modeHighLevelEventAware` set

`processLocation`
: The beginning address of the application partition.

`processSize`
: The number of bytes in the application partition (including the heap, stack, and A5 world).

`processFreeMem`
: The number of free bytes in the application heap.

`processLauncher`
: The process serial number of the process that launched the application or desk accessory. If the original launcher of the process is no longer open, the `lowLongOfPSN` field of the process serial number structure contains the constant `kNoProcess`.

`processLaunchDate`
: The value of the `Ticks` global variable at the time that the process was launched.

`processActiveTime`
: The accumulated time, in ticks, during which the process has used the CPU, including both foreground and background processing time.

`processAppSpec`
: The address of a file specification structure that stores the location of the file containing the application or `'DRVR'` resource. You should specify `NULL` in the `processAppSpec` field if you do not want the `FSSpec` structure of the file returned.

Discussion
A process information record is returned by the `GetProcessInformation` (page 1448) function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Processes.h`

ProcessInfoExtendedRec

Defines an extended version of the process information record.

```
struct ProcessInfoExtendedRec {
    unsigned long processInfoLength;
    StringPtr processName;
    ProcessSerialNumber processNumber;
    unsigned long processType;
    OSType processSignature;
    unsigned long processMode;
    Ptr processLocation;
    unsigned long processSize;
    unsigned long processFreeMem;
    ProcessSerialNumber processLauncher;
    unsigned long processLaunchDate;
    unsigned long processActiveTime;
    FSSpecPtr processAppSpec;
    unsigned long processTempMemTotal;
    unsigned long processPurgeableTempMemTotal;
};
typedef struct ProcessInfoExtendedRec ProcessInfoExtendedRec;
typedef ProcessInfoExtendedRec * ProcessInfoExtendedRecPtr;
```

Discussion
See `ProcessInfoRec` (page 1459) for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Processes.h`

ProcessSerialNumber

Defines the unique identifier for an open process.

```
struct ProcessSerialNumber {
    unsigned long highLongOfPSN;
    unsigned long lowLongOfPSN;
};
typedef struct ProcessSerialNumber ProcessSerialNumber;
typedef ProcessSerialNumber * ProcessSerialNumberPtr;
```

Fields

`highLongOfPSN`
The high-order long integer of the process serial number.

`lowLongOfPSN`
The low-order long integer of the process serial number.

Discussion
All applications (defined as things which can appear in the Dock that are not documents and are launched by the Finder or Dock) on Mac OS X have a unique process serial number. This number is created when the application launches, and remains until the application quits. Other system services, like Apple events, use the `ProcessSerialNumber` structure to specify an application.

During launch, every application "checks in" with the Process Manager. Before this checkin, the application can not receive events or draw to the screen. Prior to Mac OS 10.2, this check in occurred before the applications's `main` function was entered. In Mac OS 10.2 and later, this check in does not occur until the first time the application calls a Process Manager function, or until it enters `CFRunLoopRun` for the main

event loop. This allows tools and other executables which do not need to receive events to link against more of the higher level toolbox frameworks, but may cause a problem if the application expects to be able to retrieve events or use CoreGraphics services before this checkin has occurred. An application can force the connection to the Process Manager to be set up by calling any Process Manager routine, but the recommended way to do this is to call `GetCurrentProcess` (page 1446) to ask for the current application's PSN. Doing so initializes the connection to the Process Manager if it has not already been set up and "check in" the application with the system.

You should not make any assumptions about the meaning of the bits in a process serial number. To compare two process serial numbers, you should use the function `SameProcess` (page 1453).

You can obtain a process serial number in one of the following ways:

- Process serial numbers are returned by the functions `LaunchApplication` (page 1451), `GetCurrentProcess` (page 1446), and `GetFrontProcess` (page 1446).
- Some high-level events return process serial numbers.

If you want to specify a process using the "Process Identification Constants" (page 1466), you must populate a process serial number structure, passing 0 in `highLongOfPSN` and the appropriate constant (such as `kCurrentProcess`) in `lowLongOfPSN`. For example, to bring the current process forward, you can use the following code:

```
ProcessSerialNumber psn = { 0, kCurrentProcess };
SetFrontProcess( &psn );
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MacTypes.h`

SizeResourceRec

Defines a representation of the `SIZE` resource.

```
struct SizeResourceRec {
    unsigned short flags;
    unsigned long preferredHeapSize;
    unsigned long minimumHeapSize;
};
typedef struct SizeResourceRec SizeResourceRec;
typedef SizeResourceRec * SizeResourceRecPtr;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Processes.h`

Constants

Control Panel Result Codes

Specifies the values that a control panel can return.

Unsupported

```
enum {
    cdevGenErr = -1,
    cdevMemErr = 0,
    cdevResErr = 1,
    cdevUnset = 3
};
```

Extension Launch Codes

Specifies the values used when launching extensions.

```
enum {
    extendedBlock = 0x4C43,
    extendedBlockLen = sizeof(LaunchParamBlockRec) - 12
};
```

Control Panel Message Codes

Specifies the values for messages to a control panel.

```
enum {
    initDev = 0,
    hitDev = 1,
    closeDev = 2,
    nulDev = 3,
    updateDev = 4,
    activDev = 5,
    deactivDev = 6,
    keyEvtDev = 7,
    macDev = 8,
    undoDev = 9,
    cutDev = 10,
    copyDev = 11,
    pasteDev = 12,
    clearDev = 13,
    cursorDev = 14
};
```

Termination Options

Specifies masks to control the timing of application termination during system shutdown or restart.

```
enum {
    kQuitBeforeNormalTimeMask = 1,
    kQuitAtNormalTimeMask = 2,
    kQuitBeforeFBAsQuitMask = 4,
    kQuitBeforeShellQuitsMask = 8,
    kQuitBeforeTerminatorAppQuitsMask = 16,
    kQuitNeverMask = 32,
    kQuitOptionsMask = 0x7F,
    kQuitNotQuitDuringInstallMask = 0x0100,
    kQuitNotQuitDuringLogoutMask = 0x0200
};
```

Discussion
Applications and background applications can control when they are asked to quit by the system at restart and shutdown by setting these bits in a `'quit'(0)` resource located in the resource fork.

Applications without this resource are terminated at `kQuitAtNormalTime`.

Availability
Available in CarbonLib 1.0 and later. Not available in Mac OS X version 10.0 and later.

Front Process Options

Specifies options for bringing windows forward when a process is activated.

```
enum {
    kSetFrontProcessFrontWindowOnly = (1 << 0)
};
```

Constants

`kSetFrontProcessFrontWindowOnly`
Activate the process, but bring only the frontmost non-floating window forward.

Available in Mac OS X version 10.2 and later.

Declared in `Processes.h`.

Launch Options

Specifies the valid launch options in the `launchControlFlags` field of the launch parameter block.

```
typedef unsigned short LaunchFlags;
enum {
  launchContinue                = 0x4000,
  launchNoFileFlags             = 0x0800,
  launchUseMinimum              = 0x0400,
  launchDontSwitch              = 0x0200,
  launchAllow24Bit              = 0x0100,
  launchInhibitDaemon           = 0x0080
};
```

Constants

`launchContinue`

Set this flag if you want your application to continue after the specified application is launched. If you do not set this flag, `LaunchApplication` terminates your application after launching the specified application, even if the launch fails.

Available in Mac OS X v10.0 and later.

Declared in `Processes.h`.

`launchNoFileFlags`

Set this flag if you want the `LaunchApplication` function to ignore any value specified in the `launchFileFlags` field. If you set the `launchNoFileFlags` flag, the `LaunchApplication` function extracts the Finder flags from the application file for you. If you want to supply the file flags, clear the `launchNoFileFlags` flag and specify the Finder flags in the `launchFileFlags` field of the launch parameter block.

Available in Mac OS X v10.0 and later.

Declared in `Processes.h`.

`launchUseMinimum`

Clear this flag if you want the `LaunchApplication` function to attempt to launch the application in the preferred size (as specified in the application's `'SIZE'` resource). If you set the `launchUseMinimum` flag, the `LaunchApplication` function attempts to launch the application using the largest available size greater than or equal to the minimum size but less than the preferred size. If the `LaunchApplication` function returns the result code `memFullErr` or `memFragErr`, the application cannot be launched under the current memory conditions.

Available in Mac OS X v10.0 and later.

Declared in `Processes.h`.

`launchDontSwitch`

Set this flag if you do not want the launched application brought to the front. If you set this flag, the launched application runs in the background until the user brings the application to the front—for example, by clicking in one of the application's windows. Note that most applications expect to be launched in the foreground. If you clear the `launchDontSwitch` flag, the launched application is brought to the front, and your application is sent to the background.

Available in Mac OS X v10.0 and later.

Declared in `Processes.h`.

`launchAllow24Bit`

Available in Mac OS X v10.0 and later.

Declared in `Processes.h`.

`launchInhibitDaemon`
Set this flag if you do not want `LaunchApplication` to launch a background-only application. (A background-only application has the `onlyBackground` flag set in its `'SIZE'` resource.)

Available in Mac OS X v10.0 and later.

Declared in `Processes.h`.

Discussion
For more information, see `LaunchApplication` (page 1451) and `LaunchParamBlockRec` (page 1457).

Process Mode Flags

Specifies the type of information returned in a process information record.

```
enum {
    modeReserved = 0x01000000,
    modeControlPanel = 0x00080000,
    modeLaunchDontSwitch = 0x00040000,
    modeDeskAccessory = 0x00020000,
    modeMultiLaunch = 0x00010000,
    modeNeedSuspendResume = 0x00004000,
    modeCanBackground = 0x00001000,
    modeDoesActivateOnFGSwitch = 0x00000800,
    modeOnlyBackground = 0x00000400,
    modeGetFrontClicks = 0x00000200,
    modeGetAppDiedMsg = 0x00000100,
    mode32BitCompatible = 0x00000080,
    modeHighLevelEventAware = 0x00000040,
    modeLocalAndRemoteHLEvents = 0x00000020,
    modeStationeryAware = 0x00000010,
    modeUseTextEditServices = 0x00000008,
    modeDisplayManagerAware = 0x00000004
};
```

Discussion
These constants indicate, in the `processMode` field of the `ProcessInfoRec` (page 1459) structure, whether the process is an application or a desk accessory. If the process is an application, these flags return information about the application's `'SIZE'` resource.

Process Identification Constants

Specifies constants used instead of a process serial number to identify a process.

```
enum {
    kNoProcess = 0,
    kSystemProcess = 1,
    kCurrentProcess = 2
};
```

Constants
`kNoProcess`
Identifies a process that doesn't exist.

Available in Mac OS X v10.0 and later.

Declared in `Processes.h`.

`kSystemProcess`
Identifies a process that belongs to the Operating System.

Available in Mac OS X v10.0 and later.

Declared in `Processes.h`.

`kCurrentProcess`
Identifies the current process.

Available in Mac OS X v10.0 and later.

Declared in `Processes.h`.

Discussion
If you want to use these constants to specify a process, you must populate a process serial number structure (`ProcessSerialNumber` (page 1461)), passing 0 in the `highLongOfPSN` field and the appropriate constant (such as `kCurrentProcess`) in the `lowLongOfPSN`. For example, to bring the current process forward, you can use the following code:

```
ProcessSerialNumber psn = { 0, kCurrentProcess };
SetFrontProcess( &psn );
```

Process Transformation Constant

Specify tranformation types to be applied when calling `TransformProcessType` (page 1456).

```
enum {
  kProcessTransformToForegroundApplication = 1L
};
typedef UInt32 ProcessApplicationTransformState;
```

Constants
`kProcessTransformToForegroundApplication`
Use to convert a background-only application to a foreground application.

Available in Mac OS X v10.3 and later.

Declared in `Processes.h`.

Result Codes

The table below lists the most common result codes returned by the Process Manager.

Result Code	Value	Description
`procNotFound`	-600	No eligible process with specified process serial number. Available in Mac OS X v10.0 and later.
`memFragErr`	-601	Not enough room to launch application with special requirements. Available in Mac OS X v10.0 and later.
`appModeErr`	-602	Addressing mode is 32-bit, but application is not 32-bit clean. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
protocolErr	-603	app made module calls in improper order Available in Mac OS X v10.0 and later.
hardwareConfigErr	-604	Hardware configuration not supported. Available in Mac OS X v10.0 and later.
appMemFullErr	-605	Partition size specified in SIZE resource is not big enough for launch. Available in Mac OS X v10.0 and later.
appIsDaemon	-606	Application runs in background only. Available in Mac OS X v10.0 and later.
wrongApplicationPlatform	-875	The application could not launch because the required platform is not available. Available in Mac OS X v10.0 and later.
appVersionTooOld	-876	The application's creator and version are incompatible with the current version of Mac OS. Available in Mac OS X v10.0 and later.
notAppropriateForClassic	-877	This application will not (or should not) run in Classic. Available in Mac OS X v10.0 and later.

Quartz Display Services Reference

Framework:	ApplicationServices/ApplicationServices.h
Declared in	CGDirectDisplay.h CGDirectPalette.h CGDisplayConfiguration.h CGDisplayFade.h CGError.h CGRemoteOperation.h CGSession.h CGWindowLevel.h
Companion guide	Quartz Display Services Programming Topics

Overview

Note: This document was previously titled *Quartz Services Reference*. Some information related to low-level events has been moved from this document into *Quartz Event Services Reference*.

Quartz Display Services provides direct access to certain low-level features in the Mac OS X window server related to the configuration and control of display hardware. For example, you can use Quartz Display Services to:

- Examine and change display mode properties such as width, height, and pixel depth
- Configure a set of displays in a single operation
- Capture one or more displays for exclusive use
- Perform fade effects
- Activate display mirroring
- Configure gamma color correction tables and color palettes
- Receive notification of screen update operations

Functions by Task

Finding Displays

`CGMainDisplayID` (page 1522)
Returns the display ID of the main display.

`CGGetOnlineDisplayList` (page 1521)
Provides a list of displays that are online (active, mirrored, or sleeping).

`CGGetActiveDisplayList` (page 1515)
Provides a list of displays that are active (or drawable).

`CGGetDisplaysWithOpenGLDisplayMask` (page 1516)
Provides a list of displays that corresponds to the bits set in an OpenGL display mask.

`CGGetDisplaysWithPoint` (page 1517)
Provides a list of online displays with bounds that include the specified point.

`CGGetDisplaysWithRect` (page 1518)
Gets a list of online displays with bounds that intersect the specified rectangle.

`CGOpenGLDisplayMaskToDisplayID` (page 1522)
Maps an OpenGL display mask to a display ID.

`CGDisplayIDToOpenGLDisplayMask` (page 1498)
Maps a display ID to an OpenGL display mask.

Capturing and Releasing Displays

`CGDisplayCapture` (page 1493)
Captures a display for exclusive use by an application.

`CGDisplayCaptureWithOptions` (page 1493)
Captures a display for exclusive use by an application, using the specified options.

`CGDisplayRelease` (page 1507)
Releases a captured display.

`CGDisplayIsCaptured` (page 1501)
Returns a Boolean value indicating whether a display is captured.

`CGCaptureAllDisplays` (page 1478)
Captures all attached displays.

`CGCaptureAllDisplaysWithOptions` (page 1479)
Captures all attached displays, using the specified options.

`CGReleaseAllDisplays` (page 1529)
Releases all captured displays.

`CGShieldingWindowID` (page 1535)
Returns the window ID of the shield window for a captured display.

`CGShieldingWindowLevel` (page 1536)
Returns the window level of the shield window for a captured display.

`CGDisplayAddressForPosition` (page 1485)
Returns the address in frame buffer memory that corresponds to a position on an online display.

`CGDisplayBaseAddress` (page 1487)
Returns the base address in frame buffer memory of an online display.

`CGDisplayGetDrawingContext` (page 1497)
Returns a graphics context suitable for drawing to a captured display.

Configuring Displays

`CGBeginDisplayConfiguration` (page 1477)
Begins a new set of display configuration changes.

`CGCancelDisplayConfiguration` (page 1478)
Cancels a set of display configuration changes.

`CGCompleteDisplayConfiguration` (page 1479)
Completes a set of display configuration changes.

`CGConfigureDisplayMirrorOfDisplay` (page 1481)
Changes the configuration of a mirroring set.

`CGConfigureDisplayMode` (page 1482)
Configures the display mode of a display.

`CGConfigureDisplayOrigin` (page 1483)
Configures the origin of a display in global display (desktop) coordinates.

`CGRestorePermanentDisplayConfiguration` (page 1531)
Restores the permanent display configuration settings for the current user.

`CGConfigureDisplayStereoOperation` (page 1484)
Enables or disables stereo operation for a display, as part of a display configuration.

`CGDisplaySetStereoOperation` (page 1511)
Immediately enables or disables stereo operation for a display.

Getting the Display Configuration

`CGDisplayCopyColorSpace` (page 1494)
Returns the color space for a display.

`CGDisplayIOServicePort` (page 1498)
Returns the I/O Kit service port of the specified display.

`CGDisplayIsActive` (page 1499)
Returns a Boolean value indicating whether a display is active.

`CGDisplayIsAlwaysInMirrorSet` (page 1499)
Returns a Boolean value indicating whether a display is always in a mirroring set.

`CGDisplayIsAsleep` (page 1500)
Returns a Boolean value indicating whether a display is sleeping (and is therefore not drawable.)

`CGDisplayIsBuiltin` (page 1500)
Returns a Boolean value indicating whether a display is built-in, such as the internal display in portable systems.

`CGDisplayIsInHWMirrorSet` (page 1501)
Returns a Boolean value indicating whether a display is in a hardware mirroring set.

`CGDisplayIsInMirrorSet` (page 1502)
Returns a Boolean value indicating whether a display is in a mirroring set.

`CGDisplayIsMain` (page 1502)
Returns a Boolean value indicating whether a display is the main display.

`CGDisplayIsOnline` (page 1503)
Returns a Boolean value indicating whether a display is connected or online.

`CGDisplayIsStereo` (page 1503)
Returns a Boolean value indicating whether a display is running in a stereo graphics mode.

`CGDisplayMirrorsDisplay` (page 1504)
For a secondary display in a mirroring set, returns the primary display.

`CGDisplayModelNumber` (page 1504)
Returns the model number of a display monitor.

`CGDisplayPrimaryDisplay` (page 1506)
Returns the primary display in a hardware mirroring set.

`CGDisplayRotation` (page 1508)
Returns the rotation angle of a display in degrees.

`CGDisplayScreenSize` (page 1509)
Returns the width and height of a display in millimeters.

`CGDisplaySerialNumber` (page 1510)
Returns the serial number of a display monitor.

`CGDisplayUnitNumber` (page 1513)
Returns the logical unit number of a display.

`CGDisplayUsesOpenGLAcceleration` (page 1514)
Returns a Boolean value indicating whether Quartz is using OpenGL-based window acceleration (Quartz Extreme) to render in a display.

`CGDisplayVendorNumber` (page 1514)
Returns the vendor number of the specified display's monitor.

Registering for Notification of Display Configuration Changes

These functions are used to register and unregister a callback function for notification of display configuration changes.

`CGDisplayRegisterReconfigurationCallback` (page 1507)
Registers a callback function to be invoked whenever a local display is reconfigured.

`CGDisplayRemoveReconfigurationCallback` (page 1508)
Removes the registration of a callback function that's invoked whenever a local display is reconfigured.

Retrieving Display Parameters

`CGDisplayBounds` (page 1491)
Returns the bounds of a display in global display space.

`CGDisplayPixelsHigh` (page 1505)
Returns the display height in pixel units.

`CGDisplayPixelsWide` (page 1506)
Returns the display width in pixel units.

`CGDisplayBitsPerPixel` (page 1491)
Returns the number of bits used to represent a pixel in the frame buffer.

`CGDisplayBitsPerSample` (page 1491)
Returns the number of bits used to represent a pixel component in the frame buffer.

`CGDisplaySamplesPerPixel` (page 1509)
Returns the number of color components used to represent a pixel.

`CGDisplayBytesPerRow` (page 1492)
Returns the number of bytes per row in a display.

Using Display Modes

`CGDisplayAvailableModes` (page 1486)
Returns information about the currently available display modes.

`CGDisplayBestModeForParameters` (page 1488)
Returns information about the display mode closest to a specified depth and screen size.

`CGDisplayBestModeForParametersAndRefreshRate` (page 1488)
Returns information about the display mode closest to a specified depth, screen size, and refresh rate.

`CGDisplayBestModeForParametersAndRefreshRateWithProperty` (page 1490)
Returns information about the display mode closest to a specified depth, screen size, and refresh rate, with a required property.

`CGDisplayCurrentMode` (page 1494)
Returns information about the current display mode.

`CGDisplaySwitchToMode` (page 1512)
Switches a display to a different mode.

Adjusting the Display Gamma

`CGSetDisplayTransferByFormula` (page 1533)
Sets the gamma function for a display, by specifying the coefficients of the gamma transfer formula.

`CGGetDisplayTransferByFormula` (page 1518)
Gets the coefficients of the gamma transfer formula for a display.

`CGSetDisplayTransferByTable` (page 1535)
Sets the color gamma function for a display, by specifying the values in the RGB gamma tables.

`CGGetDisplayTransferByTable` (page 1520)
Gets the values in the RGB gamma tables for a display.

`CGSetDisplayTransferByByteTable` (page 1532)
Sets the byte values in the 8-bit RGB gamma tables for a display.

`CGDisplayRestoreColorSyncSettings` (page 1508)
Restores the gamma tables to the values in the user's ColorSync display profile.

`CGDisplayGammaTableCapacity` (page 1497)
Returns the capacity, or number of entries, in the gamma table for a display.

Working With Color Palettes

`CGPaletteCreateDefaultColorPalette` (page 1523)
Returns a new display palette representing the default 8-bit color palette.

`CGPaletteCreateFromPaletteBlendedWithColor` (page 1524)
Returns a new tinted display palette. The new palette is derived from an existing palette blended with a solid color, at a specified level of intensity.

`CGPaletteCreateWithByteSamples` (page 1524)
Returns a new display palette using 8-bit sample data.

`CGPaletteCreateWithCapacity` (page 1525)
Returns a new display palette with a specified capacity. The new palette is initialized from the default color palette.

`CGPaletteCreateWithDisplay` (page 1525)
Returns a copy of the current palette for a display.

`CGPaletteCreateWithSamples` (page 1525)
Returns a new display palette using RGB sample data.

`CGPaletteCreateCopy` (page 1523)
Returns a copy of a specified display palette.

`CGPaletteRelease` (page 1528)
Decrements the retain count of a display palette.

`CGPaletteGetColorAtIndex` (page 1526)
Returns the color value at the specified index.

`CGPaletteGetIndexForColor` (page 1526)
Returns the index of the display palette entry that most closely matches a specified color value.

`CGPaletteGetNumberOfSamples` (page 1527)
Returns the number of colors in a display palette.

`CGPaletteIsEqualToPalette` (page 1527)
Returns a Boolean value indicating whether two display palettes are equal.

`CGPaletteSetColorAtIndex` (page 1528)
Updates the color value at the specified index in a display palette.

`CGDisplayCanSetPalette` (page 1492)
Returns a Boolean value indicating whether the current display mode supports palettes.

`CGDisplaySetPalette` (page 1510)
Sets the palette for a display.

Display Fade Effects

`CGConfigureDisplayFadeEffect` (page 1480)
Modifies the settings of the built-in fade effect that occurs during a display configuration.

`CGAcquireDisplayFadeReservation` (page 1476)
Reserves the fade hardware for a specified time interval.

`CGDisplayFade` (page 1495)
Performs a single fade operation.

`CGDisplayFadeOperationInProgress` (page 1496)
Returns a Boolean value indicating whether a fade operation is currently in progress.

`CGReleaseDisplayFadeReservation` (page 1530)
Releases a display fade reservation, and unfades the display if needed.

Beam Position

These functions are advisory in nature and depend on IO Kit and hardware-specific drivers to implement support. If you need extremely precise timing, or access to vertical blanking interrupts, you should consider writing a device driver to tie into hardware-specific capabilities.

`CGDisplayBeamPosition` (page 1487)
Returns the current beam position on a display.

`CGDisplayWaitForBeamPositionOutsideLines` (page 1515)
Waits until the beam position moves outside a region in a display screen. This function is not designed for VBL drawing synchronization.

Controlling the Mouse Cursor

`CGDisplayHideCursor` (page 1497)
Hides the mouse cursor, and increments the hide cursor count.

`CGDisplayShowCursor` (page 1512)
Decrements the hide cursor count, and shows the mouse cursor if the count is zero.

`CGDisplayMoveCursorToPoint` (page 1505)
Moves the mouse cursor to a specified point relative to the display origin (the upper left corner of the display).

`CGCursorIsVisible` (page 1485)
Returns a Boolean value indicating whether the mouse cursor is visible.

`CGCursorIsDrawnInFramebuffer` (page 1484)
Returns a Boolean value indicating whether the mouse cursor is drawn in frame buffer memory.

`CGAssociateMouseAndMouseCursorPosition` (page 1477)
Connects or disconnects the mouse and cursor while an application is in the foreground.

`CGWarpMouseCursorPosition` (page 1539)
Moves the mouse cursor without generating events.

`CGGetLastMouseDelta` (page 1520)
Reports the change in mouse position since the last mouse movement event received by the application.

Getting Window Server Information

`CGSessionCopyCurrentDictionary` (page 1532)
Returns information about the caller's window server session.

`CGWindowServerCFMachPort` (page 1540)
Returns a Core Foundation mach port (CFMachPort) that corresponds to the Mac OS X window server.

`CGWindowLevelForKey` (page 1539)
Returns the window level that corresponds to one of the standard window types.

Getting Information About Refresh and Move Operations

You can use these functions to find out what areas on local displays are changing their appearance as the result of operations such as drawing, window movement or scrolling, and display reconfiguration.

`CGRegisterScreenRefreshCallback` (page 1529)
Registers a callback function to be invoked when local displays are refreshed or modified.

`CGUnregisterScreenRefreshCallback` (page 1536)
Removes a previously registered callback function invoked when local displays are refreshed or modified.

`CGWaitForScreenRefreshRects` (page 1537)
Waits for screen refresh operations.

`CGScreenRegisterMoveCallback` (page 1531)
Registers a callback function to be invoked when an area of the display is moved.

`CGScreenUnregisterMoveCallback` (page 1532)
Removes a previously registered callback function invoked when an area of the display is moved.

`CGWaitForScreenUpdateRects` (page 1538)
Waits for screen update operations.

`CGReleaseScreenRefreshRects` (page 1530)
Deallocates a list of rectangles that represent changed areas on local displays.

Functions

CGAcquireDisplayFadeReservation

Reserves the fade hardware for a specified time interval.

```
CGError CGAcquireDisplayFadeReservation (
   CGDisplayReservationInterval seconds,
   CGDisplayFadeReservationToken *pNewToken
);
```

Parameters

seconds
The desired number of seconds to reserve the fade hardware. An application can specify any value in the interval `(0, kCGMaxDisplayReservationInterval]`.

pNewToken
A pointer to storage (provided by the caller) for a fade reservation token. On return, the storage contains a new token.

Return Value
Returns `kCGErrorNoneAvailable` if another fade reservation is in effect. Otherwise, returns `kCGErrorSuccess`.

Discussion
Before performing a fade operation, an application must reserve the fade hardware for a specified period of time. Quartz returns a token that represents a new fade reservation. The application uses this token as an argument in subsequent calls to other display fade functions.

During the fade reservation interval, the application has exclusive rights to use the fade hardware. At the end of the interval, the token becomes invalid and the hardware automatically returns to a normal state. Typically the application calls `CGReleaseDisplayFadeReservation` (page 1530) to release the fade reservation before it expires.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`CGDisplayFade.h`

CGAssociateMouseAndMouseCursorPosition

Connects or disconnects the mouse and cursor while an application is in the foreground.

```
CGError CGAssociateMouseAndMouseCursorPosition (
   boolean_t connected
);
```

Parameters

connected
Pass `true` if the mouse and cursor should be connected; otherwise, pass `false`.

Return Value
A result code. See "Quartz Display Services Result Codes" (page 1564).

Discussion
When you call this function to disconnect the cursor and mouse, all events received by your application have a constant absolute location but contain mouse delta (change in X and Y) data. You may hide the cursor or change it into something appropriate for your application. You can reposition the cursor by using the function `CGDisplayMoveCursorToPoint` (page 1505) or the function `CGWarpMouseCursorPosition` (page 1539).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGRemoteOperation.h`

CGBeginDisplayConfiguration

Begins a new set of display configuration changes.

```
CGError CGBeginDisplayConfiguration (
   CGDisplayConfigRef *pConfigRef
);
```

Parameters

pConfigRef

A pointer to storage you provide for a display configuration. On return, your storage contains a new display configuration.

Return Value
A result code. If the object is successfully created, the result is `kCGErrorSuccess`. For other possible values, see "Quartz Display Services Result Codes" (page 1564).

Discussion
This function creates a display configuration object that provides a context for a set of display configuration changes. After you specify the desired changes, you use `CGCompleteDisplayConfiguration` (page 1479) to apply them in a single transaction.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`CGDisplayConfiguration.h`

CGCancelDisplayConfiguration

Cancels a set of display configuration changes.

```
CGError CGCancelDisplayConfiguration (
   CGDisplayConfigRef configRef
);
```

Parameters

configRef

The display configuration to cancel. On return, the configuration is cancelled and is no longer valid.

Return Value
A result code. See "Quartz Display Services Result Codes" (page 1564).

Discussion
This function is used to abandon a display configuration. As a side effect, the display configuration object is released.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`CGDisplayConfiguration.h`

CGCaptureAllDisplays

Captures all attached displays.

```
CGDisplayErr CGCaptureAllDisplays (
   void
);
```

Return Value
A result code. See "Quartz Display Services Result Codes" (page 1564).

Discussion
This function captures all attached displays in a single operation. This operation provides an immersive environment for your application, and it prevents other applications from trying to adjust to display changes.

Availability
Available in Mac OS X v10.0 and later.

See Also
`CGDisplayCapture` (page 1493)

Declared In
`CGDirectDisplay.h`

CGCaptureAllDisplaysWithOptions

Captures all attached displays, using the specified options.

```
CGDisplayErr CGCaptureAllDisplaysWithOptions (
   CGCaptureOptions options
);
```

Parameters

options
The options to use. See "Display Capture Options" (page 1553).

Return Value
A result code. See "Quartz Display Services Result Codes" (page 1564).

Discussion
This function allows you to specify one or more options to use during capture of all attached displays.

Availability
Available in Mac OS X v10.3 and later.

See Also
`CGCaptureAllDisplays` (page 1478)

Declared In
`CGDirectDisplay.h`

CGCompleteDisplayConfiguration

Completes a set of display configuration changes.

```
CGError CGCompleteDisplayConfiguration (
   CGDisplayConfigRef configRef,
   CGConfigureOption option
);
```

Parameters

configRef

The display configuration with the desired changes. On return, this configuration is no longer valid.

option

The scope of the display configuration changes. Pass one of the constants listed in "Display Configuration Scopes" (page 1555).

Return Value

A result code. See "Quartz Display Services Result Codes" (page 1564).

Discussion

This function applies a set of display configuration changes as a single atomic transaction. The duration or scope of the changes depends on the value of the `option` parameter. The possible scopes are fully described in "Display Configuration Scopes" (page 1555).

A configuration change may fail if an unsupported display mode is requested, or if another application is running in full-screen mode.

Availability

Available in Mac OS X v10.2 and later.

Declared In

`CGDisplayConfiguration.h`

CGConfigureDisplayFadeEffect

Modifies the settings of the built-in fade effect that occurs during a display configuration.

```
CGError CGConfigureDisplayFadeEffect (
   CGDisplayConfigRef configRef,
   CGDisplayFadeInterval fadeOutSeconds,
   CGDisplayFadeInterval fadeInSeconds,
   float fadeRed,
   float fadeGreen,
   float fadeBlue
);
```

Parameters

configRef

A display configuration, acquired by calling `CGBeginDisplayConfiguration` (page 1477).

fadeOutSeconds

The time in seconds to fade from the normal display to the specified fade color. The fade out is completed before the display configuration is changed. If the interval is 0, Quartz applies the color immediately.

fadeInSeconds

Time in seconds to return from the specified fade color to the normal display. The fade-in is run asynchronously after the display configuration is changed.

fadeRed
An intensity value in the interval [0, 1] that represents the red component of the desired blend color.

fadeGreen
An intensity value in the interval [0, 1] that represents the green component of the desired blend color.

fadeBlue
An intensity value in the interval [0, 1] that represents the blue component of the desired blend color.

Return Value
A result code. See "Quartz Display Services Result Codes" (page 1564).

Discussion
This function provides a way to customize the built-in fade effect that Quartz performs when displays are reconfigured. The default time settings for this fade effect are 0.3 seconds to fade out, and 0.5 seconds to fade back in. The default fade color is French Blue for a normal desktop, and black for a captured display.

Before using this function, you need to call `CGBeginDisplayConfiguration` (page 1477) to acquire the display configuration token for the desired display. No fade reservation is needed—when you call `CGCompleteDisplayConfiguration` (page 1479), Quartz reserves the fade hardware (assuming it is available) and performs the fade.

Calling this function modifies the fade behavior for a single display configuration, and has no permanent effect.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`CGDisplayFade.h`

CGConfigureDisplayMirrorOfDisplay

Changes the configuration of a mirroring set.

```
CGError CGConfigureDisplayMirrorOfDisplay (
   CGDisplayConfigRef configRef,
   CGDirectDisplayID display,
   CGDirectDisplayID masterDisplay
);
```

Parameters

configRef
A display configuration, acquired by calling `CGBeginDisplayConfiguration` (page 1477).

display
The display to add to a mirroring set.

masterDisplay
A display in a mirroring set, or `kCGNullDirectDisplay` to disable mirroring. To specify the main display, use `CGMainDisplayID` (page 1522).

Return Value
A result code. See "Quartz Display Services Result Codes" (page 1564).

Discussion
Display mirroring and display matte generation are implemented either in hardware (preferred) or software, at the discretion of the device driver.

- Hardware mirroring

  With hardware mirroring enabled, all drawing is directed to the primary display—see `CGDisplayPrimaryDisplay` (page 1506).

  If the device driver selects hardware matte generation, the display bounds and rowbytes values are adjusted to reflect the active drawable area.

- Software mirroring

  In this form of mirroring, identical content is drawn into each display in the mirroring set. Applications that use the window system need not be concerned about mirroring, as the window system takes care of all flushing of window content to the appropriate displays.

  Applications that draw directly to the display, as with display capture, must make sure to draw the same content to all mirrored displays in a software mirror set. When drawing to software mirrored displays using a full screen OpenGL context (not drawing through a window), you should create shared OpenGL contexts for each display and re-render for each display.

You can use the function `CGGetActiveDisplayList` (page 1515) to determine which displays are active, or drawable. This automatically gives your application the correct view of the current displays.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`CGDisplayConfiguration.h`

CGConfigureDisplayMode

Configures the display mode of a display.

```
CGError CGConfigureDisplayMode (
   CGDisplayConfigRef configRef,
   CGDirectDisplayID display,
   CFDictionaryRef mode
);
```

Parameters

configRef
A display configuration, acquired by calling `CGBeginDisplayConfiguration` (page 1477).

display
The display being configured.

mode
A display mode dictionary (see the discussion below).

Return Value
A result code. See "Quartz Display Services Result Codes" (page 1564).

Discussion
A display mode is a set of properties such as width, height, pixel depth, and refresh rate, and options such as stretched LCD panel filling.

The display mode you provide must be one of the following:

- A dictionary returned by one of the `CGDisplayBestMode` functions, such as `CGDisplayBestModeForParameters` (page 1488).
- A dictionary in the array returned by `CGDisplayAvailableModes` (page 1486).

If you use this function to change the mode of a display in a mirroring set, Quartz may adjust the bounds, resolutions, and depth of the other displays in the set to a safe mode, with matching depth and the smallest enclosing size.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`CGDisplayConfiguration.h`

CGConfigureDisplayOrigin

Configures the origin of a display in global display (desktop) coordinates.

```
CGError CGConfigureDisplayOrigin (
   CGDisplayConfigRef configRef,
   CGDirectDisplayID display,
   CGDisplayCoord x,
   CGDisplayCoord y
);
```

Parameters

configRef
A display configuration, acquired by calling `CGBeginDisplayConfiguration` (page 1477).

display
The display being configured.

x
The desired x-coordinate for the upper left corner of the display.

y
The desired y-coordinate for the upper left corner of the display.

Return Value
A result code. See "Quartz Display Services Result Codes" (page 1564).

Discussion
In Quartz, the upper left corner of a display is called the origin. The origin of a display is always specified in global display (desktop) coordinates. The origin of the main or primary display is (0,0).

The new origin is placed as close as possible to the requested location, without overlapping or leaving a gap between displays.

If you use this function to change the origin of a mirrored display, the display may be removed from the mirroring set.

Availability
Available in Mac OS X v10.2 and later.

Declared In
CGDisplayConfiguration.h

CGConfigureDisplayStereoOperation

Enables or disables stereo operation for a display, as part of a display configuration.

```
CGError CGConfigureDisplayStereoOperation (
   CGDisplayConfigRef configRef,
   CGDirectDisplayID display,
   boolean_t stereo,
   boolean_t forceBlueLine
);
```

Parameters

configRef
A display configuration, acquired by calling `CGBeginDisplayConfiguration` (page 1477).

display
The display being configured.

stereo
Pass `true` if you want to enable stereo operation. To disable it, pass `false`.

forceBlueLine
When in stereo operation, a display may need to generate a special stereo sync signal as part of the video output. The sync signal consists of a blue line which occupies the first 25% of the last scanline for the left eye view, and the first 75% of the last scanline for the right eye view. The remainder of the scanline is black. To force the display to generate this sync signal, pass `true`; otherwise, pass `false`.

Return Value
A result code. See "Quartz Display Services Result Codes" (page 1564).

Discussion
The system normally detects the presence of a stereo window and automatically switches a display containing a stereo window to stereo operation. This function provides a mechanism to force a display to stereo operation, and to set options (blue line sync signal) when in stereo operation.

On success, the display resolution, mirroring mode, and available display modes may change due to hardware-specific capabilities and limitations. You should check these settings to verify that they are appropriate for your application.

Availability
Available in Mac OS X v10.4 and later.

Declared In
CGDisplayConfiguration.h

CGCursorIsDrawnInFramebuffer

Returns a Boolean value indicating whether the mouse cursor is drawn in frame buffer memory.

```
boolean_t CGCursorIsDrawnInFramebuffer (
   void
);
```

Return Value
If `true`, the cursor is drawn in frame buffer memory; otherwise, `false`.

Discussion
This function returns a Boolean value that indicates whether or not the cursor is drawn in the frame buffer. (The cursor could exist in an overlay plane or a similar mechanism that puts pixels on-screen without altering frame buffer content.) If the cursor is drawn in the frame buffer, it is read back along with window data.

The reported Boolean value is based on the union of the state of the cursor on all displays. If the cursor is drawn in the frame buffer on any display, the function returns `true`.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`CGRemoteOperation.h`

CGCursorIsVisible

Returns a Boolean value indicating whether the mouse cursor is visible.

```
boolean_t CGCursorIsVisible (
   void
);
```

Return Value
If `true`, the cursor is visible on any display; otherwise, `false`.

Discussion
To hide or show the cursor, you can use the functions `CGDisplayHideCursor` (page 1497) and `CGDisplayShowCursor` (page 1512).

Availability
Available in Mac OS X v10.3 and later.

Declared In
`CGRemoteOperation.h`

CGDisplayAddressForPosition

Returns the address in frame buffer memory that corresponds to a position on an online display.

```
void * CGDisplayAddressForPosition (
   CGDirectDisplayID display,
   CGDisplayCoord x,
   CGDisplayCoord y
);
```

Parameters

display

The display to access.

x

The x-coordinate of a position in global display space. The origin is the upper left corner of the main display.

y

The y-coordinate of a position in global display space. The origin is the upper left corner of the main display, and the y-axis is oriented down.

Return Value

The address in frame buffer memory that corresponds to the specified position. If the display ID is invalid or the point lies outside the bounds of the display, the return value is `NULL`.

Discussion

If the display has not been captured, the returned address may refer to read-only memory.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CGDirectDisplay.h`

CGDisplayAvailableModes

Returns information about the currently available display modes.

```
CFArrayRef CGDisplayAvailableModes (
   CGDirectDisplayID display
);
```

Parameters

display

The display to access.

Return Value

An array of dictionaries with display mode information, or `NULL` if the display is invalid. The array is owned by the system and you should not release it. Each dictionary in the array contains information about a mode that the display supports. For a list of the properties in a display mode dictionary, see "Display Mode Standard Properties" (page 1557) and "Display Mode Optional Properties" (page 1558). For general information about using dictionaries, see *CFDictionary Reference*.

Availability

Available in Mac OS X v10.0 and later.

Related Sample Code

QTCarbonShell

Declared In
CGDirectDisplay.h

CGDisplayBaseAddress

Returns the base address in frame buffer memory of an online display.

```
void * CGDisplayBaseAddress (
   CGDirectDisplayID display
);
```

Parameters

display
The display to access.

Return Value
The base address in frame buffer memory of the specified display. If the display ID is invalid, the return value is NULL.

Discussion
If the display has not been captured, the returned address may refer to read-only memory.

Availability
Available in Mac OS X v10.0 and later.

Declared In
CGDirectDisplay.h

CGDisplayBeamPosition

Returns the current beam position on a display.

```
CGBeamPosition CGDisplayBeamPosition (
   CGDirectDisplayID display
);
```

Parameters

display
The display to access.

Return Value
The current beam position on the specified display. If the display does not implement conventional video vertical and horizontal sweep in painting, or the driver does not implement this functionality, 0 is returned.

Discussion
This function returns the number of the scan line on which the beam is currently positioned, expressed as a non-negative integer. The value increases as the beam moves lower on the display.

Availability
Available in Mac OS X v10.0 and later.

Declared In
CGDirectDisplay.h

CGDisplayBestModeForParameters

Returns information about the display mode closest to a specified depth and screen size.

```
CFDictionaryRef CGDisplayBestModeForParameters (
   CGDirectDisplayID display,
   size_t bitsPerPixel,
   size_t width,
   size_t height,
   boolean_t *exactMatch
);
```

Parameters

display

The display to optimize.

bitsPerPixel

Optimal display depth in bits per pixel. Note that this value is not the same as pixel depth, which is the number of bits per channel or component.

width

Optimal display width in pixel units.

height

Optimal display height in pixel units.

exactMatch

A pointer to a Boolean variable. On return, its value is `true` if an exact match in display depth, width, and height is found; otherwise, `false`. If this information is not needed, pass `NULL`.

Return Value

A display mode dictionary, or `NULL` if the display is invalid. The dictionary is owned by the system and you should not release it. The dictionary contains information about the display mode closest to the specified depth and screen size. For a list of the properties in a display mode dictionary, see "Display Mode Standard Properties" (page 1557) and "Display Mode Optional Properties" (page 1558). For general information about using dictionaries, see *CFDictionary Reference*.

Discussion

This function tries to find an optimal display mode for the specified display. The function first tries to find a mode with the specified pixel depth and dimensions equal to or greater than the specified width and height. If no depth match is found, it tries to find a mode with greater depth and the same or greater dimensions. If a suitable display mode is not found, this function simply returns the current display mode.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CGDirectDisplay.h`

CGDisplayBestModeForParametersAndRefreshRate

Returns information about the display mode closest to a specified depth, screen size, and refresh rate.

```
CFDictionaryRef CGDisplayBestModeForParametersAndRefreshRate (
   CGDirectDisplayID display,
   size_t bitsPerPixel,
   size_t width,
   size_t height,
   CGRefreshRate refresh,
   boolean_t *exactMatch
);
```

Parameters

display

The display to access.

bitsPerPixel

Optimal display depth, in bits per pixel. Note that this value is not the same as pixel depth, which is the number of bits per channel or component.

width

Optimal display width, in pixel units.

height

Optimal display height, in pixel units.

refresh

Optimal display refresh rate, in frames per second.

exactMatch

A pointer to a Boolean variable. On return, its value is `true` if an exact match in display depth, width, height, and refresh rate is found; otherwise, `false`. If this information is not needed, pass `NULL`.

Return Value

A display mode dictionary, or `NULL` if the display is invalid. The dictionary is owned by the system and you should not release it. The dictionary contains information about the display mode closest to the specified depth, screen size, and refresh rate. For a list of the properties in a display mode dictionary, see "Display Mode Standard Properties" (page 1557) and "Display Mode Optional Properties" (page 1558). For general information about using dictionaries, see *CFDictionary Reference*.

Discussion

This function searches the list of available display modes for a mode that comes closest to satisfying these criteria:

- Has a pixel depth equal to or greater than the specified depth
- Has dimensions equal to or greater than the specified height and width
- Uses a refresh rate equal to or near the specified rate

If a suitable display mode is not found, this function simply returns the current display mode.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CGDirectDisplay.h`

CGDisplayBestModeForParametersAndRefreshRateWithProperty

Returns information about the display mode closest to a specified depth, screen size, and refresh rate, with a required property.

```
CFDictionaryRef CGDisplayBestModeForParametersAndRefreshRateWithProperty (
   CGDirectDisplayID display,
   size_t bitsPerPixel,
   size_t width,
   size_t height,
   CGRefreshRate refresh,
   CFStringRef property,
   boolean_t *exactMatch
);
```

Parameters

display

The display to access.

bitsPerPixel

Optimal display depth, in bits per pixel. Note that this value is not the same as pixel depth, which is the number of bits per channel or component.

width

Optimal display width, in pixels.

height

Optimal display height, in pixels.

refresh

Optimal display refresh rate, in refreshes per second.

property

A required display mode property. For a list of the properties you can specify, see "Display Mode Optional Properties" (page 1558).

exactMatch

A pointer to a Boolean variable. On return, its value is `true` if an exact match in display depth, width, height, refresh rate, and property is found; otherwise, `false`. If this information is not needed, pass `NULL`.

Return Value

A display mode dictionary, or `NULL` if the display is invalid. The dictionary is owned by the system and you should not release it. The dictionary contains information about the display mode with the specified property that comes closest to the specified depth, screen size, and refresh rate. For a list of the properties in a display mode dictionary, see "Display Mode Standard Properties" (page 1557) and "Display Mode Optional Properties" (page 1558). For general information about using dictionaries, see *CFDictionary Reference*.

Discussion

This function searches the list of available display modes for a mode that includes the specified property and comes closest to satisfying these criteria:

- Has a pixel depth equal to or greater than the specified depth
- Has dimensions equal to or greater than the specified height and width
- Uses a refresh rate equal to or near the specified rate

If no matching display mode is found, this function simply returns the current display mode.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`CGDirectDisplay.h`

CGDisplayBitsPerPixel

Returns the number of bits used to represent a pixel in the frame buffer.

```
size_t CGDisplayBitsPerPixel (
   CGDirectDisplayID display
);
```

Parameters

display
The display to access.

Return Value
The number of bits used to represent a pixel in the frame buffer.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGDirectDisplay.h`

CGDisplayBitsPerSample

Returns the number of bits used to represent a pixel component in the frame buffer.

```
size_t CGDisplayBitsPerSample (
   CGDirectDisplayID display
);
```

Parameters

display
The display to access.

Return Value
The number of bits used to represent a pixel component such as a color value in the frame buffer.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGDirectDisplay.h`

CGDisplayBounds

Returns the bounds of a display in global display space.

```
CGRect CGDisplayBounds (
   CGDirectDisplayID display
);
```

Parameters

display

The display to access.

Return Value

The bounds of the display, expressed as a rectangle in the global display coordinate space (relative to the upper left corner of the main display).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CGDirectDisplay.h`

CGDisplayBytesPerRow

Returns the number of bytes per row in a display.

```
size_t CGDisplayBytesPerRow (
   CGDirectDisplayID display
);
```

Parameters

display

The display to access.

Return Value

The number of bytes per row in the display. This number also represents the stride between pixels in the same column of the display.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CGDirectDisplay.h`

CGDisplayCanSetPalette

Returns a Boolean value indicating whether the current display mode supports palettes.

```
boolean_t CGDisplayCanSetPalette (
   CGDirectDisplayID display
);
```

Parameters

display

The display to access.

Return Value

If `true`, the current display mode supports palettes; otherwise, `false`.

Discussion
Palettes are supported in any display selected to run in a 256-color display mode.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGDirectDisplay.h`

CGDisplayCapture

Captures a display for exclusive use by an application.

```
CGDisplayErr CGDisplayCapture (
   CGDirectDisplayID display
);
```

Parameters

display
The display to capture.

Return Value
A result code. See "Quartz Display Services Result Codes" (page 1564).

Discussion
When an application captures a display, Quartz does not allow other applications and system services to use the display or change its configuration.

If hardware or software mirroring is in effect, the easiest way to capture the primary display and all mirrored displays is to use the function `CGCaptureAllDisplays` (page 1478). In case of software mirroring, applications that draw directly to the display must make sure to draw the same content to all displays in the mirror set.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGDirectDisplay.h`

CGDisplayCaptureWithOptions

Captures a display for exclusive use by an application, using the specified options.

```
CGDisplayErr CGDisplayCaptureWithOptions (
   CGDirectDisplayID display,
   CGCaptureOptions options
);
```

Parameters

display
The display to capture.

options
The options to use. See "Display Capture Options" (page 1553).

Return Value
A result code. See "Quartz Display Services Result Codes" (page 1564).

Discussion
This function allows you to specify one or more options to use during capture of a display.

Availability
Available in Mac OS X v10.3 and later.

See Also
`CGDisplayCapture` (page 1493)

Declared In
`CGDirectDisplay.h`

CGDisplayCopyColorSpace

Returns the color space for a display.

```
CGColorSpaceRef CGDisplayCopyColorSpace (
    CGDirectDisplayID display
);
```

Parameters

display
The display whose color space you want to obtain.

Return Value
The current color space for the specified display. The caller is responsible for releasing the color space with the `CGColorSpaceRelease` (page 55) function.

Discussion
This function returns a display-dependent ICC-based color space. You can use this function when rendering content for a specific display in order to produce color-matched output for that display.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`CGDisplayConfiguration.h`

CGDisplayCurrentMode

Returns information about the current display mode.

```
CFDictionaryRef CGDisplayCurrentMode (
   CGDirectDisplayID display
);
```

Parameters

display
The display to access.

Return Value
A display mode dictionary, or `NULL` if the display is invalid. The dictionary is owned by the system and you should not release it. The dictionary contains information about the current display mode. For a list of the properties in a display mode dictionary, see "Display Mode Standard Properties" (page 1557) and "Display Mode Optional Properties" (page 1558). For general information about using dictionaries, see *CFDictionary Reference*.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGDirectDisplay.h`

CGDisplayFade

Performs a single fade operation.

```
CGError CGDisplayFade (
   CGDisplayFadeReservationToken myToken,
   CGDisplayFadeInterval seconds,
   CGDisplayBlendFraction startBlend,
   CGDisplayBlendFraction endBlend,
   float redBlend,
   float greenBlend,
   float blueBlend,
   boolean_t synchronous
);
```

Parameters

myToken
A reservation token for the fade hardware, acquired by calling `CGAcquireDisplayFadeReservation` (page 1476).

seconds
The desired number of seconds for the fade operation. You should use a value in the interval `[0, kCGMaxDisplayReservationInterval]`. If the value is 0, the ending blend color is applied immediately.

startBlend
An intensity value in the interval [0, 1] that specifies the alpha component of the desired blend color at the beginning of the fade operation. See "Display Fade Blend Fractions" (page 1556).

endBlend
An intensity value in the interval [0, 1] that specifies the alpha component of the desired blend color at the end of the fade operation. See "Display Fade Blend Fractions" (page 1556).

redBlend
An intensity value in the interval [0, 1] that specifies the red component of the desired blend color.

greenBlend
An intensity value in the interval [0, 1] that specifies the green component of the desired blend color.

blueBlend
An intensity value in the interval [0, 1] that specifies the blue component of the desired blend color.

synchronous

Pass `true` if you want the fade operation to be synchronous; otherwise, pass `false`. If a fade operation is synchronous, the function does not return until the operation is complete.

Return Value
A result code. See "Quartz Display Services Result Codes" (page 1564).

Discussion
Over the fade operation time interval, Quartz interpolates a blending coefficient between the starting and ending values given, applying a nonlinear (sine-based) bias term. Using this coefficient, the video output is blended with the specified color.

The following example shows how to perform a two-second synchronous fade-out to black:

```
CGDisplayFade (
    myToken,
    2.0,                        // 2 seconds
    kCGDisplayBlendNormal,      // starting state
    kCGDisplayBlendSolidColor,  // ending state
    0.0, 0.0, 0.0,              // black
    true                        // wait for completion
);
```

To perform a two-second asynchronous fade-in from black:

```
CGDisplayFade (
    myToken,
    2.0,                        // 2 seconds
    kCGDisplayBlendSolidColor,  // starting state
    kCGDisplayBlendNormal,      // ending state
    0.0, 0.0, 0.0,              // black
    false                       // don't wait for completion
);
```

If you specify an asynchronous fade operation, it's safe to call `CGReleaseDisplayFadeReservation` (page 1530) immediately after this function returns.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`CGDisplayFade.h`

CGDisplayFadeOperationInProgress

Returns a Boolean value indicating whether a fade operation is currently in progress.

```
boolean_t CGDisplayFadeOperationInProgress (
   void
);
```

Return Value
If `true`, a fade operation is currently in progress; otherwise, `false`.

Discussion
You may call this function from any task running on the system. The calling task need not have a valid fade reservation.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`CGDisplayFade.h`

CGDisplayGammaTableCapacity

Returns the capacity, or number of entries, in the gamma table for a display.

```
CGTableCount CGDisplayGammaTableCapacity (
   CGDirectDisplayID display
);
```

Availability
Available in Mac OS X v10.3 and later.

Declared In
`CGDirectDisplay.h`

CGDisplayGetDrawingContext

Returns a graphics context suitable for drawing to a captured display.

```
CGContextRef CGDisplayGetDrawingContext (
   CGDirectDisplayID display
);
```

Parameters
display
The display to access.

Return Value
A Quartz graphics context suitable for drawing to a captured display, or `NULL` if the display has not been captured. The context is owned by the system and you should not release it.

Discussion
After capturing a display or changing the configuration of a captured display, you can use this function to obtain the current graphics context for the display. The graphics context remains valid while the display is captured and the display configuration is unchanged. Releasing the captured display or reconfiguring the display invalidates the context. To determine when the display configuration is changing, you can use the function `CGDisplayRegisterReconfigurationCallback` (page 1507) to register a display reconfiguration callback.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`CGDirectDisplay.h`

CGDisplayHideCursor

Hides the mouse cursor, and increments the hide cursor count.

```
CGDisplayErr CGDisplayHideCursor (
   CGDirectDisplayID display
);
```

Parameters

display

This parameter is not used. By default, you may pass `kCGDirectMainDisplay`.

Return Value

A result code. See "Quartz Display Services Result Codes" (page 1564).

Discussion

This function hides the cursor regardless of its current location; the `display` parameter is ignored. In most cases, the caller must be the foreground application to affect the cursor.

Availability

Available in Mac OS X v10.0 and later.

See Also

`CGDisplayShowCursor` (page 1512)

Declared In

`CGDirectDisplay.h`

CGDisplayIDToOpenGLDisplayMask

Maps a display ID to an OpenGL display mask.

```
CGOpenGLDisplayMask CGDisplayIDToOpenGLDisplayMask (
   CGDirectDisplayID display
);
```

Parameters

display

The display ID to be converted.

Return Value

The OpenGL display mask that corresponds to the specified display.

Discussion

OpenGL sometimes identifies a display using a bitmask with one bit set. This function maps a display ID to the corresponding OpenGL display mask.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CGDirectDisplay.h`

CGDisplayIOServicePort

Returns the I/O Kit service port of the specified display.

```
io_service_t CGDisplayIOServicePort (
   CGDirectDisplayID display
);
```

Parameters

display

The display to access.

Return Value

The I/O Kit service port for the specified display.

Discussion

An I/O Kit service port can be passed to I/O Kit to obtain additional information about the display.

The port is owned by the graphics system, and should not be destroyed.

Availability

Available in Mac OS X v10.2 and later.

Declared In

`CGDisplayConfiguration.h`

CGDisplayIsActive

Returns a Boolean value indicating whether a display is active.

```
boolean_t CGDisplayIsActive (
   CGDirectDisplayID display
);
```

Parameters

display

The display to access.

Return Value

If `true`, the specified display is active; otherwise, `false`.

Discussion

An active display is connected, awake, and available for drawing. In a hardware mirroring set, only the primary display is active.

Availability

Available in Mac OS X v10.2 and later.

Declared In

`CGDisplayConfiguration.h`

CGDisplayIsAlwaysInMirrorSet

Returns a Boolean value indicating whether a display is always in a mirroring set.

```
boolean_t CGDisplayIsAlwaysInMirrorSet (
   CGDirectDisplayID display
);
```

Parameters

display

The display to access.

Return Value

If `true`, the specified display is in a mirroring set and cannot be removed from this set.

Discussion

Some hardware configurations support the connection of auxiliary displays that always mirror the main display, and therefore cannot be removed from the mirroring set to which they belong.

Availability

Available in Mac OS X v10.2 and later.

Declared In

`CGDisplayConfiguration.h`

CGDisplayIsAsleep

Returns a Boolean value indicating whether a display is sleeping (and is therefore not drawable.)

```
boolean_t CGDisplayIsAsleep (
   CGDirectDisplayID display
);
```

Parameters

display

The display to access.

Return Value

If `true`, the specified display is in sleep mode; otherwise, `false`.

Discussion

A display is sleeping when its frame buffer and the attached monitor are in reduced power mode. A sleeping display is still considered to be a part of global display (desktop) space, but it is not drawable.

Availability

Available in Mac OS X v10.2 and later.

Declared In

`CGDisplayConfiguration.h`

CGDisplayIsBuiltin

Returns a Boolean value indicating whether a display is built-in, such as the internal display in portable systems.

```
boolean_t CGDisplayIsBuiltin (
   CGDirectDisplayID display
);
```

Parameters

display

The display to access.

Return Value

If `true`, the specified display is considered to be a built-in display; otherwise, `false`.

Discussion

Portable systems typically identify the internal LCD panel as a built-in display.

Note that it is possible and reasonable for a system to have no displays marked as built-in. For example, a portable system running with the lid closed may report no built-in displays.

Availability

Available in Mac OS X v10.2 and later.

Declared In

`CGDisplayConfiguration.h`

CGDisplayIsCaptured

Returns a Boolean value indicating whether a display is captured.

```
boolean_t CGDisplayIsCaptured (
   CGDirectDisplayID display
);
```

Parameters

display

The display to access.

Return Value

If `true`, the specified display is captured; otherwise, `false`.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CGDirectDisplay.h`

CGDisplayIsInHWMirrorSet

Returns a Boolean value indicating whether a display is in a hardware mirroring set.

```
boolean_t CGDisplayIsInHWMirrorSet (
   CGDirectDisplayID display
);
```

Parameters

display

The display to access.

Return Value
If `true`, the specified display is a member of a hardware mirroring set; otherwise, `false`.

Discussion
When hardware mirroring is enabled, the contents of a single frame buffer are rendered in all displays in the hardware mirroring set. All drawing operations are directed to the primary display in the set—see `CGDisplayPrimaryDisplay` (page 1506).

For more information about display mirroring, see `CGConfigureDisplayMirrorOfDisplay` (page 1481).

Availability
Available in Mac OS X v10.2 and later.

Declared In
`CGDisplayConfiguration.h`

CGDisplayIsInMirrorSet

Returns a Boolean value indicating whether a display is in a mirroring set.

```
boolean_t CGDisplayIsInMirrorSet (
   CGDirectDisplayID display
);
```

Parameters

display
The display to access.

Return Value
If `true`, the specified display is a member of a software or hardware mirroring set; otherwise, `false`.

Discussion
For more information about display mirroring, see `CGConfigureDisplayMirrorOfDisplay` (page 1481).

Availability
Available in Mac OS X v10.2 and later.

Declared In
`CGDisplayConfiguration.h`

CGDisplayIsMain

Returns a Boolean value indicating whether a display is the main display.

```
boolean_t CGDisplayIsMain (
   CGDirectDisplayID display
);
```

Parameters

display
The display to access.

Return Value
If `true`, the specified display is currently the main display; otherwise, `false`.

Discussion
For information about the characteristics of a main display, see `CGMainDisplayID` (page 1522).

Availability
Available in Mac OS X v10.2 and later.

Declared In
`CGDisplayConfiguration.h`

CGDisplayIsOnline

Returns a Boolean value indicating whether a display is connected or online.

```
boolean_t CGDisplayIsOnline (
   CGDirectDisplayID display
);
```

Parameters

display
The display to access.

Return Value
If `true`, the specified display is connected; otherwise, `false`.

Discussion
A display is considered connected or online when the frame buffer hardware is connected to a monitor.

You can use this function to determine if someone has hot-plugged a display to the system. Note that hot-plugging is a hardware feature that may not be present on all displays.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`CGDisplayConfiguration.h`

CGDisplayIsStereo

Returns a Boolean value indicating whether a display is running in a stereo graphics mode.

```
boolean_t CGDisplayIsStereo (
   CGDirectDisplayID display
);
```

Parameters

display
The display to access.

Return Value
If `true`, the specified display is running in a stereo graphics mode; otherwise, `false`.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGDisplayConfiguration.h`

CGDisplayMirrorsDisplay

For a secondary display in a mirroring set, returns the primary display.

```
CGDirectDisplayID CGDisplayMirrorsDisplay (
   CGDirectDisplayID display
);
```

Parameters

display
A secondary display in a mirroring set.

Return Value
Returns the primary display in the mirroring set. Returns `kCGNullDirectDisplay` if the specified display is actually the primary display or is not in a mirroring set.

Discussion
For more information about display mirroring, see `CGConfigureDisplayMirrorOfDisplay` (page 1481).

Availability
Available in Mac OS X v10.2 and later.

Declared In
`CGDisplayConfiguration.h`

CGDisplayModelNumber

Returns the model number of a display monitor.

```
uint32_t CGDisplayModelNumber (
   CGDirectDisplayID display
);
```

Parameters

display
The display to access.

Return Value
A model number for the monitor associated with the specified display, or a constant to indicate an exception—see the discussion below.

Discussion
This function uses I/O Kit to identify the monitor associated with the specified display. The return value depends on the following:

- If I/O Kit can identify the monitor, the product ID code for the monitor is returned.
- If I/O Kit can't identify the monitor, `kDisplayProductIDGeneric` is returned.
- If no monitor is connected, a value of `0xFFFFFFFF` is returned.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`CGDisplayConfiguration.h`

CGDisplayMoveCursorToPoint

Moves the mouse cursor to a specified point relative to the display origin (the upper left corner of the display).

```
CGDisplayErr CGDisplayMoveCursorToPoint (
   CGDirectDisplayID display,
   CGPoint point
);
```

Parameters

display
The display to access.

point
The coordinates of a point in local display space. The origin is the upper left corner of the specified display.

Return Value
A result code. See "Quartz Display Services Result Codes" (page 1564).

Discussion
No events are generated as a result of this move. Points that would lie outside the desktop are clipped to the desktop.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGDirectDisplay.h`

CGDisplayPixelsHigh

Returns the display height in pixel units.

```
size_t CGDisplayPixelsHigh (
   CGDirectDisplayID display
);
```

Parameters

display
The display to access.

Return Value
The display height in pixel units.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGDirectDisplay.h`

CGDisplayPixelsWide

Returns the display width in pixel units.

```
size_t CGDisplayPixelsWide (
   CGDirectDisplayID display
);
```

Parameters

display
The display to access.

Return Value
The display width in pixel units.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGDirectDisplay.h`

CGDisplayPrimaryDisplay

Returns the primary display in a hardware mirroring set.

```
CGDirectDisplayID CGDisplayPrimaryDisplay (
   CGDirectDisplayID display
);
```

Parameters

display
A display in a hardware mirror set.

Return Value
The primary display in the mirror set. If `display` is not hardware-mirrored, this function simply returns `display`.

Discussion
In hardware mirroring, the contents of a single frame buffer are rendered in two or more displays simultaneously. The mirrored displays are said to be in a *hardware mirroring set*.

At the discretion of the device driver, one of the displays in a hardware mirroring set is designated as the *primary* display. The device driver binds the drawing engine, hardware accelerator, and 3D engine to the primary display, and directs all drawing operations to this display.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`CGDisplayConfiguration.h`

CGDisplayRegisterReconfigurationCallback

Registers a callback function to be invoked whenever a local display is reconfigured.

```
CGError CGDisplayRegisterReconfigurationCallback (
   CGDisplayReconfigurationCallBack proc,
   void *userInfo
);
```

Parameters

proc

A pointer to the callback function to be registered.

userInfo

A pointer to user-defined data, or `NULL`. The `userInfo` argument is passed back to the callback function each time it's invoked.

Discussion

Whenever local displays are reconfigured, the callback function you register is invoked twice for each display that's added, removed, or currently online—once before the reconfiguration, and once after the reconfiguration. For more information, see the callback type `CGDisplayReconfigurationCallBack` (page 1540).

A callback function may be registered multiple times with different user-defined data pointers, resulting in multiple registration entries. For each registration, when notification is no longer needed you should remove the registration by calling the function `CGDisplayRemoveReconfigurationCallback` (page 1508).

Availability

Available in Mac OS X v10.3 and later.

Declared In

`CGDisplayConfiguration.h`

CGDisplayRelease

Releases a captured display.

```
CGDisplayErr CGDisplayRelease (
   CGDirectDisplayID display
);
```

Parameters

display

The display to release.

Return Value

A result code. See "Quartz Display Services Result Codes" (page 1564).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CGDirectDisplay.h`

CGDisplayRemoveReconfigurationCallback

Removes the registration of a callback function that's invoked whenever a local display is reconfigured.

```
CGError CGDisplayRemoveReconfigurationCallback (
   CGDisplayReconfigurationCallBack proc,
   void *userInfo
);
```

Parameters

proc

A pointer to the callback function associated with the registration to be removed.

userInfo

A pointer to user-defined data associated with the registration to be removed, or `NULL`. This is the same pointer that's passed to the function `CGDisplayRegisterReconfigurationCallback` (page 1507) when registering the callback.

Discussion

When you call this function, the two arguments must match the registered entry to be removed.

Availability

Available in Mac OS X v10.3 and later.

Declared In

`CGDisplayConfiguration.h`

CGDisplayRestoreColorSyncSettings

Restores the gamma tables to the values in the user's ColorSync display profile.

```
void CGDisplayRestoreColorSyncSettings (
   void
);
```

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CGDirectDisplay.h`

CGDisplayRotation

Returns the rotation angle of a display in degrees.

```
double CGDisplayRotation (
    CGDirectDisplayID display
);
```

Parameters

display

The display to access.

Return Value

The rotation angle of the display in degrees, or 0 if the display is not valid.

Discussion
This function returns the rotation angle of a display in a clockwise direction. For example, if the specified display is rotated clockwise 90 degrees then this function returns 90.0. After a 90 degree clockwise rotation, the physical bottom of the display is on the left side and the physical top is on the right side.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`CGDisplayConfiguration.h`

CGDisplaySamplesPerPixel

Returns the number of color components used to represent a pixel.

```
size_t CGDisplaySamplesPerPixel (
   CGDirectDisplayID display
);
```

Parameters

display
The display to access.

Return Value
The number of color components used to represent a pixel.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGDirectDisplay.h`

CGDisplayScreenSize

Returns the width and height of a display in millimeters.

```
CGSize CGDisplayScreenSize (
   CGDirectDisplayID display
);
```

Parameters

display
The display to access.

Return Value
The size of the specified display in millimeters, or 0 if the display is not valid.

Discussion
If Extended Display Identification Data (EDID) for the display device is not available, the size is estimated based on the device width and height in pixels from `CGDisplayBounds` (page 1491), with an assumed resolution of 2.835 pixels/mm or 72 DPI, a reasonable guess for displays predating EDID support.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`CGDisplayConfiguration.h`

CGDisplaySerialNumber

Returns the serial number of a display monitor.

```
uint32_t CGDisplaySerialNumber (
   CGDirectDisplayID display
);
```

Parameters

display
The display to access.

Return Value
A serial number for the monitor associated with the specified display, or a constant to indicate an exception—see the discussion below.

Discussion
This function uses I/O Kit to identify the monitor associated with the specified display.

If I/O Kit can identify the monitor:

- If the manufacturer has encoded a serial number for the monitor, the number is returned.
- If there is no encoded serial number, `0x00000000` is returned.

If I/O Kit cannot identify the monitor:

- If a monitor is connected to the display, `0x00000000` is returned.
- If no monitor is connected to the display hardware, a value of `0xFFFFFFFF` is returned.

Note that a serial number is meaningful only in conjunction with a specific vendor and product or model.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`CGDisplayConfiguration.h`

CGDisplaySetPalette

Sets the palette for a display.

```
CGDisplayErr CGDisplaySetPalette (
   CGDirectDisplayID display,
   const CGDirectPaletteRef palette
);
```

Parameters

display
The display to access.

palette
The display palette to set.

Return Value
A result code. See "Quartz Display Services Result Codes" (page 1564).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGDirectDisplay.h`

CGDisplaySetStereoOperation

Immediately enables or disables stereo operation for a display.

```
CGError CGDisplaySetStereoOperation (
   CGDirectDisplayID display,
   boolean_t stereo,
   boolean_t forceBlueLine,
   CGConfigureOption option
);
```

Parameters

display
The display being configured.

stereo
Pass `true` if you want to enable stereo operation. To disable it, pass `false`.

forceBlueLine
When in stereo operation, a display may need to generate a special stereo sync signal as part of the video output. The sync signal consists of a blue line which occupies the first 25% of the last scanline for the left eye view, and the first 75% of the last scanline for the right eye view. The remainder of the scanline is black. To force the display to generate this sync signal, pass `true`; otherwise pass `false`.

option
A constant that specifies the scope of the display configuration changes. For more information, see "Display Configuration Scopes" (page 1555).

Return Value
A result code. See "Quartz Display Services Result Codes" (page 1564).

Discussion
The system normally detects the presence of a stereo window and automatically switches a display containing a stereo window to stereo operation. This function provides a mechanism to force a display to stereo operation immediately, and to set options (blue line sync signal) when in stereo operation.

On success, the display resolution, mirroring mode, and available display modes may change due to hardware-specific capabilities and limitations. You should check these settings to verify that they are appropriate for your application.

Availability
Available in Mac OS X v10.4 and later.

Declared In
CGDisplayConfiguration.h

CGDisplayShowCursor

Decrements the hide cursor count, and shows the mouse cursor if the count is zero.

```
CGDisplayErr CGDisplayShowCursor (
   CGDirectDisplayID display
);
```

Parameters

display
This parameter is not used. By default, you may pass kCGDirectMainDisplay.

Return Value
A result code. See "Quartz Display Services Result Codes" (page 1564).

Discussion
If the hide cursor count is zero, this function shows the cursor regardless of its current location; the display parameter is ignored. In most cases, the caller must be the foreground application to affect the cursor.

Availability
Available in Mac OS X v10.0 and later.

See Also
CGDisplayHideCursor (page 1497)

Declared In
CGDirectDisplay.h

CGDisplaySwitchToMode

Switches a display to a different mode.

```
CGDisplayErr CGDisplaySwitchToMode (
   CGDirectDisplayID display,
   CFDictionaryRef mode
);
```

Parameters

display
The display to access.

mode
A display mode dictionary that contains information about the display mode to set. The dictionary passed in must be a dictionary returned by another Quartz display function such as CGDisplayAvailableModes (page 1486) or CGDisplayBestModeForParameters (page 1488). For a list of the properties in a display mode dictionary, see "Display Mode Standard Properties" (page 1557) and "Display Mode Optional Properties" (page 1558). For general information about using dictionaries, see *CFDictionary Reference*.

Return Value
A result code. See "Quartz Display Services Result Codes" (page 1564).

Discussion
This function switches the display mode of the specified display. The operation is always synchronous; the function does not return until the mode switch is complete. Note that after switching, display parameters and addresses may change.

The selected display mode persists for the life of the calling program. When the program terminates, the display mode automatically reverts to the permanent setting in the Displays panel of System Preferences.

When changing the display mode of a display in a mirroring set, other displays in the mirroring set will be assigned a mode that's capable of mirroring the bounds of the display being adjusted. To avoid this automatic behavior, you can use the following procedure: call `CGBeginDisplayConfiguration`, call `CGConfigureDisplayMode` for each display to explicitly set the mode, and finally call `CGCompleteDisplayConfiguration`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGDirectDisplay.h`

CGDisplayUnitNumber

Returns the logical unit number of a display.

```
uint32_t CGDisplayUnitNumber (
   CGDirectDisplayID display
);
```

Parameters

display
The display to access.

Return Value
A logical unit number for the specified display.

Discussion
The logical unit number represents a particular node in the I/O Kit device tree associated with the display's frame buffer. For a particular hardware configuration, this value will not change when the attached monitor is changed.

The unit number will change if the I/O Kit device tree changes, as when hardware is reconfigured, drivers are replaced, or significant changes occur to I/O Kit, so it should not be assumed to be invariant across login sessions.

For more information about I/O Kit, see the Apple publication *"I/O Kit Fundamentals"*.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`CGDisplayConfiguration.h`

CGDisplayUsesOpenGLAcceleration

Returns a Boolean value indicating whether Quartz is using OpenGL-based window acceleration (Quartz Extreme) to render in a display.

```
boolean_t CGDisplayUsesOpenGLAcceleration (
   CGDirectDisplayID display
);
```

Parameters

display

The display to access.

Return Value

If `true`, Quartz Extreme is used to render in the specified display; otherwise, `false`.

Discussion

Quartz Extreme is an OpenGL-based, hardware-accelerated window compositor available in Mac OS X version 10.2 and later. Quartz Extreme requires a minimum hardware configuration to operate.

The information this function provides is typically used to adjust the demands of drawing operations to the capabilities of the display hardware. For example, an application running on an unaccelerated system could disable live window-resizing.

Availability

Available in Mac OS X v10.2 and later.

Declared In

`CGDisplayConfiguration.h`

CGDisplayVendorNumber

Returns the vendor number of the specified display's monitor.

```
uint32_t CGDisplayVendorNumber (
   CGDirectDisplayID display
);
```

Parameters

display

The display to access.

Return Value

A vendor number for the monitor associated with the specified display, or a constant to indicate an exception—see the discussion below.

Discussion

This function uses I/O Kit to identify the monitor associated with the specified display.

There are three cases:

- If I/O Kit can identify the monitor, the vendor ID is returned.
- If I/O Kit cannot identify the monitor, `kDisplayVendorIDUnknown` is returned.
- If there is no monitor associated with the display, `0xFFFFFFFF` is returned.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`CGDisplayConfiguration.h`

CGDisplayWaitForBeamPositionOutsideLines

Waits until the beam position moves outside a region in a display screen. This function is not designed for VBL drawing synchronization.

```
CGDisplayErr CGDisplayWaitForBeamPositionOutsideLines (
   CGDirectDisplayID display,
   CGBeamPosition upperScanLine,
   CGBeamPosition lowerScanLine
);
```

Parameters

display
The display to access.

upperScanLine
The upper scan line number.

lowerScanLine
The lower scan line number.

Return Value
A result code. See "Quartz Display Services Result Codes" (page 1564).

Discussion
This function waits until the beam position is outside the range specified by the arguments `upperScanLine` and `lowerScanLine`. If the value of `upperScanLine` is greater than the value of `lowerScanLine`, or if `upperScanLine` and `lowerScanLine` encompass the entire display height, this function returns an error.

Some displays may not use conventional video vertical and horizontal sweep in painting. These displays report a `kCGDisplayRefreshRate` of 0 in the dictionary returned by `CGDisplayCurrentMode` (page 1494). Also, some display device drivers may not implement support for this mechanism. On such displays, this function returns at once.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGDirectDisplay.h`

CGGetActiveDisplayList

Provides a list of displays that are active (or drawable).

```
CGDisplayErr CGGetActiveDisplayList (
   CGDisplayCount maxDisplays,
   CGDirectDisplayID *activeDspys,
   CGDisplayCount *dspyCnt
);
```

Parameters

maxDisplays

The size of the `activeDspys` array. This value determines the maximum number of displays that can be returned.

activeDspys

A pointer to storage provided by the caller for an array of display IDs. On return, the array contains a list of active displays. If you pass `NULL`, on return the display count contains the total number of active displays.

dspyCnt

A pointer to a display count variable provided by the caller. On return, the display count contains the actual number of displays returned in the `activeDspys` array. This value is at most `maxDisplays`.

Return Value
A result code. See "Quartz Display Services Result Codes" (page 1564).

Discussion
The first entry in the list of active displays is the main display. In case of mirroring, the first entry is the largest drawable display or, if all are the same size, the display with the greatest pixel depth.

Note that when hardware mirroring is being used between displays, only the primary display is active and appears in the list. When software mirroring is being used, all the mirrored displays are active and appear in the list. For more information about mirroring, see `CGConfigureDisplayMirrorOfDisplay` (page 1481).

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
QTCarbonShell

Declared In
`CGDirectDisplay.h`

CGGetDisplaysWithOpenGLDisplayMask

Provides a list of displays that corresponds to the bits set in an OpenGL display mask.

```
CGDisplayErr CGGetDisplaysWithOpenGLDisplayMask (
   CGOpenGLDisplayMask mask,
   CGDisplayCount maxDisplays,
   CGDirectDisplayID *dspys,
   CGDisplayCount *dspyCnt
);
```

Parameters

mask

An OpenGL display mask that identifies one or more displays.

maxDisplays

The size of the `dspys` array. This value determines the maximum number of displays that can be returned.

dspys

A pointer to storage provided by the caller for an array of display IDs. On return, the array contains a list of displays that corresponds to the bits set in the mask. If you pass `NULL`, on return the display count contains the total number of displays specified in the mask.

dspyCnt

A pointer to a display count variable provided by the caller. On return, the display count contains the actual number of displays returned in the `dspys` array. This value is at most `maxDisplays`.

Return Value
A result code. See "Quartz Display Services Result Codes" (page 1564).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGDirectDisplay.h`

CGGetDisplaysWithPoint

Provides a list of online displays with bounds that include the specified point.

```
CGDisplayErr CGGetDisplaysWithPoint (
   CGPoint point,
   CGDisplayCount maxDisplays,
   CGDirectDisplayID *dspys,
   CGDisplayCount *dspyCnt
);
```

Parameters

point

The coordinates of a point in global display space. The origin is the upper left corner of the main display.

maxDisplays

The size of the `dspys` array. This value determines the maximum number of displays that can be returned.

dspys

A pointer to storage provided by the caller for an array of display IDs. On return, the array contains a list of displays with bounds that include the point. If you pass `NULL`, on return the display count contains the total number of displays with bounds that include the point.

dspyCnt

A pointer to a display count variable provided by the caller. On return, the display count contains the actual number of displays returned in the `dspys` array. This value is at most `maxDisplays`.

Return Value
A result code. See "Quartz Display Services Result Codes" (page 1564).

Availability
Available in Mac OS X v10.0 and later.

Declared In
CGDirectDisplay.h

CGGetDisplaysWithRect

Gets a list of online displays with bounds that intersect the specified rectangle.

```
CGDisplayErr CGGetDisplaysWithRect (
   CGRect rect,
   CGDisplayCount maxDisplays,
   CGDirectDisplayID *dspys,
   CGDisplayCount *dspyCnt
);
```

Parameters

rect

The location and size of a rectangle in global display space. The origin is the upper left corner of the main display.

maxDisplays

The size of the *dspys* array. This value determines the maximum number of displays that can be returned in the *dspys* parameter. Generally, you should specify a number greater than 0 for this parameter. If you specify 0, the value returned in *dspyCnt* is undefined and this function sets the *dspys* parameter to NULL.

dspys

A pointer to storage provided by the caller for an array of display IDs. On return, the array contains a list of displays whose bounds intersect the specified rectangle.

dspyCnt

A pointer to a display count variable provided by the caller. On return, this variable contains the number of displays that were returned in the *dspys* parameter. You must provide a non-NULL value for this parameter.

Return Value
A result code. See "Quartz Display Services Result Codes" (page 1564).

Availability
Available in Mac OS X v10.0 and later.

Declared In
CGDirectDisplay.h

CGGetDisplayTransferByFormula

Gets the coefficients of the gamma transfer formula for a display.

```
CGDisplayErr CGGetDisplayTransferByFormula (
   CGDirectDisplayID display,
   CGGammaValue *redMin,
   CGGammaValue *redMax,
   CGGammaValue *redGamma,
   CGGammaValue *greenMin,
   CGGammaValue *greenMax,
   CGGammaValue *greenGamma,
   CGGammaValue *blueMin,
   CGGammaValue *blueMax,
   CGGammaValue *blueGamma
);
```

Parameters

display
The display to access.

redMin
The minimum value of the red channel in the gamma table. The value is a number in the interval [0, redMax).

redMax
The maximum value of the red channel in the gamma table. The value is a number in the interval (redMin, 1].

redGamma
A positive value used to compute the red channel in the gamma table.

greenMin
The minimum value of the green channel in the gamma table. The value is a number in the interval [0, greenMax).

greenMax
The maximum value of the green channel in the gamma table. The value is a number in the interval (greenMin, 1].

greenGamma
A positive value used to compute the green channel in the gamma table.

blueMin
The minimum value of the blue channel in the gamma table. The value is a number in the interval [0, blueMax).

blueMax
The maximum value of the blue channel in the gamma table. The value is a number in the interval (blueMin, 1].

blueGamma
A positive value used to compute the blue channel in the gamma table.

Return Value
A result code. See "Quartz Display Services Result Codes" (page 1564).

Discussion
For information about the gamma transfer formula, see the description of the function `CGSetDisplayTransferByFormula` (page 1533).

Availability
Available in Mac OS X v10.0 and later.

Declared In
CGDirectDisplay.h

CGGetDisplayTransferByTable

Gets the values in the RGB gamma tables for a display.

```
CGDisplayErr CGGetDisplayTransferByTable (
   CGDirectDisplayID display,
   CGTableCount capacity,
   CGGammaValue *redTable,
   CGGammaValue *greenTable,
   CGGammaValue *blueTable,
   CGTableCount *sampleCount
);
```

Parameters

display
The display to access.

capacity
The number of entries each table can hold.

redTable
A pointer to an array of type `CGGammaValue` with size `capacity`. On return, the array contains the values of the red channel in the display's gamma table.

greenTable
A pointer to an array of type `CGGammaValue` with size `capacity`. On return, the array contains the values of the green channel in the display's gamma table.

blueTable
A pointer to an array of type `CGGammaValue` with size `capacity`. On return, the array contains the values of the blue channel in the display's gamma table.

sampleCount
The number of samples actually copied into each array.

Return Value
A result code. See "Quartz Display Services Result Codes" (page 1564).

Availability
Available in Mac OS X v10.0 and later.

Declared In
CGDirectDisplay.h

CGGetLastMouseDelta

Reports the change in mouse position since the last mouse movement event received by the application.

```
void CGGetLastMouseDelta (
   CGMouseDelta *deltaX,
   CGMouseDelta *deltaY
);
```

Parameters

deltaX

A pointer to a `CGMouseDelta` variable. On return, this variable contains the horizontal change in the mouse position since the last mouse movement event.

deltaY

A pointer to a `CGMouseDelta` variable. On return, this variable contains the vertical change in the mouse position since the last mouse movement event.

Discussion

This function is not recommended for general use. Instead, you should use the mouse tracking functions in the Carbon Event Manager.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CGDirectDisplay.h`

CGGetOnlineDisplayList

Provides a list of displays that are online (active, mirrored, or sleeping).

```
CGDisplayErr CGGetOnlineDisplayList (
   CGDisplayCount maxDisplays,
   CGDirectDisplayID *onlineDspys,
   CGDisplayCount *dspyCnt
);
```

Parameters

maxDisplays

The size of the `onlineDspys` array. This value determines the maximum number of display IDs that can be returned.

onlineDspys

A pointer to storage provided by the caller for an array of display IDs. On return, the array contains a list of the online displays. If you pass `NULL`, on return the display count contains the total number of online displays.

dspyCnt

A pointer to a display count variable provided by the caller. On return, the display count contains the actual number of displays returned in the `onlineDspys` array. This value is at most `maxDisplays`.

Return Value

A result code. See "Quartz Display Services Result Codes" (page 1564).

Discussion

If the frame buffer hardware is connected, a display is considered connected or online.

When hardware mirroring is used, a display can be online but not active or drawable. Programs which manipulate display settings such as the palette or gamma tables need access to all displays, including hardware mirrors which are not drawable.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`CGDirectDisplay.h`

CGMainDisplayID

Returns the display ID of the main display.

```
CGDirectDisplayID CGMainDisplayID (
   void
);
```

Return Value
The display ID assigned to the main display.

Discussion
The main display is the display with its screen location at (0,0) in global coordinates. In a system without display mirroring, the display with the menu bar is typically the main display.

If mirroring is enabled and the menu bar appears on more than one display, this function provides a reliable way to find the main display.

In case of hardware mirroring, the drawable display becomes the main display. In case of software mirroring, the display with the highest resolution and deepest pixel depth typically becomes the main display.

Availability
Available in Mac OS X v10.2 and later.

Related Sample Code
LiveVideoMixer2

Declared In
`CGDirectDisplay.h`

CGOpenGLDisplayMaskToDisplayID

Maps an OpenGL display mask to a display ID.

```
CGDirectDisplayID CGOpenGLDisplayMaskToDisplayID (
   CGOpenGLDisplayMask mask
);
```

Parameters

mask
The OpenGL display mask to be converted.

Return Value
The display ID assigned to the specified display mask, or `kCGNullDirectDisplay` if no display matches the mask.

Discussion
OpenGL sometimes identifies a display using a bitmask with one bit set. This function maps such a display mask to the corresponding display ID. If you pass in a mask with multiple bits set, this function returns a display ID matching one of these bits.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`CGDirectDisplay.h`

CGPaletteCreateCopy

Returns a copy of a specified display palette.

```
CGDirectPaletteRef CGPaletteCreateCopy (
   CGDirectPaletteRef palette
);
```

Parameters

palette
The display palette to copy.

Return Value
A new display palette object. When you no longer need the palette, you should release it using the function `CGPaletteRelease` (page 1528).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGDirectPalette.h`

CGPaletteCreateDefaultColorPalette

Returns a new display palette representing the default 8-bit color palette.

```
CGDirectPaletteRef CGPaletteCreateDefaultColorPalette (
   void
);
```

Return Value
A new display palette object. When you no longer need the palette, you should release it using the function `CGPaletteRelease` (page 1528).

Discussion
Palettes are used with 256 color display modes. The default palette is the old default 8-bit Mac OS palette, with white at index 0 and black at index 255.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGDirectPalette.h`

CGPaletteCreateFromPaletteBlendedWithColor

Returns a new tinted display palette. The new palette is derived from an existing palette blended with a solid color, at a specified level of intensity.

```
CGDirectPaletteRef CGPaletteCreateFromPaletteBlendedWithColor (
   CGDirectPaletteRef palette,
   CGPaletteBlendFraction fraction,
   CGDeviceColor color
);
```

Parameters

palette

The palette to blend.

fraction

A value between 0 and 1 that represents the blend intensity. See `CGPaletteBlendFraction` (page 1551).

color

The blend color. See `CGDeviceColor` (page 1545).

Return Value

A new display palette object. When you no longer need the palette, you should release it using the function `CGPaletteRelease` (page 1528).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CGDirectPalette.h`

CGPaletteCreateWithByteSamples

Returns a new display palette using 8-bit sample data.

```
CGDirectPaletteRef CGPaletteCreateWithByteSamples (
   CGDeviceByteColor *sampleTable,
   CGTableCount sampleCount
);
```

Parameters

sampleTable

A color table with integer values that represent the intensity of the red,green, and blue components in each table entry. Each value ranges from 0 (no color) to 255 (full intensity). See `CGDeviceByteColor` (page 1544).

sampleCount

The number of entries in the specified color table.

Return Value

A new display palette object. When you no longer need the palette, you should release it using the function `CGPaletteRelease` (page 1528).

Availability

Available in Mac OS X v10.0 and later.

Declared In
CGDirectPalette.h

CGPaletteCreateWithCapacity

Returns a new display palette with a specified capacity. The new palette is initialized from the default color palette.

```
CGDirectPaletteRef CGPaletteCreateWithCapacity (
   CGTableCount capacity
);
```

Parameters

capacity
The number of entries in the new palette.

Return Value
A new display palette object. When you no longer need the palette, you should release it using the function CGPaletteRelease (page 1528).

Availability
Available in Mac OS X v10.0 and later.

Declared In
CGDirectPalette.h

CGPaletteCreateWithDisplay

Returns a copy of the current palette for a display.

```
CGDirectPaletteRef CGPaletteCreateWithDisplay (
   CGDirectDisplayID display
);
```

Parameters

display
The display to access.

Return Value
A new display palette object, or NULL if the current display mode does not support a palette. When you no longer need the palette, you should release it using the function CGPaletteRelease (page 1528).

Availability
Available in Mac OS X v10.0 and later.

Declared In
CGDirectPalette.h

CGPaletteCreateWithSamples

Returns a new display palette using RGB sample data.

```
CGDirectPaletteRef CGPaletteCreateWithSamples (
   CGDeviceColor *sampleTable,
   CGTableCount sampleCount
);
```

Parameters

sampleTable

A color table with floating point values that represent the intensity of the red,green, and blue components in each table entry. Each value ranges from 0 (no color) to 1 (full intensity). See `CGDeviceColor` (page 1545).

sampleCount

The number of entries in the specified color table.

Return Value

A new display palette object. When you no longer need the palette, you should release it using the function `CGPaletteRelease` (page 1528).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CGDirectPalette.h`

CGPaletteGetColorAtIndex

Returns the color value at the specified index.

```
CGDeviceColor CGPaletteGetColorAtIndex (
   CGDirectPaletteRef palette,
   CGTableCount index
);
```

Parameters

palette

The display palette to access.

index

The zero-based index of the desired palette entry.

Return Value

A color value. See `CGDeviceColor` (page 1545).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CGDirectPalette.h`

CGPaletteGetIndexForColor

Returns the index of the display palette entry that most closely matches a specified color value.

```
CGTableCount CGPaletteGetIndexForColor (
   CGDirectPaletteRef palette,
   CGDeviceColor color
);
```

Parameters

palette

The display palette to access.

color

The color value to match. See `CGDeviceColor` (page 1545).

Return Value

The index of the display palette entry that most closely matches the specified color value.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CGDirectPalette.h`

CGPaletteGetNumberOfSamples

Returns the number of colors in a display palette.

```
CGTableCount CGPaletteGetNumberOfSamples (
   CGDirectPaletteRef palette
);
```

Parameters

palette

The display palette to access.

Return Value

The number of colors in the specified display palette.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CGDirectPalette.h`

CGPaletteIsEqualToPalette

Returns a Boolean value indicating whether two display palettes are equal.

```
Boolean CGPaletteIsEqualToPalette (
   CGDirectPaletteRef palette1,
   CGDirectPaletteRef palette2
);
```

Parameters

palette1

The first display palette to compare.

palette2
The second display palette to compare.

Return Value
If `true`, the two specified display palettes are equal; otherwise, `false`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGDirectPalette.h`

CGPaletteRelease

Decrements the retain count of a display palette.

```
void CGPaletteRelease (
   CGDirectPaletteRef palette
);
```

Parameters

palette
The display palette to release.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGDirectPalette.h`

CGPaletteSetColorAtIndex

Updates the color value at the specified index in a display palette.

```
void CGPaletteSetColorAtIndex (
   CGDirectPaletteRef palette,
   CGDeviceColor color,
   CGTableCount index
);
```

Parameters

palette
The display palette to access.

color
The new color value.

index
The index of the palette entry to update.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGDirectPalette.h`

CGRegisterScreenRefreshCallback

Registers a callback function to be invoked when local displays are refreshed or modified.

```
CGError CGRegisterScreenRefreshCallback (
   CGScreenRefreshCallback function,
   void *userParameter
);
```

Parameters

function

A pointer to the callback function to be registered.

userParameter

A pointer to user-defined data, or `NULL`. The `userParameter` argument is passed back to the callback function each time it's invoked.

Return Value

A result code. See "Quartz Display Services Result Codes" (page 1564).

Discussion

A callback function may be registered multiple times with different user-defined data pointers, resulting in multiple registration entries. For each registration, when notification is no longer needed you should call the function `CGUnregisterScreenRefreshCallback` (page 1536) to remove the registration.

The callback function you register is invoked only if your application has an active event loop. The callback is invoked in the same thread of execution that is processing events within your application.

Special Considerations

In Mac OS X v10.4 and earlier, the result code returned by this function is a random value and should be ignored. In Mac OS X v10.5 and later, the result code is valid.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CGRemoteOperation.h`

CGReleaseAllDisplays

Releases all captured displays.

```
CGDisplayErr CGReleaseAllDisplays (
   void
);
```

Return Value

A result code. See "Quartz Display Services Result Codes" (page 1564).

Discussion

This function releases all captured displays and restores the display modes to the user's preferences. It may be used in conjunction with any of the functions that capture displays, such as `CGCaptureAllDisplays` (page 1478).

Availability

Available in Mac OS X v10.0 and later.

Declared In
CGDirectDisplay.h

CGReleaseDisplayFadeReservation

Releases a display fade reservation, and unfades the display if needed.

```
CGError CGReleaseDisplayFadeReservation (
   CGDisplayFadeReservationToken myToken
);
```

Parameters

myToken

The current fade reservation token to be released. On return, the reservation token is no longer valid and should be discarded.

Return Value
A result code. See "Quartz Display Services Result Codes" (page 1564).

Discussion
If you call this function while an asynchronous fade operation is running, there are two possible outcomes:

- If the ending blend value is `kCGDisplayBlendNormal`, the fade operation is allowed to run to completion.
- If the ending blend value is not `kCGDisplayBlendNormal`, the fade operation is terminated immediately and the display is returned to normal.

In both cases, the reservation is actually released when the fade operation completes.

Availability
Available in Mac OS X v10.2 and later.

Declared In
CGDisplayFade.h

CGReleaseScreenRefreshRects

Deallocates a list of rectangles that represent changed areas on local displays.

```
void CGReleaseScreenRefreshRects (
   CGRect *rectArray
);
```

Parameters

rectArray

A list of rectangles obtained by calling `CGWaitForScreenRefreshRects` (page 1537) or `CGWaitForScreenUpdateRects` (page 1538).

Availability
Available in Mac OS X v10.0 and later.

Declared In
CGRemoteOperation.h

CGRestorePermanentDisplayConfiguration

Restores the permanent display configuration settings for the current user.

```
void CGRestorePermanentDisplayConfiguration (
   void
);
```

Discussion
This function provides a convenient way to restore the permanent display configuration.

Applications that temporarily change the display configuration—such as applications and games that switch to full-screen display mode—can use this function to undo the changes.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`CGDisplayConfiguration.h`

CGScreenRegisterMoveCallback

Registers a callback function to be invoked when an area of the display is moved.

```
CGError CGScreenRegisterMoveCallback (
   CGScreenUpdateMoveCallback function,
   void *userParameter
);
```

Parameters

function
A pointer to the callback function to be registered.

userParameter
A pointer to user-defined data, or `NULL`. The `userParameter` argument is passed back to the callback function each time it's invoked.

Return Value
A result code. See "Quartz Display Services Result Codes" (page 1564).

Discussion
A callback function may be registered multiple times with different user-defined data pointers, resulting in multiple registration entries. For each registration, when notification is no longer needed you should remove the registration by calling the function `CGScreenUnregisterMoveCallback` (page 1532).

The callback function you register is invoked only if your application has an active event loop. The callback is invoked in the same thread of execution that is processing events within your application.

Special Considerations

This function is implemented in Mac OS X version 10.4.3 and later.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`CGRemoteOperation.h`

CGScreenUnregisterMoveCallback

Removes a previously registered callback function invoked when an area of the display is moved.

```
void CGScreenUnregisterMoveCallback (
   CGScreenUpdateMoveCallback function,
   void *userParameter
);
```

Parameters

function

A pointer to the callback function to be unregistered.

userParameter

A pointer to user-defined data, or `NULL`. You should pass the same value you used when you registered the callback function.

Return Value

A result code. See "Quartz Display Services Result Codes" (page 1564).

Discussion

When you call this function, the two arguments must match the registered entry to be removed.

Availability

Available in Mac OS X v10.3 and later.

Declared In

`CGRemoteOperation.h`

CGSessionCopyCurrentDictionary

Returns information about the caller's window server session.

```
CFDictionaryRef CGSessionCopyCurrentDictionary (
   void
);
```

Return Value

A window server session dictionary, or `NULL` if the caller is not running within a Quartz GUI session or the window server is disabled. You should release the dictionary when you are finished using it. For information about the key-value pairs in this dictionary, see "Window Server Session Properties" (page 1563).

Availability

Available in Mac OS X v10.3 and later.

Declared In

`CGSession.h`

CGSetDisplayTransferByByteTable

Sets the byte values in the 8-bit RGB gamma tables for a display.

```
CGDisplayErr CGSetDisplayTransferByByteTable (
   CGDirectDisplayID display,
   CGTableCount tableSize,
   const CGByteValue *redTable,
   const CGByteValue *greenTable,
   const CGByteValue *blueTable
);
```

Parameters

display

The display to access.

tableSize

The number of entries in each table.

redTable

An array of size `tableSize` containing the byte values of the red channel in the display's gamma table.

greenTable

An array of size `tableSize` containing the byte values of the green channel in the display's gamma table.

blueTable

An array of size `tableSize` containing the byte values of the blue channel in the display's gamma table.

Return Value

A result code. See "Quartz Display Services Result Codes" (page 1564).

Discussion

The same table may be passed in for the red, green, and blue channels. The tables are interpolated as needed to generate the number of samples required by the graphics hardware.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CGDirectDisplay.h`

CGSetDisplayTransferByFormula

Sets the gamma function for a display, by specifying the coefficients of the gamma transfer formula.

```
CGDisplayErr CGSetDisplayTransferByFormula (
   CGDirectDisplayID display,
   CGGammaValue redMin,
   CGGammaValue redMax,
   CGGammaValue redGamma,
   CGGammaValue greenMin,
   CGGammaValue greenMax,
   CGGammaValue greenGamma,
   CGGammaValue blueMin,
   CGGammaValue blueMax,
   CGGammaValue blueGamma
);
```

Parameters

display

The display to access.

redMin

The minimum value of the red channel in the gamma table. The value should be a number in the interval [0, redMax).

redMax

The maximum value of the red channel in the gamma table. The value should be a number in the interval (redMin, 1].

redGamma

A positive value used to compute the red channel in the gamma table.

greenMin

The minimum value of the green channel in the gamma table. The value should be a number in the interval [0, greenMax).

greenMax

The maximum value of the green channel in the gamma table. The value should be a number in the interval (greenMin, 1].

greenGamma

A positive value used to compute the green channel in the gamma table.

blueMin

The minimum value of the blue channel in the gamma table. The value should be a number in the interval [0, blueMax).

blueMax

The maximum value of the blue channel in the gamma table. The value should be a number in the interval (blueMin, 1].

blueGamma

A positive value used to compute the blue channel in the gamma table.

Return Value

A result code. See "Quartz Display Services Result Codes" (page 1564).

Discussion

This function uses the specified parameter values to compute a gamma correction table for the specified display. The values in the table are computed by sampling the following gamma transfer formula for a range of indices from 0 to 1:

```
value = Min + ((Max - Min) * pow(index, Gamma))
```

The resulting values are converted to a machine-specific format and loaded into display hardware.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGDirectDisplay.h`

CGSetDisplayTransferByTable

Sets the color gamma function for a display, by specifying the values in the RGB gamma tables.

```
CGDisplayErr CGSetDisplayTransferByTable (
   CGDirectDisplayID display,
   CGTableCount tableSize,
   const CGGammaValue *redTable,
   const CGGammaValue *greenTable,
   const CGGammaValue *blueTable
);
```

Parameters

display
The display to access.

tableSize
The number of entries in each table.

redTable
An array of size `tableSize` containing the values of the red channel in the display's gamma table. The values should be in the range 0.0 to 1.0.

greenTable
An array of size `tableSize` containing the values of the green channel in the display's gamma table. The values should be in the range 0.0 to 1.0.

blueTable
An array of size `tableSize` containing the values of the blue channel in the display's gamma table. The values should be in the range 0.0 to 1.0.

Return Value
A result code. See "Quartz Display Services Result Codes" (page 1564).

Discussion
The same table may be passed in for the red, green, and blue channels. The tables are interpolated as needed to generate the number of samples required by the graphics hardware.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGDirectDisplay.h`

CGShieldingWindowID

Returns the window ID of the shield window for a captured display.

```
uint32_t CGShieldingWindowID (
   CGDirectDisplayID display
);
```

Parameters

display

The display to access.

Return Value

The window ID of the shield window for the specified display, or `NULL` if the display is not shielded.

Discussion

To prevent updates by direct-to-screen programs (such as Classic), Quartz draws a shield window that fills the entire screen of a captured display.

This function is not recommended for use in applications. Note that the graphics context associated with this window is not a full-featured drawing context. To get a full-featured drawing context for a captured display, you should use the function `CGDisplayGetDrawingContext` (page 1497).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CGDirectDisplay.h`

CGShieldingWindowLevel

Returns the window level of the shield window for a captured display.

```
int32_t CGShieldingWindowLevel (
   void
);
```

Return Value

The window level of the shield window for a captured display.

Discussion

This function returns a value that is sometimes used to position a window over the shield window for a captured display. Attempting to position a window over a captured display may be unsuccessful—or may present undesirable results such as illegible or invisible content—because of interactions between full-screen graphics (such as OpenGL full-screen drawing contexts) and the graphics hardware. Because of these limitations, and because the implementation of display capture may change in the future, this technique is not recommended.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CGDirectDisplay.h`

CGUnregisterScreenRefreshCallback

Removes a previously registered callback function invoked when local displays are refreshed or modified.

```
void CGUnregisterScreenRefreshCallback (
   CGScreenRefreshCallback function,
   void *userParameter
);
```

Parameters

function

A pointer to the callback function to be unregistered.

userParameter

A pointer to user-defined data, or `NULL`. You should pass the same value you used when you registered the callback function.

Discussion

When you call this function, the two arguments must match the registered entry to be removed.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CGRemoteOperation.h`

CGWaitForScreenRefreshRects

Waits for screen refresh operations.

```
CGError CGWaitForScreenRefreshRects (
   CGRect **pRectArray,
   CGRectCount *pCount
);
```

Parameters

pRectArray

A pointer to a `CGRect*` variable. On return, the variable contains an array of rectangles that bound the refreshed areas, specified in global coordinates. When you no longer need the array, you should deallocate it by calling `CGReleaseScreenRefreshRects` (page 1530).

pCount

A pointer to a `CGRectCount` variable. On return, the variable contains the number of entries in the returned array of rectangles.

Return Value

A result code. See "Quartz Display Services Result Codes" (page 1564).

Discussion

In some applications it may be preferable to wait for screen refresh data synchronously, using this function. You should call this function in a thread other than the main event-processing thread.

As an alternative, Quartz also supports asynchronous notification—see `CGRegisterScreenRefreshCallback` (page 1529). If refresh callback functions are registered, this function should not be used.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CGRemoteOperation.h`

CGWaitForScreenUpdateRects

Waits for screen update operations.

```
CGError CGWaitForScreenUpdateRects (
   CGScreenUpdateOperation requestedOperations,
   CGScreenUpdateOperation *currentOperation,
   CGRect **pRectArray,
   size_t *pCount,
   CGScreenUpdateMoveDelta *pDelta
);
```

Parameters

requestedOperations

The desired types of screen update operations. There are several possible choices:

- Specify `kCGScreenUpdateOperationRefresh` if you want all move operations to be returned as refresh operations.
- Specify `(kCGScreenUpdateOperationRefresh | kCGScreenUpdateOperationMove)` if you want to distinguish between move and refresh operations.
- Add `kCGScreenUpdateOperationReducedDirtyRectangleCount` to the screen operations if you want to minimize the number of rectangles returned to represent changed areas of the display.

currentOperation

A pointer to a `CGScreenUpdateOperation` variable. On return, the variable indicates the type of update operation (refresh or move).

pRectArray

A pointer to a `CGRect*` variable. On return, the variable contains an array of rectangles that bound the updated areas, specified in global coordinates. When you no longer need the array, you should deallocate it by calling `CGReleaseScreenRefreshRects` (page 1530).

pCount

A pointer to a `size_t` variable. On return, the variable contains the number of entries in the returned array of rectangles.

pDelta

A pointer to a `CGScreenUpdateMoveDelta` variable. On return, if the value of the `currentOperation` parameter is `kCGScreenUpdateOperationMove` the variable contains the distance moved.

Return Value

A result code. See "Quartz Display Services Result Codes" (page 1564).

Discussion

In some applications it may be preferable to wait for screen update data synchronously, using this function. You should call this function in a thread other than the main event-processing thread.

As an alternative, Quartz also supports asynchronous notification—see `CGRegisterScreenRefreshCallback` (page 1529) and `CGScreenRegisterMoveCallback` (page 1531). If refresh or move callback functions are registered, this function should not be used.

Special Considerations

This function is implemented in Mac OS X version 10.4.3 and later.

Availability

Available in Mac OS X v10.3 and later.

Declared In
CGRemoteOperation.h

CGWarpMouseCursorPosition

Moves the mouse cursor without generating events.

```
CGError CGWarpMouseCursorPosition (
   CGPoint newCursorPosition
);
```

Parameters

newCursorPosition
The new mouse cursor position in global display coordinates.

Return Value
A result code. See "Quartz Display Services Result Codes" (page 1564).

Discussion
You can use this function to 'warp' or alter the cursor position without generating or posting an event. For example, this function is often used to move the cursor position back to the center of the screen by games that do not want the cursor pinned by display edges.

Availability
Available in Mac OS X v10.0 and later.

Declared In
CGRemoteOperation.h

CGWindowLevelForKey

Returns the window level that corresponds to one of the standard window types.

```
CGWindowLevel CGWindowLevelForKey (
   CGWindowLevelKey key
);
```

Parameters

key
A window level key constant that represents one of the standard window types. See "Window Level Keys" (page 1560).

Return Value
The window level that corresponds to the specified key.

Discussion
This function is not recommended for use in applications. (This function is provided for application frameworks that create and manage windows, such as Carbon and Cocoa.)

Availability
Available in Mac OS X v10.0 and later.

Declared In
CGWindowLevel.h

CGWindowServerCFMachPort

Returns a Core Foundation mach port (CFMachPort) that corresponds to the Mac OS X window server.

```
CFMachPortRef CGWindowServerCFMachPort (
   void
);
```

Return Value
A Core Foundation mach port, or `NULL` if the window server is not running. When you no longer need the port, you should release it using the function `CFRelease`.

Discussion
You can use this function to detect if the window server process exits or is not running. If this function returns `NULL`, the window server is not running. This code example shows how to register a callback function to detect when the window server exits:

```
static void handleWindowServerDeath( CFMachPortRef port, void *info  )
{
    printf( "Window Server port death detected!\n" );
    CFRelease(port);
    exit(1);
}

static void watchForWindowServerDeath()
{
    CFMachPortRef port = CGWindowServerCFMachPort();
    CFMachPortSetInvalidationCallBack(port, handleWindowServerDeath);
}
```

Note that this callback will not work unless your program has an active run loop.

Availability
Available in Mac OS X v10.1 and later.

Declared In
`CGRemoteOperation.h`

Callbacks

CGDisplayReconfigurationCallBack

A client-supplied callback function that's invoked whenever the configuration of a local display is changed.

```
typedef void (*CGDisplayReconfigurationCallBack) (
   CGDirectDisplayID display,
   CGDisplayChangeSummaryFlags flags,
   void *userInfo
);
```

If you name your function `MyDisplayReconfigurationCallBack`, you would declare it like this:

```
void MyDisplayReconfigurationCallBack (
   CGDirectDisplayID display,
```

```
    CGDisplayChangeSummaryFlags flags,
    void *userInfo
);
```

Parameters

display

The display being reconfigured.

flags

Flags that indicate which display configuration parameters are changing.

userInfo

The `userInfo` argument passed to the function `CGDisplayRegisterReconfigurationCallback` (page 1507) when the callback function is registered.

Discussion

To register a display reconfiguration callback function, you call the function `CGDisplayRegisterReconfigurationCallback` (page 1507). Quartz invokes your callback function when:

- Your application calls a function to reconfigure a local display.
- Your application is listening for events in the event-processing thread, and another application calls a function to reconfigure a local display.
- The user changes the display hardware configuration—for example, by disconnecting a display or changing a system preferences setting.

Before display reconfiguration, Quartz invokes your callback function once for each online display to indicate a pending configuration change. The `flags` argument is always set to `kCGDisplayBeginConfigurationFlag`. Other than the display ID, this callback does not carry other per-display information, as details of how a reconfiguration affects a particular device rely on device-specific behaviors which may not be exposed by a device driver.

After display reconfiguration, Quartz invokes your callback function once for each added, removed, and online display. At this time, all display state reported by Core Graphics, QuickDraw, and the Carbon Display Manager will be up to date. This callback runs after the Carbon Display Manager notification callbacks. The `flags` argument indicates how the display configuration has changed. Note that in the case of removed displays, calls into Quartz with the removed display ID will fail.

The following code example illustrates how to test for specific conditions:

```
void MyDisplayReconfigurationCallBack (
    CGDirectDisplayID display,
    CGDisplayChangeSummaryFlags flags,
    void *userInfo)
{
     if (flags & kCGDisplayAddFlag) {
         // display has been added
     }
     else if (flags & kCGDisplayRemoveFlag) {
         // display has been removed
     }
}
```

Your callback function should avoid attempting to change display configurations, and should not raise exceptions or perform a non-local return such as calling `longjmp`. When you are finished using a callback registration, you should call the function `CGDisplayRemoveReconfigurationCallback` (page 1508) to remove it.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`CGDisplayConfiguration.h`

CGScreenRefreshCallback

A client-supplied callback function that's invoked when an area of the display is modified or refreshed.

```
typedef void (*CGScreenRefreshCallback) (
   CGRectCount count,
   const CGRect * rectArray,
   void * userParameter
);
```

If you name your function `MyScreenRefreshCallback`, you would declare it like this:

```
void MyScreenRefreshCallback (
   CGRectCount count,
   const CGRect * rectArray,
   void * userParameter
);
```

Parameters

count
The number of rectangles in the `rectArray` parameter.

rectArray
A list of the rectangles in the refreshed areas, specified in global coordinates. You should not modify or deallocate memory pointed to by `rectArray`.

userParameter
The user data you specify when you register this callback.

Discussion
To register a screen refresh callback function, you call the function `CGRegisterScreenRefreshCallback` (page 1529). Quartz invokes your callback function when operations such as drawing, window movement, scrolling, or display reconfiguration occur on local displays. When you are finished using a callback registration, you should call the function `CGUnregisterScreenRefreshCallback` (page 1536) to remove it.

Note that a single rectangle may occupy multiple displays, either by overlapping the displays or by residing on coincident displays when mirroring is active. You can use the function `CGGetDisplaysWithRect` (page 1518) to determine the displays a rectangle occupies.

Availability
Available in Mac OS X v10.0 and later.

Declared In
CGRemoteOperation.h

CGScreenUpdateMoveCallback

A client-supplied callback function that's invoked when an area of the display is moved.

```
typedef void (*CGScreenUpdateMoveCallback) (
   CGScreenUpdateMoveDelta delta,
   CGRectCount count,
   const CGRect * rectArray,
   void * userParameter
);
```

If you name your function `MyScreenUpdateMoveCallback`, you would declare it like this:

```
void MyScreenUpdateMoveCallback (
   CGScreenUpdateMoveDelta delta,
   CGRectCount count,
   const CGRect * rectArray,
   void * userParameter
);
```

Parameters

delta
The distance the display area has moved.

count
The number of rectangles in the `rectArray` parameter.

rectArray
A list of the rectangles in the moved areas, specified in global coordinates. The rectangles describe the area prior to the move operation. You should not modify or deallocate memory pointed to by `rectArray`.

userParameter
The user data you specify when you register this callback.

Discussion
To register a screen move callback function, you call the function `CGScreenRegisterMoveCallback` (page 1531). Quartz invokes your callback function when operations such as window movement or scrolling occur on local displays. When you are finished using a callback registration, you should call the function `CGScreenUnregisterMoveCallback` (page 1532) to remove it.

Note that a single rectangle may occupy multiple displays, either by overlapping the displays or by residing on coincident displays when mirroring is active. You can use the function `CGGetDisplaysWithRect` (page 1518) to determine the displays a rectangle occupies.

Availability
Available in Mac OS X v10.3 and later.

Declared In
CGRemoteOperation.h

Data Types

CGBeamPosition

Represents a horizontal scan line on a monitor that uses a scanning electron beam to refresh the screen.

```
typedef uint32_t CGBeamPosition;
```

Discussion
CRT and analog-driven displays use a horizontal scanning beam to refresh the screen. The beam position is a number assigned to a horizontal scan line on the screen. Scan lines are numbered `0` to `n-1` from top of screen, where `n` represents the total number of scan lines.

The concept of beam position does not apply to flat-panel LCD displays. While all displays have some concept of scan lines with respect to the frame buffer, LCD displays may not use linear scanning to refresh the screen.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGDirectDisplay.h`

CGByteValue

Represents a unit of information in a byte-addressable array or data structure.

```
typedef uint8_t CGByteValue;
```

Discussion
Quartz uses `CGByteValue` to represent integer-based color values in a display palette or a gamma table. For example, see `CGDeviceByteColor` (page 1544).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGDirectDisplay.h`

CGDeviceByteColor

Represents a color in a Quartz display palette, using 8-bit integer components.

```
struct CGDeviceByteColor {
    CGByteValue red;
    CGByteValue green;
    CGByteValue blue;
};
typedef struct CGDeviceByteColor CGDeviceByteColor;
```

Fields
`red`
The red component of a palette entry.

`green`
The green component of a palette entry.

`blue`
The blue component of a palette entry.

Discussion
This data structure consists of three integer values that represent the intensity of the red,green, and blue components in a display palette entry. Each component ranges from 0 (no color) to 255 (full intensity).

Quartz provides `CGDeviceByteColor` to allow you to create a display palette using integer-based sample data. Once loaded, you can retrieve color data from the palette only as entries of type `CGDeviceColor` (page 1545).

For more information about display palettes, see `CGDirectPaletteRef` (page 1546).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGDirectPalette.h`

CGDeviceColor

Represents a color in a Quartz display palette.

```
struct CGDeviceColor {
    float red;
    float green;
    float blue;
};
typedef struct CGDeviceColor CGDeviceColor;
```

Fields
`red`
The red component of a palette entry.

`green`
The green component of a palette entry.

`blue`
The blue component of a palette entry.

Discussion
This data structure consists of three floating point values that represent the intensity of the red,green, and blue components in a display palette entry. Each component ranges from 0 (no color) to 1 (full intensity). Values outside this range are clamped to 0 or 1 when the palette is created.

Quartz uses `CGDeviceColor` as the canonical form for a color entry in a display palette. Palette entries can be created and retrieved in this form.

For more information about display palettes, see `CGDirectPaletteRef` (page 1546).

Availability
Available in Mac OS X v10.0 and later.

Declared In
CGDirectPalette.h

CGDirectDisplayID

Represents a unique identifier for an attached display.

```
typedef uint32_t CGDirectDisplayID;
```

Discussion
In Quartz, the term *display* refers to a graphics hardware system consisting of a framebuffer, a color correction (gamma) table or color palette, and possibly an attached monitor. If no monitor is attached, a display is characterized as offline.

When a monitor is attached, Quartz assigns a unique display identifier (ID). A display ID can persist across processes and system reboot, and typically remains constant as long as certain display parameters do not change.

When assigning a display ID, Quartz considers the following parameters:

- vendor
- model
- serial number
- position in the I/O Kit registry

For information about how to obtain a display ID, see "Finding Displays" (page 1470).

Availability
Available in Mac OS X v10.0 and later.

Declared In
CGDirectDisplay.h

CGDirectPaletteRef

Defines a reference to a Quartz 8-bit display palette.

```
typedef struct _CGDirectPaletteRef * CGDirectPaletteRef;
```

Discussion
A display palette is a bounded set of color values available for display. Some display operating modes have a maximum color depth of 8 bits (256 colors). The CGDirectPalette API is designed for application and game developers that want to create and use display palettes for these older displays.

Quartz uses reference counting to manage display palettes. See "Working With Color Palettes" (page 1474) for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
CGDirectDisplay.h

CGDisplayBlendFraction

Represents the percentage of blend color used in a fade operation.

```
typedef float CGDisplayBlendFraction;
```

Discussion
The blend fraction ranges from 0 (no color) to 1 (full intensity). If you specify 0, the blend color is not applied. If you specify 1, the user sees only the blend color on the screen.

In a fade operation, Quartz blends a color specified by the application with the current contents of the frame buffer. The blend color can be applied both at the beginning and the end of a fade operation.

Color blending during a fade operation is analogous to alpha blending in Quartz 2D, and the visual appearance is similar. However, the implementation is quite different. In a fade operation, the blend color is applied at the very end of the graphics pipeline, as the frame buffer is transferred to video output.

For example, the Universal Access preference panel in Mac OS X allows you to select a flashing screen effect (sometimes called a visual bell) to accompany the system alert sound. When you select this option, the system uses a Quartz fade operation to produce the flash. The blend color is applied using a blend fraction of 0.5 or 50%.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`CGDisplayFade.h`

CGDisplayConfigRef

Defines a reference to a display configuration transaction.

```
typedef struct _CGDisplayConfigRef * CGDisplayConfigRef;
```

Discussion
This data type makes it possible to

- create a new display configuration transaction using the function `CGBeginDisplayConfiguration` (page 1477)
- record a set of configuration changes, each bound to one or more displays
- apply the changes in a single transaction using the function `CGCompleteDisplayConfiguration` (page 1479), or discard the changes using the function `CGCancelDisplayConfiguration` (page 1478)

There are no restrictions on the order in which you accumulate configuration changes in a transaction.

Configuration changes sometimes conflict with each other. For example, a new origin might be rendered invalid by a subsequent configuration change.

If possible, Quartz uses a “best fit” strategy to resolve conflicts between configuration changes. For example, when you change the resolution of a single display in a two-display system, Quartz automatically re-tiles the displays to prevent separation or overlap of the adjoining edges.

Availability
Available in Mac OS X v10.2 and later.

Declared In
CGDisplayConfiguration.h

CGDisplayCoord

Represents a coordinate position in global display space.

```
typedef int32_t CGDisplayCoord;
```

Discussion
Quartz uses `CGDisplayCoord` to represent the x- and y-coordinates of points in the per-display coordinate system. The origin is defined as the upper-left corner of the screen.

This data type is also used in functions that need to find the address of a specific pixel and monitor. For example, the function `CGDisplayAddressForPosition` (page 1485) finds the address in frame buffer memory that corresponds to a given position or point.

Availability
Available in Mac OS X v10.0 and later.

Declared In
CGDirectDisplay.h

CGDisplayCount

Represents the number of displays in various lists.

```
typedef uint32_t CGDisplayCount;
```

Discussion
Quartz uses `CGDisplayCount` to represent a count of either the current or the maximum number of displays in a display list. For example, see the function `CGGetActiveDisplayList` (page 1515).

Availability
Available in Mac OS X v10.0 and later.

Declared In
CGDirectDisplay.h

CGDisplayErr

Defines a uniform type for result codes returned by functions in Quartz Display Services.

```
typedef CGError CGDisplayErr;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
CGDirectDisplay.h

CGDisplayFadeInterval

Represents the duration in seconds of a fade operation or a fade hardware reservation.

```
typedef float CGDisplayFadeInterval;
```

Discussion
Quartz uses this data type to specify the duration of both fade-out and fade-in operations. Values may range from zero to `kCGMaxDisplayReservationInterval` seconds. A zero value means fade immediately—see `CGDisplayFade` (page 1495).

Availability
Available in Mac OS X v10.2 and later.

Declared In
`CGDisplayFade.h`

CGDisplayFadeReservationToken

Defines a token issued by Quartz when reserving one or more displays for a fade operation during a specified interval.

```
typedef uint32_t CGDisplayFadeReservationToken;
```

Discussion
Quartz lets you reserve the display hardware to perform a fade operation. Fade reservations are valid for up to 15 seconds. Only one token is needed for both fade-out and fade-in.

You should release a fade reservation immediately when you no longer need it. If the reservation expires, releasing it is safe but not necessary.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`CGDisplayFade.h`

CGDisplayReservationInterval

Represents the time interval for a fade reservation.

```
typedef float CGDisplayReservationInterval;
```

Discussion
A fade reservation interval is a period of time during which a specific display is reserved for a fade operation. Fade reservation intervals range from 1 to `kCGMaxDisplayReservationInterval` seconds.

For more information about fade reservations, see the function `CGAcquireDisplayFadeReservation` (page 1476). Fade reservation tokens are discussed in `CGDisplayFadeReservationToken` (page 1549).

Availability
Available in Mac OS X v10.2 and later.

Declared In
`CGDisplayFade.h`

CGError

Defines a uniform type for result codes returned by functions in Quartz Services.

```
typedef int32_t CGError;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGError.h`

CGGammaValue

Represents information used to map a color generated in software to a color supported by the display hardware.

```
typedef float CGGammaValue;
```

Discussion
In Mac OS X, the Display panel in System Preferences is used to set the default gamma for a display. Quartz also allows an application to provide its own custom gamma information, using functions such as `CGSetDisplayTransferByTable` (page 1535) and `CGSetDisplayTransferByFormula` (page 1533).

These functions take `CGGammaValue` arguments that specify

- a set of gamma table entries ranging from 0 to 1
- the positive real coefficients in a gamma equation

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGDirectDisplay.h`

CGMouseDelta

Represents a change in mouse position, in mouse units.

```
typedef int32_t CGMouseDelta;
```

Discussion
A mouse unit is a hardware-specific unit of measure, and generally has higher resolution than pixel units.

Note that the function `CGGetLastMouseDelta` (page 1520) is no longer recommended—instead, you should use mouse tracking functions in the Carbon Event Manager.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGDirectDisplay.h`

CGOpenGLDisplayMask

Defines a bitmask used in OpenGL to specify a set of attached displays.

```
typedef uint32_t CGOpenGLDisplayMask;
```

Discussion
In Mac OS X, OpenGL can provide information about the capabilities of the hardware renderers driving a specified set of displays. A 32-bit mask is used to specify the displays—each bit in the mask represents a single display.

To learn how to find the mask bit that corresponds to a given display, see the function `CGDisplayIDToOpenGLDisplayMask` (page 1498).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGDirectDisplay.h`

CGPaletteBlendFraction

Represents the intensity of a solid color used to tint a display palette.

```
typedef float CGPaletteBlendFraction;
```

Discussion
A palette blend-fraction value can range from 0 (no color) to 1 (full intensity). At full intensity, the palette is completely washed out by the color.

For more information, see the function `CGPaletteCreateFromPaletteBlendedWithColor` (page 1524).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGDirectPalette.h`

CGRectCount

Represents the size of an array of Quartz rectangles.

```
typedef uint32_t CGRectCount;
```

Discussion
For example, see the function `CGWaitForScreenRefreshRects` (page 1537).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGRemoteOperation.h`

CGRefreshRate

Represents a display's refresh rate in frames per second.

```
typedef double CGRefreshRate;
```

Discussion
When requesting a new display mode, you can specify a desired refresh rate as a hint to Quartz. For example, see the function `CGDisplayBestModeForParametersAndRefreshRate` (page 1488).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGDirectDisplay.h`

CGScreenUpdateMoveDelta

Represents the distance a region on the screen moves in pixel units.

```
struct _CGScreenUpdateMoveDelta {
      int32_t dX, dY;
};
typedef struct _CGScreenUpdateMoveDelta CGScreenUpdateMoveDelta;
```

Discussion
Move operation notifications are restricted to changes that move a region by an integer number of pixels. The fields `dX` and `dY` describe the direction of movement:

- Positive values of `dX` indicate movement to the right.
- Negative values of `dX` indicate movement to the left.
- Positive values of `dY` indicate movement downward.
- Negative values of `dY` indicate movement upward.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`CGRemoteOperation.h`

CGTableCount

Defines a uniform type to represent the number of entries in a table.

```
typedef uint32_t CGTableCount;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGDirectDisplay.h`

CGWindowLevel

Represents a level assigned to a window by an application framework.

```
typedef int32_t CGWindowLevel;
```

Discussion
In Mac OS X, application frameworks support the concept of multiple window levels (or layers). Window levels are assigned and managed by each individual framework.

Note that in an Aqua-compliant application, each document window exists in its own layer. As a result, windows created by different applications can be interleaved.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGWindowLevel.h`

Constants

Display Capture Options

Specify configuration parameters when capturing displays.

```
enum {
    kCGCaptureNoOptions = 0,
    kCGCaptureNoFill = (1 << 0)
};
typedef uint32_t CGCaptureOptions;
```

Constants

`kCGCaptureNoOptions`
Specifies that the system should use the default fill behavior, which is fill with black.
Available in Mac OS X v10.3 and later.
Declared in `CGDirectDisplay.h`.

`kCGCaptureNoFill`
Disables fill with black.
Available in Mac OS X v10.3 and later.
Declared in `CGDirectDisplay.h`.

Discussion
For information about how these constants are used, see the functions `CGDisplayCaptureWithOptions` (page 1493) and `CGCaptureAllDisplaysWithOptions` (page 1479).

Display Configuration Change Flags

Specify the configuration parameters passed to a display reconfiguration callback function.

```
enum {
    kCGDisplayBeginConfigurationFlag = (1 << 0),
    kCGDisplayMovedFlag              = (1 << 1),
    kCGDisplaySetMainFlag            = (1 << 2),
    kCGDisplaySetModeFlag            = (1 << 3),
    kCGDisplayAddFlag                = (1 << 4),
    kCGDisplayRemoveFlag             = (1 << 5),
    kCGDisplayEnabledFlag            = (1 << 8),
    kCGDisplayDisabledFlag           = (1 << 9),
    kCGDisplayMirrorFlag             = (1 << 10),
    kCGDisplayUnMirrorFlag           = (1 << 11),
    kCGDisplayDesktopShapeChangedFlag = (1 << 12)
};
typedef u_int32_t CGDisplayChangeSummaryFlags;
```

Constants

`kCGDisplayBeginConfigurationFlag`
The display configuration is about to change.
Available in Mac OS X v10.3 and later.
Declared in `CGDisplayConfiguration.h`.

`kCGDisplayMovedFlag`
The location of the upper-left corner of the display in global display space has changed.
Available in Mac OS X v10.3 and later.
Declared in `CGDisplayConfiguration.h`.

`kCGDisplaySetMainFlag`
The display is now the main display.
Available in Mac OS X v10.3 and later.
Declared in `CGDisplayConfiguration.h`.

`kCGDisplaySetModeFlag`
The display mode has changed.
Available in Mac OS X v10.3 and later.
Declared in `CGDisplayConfiguration.h`.

`kCGDisplayAddFlag`
The display has been added to the active display list.
Available in Mac OS X v10.3 and later.
Declared in `CGDisplayConfiguration.h`.

`kCGDisplayRemoveFlag`
The display has been removed from the active display list.
Available in Mac OS X v10.3 and later.
Declared in `CGDisplayConfiguration.h`.

`kCGDisplayEnabledFlag`
The display has been enabled.
Available in Mac OS X v10.3 and later.
Declared in `CGDisplayConfiguration.h`.

`kCGDisplayDisabledFlag`
The display has been disabled.

Available in Mac OS X v10.3 and later.

Declared in `CGDisplayConfiguration.h`.

`kCGDisplayMirrorFlag`
The display is now mirroring another display.

Available in Mac OS X v10.3 and later.

Declared in `CGDisplayConfiguration.h`.

`kCGDisplayUnMirrorFlag`
The display is no longer mirroring another display.

Available in Mac OS X v10.3 and later.

Declared in `CGDisplayConfiguration.h`.

`kCGDisplayDesktopShapeChangedFlag`
The shape of the desktop (the union of display areas) has changed.

Available in Mac OS X v10.5 and later.

Declared in `CGDisplayConfiguration.h`.

Discussion
For information about how these constants are used, see the callback `CGDisplayReconfigurationCallBack` (page 1540).

Display Configuration Scopes

Specify the scope of the changes in a display configuration transaction.

```
enum {
    kCGConfigureForAppOnly = 0,
    kCGConfigureForSession = 1,
    kCGConfigurePermanently = 2
};
```

Constants
`kCGConfigureForAppOnly`
Specifies that changes persist for the lifetime of the current application. After the application terminates, the display configuration settings revert to the current login session.

Available in Mac OS X v10.2 and later.

Declared in `CGDisplayConfiguration.h`.

`kCGConfigureForSession`
Specifies that changes persist for the lifetime of the current login session. After the current session terminates, the displays revert to the last saved permanent configuration.

Available in Mac OS X v10.2 and later.

Declared in `CGDisplayConfiguration.h`.

`kCGConfigurePermanently`
Specifies that changes persist in future login sessions by the same user. If the requested changes cannot be supported by the Aqua UI (resolution and pixel depth constraints apply), the settings for the current login session are used instead, and any changes have session scope.

Available in Mac OS X v10.2 and later.

Declared in `CGDisplayConfiguration.h`.

Discussion
For information about how these constants are used, see the function `CGCompleteDisplayConfiguration` (page 1479).

Display Fade Blend Fractions

Specify the lower and upper bounds for blend color fractions during a display fade operation.

```
#define kCGDisplayBlendNormal (0.0)
#define kCGDisplayBlendSolidColor (1.0)
```

Constants
`kCGDisplayBlendNormal`
Specifies that the blend color is not applied at the start or end of a fade operation.

Available in Mac OS X v10.2 and later.

Declared in `CGDisplayFade.h`.

`kCGDisplayBlendSolidColor`
Specifies that the user sees only the blend color at the start or end of a fade operation.

Available in Mac OS X v10.2 and later.

Declared in `CGDisplayFade.h`.

Discussion
For general information about blend fractions, see the data type `CGDisplayBlendFraction` (page 1547). For information about how these constants are used, see the function `CGDisplayFade` (page 1495).

Display Fade Constants

Specifies values relating to fade operations.

```
#define kCGMaxDisplayReservationInterval (15.0)
#define kCGDisplayFadeReservationInvalidToken (0)
```

Constants
`kCGMaxDisplayReservationInterval`
Specifies the maximum number of seconds for fade hardware reservations and display fade operations. For general information about fade intervals, see the data type `CGDisplayFadeInterval` (page 1549).

Available in Mac OS X v10.2 and later.

Declared in `CGDisplayFade.h`.

`kCGDisplayFadeReservationInvalidToken`
Specifies an invalid fade reservation token. For general information about fade reservation tokens, see the data type `CGDisplayFadeReservationToken` (page 1549).

Available in Mac OS X v10.2 and later.

Declared in `CGDisplayFade.h`.

Display ID Defaults

Default values for a display ID.

```
#define kCGDirectMainDisplay (CGMainDisplayID())
#define kCGNullDirectDisplay ((CGDirectDisplayID)0)
```

Constants

`kCGDirectMainDisplay`
Specifies the current main display ID.

Available in Mac OS X v10.0 and later.

Declared in `CGDirectDisplay.h`.

`kCGNullDirectDisplay`
Specifies a value that will never correspond to actual hardware.

Available in Mac OS X v10.2 and later.

Declared in `CGDirectDisplay.h`.

Display Mode Standard Properties

Specify keys for the standard properties in a display mode dictionary.

```
#define kCGDisplayWidth CFSTR("Width")
#define kCGDisplayHeight CFSTR("Height")
#define kCGDisplayMode CFSTR("Mode")
#define kCGDisplayBitsPerPixel CFSTR("BitsPerPixel")
#define kCGDisplayBitsPerSample CFSTR("BitsPerSample")
#define kCGDisplaySamplesPerPixel CFSTR("SamplesPerPixel")
#define kCGDisplayRefreshRate CFSTR("RefreshRate")
#define kCGDisplayModeUsableForDesktopGUICFSTR("UsableForDesktopGUI")
#define kCGDisplayIOFlags CFSTR("IOFlags")
#define kCGDisplayBytesPerRow CFSTR("kCGDisplayBytesPerRow")
```

Constants

`kCGDisplayWidth`
Specifies a CFNumber integer value that represents the width of the display in pixels.

Available in Mac OS X v10.2 and later.

Declared in `CGDirectDisplay.h`.

`kCGDisplayHeight`
Specifies a CFNumber integer value that represents the height of the display in pixels.

Available in Mac OS X v10.2 and later.

Declared in `CGDirectDisplay.h`.

`kCGDisplayMode`
Specifies a CFNumber integer value that represents the I/O Kit display mode number.

Available in Mac OS X v10.2 and later.

Declared in `CGDirectDisplay.h`.

`kCGDisplayBitsPerPixel`
Specifies a CFNumber integer value that represents the number of bits in a pixel.

Available in Mac OS X v10.2 and later.

Declared in `CGDirectDisplay.h`.

`kCGDisplayBitsPerSample`
Specifies a CFNumber integer value that represents the number of bits in an individual sample (for example, a color value in an RGB pixel).

Available in Mac OS X v10.2 and later.

Declared in `CGDirectDisplay.h`.

`kCGDisplaySamplesPerPixel`
Specifies a CFNumber integer value that represents the number of samples in a pixel.

Available in Mac OS X v10.2 and later.

Declared in `CGDirectDisplay.h`.

`kCGDisplayRefreshRate`
Specifies a CFNumber double-precision floating point value that represents the refresh rate of a CRT display. Some displays may not use conventional video vertical and horizontal sweep in painting the screen; these displays report a refresh rate of 0.

Available in Mac OS X v10.2 and later.

Declared in `CGDirectDisplay.h`.

`kCGDisplayModeUsableForDesktopGUI`
Specifies a CFBoolean value that indicates whether the display is suitable for use with the Mac OS X graphical user interface. The criteria include factors such as sufficient width and height and adequate pixel depth.

Available in Mac OS X v10.2 and later.

Declared in `CGDirectDisplay.h`.

`kCGDisplayIOFlags`
Specifies a CFNumber integer value that contains the I/O Kit display mode flags. For more information, see the header file `IOKit/IOGraphicsTypes.h`.

Available in Mac OS X v10.2 and later.

Declared in `CGDirectDisplay.h`.

`kCGDisplayBytesPerRow`
Specifies a CFNumber integer value that represents the number of bytes in a row on the display.

Available in Mac OS X v10.2 and later.

Declared in `CGDirectDisplay.h`.

Discussion
To learn how to use these keys to access the values in a display mode dictionary, see *CFDictionary Reference*.

Display Mode Optional Properties

Specify keys for optional properties in a display mode dictionary.

```
#define kCGDisplayModeIsSafeForHardware CFSTR ("kCGDisplayModeIsSafeForHardware")
#define kCGDisplayModeIsInterlaced CFSTR("kCGDisplayModeIsInterlaced")
#define kCGDisplayModeIsStretched CFSTR("kCGDisplayModeIsStretched")
#define kCGDisplayModeIsTelevisionOutput CFSTR ("kCGDisplayModeIsTelevisionOutput")
```

Constants

`kCGDisplayModeIsSafeForHardware`

Specifies a CFBoolean value indicating that the display mode doesn't need a confirmation dialog to be set.

Available in Mac OS X v10.2 and later.

Declared in `CGDirectDisplay.h`.

`kCGDisplayModeIsInterlaced`

Specifies a CFBoolean value indicating that the I/O Kit interlace mode flag is set.

Available in Mac OS X v10.2 and later.

Declared in `CGDirectDisplay.h`.

`kCGDisplayModeIsStretched`

Specifies a CFBoolean value indicating that the I/O Kit stretched mode flag is set.

Available in Mac OS X v10.2 and later.

Declared in `CGDirectDisplay.h`.

`kCGDisplayModeIsTelevisionOutput`

Specifies a CFBoolean value indicating that the I/O Kit television output mode flag is set.

Available in Mac OS X v10.2 and later.

Declared in `CGDirectDisplay.h`.

Discussion

A given key is present in a display mode dictionary only if the property applies, and is always associated with a value of `kCFBooleanTrue`. Keys not relevant to a particular display mode will not appear in the mode dictionary.

Reserved Window Levels

Specifies window level constants.

```
#define kCGNumReservedWindowLevels      (16)
```

Constants

`kCGNumReservedWindowLevels`

The number of window levels reserved by Apple for internal use. Application frameworks such as Carbon and Cocoa use this constant during compilation

Available in Mac OS X v10.0 and later.

Declared in `CGWindowLevel.h`.

Screen Update Operations

Specify types of screen update operations.

```
enum _CGScreenUpdateOperation {
    kCGScreenUpdateOperationRefresh = 0,
    kCGScreenUpdateOperationMove = (1 << 0),
    kCGScreenUpdateOperationReducedDirtyRectangleCount = (1 <<  31)
};
typedef uint32_t CGScreenUpdateOperation;
```

Constants

`kCGScreenUpdateOperationRefresh`
Specifies a screen refresh operation.
Available in Mac OS X v10.3 and later.
Declared in `CGRemoteOperation.h`.

`kCGScreenUpdateOperationMove`
Specifies a screen move operation.
Available in Mac OS X v10.3 and later.
Declared in `CGRemoteOperation.h`.

`kCGScreenUpdateOperationReducedDirtyRectangleCount`
When presented as part of the requested operations to the function `CGWaitForScreenUpdateRects` (page 1538), specifies that the function should try to minimize the number of rectangles returned to represent the changed areas of the display. The function may combine adjacent rectangles within a larger bounding rectangle, which may include unmodified areas of the display.
Available in Mac OS X v10.4 and later.
Declared in `CGRemoteOperation.h`.

Discussion

For information about how these constants are used, see the function `CGWaitForScreenUpdateRects` (page 1538).

Window Level Keys

Keys that represent the standard window levels in Mac OS X. Quartz includes these keys to support application frameworks such as Carbon and Cocoa. Applications do not need to use them directly.

```
enum _CGCommonWindowLevelKey {
 kCGBaseWindowLevelKey = 0,
 kCGMinimumWindowLevelKey,
 kCGDesktopWindowLevelKey,
 kCGBackstopMenuLevelKey,
 kCGNormalWindowLevelKey,
 kCGFloatingWindowLevelKey,
 kCGTornOffMenuWindowLevelKey,
 kCGDockWindowLevelKey,
 kCGMainMenuWindowLevelKey,
 kCGStatusWindowLevelKey,
 kCGModalPanelWindowLevelKey,
 kCGPopUpMenuWindowLevelKey,
 kCGDraggingWindowLevelKey,
 kCGScreenSaverWindowLevelKey,
 kCGMaximumWindowLevelKey,
 kCGOverlayWindowLevelKey,
 kCGHelpWindowLevelKey,
 kCGUtilityWindowLevelKey,
 kCGDesktopIconWindowLevelKey,
 kCGCursorWindowLevelKey,
 kCGNumberOfWindowLevelKeys
};
typedef int32_t CGWindowLevelKey;
```

Constants

`kCGBaseWindowLevelKey`
The base key used to define window levels. Do not use.
Available in Mac OS X v10.0 and later.
Declared in `CGWindowLevel.h`.

`kCGMinimumWindowLevelKey`
The lowest available window level.
Available in Mac OS X v10.0 and later.
Declared in `CGWindowLevel.h`.

`kCGDesktopWindowLevelKey`
The level for the desktop.
Available in Mac OS X v10.0 and later.
Declared in `CGWindowLevel.h`.

`kCGBackstopMenuLevelKey`
The level of the backstop menu.
Available in Mac OS X v10.0 and later.
Declared in `CGWindowLevel.h`.

`kCGNormalWindowLevelKey`
The level for normal windows.
Available in Mac OS X v10.0 and later.
Declared in `CGWindowLevel.h`.

`kCGFloatingWindowLevelKey`
The level for floating windows.
Available in Mac OS X v10.0 and later.
Declared in `CGWindowLevel.h`.

`kCGTornOffMenuWindowLevelKey`
The level for torn off menus.

Available in Mac OS X v10.0 and later.

Declared in `CGWindowLevel.h`.

`kCGDockWindowLevelKey`
The level for the dock.

Available in Mac OS X v10.0 and later.

Declared in `CGWindowLevel.h`.

`kCGMainMenuWindowLevelKey`
The level for the menus displayed in the menu bar.

Available in Mac OS X v10.0 and later.

Declared in `CGWindowLevel.h`.

`kCGStatusWindowLevelKey`
The level for status windows.

Available in Mac OS X v10.0 and later.

Declared in `CGWindowLevel.h`.

`kCGModalPanelWindowLevelKey`
The level for modal panels.

Available in Mac OS X v10.0 and later.

Declared in `CGWindowLevel.h`.

`kCGPopUpMenuWindowLevelKey`
The level for pop-up menus.

Available in Mac OS X v10.0 and later.

Declared in `CGWindowLevel.h`.

`kCGDraggingWindowLevelKey`
The level for a window being dragged.

Available in Mac OS X v10.0 and later.

Declared in `CGWindowLevel.h`.

`kCGScreenSaverWindowLevelKey`
The level for screen savers.

Available in Mac OS X v10.0 and later.

Declared in `CGWindowLevel.h`.

`kCGMaximumWindowLevelKey`
The highest allowed window level.

Available in Mac OS X v10.0 and later.

Declared in `CGWindowLevel.h`.

`kCGOverlayWindowLevelKey`
The level for overlay windows.

Available in Mac OS X v10.1 and later.

Declared in `CGWindowLevel.h`.

`kCGHelpWindowLevelKey`
The level for help windows.

Available in Mac OS X v10.1 and later.

Declared in `CGWindowLevel.h`.

`kCGUtilityWindowLevelKey`
The level for utility windows.

Available in Mac OS X v10.1 and later.

Declared in `CGWindowLevel.h`.

`kCGDesktopIconWindowLevelKey`
The level for desktop icons.

Available in Mac OS X v10.1 and later.

Declared in `CGWindowLevel.h`.

`kCGCursorWindowLevelKey`
The level for the cursor.

Available in Mac OS X v10.2 and later.

Declared in `CGWindowLevel.h`.

`kCGNumberOfWindowLevelKeys`
The total number of window levels.

Available in Mac OS X v10.0 and later.

Declared in `CGWindowLevel.h`.

Window Server Session Properties

Specify keys for the standard properties in a window server session dictionary.

```
#define kCGSessionUserIDKey CFSTR("kCGSSessionUserIDKey")
#define kCGSessionUserNameKey CFSTR("kCGSSessionUserNameKey")
#define kCGSessionConsoleSetKey CFSTR("kCGSSessionConsoleSetKey")
#define kCGSessionOnConsoleKey CFSTR("kCGSSessionOnConsoleKey")
#define kCGSessionLoginDoneKey CFSTR("kCGSessionLoginDoneKey")
```

Constants

`kCGSessionUserIDKey`
Specifies a CFNumber 32-bit unsigned integer value that encodes a user ID for the session's current user.

Available in Mac OS X v10.3 and later.

Declared in `CGSession.h`.

`kCGSessionUserNameKey`
Specifies a CFString value that encodes the session's short user name as set by the login operation.

Available in Mac OS X v10.3 and later.

Declared in `CGSession.h`.

`kCGSessionConsoleSetKey`
: Specifies a CFNumber 32-bit unsigned integer value that represents a set of hardware composing a console.

Available in Mac OS X v10.3 and later.

Declared in `CGSession.h`.

`kCGSessionOnConsoleKey`
: Specifies a CFBoolean value indicating whether the session is on a console.

Available in Mac OS X v10.3 and later.

Declared in `CGSession.h`.

`kCGSessionLoginDoneKey`
: Specifies a CFBoolean value indicating whether the login operation has been done.

Available in Mac OS X v10.3 and later.

Declared in `CGSession.h`.

Discussion
To learn how to use these keys to access the values in a session dictionary, see *CFDictionary Reference*.

Result Codes

This table lists the result codes returned by functions in Quartz Display Services.

Result Code	Value	Description
`kCGErrorSuccess`	0	The requested operation was completed successfully. Available in Mac OS X v10.0 and later.
`kCGErrorFailure`	1000	A general failure occurred. Available in Mac OS X v10.0 and later.
`kCGErrorIllegalArgument`	1001	One or more of the parameters passed to a function are invalid. Check for `NULL` pointers. Available in Mac OS X v10.0 and later.
`kCGErrorInvalidConnection`	1002	The parameter representing a connection to the window server is invalid. Available in Mac OS X v10.0 and later.
`kCGErrorInvalidContext`	1003	The `CPSProcessSerNum` or context identifier parameter is not valid. Available in Mac OS X v10.0 and later.
`kCGErrorCannotComplete`	1004	The requested operation is inappropriate for the parameters passed in, or the current system state. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
kCGErrorNameTooLong	1005	A parameter, typically a C string, is too long to be used without truncation. Available in Mac OS X v10.0 and later.
kCGErrorNotImplemented	1006	Return value from obsolete function stubs present for binary compatibility, but not normally called. Available in Mac OS X v10.0 and later.
kCGErrorRangeCheck	1007	A parameter passed in has a value that is inappropriate, or which does not map to a useful operation or value. Available in Mac OS X v10.0 and later.
kCGErrorTypeCheck	1008	A data type or token was encountered that did not match the expected type or token. Available in Mac OS X v10.0 and later.
kCGErrorNoCurrentPoint	1009	An operation relative to a known point or coordinate could not be done, as there is no known point. Available in Mac OS X v10.0 and later.
kCGErrorInvalidOperation	1010	The requested operation is not valid for the parameters passed in, or the current system state. Available in Mac OS X v10.0 and later.
kCGErrorNoneAvailable	1011	The requested operation could not be completed as the indicated resources were not found. Available in Mac OS X v10.0 and later.

Quartz Event Services Reference

Framework: ApplicationServices/ApplicationServices.h

Declared in CGEvent.h
CGEventSource.h
CGEventTypes.h
CGRemoteOperation.h

Overview

This document describes the C API for event taps, which are filters used to observe and alter the stream of low-level user input events in Mac OS X. Event taps make it possible to monitor and filter input events from several points within the system, prior to their delivery to a foreground application. Event taps complement and extend the capabilities of the Carbon event monitor mechanism, which allows an application to observe input events delivered to other processes (see the function `GetEventMonitorTarget`).

Event taps are designed to serve as a Section 508 enabling technology. For example, consider a software system to assist a person with language impairments, designed to perform keyboard filtering with spoken review. Such a system could use an event tap to monitor all keystrokes, perform dictionary checks and matches, and recite the assembled word back to the user on detection of a word break in the input stream. If acceptable to the user, as indicated by an additional input keystroke or other gesture, the events would be posted into the system for delivery to the foreground application.

Introduced in Mac OS X version 10.4, event taps provide functionality similar to the Win32 functions `SetWinEventHook` when used to establish an out-of-context event hook, and `SendInput`. Quartz Event Services also includes an older set of event-related functions declared in the file `CGRemoteOperation.h`. These functions are still supported, but they are not recommended for new development.

Functions by Task

Working With Quartz Events

`CGEventGetTypeID` (page 1579)
Returns the type identifier for the opaque type `CGEventRef`.

`CGEventCreate` (page 1571)
Returns a new Quartz event.

`CGEventCreateData` (page 1572)
Returns a flattened data representation of a Quartz event.

`CGEventCreateFromData` (page 1573)
Returns a Quartz event created from a flattened data representation of the event.

`CGEventCreateMouseEvent` (page 1574)
Returns a new Quartz mouse event.

`CGEventCreateKeyboardEvent` (page 1573)
Returns a new Quartz keyboard event.

`CGEventCreateScrollWheelEvent` (page 1575)
Returns a new Quartz scrolling event.

`CGEventCreateCopy` (page 1572)
Returns a copy of an existing Quartz event.

`CGEventCreateSourceFromEvent` (page 1576)
Returns a Quartz event source created from an existing Quartz event.

`CGEventSetSource` (page 1585)
Sets the event source of a Quartz event.

`CGEventGetType` (page 1579)
Returns the event type of a Quartz event (left mouse down, for example).

`CGEventSetType` (page 1586)
Sets the event type of a Quartz event (left mouse down, for example).

`CGEventGetTimestamp` (page 1578)
Returns the timestamp of a Quartz event.

`CGEventSetTimestamp` (page 1585)
Sets the timestamp of a Quartz event.

`CGEventGetLocation` (page 1578)
Returns the location of a Quartz mouse event.

`CGEventGetUnflippedLocation` (page 1579)
Returns the location of a Quartz mouse event.

`CGEventGetFlags` (page 1577)
Returns the event flags of a Quartz event.

`CGEventSetFlags` (page 1583)
Sets the event flags of a Quartz event.

`CGEventKeyboardGetUnicodeString` (page 1580)
Returns the Unicode string associated with a Quartz keyboard event.

`CGEventKeyboardSetUnicodeString` (page 1581)
Sets the Unicode string associated with a Quartz keyboard event.

`CGEventGetIntegerValueField` (page 1577)
Returns the integer value of a field in a Quartz event.

`CGEventSetIntegerValueField` (page 1584)
Sets the integer value of a field in a Quartz event.

`CGEventGetDoubleValueField` (page 1576)
Returns the floating-point value of a field in a Quartz event.

`CGEventSetDoubleValueField` (page 1583)
Sets the floating-point value of a field in a Quartz event.

`CGEventSetLocation` (page 1584) Deprecated in Mac OS X v10.5
Sets the location of a Quartz mouse event.

Working With Quartz Event Taps

`CGEventTapCreate` (page 1595)
Creates an event tap.

`CGEventTapCreateForPSN` (page 1597)
Creates an event tap for a specified process.

`CGEventTapEnable` (page 1598)
Enables or disables an event tap.

`CGEventTapIsEnabled` (page 1598)
Returns a Boolean value indicating whether an event tap is enabled.

`CGEventTapPostEvent` (page 1599)
Posts a Quartz event from an event tap into the event stream.

`CGEventPost` (page 1582)
Posts a Quartz event into the event stream at a specified location.

`CGEventPostToPSN` (page 1582)
Posts a Quartz event into the event stream for a specific application.

`CGGetEventTapList` (page 1599)
Gets a list of currently installed event taps.

`CGEventMaskBit` (page 1581)
Generates an event mask for a single type of event.

Working With Quartz Event Sources

`CGEventSourceGetTypeID` (page 1591)
Returns the type identifier for the opaque type `CGEventSourceRef`.

`CGEventSourceCreate` (page 1587)
Returns a Quartz event source created with a specified source state.

`CGEventSourceGetKeyboardType` (page 1588)
Returns the keyboard type to be used with a Quartz event source.

`CGEventSourceSetKeyboardType` (page 1593)
Sets the keyboard type to be used with a Quartz event source.

`CGEventSourceGetSourceStateID` (page 1590)
Returns the source state associated with a Quartz event source.

`CGEventSourceButtonState` (page 1586)
Returns a Boolean value indicating the current button state of a Quartz event source.

`CGEventSourceKeyState` (page 1592)
Returns a Boolean value indicating the current keyboard state of a Quartz event source.

`CGEventSourceFlagsState` (page 1588)
Returns the current flags of a Quartz event source.

`CGEventSourceSecondsSinceLastEventType` (page 1592)
Returns the elapsed time since the last event for a Quartz event source.

`CGEventSourceCounterForEventType` (page 1587)
Returns a count of events of a given type seen since the window server started.

`CGEventSourceGetUserData` (page 1591)
Returns the 64-bit user-specified data for a Quartz event source.

`CGEventSourceSetUserData` (page 1595)
Sets the 64-bit user-specified data for a Quartz event source.

`CGEventSourceGetLocalEventsFilterDuringSuppressionState` (page 1589)
Returns the mask that indicates which classes of local hardware events are enabled during event suppression.

`CGEventSourceSetLocalEventsFilterDuringSuppressionState` (page 1593)
Sets the mask that indicates which classes of local hardware events are enabled during event suppression.

`CGEventSourceSetLocalEventsSuppressionInterval` (page 1594)
Sets the interval that local hardware events may be suppressed following the posting of a Quartz event.

`CGEventSourceGetPixelsPerLine` (page 1590)
Gets the scale of pixels per line in a scrolling event source.

`CGEventSourceSetPixelsPerLine` (page 1594)
Sets the scale of pixels per line in a scrolling event source.

`CGEventSourceGetLocalEventsSuppressionInterval` (page 1589) Deprecated in Mac OS X v10.4
Returns the interval that local hardware events may be suppressed following the posting of a Quartz event.

Obsolete Functions

`CGPostKeyboardEvent` (page 1600)
Synthesizes a low-level keyboard event on the local machine.

`CGPostMouseEvent` (page 1601)
Synthesizes a low-level mouse-button event on the local machine.

`CGPostScrollWheelEvent` (page 1602)
Synthesizes a low-level scrolling event on the local machine.

`CGEnableEventStateCombining` (page 1571)
Enables or disables the merging of actual key and mouse state with the application-specified state in a synthetic event.

`CGInhibitLocalEvents` (page 1600)
Turns off local hardware events in the current session.

`CGSetLocalEventsFilterDuringSuppressionState` (page 1603)
Filters local hardware events from the keyboard and mouse during the short interval after a synthetic event is posted.

`CGSetLocalEventsSuppressionInterval` (page 1603)
Sets the time interval in seconds that local hardware events are suppressed after posting a synthetic event.

`CGEventGetSource` (page 1578) Deprecated in Mac OS X v10.4
Returns a Quartz event source created from an existing Quartz event. (Deprecated. Use `CGEventCreateSourceFromEvent` (page 1576) instead.)

Functions

CGEnableEventStateCombining

Enables or disables the merging of actual key and mouse state with the application-specified state in a synthetic event.

```
CGError CGEnableEventStateCombining (
   boolean_t doCombineState
);
```

Parameters

doCombineState

Pass `true` to specify that the actual key and mouse state are merged with the application-specified state in a synthetic event; otherwise, pass `false`.

Return Value

A result code. See the result codes described in *Quartz Display Services Reference*.

Discussion

By default, the flags that indicate modifier key state (Command, Option, Shift, Control, and so on) from the system's keyboard and from other event sources are ORed together as an event is posted into the system, and current key and mouse button state is considered in generating new events. This function allows your application to enable or disable the merging of event state. When combining is turned off, the event state propagated in the events posted by your application reflect state built up only by your application. The state within your application's generated event will not be combined with the system's current state, so the system-wide state reflecting key and mouse button state will remain unchanged. When called with `doCombineState` equal to `false`, this function initializes local (per application) state tracking information to a state of all keys, modifiers, and mouse buttons up. When called with `doCombineState` equal to `true`, the current global state of keys, modifiers, and mouse buttons are used in generating events.

This function is not recommended for general use because of undocumented special cases and undesirable side effects. The recommended replacement for this function is to use Quartz events and Quartz event sources. This allows you to control exactly which, if any, external event sources will contribute to the state used to create an event.

Availability

Available in Mac OS X v10.1 and later.

Declared In

`CGRemoteOperation.h`

CGEventCreate

Returns a new Quartz event.

```
CGEventRef CGEventCreate (
   CGEventSourceRef source
);
```

Parameters

source

The event source, or `NULL` to use a default source.

Return Value

A new event to be filled in, or `NULL` if the event could not be created. When you no longer need the event, you should release it using the function `CFRelease`.

Availability

Available in Mac OS X v10.4 and later.

Declared In

`CGEvent.h`

CGEventCreateCopy

Returns a copy of an existing Quartz event.

```
CGEventRef CGEventCreateCopy (
   CGEventRef event
);
```

Parameters

event

The event being copied.

Return Value

A copy of the specified event. When you no longer need the copy, you should release it using the function `CFRelease`.

Availability

Available in Mac OS X v10.4 and later.

Declared In

`CGEvent.h`

CGEventCreateData

Returns a flattened data representation of a Quartz event.

```
CFDataRef CGEventCreateData (
   CFAllocatorRef allocator,
   CGEventRef event
);
```

Parameters

allocator

The allocator to use to allocate memory for the data object. To use the current default allocator, pass `NULL` or `kCFAllocatorDefault`.

event
The event to flatten.

Return Value
The flattened data representation of the event, or `NULL` if the `event` parameter is invalid. When you no longer need the data object, you should release it using the function `CFRelease`.

Discussion
You can use this function to flatten an event for network transport to another system.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGEvent.h`

CGEventCreateFromData

Returns a Quartz event created from a flattened data representation of the event.

```
CGEventRef CGEventCreateFromData (
   CFAllocatorRef allocator,
   CFDataRef eventData
);
```

Parameters

allocator
The allocator to use to allocate memory for the event object. To use the current default allocator, pass `NULL` or `kCFAllocatorDefault`.

eventData
The flattened data representation of the event to reconstruct.

Return Value
An event built from the flattened data representation, or `NULL` if the `eventData` parameter is invalid.

Discussion
You can use this function to reconstruct a Quartz event received by network transport from another system.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGEvent.h`

CGEventCreateKeyboardEvent

Returns a new Quartz keyboard event.

```
CGEventRef CGEventCreateKeyboardEvent (
   CGEventSourceRef source,
   CGKeyCode virtualKey,
   bool keyDown
);
```

Parameters

source

An event source taken from another event, or `NULL`.

virtualKey

The virtual key code for the event.

keyDown

Pass `true` to specify that the key position is down. To specify that the key position is up, pass `false`. This value is used to determine the type of the keyboard event—see "Event Types" (page 1623).

Return Value

A new keyboard event, or `NULL` if the event could not be created. When you no longer need the event, you should release it using the function `CFRelease`.

Discussion

All keystrokes needed to generate a character must be entered, including modifier keys. For example, to produce a 'Z', the SHIFT key must be down, the 'z' key must go down, and then the SHIFT and 'z' key must be released:

```
CGEventRef event1, event2, event3, event4;
event1 = CGEventCreateKeyboardEvent (NULL, (CGKeyCode)56, true);
event2 = CGEventCreateKeyboardEvent (NULL, (CGKeyCode)6, true);
event3 = CGEventCreateKeyboardEvent (NULL, (CGKeyCode)6, false);
event4 = CGEventCreateKeyboardEvent (NULL, (CGKeyCode)56, false);
```

Availability

Available in Mac OS X v10.4 and later.

Declared In

`CGEvent.h`

CGEventCreateMouseEvent

Returns a new Quartz mouse event.

```
CGEventRef CGEventCreateMouseEvent (
   CGEventSourceRef source,
   CGEventType mouseType,
   CGPoint mouseCursorPosition,
   CGMouseButton mouseButton
);
```

Parameters

source

An event source taken from another event, or `NULL`.

mouseType

A mouse event type. Pass one of the constants listed in "Event Types" (page 1623).

mouseCursorPosition
The position of the mouse cursor in global coordinates.

mouseButton
The button that's changing state. Pass one of the constants listed in "Mouse Buttons" (page 1626). This parameter is ignored unless the *mouseType* parameter is `kCGEventOtherMouseDown`, `kCGEventOtherMouseDragged`, or `kCGEventOtherMouseUp`.

Return Value
A new mouse event, or `NULL` if the event could not be created. When you no longer need the event, you should release it using the function `CFRelease`.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGEvent.h`

CGEventCreateScrollWheelEvent

Returns a new Quartz scrolling event.

```
CGEventRef CGEventCreateScrollWheelEvent (
    CGEventSourceRef source,
    CGScrollEventUnit units,
    CGWheelCount wheelCount,
    int32_t wheel1,

);
```

Parameters

source
An event source taken from another event, or `NULL`.

units
The unit of measurement for the scrolling event. Pass one of the constants listed in "Scrolling Event Units" (page 1627).

wheelCount
The number of scrolling devices on the mouse, up to a maximum of 3.

wheel1
A value that reflects the movement of the primary scrolling device on the mouse. Scrolling movement is generally represented by small signed integer values, typically in a range from -10 to +10. Large values may have unexpected results, depending on the application that processes the event.

...
Up to two values that reflect the movements of the other scrolling devices on the mouse, if any.

Return Value
A new scrolling event, or `NULL` if the event could not be created. When you no longer need the event, you should release it using the function `CFRelease`.

Discussion
This function allows you to create a scrolling event and customize the event before posting it to the event system.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`CGEvent.h`

CGEventCreateSourceFromEvent

Returns a Quartz event source created from an existing Quartz event.

```
CGEventSourceRef CGEventCreateSourceFromEvent (
   CGEventRef event
);
```

Parameters

event

The event to access.

Return Value
An event source created from the specified event, or `NULL` if the event was generated with a private event source owned by another process. When you no longer need this event source, you should release it using the function `CFRelease`.

Discussion
Event filters may use the event source to generate events that are compatible with an event being filtered.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGEvent.h`

CGEventGetDoubleValueField

Returns the floating-point value of a field in a Quartz event.

```
double CGEventGetDoubleValueField (
   CGEventRef event,
   CGEventField field
);
```

Parameters

event

The event to access.

field

A field in the specified event. Pass one of the constants listed in "Event Fields" (page 1610).

Return Value
A floating point representation of the current value of the specified field.

Discussion
In cases where the field value is represented within the event by a fixed point number or an integer, the result is scaled to the appropriate range as part of creating the floating point representation.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGEvent.h`

CGEventGetFlags

Returns the event flags of a Quartz event.

```
CGEventFlags CGEventGetFlags (
   CGEventRef event
);
```

Parameters

event
The event to access.

Return Value
The current flags of the specified event. For more information, see "Event Flags" (page 1618).

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGEvent.h`

CGEventGetIntegerValueField

Returns the integer value of a field in a Quartz event.

```
int64_t CGEventGetIntegerValueField (
   CGEventRef event,
   CGEventField field
);
```

Parameters

event
The event to access.

field
A field in the specified event. Pass one of the constants listed in "Event Fields" (page 1610).

Return Value
A 64-bit integer representation of the current value of the specified field.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGEvent.h`

CGEventGetLocation

Returns the location of a Quartz mouse event.

```
CGPoint CGEventGetLocation (
   CGEventRef event
);
```

Parameters

event

The mouse event to locate.

Return Value

The current location of the specified mouse event in global display coordinates.

Availability

Available in Mac OS X v10.4 and later.

Declared In

CGEvent.h

CGEventGetSource

Returns a Quartz event source created from an existing Quartz event. (Deprecated in Mac OS X v10.4. Use CGEventCreateSourceFromEvent (page 1576) instead.)

```
CGEventSourceRef CGEventGetSource (
    CGEventRef event
);
```

Availability

Available in Mac OS X v10.4 through Mac OS X v10.4.

Deprecated in Mac OS X v10.4.

Declared In

CGEvent.h

CGEventGetTimestamp

Returns the timestamp of a Quartz event.

```
CGEventTimestamp CGEventGetTimestamp (
   CGEventRef event
);
```

Parameters

event

The event to access.

Return Value

The current timestamp of the specified event.

Availability

Available in Mac OS X v10.4 and later.

Declared In
CGEvent.h

CGEventGetType

Returns the event type of a Quartz event (left mouse down, for example).

```
CGEventType CGEventGetType (
   CGEventRef event
);
```

Parameters

event
The event to access.

Return Value
The current event type of the specified event. The return value is one of the constants listed in "Event Types" (page 1623).

Availability
Available in Mac OS X v10.4 and later.

See Also
CGEventSetType (page 1586)

Declared In
CGEvent.h

CGEventGetTypeID

Returns the type identifier for the opaque type CGEventRef.

```
CFTypeID CGEventGetTypeID (
   void
);
```

Return Value
The Core Foundation type identifier for the opaque type CGEventRef (page 1606).

Availability
Available in Mac OS X v10.4 and later.

Declared In
CGEvent.h

CGEventGetUnflippedLocation

Returns the location of a Quartz mouse event.

```
CGPoint CGEventGetUnflippedLocation (
    CGEventRef event
);
```

Parameters

event

The mouse event whose location you wish to obtain.

Return Value

The current location of the specified mouse event relative to the lower-left corner of the main display.

Discussion

This function returns the location of the mouse cursor associated with the event. The coordinate system used is relative to the lower-left corner of the main display, and is compatible with the global coordinate system used by the Application Kit.

Note that the y-coordinate of the returned location is off by one from an idealized coordinate system originating at the lower-left corner of the main display. Effectively, the function is defined as follows:

```
CGPoint p = CGEventGetLocation(event);
p.y = main_display_height - p.y;
/* not p.y = (main_display_height - 1) - p.y */
return p;
```

Availability

Available in Mac OS X v10.5 and later.

Declared In

`CGEvent.h`

CGEventKeyboardGetUnicodeString

Returns the Unicode string associated with a Quartz keyboard event.

```
void CGEventKeyboardGetUnicodeString (
   CGEventRef event,
   UniCharCount maxStringLength,
   UniCharCount *actualStringLength,
   UniChar unicodeString[]
);
```

Parameters

event

The keyboard event to access.

maxStringLength

The length of the array you provide in the `unicodeString` parameter.

actualStringLength

A pointer to a `UniCharCount` variable. On return, the variable contains the actual count of Unicode characters in the event data.

unicodeString

A pointer to a `UniChar` array. You are responsible for allocating storage for the array. On return, your array contains the Unicode string associated with the specified event.

Discussion
When you call this function and specify a `NULL` string or a maximum string length of 0, the function still returns the actual count of Unicode characters in the event data.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGEvent.h`

CGEventKeyboardSetUnicodeString

Sets the Unicode string associated with a Quartz keyboard event.

```
void CGEventKeyboardSetUnicodeString (
   CGEventRef event,
   UniCharCount stringLength,
   const UniChar unicodeString[]
);
```

Parameters

event
The keyboard event to access.

stringLength
The length of the array you provide in the `unicodeString` parameter.

unicodeString
An array that contains the new Unicode string associated with the specified event.

Discussion
By default, the system translates the virtual key code in a keyboard event into a Unicode string based on the keyboard ID in the event source. This function allows you to manually override this string. Note that application frameworks may ignore the Unicode string in a keyboard event and do their own translation based on the virtual keycode and perceived event state.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGEvent.h`

CGEventMaskBit

Generates an event mask for a single type of event.

```
CGEventMask CGEventMaskBit (
   CGEventType eventType
);
```

Parameters

eventType
An event type constant. Pass one of the constants listed in "Event Types" (page 1623).

Return Value
An event mask that represents the specified event.

Discussion
This macro converts an event type constant into a mask. You can use this mask to specify that an event tap should observe the event. For more information, see `CGEventMask` (page 1606).

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGEventTypes.h`

CGEventPost

Posts a Quartz event into the event stream at a specified location.

```
void CGEventPost (
   CGEventTapLocation tap,
   CGEventRef event
);
```

Parameters

tap
The location at which to post the event. Pass one of the constants listed in "Event Tap Locations" (page 1621).

event
The event to post.

Discussion
This function posts the specified event immediately before any event taps instantiated for that location, and the event passes through any such taps.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGEvent.h`

CGEventPostToPSN

Posts a Quartz event into the event stream for a specific application.

```
void CGEventPostToPSN (
   void *processSerialNumber,
   CGEventRef event
);
```

Parameters

processSerialNumber
The process to receive the event.

event
The event to post.

Discussion
This function makes it possible for an application to establish an event routing policy, for example, by tapping events at the `kCGAnnotatedSessionEventTap` location and then posting the events to another desired process.

This function posts the specified event immediately before any event taps instantiated for the specified process, and the event passes through any such taps.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGEvent.h`

CGEventSetDoubleValueField

Sets the floating-point value of a field in a Quartz event.

```
void CGEventSetDoubleValueField (
   CGEventRef event,
   CGEventField field,
   double value
);
```

Parameters

event
The event to access.

field
A field in the specified event. Pass one of the constants listed in "Event Fields" (page 1610).

value
The new value of the specified field.

Discussion
Before calling this function, the event type must be set using a typed event creation function such as `CGEventCreateMouseEvent` (page 1574), or by calling `CGEventSetType` (page 1586).

In cases where the field's value is represented within the event by a fixed point number or integer, the `value` parameter is scaled as needed and converted to the appropriate type.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGEvent.h`

CGEventSetFlags

Sets the event flags of a Quartz event.

```
void CGEventSetFlags (
   CGEventRef event,
   CGEventFlags flags
);
```

Parameters

event

The event to access.

location

The new flags of the specified event. See "Event Flags" (page 1618).

Availability
Available in Mac OS X v10.4 and later.

Declared In
CGEvent.h

CGEventSetIntegerValueField

Sets the integer value of a field in a Quartz event.

```
void CGEventSetIntegerValueField (
   CGEventRef event,
   CGEventField field,
   int64_t value
);
```

Parameters

event

The event to access.

field

A field in the specified event. Pass one of the constants listed in "Event Fields" (page 1610).

value

The new value of the specified field.

Discussion
Before calling this function, the event type must be set using a typed event creation function such as `CGEventCreateMouseEvent` (page 1574), or by calling `CGEventSetType` (page 1586).

If you are creating a mouse event generated by a tablet, call this function and specify the field `kCGMouseEventSubtype` with a value of `kCGEventMouseSubtypeTabletPoint` or `kCGEventMouseSubtypeTabletProximity` before setting other parameters.

Availability
Available in Mac OS X v10.4 and later.

Declared In
CGEvent.h

CGEventSetLocation

Sets the location of a Quartz mouse event.

```
void CGEventSetLocation (
   CGEventRef event,
   CGPoint location
);
```

Parameters

event

The mouse event whose location to set.

location

The new location of the specified mouse event in global display coordinates.

Availability
Available in Mac OS X v10.4 and later.

Declared In
CGEvent.h

CGEventSetSource

Sets the event source of a Quartz event.

```
void CGEventSetSource (
   CGEventRef event,
   CGEventSourceRef source
);
```

Parameters

event

The event to access.

source

The new event source of the specified event.

Availability
Available in Mac OS X v10.4 and later.

Declared In
CGEvent.h

CGEventSetTimestamp

Sets the timestamp of a Quartz event.

```
void CGEventSetTimestamp (
   CGEventRef event,
   CGEventTimestamp timestamp
);
```

Parameters

event

The event to access.

timestamp

The new timestamp of the specified event.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGEvent.h`

CGEventSetType

Sets the event type of a Quartz event (left mouse down, for example).

```
void CGEventSetType (
   CGEventRef event,
   CGEventType type
);
```

Parameters

event
The event to access.

type
The new event type of the specified event. The return value is one of the constants listed in "Event Types" (page 1623).

Availability
Available in Mac OS X v10.4 and later.

See Also
`CGEventGetType` (page 1579)

Declared In
`CGEvent.h`

CGEventSourceButtonState

Returns a Boolean value indicating the current button state of a Quartz event source.

```
bool CGEventSourceButtonState (
   CGEventSourceStateID sourceState,
   CGMouseButton button
);
```

Parameters

sourceState
The source state to access. Pass one of the constants listed in "Event Source States" (page 1619).

button
The mouse button to test. Pass one of the constants listed in "Mouse Buttons" (page 1626).

Return Value
If `true`, the button is down. If `false`, the button is up.

Availability
Available in Mac OS X v10.4 and later.

Declared In
CGEventSource.h

CGEventSourceCounterForEventType

Returns a count of events of a given type seen since the window server started.

```
uint32_t CGEventSourceCounterForEventType (
   CGEventSourceStateID source,
   CGEventType evType
);
```

Parameters

sourceState
The source state to access. Pass one of the constants listed in "Event Source States" (page 1619).

eventType
The event type to access. To get the count of input events—keyboard, mouse, or tablet—specify kCGAnyInputEventType.

Return Value
The count of events of the specified type seen since the window server started.

Discussion
Quartz provides these counters for applications that monitor user activity. For example, an application could prompt a typist to take a break to reduce repetitive stress injuries.

Modifier keys produce kCGEventFlagsChanged events, not kCGEventKeyDown events, and do so both on press and release. The volume, brightness, and CD eject keys on some keyboards (both desktop and laptop) do not generate key up or key down events.

For various reasons, the number of key up and key down events may not be the same when all keyboard keys are up. As a result, a mismatch does not necessarily indicate that some keys are down.

Key autorepeat events are not counted.

Availability
Available in Mac OS X v10.4 and later.

Declared In
CGEventSource.h

CGEventSourceCreate

Returns a Quartz event source created with a specified source state.

```
CGEventSourceRef CGEventSourceCreate (
   CGEventSourceStateID sourceState
);
```

Parameters

sourceState
The event state table to use for this event source. Pass one of the constants listed in "Event Source States" (page 1619).

Return Value
A new event source, or `NULL` if the specified source state is not valid. When you no longer need the event source, you should release it using the function `CFRelease`.

Discussion
If two or more event sources are using the same source state and one of them is released, the remaining event sources will behave as if all keys and buttons on input devices are up in generating new events from this source.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGEventSource.h`

CGEventSourceFlagsState

Returns the current flags of a Quartz event source.

```
CGEventFlags CGEventSourceFlagsState (
   CGEventSourceStateID sourceState
);
```

Parameters

sourceState
The source state to access. Pass one of the constants listed in "Event Source States" (page 1619).

Return Value
The current flags of the specified event source. For more information, see "Event Flags" (page 1618).

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGEventSource.h`

CGEventSourceGetKeyboardType

Returns the keyboard type to be used with a Quartz event source.

```
CGEventSourceKeyboardType CGEventSourceGetKeyboardType (
   CGEventSourceRef source
);
```

Parameters

source
The event source to access. Pass one of the constants listed in "Event Source States" (page 1619).

Return Value
The keyboard type to be used with the specified event source.

Availability
Available in Mac OS X v10.4 and later.

Declared In
CGEventSource.h

CGEventSourceGetLocalEventsFilterDuringSuppressionState

Returns the mask that indicates which classes of local hardware events are enabled during event suppression.

```
CGEventFilterMask CGEventSourceGetLocalEventsFilterDuringSuppressionState (
   CGEventSourceRef source,
   CGEventSuppressionState state
);
```

Parameters

source

The event source to access.

state

The type of event suppression interval during which the filter is applied. Pass one of the constants listed in "Event Suppression States" (page 1621).

Return Value
A mask that specifies the categories of local hardware events to enable during the event suppression interval. See "Event Filter Masks" (page 1618).

Discussion
You can configure the system to suppress local hardware events from the keyboard or mouse during a short interval after a Quartz event is posted or during a synthetic mouse drag (mouse movement with the left or only mouse button down). For information about setting this local events filter, see `CGEventSourceSetLocalEventsFilterDuringSuppressionState` (page 1593).

This function lets you specify an event source and a suppression state (event suppression interval or mouse drag), and returns a filter mask of event categories to be passed through during suppression.

Availability
Available in Mac OS X v10.4 and later.

Declared In
CGEventSource.h

CGEventSourceGetLocalEventsSuppressionInterval

Returns the interval that local hardware events may be suppressed following the posting of a Quartz event.

```
CFTimeInterval CGEventSourceGetLocalEventsSuppressionInterval (
   CGEventSourceRef source
);
```

Parameters

source

The event source to access.

Discussion
By default, the system does not suppress local hardware events from the keyboard or mouse during a short interval after a Quartz event is posted. You can use the function `CGEventSourceSetLocalEventsFilterDuringSuppressionState` (page 1593) to modify this behavior.

This function gets the period of time in seconds that local hardware events may be suppressed after posting a Quartz event created with the specified event source. You can use the function `CGEventSourceSetLocalEventsSuppressionInterval` (page 1594) to change this time interval.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGEventSource.h`

CGEventSourceGetPixelsPerLine

Gets the scale of pixels per line in a scrolling event source.

```
double CGEventSourceGetPixelsPerLine (
    CGEventSourceRef source
);
```

Parameters

source
The event source to access.

Return Value
The scale of pixels per line in a scrolling event.

Discussion
This function returns the scale of pixels per line in the specified event source. For example, if the scale in the event source is 10.5 pixels per line, this function would return 10.5. Every scrolling event can be interpreted to be scrolling by pixel or by line. By default, the scale is about ten pixels per line. You can alter the scale with the function `CGEventSourceSetPixelsPerLine`.

Availability
Available in Mac OS X v10.5 and later.

See Also
`CGEventSourceSetPixelsPerLine` (page 1594)

Declared In
`CGEventSource.h`

CGEventSourceGetSourceStateID

Returns the source state associated with a Quartz event source.

```
CGEventSourceStateID CGEventSourceGetSourceStateID (
   CGEventSourceRef source
);
```

Parameters

source
The event source to access.

Return Value
The source state associated with the specified event source.

Discussion
This function returns the ID of the source state table associated with an event source.

For event sources created with the `kCGEventSourceStatePrivate` source state, this function returns the ID of the private source state table created for the event source. This unique ID may be passed to the `CGEventSourceCreate` function to create a second event source sharing the same state table. This may be useful, for example, in creating separate mouse and keyboard sources which share a common private state.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGEventSource.h`

CGEventSourceGetTypeID

Returns the type identifier for the opaque type `CGEventSourceRef`.

```
CFTypeID CGEventSourceGetTypeID (
   void
);
```

Return Value
The Core Foundation type identifier for the opaque type `CGEventSourceRef` (page 1607).

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGEventSource.h`

CGEventSourceGetUserData

Returns the 64-bit user-specified data for a Quartz event source.

```
int64_t CGEventSourceGetUserData (
   CGEventSourceRef source
);
```

Parameters

source
The event source to access.

Return Value
The user-specified data.

Discussion
Each input event includes 64 bits of user-specified data. This function gets the user-specified data for all events created by the specified event source. This data may also be obtained per event using the `CGEventGetIntegerValueField` (page 1577) function.

Availability
Available in Mac OS X v10.4 and later.

Declared In
CGEventSource.h

CGEventSourceKeyState

Returns a Boolean value indicating the current keyboard state of a Quartz event source.

```
bool CGEventSourceKeyState (
   CGEventSourceStateID sourceState,
   CGKeyCode key
);
```

Parameters

sourceState
The source state to access. Pass one of the constants listed in "Event Source States" (page 1619).

key
The virtual key code to test.

Return Value
If `true`, the key is down. If `false`, the key is up.

Availability
Available in Mac OS X v10.4 and later.

Declared In
CGEventSource.h

CGEventSourceSecondsSinceLastEventType

Returns the elapsed time since the last event for a Quartz event source.

```
CFTimeInterval CGEventSourceSecondsSinceLastEventType (
   CGEventSourceStateID source,
   CGEventType eventType
);
```

Parameters

source
The source state to access. Pass one of the constants listed in "Event Source States" (page 1619).

eventType
The event type to access. To get the elapsed time since the previous input event—keyboard, mouse, or tablet—specify `kCGAnyInputEventType`.

Return Value
The time in seconds since the previous input event of the specified type.

Availability
Available in Mac OS X v10.4 and later.

Declared In
CGEventSource.h

CGEventSourceSetKeyboardType

Sets the keyboard type to be used with a Quartz event source.

```
void CGEventSourceSetKeyboardType (
   CGEventSourceRef source,
   CGEventSourceKeyboardType keyboardType
);
```

Parameters

source
The event source to access.

keyboardType
The keyboard type to be used with the specified event source.

Availability

Available in Mac OS X v10.4 and later.

Declared In

CGEventSource.h

CGEventSourceSetLocalEventsFilterDuringSuppressionState

Sets the mask that indicates which classes of local hardware events are enabled during event suppression.

```
void CGEventSourceSetLocalEventsFilterDuringSuppressionState (
   CGEventSourceRef source,
   CGEventFilterMask filter,
   CGEventSuppressionState state
);
```

Parameters

source
The event source to access.

filter
A mask that specifies the categories of local hardware events to enable during the event suppression interval. See "Event Filter Masks" (page 1618).

state
The type of event suppression interval during which the filter is applied. Pass one of the constants listed in "Event Suppression States" (page 1621).

Discussion

By default, the system does not suppress local hardware events from the keyboard or mouse during a short interval after a Quartz event is posted—see `CGEventSourceSetLocalEventsSuppressionInterval` (page 1594)—and during a synthetic mouse drag (mouse movement with the left or only mouse button down).

Some applications may want to disable events from some of the local hardware during this interval. For example, if you post mouse events only, you may wish to suppress local mouse events and permit local keyboard events to pass through. This function lets you specify an event source, a suppression state (event suppression interval or mouse drag), and a filter mask of event classes to be passed through. The new local events filter takes effect with the next Quartz event you post using this event source.

Availability

Available in Mac OS X v10.4 and later.

Declared In
CGEventSource.h

CGEventSourceSetLocalEventsSuppressionInterval

Sets the interval that local hardware events may be suppressed following the posting of a Quartz event.

```
void CGEventSourceSetLocalEventsSuppressionInterval (
   CGEventSourceRef source,
   CFTimeInterval seconds
);
```

Parameters

source
The event source to access.

seconds
The period of time in seconds that local hardware events (keyboard or mouse) are suppressed after posting a Quartz event created with the specified event source. The value should be a number in the range [0.0, 10.0].

Discussion
By default, the system does not suppress local hardware events from the keyboard or mouse during a short interval after a Quartz event is posted. You can use the function CGEventSourceSetLocalEventsFilterDuringSuppressionState (page 1593) to modify this behavior.

This function sets the period of time in seconds that local hardware events may be suppressed after posting a Quartz event created with the specified event source. The default suppression interval is 0.25 seconds.

Availability
Available in Mac OS X v10.4 and later.

Declared In
CGEventSource.h

CGEventSourceSetPixelsPerLine

Sets the scale of pixels per line in a scrolling event source.

```
void CGEventSourceSetPixelsPerLine (
    CGEventSourceRef source,
    double pixelsPerLine
);
```

Parameters

source
The event source to access.

pixelsPerLine
The scale of pixels per line in the specified event source.

Discussion
This function sets the scale of pixels per line in the specified event source. For example, if you pass the value 12.0 in the *pixelsPerLine* parameter, the scale of pixels per line in the event source would be changed to 12.0. Every scrolling event can be interpreted to be scrolling by pixel or by line. By default, the scale is about ten pixels per line. You can retrieve the scale with the function `CGEventSourceGetPixelsPerLine`.

Availability
Available in Mac OS X v10.5 and later.

See Also
`CGEventSourceGetPixelsPerLine` (page 1590)

Declared In
`CGEventSource.h`

CGEventSourceSetUserData

Sets the 64-bit user-specified data for a Quartz event source.

```
void CGEventSourceSetUserData (
   CGEventSourceRef source,
   int64_t userData
);
```

Parameters

source
The event source to access.

userData
The user-specified data. For example, you could specify a vendor hardware ID.

Discussion
Each input event includes 64 bits of user-specified data. This function sets the user-specified data for all events created by the specified event source. This data may also be set per event using the `CGEventGetIntegerValueField` (page 1577) function.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGEventSource.h`

CGEventTapCreate

Creates an event tap.

```
CFMachPortRef CGEventTapCreate (
   CGEventTapLocation tap,
   CGEventTapPlacement place,
   CGEventTapOptions options,
   CGEventMask eventsOfInterest,
   CGEventTapCallBack callback,
   void *refcon
);
```

Parameters

tap

The location of the new event tap. Pass one of the constants listed in "Event Tap Locations" (page 1621). Only processes running as the root user may locate an event tap at the point where HID events enter the window server; for other users, this function returns `NULL`.

place

The placement of the new event tap in the list of active event taps. Pass one of the constants listed in "Event Tap Placement" (page 1622).

options

A constant that specifies whether the new event tap is a passive listener or an active filter.

eventsOfInterest

A bit mask that specifies the set of events to be observed. For a list of possible events, see "Event Types" (page 1623). For information on how to specify the mask, see `CGEventMask` (page 1606). If the event tap is not permitted to monitor one or more of the events specified in the `eventsOfInterest` parameter, then the appropriate bits in the mask are cleared. If that action results in an empty mask, this function returns `NULL`.

callback

An event tap callback function that you provide. Your callback function is invoked from the run loop to which the event tap is added as a source. The thread safety of the callback is defined by the run loop's environment. To learn more about event tap callbacks, see `CGEventTapCallBack` (page 1604).

refcon

A pointer to user-defined data. This pointer is passed into the callback function specified in the `callback` parameter.

Return Value

A Core Foundation mach port that represents the new event tap, or `NULL` if the event tap could not be created. When you are finished using the event tap, you should release the mach port using the function `CFRelease`. Releasing the mach port also releases the tap.

Discussion

Event taps receive key up and key down events if one of the following conditions is true:

- The current process is running as the root user.
- Access for assistive devices is enabled. In Mac OS X v10.4, you can enable this feature using System Preferences, Universal Access panel, Keyboard view.

After creating an event tap, you can add it to a run loop as follows:

1. Pass the event tap to the `CFMachPortCreateRunLoopSource` function to create a run loop event source.
2. Call the `CFRunLoopAddSource` function to add the source to the appropriate run loop.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGEvent.h`

CGEventTapCreateForPSN

Creates an event tap for a specified process.

```
CFMachPortRef CGEventTapCreateForPSN (
   void *processSerialNumber,
   CGEventTapPlacement place,
   CGEventTapOptions options,
   CGEventMask eventsOfInterest,
   CGEventTapCallBack callback,
   void *refcon
);
```

Parameters

processSerialNumber
The process to monitor.

place
The placement of the new event tap in the list of active event taps. Pass one of the constants listed in "Event Tap Placement" (page 1622).

options
A constant that specifies whether the new event tap is a passive listener or an active filter.

eventsOfInterest
A bit mask that specifies the set of events to be observed. For a list of possible events, see "Event Types" (page 1623). For information on how to specify the mask, see `CGEventMask` (page 1606). If the event tap is not permitted to monitor one or more of the events specified in the `eventsOfInterest` parameter, then the appropriate bits in the mask are cleared. If that action results in an empty mask, this function returns `NULL`.

callback
An event tap callback function that you provide. Your callback function is invoked from the run loop to which the event tap is added as a source. The thread safety of the callback is defined by the run loop's environment. To learn more about event tap callbacks, see `CGEventTapCallBack` (page 1604).

refcon
A pointer to user-defined data. This pointer is passed into the callback function specified in the `callback` parameter.

Return Value
A Core Foundation mach port that represents the new event tap, or `NULL` if the event tap could not be created. When you are finished using the event tap, you should release the mach port using the function `CFRelease`. Releasing the mach port also releases the tap.

Discussion
This function creates an event tap that receives events being routed by the window server to the specified process. For more information about creating event taps, see `CGEventTapCreate` (page 1595).

Availability
Available in Mac OS X v10.4 and later.

Declared In
CGEvent.h

CGEventTapEnable

Enables or disables an event tap.

```
void CGEventTapEnable (
   CFMachPortRef myTap,
   bool enable
);
```

Parameters

myTap

The event tap to enable or disable.

enable

Pass `true` to enable the event tap. To disable it, pass `false`.

Discussion
Event taps are normally enabled when created. If an event tap becomes unresponsive, or if a user requests that event taps be disabled, then a `kCGEventTapDisabled` event is passed to the event tap callback function. Event taps may be re-enabled by calling this function.

Availability
Available in Mac OS X v10.4 and later.

Declared In
CGEvent.h

CGEventTapIsEnabled

Returns a Boolean value indicating whether an event tap is enabled.

```
bool CGEventTapIsEnabled (
   CFMachPortRef myTap
);
```

Parameters

myTap

The event tap to test.

Return Value
If `true`, the specified event tap is enabled; otherwise, `false`.

Discussion
For more information, see the function `CGEventTapEnable` (page 1598).

Availability
Available in Mac OS X v10.4 and later.

Declared In
CGEvent.h

CGEventTapPostEvent

Posts a Quartz event from an event tap into the event stream.

```
void CGEventTapPostEvent (
   CGEventTapProxy proxy,
   CGEventRef event
);
```

Parameters

proxy

A proxy that identifies the event tap posting the event. Your event tap callback function is passed this proxy when it is invoked.

event

The event to post.

Discussion

You can use this function to post a new event at the same point to which an event returned from an event tap callback function would be posted. The new event enters the system before the event returned by the callback enters the system. Events posted into the system will be seen by all taps placed after the tap posting the event.

Availability

Available in Mac OS X v10.4 and later.

Declared In

`CGEvent.h`

CGGetEventTapList

Gets a list of currently installed event taps.

```
CGError CGGetEventTapList (
   CGTableCount maxNumberOfTaps,
   CGEventTapInformation tapList[],
   CGTableCount *eventTapCount
);
```

Parameters

maxNumberOfTaps

The length of the array you provide in the `tapList` parameter.

tapList

An array of event tap information structures. You are responsible for allocating storage for the array. On return, your array contains a list of currently installed event taps. If you pass `NULL` in this parameter, the `maxNumberOfTaps` parameter is ignored, and the `eventTapCount` variable is filled in with the number of event taps that are currently installed.

eventTapCount

A pointer to a `CGTableCount` variable. On return, the variable contains actual number of array elements filled in.

Return Value

A result code. See the result codes described in *Quartz Display Services Reference*.

Discussion
Each call to this function has the side effect of resetting the minimum and maximum latency values in the `tapList` parameter to the corresponding average values. Values reported in these fields reflect the minimum and maximum values seen since the preceding call, or the instantiation of the tap. This allows a monitoring tool to evaluate the best and worst case latency over time and under various operating conditions.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGEvent.h`

CGInhibitLocalEvents

Turns off local hardware events in the current session.

```
CGError CGInhibitLocalEvents (
   boolean_t doInhibit
);
```

Parameters

`doInhibit`
Pass `true` to specify that local hardware events on the remote system should be inhibited; otherwise, pass `false`.

Return Value
A result code. See the result codes described in *Quartz Display Services Reference*.

Discussion
This function is typically used during remote operation of a system to disconnect the keyboard and mouse for a short period of time, as in automated system testing or telecommuting applications.

The `CGInhibitLocalEvents` function is not recommended for general use because of undocumented special cases and undesirable side effects. For example, this function can permanently disable the keyboard and mouse, rendering the system unusable. The recommended replacement for this function is `CGEventSourceSetLocalEventsFilterDuringSuppressionState` (page 1593).

Special Considerations

In Mac OS X v10.2 and earlier, this function inhibits local events only after a synthetic keyboard or mouse event is posted by the calling application. In Mac OS X v10.3 and later, event inhibition takes effect immediately. If your application terminates for any reason, event inhibition on the remote system is immediately turned off.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGRemoteOperation.h`

CGPostKeyboardEvent

Synthesizes a low-level keyboard event on the local machine.

```
CGError CGPostKeyboardEvent (
   CGCharCode keyChar,
   CGKeyCode virtualKey,
   boolean_t keyDown
);
```

Parameters

keyChar

The value of the character to generate, or 0 to specify that the system should guess an appropriate value based on the default key mapping.

virtualKey

The virtual key code for the event. See `CGKeyCode` (page 1609).

keyDown

Pass `true` to specify that the key position is down; otherwise, pass `false`.

Return Value

A result code. See the result codes described in *Quartz Display Services Reference*.

Discussion

This function is not recommended for general use because of undocumented special cases and undesirable side effects. The recommended replacement for this function is `CGEventCreateKeyboardEvent` (page 1573), which allows you to create a keyboard event and customize the event before posting it to the event system.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CGRemoteOperation.h`

CGPostMouseEvent

Synthesizes a low-level mouse-button event on the local machine.

```
CGError CGPostMouseEvent (
   CGPoint mouseCursorPosition,
   boolean_t updateMouseCursorPosition,
   CGButtonCount buttonCount,
   boolean_t mouseButtonDown,
   ...
);
```

Parameters

mouseCursorPosition

The new coordinates of the mouse in global display space.

updateMouseCursorPosition

Pass `true` if the on-screen cursor should be moved to the location specified in the `mouseCursorPosition` parameter; otherwise, pass `false`.

buttonCount

The number of mouse buttons, up to a maximum of 32.

mouseButtonDown

Pass `true` to specify that the primary or left mouse button is down; otherwise, pass `false`.

`...`
Zero or more Boolean values that specify whether the remaining mouse buttons are down (`true`) or up (`false`). The second value, if any, should specify the state of the secondary mouse button (right). A third value would specify the state of the center button, and the remaining buttons would be in USB device order.

Return Value
A result code. See the result codes described in *Quartz Display Services Reference*.

Discussion
Based on the arguments you pass to this function, the function generates the appropriate mouse-down, mouse-up, mouse-move, or mouse-drag events by comparing the new state with the current state.

This function is not recommended for general use because of undocumented special cases and undesirable side effects. The recommended replacement for this function is `CGEventCreateMouseEvent` (page 1574), which allows you to create a mouse event and customize the event before posting it to the event system.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGRemoteOperation.h`

CGPostScrollWheelEvent

Synthesizes a low-level scrolling event on the local machine.

```
CGError CGPostScrollWheelEvent (
   CGWheelCount wheelCount,
   int32_t wheel1,
   ...
);
```

Parameters

`wheelCount`
The number of scrolling devices, up to a maximum of 3.

`wheel1`
A value that reflects the movement of the primary scrolling device on the mouse.

`...`
Up to two values that reflect the movements of the other scrolling devices on the mouse (if any).

Return Value
A result code. See the result codes described in *Quartz Display Services Reference*.

Discussion
Scrolling movement is generally represented by small signed integer values, typically in a range from -10 to +10. Large values may have unexpected results, depending on the application that processes the event.

This function is not recommended for general use because of undocumented special cases and undesirable side effects. The recommended replacement for this function is `CGEventCreateScrollWheelEvent` (page 1575), which allows you to create a scrolling event and customize the event before posting it to the event system.

Availability
Available in Mac OS X v10.0 and later.

Declared In
CGRemoteOperation.h

CGSetLocalEventsFilterDuringSuppressionState

Filters local hardware events from the keyboard and mouse during the short interval after a synthetic event is posted.

```
CGError CGSetLocalEventsFilterDuringSuppressionState (
   CGEventFilterMask filter,
   CGEventSuppressionState state
);
```

Parameters

filter

The class of local hardware events to enable after a synthetic event is posted. Pass one of the constants listed in "Event Filter Masks" (page 1618).

state

The type of interval during which the filter is applied. Pass one of the constants listed in "Event Suppression States" (page 1621).

Return Value
A result code. See the result codes described in *Quartz Display Services Reference*.

Discussion
By default, the system suppresses local hardware events from the keyboard and mouse during a short interval after a synthetic event is posted and during a synthetic mouse drag (mouse movement with the left or only mouse button down).

Some applications may want to enable events from some of the local hardware. For example, if you post mouse events only, you may wish to permit local keyboard hardware events to pass through.

This function lets you specify a state (event suppression interval or mouse drag), and a mask of event categories to be passed through. The new filter state takes effect with the next synthetic event you post.

This function is not recommended for general use because of undocumented special cases and undesirable side effects. The recommended replacement for this function is `CGEventSourceSetLocalEventsFilterDuringSuppressionState` (page 1593), which allows the filter behavior to be associated only with events created from a specific event source.

Availability
Available in Mac OS X v10.3 and later.

Declared In
CGRemoteOperation.h

CGSetLocalEventsSuppressionInterval

Sets the time interval in seconds that local hardware events are suppressed after posting a synthetic event.

```
CGError CGSetLocalEventsSuppressionInterval (
   CFTimeInterval seconds
);
```

Parameters

seconds

The desired time interval in seconds. The value should be a number in the range [0.0, 10.0].

Return Value

A result code. If the `seconds` parameter is outside the allowed range, returns `kCGErrorRangeCheck`.

Discussion

This function determines how long local events matching an event filter are to be suppressed following the posting of a synthetic event. The default time interval for event suppression is 0.25 seconds.

This function is not recommended for general use because of undocumented special cases and undesirable side effects. The recommended replacement for this function is `CGEventSourceSetLocalEventsSuppressionInterval` (page 1594), which allows the suppression interval to be adjusted for a specific event source, affecting only events posted using that event source.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CGRemoteOperation.h`

Callbacks

CGEventTapCallBack

A client-supplied callback function that's invoked whenever an associated event tap receives a Quartz event.

```
typedef CGEventRef (*CGEventTapCallBack) (
   CGEventTapProxy proxy,
   CGEventType type,
   CGEventRef event,
   void *refcon
);
```

If you name your function `MyEventTapCallBack`, you would declare it like this:

```
CGEventRef MyEventTapCallBack (
   CGEventTapProxy proxy,
   CGEventType type,
   CGEventRef event,
   void *refcon
);
```

Parameters

proxy

A proxy for the event tap. See `CGEventTapProxy` (page 1609). This callback function may pass this proxy to other functions such as the event-posting routines.

type
The event type of this event. See "Event Types" (page 1623).

event
The incoming event. This event is owned by the caller, and you do not need to release it.

refcon
A pointer to user-defined data. You specify this pointer when you create the event tap. Several different event taps could use the same callback function, each tap with its own user-defined data.

Discussion
If the event tap is an active filter, your callback function should return one of the following:

- The (possibly modified) event that is passed in. This event is passed back to the event system.
- A newly-constructed event. After the new event has been passed back to the event system, the new event will be released along with the original event.
- `NULL` if the event passed in is to be deleted.

If the event tap is an passive listener, your callback function may return the event that is passed in, or `NULL`. In either case, the event stream is not affected.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGEventTypes.h`

Data Types

CGButtonCount

Represents the number of buttons being set in a synthetic mouse event.

```
typedef uint32_t CGButtonCount;
```

Discussion
In mouse events, the button count parameter ranges from 0 to 31. See the function `CGPostMouseEvent` (page 1601).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGRemoteOperation.h`

CGCharCode

Represents a character generated by pressing one or more keys on a keyboard.

```
typedef uint16_t CGCharCode;
```

Discussion
This data type represents a 16-bit character code. Values of this type may or may not correspond to UTF-16 character codes. See the function `CGPostKeyboardEvent` (page 1600).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGRemoteOperation.h`

CGEventMask

Defines a mask that identifies the set of Quartz events to be observed in an event tap.

```
typedef uint64_t CGEventMask;
```

Discussion
When you call either `CGEventTapCreate` (page 1595) or `CGEventTapCreateForPSN` (page 1597) to register an event tap, you supply a bit mask that identifies the set of events to be observed. You specify each event using one of the event type constants listed in "Event Types" (page 1623). To form the bit mask, use the `CGEventMaskBit` macro to convert each constant into an event mask and then OR the individual masks together. For example:

```
CGEventMask mask = CGEventMaskBit(kCGEventLeftMouseDown) |
                   CGEventMaskBit(kCGEventLeftMouseUp);
```

You can also supply a mask to observe all events:

```
CGEventMask mask = kCGEventMaskForAllEvents;
```

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGEventTypes.h`

CGEventRef

Defines an opaque type that represents a low-level hardware event.

```
typedef struct __CGEvent *CGEventRef;
```

Discussion
Low-level hardware events of this type are referred to as Quartz events. A typical event in Mac OS X originates when the user manipulates an input device such as a mouse or a keyboard. The device driver associated with that device, through the I/O Kit, creates a low-level event, puts it in the window server's event queue, and notifies the window server. The window server creates a Quartz event, annotates the event, and dispatches the event to the appropriate run-loop port of the target process. There the event is picked up by the Carbon Event Manager and forwarded to the event-handling mechanism appropriate to the application environment. You can use event taps to gain access to Quartz events at several different steps in this process.

This opaque type is derived from CFType and inherits the properties that all Core Foundation types have in common. For more information, see *CFType Reference*.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGEventTypes.h`

CGEventSourceKeyboardType

Defines a code that represents the type of keyboard used with a specified event source.

```
typedef uint32_t CGEventSourceKeyboardType;
```

Discussion
This code is the same keyboard type identifier used with the `UCKeyTranslate` function to drive keyboard translation.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGEventTypes.h`

CGEventSourceRef

Defines an opaque type that represents the source of a Quartz event.

```
typedef struct __CGEventSource * CGEventSourceRef;
```

Discussion
A Quartz event source is an object that contains accumulated state related to event generation and event posting. Every event source has an associated global event state table called a source state. When you call `CGEventSourceCreate` (page 1587) to create an event source, you specify which source state to use. For more information about source states, see "Event Source States" (page 1619).

A typical use of an event source would be to obtain the source from a Quartz event received by an event tap callback function, and then to use that source for any new events created as a result of the received event. This has the effect of marking the events as being related.

This opaque type is derived from CFType and inherits the properties that all Core Foundation types have in common. For more information, see *CFType Reference*.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGEventTypes.h`

CGEventTapInformation

Defines the structure used to report information about event taps.

```
typedef struct CGEventTapInformation
{
    uint32_t            eventTapID;
    CGEventTapLocation  tapPoint;
    CGEventTapOptions   options;
    CGEventMask         eventsOfInterest;
    pid_t               tappingProcess;
    pid_t               processBeingTapped;
    bool                enabled;
    float               minUsecLatency;
    float               avgUsecLatency;
    float               maxUsecLatency;
} CGEventTapInformation;
```

Fields

`eventTapID`
The unique identifier for the event tap.

`tapPoint`
The location of the event tap. See "Event Tap Locations" (page 1621).

`options`
The type of event tap (passive listener or active filter).

`eventsOfInterest`
The mask that identifies the set of events to be observed.

`tappingProcess`
The process ID of the application that created the event tap.

`processBeingTapped`
The process ID of the target application (non-zero only if the event tap was created using the function `CGEventTapCreateForPSN` (page 1597).

`enabled`
`TRUE` if the event tap is currently enabled; otherwise `FALSE`.

`minUsecLatency`
Minimum latency in microseconds. In this data structure, **latency** is defined as the time in microseconds it takes for an event tap to process and respond to an event passed to it.

`avgUsecLatency`
Average latency in microseconds. This is a weighted average that gives greater weight to more recent events.

`maxUsecLatency`
Maximum latency in microseconds.

Discussion

To learn how to obtain information about event taps, see the function `CGGetEventTapList` (page 1599).

Availability

Available in Mac OS X v10.4 and later.

Declared In

`CGEventTypes.h`

CGEventTapProxy

Defines an opaque type that represents state within the client application that's associated with an event tap.

```
typedef struct __CGEventTapProxy * CGEventTapProxy;
```

Discussion
An event tap proxy object is passed to your event tap callback function when it receives a new Quartz event. Your callback function needs the proxy to post Quartz events using the function `CGEventTapPostEvent` (page 1599).

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGEventTypes.h`

CGEventTimestamp

Defines the elapsed time in nanoseconds since startup that a Quartz event occurred.

```
typedef uint64_t CGEventTimestamp;
```

Discussion
An event timestamp is a big, unsigned, 64-bit number. That's big, really big. You just won't believe how vastly, hugely, mind-bogglingly big it is. You may think your application has been running for a long time, but that's just peanuts to an event timestamp.

For information about how event timestamps are used, see the functions `CGEventGetTimestamp` (page 1578) and `CGEventSetTimestamp` (page 1585).

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGEventTypes.h`

CGKeyCode

Represents the virtual key codes used in keyboard events.

```
typedef uint16_t CGKeyCode;
```

Discussion
In Mac OS X, the hardware scan codes generated by keyboards are mapped to a set of virtual key codes that are hardware-independent. Pressing a given key always generates the same virtual key code on any supported keyboard.

As keys are pressed, the system uses the virtual key codes to create low-level keyboard events. For information on how to simulate a keyboard event, see the function `CGEventCreateKeyboardEvent` (page 1573).

Availability
Available in Mac OS X v10.0 and later.

Declared In
CGRemoteOperation.h

CGWheelCount

Represents the number of wheels being set in a scroll wheel event.

```
typedef uint32_t CGWheelCount;
```

Discussion
See the function CGPostScrollWheelEvent (page 1602).

Availability
Available in Mac OS X v10.0 and later.

Declared In
CGRemoteOperation.h

Constants

Event Fields

Constants used as keys to access specialized fields in low-level events.

```
enum _CGEventField {
    kCGMouseEventNumber = 0,
    kCGMouseEventClickState = 1,
    kCGMouseEventPressure = 2,
    kCGMouseEventButtonNumber = 3,
    kCGMouseEventDeltaX = 4,
    kCGMouseEventDeltaY = 5,
    kCGMouseEventInstantMouser = 6,
    kCGMouseEventSubtype = 7,
    kCGKeyboardEventAutorepeat = 8,
    kCGKeyboardEventKeycode = 9,
    kCGKeyboardEventKeyboardType = 10,
    kCGScrollWheelEventDeltaAxis1 = 11,
    kCGScrollWheelEventDeltaAxis2 = 12,
    kCGScrollWheelEventDeltaAxis3 = 13,
    kCGScrollWheelEventFixedPtDeltaAxis1 = 93,
    kCGScrollWheelEventFixedPtDeltaAxis2 = 94,
    kCGScrollWheelEventFixedPtDeltaAxis3 = 95,
    kCGScrollWheelEventPointDeltaAxis1 = 96,
    kCGScrollWheelEventPointDeltaAxis2 = 97,
    kCGScrollWheelEventPointDeltaAxis3 = 98,
    kCGScrollWheelEventInstantMouser = 14,
    kCGTabletEventPointX = 15,
    kCGTabletEventPointY = 16,
    kCGTabletEventPointZ = 17,
    kCGTabletEventPointButtons = 18,
    kCGTabletEventPointPressure = 19,
    kCGTabletEventTiltX = 20,
    kCGTabletEventTiltY = 21,
    kCGTabletEventRotation = 22,
    kCGTabletEventTangentialPressure = 23,
    kCGTabletEventDeviceID = 24,
    kCGTabletEventVendor1 = 25,
    kCGTabletEventVendor2 = 26,
    kCGTabletEventVendor3 = 27,
    kCGTabletProximityEventVendorID = 28,
    kCGTabletProximityEventTabletID = 29,
    kCGTabletProximityEventPointerID = 30,
    kCGTabletProximityEventDeviceID = 31,
    kCGTabletProximityEventSystemTabletID = 32,
    kCGTabletProximityEventVendorPointerType = 33,
    kCGTabletProximityEventVendorPointerSerialNumber = 34,
    kCGTabletProximityEventVendorUniqueID = 35,
    kCGTabletProximityEventCapabilityMask = 36,
    kCGTabletProximityEventPointerType = 37,
    kCGTabletProximityEventEnterProximity = 38,
    kCGEventTargetProcessSerialNumber = 39,
    kCGEventTargetUnixProcessID = 40,
    kCGEventSourceUnixProcessID = 41,
    kCGEventSourceUserData = 42,
    kCGEventSourceUserID = 43,
    kCGEventSourceGroupID = 44,
    kCGEventSourceStateID = 45,
    kCGScrollWheelEventIsContinuous = 88
};
typedef uint32_t CGEventField;
```

Constants

`kCGMouseEventNumber`
Key to access an integer field that contains the mouse button event number. Matching mouse-down and mouse-up events will have the same event number.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGMouseEventClickState`
Key to access an integer field that contains the mouse button click state. A click state of 1 represents a single click. A click state of 2 represents a double-click. A click state of 3 represents a triple-click.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGMouseEventPressure`
Key to access a double field that contains the mouse button pressure. The pressure value may range from 0 to 1, with 0 representing the mouse being up. This value is commonly set by tablet pens mimicking a mouse.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGMouseEventButtonNumber`
Key to access an integer field that contains the mouse button number. For information about the possible values, see "Mouse Buttons" (page 1626).

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGMouseEventDeltaX`
Key to access an integer field that contains the horizontal mouse delta since the last mouse movement event.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGMouseEventDeltaY`
Key to access an integer field that contains the vertical mouse delta since the last mouse movement event.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGMouseEventInstantMouser`
Key to access an integer field. The value is non-zero if the event should be ignored by the Inkwell subsystem.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGMouseEventSubtype`
Key to access an integer field that encodes the mouse event subtype as a `kCFNumberIntType`.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGKeyboardEventAutorepeat`
Key to access an integer field, non-zero when this is an autorepeat of a key-down, and zero otherwise.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGKeyboardEventKeycode`
: Key to access an integer field that contains the virtual keycode of the key-down or key-up event.

  Available in Mac OS X v10.4 and later.

  Declared in `CGEventTypes.h`.

`kCGKeyboardEventKeyboardType`
: Key to access an integer field that contains the keyboard type identifier.

  Available in Mac OS X v10.4 and later.

  Declared in `CGEventTypes.h`.

`kCGScrollWheelEventDeltaAxis1`
: Key to access an integer field that contains scrolling data. This field typically contains the change in vertical position since the last scrolling event from a Mighty Mouse scroller or a single-wheel mouse scroller.

  Available in Mac OS X v10.4 and later.

  Declared in `CGEventTypes.h`.

`kCGScrollWheelEventDeltaAxis2`
: Key to access an integer field that contains scrolling data. This field typically contains the change in horizontal position since the last scrolling event from a Mighty Mouse scroller.

  Available in Mac OS X v10.4 and later.

  Declared in `CGEventTypes.h`.

`kCGScrollWheelEventDeltaAxis3`
: This field is not used.

  Available in Mac OS X v10.4 and later.

  Declared in `CGEventTypes.h`.

`kCGScrollWheelEventFixedPtDeltaAxis1`
: Key to access a field that contains scrolling data. The scrolling data represents a line-based or pixel-based change in vertical position since the last scrolling event from a Mighty Mouse scroller or a single-wheel mouse scroller. The scrolling data uses a fixed-point 16.16 signed integer format. For example, if the field contains a value of 1.0, the integer 0x00010000 is returned by `CGEventGetIntegerValueField`. If this key is passed to `CGEventGetDoubleValueField`, the fixed-point value is converted to a double value.

  Available in Mac OS X v10.5 and later.

  Declared in `CGEventTypes.h`.

`kCGScrollWheelEventFixedPtDeltaAxis2`
: Key to access a field that contains scrolling data. The scrolling data represents a line-based or pixel-based change in horizontal position since the last scrolling event from a Mighty Mouse scroller. The scrolling data uses a fixed-point 16.16 signed integer format. For example, if the field contains a value of 1.0, the integer 0x00010000 is returned by `CGEventGetIntegerValueField`. If this key is passed to `CGEventGetDoubleValueField`, the fixed-point value is converted to a double value.

  Available in Mac OS X v10.5 and later.

  Declared in `CGEventTypes.h`.

`kCGScrollWheelEventFixedPtDeltaAxis3`
: This field is not used.

  Available in Mac OS X v10.5 and later.

  Declared in `CGEventTypes.h`.

`kCGScrollWheelEventPointDeltaAxis1`
Key to access an integer field that contains pixel-based scrolling data. The scrolling data represents the change in vertical position since the last scrolling event from a Mighty Mouse scroller or a single-wheel mouse scroller.

Available in Mac OS X v10.5 and later.

Declared in `CGEventTypes.h`.

`kCGScrollWheelEventPointDeltaAxis2`
Key to access an integer field that contains pixel-based scrolling data. The scrolling data represents the change in horizontal position since the last scrolling event from a Mighty Mouse scroller.

Available in Mac OS X v10.5 and later.

Declared in `CGEventTypes.h`.

`kCGScrollWheelEventPointDeltaAxis3`
This field is not used.

Available in Mac OS X v10.5 and later.

Declared in `CGEventTypes.h`.

`kCGScrollWheelEventInstantMouser`
Key to access an integer field that indicates whether the event should be ignored by the Inkwell subsystem. If the value is non-zero, the event should be ignored.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGTabletEventPointX`
Key to access an integer field that contains the absolute X coordinate in tablet space at full tablet resolution.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGTabletEventPointY`
Key to access an integer field that contains the absolute Y coordinate in tablet space at full tablet resolution.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGTabletEventPointZ`
Key to access an integer field that contains the absolute Z coordinate in tablet space at full tablet resolution.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGTabletEventPointButtons`
Key to access an integer field that contains the tablet button state. Bit 0 is the first button, and a set bit represents a closed or pressed button. Up to 16 buttons are supported.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGTabletEventPointPressure`
Key to access a double field that contains the tablet pen pressure. A value of 0.0 represents no pressure, and 1.0 represents maximum pressure.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGTabletEventTiltX`
Key to access a double field that contains the horizontal tablet pen tilt. A value of 0.0 represents no tilt, and 1.0 represents maximum tilt.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGTabletEventTiltY`
Key to access a double field that contains the vertical tablet pen tilt. A value of 0.0 represents no tilt, and 1.0 represents maximum tilt.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGTabletEventRotation`
Key to access a double field that contains the tablet pen rotation.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGTabletEventTangentialPressure`
Key to access a double field that contains the tangential pressure on the device. A value of 0.0 represents no pressure, and 1.0 represents maximum pressure.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGTabletEventDeviceID`
Key to access an integer field that contains the system-assigned unique device ID.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGTabletEventVendor1`
Key to access an integer field that contains a vendor-specified value.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGTabletEventVendor2`
Key to access an integer field that contains a vendor-specified value.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGTabletEventVendor3`
Key to access an integer field that contains a vendor-specified value.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGTabletProximityEventVendorID`
Key to access an integer field that contains the vendor-defined ID, typically the USB vendor ID.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGTabletProximityEventTabletID`
Key to access an integer field that contains the vendor-defined tablet ID, typically the USB product ID.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGTabletProximityEventPointerID`
Key to access an integer field that contains the vendor-defined ID of the pointing device.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGTabletProximityEventDeviceID`
Key to access an integer field that contains the system-assigned device ID.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGTabletProximityEventSystemTabletID`
Key to access an integer field that contains the system-assigned unique tablet ID.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGTabletProximityEventVendorPointerType`
Key to access an integer field that contains the vendor-assigned pointer type.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGTabletProximityEventVendorPointerSerialNumber`
Key to access an integer field that contains the vendor-defined pointer serial number.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGTabletProximityEventVendorUniqueID`
Key to access an integer field that contains the vendor-defined unique ID.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGTabletProximityEventCapabilityMask`
Key to access an integer field that contains the device capabilities mask.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGTabletProximityEventPointerType`
Key to access an integer field that contains the pointer type.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGTabletProximityEventEnterProximity`
Key to access an integer field that indicates whether the pen is in proximity to the tablet. The value is non-zero if the pen is in proximity to the tablet and zero when leaving the tablet.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGEventTargetProcessSerialNumber`
Key to access a field that contains the event target process serial number. The value is a 64-bit long word.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGEventTargetUnixProcessID`
Key to access a field that contains the event target Unix process ID.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGEventSourceUnixProcessID`
Key to access a field that contains the event source Unix process ID.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGEventSourceUserData`
Key to access a field that contains the event source user-supplied data, up to 64 bits.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGEventSourceUserID`
Key to access a field that contains the event source Unix effective UID.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGEventSourceGroupID`
Key to access a field that contains the event source Unix effective GID.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGEventSourceStateID`
Key to access a field that contains the event source state ID used to create this event.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGScrollWheelEventIsContinuous`
Key to access an integer field that indicates whether a scrolling event contains continuous, pixel-based scrolling data. The value is non-zero when the scrolling data is pixel-based and zero when the scrolling data is line-based.

Available in Mac OS X v10.5 and later.

Declared in `CGEventTypes.h`.

Discussion
These constants are used as keys to access certain specialized event fields when using low-level accessor functions such as `CGEventGetIntegerValueField` (page 1577), `CGEventSetIntegerValueField` (page 1584), `CGEventGetDoubleValueField` (page 1576), and `CGEventSetDoubleValueField` (page 1583).

Event Filter Masks

Specify masks for classes of low-level events that can be filtered during event suppression states.

```
enum CGEventFilterMask {
    kCGEventFilterMaskPermitLocalMouseEvents = 0x00000001,
    kCGEventFilterMaskPermitLocalKeyboardEvents = 0x00000002,
    kCGEventFilterMaskPermitSystemDefinedEvents = 0x00000004,
    kCGEventFilterMaskPermitAllEvents = kCGEventFilterMaskPermitLocalMouseEvents
 | kCGEventFilterMaskPermitLocalKeyboardEvents |
kCGEventFilterMaskPermitSystemDefinedEvents
};
typedef uint32_t CGEventFilterMask;
```

Event Flags

Constants that indicate the modifier key state at the time an event is created, as well as other event-related states.

```
enum _CGEventFlags {
    kCGEventFlagMaskAlphaShift =    NX_ALPHASHIFTMASK,
    kCGEventFlagMaskShift =         NX_SHIFTMASK,
    kCGEventFlagMaskControl =       NX_CONTROLMASK,
    kCGEventFlagMaskAlternate =     NX_ALTERNATEMASK,
    kCGEventFlagMaskCommand =       NX_COMMANDMASK,
    kCGEventFlagMaskHelp =          NX_HELPMASK,
    kCGEventFlagMaskSecondaryFn =   NX_SECONDARYFNMASK,
    kCGEventFlagMaskNumericPad =    NX_NUMERICPADMASK,
    kCGEventFlagMaskNonCoalesced =  NX_NONCOALSESCEDMASK
};
typedef uint64_t CGEventFlags;
```

Constants

`kCGEventFlagMaskAlphaShift`
Indicates that the Caps Lock key is down for a keyboard, mouse, or flag-changed event.
Available in Mac OS X v10.4 and later.
Declared in `CGEventTypes.h`.

`kCGEventFlagMaskShift`
Indicates that the Shift key is down for a keyboard, mouse, or flag-changed event.
Available in Mac OS X v10.4 and later.
Declared in `CGEventTypes.h`.

`kCGEventFlagMaskControl`
Indicates that the Control key is down for a keyboard, mouse, or flag-changed event.
Available in Mac OS X v10.4 and later.
Declared in `CGEventTypes.h`.

`kCGEventFlagMaskAlternate`
Indicates that the Alt or Option key is down for a keyboard, mouse, or flag-changed event.
Available in Mac OS X v10.4 and later.
Declared in `CGEventTypes.h`.

`kCGEventFlagMaskCommand`
Indicates that the Command key is down for a keyboard, mouse, or flag-changed event.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGEventFlagMaskHelp`
Indicates that the Help modifier key is down for a keyboard, mouse, or flag-changed event. This key is not present on most keyboards, and is different than the Help key found in the same row as Home and Page Up.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGEventFlagMaskSecondaryFn`
Indicates that the Fn (Function) key is down for a keyboard, mouse, or flag-changed event. This key is found primarily on laptop keyboards.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGEventFlagMaskNumericPad`
Identifies key events from the numeric keypad area on extended keyboards.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGEventFlagMaskNonCoalesced`
Indicates that mouse and pen movement events are not being coalesced.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

Discussion
These constants specify masks for the bits in an event flags bit mask. Event flags indicate the modifier key state at the time an event is created, as well as other event-related states. Event flags are used in accessor functions such as `CGEventGetFlags` (page 1577), `CGEventSetFlags` (page 1583), and `CGEventSourceFlagsState` (page 1588).

Event Source States

Constants that specify the possible source states of an event source.

```
enum {
    kCGEventSourceStatePrivate = -1,
    kCGEventSourceStateCombinedSessionState = 0,
    kCGEventSourceStateHIDSystemState = 1
};
typedef uint32_t CGEventSourceStateID;
```

Constants
`kCGEventSourceStatePrivate`
Specifies that an event source should use a private event state table.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGEventSourceStateCombinedSessionState`
: Specifies that an event source should use the event state table that reflects the combined state of all event sources posting to the current user login session.

  Available in Mac OS X v10.4 and later.

  Declared in `CGEventTypes.h`.

`kCGEventSourceStateHIDSystemState`
: Specifies that an event source should use the event state table that reflects the combined state of all hardware event sources posting from the HID system.

  Available in Mac OS X v10.4 and later.

  Declared in `CGEventTypes.h`.

Discussion
A source state refers to a global event state table. These tables contain accumulated information on modifier flag state, keyboard key state, mouse button state, and related internal parameters placed in effect by posting events with associated sources.

Two pre-existing event state tables are defined:

- The `kCGEventSourceStateCombinedSessionState` table reflects the combined state of all event sources posting to the current user login session. If your program is posting events from within a login session, you should use this source state when you create an event source.
- The `kCGEventSourceStateHIDSystemState` table reflects the combined state of all hardware event sources posting from the HID system. If your program is a daemon or a user space device driver interpreting hardware state and generating events, you should use this source state when you create an event source.

Specialized applications such as remote control programs may want to generate and track event source state independent of other processes. These programs should use the `kCGEventSourceStatePrivate` value in creating their event source. An independent state table and unique source state ID (`CGEventSourceStateID`) are created to track the event source's state. This independent state table is owned by the creating event source and released with it.

Event Source Token

Specifies any input event type.

```
#define kCGAnyInputEventType ((CGEventType)(~0))
```

Constants
`kCGAnyInputEventType`
: A constant that specifies any input event type.

  Available in Mac OS X v10.4 and later.

  Declared in `CGEventTypes.h`.

Discussion
This constant is typically used with the function `CGEventSourceSecondsSinceLastEventType` (page 1592) to specify that you want the elapsed time since the last input event of any type.

Event Suppression States

Specify the event suppression states that can occur after posting an event.

```
enum CGEventSuppressionState {
    kCGEventSuppressionStateSuppressionInterval = 0,
    kCGEventSuppressionStateRemoteMouseDrag = 1,
    kCGNumberOfEventSuppressionStates = 2
};
typedef uint32_t CGEventSuppressionState;
```

Constants

`kCGEventSuppressionStateSuppressionInterval`

Specifies that certain local hardware events may be suppressed for a short interval after posting an event.

Available in Mac OS X v10.3 and later.

Declared in `CGRemoteOperation.h`.

`kCGEventSuppressionStateRemoteMouseDrag`

Specifies that certain local hardware events may be suppressed during a mouse drag operation (mouse movement with the left or only mouse button down).

Available in Mac OS X v10.3 and later.

Declared in `CGRemoteOperation.h`.

Discussion

These constants specify the types of event suppression intervals during which an event filter is applied after posting an event.

Event Tap Locations

Constants that specify possible tapping points for events.

```
enum _CGEventTapLocation {
    kCGHIDEventTap = 0,
    kCGSessionEventTap,
    kCGAnnotatedSessionEventTap
};
typedef uint32_t CGEventTapLocation;
```

Constants

`kCGHIDEventTap`

Specifies that an event tap is placed at the point where HID system events enter the window server.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGSessionEventTap`

Specifies that an event tap is placed at the point where HID system and remote control events enter a login session.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGAnnotatedSessionEventTap`
: Specifies that an event tap is placed at the point where session events have been annotated to flow to an application.

  Available in Mac OS X v10.4 and later.

  Declared in `CGEventTypes.h`.

Discussion
In addition to the three tapping points described above, an event tap may also be placed where annotated events are delivered to a specific application. For more information, see the function `CGEventTapCreateForPSN` (page 1597).

Event Tap Options

Constants that specify whether a new event tap is an active filter or a passive listener.

```
enum _CGEventTapOptions {
    kCGEventTapOptionDefault = 0x00000000,
    kCGEventTapOptionListenOnly = 0x00000001
};
typedef uint32_t CGEventTapOptions;
```

Constants
`kCGEventTapOptionDefault`
: Specifies that a new event tap is an active filter. (Applications targeting Mac OS X v10.4 should use the literal value to create an active filter event tap, as this constant was omitted from the header.)

  Available in Mac OS X v10.5 and later.

  Declared in `CGEventTypes.h`.

`kCGEventTapOptionListenOnly`
: Specifies that a new event tap is a passive listener.

  Available in Mac OS X v10.4 and later.

  Declared in `CGEventTypes.h`.

Discussion
When you create an event tap, you indicate whether it is a passive listener or active event filter. A passive listener receives events but cannot modify or divert them. An active filter may pass an event through unmodified, modify an event, or discard an event.

Event Tap Placement

Constants that specify where a new event tap is inserted into the list of active event taps.

```
enum _CGEventTapPlacement {
    kCGHeadInsertEventTap = 0,
    kCGTailAppendEventTap
};
typedef uint32_t CGEventTapPlacement;
```

Constants

`kCGHeadInsertEventTap`
Specifies that a new event tap should be inserted before any pre-existing event taps at the same location.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGTailAppendEventTap`
Specifies that a new event tap should be inserted after any pre-existing event taps at the same location.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

Discussion
Event taps may be inserted at a specified location at the head of pre-existing filters, or appended after any pre-existing filters.

Event Types

Constants that specify the different types of input events.

```
enum _CGEventType {
    kCGEventNull                = NX_NULLEVENT,
    kCGEventLeftMouseDown       = NX_LMOUSEDOWN,
    kCGEventLeftMouseUp         = NX_LMOUSEUP,
    kCGEventRightMouseDown      = NX_RMOUSEDOWN,
    kCGEventRightMouseUp        = NX_RMOUSEUP,
    kCGEventMouseMoved          = NX_MOUSEMOVED,
    kCGEventLeftMouseDragged    = NX_LMOUSEDRAGGED,
    kCGEventRightMouseDragged   = NX_RMOUSEDRAGGED,
    kCGEventKeyDown             = NX_KEYDOWN,
    kCGEventKeyUp               = NX_KEYUP,
    kCGEventFlagsChanged        = NX_FLAGSCHANGED,
    kCGEventScrollWheel         = NX_SCROLLWHEELMOVED,
    kCGEventTabletPointer       = NX_TABLETPOINTER,
    kCGEventTabletProximity     = NX_TABLETPROXIMITY,
    kCGEventOtherMouseDown      = NX_OMOUSEDOWN,
    kCGEventOtherMouseUp        = NX_OMOUSEUP,
    kCGEventOtherMouseDragged   = NX_OMOUSEDRAGGED,
    kCGEventTapDisabledByTimeout = 0xFFFFFFFE,
    kCGEventTapDisabledByUserInput = 0xFFFFFFFF
};
typedef uint32_t CGEventType;
```

Constants

`kCGEventNull`
Specifies a null event.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGEventLeftMouseDown`
Specifies a mouse down event with the left button.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGEventLeftMouseUp`
Specifies a mouse up event with the left button.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGEventRightMouseDown`
Specifies a mouse down event with the right button.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGEventRightMouseUp`
Specifies a mouse up event with the right button.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGEventMouseMoved`
Specifies a mouse moved event.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGEventLeftMouseDragged`
Specifies a mouse drag event with the left button down.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGEventRightMouseDragged`
Specifies a mouse drag event with the right button down.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGEventKeyDown`
Specifies a key down event.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGEventKeyUp`
Specifies a key up event.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGEventFlagsChanged`
Specifies a key changed event for a modifier or status key.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGEventScrollWheel`
Specifies a scroll wheel moved event.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGEventTabletPointer`
Specifies a tablet pointer event.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGEventTabletProximity`
Specifies a tablet proximity event.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGEventOtherMouseDown`
Specifies a mouse down event with one of buttons 2-31.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGEventOtherMouseUp`
Specifies a mouse up event with one of buttons 2-31.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGEventOtherMouseDragged`
Specifies a mouse drag event with one of buttons 2-31 down.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGEventTapDisabledByTimeout`
Specifies an event indicating the event tap is disabled because of timeout.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGEventTapDisabledByUserInput`
Specifies an event indicating the event tap is disabled because of user input.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

Discussion
These constants are used:

- In the functions `CGEventTapCreate` (page 1595) and `CGEventTapCreateForPSN` (page 1597) to specify the events of interest for the new event tap.
- To indicate the event type passed to your event tap callback function.
- In the function `CGEventCreateMouseEvent` (page 1574) to specify the type of mouse event.
- In the functions `CGEventGetType` (page 1579) and `CGEventSetType` (page 1586) to identify the event type.
- In the functions `CGEventSourceCounterForEventType` (page 1587) and `CGEventSourceSecondsSinceLastEventType` (page 1592) to indicate the event type.

Note that tablet devices may generate mouse events with embedded tablet data, or tablet pointer and proximity events. Tablet mouse events allow tablets to be used with applications that are not tablet-aware.

Event Type Mask

Specifies an event mask that represents all event types.

```
#define kCGEventMaskForAllEvents (~(CGEventMask)0)
```

Constants

`kCGEventMaskForAllEvents`

An event mask that specifies all event types.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

Discussion

This constant is typically used with the functions `CGEventTapCreate` (page 1595) and `CGEventTapCreateForPSN` (page 1597) to register an event tap that observes all input events.

Mouse Buttons

Constants that specify buttons on a one, two, or three-button mouse.

```
enum _CGMouseButton {
    kCGMouseButtonLeft = 0,
    kCGMouseButtonRight = 1,
    kCGMouseButtonCenter = 2
};
typedef uint32_t CGMouseButton;
```

Constants

`kCGMouseButtonLeft`

Specifies the only mouse button on a one-button mouse, or the left mouse button on a two-button or three-button mouse.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGMouseButtonRight`

Specifies the right mouse button on a two-button or three-button mouse.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGMouseButtonCenter`

Specifies the center mouse button on a three-button mouse.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

Discussion

Quartz supports up to 32 mouse buttons. The first three buttons are specified using these three constants. Additional buttons are specified in USB order using the integers 3 to 31.

These constants are used:

- In the function `CGEventCreateMouseEvent` (page 1574) to specify the button that's changing state.
- In the function `CGEventSourceButtonState` (page 1586) to specify the button that's being tested.
- To specify the value of the `kCGMouseEventButtonNumber` event field when modifying an event.

Mouse Subtypes

Constants used with the `kCGMouseEventSubtype` event field.

```
enum _CGEventMouseSubtype {
    kCGEventMouseSubtypeDefault = 0,
    kCGEventMouseSubtypeTabletPoint = 1,
    kCGEventMouseSubtypeTabletProximity = 2
};
typedef uint32_t CGEventMouseSubtype;
```

Constants

`kCGEventMouseSubtypeDefault`
Specifies that the event is an ordinary mouse event, and does not contain additional tablet device information.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGEventMouseSubtypeTabletPoint`
Specifies that the mouse event originated from a tablet device, and that the various `kCGTabletEvent` field selectors may be used to obtain tablet-specific data from the mouse event.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

`kCGEventMouseSubtypeTabletProximity`
Specifies that the mouse event originated from a tablet device with the pen in proximity but not necessarily touching the tablet, and that the various `kCGTabletProximity` field selectors may be used to obtain tablet-specific data from the mouse event. This is often used with mouse move events originating from a tablet.

Available in Mac OS X v10.4 and later.

Declared in `CGEventTypes.h`.

Discussion

Tablets may generate specially annotated mouse events that contain values associated with the `kCGMouseEventSubtype` event field. To learn how to set these values, see the function `CGEventSetIntegerValueField` (page 1584).

Scrolling Event Units

Constants that specify the unit of measurement for a scrolling event.

```
enum {
    kCGScrollEventUnitPixel = 0,
    kCGScrollEventUnitLine = 1
};
typedef uint32_t CGScrollEventUnit;
```

Constants

`kCGScrollEventUnitPixel`

Specifies that the unit of measurement is pixels.

Available in Mac OS X v10.5 and later.

Declared in `CGEventTypes.h`.

`kCGScrollEventUnitLine`

Specifies that the unit of measurement is lines.

Available in Mac OS X v10.5 and later.

Declared in `CGEventTypes.h`.

Discussion

You may pass one of these constants to the function `CGEventCreateScrollWheelEvent` (page 1575) to specify the unit of measurement for the event. The constant `kCGScrollEventUnitPixel` produces an event that most applications interpret as a smooth scrolling event. By default, the scale is about ten pixels per line. You can alter the scale with the function `CGEventSourceSetPixelsPerLine` (page 1594).

Speech Synthesis Manager Reference

Framework: ApplicationServices/ApplicationServices.h
Declared in SpeechSynthesis.h

Overview

The Speech Synthesis Manager, formerly called the Speech Manager, is the part of the Mac OS that provides a standardized method for Macintosh applications to generate synthesized speech. For example, you may want your application to incorporate the capability to speak its dialog box messages to the user. A word-processing application might use the Speech Synthesis Manager to implement a command that speaks a selected section of a document to the user. Because sound samples can take up large amounts of room on disk, using text in place of sampled sound is extremely efficient, and so a multimedia application might use the Speech Synthesis Manager to provide a narration of a QuickTime movie instead of including sampled-sound data on a movie track.

Mac OS X v10.5 introduces native support for performing speech synthesis tasks using Core Foundation-based objects, such as speaking text represented as `CFString` objects and managing speech channel properties using a `CFDictionary`-based property dictionary. You should begin using the new, Core Foundation-based programming interfaces as soon as it's convenient, because future synthesizers will accept Core Foundation strings and data structures directly through the speech synthesis framework. In the meantime, existing buffer-based clients and synthesizers will continue to work as before, with strings and other data structures getting automatically converted as necessary.

Functions by Task

Changing Speech Attributes

`SetSpeechInfo` (page 1650)
Changes a setting of a particular speech channel.

`SetSpeechProperty` (page 1651)
Sets the value of the specified speech-channel property.

`SetSpeechPitch` (page 1651)
Sets the speech pitch on a designated speech channel.

`SetSpeechRate` (page 1652)
Sets the speech rate of a designated speech channel.

Converting Text To Phonemes

`TextToPhonemes` (page 1659)
Converts a buffer of textual data into phonemic data.

`CopyPhonemesFromText` (page 1633) Deprecated in Mac OS X v10.4
Converts the specified text string into its equivalent phonemic representation.

Installing a Pronunciation Dictionary

`UseDictionary` (page 1660)
Installs the designated dictionary into a speech channel.

`UseSpeechDictionary` (page 1661)
Registers a speech dictionary with a speech channel.

Managing Speech Channels

`DisposeSpeechChannel` (page 1635)
Disposes of an existing speech channel.

`NewSpeechChannel` (page 1646)
Creates a new speech channel.

Obtaining Information About Speech and Speech Channels

`CopySpeechProperty` (page 1634)
Gets the value associated with the specified property of a speech channel.

`GetSpeechInfo` (page 1638)
Gets information about a designated speech channel.

`GetSpeechPitch` (page 1639)
Gets a speech channel's current speech pitch.

`GetSpeechRate` (page 1640)
Gets a speech channel's current speech rate.

`SpeechBusy` (page 1656)
Determines whether any channels of speech are currently synthesizing speech.

`SpeechBusySystemWide` (page 1656)
Determines if any speech is currently being synthesized in your application or elsewhere on the computer.

`SpeechManagerVersion` (page 1657)
Determines the current version of the Speech Synthesis Manager installed in the system.

Getting Information About Voices

`CountVoices` (page 1634)
Determines how many voices are available.

`GetIndVoice` (page 1638)
Gets a voice specification structure for a voice by passing an index to the `GetIndVoice` function.

`GetVoiceDescription` (page 1640)
Gets a description of a voice by using the `GetVoiceDescription` function.

`GetVoiceInfo` (page 1641)
Gets the same information about a voice that the `GetVoiceDescription` function provides, or to determine in which file and resource a voice is stored.

`MakeVoiceSpec` (page 1645)
Sets the fields of a voice specification structure.

Starting, Stopping, and Pausing Speech

`ContinueSpeech` (page 1632)
Resumes speech paused by the `PauseSpeechAt` function.

`PauseSpeechAt` (page 1649)
Pauses speech on a speech channel.

`SpeakBuffer` (page 1652)
Speaks a buffer of text, using certain flags to control speech behavior.

`SpeakString` (page 1654)
Begins speaking a text string.

`SpeakText` (page 1655)
Begins speaking a buffer of text.

`StopSpeech` (page 1657)
Terminates speech immediately on the specified channel.

`StopSpeechAt` (page 1658)
Terminates speech delivery on a specified channel either immediately or at the end of the current word or sentence.

`SpeakCFString` (page 1653) Deprecated in Mac OS X v10.5
Begins speaking a string represented as a `CFString` object.

Creating, Invoking, and Disposing Universal Procedure Pointers

`DisposeSpeechDoneUPP` (page 1635)
Disposes of a universal procedure pointer (UPP) to a speech-done callback function.

`DisposeSpeechErrorUPP` (page 1636)
Disposes of a universal procedure pointer (UPP) to an error callback function.

`DisposeSpeechPhonemeUPP` (page 1636)
Disposes of a universal procedure pointer (UPP) to a phoneme callback function.

`DisposeSpeechSyncUPP` (page 1637)
Disposes of a universal procedure pointer (UPP) to a synchronization callback function.

`DisposeSpeechTextDoneUPP` (page 1637)
Disposes of a universal procedure pointer (UPP) to a text-done callback function.

`DisposeSpeechWordUPP` (page 1637)
Disposes of a universal procedure pointer (UPP) to a word callback function.

`InvokeSpeechDoneUPP` (page 1642)
Invokes your speech-done callback function.

`InvokeSpeechErrorUPP` (page 1643)
Invokes your error callback function.

`InvokeSpeechPhonemeUPP` (page 1643)
Invokes your phoneme callback function.

`InvokeSpeechSyncUPP` (page 1644)
Invokes your synchronization callback function.

`InvokeSpeechTextDoneUPP` (page 1644)
Invokes your text-done callback function.

`InvokeSpeechWordUPP` (page 1645)
Invokes your word callback function.

`NewSpeechDoneUPP` (page 1646)
Creates a new universal procedure pointer (UPP) to a speech-done callback function.

`NewSpeechErrorUPP` (page 1647)
Creates a new universal procedure pointer to an error callback function.

`NewSpeechPhonemeUPP` (page 1647)
Disposes of a universal procedure pointer (UPP) to a phoneme callback function.

`NewSpeechSyncUPP` (page 1648)
Creates a new universal procedure pointer (UPP) to a synchronization callback function.

`NewSpeechTextDoneUPP` (page 1648)
Creates a new universal procedure pointer (UPP) to a text-done callback function.

`NewSpeechWordUPP` (page 1649)
Creates a new universal procedure pointer (UPP) to a word callback function.

Functions

ContinueSpeech

Resumes speech paused by the `PauseSpeechAt` function.

```
OSErr ContinueSpeech (
   SpeechChannel chan
);
```

Parameters

chan
The paused speech channel on which speech is to be resumed.

Return Value

A result code. See "Speech Synthesis Manager Result Codes" (page 1705).

Discussion
At any time after the `PauseSpeechAt` function is called, the `ContinueSpeech` function can be called to continue speaking from the beginning of the word in which speech paused. Calling `ContinueSpeech` on a channel that is not currently in a paused state has no effect on the speech channel or on future calls to the `PauseSpeechAt` function. If you call `ContinueSpeech` on a channel before a pause is effective, `ContinueSpeech` cancels the pause.

If the `PauseSpeechAt` function stopped speech in the middle of a word, the Speech Synthesis Manager will start speaking that word from the beginning when you call `ContinueSpeech`.

Availability
Available in CarbonLib 1.0 and later when Text to Speech 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechSynthesis.h`

CopyPhonemesFromText

Converts the specified text string into its equivalent phonemic representation.

```
OSErr CopyPhonemesFromText (
   SpeechChannel chan,
   CFStringRef text,
   CFStringRef * phonemes
);
```

Parameters

chan
A speech channel whose associated synthesizer and properties are to be used in the conversion process.

text
The text from which to extract phonemic data.

phonemes
On return, a `CFString` object that contains the extracted phonemic data. The caller is responsible for releasing this object.

Return Value
A result code. See "Speech Synthesis Manager Result Codes" (page 1705).

Discussion
The `CopyPhonemesFromText` function is the Core Foundation-based equivalent of the `TextToPhonemes` (page 1659) function.

Converting textual data into phonemic data is particularly useful during application development, when you might wish to adjust phrases that your application generates to produce smoother speech. By first converting the target phrase into phonemes, you can see what the synthesizer will try to speak. Then you need correct only the parts that would not have been spoken the way you want.

The data the `CopyPhonemesFromText` function stores in the `phonemes` parameter corresponds precisely to the phonemes that would be spoken had the input text been sent to `SpeakCFString` instead. All current property settings for the speech channel specified by `chan` are applied to the converted speech. No callbacks are generated while the `CopyPhonemesFromText` function is generating its output.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`SpeechSynthesis.h`

CopySpeechProperty

Gets the value associated with the specified property of a speech channel.

```
OSErr CopySpeechProperty (
   SpeechChannel chan,
   CFStringRef property,
   CFTypeRef * object
);
```

Parameters

chan

The speech channel with which the specified property is associated.

property

A speech-channel property about which information is being requested. See "`Speech-Channel Properties`" (page 1692) for information on the properties you can specify.

object

On return, a pointer to a Core Foundation object that holds the value of the specified property. The type of the object depends on the specific property passed in. For some properties, the value of *object* can be `NULL`. When the returned object is a `CFDictionary` object, you can use `CFDictionary` functions, such as `CFDictionaryGetValue`, to retrieve the values associated with the keys that are associated with the specified property.

Return Value
A result code. See "Speech Synthesis Manager Result Codes" (page 1705).

Discussion
The `CopySpeechProperty` function is the Core Foundation-based equivalent of the `GetSpeechInfo` (page 1638) function.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`SpeechSynthesis.h`

CountVoices

Determines how many voices are available.

```
OSErr CountVoices (
   SInt16 *numVoices
);
```

Parameters

numVoices

On exit, a pointer to the number of voices that the application can use.

Return Value
A result code. See "Speech Synthesis Manager Result Codes" (page 1705).

Discussion
The `CountVoices` function returns, in the `numVoices` parameter, the number of voices available. The application can then use this information to call the `GetIndVoice` function to obtain voice specification structures for one or more of the voices.

Each time `CountVoices` is called, the Speech Synthesis Manager searches for new voices.

Availability
Available in CarbonLib 1.0 and later when Text to Speech 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechSynthesis.h`

DisposeSpeechChannel

Disposes of an existing speech channel.

```
OSErr DisposeSpeechChannel (
   SpeechChannel chan
);
```

Parameters

chan
The speech channel to dispose of.

Return Value
A result code. See "Speech Synthesis Manager Result Codes" (page 1705).

Discussion
The `DisposeSpeechChannel` function disposes of the speech channel specified in the `chan` parameter and releases all memory the channel occupies. If the speech channel specified is producing speech, then the `DisposeSpeechChannel` function immediately stops speech before disposing of the channel. If you have defined a text-done callback function or a speech-done callback function, the function will not be called before the channel is disposed of.

The Speech Synthesis Manager releases any speech channels that have not been explicitly disposed of by an application when the application quits. In general, however, your application should dispose of any speech channels it has created whenever it receives a suspend event. This ensures that other applications can take full advantage of Speech Synthesis Manager and Sound Manager capabilities.

Availability
Available in CarbonLib 1.0 and later when Text to Speech 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechSynthesis.h`

DisposeSpeechDoneUPP

Disposes of a universal procedure pointer (UPP) to a speech-done callback function.

```
void DisposeSpeechDoneUPP (
   SpeechDoneUPP userUPP
);
```

Parameters

userUPP

The UPP to dispose of.

Availability

Available in CarbonLib 1.0.2 and later.

Available in Mac OS X 10.0 and later.

Declared In

`SpeechSynthesis.h`

DisposeSpeechErrorUPP

Disposes of a universal procedure pointer (UPP) to an error callback function.

```
void DisposeSpeechErrorUPP (
   SpeechErrorUPP userUPP
);
```

Parameters

userUPP

The UPP to dispose of.

Availability

Available in CarbonLib 1.0.2 and later.

Available in Mac OS X 10.0 and later.

Declared In

`SpeechSynthesis.h`

DisposeSpeechPhonemeUPP

Disposes of a universal procedure pointer (UPP) to a phoneme callback function.

```
void DisposeSpeechPhonemeUPP (
   SpeechPhonemeUPP userUPP
);
```

Parameters

userUPP

The UPP to dispose of.

Availability

Available in CarbonLib 1.0.2 and later.

Available in Mac OS X 10.0 and later.

Declared In

`SpeechSynthesis.h`

DisposeSpeechSyncUPP

Disposes of a universal procedure pointer (UPP) to a synchronization callback function.

```
void DisposeSpeechSyncUPP (
   SpeechSyncUPP userUPP
);
```

Parameters

userUPP

The UPP to dispose of.

Availability

Available in CarbonLib 1.0.2 and later.

Available in Mac OS X 10.0 and later.

Declared In

SpeechSynthesis.h

DisposeSpeechTextDoneUPP

Disposes of a universal procedure pointer (UPP) to a text-done callback function.

```
void DisposeSpeechTextDoneUPP (
   SpeechTextDoneUPP userUPP
);
```

Parameters

userUPP

The UPP to dispose of.

Availability

Available in CarbonLib 1.0.2 and later.

Available in Mac OS X 10.0 and later.

Declared In

SpeechSynthesis.h

DisposeSpeechWordUPP

Disposes of a universal procedure pointer (UPP) to a word callback function.

```
void DisposeSpeechWordUPP (
   SpeechWordUPP userUPP
);
```

Parameters

userUPP

The UPP to dispose of.

Availability

Available in CarbonLib 1.0.2 and later.

Available in Mac OS X 10.0 and later.

Declared In
SpeechSynthesis.h

GetIndVoice

Gets a voice specification structure for a voice by passing an index to the GetIndVoice function.

```
OSErr GetIndVoice (
   SInt16 index,
   VoiceSpec *voice
);
```

Parameters

index

The index of the voice for which to obtain a voice specification structure. This number must range from 1 to the total number of voices, as returned by the CountVoices function.

voice

A pointer to the voice specification structure whose fields are to be filled in.

Return Value
A result code. See "Speech Synthesis Manager Result Codes" (page 1705).

Discussion
The GetIndVoice function returns, in the voice specification structure pointed to by the voice parameter, a specification of the voice whose index is provided in the index parameter. Your application should make no assumptions about the order in which voices are indexed.

Your application should not add, remove, or modify a voice and then call the GetIndVoice function with an index value other than 1. To allow the Speech Synthesis Manager to update its information about voices, your application should always either call the CountVoices function or call the GetIndVoice function with an index value of 1 after adding, removing, or modifying a voice or after a time at which the user might have done so.

If you specify an index value beyond the number of available voices, the GetIndVoice function returns a voiceNotFound error.

Availability
Available in CarbonLib 1.0 and later when Text to Speech 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
SpeechSynthesis.h

GetSpeechInfo

Gets information about a designated speech channel.

```
OSErr GetSpeechInfo (
   SpeechChannel chan,
   OSType selector,
   void *speechInfo
);
```

Parameters

chan

The speech channel about which information is being requested.

selector

A speech information selector that indicates the type of information being requested.

For a complete list of speech information selectors, see "Speech-Channel Information Constants" (page 1685). This list indicates how your application should set the `speechInfo` parameter for each selector.

speechInfo

A pointer whose meaning depends on the speech information selector specified in the `selector` parameter.

Return Value

A result code. See "Speech Synthesis Manager Result Codes" (page 1705).

Discussion

The `GetSpeechInfo` function returns, in the data structure pointed to by the `speechInfo` parameter, the type of information requested by the `selector` parameter as it applies to the speech channel specified in the `chan` parameter.

The format of the data structure specified by the `speechInfo` parameter depends on the selector you choose. For example, a selector might require that your application allocate a block of memory of a certain size and pass a pointer to that block. Another selector might require that `speechInfo` be set to the address of a handle variable. In this case, the `GetSpeechInfo` function would allocate a relocatable block of memory and change the handle variable specified to reference the block.

Availability

Available in CarbonLib 1.0 and later when Text to Speech 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Declared In

`SpeechSynthesis.h`

GetSpeechPitch

Gets a speech channel's current speech pitch.

```
OSErr GetSpeechPitch (
   SpeechChannel chan,
   Fixed *pitch
);
```

Parameters

chan

The speech channel whose pitch you wish to determine.

pitch

On return, a pointer to the current pitch of the voice in the speech channel, expressed as a fixed-point frequency value.

Return Value
A result code. See "Speech Synthesis Manager Result Codes" (page 1705).

Discussion
Typical voice frequencies range from around 90 hertz for a low-pitched male voice to perhaps 300 hertz for a high-pitched child's voice. These frequencies correspond to approximate pitch values in the ranges of 30.000 to 40.000 and 55.000 to 65.000, respectively.

Availability
Available in CarbonLib 1.0 and later when Text to Speech 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechSynthesis.h`

GetSpeechRate

Gets a speech channel's current speech rate.

```
OSErr GetSpeechRate (
   SpeechChannel chan,
   Fixed *rate
);
```

Parameters

chan
The speech channel whose rate you wish to determine.

rate
On return, a pointer to the speech channel's speech rate in words per minute, expressed as an integer value.

Return Value
A result code. See "Speech Synthesis Manager Result Codes" (page 1705).

Availability
Available in CarbonLib 1.0 and later when Text to Speech 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechSynthesis.h`

GetVoiceDescription

Gets a description of a voice by using the `GetVoiceDescription` function.

```
OSErr GetVoiceDescription (
   const VoiceSpec *voice,
   VoiceDescription *info,
   long infoLength
);
```

Parameters

voice

A pointer to the voice specification structure identifying the voice to be described, or `NULL` to obtain a description of the system default voice.

info

A pointer to a voice description structure. If this parameter is `NULL`, the function does not fill in the fields of the voice description structure; instead, it simply determines whether the `voice` parameter specifies an available voice and, if not, returns a `voiceNotFound` error.

infoLength

The length, in bytes, of the voice description structure. In the current version of the Speech Synthesis Manager, the voice description structure contains 362 bytes. However, you should always use the `SizeOf` function to determine the length of this structure.

Return Value

A result code. See "Speech Synthesis Manager Result Codes" (page 1705).

Discussion

The `GetVoiceDescription` function fills out the voice description structure pointed to by the `info` parameter with the correct information for the voice specified by the `voice` parameter. It fills in the `length` field of the voice description structure with the number of bytes actually copied. This value will always be less than or equal to the value that your application passes in `infoLength` before calling `GetVoiceDescription`. This scheme allows applications targeted for the current version of the Speech Synthesis Manager to work on future versions that might have longer voice description structures; it also allows you to write code for future versions of the Speech Synthesis Manager that will also run on computers that support only the current version.

If the voice specification structure does not identify an available voice, `GetVoiceDescription` returns a `voiceNotFound` error.

Availability

Available in CarbonLib 1.0 and later when Text to Speech 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Declared In

`SpeechSynthesis.h`

GetVoiceInfo

Gets the same information about a voice that the `GetVoiceDescription` function provides, or to determine in which file and resource a voice is stored.

```
OSErr GetVoiceInfo (
   const VoiceSpec *voice,
   OSType selector,
   void *voiceInfo
);
```

Parameters

voice

A pointer to the voice specification structure identifying the voice about which your application requires information, or `NULL` to obtain information on the system default voice.

selector

A specification of the type of data being requested. For current versions of the Speech Synthesis Manager, you should set this field either to `soVoiceDescription`, if you would like to use the `GetVoiceInfo` function to mimic the `GetVoiceDescription` function, or to `soVoiceFile`, if you would like to obtain information about the location of a voice on disk.

voiceInfo

A pointer to the appropriate data structure. If the selector is `soVoiceDescription`, then `voiceInfo` should be a pointer to a voice description structure, and the `length` field of the structure should be set to the length of the voice description structure. If the selector is `soVoiceFile`, then `voiceInfo` should be a pointer to a voice file information structure.

Return Value
A result code. See "Speech Synthesis Manager Result Codes" (page 1705).

Discussion
This function is intended primarily for use by synthesizers, but an application can call it too.

The `GetVoiceInfo` function accepts a selector in the `selector` parameter that determines the type of information you wish to obtain about the voice specified in the `voice` parameter. The function then fills the fields of the data structure appropriate to the selector you specify in the `voiceInfo` parameter.

If the voice specification is invalid, `GetVoiceInfo` returns a `voiceNotFound` error. If there is not enough memory to load the voice into memory to obtain information about it, `GetVoiceInfo` returns the result code `memFullErr`.

Availability
Available in CarbonLib 1.0 and later when Text to Speech 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechSynthesis.h`

InvokeSpeechDoneUPP

Invokes your speech-done callback function.

```
void InvokeSpeechDoneUPP (
   SpeechChannel chan,
   SRefCon refCon,
   SpeechDoneUPP userUPP
);
```

Discussion
You should not need to call the `InvokeSpeechDoneUPP` function, because the system calls your speech-done callback function for you.

Availability
Available in CarbonLib 1.0.2 and later.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechSynthesis.h`

InvokeSpeechErrorUPP

Invokes your error callback function.

```
void InvokeSpeechErrorUPP (
   SpeechChannel chan,
   SRefCon refCon,
   OSErr theError,
   long bytePos,
   SpeechErrorUPP userUPP
);
```

Discussion
You should not need to call the `InvokeSpeechErrorUPP` function, because the system calls your error callback function for you.

Availability
Available in CarbonLib 1.0.2 and later.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechSynthesis.h`

InvokeSpeechPhonemeUPP

Invokes your phoneme callback function.

```
void InvokeSpeechPhonemeUPP (
   SpeechChannel chan,
   SRefCon refCon,
   SInt16 phonemeOpcode,
   SpeechPhonemeUPP userUPP
);
```

Discussion
You should not need to call the `InvokeSpeechPhonemeUPP` function, because the system calls your phoneme callback function for you.

Availability
Available in CarbonLib 1.0.2 and later.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechSynthesis.h`

InvokeSpeechSyncUPP

Invokes your synchronization callback function.

```
void InvokeSpeechSyncUPP (
   SpeechChannel chan,
   SRefCon refCon,
   OSType syncMessage,
   SpeechSyncUPP userUPP
);
```

Discussion
You should not need to call the `InvokeSpeechSyncUPP` function, because the system calls your synchronization callback function for you.

Availability
Available in CarbonLib 1.0.2 and later.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechSynthesis.h`

InvokeSpeechTextDoneUPP

Invokes your text-done callback function.

```
void InvokeSpeechTextDoneUPP (
   SpeechChannel chan,
   SRefCon refCon,
   const void **nextBuf,
   unsigned long *byteLen,
   SInt32 *controlFlags,
   SpeechTextDoneUPP userUPP
);
```

Discussion
You should not need to call the `InvokeSpeechTextDoneUPP` function, because the system calls your text-done callback function for you.

Availability
Available in CarbonLib 1.0.2 and later.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechSynthesis.h`

InvokeSpeechWordUPP

Invokes your word callback function.

```
void InvokeSpeechWordUPP (
   SpeechChannel chan,
   SRefCon refCon,
   unsigned long wordPos,
   UInt16 wordLen,
   SpeechWordUPP userUPP
);
```

Discussion
You should not need to call the `InvokeSpeechWordUPP` function, because the system calls your word callback function for you.

Availability
Available in CarbonLib 1.0.2 and later.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechSynthesis.h`

MakeVoiceSpec

Sets the fields of a voice specification structure.

```
OSErr MakeVoiceSpec (
   OSType creator,
   OSType id,
   VoiceSpec *voice
);
```

Parameters

creator
The ID of the synthesizer that your application requires.

id
The ID of the voice on the synthesizer specified by the `creator` parameter.

voice
A pointer to the voice specification structure whose fields are to be filled in.

Return Value
A result code. See "Speech Synthesis Manager Result Codes" (page 1705).

Discussion
A voice specification structure is a unique voice ID used by the Speech Synthesis Manager. Most voice management functions expect to be passed a pointer to a voice specification structure. When you already know the creator and ID for a voice, you should use the `MakeVoiceSpec` function to create such a structure rather than filling in the fields of one directly. On exit, the voice specification structure pointed to by the `voice` parameter contains the appropriate values. You should never set the fields of such a structure directly.

Availability
Available in CarbonLib 1.0 and later when Text to Speech 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
SpeechSynthesis.h

NewSpeechChannel

Creates a new speech channel.

```
OSErr NewSpeechChannel (
   VoiceSpec *voice,
   SpeechChannel *chan
);
```

Parameters

voice

A pointer to the voice specification structure corresponding to the voice to be used for the new speech channel. Pass NULL to create a speech channel using the system default voice. Specifying a voice means the initial speaking rate is determined by the synthesizer's default speaking rate; passing NULL means the speaking rate is automatically set to the rate the user specifies in Speech preferences.

chan

On return, a pointer to a valid speech channel.

Return Value
A result code. See "Speech Synthesis Manager Result Codes" (page 1705).

Discussion
The NewSpeechChannel function allocates memory for a speech channel structure and sets the speech channel variable pointed to by the chan parameter to point to this speech channel structure. The Speech Synthesis Manager automatically locates and opens a connection to the proper synthesizer for the voice specified by the voice parameter.

There is no predefined limit to the number of speech channels an application can create. However, system constraints on available RAM, processor loading, and number of available sound channels limit the number of speech channels actually possible.

Your application should not attempt to manipulate the data pointed to by a variable of type SpeechChannel. The internal format that the Speech Synthesis Manager uses for speech channel data is not documented and may change in future versions of system software.

Availability
Available in CarbonLib 1.0 and later when Text to Speech 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
SpeechSynthesis.h

NewSpeechDoneUPP

Creates a new universal procedure pointer (UPP) to a speech-done callback function.

```
SpeechDoneUPP NewSpeechDoneUPP (
   SpeechDoneProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your speech-done callback function.

Return Value

A UPP to the speech-done callback function. See the description of the `SpeechDoneUPP` data type.

Availability

Available in CarbonLib 1.0.2 and later.

Available in Mac OS X 10.0 and later.

Declared In

`SpeechSynthesis.h`

NewSpeechErrorUPP

Creates a new universal procedure pointer to an error callback function.

```
SpeechErrorUPP NewSpeechErrorUPP (
   SpeechErrorProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your error callback function.

Return Value

A UPP to the error callback function. See the description of the `SpeechErrorUPP` data type.

Availability

Available in CarbonLib 1.0.2 and later.

Available in Mac OS X 10.0 and later.

Declared In

`SpeechSynthesis.h`

NewSpeechPhonemeUPP

Disposes of a universal procedure pointer (UPP) to a phoneme callback function.

```
SpeechPhonemeUPP NewSpeechPhonemeUPP (
   SpeechPhonemeProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your phoneme callback function.

Return Value

A UPP to the phoneme callback function. See the description of the `SpeechPhonemeUPP` data type.

Availability
Available in CarbonLib 1.0.2 and later.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechSynthesis.h`

NewSpeechSyncUPP

Creates a new universal procedure pointer (UPP) to a synchronization callback function.

```
SpeechSyncUPP NewSpeechSyncUPP (
   SpeechSyncProcPtr userRoutine
);
```

Parameters

`userRoutine`
A pointer to your synchronization callback function.

Return Value
A UPP to the synchronization callback function. See the description of the `SpeechSyncUPP` data type.

Availability
Available in CarbonLib 1.0.2 and later.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechSynthesis.h`

NewSpeechTextDoneUPP

Creates a new universal procedure pointer (UPP) to a text-done callback function.

```
SpeechTextDoneUPP NewSpeechTextDoneUPP (
   SpeechTextDoneProcPtr userRoutine
);
```

Parameters

`userRoutine`
A pointer to your text-done callback function.

Return Value
A UPP to the text-done callback function. See the description of the `SpeechTextDoneUPP` data type.

Availability
Available in CarbonLib 1.0.2 and later.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechSynthesis.h`

NewSpeechWordUPP

Creates a new universal procedure pointer (UPP) to a word callback function.

```
SpeechWordUPP NewSpeechWordUPP (
   SpeechWordProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your word callback function.

Return Value

A UPP to the word callback function. See the description of the `SpeechWordUPP` data type.

Availability

Available in CarbonLib 1.0.2 and later.

Available in Mac OS X 10.0 and later.

Declared In

`SpeechSynthesis.h`

PauseSpeechAt

Pauses speech on a speech channel.

```
OSErr PauseSpeechAt (
   SpeechChannel chan,
   SInt32 whereToPause
);
```

Parameters

chan

The speech channel on which speech is to be paused.

whereToPause

A constant indicating when speech processing should be paused. Pass the constant `kImmediate` to pause immediately, even in the middle of a word. Pass `kEndOfWord` or `kEndOfSentence` to pause speech at the end of the current word or sentence, respectively.

Return Value

A result code. See "Speech Synthesis Manager Result Codes" (page 1705).

Discussion

The `PauseSpeechAt` function makes speech production pause at a specified point in the text. `PauseSpeechAt` returns immediately, although speech output will continue until the specified point.

You can determine whether your application has paused speech output on a speech channel by obtaining a speech status information structure through the `GetSpeechInfo` function. While a speech channel is paused, the speech status information structure indicates that `outputBusy` and `outputPaused` are both `TRUE`.

If the end of the input text buffer is reached before the specified pause point, speech output pauses at the end of the buffer.

The `PauseSpeechAt` function differs from the `StopSpeech` and `StopSpeechAt` functions in that a subsequent call to `ContinueSpeech`, described next, causes the contents of the current text buffer to continue being spoken.

If you plan to continue speech synthesis from a paused speech channel, the text buffer being processed must remain available at all times and must not move while the channel is in a paused state.

Availability
Available in CarbonLib 1.0 and later when Text to Speech 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechSynthesis.h`

SetSpeechInfo

Changes a setting of a particular speech channel.

```
OSErr SetSpeechInfo (
   SpeechChannel chan,
   OSType selector,
   const void *speechInfo
);
```

Parameters

chan
The speech channel for which your application wishes to change a setting.

selector
A speech information selector that indicates the type of information being changed.

For a complete list of speech information selectors, see "Speech-Channel Information Constants" (page 1685). This list indicates how your application should set the `speechInfo` parameter for each selector.

speechInfo
A pointer whose meaning depends on the speech information selector specified in the `selector` parameter.

Return Value
A result code. See "Speech Synthesis Manager Result Codes" (page 1705).

Discussion
The `SetSpeechInfo` function changes the type of setting indicated by the `selector` parameter in the speech channel specified by the `chan` parameter, based on the data your application provides via the `speechInfo` parameter.

The format of the data structure specified by the `speechInfo` parameter depends on the selector you choose. Ordinarily, a selector requires that `speechInfo` be a pointer to a data structure that specifies a new setting for the speech channel.

Availability
Available in CarbonLib 1.0 and later when Text to Speech 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechSynthesis.h`

SetSpeechPitch

Sets the speech pitch on a designated speech channel.

```
OSErr SetSpeechPitch (
   SpeechChannel chan,
   Fixed pitch
);
```

Parameters

chan

The speech channel whose pitch you wish to set.

pitch

The new pitch for the speech channel, expressed as a fixed-point frequency value.

Return Value

A result code. See "Speech Synthesis Manager Result Codes" (page 1705).

Discussion

The `SetSpeechPitch` function changes the current speech pitch on the speech channel specified by the `chan` parameter to the pitch specified by the `pitch` parameter. Typical voice frequencies range from around 90 hertz for a low-pitched male voice to perhaps 300 hertz for a high-pitched child's voice. These frequencies correspond to approximate pitch values in the ranges of 30.000 to 40.000 and 55.000 to 65.000, respectively. Although fixed-point values allow you to specify a wide range of pitches, not all synthesizers will support the full range of pitches. If your application specifies a pitch that a synthesizer cannot handle, it may adjust the pitch to fit within an acceptable range.

Availability

Available in CarbonLib 1.0 and later when Text to Speech 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Declared In

`SpeechSynthesis.h`

SetSpeechProperty

Sets the value of the specified speech-channel property.

```
OSErr SetSpeechProperty (
   SpeechChannel chan,
   CFStringRef property,
   CFTypeRef object
);
```

Parameters

chan

The speech channel whose property to set.

property

The speech-channel property to set to the specified value.

object

The value to which the specified speech-channel property should be set. For some properties, this value can be `NULL`.

Return Value
A result code. See "Speech Synthesis Manager Result Codes" (page 1705).

Discussion
The `SetSpeechProperty` function is the Core Foundation-based equivalent of the `SetSpeechInfo` (page 1650) function.

See "`Speech-Channel Properties`" (page 1692) for information on the properties you can specify.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`SpeechSynthesis.h`

SetSpeechRate

Sets the speech rate of a designated speech channel.

```
OSErr SetSpeechRate (
   SpeechChannel chan,
   Fixed rate
);
```

Parameters

`chan`
The speech channel whose rate you wish to set.

`rate`
The new speech rate in words per minute, expressed as an integer value.

Return Value
A result code. See "Speech Synthesis Manager Result Codes" (page 1705).

Discussion
The `SetSpeechRate` function adjusts the speech rate on the speech channel specified by the `chan` parameter to the rate specified by the `rate` parameter. As a general rule, speaking rates range from around 150 words per minute to around 220 words per minute. It is important to keep in mind, however, that users will differ greatly in their ability to understand synthesized speech at a particular rate based upon their level of experience listening to the voice and their ability to anticipate the types of utterances they will encounter.

Note: the new speech rate should be expressed as an integer (not a fixed point decimal number as the data type implies).

Availability
Available in CarbonLib 1.0 and later when Text to Speech 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechSynthesis.h`

SpeakBuffer

Speaks a buffer of text, using certain flags to control speech behavior.

```
OSErr SpeakBuffer (
   SpeechChannel chan,
   const void *textBuf,
   unsigned long textBytes,
   SInt32 controlFlags
);
```

Parameters

chan

The speech channel through which speech is to be spoken.

textBuf

A pointer to the first byte of text to spoken.

textBytes

The number of bytes of text to spoken.

controlFlags

Control flags to customize speech behavior.

Return Value

A result code. See "Speech Synthesis Manager Result Codes" (page 1705).

Discussion

The `SpeakBuffer` function behaves identically to the `SpeakText` function, but allows control of several speech parameters by setting values of the `controlFlags` parameter. The `controlFlags` parameter relies on specific constants, which may be applied additively. See "Control Flags Constants" (page 1680).

Each constant specifies a flag bit of the `controlFlags` parameter, so by passing the constants additively you can enable multiple capabilities of `SpeakBuffer`. If you pass `0` in the `controlFlags` parameter, `SpeakBuffer` works just like `SpeakText`. By passing `kNoEndingProsody + kNoSpeechInterrupt` in the `controlFlags` parameter, `SpeakBuffer` works like `SpeakText` except that the `kNoEndingProsody` and `kNoSpeechInterrupt` features have been selected. Future versions of the Speech Synthesis Manager may define additional constants.

When the `controlFlags` parameter is set to `0`, `SpeakBuffer` behaves identically to `SpeakText`.

Availability

Available in CarbonLib 1.0 and later when Text to Speech 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Declared In

`SpeechSynthesis.h`

SpeakCFString

Begins speaking a string represented as a `CFString` object.

```
OSErr SpeakCFString (
   SpeechChannel chan,
   CFStringRef aString,
   CFDictionaryRef options
);
```

Parameters

chan

The speech channel through which speech is to be spoken.

aString

The string to be spoken, represented as a `CFString` object.

options

An optional dictionary of key-value pairs used to customize speech behavior. See "`Synthesizer Option Keys`" (page 1698) for the available keys.

Return Value
A result code. See "Speech Synthesis Manager Result Codes" (page 1705).

Discussion
The `SpeakCFString` function is the Core Foundation-based equivalent of the `SpeakBuffer` (page 1652) function.

The `SpeakCFString` function converts the text string specified in *aString* into speech, using the voice and control settings in effect for the speech channel specified in *chan*. (Before you use `SpeakCFString`, therefore, be sure you've created a speech channel with the `NewSpeechChannel` (page 1646) function.) The `SpeakCFString` function generates speech asynchronously, which means that control is returned to your application before speech has finished, perhaps even before the speech is first audible.

If `SpeakCFString` is called while the speech channel is currently speaking the contents of another text string, the speech stops immediately and the new text string is spoken as soon as possible.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`SpeechSynthesis.h`

SpeakString

Begins speaking a text string.

```
OSErr SpeakString (
   ConstStr255Param textToBeSpoken
);
```

Parameters

textToBeSpoken

The string to be spoken.

Return Value
A result code. See "Speech Synthesis Manager Result Codes" (page 1705).

Discussion
The `SpeakString` function attempts to speak the Pascal-style text string contained in the string `textToBeSpoken`. Speech is produced asynchronously using the default system voice. When an application calls this function, the Speech Synthesis Manager makes a copy of the passed string and creates any structures required to speak it. As soon as speaking has begun, control is returned to the application. The synthesized speech is generated asynchronously to the application so that normal processing can continue while the text is being spoken. No further interaction with the Speech Synthesis Manager is required at this point, and the application is free to release the memory that the original string occupied.

If `SpeakString` is called while a prior string is still being spoken, the sound currently being synthesized is interrupted immediately. Conversion of the new text into speech is then begun. If you pass a zero-length string (or, in C, a `null` pointer) to `SpeakString`, the Speech Synthesis Manager stops any speech previously being synthesized by `SpeakString` without generating additional speech. If your application uses `SpeakString`, it is often a good idea to stop any speech in progress whenever your application receives a suspend event. Calling `SpeakString` with a zero-length string has no effect on speech channels other than the one managed internally by the Speech Synthesis Manager for the `SpeakString` function.)

The text passed to the `SpeakString` function may contain embedded speech commands.

Availability
Available in CarbonLib 1.0 and later when Text to Speech 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechSynthesis.h`

SpeakText

Begins speaking a buffer of text.

```
OSErr SpeakText (
   SpeechChannel chan,
   const void *textBuf,
   unsigned long textBytes
);
```

Parameters

chan
The speech channel through which speech is to be spoken.

textBuf
A pointer to the first byte of text to spoken.

textBytes
The number of bytes of text to spoken.

Return Value
A result code. See "Speech Synthesis Manager Result Codes" (page 1705).

Discussion
Like `SpeakString`, the `SpeakText` function also generates speech, but through a speech channel through which you can exert control over the generated speech.

The SpeakText function converts the text stream specified by the textBuf and textBytes parameters into speech using the voice and control settings for the speech channel chan, which should be created with the NewSpeechChannel function. The speech is generated asynchronously. This means that control is returned to your application before the speech has finished (and probably even before it has begun). The maximum length of the text buffer that can be spoken is limited only by the available RAM.

If SpeakText is called while the channel is currently busy speaking the contents of a prior text buffer, it immediately stops speaking from the prior buffer and begins speaking from the new text buffer as soon as possible. If you pass a zero-length string (or, in C, a null pointer) to SpeakText, the Speech Synthesis Manager stops all speech currently being synthesized by the speech channel specified in the chan parameter without generating additional speech.

The text buffer must be locked in memory and must not move while the Speech Synthesis Manager processes it. This buffer is read at interrupt time, and moving it could cause a system crash. If your application defines a text-done callback function, then it can move the text buffer or dispose of it once the callback function is executed.

Availability
Available in CarbonLib 1.0 and later when Text to Speech 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
SpeechSynthesis.h

SpeechBusy

Determines whether any channels of speech are currently synthesizing speech.

```
SInt16 SpeechBusy (
   void
);
```

Return Value
The number of speech channels that are currently synthesizing speech in the application. This is useful when you want to ensure that an earlier speech request has been completed before having the system speak again. Paused speech channels are counted among those that are synthesizing speech.

The speech channel that the Speech Synthesis Manager allocates internally in response to calls to the SpeakString function is counted in the number returned by SpeechBusy. Thus, if you use just SpeakString to initiate speech, SpeechBusy always returns 1 as long as speech is being produced. When SpeechBusy returns 0, all speech has finished.

Availability
Available in CarbonLib 1.0 and later when Text to Speech 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
SpeechSynthesis.h

SpeechBusySystemWide

Determines if any speech is currently being synthesized in your application or elsewhere on the computer.

```
SInt16 SpeechBusySystemWide (
   void
);
```

Return Value
The total number of speech channels currently synthesizing speech on the computer, whether they were initiated by your application or process's code or by some other process executing concurrently. Paused speech channels are counted among those channels that are synthesizing speech.

Discussion
This function is useful when you want to ensure that no speech is currently being produced anywhere on the Macintosh computer before initiating speech. Although the Speech Synthesis Manager allows different applications to produce speech simultaneously, this can be confusing to the user. As a result, it is often a good idea for your application to check that no other process is producing speech before producing speech itself. If the difference between the values returned by `SpeechBusySystemWide` and the `SpeechBusy` function is `0`, no other process is producing speech.

Availability
Available in CarbonLib 1.0 and later when Text to Speech 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechSynthesis.h`

SpeechManagerVersion

Determines the current version of the Speech Synthesis Manager installed in the system.

```
NumVersion SpeechManagerVersion (
   void
);
```

Return Value
The version of the Speech Synthesis Manager installed in the system, in the format of the first 4 bytes of a `'vers'` resource.

Discussion
Use this call to determine whether your program can access features of the Speech Synthesis Manager that are included in some Speech Synthesis Manager releases but not in earlier ones.

Availability
Available in CarbonLib 1.0 and later when Text to Speech 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechSynthesis.h`

StopSpeech

Terminates speech immediately on the specified channel.

```
OSErr StopSpeech (
   SpeechChannel chan
);
```

Parameters

chan

The speech channel on which speech is to be stopped.

Return Value
A result code. See "Speech Synthesis Manager Result Codes" (page 1705).

Discussion
The `StopSpeech` function immediately terminates speech on the channel specified by the `chan` parameter. After returning from `StopSpeech`, your application can safely release any text buffer that the speech synthesizer has been using. You can call `StopSpeech` for an already idle channel without ill effect.

You can also stop speech by passing a zero-length string (or, in C, a `null` pointer) to one of the `SpeakString`, `SpeakText`, or `SpeakBuffer` functions. Doing this stops speech only in the specified speech channel (or, in the case of `SpeakString`, in the speech channel managed internally by the Speech Synthesis Manager).

Before calling the `StopSpeech` function, you can use the `SpeechBusy` function, which is described in `SpeechBusy` (page 1656), to determine if a synthesizer is still speaking. If you are working with multiple speech channels, you can use the status selector with the function `GetSpeechInfo` which is described in `GetSpeechInfo` (page 1638), to determine if a specific channel is still speaking.

Availability
Available in CarbonLib 1.0 and later when Text to Speech 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechSynthesis.h`

StopSpeechAt

Terminates speech delivery on a specified channel either immediately or at the end of the current word or sentence.

```
OSErr StopSpeechAt (
   SpeechChannel chan,
   SInt32 whereToStop
);
```

Parameters

chan

The speech channel on which speech is to be stopped.

whereToStop

A constant indicating when speech processing should stop. Pass the constant `kImmediate` to stop immediately, even in the middle of a word. Pass `kEndOfWord` or `kEndOfSentence` to stop speech at the end of the current word or sentence, respectively.

Return Value
A result code. See "Speech Synthesis Manager Result Codes" (page 1705).

Discussion
The `StopSpeechAt` function halts the production of speech on the channel specified by `chan` at a specified point in the text. This function returns immediately, although speech output continues until the specified point has been reached.

If you call the `StopSpeechAt` function before the Speech Synthesis Manager finishes processing input text, then the function might return before some input text has yet to be spoken. Thus, before disposing of the text buffer, your application should wait until its text-done callback function has been called (if one has been defined), or until it can determine (by, for example obtaining a speech status information structure) that the Speech Synthesis Manager is no longer processing input text.

If the end of the input text buffer is reached before the specified stopping point, the speech synthesizer stops at the end of the buffer without generating an error.

Availability
Available in CarbonLib 1.0 and later when Text to Speech 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechSynthesis.h`

TextToPhonemes

Converts a buffer of textual data into phonemic data.

```
OSErr TextToPhonemes (
   SpeechChannel chan,
   const void *textBuf,
   unsigned long textBytes,
   Handle phonemeBuf,
   long *phonemeBytes
);
```

Parameters

chan
A speech channel whose associated synthesizer and voice are to be used for the conversion process.

textBuf
A pointer to a buffer of text to be converted.

textBytes
The number of bytes of text to be converted.

phonemeBuf
A handle to a buffer to be used to store the phonemic data. The `TextToPhonemes` function may resize the relocatable block referenced by this handle.

phonemeBytes
On return, a pointer to the number of bytes of phonemic data written to the handle.

Return Value
A result code. See "Speech Synthesis Manager Result Codes" (page 1705).

Discussion
Converting textual data into phonemic data is particularly useful during application development, when you might wish to adjust phrases that your application generates to produce smoother speech. By first converting the target phrase into phonemes, you can see what the synthesizer will try to speak. Then you need correct only the parts that would not have been spoken the way you want.

The `TextToPhonemes` function converts the `textBytes` bytes of textual data pointed to by the `textBuf` parameter to phonemic data, which it writes into the relocatable block specified by the `phonemeBuf` parameter. If necessary, `TextToPhonemes` resizes this relocatable block. The `TextToPhonemes` function sets the `phonemeBytes` parameter to the number of bytes of phonemic data actually written.

If the textual data is contained in a relocatable block, a handle to that block must be locked before the `TextToPhonemes` function is called.

The data returned by `TextToPhonemes` corresponds precisely to the phonemes that would be spoken had the input text been sent to `SpeakText` instead. All current mode settings for the speech channel specified by `chan` are applied to the converted speech. No callbacks are generated while the `TextToPhonemes` function is generating its output.

Availability
Available in CarbonLib 1.0 and later when Text to Speech 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechSynthesis.h`

UseDictionary

Installs the designated dictionary into a speech channel.

```
OSErr UseDictionary (
   SpeechChannel chan,
   Handle dictionary
);
```

Parameters

chan
The speech channel into which a dictionary is to be installed.

dictionary
A handle to the dictionary data. This is often a handle to a resource of type `'dict'`.

Return Value
A result code. See "Speech Synthesis Manager Result Codes" (page 1705).

Discussion
The `UseDictionary` function attempts to install the dictionary data referenced by the `dictionary` parameter into the speech channel referenced by the `chan` parameter. The synthesizer will use whatever elements of the dictionary resource it considers useful to the speech conversion process. Some speech synthesizers might ignore certain types of dictionary entries.

After the `UseDictionary` function returns, your application is free to release any storage allocated for the dictionary handle. The search order for application-provided dictionaries is last-in, first-searched.

All details of how an application-provided dictionary is represented within the speech synthesizer are dependent on the specific synthesizer implementation and are private to the synthesizer.

Pronunciation dictionaries allow your application to override the default Speech Synthesis Manager pronunciations of individual words, such as names with unusual spellings.

Availability
Available in CarbonLib 1.0 and later when Text to Speech 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechSynthesis.h`

UseSpeechDictionary

Registers a speech dictionary with a speech channel.

```
OSErr UseSpeechDictionary (
   SpeechChannel chan,
   CFDictionaryRef speechDictionary
);
```

Parameters

chan
The speech channel with which the specified speech dictionary is to be registered.

speechDictionary
A speech dictionary to be registered with the specified speech channel, represented as a `CFDictionary` object. See "Speech Dictionary Keys" (page 1704) for the keys you can use in the dictionary.

Return Value
A result code. See "Speech Synthesis Manager Result Codes" (page 1705).

Discussion
The UseSpeechDictionary function is the Core Foundation-based equivalent of the `UseDictionary` (page 1660) function.

The `UseSpeechDictionary` function registers the `CFDictionary` object referenced by the `speechDictionary` parameter with the speech channel referenced by the `chan` parameter. Speech dictionaries allow your application to override a synthesizer's default pronunciations of individual words, such as names with unusual spellings. A synthesizer will use whatever elements of the dictionary it considers useful in the speech conversion process. Some speech synthesizers might ignore certain types of dictionary entries.

Multiple dictionaries can be registered with a synthesizer. If the same word appears in multiple dictionaries, the synthesizer will use the one from the dictionary with the most recent date.

Note that because a speech dictionary is a `CFDictionary` object, it can be loaded from an XML-based property list file. An example of such a file is shown below:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE plist PUBLIC "-//Apple//DTD PLIST 1.0//EN"
"http://www.apple.com/DTDs/PropertyList-1.0.dtd">
<plist version="1.0">
<dict>
```

```
    <key>LocaleIdentifier</key>
    <string>en_US</string>
    <key>ModificationDate</key>
    <string>2006-12-21 11:59:25 -0800</string>
    <key>Pronunciations</key>
    <array>
        <dict>
            <key>Phonemes</key>
            <string>_hEY_yUW</string>
            <key>Spelling</key>
            <string>Hello</string>
        </dict>
    </array>
    <key>Abbreviations</key>
    <array>
        <dict>
            <key>Phonemes</key>
            <string>_OW_sAEkz</string>
            <key>Spelling</key>
            <string>OSAX</string>
        </dict>
    </array>
</dict>
</plist>
```

After the `UseSpeechDictionary` function returns, your application is free to release the `CFDictionary` object referenced by the `speechDictionary` parameter.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`SpeechSynthesis.h`

Callbacks

SpeechDoneProcPtr

Defines a pointer to a speech-done callback function which is called when the Speech Synthesis Manager finishes speaking a buffer of text.

```
typedef void (*SpeechDoneProcPtr) (
    SpeechChannel chan,
    SRefCon refCon
);
```

If you name your function `MySpeechDoneProc`, you would declare it like this:

```
void MySpeechDoneProc (
    SpeechChannel chan,
    long refCon
);
```

Parameters

chan

The speech channel that has finished processing input text.

refCon

The reference constant associated with the speech channel.

Discussion

If a speech-done callback function is installed in a speech channel, then the Speech Synthesis Manager calls this function when it finishes speaking a buffer of text.

You can specify a speech-done callback function by passing the `soSpeechDoneCallBack` selector to the `SetSpeechInfo` function.

You might use a speech-done callback function if you need to update some visual indicator that shows what text is currently being spoken. For example, suppose your application passes text buffers to the Speech Synthesis Manager one paragraph at a time. Your speech-done callback function might set a global flag variable to indicate to the application that the Speech Synthesis Manager has finished speaking a paragraph. When a function called by your application's main event loop checks the global flag variable and determines that it has been set, the function might ensure that the next paragraph of text is visible.

You might use a speech-done callback function to set a flag variable that alerts the application that it should pass a new buffer of text to the Speech Synthesis Manager. If you do so, however, there might be a noticeable pause as the Speech Synthesis Manager switches from processing one text buffer to another. Ordinarily, it is easier to achieve this goal by using a text-done callback function, as described earlier.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`SpeechSynthesis.h`

SpeechErrorCFProcPtr

Defines a pointer to an error callback function that handles syntax errors within commands embedded in a `CFString` object being processed by the Speech Synthesis Manager.

```
typedef void (*SpeechErrorCFProcPtr) (
    SpeechChannel chan,
    SRefCon refCon,
    CFErrorRef theError
);
```

If you name your function `MySpeechErrorCFProc`, you would declare it like this:

```
void MySpeechErrorCFProc (
    SpeechChannel chan,
    long refCon,
    CFErrorRef theError
);
```

Parameters

chan

The speech channel that has finished processing input text.

refCon
The reference constant associated with the speech channel.

theError
The error that occurred in processing an embedded command.

Discussion
An error callback function defined by the `SpeechErrorCFProcPtr` is the Core Foundation-based equivalent of an error callback function defined by `SpeechErrorProcPtr` (page 1664). The Speech Synthesis Manager calls a speech channel's error callback function whenever it encounters a syntax error within a command embedded in a `CFString` object it is processing. This can be useful during application debugging, to detect problems with commands that you have embedded in strings that your application speaks. It can also be useful if your application allows users to embed commands within strings. Your application might display an alert indicating that the Speech Synthesis Manager encountered a problem in processing an embedded command.

Ordinarily, the error information that the Speech Synthesis Manager provides the error callback function should be sufficient. However, if your application needs information about errors that occurred before the error callback function was enabled, the application (including the error callback function) can call the `CopySpeechProperty` (page 1634) function with the `kSpeechErrorsProperty` property.

You can specify an error callback function by passing the `kSpeechErrorCFCallback` property to the `SetSpeechProperty` (page 1651) function.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`SpeechSynthesis.h`

SpeechErrorProcPtr

Defines a pointer to an error callback function that handles syntax errors within commands embedded in a text buffer being processed by the Speech Synthesis Manager.

```
typedef void (*SpeechErrorProcPtr) (
    SpeechChannel chan,
    SRefCon refCon,
    OSErr theError,
    long bytePos
);
```

If you name your function `MySpeechErrorProc`, you would declare it like this:

```
void MySpeechErrorProc (
    SpeechChannel chan,
    long refCon,
    OSErr theError,
    long bytePos
);
```

Parameters

chan
The speech channel that has finished processing input text.

refCon
The reference constant associated with the speech channel.

theError
The error that occurred in processing an embedded command.

bytePos
The number of bytes from the beginning of the text buffer being spoken to the error encountered.

Discussion
The Speech Synthesis Manager calls a speech channel's error callback function whenever it encounters a syntax error within a command embedded in a text buffer it is processing. This can be useful during application debugging, to detect problems with commands that you have embedded in text buffers that your application speaks. It can also be useful if your application allows users to embed commands within text buffers. Your application might display an alert indicating that the Speech Synthesis Manager encountered a problem in processing an embedded command.

Ordinarily, the error information that the Speech Synthesis Manager provides the error callback function should be sufficient. However, if your application needs information about errors that occurred before the error callback function was enabled, the application (including the error callback function) can call the `GetSpeechInfo` function with the `soErrors` selector.

You can specify an error callback function by passing the `soErrorCallBack` selector to the `SetSpeechInfo` function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`SpeechSynthesis.h`

SpeechPhonemeProcPtr

Defines a pointer to a phoneme callback function that is called by the Speech Synthesis Manager before it pronounces a phoneme.

```
typedef void (*SpeechPhonemeProcPtr)
(
    SpeechChannel chan,
    SRefCon refCon,
    short phonemeOpcode
);
```

If you name your function `MySpeechPhonemeProc`, you would declare it like this:

```
void MySpeechPhonemeProc (
    SpeechChannel chan,
    long refCon,
    short phonemeOpcode
);
```

Parameters

chan
The speech channel that has finished processing input text.

refCon
The reference constant associated with the speech channel.

phonemeOpcode
The phoneme about to be pronounced.

Discussion
The Speech Synthesis Manager calls a speech channel's phoneme callback function just before it pronounces a phoneme. For example, your application might use such a callback function to enable mouth synchronization. In this case, the callback function would set a global flag variable to indicate that the phoneme being pronounced is changing and another global variable to `phonemeOpcode`. A function called by your application's main event loop could detect that the phoneme being pronounced is changing and update a picture of a mouth to reflect the current phoneme. In practice, providing a visual indication of the pronunciation of a phoneme requires several consecutive pictures of mouth movement to be rapidly displayed. Consult the linguistics literature for information on mouth movements associated with different phonemes.

You can specify a phoneme callback function by passing the `soPhonemeCallBack` selector to the `SetSpeechInfo` function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`SpeechSynthesis.h`

SpeechSyncProcPtr

Defines a pointer to a synchronization callback function that is called when the Speech Synthesis Manager encounters a synchronization command embedded in a text buffer.

```
typedef void (*SpeechSyncProcPtr) (
    SpeechChannel chan,
    SRefCon refCon,
    OSType syncMessage
);
```

If you name your function `MySpeechSyncProc`, you would declare it like this:

```
void MySpeechSyncProc (
    SpeechChannel chan,
    long refCon,
    OSType syncMessage
);
```

Parameters

chan
The speech channel that has finished processing input text.

refCon
The reference constant associated with the speech channel.

syncMessage
The synchronization message passed in the embedded command. Usually, you use this message to distinguish between several different types of synchronization commands, but you can use it any way you wish.

Discussion
The Speech Synthesis Manager calls a speech channel's synchronization callback function whenever it encounters a synchronization command embedded in a text buffer. You might use the synchronization callback function to provide a callback not ordinarily provided. For example, you might inset synchronization commands at the end of every sentence in a text buffer, or you might enter synchronization commands after every numeric value in the text. However, to synchronize your application with phonemes or words, it makes more sense to use the built-in phoneme and word callback functions, defined in `SpeechPhonemeProcPtr` (page 1665).

You can specify a synchronization callback function by passing the `soSyncCallBack` selector to the `SetSpeechInfo` function and embedding a synchronization command within a text buffer passed to the `SpeakText` or `SpeakBuffer` function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`SpeechSynthesis.h`

SpeechTextDoneProcPtr

Defines a pointer to a text-done callback function that is called when the Speech Synthesis Manager has finished processing a buffer of text.

```
typedef void (*SpeechTextDoneProcPtr)
(
    SpeechChannel chan,
    SRefCon refCon,
    void ** nextBuf,
    unsigned long * byteLen,
    long * controlFlags
);
```

If you name your function `MySpeechTextDoneProc`, you would declare it like this:

```
void MySpeechTextDoneProc (
    SpeechChannel chan,
    long refCon,
    void ** nextBuf,
    unsigned long * byteLen,
    long * controlFlags
);
```

Parameters

chan
The speech channel that has finished processing input text.

refCon
The reference constant associated with the speech channel.

nextBuf
On return, a pointer to the next buffer of text to process or `NULL` if your application has no additional text to be spoken. This parameter is mostly for internal use by the Speech Synthesis Manager.

byteLen

On return, a pointer to the number of bytes of the text buffer pointed to by the `nextBuf` parameter.

controlFlags

On return, a pointer to the control flags to be used in generating the next buffer of text.

Discussion

If a text-done callback function is installed in a speech channel, then the Speech Synthesis Manager calls this function when it finishes processing a buffer of text. The Speech Synthesis Manager might not yet have completed finishing speaking the text and indeed might not have started speaking it.

You can specify a text-done callback function by passing the `soTextDoneCallBack` selector to the `SetSpeechInfo` function.

A common use of a text-done callback function is to alert your application once the text passed to the `SpeakText` or `SpeakBuffer` function can be disposed of (or, when the text is contained within a locked relocatable block, when the relocatable block can be unlocked). The Speech Synthesis Manager copies the text you pass to the `SpeakText` or `SpeakBuffer` function into an internal buffer. Once it has finished processing the text, you may dispose of the original text buffer, even if speech is not yet complete. However, if you wish to write a callback function that executes when speech is completed, see the definition of a speech-done callback function below.

Although most applications will not need to, your callback function can indicate to the Speech Synthesis Manager whether there is another buffer of text to speak. If there is another buffer, your callback function should reference it by setting the `nextBuf` and `byteLen` parameters to appropriate values. (Your callback function might also change the control flags to be used to process the speech by altering the value in the `controlFlags` parameter.) Setting these parameters allows the Speech Synthesis Manager to generate uninterrupted speech. If there is no more text to speak, your callback function should set `nextBuf` to `NULL`. In this case, the Speech Synthesis Manager ignores the `byteLen` and `controlFlags` parameters.

If your text-done callback function does not change the values of the `nextBuf` and `byteLen` parameters, the text buffer just spoken will be spoken again.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`SpeechSynthesis.h`

SpeechWordCFProcPtr

Defines a pointer to a Core Foundation-based word callback function that is called by the Speech Synthesis Manager before it pronounces a word.

```
typedef void (*SpeechWordCFProcPtr) (
    SpeechChannel chan,
    SRefCon refCon,
    CFStringRef aString,
    CFRange wordRange
);
```

If you name your function `MySpeechWordCFProc`, you would declare it like this:

```
void MySpeechWordCFProc (
    SpeechChannel chan,
    SRefCon refCon,
```

```
    CFStringRef aString,
    CFRange wordRange
);
```

Parameters

chan

The speech channel that has finished processing input text.

refCon

The reference constant associated with the speech channel.

aString

The original string passed to the speech synthesizer in the `SpeakCFString` (page 1653) call.

wordRange

The range of characters in `aString` that corresponds to the word.

Discussion

A word callback function defined by the `SpeechWordCFProcPtr` is the Core Foundation-based equivalent of a word callback function defined by `SpeechWordProcPtr` (page 1669). The Speech Synthesis Manager calls a speech channel's word callback function just before it pronounces a word. You might use such a callback function, for example, to highlight the word about to be spoken in a window.

You can specify a word callback function by passing the `kSpeechWordCFCallBack` property to the`SetSpeechProperty` (page 1651) function.

Availability

Available in Mac OS X v10.5 and later.

Declared In

`SpeechSynthesis.h`

SpeechWordProcPtr

Defines a pointer to a word callback function that is called by the Speech Synthesis Manager before it pronounces a word.

```
typedef void (*SpeechWordProcPtr) (
    SpeechChannel chan,
    SRefCon refCon,
    unsigned long wordPos,
    unsigned short wordLen
);
```

If you name your function `MySpeechWordProc`, you would declare it like this:

```
void MySpeechWordProc (
    SpeechChannel chan,
    long refCon,
    unsigned long wordPos,
    unsigned short wordLen
);
```

Parameters

chan

The speech channel that has finished processing input text.

refCon

The reference constant associated with the speech channel.

wordPos

The number of bytes between the beginning of the text buffer and the beginning of the word about to be pronounced.

wordLen

The length in bytes of the word about to be pronounced.

Discussion

The Speech Synthesis Manager calls a speech channel's word callback function just before it pronounces a word. You might use such a callback function, for example, to draw the word about to be spoken in a window. In this case, the callback function would set a global flag variable to indicate that the word being spoken is changing and another two global variables to `wordPos` and `wordLen`. A function called by your application's main event loop could detect that the word being spoken is changing and draw the word in a window.

You can specify a word callback function by passing the `soWordCallBack` selector to the `SetSpeechInfo` function.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`SpeechSynthesis.h`

Data Types

DelimiterInfo

Defines a delimiter information structure.

```
struct DelimiterInfo {
    Byte startDelimiter[2];
    Byte endDelimiter[2];
};
typedef struct DelimiterInfo DelimiterInfo;
```

Fields

`startDelimiter`

The start delimiter for an embedded command. By default, the start delimiter is "`[[`".

`endDelimiter`

The end delimiter for an embedded command. By default, the end delimiter is "`]]`".

Discussion

A delimiter information structure defines the characters used to indicate the beginning and end of a command embedded in text. A delimiter can be one or two characters.

Ordinarily, applications that support embedded speech commands should not change the start or end delimiters. However, if for some reason you must change the delimiters, you can use the `SetSpeechInfo` function with the `soCommandDelimiter` selector. For example, you might do this if a text buffer naturally includes the delimiter strings. Before passing such a buffer to the Speech Synthesis Manager, you can change the delimiter strings to some two-character sequences not used in the buffer and then change the delimiter strings back once processing of the buffer is complete.

If a single-byte delimiter is desired, it should be followed by a `NULL` (0) byte. If the delimiter strings both consist of two `NULL` bytes, embedded command processing is disabled.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`SpeechSynthesis.h`

PhonemeDescriptor

Defines a phoneme descriptor structure.

```
struct PhonemeDescriptor {
    SInt16 phonemeCount;
    PhonemeInfo thePhonemes[1];
};
typedef struct PhonemeDescriptor PhonemeDescriptor;
```

Fields

`phonemeCount`
The number of phonemes that the current synthesizer defines. Typically, this will correspond to the number of phonemes in the language supported by the synthesizer.

`thePhonemes`
An array of phoneme information structures.

Discussion
By calling the `GetSpeechInfo` (page 1638) function with the `soPhonemeSymbols` selector, you can obtain a phoneme descriptor structure, which describes all phonemes defined for the current synthesizer.

A common use for a phoneme descriptor structure is to provide a graphical display to the user of all available phonemes. Such a list is used only for a user entering phonemic data directly rather than just entering text.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`SpeechSynthesis.h`

PhonemeInfo

Defines a structure that stores information about a phoneme.

```
struct PhonemeInfo {
    SInt16 opcode;
    Str15 phStr;
    Str31 exampleStr;
    SInt16 hiliteStart;
    SInt16 hiliteEnd;
};
typedef struct PhonemeInfo PhonemeInfo;
```

Fields

`opcode`
The opcode for the phoneme.

`phStr`
The string used to represent the phoneme. The string does not necessarily have a phonetic connection to the phoneme, but might simply be an abstract textual representation of it.

`exampleStr`
An example word that illustrates use of the phoneme.

`hiliteStart`
The number of characters in the example word that precede the portion of that word representing the phoneme.

`hiliteEnd`
The number of characters between the beginning of the example word and the end of the portion of that word representing the phoneme.

Discussion

Ordinarily, you use a phoneme information structure to show the user how to enter text to represent a particular phoneme when the `'PHON'` input mode is activated.

You might use the information contained in the `hiliteStart` and `hiliteEnd` fields to highlight the characters in the example word that represent the phoneme.

To obtain a phoneme information structure for an individual phoneme, you must obtain a list of phonemes through a phoneme descriptor structure.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`SpeechSynthesis.h`

SpeechChannelRecord

Represents a speech channel.

```
struct SpeechChannelRecord {
    long data[1];
};
typedef struct SpeechChannelRecord SpeechChannelRecord;
typedef SpeechChannelRecord * SpeechChannel;
```

Availability

Available in Mac OS X v10.0 and later.

Declared In
SpeechSynthesis.h

SpeechDoneUPP

Defines a universal procedure pointer (UPP) to a speech-done callback function.

```
typedef SpeechDoneProcPtr SpeechDoneUPP;
```

Discussion
For more information, see the description of the SpeechDoneProcPtr (page 1662) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
SpeechSynthesis.h

SpeechErrorInfo

Defines a speech error information structure.

```
struct SpeechErrorInfo {
    SInt16 count;
    OSErr oldest;
    long oldPos;
    OSErr newest;
    long newPos;
};
typedef struct SpeechErrorInfo SpeechErrorInfo;
```

Fields

count
: The number of errors that have occurred in processing the current text buffer since the last call to the GetSpeechInfo function with the soErrors selector. Of these errors, you can find information about only the first and last error that occurred.

oldest
: The error code of the first error that occurred after the previous call to the GetSpeechInfo function with the soErrors selector.

oldPos
: The character position within the text buffer being processed of the first error that occurred after the previous call to the GetSpeechInfo function with the soErrors selector.

newest
: The error code of the most recent error.

newPos
: The character position within the text buffer being processed of the most recent error.

Discussion
By calling the GetSpeechInfo (page 1638) function with the soErrors selector, you can obtain a speech error information structure, which shows what Speech Synthesis Manager errors occurred while processing a text buffer on a given speech channel.

Speech error information structures never include errors that are returned by Speech Synthesis Manager functions. Instead, they reflect only errors encountered directly in the processing of text, and, in particular, in the processing of commands embedded within text.

The speech error information structure keeps track of only the most recent error and the first error that occurred after the previous call to the `GetSpeechInfo` function with the `soErrors` selector. If your application needs to keep track of all errors, then you should install an error callback function, `SpeechErrorProcPtr` (page 1664).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`SpeechSynthesis.h`

SpeechErrorUPP

Defines a universal procedure pointer (UPP) to an error callback function.

```
typedef SpeechErrorProcPtr SpeechErrorUPP;
```

Discussion
For more information, see the description of the `SpeechErrorProcPtr` (page 1664) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`SpeechSynthesis.h`

SpeechPhonemeUPP

Defines a universal procedure pointer (UPP) to a phoneme callback function.

```
typedef SpeechPhonemeProcPtr SpeechPhonemeUPP;
```

Discussion
For more information, see the description of the `SpeechPhonemeProcPtr` (page 1665) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`SpeechSynthesis.h`

SpeechStatusInfo

Defines a a speech status information structure, which stores information about the status of a speech channel.

```
struct SpeechStatusInfo {
    Boolean outputBusy;
    Boolean outputPaused;
    long inputBytesLeft;
    SInt16 phonemeCode;
};
typedef struct SpeechStatusInfo SpeechStatusInfo;
```

Fields

`outputBusy`

Whether the speech channel is currently producing speech. A speech channel is considered to be producing speech even at some times when no audio data is being produced through the Macintosh speaker. This occurs, for example, when the Speech Synthesis Manager is processing an input buffer but has not yet initiated speech or when speech output is paused.

`outputPaused`

Whether speech output in the speech channel has been paused by a call to the `PauseSpeechAt` (page 1649) function.

`inputBytesLeft`

The number of input bytes of the text that the speech channel must still process. When `inputBytesLeft` is 0, the buffer of input text passed to one of the `SpeakText` or `SpeakBuffer` functions may be disposed of. When you call the `SpeakString` function, the Speech Synthesis Manager stores a duplicate of the string to be spoken in an internal buffer; thus, you may delete the original string immediately after calling `SpeakString`.

`phonemeCode`

The opcode for the phoneme that the speech channel is currently processing.

Discussion

By calling the `GetSpeechInfo` (page 1638) function with the `soStatus` selector, you can find out information about the status of a speech channel.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`SpeechSynthesis.h`

SpeechSyncUPP

Defines a universal procedure pointer (UPP) to a synchronization callback function.

```
typedef SpeechSyncProcPtr SpeechSyncUPP;
```

Discussion

For more information, see the description of the `SpeechSyncProcPtr` (page 1666) callback function.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`SpeechSynthesis.h`

SpeechTextDoneUPP

Defines a universal procedure pointer (UPP) to a text-done callback function.

```
typedef SpeechTextDoneProcPtr SpeechTextDoneUPP;
```

Discussion
For more information, see the description of the `SpeechTextDoneProcPtr` (page 1667) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`SpeechSynthesis.h`

SpeechVersionInfo

Defines a speech version information structure.

```
struct SpeechVersionInfo {
    OSType synthType;
    OSType synthSubType;
    OSType synthManufacturer;
    SInt32 synthFlags;
    NumVersion synthVersion;
};
typedef struct SpeechVersionInfo SpeechVersionInfo;
```

Fields

`synthType`
The general type of the synthesizer. For the current version of the Speech Synthesis Manager, this field always contains the value `kTextToSpeechSynthType`, indicating that the synthesizer converts text into speech.

`synthSubType`
The specific type of the synthesizer. Currently, no specific types of synthesizer are defined. If you define a new type of synthesizer, you should register the four-character code for your type with Developer Technical Support.

`synthManufacturer`
A unique identification of a synthesizer engine. If you develop synthesizers, then you should register a different four-character code for each synthesizer you develop with Developer Technical Support. The `creatorID` field of the voice specification structure and the `synthCreator` field of a speech extension data structure should each be set to the value stored in this field for the desired synthesizer.

`synthFlags`
A set of flags indicating which synthesizer features are activated. Specific constants define the bits in this field whose meanings are defined for all synthesizers.

`synthVersion`
The version number of the synthesizer.

Discussion
By calling the `GetSpeechInfo` (page 1638) function with the `soSynthType` selector, you can obtain a speech version information structure, which provides information about the speech synthesizer currently being used.

Availability
Available in Mac OS X v10.0 and later.

Declared In
SpeechSynthesis.h

SpeechWordUPP

Defines a universal procedure pointer (UPP) to a word callback function.

```
typedef SpeechWordProcPtr SpeechWordUPP;
```

Discussion
For more information, see the description of the SpeechWordProcPtr (page 1669) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
SpeechSynthesis.h

SpeechXtndData

Defines a speech extension data structure.

```
struct SpeechXtndData {
    OSType synthCreator;
    Byte synthData[2];
};
typedef struct SpeechXtndData SpeechXtndData;
```

Fields

synthCreator
: The synthesizer's creator ID, identical to the value stored in the synthManufacturer field of a speech version information structure. You should set this field to the appropriate value before calling GetSpeechInfo or SetSpeechInfo.

synthData
: Synthesizer-specific data. The size and format of the data in this field may vary.

Discussion
The speech extension data structure allows you to use the GetSpeechInfo (page 1638) and SetSpeechInfo (page 1650) functions with selectors defined by particular synthesizers. By requiring that you pass to one of these functions a pointer to a speech extension data structure, synthesizers can permit the exchange of data in any format.

Availability
Available in Mac OS X v10.0 and later.

Declared In
SpeechSynthesis.h

VoiceDescription

Defines a voice description structure.

```
struct VoiceDescription {
    SInt32 length;
    VoiceSpec voice;
    SInt32 version;
    Str63 name;
    Str255 comment;
    SInt16 gender;
    SInt16 age;
    SInt16 script;
    SInt16 language;
    SInt16 region;
    SInt32 reserved[4];
};
typedef struct VoiceDescription VoiceDescription;
```

Fields

`length`
The size of the voice description structure, in bytes.

`voice`
A voice specification structure that uniquely identifies the voice.

`version`
The version number of the voice.

`name`
The name of the voice, preceded by a length byte. Names must be 63 characters or less.

`comment`
Additional text information about the voice. Some synthesizers use this field to store a phrase that can be spoken.

`gender`
The gender of the individual represented by the voice. See "Gender Constants" (page 1681).

`age`
The approximate age in years of the individual represented by the voice.

`script`
In Mac OS X v10.4.7 and later, the encoding code of the text that the voice can process.

Note that this field contains a 16-bit value. You can use any of the 16-bit values described in `External_String_Encodings` or `CFStringBuiltInEncodings`. However, if you need to use a 32-bit value, such as `kCFStringEncodingUTF8`, you pass the value in the first array element of the `reserved` field, and you also specify `-1` or `kCFStringEncodingInvalidId` in the `script` field.

`language`
A code that indicates the language of voice output.

`region`
A code that indicates the region represented by the voice.

`reserved`
Reserved. May be used to hold a 32-bit encoding value, if necessary (see the description of the `script` field for more information).

Discussion

By calling the `GetVoiceDescription` (page 1640) function, you can obtain information about a voice in a voice description structure.

Availability

Available in Mac OS X v10.0 and later.

Declared In
SpeechSynthesis.h

VoiceFileInfo

Defines a voice file information structure.

```
struct VoiceFileInfo {
    FSSpec fileSpec;
    SInt16 resID;
};
typedef struct VoiceFileInfo VoiceFileInfo;
```

Fields

`fileSpec`
A file system specification structure that contains the volume, directory, and name of the file containing the voice. Generally, files containing a single voice are of type `kTextToSpeechVoiceFileType`, and files containing multiple voices are of type `kTextToSpeechVoiceBundleType`.

`resID`
The resource ID of the voice in the file. Voices are stored in resources of type `kTextToSpeechVoiceType`.

Discussion
A voice file information structure specifies the file in which a voice is stored and the resource ID of the voice within that file. Use the `GetVoiceInfo` (page 1641) function to obtain a voice file information structure for a voice.

Availability
Available in Mac OS X v10.0 and later.

Declared In
SpeechSynthesis.h

VoiceSpec

Defines a voice specification structure.

```
struct VoiceSpec {
    OSType creator;
    OSType id;
};
typedef struct VoiceSpec VoiceSpec;
typedef VoiceSpec * VoiceSpecPtr;
```

Fields

`creator`
The synthesizer that is required to use the voice. This is equivalent to the value contained in the `synthManufacturer` field of a speech version information structure and that contained in the `synthCreator` field of a speech extension data structure. The set of `OSType` values specified entirely by space characters and lowercase letters is reserved.

`id`
The voice ID of the voice for the synthesizer. Every voice on a synthesizer has a unique ID.

Discussion
A voice specification structure provides a unique specification that you must use to obtain information about a voice. You also must use a voice specification structure if you wish to create a speech channel that generates speech in a voice other than the current system default voice.

To ensure compatibility with future versions of the Speech Synthesis Manager, you should never fill in the fields of a voice specification structure yourself. Instead, you should create a voice specification structure by using the `MakeVoiceSpec` (page 1645) function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`SpeechSynthesis.h`

Constants

Control Flags Constants

Flags that indicate which synthesizer features are active.

```
enum {
    kNoEndingProsody = 1,
    kNoSpeechInterrupt = 2,
    kPreflightThenPause = 4
};
```

Constants
`kNoEndingProsody`
Disables prosody at end of sentences. The `kNoEndingProsody` flag bit is used to control whether or not the speech synthesizer automatically applies ending prosody, the speech tone and cadence that normally occur at the end of a statement. Under normal circumstances (for example, when the flag bit is not set), ending prosody is applied to the speech when the end of the `textBuf` data is reached. This default behavior can be disabled by setting the `kNoEndingProsody` flag bit.

Some synthesizers do not speak until the `kNoEndingProsody` flag bit is reset, or they encounter a period in the text, or `textBuf` is full.

Available in Mac OS X v10.0 and later.

Declared in `SpeechSynthesis.h`.

`kNoSpeechInterrupt`

Does not interrupt current speech. The `kNoSpeechInterrupt` flag bit is used to control the behavior of `SpeakBuffer` when called on a speech channel that is still busy. When the flag bit is not set, `SpeakBuffer` behaves similarly to `SpeakString` and `SpeakText`. Any speech currently being produced on the specified speech channel is immediately interrupted, and then the new text buffer is spoken. When the `kNoSpeechInterrupt` flag bit is set, however, a request to speak on a channel that is still busy processing a prior text buffer will result in an error. The new buffer is ignored and the error `synthNotReady` is returned. If the prior text buffer has been fully processed, the new buffer is spoken normally. One way of achieving continuous speech without using callback functions is to continually call `SpeakBuffer` with the `kNoSpeechInterrupt` flag bit set until the function returns `noErr`. The function will then execute as soon as the first text buffer has been processed.

Available in Mac OS X v10.0 and later.

Declared in `SpeechSynthesis.h`.

`kPreflightThenPause`

Computes speech without generating.The `kPreflightThenPause` flag bit is used to minimize the latency experienced when the speech synthesizer is attempting to speak. Ordinarily, whenever a call to `SpeakString`, `SpeakText`, or `SpeakBuffer` is made, the speech synthesizer must perform a certain amount of initial processing before speech output is heard. This startup latency can vary from a few milliseconds to several seconds depending upon which speech synthesizer is being used. Recognizing that larger startup delays might be detrimental to certain applications, a mechanism exists to allow the synthesizer to perform any necessary computations at noncritical times. Once the computations have been completed, the speech is able to start instantly. When the `kPreflightThenPause` flag bit is set, the speech synthesizer will process the input text as necessary to the point where it is ready to begin producing speech output. At this point, the synthesizer will enter a paused state and return to the caller. When the application is ready to produce speech, it should call the `ContinueSpeech` function to begin speaking.

Available in Mac OS X v10.0 and later.

Declared in `SpeechSynthesis.h`.

Discussion
These constants are used in the `controlFlags` parameter of the `SpeakBuffer` (page 1652) function and in the `synthFlagsl` field of the `SpeechVersionInfo` (page 1676) structure.

Declared In
`SpeechSynthesis.h`

Gender Constants

Constants that indicate the gender of the individual represented by a voice.

```
enum {
    kNeuter = 0,
    kMale = 1,
    kFemale = 2
};
```

Constants
`kNeuter`

Neuter voice.

Available in Mac OS X v10.0 and later.

Declared in `SpeechSynthesis.h`.

`kMale`
Male voice.

Available in Mac OS X v10.0 and later.

Declared in `SpeechSynthesis.h`.

`kFemale`
Female voice.

Available in Mac OS X v10.0 and later.

Declared in `SpeechSynthesis.h`.

Discussion
These constants are used in the `gender` field of the `VoiceDescription` (page 1677) structure.

Declared In
`SpeechSynthesis.h`

Stop Speech Locations

Locations that indicate where speech should be paused or stopped.

```
enum {
    kImmediate = 0,
    kEndOfWord = 1,
    kEndOfSentence = 2
};
```

Constants
`kImmediate`
Speech should be paused or stopped immediately.

Available in Mac OS X v10.0 and later.

Declared in `SpeechSynthesis.h`.

`kEndOfWord`
Speech should be paused or stopped at the end of the word.

Available in Mac OS X v10.0 and later.

Declared in `SpeechSynthesis.h`.

`kEndOfSentence`
Speech should be paused or stopped at the end of the sentence.

Available in Mac OS X v10.0 and later.

Declared in `SpeechSynthesis.h`.

Discussion
See the functions `PauseSpeechAt` (page 1649) and `StopSpeechAt` (page 1658) for more information.

Declared In
`SpeechSynthesis.h`

Speech Synthesis Manager Operating System Types

The `OSType` definitions used by the Speech Synthesis Manager.

```
enum {
    kTextToSpeechSynthType = 'ttsc',
    kTextToSpeechVoiceType = 'ttvd',
    kTextToSpeechVoiceFileType = 'ttvf',
    kTextToSpeechVoiceBundleType = 'ttvb'
};
```

Constants

`kTextToSpeechSynthType`
The type of a synthesizer component.
Available in Mac OS X v10.0 and later.
Declared in `SpeechSynthesis.h`.

`kTextToSpeechVoiceType`
The type of a voice resource.
Available in Mac OS X v10.0 and later.
Declared in `SpeechSynthesis.h`.

`kTextToSpeechVoiceFileType`
The type of a voice file. Typically. files containing a single voice are of type `kTextToSpeechVoiceFileType`.
Available in Mac OS X v10.0 and later.
Declared in `SpeechSynthesis.h`.

`kTextToSpeechVoiceBundleType`
The type of a voice bundle file. Typically, files containing multiple voices are of type `kTextToSpeechVoiceBundleType`.
Available in Mac OS X v10.0 and later.
Declared in `SpeechSynthesis.h`.

Declared In
`SpeechSynthesis.h`

Speech-Channel Modes

The available text-processing and number-processing modes for a speech channel.

```
enum {
    modeText = 'TEXT',
    modePhonemes = 'PHON',
    modeNormal = 'NORM',
    modeLiteral = 'LTRL'
};
```

Constants

`modeText`
Indicates that the speech channel is in text-processing mode.
Available in Mac OS X v10.0 and later.
Declared in `SpeechSynthesis.h`.

`modePhonemes`
Indicates that the speech channel is in phoneme-processing mode. When in phoneme-processing mode, a text buffer is interpreted to be a series of characters representing various phonemes and prosodic controls.

Available in Mac OS X v10.0 and later.

Declared in `SpeechSynthesis.h`.

`modeNormal`
Indicates that the synthesizer assembles digits into numbers (so that “12” is spoken as "twelve").

Available in Mac OS X v10.0 and later.

Declared in `SpeechSynthesis.h`.

`modeLiteral`
Indicates that each digit is spoken literally (so that “12” is spoken as "one, two").

Available in Mac OS X v10.0 and later.

Declared in `SpeechSynthesis.h`.

Declared In
`SpeechSynthesis.h`

Speech-Channel Modes for Core Foundation-based Functions

The available text-processing and number-processing modes for a speech channel.

```
CFStringRef kSpeechModeText = CFSTR("TEXT");
CFStringRef kSpeechModePhoneme = CFSTR("PHON");
CFStringRef kSpeechModeNormal = CFSTR("NORM");
CFStringRef kSpeechModeLiteral = CFSTR("LTRL");
```

Constants
`kSpeechModeText`
Indicates that the speech channel is in text-processing mode.

Available in Mac OS X v10.5 and later.

Declared in `SpeechSynthesis.h`.

`kSpeechModePhoneme`
Indicates that the speech channel is in phoneme-processing mode. When in phoneme-processing mode, a text buffer is interpreted to be a series of characters representing various phonemes and prosodic controls.

Available in Mac OS X v10.5 and later.

Declared in `SpeechSynthesis.h`.

`kSpeechModeNormal`
Indicates that the synthesizer assembles digits into numbers (so that “12” is spoken as "twelve").

Available in Mac OS X v10.5 and later.

Declared in `SpeechSynthesis.h`.

`kSpeechModeLiteral`
Indicates that each digit is spoken literally (so that “12” is spoken as "one, two").

Available in Mac OS X v10.5 and later.

Declared in `SpeechSynthesis.h`.

Declared In
SpeechSynthesis.h

Voice Information Selectors

The types of voice data that can be requested by the GetVoiceInfo function.

```
enum {
    soVoiceDescription = 'info',
    soVoiceFile = 'fref'
};
```

Constants
soVoiceDescription
Get basic voice information.
Available in Mac OS X v10.0 and later.
Declared in SpeechSynthesis.h.

soVoiceFile
Get voice file reference information.
Available in Mac OS X v10.0 and later.
Declared in SpeechSynthesis.h.

Declared In
SpeechSynthesis.h

Speech-Channel Information Constants

Selectors that can be passed to the GetSpeechInfo or SetSpeechInfo functions.

```
enum {
    soStatus = 'stat',
    soErrors = 'erro',
    soInputMode = 'inpt',
    soCharacterMode = 'char',
    soNumberMode = 'nmbr',
    soRate = 'rate',
    soPitchBase = 'pbas',
    soPitchMod = 'pmod',
    soVolume = 'volm',
    soSynthType = 'vers',
    soRecentSync = 'sync',
    soPhonemeSymbols = 'phsy',
    soCurrentVoice = 'cvox',
    soCommandDelimiter = 'dlim',
    soReset = 'rset',
    soCurrentA5 = 'myA5',
    soRefCon = 'refc',
    soTextDoneCallBack = 'tdcb',
    soSpeechDoneCallBack = 'sdcb',
    soSyncCallBack = 'sycb',
    soErrorCallBack = 'ercb',
    soPhonemeCallBack = 'phcb',
    soWordCallBack = 'wdcb',
    soSynthExtension = 'xtnd',
    soSoundOutput = 'sndo',
    soOutputToFileWithCFURL = 'opaf'
};
```

Constants

`soStatus`

Get a speech status information structure for the speech channel. The `speechInfo` parameter is a pointer to a speech status information structure, described in `SpeechStatusInfo` (page 1674).

This selector works with the `GetSpeechInfo` (page 1638) function.

Available in Mac OS X v10.0 and later.

Declared in `SpeechSynthesis.h`.

`soErrors`

Get saved error information for the speech channel and clear its error registers. This selector lets you poll for various run-time errors that occur during speaking, such as the detection of badly formed embedded commands. Errors returned directly by Speech Synthesis Manager functions are not reported here. If your application defines an error callback function, the callback should use the `soErrors` selector to obtain error information. The `speechInfo` parameter is a pointer to a speech error information structure, described in `SpeechErrorInfo` (page 1673).

This selector works with the `GetSpeechInfo` (page 1638) function.

Available in Mac OS X v10.0 and later.

Declared in `SpeechSynthesis.h`.

`soInputMode`

Get or set the speech channel's current text-processing mode. The returned value specifies whether the channel is currently in text input mode or phoneme input mode. The `speechInfo` parameter is a pointer to a variable of type `OSType`, which specifies a text-processing mode. The constants `modeText` and `modePhonemes` specify the available text-processing modes.

The `modeText` constant indicates that the speech channel is in text-processing mode. The `modePhonemes` constant indicates that the speech channel is in phoneme-processing mode. When in phoneme-processing mode, a text buffer is interpreted to be a series of characters representing various phonemes and prosodic controls. Some synthesizers might support additional input-processing modes and define constants for these modes.

This selector works with both the `GetSpeechInfo` (page 1638) and `SetSpeechInfo` (page 1650) functions.

Available in Mac OS X v10.0 and later.

Declared in `SpeechSynthesis.h`.

`soCharacterMode`

Get or set the speech channel's character-processing mode. Two constants are currently defined for the processing mode, `modeNormal` and `modeLiteral`. When the character-processing mode is `modeNormal`, input characters are spoken as you would expect to hear them. When the mode is `modeLiteral`, each character is spoken literally, so that the word "cat" would be spoken "C–A–T". The `speechInfo` parameter points to a variable of type `OSType`, which is the character-processing mode.

This selector works with both the `GetSpeechInfo` (page 1638) and `SetSpeechInfo` (page 1650) functions.

Available in Mac OS X v10.0 and later.

Declared in `SpeechSynthesis.h`.

`soNumberMode`

Get or set the speech channel's current number-processing mode. Two `OSType` constants are currently defined, `modeNormal` and `modeLiteral`. When the number-processing mode is `modeNormal`, the synthesizer assembles digits into numbers (so that 12 is spoken as "twelve"). When the mode is `modeLiteral`, each digit is spoken literally (so that 12 is spoken as "one, two"). The `speechInfo` parameter is a pointer to a variable of type `OSType`, which specifies the number-processing mode.

This selector works with both the `GetSpeechInfo` (page 1638) and `SetSpeechInfo` (page 1650) functions.

Available in Mac OS X v10.0 and later.

Declared in `SpeechSynthesis.h`.

`soRate`

Get or set a speech channel's speech rate. The `speechInfo` parameter is a pointer to a variable of type `Fixed`. The possible range of speech rates is from 0.000 to 65535.65535. The range of supported rates is not predefined by the Speech Synthesis Manager; each speech synthesizer provides its own range of speech rates. Average human speech occurs at a rate of 180 to 220 words per minute.

This selector works with both the `GetSpeechInfo` (page 1638) and `SetSpeechInfo` (page 1650) functions.

Available in Mac OS X v10.0 and later.

Declared in `SpeechSynthesis.h`.

`soPitchBase`

Get or set the speech channel's baseline speech pitch. This selector is intended for use by the Speech Synthesis Manager; ordinarily, an application uses the `GetSpeechPitch` (page 1639) and `SetSpeechPitch` (page 1651) functions. The `speechInfo` parameter is a pointer to a variable of type `Fixed`.

This selector works with both the `GetSpeechInfo` (page 1638) and `SetSpeechInfo` (page 1650) functions.

Available in Mac OS X v10.0 and later.

Declared in `SpeechSynthesis.h`.

`soPitchMod`

Get or set a speech channel's pitch modulation. The `speechInfo` parameter is a pointer to a variable of type `Fixed`. Pitch modulation is also expressed as a fixed-point value in the range of 0.000 to 127.000. These values correspond to MIDI note values, where 60.000 is equal to middle C on a piano scale. The most useful speech pitches fall in the range of 40.000 to 55.000. A pitch modulation value of 0.000 corresponds to a monotone in which all speech is generated at the frequency corresponding to the speech pitch. Given a speech pitch value of 46.000, a pitch modulation of 2.000 would mean that the widest possible range of pitches corresponding to the actual frequency of generated text would be 44.000 to 48.000.

This selector works with both the `GetSpeechInfo` (page 1638) and `SetSpeechInfo` (page 1650) functions.

Available in Mac OS X v10.0 and later.

Declared in `SpeechSynthesis.h`.

`soVolume`

Get or set the speech volume for a speech channel. The `speechInfo` parameter is a pointer to a variable of type `Fixed`. Volumes are expressed in fixed-point units ranging from 0.0 through 1.0. A value of 0.0 corresponds to silence, and a value of 1.0 corresponds to the maximum possible volume. Volume units lie on a scale that is linear with amplitude or voltage. A doubling of perceived loudness corresponds to a doubling of the volume.

This selector works with both the `GetSpeechInfo` (page 1638) and `SetSpeechInfo` (page 1650) functions.

Available in Mac OS X v10.0 and later.

Declared in `SpeechSynthesis.h`.

`soSynthType`

Get a speech version information structure for the speech synthesizer being used on the specified speech channel. The `speechInfo` parameter is a pointer to a speech version information structure, described in `SpeechVersionInfo` (page 1676).

This selector works with the `GetSpeechInfo` (page 1638) function.

Available in Mac OS X v10.0 and later.

Declared in `SpeechSynthesis.h`.

`soRecentSync`

Get the message code for the most recently encountered synchronization command. If no synchronization command has been encountered, 0 is returned. The `speechInfo` parameter is a pointer to a variable of type `OSType`.

This selector works with the `GetSpeechInfo` (page 1638) function.

Available in Mac OS X v10.0 and later.

Declared in `SpeechSynthesis.h`.

`soPhonemeSymbols`

Get a list of phoneme symbols and example words defined for the speech channel's synthesizer. Your application might use this information to show the user what symbols to use when entering phonemic text directly. The `speechInfo` parameter is a pointer to a variable of type Handle that, on exit from the `GetSpeechInfo` function, is a handle to a phoneme descriptor structure, described in `PhonemeDescriptor` (page 1671).

This selector works with the `GetSpeechInfo` (page 1638) function.

Available in Mac OS X v10.0 and later.

Declared in `SpeechSynthesis.h`.

`soCurrentVoice`

Set the current voice on the current speech channel to the specified voice. The `speechInfo` parameter is a pointer to a voice specification structure. Your application should create the structure by calling `MakeVoiceSpec` (page 1645). `SetSpeechInfo` will return an `incompatibleVoice` error if the specified voice is incompatible with the speech synthesizer associated with the speech channel. If you have a speech channel open using a voice from a particular synthesizer and you try to switch to a voice that works with a different synthesizer, you receive an `incompatibleVoice` error. You need to create a new channel to use with the new voice.

This selector works with the `SetSpeechInfo` (page 1650) function.

Available in Mac OS X v10.0 and later.

Declared in `SpeechSynthesis.h`.

`soCommandDelimiter`

Set the embedded speech command delimiter characters to be used for the speech channel. By default the opening delimiter is "`[[`" and the closing delimiter is "`]]`". Your application might need to change these delimiters temporarily if those character sequences occur naturally in a text buffer that is to be spoken. Your application can also disable embedded command processing by passing empty delimiters (2 `NULL` bytes). The `speechInfo` parameter is a pointer to a delimiter information structure, described in `DelimiterInfo` (page 1670).

This selector works with the `SetSpeechInfo` (page 1650) function.

Available in Mac OS X v10.0 and later.

Declared in `SpeechSynthesis.h`.

`soReset`

Set a speech channel back to its default state. For example, speech pitch and speech rate are set to default values. The `speechInfo` parameter should be set to `NULL`.

This selector works with the `SetSpeechInfo` (page 1650) function.

Available in Mac OS X v10.0 and later.

Declared in `SpeechSynthesis.h`.

`soCurrentA5`

Set the value that the Speech Synthesis Manager assigns to the A5 register before invoking any application-defined callback functions for the speech channel. The A5 register must be set correctly if the callback functions are to be able to access application global variables. The `speechInfo` parameter should be set to the pointer contained in the A5 register at a time when the application is not executing interrupt code or to `NULL` if your application wishes to clear a value previously set with the `soCurrentA5` selector.

This selector works with the `SetSpeechInfo` (page 1650) function.

Available in Mac OS X v10.0 and later.

Declared in `SpeechSynthesis.h`.

`soRefCon`

Set a speech channel's reference constant value. The reference constant value is passed to application-defined callback functions and might contain any value convenient for the application. The `speechInfo` parameter is a long integer containing the reference constant value. In contrast with other selectors, this selector does not require that the `speechInfo` parameter's value be a pointer value. Typically, however, an application does use this selector to pass a pointer or handle value to callback functions.

This selector works with the `SetSpeechInfo` (page 1650) function.

Available in Mac OS X v10.0 and later.

Declared in `SpeechSynthesis.h`.

`soTextDoneCallBack`

Set the callback function to be called when the Speech Synthesis Manager has finished processing speech being generated on the speech channel. The `speechInfo` parameter is a pointer to an application-defined text-done callback function, whose syntax is described in `SpeechTextDoneProcPtr` (page 1667). Passing `NULL` in `speechInfo` disables the text-done callback function.

This selector works with the `SetSpeechInfo` (page 1650) function.

Available in Mac OS X v10.0 and later.

Declared in `SpeechSynthesis.h`.

`soSpeechDoneCallBack`

Set the callback function to be called when the Speech Synthesis Manager has finished generating speech on the speech channel. The `speechInfo` parameter is a pointer to an application-defined speech-done callback function, whose syntax is described in `SpeechDoneProcPtr` (page 1662). Passing `NULL` in `speechInfo` disables the speech-done callback function.

This selector works with the `SetSpeechInfo` (page 1650) function.

Available in Mac OS X v10.0 and later.

Declared in `SpeechSynthesis.h`.

`soSyncCallBack`

Set the callback function to be called when the Speech Synthesis Manager encounters a synchronization command within an embedded speech command in text being processed on the speech channel. The `speechInfo` parameter is a pointer to an application-defined synchronization callback function, whose syntax is described in `SpeechSyncProcPtr` (page 1666). Passing `NULL` in `speechInfo` disables the synchronization callback function.

This selector works with the `SetSpeechInfo` (page 1650) function.

Available in Mac OS X v10.0 and later.

Declared in `SpeechSynthesis.h`.

`soErrorCallBack`

Set the callback function to be called when an error is encountered during the processing of an embedded command. The callback function might also be called if other conditions (such as insufficient memory) arise during the speech conversion process. When a Speech Synthesis Manager function returns an error directly, the error callback function is not called. The callback function is passed information about the most recent error; it can determine information about the oldest pending error by using the speech information selector `soErrors`. The `speechInfo` parameter is a pointer to an application-defined error callback function. Passing `NULL` in `speechInfo` disables the error callback function, `SpeechErrorProcPtr` (page 1664).

This selector works with the `SetSpeechInfo` (page 1650) function.

Available in Mac OS X v10.0 and later.

Declared in `SpeechSynthesis.h`.

`soPhonemeCallBack`

Set the callback function to be called every time the Speech Synthesis Manager is about to generate a phoneme on the speech channel. The `speechInfo` parameter is a pointer to an application-defined phoneme callback function, whose syntax is described in `SpeechPhonemeProcPtr` (page 1665). Passing `NULL` in `speechInfo` disables the phoneme callback function.

This selector works with the `SetSpeechInfo` (page 1650) function.

Available in Mac OS X v10.0 and later.

Declared in `SpeechSynthesis.h`.

`soWordCallBack`

Set the callback function to be called every time the Speech Synthesis Manager is about to generate a word on the speech channel. The `speechInfo` parameter is a pointer to an application-defined word callback function, whose syntax is described in `SpeechWordProcPtr` (page 1669). Passing `NULL` in `speechInfo` disables the word callback function.

This selector works with the `SetSpeechInfo` (page 1650) function.

Available in Mac OS X v10.0 and later.

Declared in `SpeechSynthesis.h`.

`soSynthExtension`

Get or set synthesizer-specific information or settings. The `speechInfo` parameter is a pointer to a speech extension data structure, described in `SpeechXtndData` (page 1677). Your application should set the `synthCreator` field of this structure before calling `GetSpeechInfo` (page 1638) or `SetSpeechInfo` (page 1650). Ordinarily, your application must pass additional information to the synthesizer in the `synthData` field.

This selector works with both the `GetSpeechInfo` (page 1638) and `SetSpeechInfo` (page 1650) functions.

Available in Mac OS X v10.0 and later.

Declared in `SpeechSynthesis.h`.

`soSoundOutput`

Get or set the speech channel's current output channel. (**Deprecated.** Use `soOutputToFileWithCFURL` (page 1692) instead.)

Available in Mac OS X v10.0 and later.

Declared in `SpeechSynthesis.h`.

`soOutputToFileWithCFURL`

Pass a `CFURLRef` to write to this file, `NULL` to generate sound.

This selector works with the `SetSpeechInfo` (page 1650) function.

Declared in `SpeechSynthesis.h`.

Available in Mac OS X v10.5 and later.

Discussion
See the `GetSpeechInfo` (page 1638) and `SetSpeechInfo` (page 1650) functions.

Declared In
`SpeechSynthesis.h`

Speech-Channel Properties

Properties used with `CopySpeechProperty` (page 1634) or `SetSpeechProperty` (page 1651) to get or set the characteristics of a speech channel.

```
CFStringRef kSpeechStatusProperty = CFSTR("stat");
CFStringRef kSpeechErrorsProperty = CFSTR("erro");
CFStringRef kSpeechInputModeProperty = CFSTR("inpt");
CFStringRef kSpeechCharacterModeProperty = CFSTR("char");
CFStringRef kSpeechNumberModeProperty = CFSTR("nmbr");
CFStringRef kSpeechRateProperty = CFSTR("rate");
CFStringRef kSpeechPitchBaseProperty = CFSTR("pbas");
CFStringRef kSpeechPitchModProperty = CFSTR("pmod");
CFStringRef kSpeechVolumeProperty = CFSTR("volm");
CFStringRef kSpeechSynthesizerInfoProperty = CFSTR("vers");
CFStringRef kSpeechRecentSyncProperty = CFSTR("sync");
CFStringRef kSpeechPhonemeSymbolsProperty = CFSTR("phsy");
CFStringRef kSpeechCurrentVoiceProperty = CFSTR("cvox");
CFStringRef kSpeechCommandDelimiterProperty = CFSTR("dlim");
CFStringRef kSpeechResetProperty = CFSTR("rset");
CFStringRef kSpeechOutputToFileURLProperty = CFSTR("opaf");
CFStringRef kSpeechRefConProperty = CFSTR("refc");
CFStringRef kSpeechTextDoneCallBack = CFSTR("tdcb");
CFStringRef kSpeechSpeechDoneCallBack = CFSTR("sdcb");
CFStringRef kSpeechSyncCallBack = CFSTR("sycb");
CFStringRef kSpeechPhonemeCallBack = CFSTR("phcb");
CFStringRef kSpeechErrorCFCallBack = CFSTR("eccb");
CFStringRef kSpeechWordCFCallBack = CFSTR("wccb");
```

Constants
`kSpeechStatusProperty`

Get speech-status information for the speech channel.

The value associated with this property is a `CFDictionary` object that contains speech-status information for the speech channel. See "`Speech Status Keys`" (page 1699) for a description of the keys present in the dictionary.

This property works with the `CopySpeechProperty` (page 1634) function.

Declared in `SpeechSynthesis.h`.

Available in Mac OS X v10.5 and later.

`kSpeechErrorsProperty`

Get speech-error information for the speech channel.

The value associated with this property is a `CFDictionary` object that contains speech-error information. See "Speech Error Keys" (page 1700) for a description of the keys present in the dictionary.

This property lets you get information about various run-time errors that occur during speaking, such as the detection of badly formed embedded commands. Errors returned directly by the Speech Synthesis Manager are not reported here. If your application defines an error callback function, the function can use this property to get error information.

This property works with the `CopySpeechProperty` (page 1634) function.

Declared in `SpeechSynthesis.h`.

Available in Mac OS X v10.5 and later.

`kSpeechInputModeProperty`

Get or set the speech channel's current text-processing mode.

The value associated with this property is a `CFString` object that specifies whether the channel is currently in text input mode or phoneme input mode. The constants `kSpeechModeText` and `kSpeechModePhoneme` (defined in "Speech-Channel Modes for Core Foundation-based Functions" (page 1684)) are the possible values of this string.

When in phoneme-processing mode, a text string is interpreted to be a series of characters representing various phonemes and prosodic controls. Some synthesizers might support additional input-processing modes and define constants for these modes.

This property works with the `CopySpeechProperty` (page 1634) and `SetSpeechProperty` (page 1651) functions.

Declared in `SpeechSynthesis.h`.

Available in Mac OS X v10.5 and later.

`kSpeechCharacterModeProperty`

Get or set the speech channel's current character-processing mode.

The value associated with this property is a `CFString` object that specifies whether the speech channel is currently in normal or literal character-processing mode. The constants `kSpeechModeNormal` and `kSpeechModeLiteral` (defined in "Speech-Channel Modes for Core Foundation-based Functions" (page 1684)) are the possible values of this string.

When the character-processing mode is `kSpeechModeNormal`, input characters are spoken as you would expect to hear them. When the mode is `kSpeechModeLiteral`, each character is spoken literally, so that the word "cat" is spoken "C–A–T".

This property works with the `CopySpeechProperty` (page 1634) and `SetSpeechProperty` (page 1651) functions.

Declared in `SpeechSynthesis.h`.

Available in Mac OS X v10.5 and later.

`kSpeechNumberModeProperty`

Get or set the speech channel's current number-processing mode.

The value associated with this property is a `CFString` object that specifies whether the speech channel is currently in normal or literal number-processing mode. The constants `kSpeechModeNormal` and `kSpeechModeLiteral` (defined in "Speech-Channel Modes for Core Foundation-based Functions" (page 1684)) are the possible values of this string.

When the number-processing mode is `kSpeechModeNormal`, the synthesizer assembles digits into numbers (so that "12" is spoken as "twelve"). When the mode is `kSpeechModeLiteral`, each digit is spoken literally (so that "12" is spoken as "one, two").

This property works with the `CopySpeechProperty` (page 1634) and `SetSpeechProperty` (page 1651) functions.

Declared in `SpeechSynthesis.h`.

Available in Mac OS X v10.5 and later.

`kSpeechRateProperty`

Get or set a speech channel's speech rate.

The value associated with this property is a `CFNumber` object that specifies the speech channel's speaking rate.

The range of supported rates is not predefined by the Speech Synthesis Manager; each speech synthesizer provides its own range of speech rates. Average human speech occurs at a rate of 180 to 220 words per minute.

This property works with the `CopySpeechProperty` (page 1634) and `SetSpeechProperty` (page 1651) functions.

Declared in `SpeechSynthesis.h`.

Available in Mac OS X v10.5 and later.

`kSpeechPitchBaseProperty`

Get or set the speech channel's baseline speech pitch.

The value associated with this property is a `CFNumber` object that specifies the speech channel's baseline speech pitch.

Typical voice frequencies range from around 90 hertz for a low-pitched male voice to perhaps 300 hertz for a high-pitched child's voice. These frequencies correspond to approximate pitch values in the ranges of 30.000 to 40.000 and 55.000 to 65.000, respectively.

This property works with the `CopySpeechProperty` (page 1634) and `SetSpeechProperty` (page 1651) functions.

Declared in `SpeechSynthesis.h`.

Available in Mac OS X v10.5 and later.

`kSpeechPitchModProperty`

Get or set a speech channel's pitch modulation.

The value associated with this property is a `CFNumber` object that specifies the speech channel's pitch modulation.

Pitch modulation is also expressed as a floating-point value in the range of 0.000 to 127.000. These values correspond to MIDI note values, where 60.000 is equal to middle C on a piano scale. The most useful speech pitches fall in the range of 40.000 to 55.000. A pitch modulation value of 0.000 corresponds to a monotone in which all speech is generated at the frequency corresponding to the speech pitch. Given a speech pitch value of 46.000, a pitch modulation of 2.000 would mean that the widest possible range of pitches corresponding to the actual frequency of generated text would be 44.000 to 48.000.

This property works with the `CopySpeechProperty` (page 1634) and `SetSpeechProperty` (page 1651) functions.

Declared in `SpeechSynthesis.h`.

Available in Mac OS X v10.5 and later.

`kSpeechVolumeProperty`

Get or set the speech volume for a speech channel.

The value associated with this property is a `CFNumber` object that specifies the speech channel's speech volume.

Volumes are expressed in floating-point values ranging from 0.0 through 1.0. A value of 0.0 corresponds to silence, and a value of 1.0 corresponds to the maximum possible volume. Volume units lie on a scale that is linear with amplitude or voltage. A doubling of perceived loudness corresponds to a doubling of the volume.

This property works with the `CopySpeechProperty` (page 1634) and `SetSpeechProperty` (page 1651) functions.

Declared in `SpeechSynthesis.h`.

Available in Mac OS X v10.5 and later.

`kSpeechSynthesizerInfoProperty`

Get information about the speech synthesizer being used on the specified speech channel.

The value associated with this property is a `CFDictionary` object that contains information about the speech synthesizer being used on the specified speech channel. See "`Speech Synthesizer Information Keys`" (page 1701) for a description of the keys present in the dictionary.

This property works with the `CopySpeechProperty` (page 1634) function.

Declared in `SpeechSynthesis.h`.

Available in Mac OS X v10.5 and later.

`kSpeechRecentSyncProperty`

Get the message code for the most recently encountered synchronization command.

The value associated with this property is a `CFNumber` object that specifies the most recently encountered synchronization command. This property works with the `CopySpeechProperty` (page 1634) function.

Declared in `SpeechSynthesis.h`.

Available in Mac OS X v10.5 and later.

`kSpeechPhonemeSymbolsProperty`

Get a list of phoneme symbols and example words defined for the speech channel's synthesizer.

The value associated with this property is a `CFDictionary` object that contains the phoneme symbols and example words defined for the current synthesizer. Your application might use this information to show the user what symbols to use when entering phonemic text directly. See "Phoneme Symbols Keys" (page 1702) for a description of the keys present in the dictionary.

This property works with the `CopySpeechProperty` (page 1634) function.

Declared in `SpeechSynthesis.h`.

Available in Mac OS X v10.5 and later.

`kSpeechCurrentVoiceProperty`

Set the current voice on the current speech channel to the specified voice.

The value associated with this property is a `CFDictionary` object that contains the phoneme symbols and example words defined for the current synthesizer. Your application might use this information to show the user what symbols to use when entering phonemic text directly. See "Phoneme Symbols Keys" (page 1702) for the keys you can use to specify values in this dictionary.

This property works with the `SetSpeechProperty` (page 1651) function.

Declared in `SpeechSynthesis.h`.

Available in Mac OS X v10.5 and later.

`kSpeechCommandDelimiterProperty`

Set the embedded speech command delimiter characters to be used for the speech channel.

By default, the opening delimiter is "`[[`" and the closing delimiter is "`]]`". Your application might need to change these delimiters temporarily if those character sequences occur naturally in a text buffer that is to be spoken. Your application can also disable embedded command processing by passing empty delimiters (as empty strings). The value associated with this property is a `CFDictionary` object that contains the delimiter information. See "Command Delimiter Keys" (page 1703) for the keys you can use to specify values in this dictionary.

This property works with the `SetSpeechProperty` (page 1651) function.

Declared in `SpeechSynthesis.h`.

Available in Mac OS X v10.5 and later.

`kSpeechResetProperty`

Set a speech channel back to its default state.

You can use this function to, for example, set speech pitch and speech rate to default values. There is no value associated with this property; to reset the channel to its default state, set the string to `NULL`.

This property works with the `SetSpeechProperty` (page 1651) function.

Declared in `SpeechSynthesis.h`.

Available in Mac OS X v10.5 and later.

`kSpeechOutputToFileURLProperty`

Set the speech output destination to a file or to the computer's speakers.

The value associated with this property is a `CFURL` object. To write the speech output to a file, use the file's `CFURLRef`; to generate the sound through the computer's speakers, use `NULL`.

This property works with the `SetSpeechProperty` (page 1651) function.

Declared in `SpeechSynthesis.h`.

Available in Mac OS X v10.5 and later.

`kSpeechRefConProperty`

Set a speech channel's reference constant value.

The reference constant value is passed to application-defined callback functions and might contain any value convenient for the application. The value associated with this property is a `CFNumber` object that contains an integer value. For example, an application might set the value of the `CFNumber` object to an address in memory that contains a reference to an object or a pointer to a function.

This property works with the `SetSpeechProperty` (page 1651) function.

Declared in `SpeechSynthesis.h`.

Available in Mac OS X v10.5 and later.

`kSpeechTextDoneCallBack`

Set the callback function to be called when the Speech Synthesis Manager has finished processing speech being generated on the speech channel.

The value associated with this property is a `CFNumber` object whose value is a pointer to an application-defined text-done callback function, whose syntax is described in `SpeechTextDoneProcPtr` (page 1667). Passing a `CFNumber` object that contains the value `NULL` disables the text-done callback function.

This property works with the `SetSpeechProperty` (page 1651) function.

Declared in `SpeechSynthesis.h`.

Available in Mac OS X v10.5 and later.

`kSpeechSpeechDoneCallBack`

Set the callback function to be called when the Speech Synthesis Manager has finished generating speech on the speech channel.

The value associated with this property is `CFNumber` object whose value is a pointer to an application-defined speech-done callback function, whose syntax is described in `SpeechDoneProcPtr` (page 1662). Passing `NULL` for the value of this property disables the speech-done callback function.

This property works with the `SetSpeechProperty` (page 1651) function.

Declared in `SpeechSynthesis.h`.

Available in Mac OS X v10.5 and later.

`kSpeechSyncCallBack`

Set the callback function to be called when the Speech Synthesis Manager encounters a synchronization command within an embedded speech command in text being processed on the speech channel.

The value associated with this property is `CFNumber` object whose value is a pointer to an application-defined synchronization callback function, whose syntax is described in `SpeechSyncProcPtr` (page 1666). Passing a `CFNumber` object that contains the value `NULL` for the value of this property disables the synchronization callback function.

This property works with the `SetSpeechProperty` (page 1651) function.

Declared in `SpeechSynthesis.h`.

Available in Mac OS X v10.5 and later.

`kSpeechPhonemeCallBack`

Set the callback function to be called every time the Speech Synthesis Manager is about to generate a phoneme on the speech channel.

The value associated with this property is `CFNumber` object whose value is a pointer to an application-defined phoneme callback function, whose syntax is described in `SpeechPhonemeProcPtr` (page 1665). Passing a `CFNumber` object that contains the value `NULL` for the value of this property disables the phoneme callback function.

This property works with the `SetSpeechProperty` (page 1651) function.

Declared in `SpeechSynthesis.h`.

Available in Mac OS X v10.5 and later.

`kSpeechErrorCFCallBack`

Set the callback function to be called when an error is encountered during the processing of an embedded command.

When a Speech Synthesis Manager function returns an error directly, the error callback function is not called. The callback function is passed information about the most recent error; it can determine information about the oldest pending error by using the speech information property `kSpeechErrorsProperty`. The value associated with this property is `CFNumber` object whose value is a pointer to an application-defined error callback function, whose syntax is described in `SpeechErrorCFProcPtr` (page 1663). Passing a `CFNumber` object that contains the value `NULL` for the value of this property disables the error callback function.

This property works with the `SetSpeechProperty` (page 1651) function.

Declared in `SpeechSynthesis.h`.

Available in Mac OS X v10.5 and later.

`kSpeechWordCFCallBack`

Set the callback function to be called every time the Speech Synthesis Manager is about to generate a word on the speech channel.

The value associated with this property is `CFNumber` object whose value is a pointer to an application-defined word callback function, whose syntax is described in `SpeechWordCFProcPtr` (page 1668). Passing a `CFNumber` object that contains the value `NULL` for the value of this property disables the word callback function.

This property works with the `SetSpeechProperty` (page 1651) function.

Declared in `SpeechSynthesis.h`.

Available in Mac OS X v10.5 and later.

Declared In
`SpeechSynthesis.h`

Synthesizer Option Keys

Keys used to specify synthesizer options.

```
CFStringRef kSpeechNoEndingProsody = CFSTR("NoEndingProsody");
CFStringRef kSpeechNoSpeechInterrupt = CFSTR("NoSpeechInterrupt");
CFStringRef kSpeechPreflightThenPause = CFSTR("PreflightThenPause");
```

Constants

`kSpeechNoEndingProsody`

Disable prosody at the end of sentences.

The `kSpeechNoEndingProsody` key is used to indicate whether the speech synthesizer should automatically apply ending prosody, which is the speech tone and cadence that normally occur at the end of a sentence. When the key is not specified, ending prosody is applied to the speech at the end of `aString`. This behavior can be disabled by specifying the `kSpeechNoEndingProsody` key in the `options` dictionary.

Declared in `SpeechSynthesis.h`.

Available in Mac OS X v10.5 and later.

`kSpeechNoSpeechInterrupt`

Do not interrupt current speech.

The `kSpeechNoSpeechInterrupt` key is used to control the behavior of `SpeakCFString` (page 1653) when it is called on a speech channel that is busy. When `kSpeechNoSpeechInterrupt` is not specified in the `options` dictionary, `SpeakCFString` immediately interrupts the speech currently being produced on the specified speech channel and the new `aString` text is spoken. When `kSpeechNoSpeechInterrupt` is specified in the `options` dictionary, the request to speak on a speech channel that is already busy causes the new `aString` text to be ignored and the `synthNotReady` error to be returned. As soon as the prior string has been fully processed, the new string is then spoken.

Declared in `SpeechSynthesis.h`.

Available in Mac OS X v10.5 and later.

`kSpeechPreflightThenPause`

Compute speech without generating it.

The `kSpeechPreflightThenPause` key is used to minimize the latency experienced when the speech synthesizer is attempting to speak.

Declared in `SpeechSynthesis.h`.

Available in Mac OS X v10.5 and later.

Declared In

`SpeechSynthesis.h`

Speech Status Keys

Keys used with the `kSpeechStatusProperty` property to specify the status of the speech channel.

```
CFStringRef kSpeechStatusOutputBusy = CFSTR("OutputBusy");
CFStringRef kSpeechStatusOutputPaused = CFSTR("OutputPaused");
CFStringRef kSpeechStatusNumberOfCharactersLeft = CFSTR("NumberOfCharactersLeft");
CFStringRef kSpeechStatusPhonemeCode = CFSTR("PhonemeCode");
```

Constants

`kSpeechStatusOutputBusy`

Indicates whether the speech channel is currently producing speech.

A speech channel is considered to be producing speech even at some times when no audio data is being produced through the computer's speaker. This occurs, for example, when the Speech Synthesis Manager is processing input, but has not yet initiated speech or when speech output is paused.

Declared in `SpeechSynthesis.h`.

Available in Mac OS X v10.5 and later.

`kSpeechStatusOutputPaused`

Indicates whether speech output in the speech channel has been paused by a call to the `PauseSpeechAt` (page 1649) function.

Available in Mac OS X v10.5 and later.

Declared in `SpeechSynthesis.h`.

`kSpeechStatusNumberOfCharactersLeft`

The number of characters left in the input string of text.

When the value of this constant is zero, you can destroy the input string.

Declared in `SpeechSynthesis.h`.

Available in Mac OS X v10.5 and later.

`kSpeechStatusPhonemeCode`

The opcode for the phoneme that the speech channel is currently processing.

Available in Mac OS X v10.5 and later.

Declared in `SpeechSynthesis.h`.

Declared In

`SpeechSynthesis.h`

Speech Error Keys

Keys used with the `kSpeechErrorsProperty` property to describe errors encountered during speech processing and production.

```
CFStringRef kSpeechErrorCount = CFSTR("Count");
CFStringRef kSpeechErrorOldest = CFSTR("OldestCode");
CFStringRef kSpeechErrorOldestCharacterOffset = CFSTR("OldestCharacterOffset");
CFStringRef kSpeechErrorNewest = CFSTR("NewestCode");
CFStringRef kSpeechErrorNewestCharacterOffset = CFSTR("NewestCharacterOffset");
```

Constants

`kSpeechErrorCount`

The number of errors that have occurred in processing the current text string, since the last call to the `CopySpeechProperty` (page 1634) function with the `kSpeechErrorsProperty` property.

Using the `kSpeechErrorOldest` keys and the `kSpeechErrorNewest` keys, you can get information about the oldest and most recent errors that occurred since the last call to `CopySpeechProperty` (page 1634), but you cannot get information about any intervening errors.

Declared in `SpeechSynthesis.h`.

Available in Mac OS X v10.5 and later.

`kSpeechErrorOldest`

The error code of the first error that occurred since the last call to the `CopySpeechProperty` (page 1634) function with the `kSpeechErrorsProperty` property.

Available in Mac OS X v10.5 and later.

Declared in `SpeechSynthesis.h`.

`kSpeechErrorOldestCharacterOffset`

The position in the text string of the first error that occurred since the last call to the `CopySpeechProperty` (page 1634) function with the `kSpeechErrorsProperty` property.

Available in Mac OS X v10.5 and later.

Declared in `SpeechSynthesis.h`.

`kSpeechErrorNewest`

The error code of the most recent error that occurred since the last call to the `CopySpeechProperty` (page 1634) function with the `kSpeechErrorsProperty` property.

Available in Mac OS X v10.5 and later.

Declared in `SpeechSynthesis.h`.

`kSpeechErrorNewestCharacterOffset`

The position in the text string of the most recent error that occurred since the last call to the `CopySpeechProperty` (page 1634) function with the `kSpeechErrorsProperty` property.

Available in Mac OS X v10.5 and later.

Declared in `SpeechSynthesis.h`.

Declared In

`SpeechSynthesis.h`

Speech Synthesizer Information Keys

Keys used with the `kSpeechSynthesizerInfoProperty` property to get information about the synthesizer.

```
CFStringRef kSpeechSynthesizerInfoIdentifier = CFSTR("Identifier");
CFStringRef kSpeechSynthesizerInfoVersion = CFSTR("Version");
```

Constants

`kSpeechSynthesizerInfoIdentifier`

The identifier of the speech synthesizer.

Available in Mac OS X v10.5 and later.

Declared in `SpeechSynthesis.h`.

`kSpeechSynthesizerInfoVersion`

The version of the speech synthesizer.

Available in Mac OS X v10.5 and later.

Declared in `SpeechSynthesis.h`.

Declared In

`SpeechSynthesis.h`

Phoneme Symbols Keys

Keys used with the `kSpeechPhonemeSymbolsProperty` property to provide information about the phoneme being processed.

```
CFStringRef kSpeechPhonemeInfoOpcode = CFSTR("Opcode");
CFStringRef kSpeechPhonemeInfoSymbol = CFSTR("Symbol");
CFStringRef kSpeechPhonemeInfoExample = CFSTR("Example");
CFStringRef kSpeechPhonemeInfoHiliteStart = CFSTR("HiliteStart");
CFStringRef kSpeechPhonemeInfoHiliteEnd = CFSTR("HiliteEnd");
```

Constants

`kSpeechPhonemeInfoOpcode`

The opcode of the phoneme.

Available in Mac OS X v10.5 and later.

Declared in `SpeechSynthesis.h`.

`kSpeechPhonemeInfoSymbol`

The symbol used to represent the phoneme.

The symbol does not necessarily have a phonetic connection to the phoneme, but might simply be an abstract textual representation of it.

Declared in `SpeechSynthesis.h`.

Available in Mac OS X v10.5 and later.

`kSpeechPhonemeInfoExample`

An example word that illustrates the use of the phoneme.

Available in Mac OS X v10.5 and later.

Declared in `SpeechSynthesis.h`.

`kSpeechPhonemeInfoHiliteStart`

The character offset into the example word that identifies the location of the beginning of the phoneme.

Available in Mac OS X v10.5 and later.

Declared in `SpeechSynthesis.h`.

`kSpeechPhonemeInfoHiliteEnd`
The character offset into the example word that identifies the location of the end of the phoneme.

Available in Mac OS X v10.5 and later.

Declared in `SpeechSynthesis.h`.

Declared In
`SpeechSynthesis.h`

Current Voice Keys

Keys used with the `kSpeechCurrentVoiceProperty` property to specify information about the current voice.

```
CFStringRef kSpeechVoiceCreator = CFSTR("Creator");
CFStringRef kSpeechVoiceID = CFSTR("ID");
```

Constants
`kSpeechVoiceCreator`
The synthesizer that is required to use the voice.

Declared in `SpeechSynthesis.h`.

Available in Mac OS X v10.5 and later.

`kSpeechVoiceID`
The voice ID of the voice for the synthesizer (every voice on a synthesizer has a unique ID).

Available in Mac OS X v10.5 and later.

Declared in `SpeechSynthesis.h`.

Declared In
`SpeechSynthesis.h`

Command Delimiter Keys

Keys used with the `kSpeechCommandDelimiterProperty` property to specify information about the command delimiter strings.

```
CFStringRef kSpeechCommandPrefix = CFSTR("Prefix");
CFStringRef kSpeechCommandSuffix = CFSTR("Suffix");
```

Constants
`kSpeechCommandPrefix`
The command delimiter string that prefixes a command (by default, this is `[[`).

Available in Mac OS X v10.5 and later.

Declared in `SpeechSynthesis.h`.

`kSpeechCommandSuffix`
The command delimiter string that suffixes a command (by default, this is `]]`).

Available in Mac OS X v10.5 and later.

Declared in `SpeechSynthesis.h`.

Availability
Available in Mac OS X v10.5 and later.

Declared In
SpeechSynthesis.h

Speech Dictionary Keys

Keys used in a speech dictionary to override the synthesizer's default pronunciation of a word.

```
CFStringRef kSpeechDictionaryLocaleIdentifier = CFSTR("LocaleIdentifier");
CFStringRef kSpeechDictionaryModificationDate = CFSTR("ModificationDate");
CFStringRef kSpeechDictionaryPronunciations = CFSTR("Pronunciations");
CFStringRef kSpeechDictionaryAbbreviations = CFSTR("Abbreviations");
CFStringRef kSpeechDictionaryEntrySpelling = CFSTR("Spelling");
CFStringRef kSpeechDictionaryEntryPhonemes = CFSTR("Phonemes");
```

Constants

`kSpeechDictionaryLocaleIdentifier`
The locale associated with the pronunciation.
Available in Mac OS X v10.5 and later.
Declared in SpeechSynthesis.h.

`kSpeechDictionaryModificationDate`
The date the dictionary was last modified.
Available in Mac OS X v10.5 and later.
Declared in SpeechSynthesis.h.

`kSpeechDictionaryPronunciations`
The set of custom pronunciations.
Available in Mac OS X v10.5 and later.
Declared in SpeechSynthesis.h.

`kSpeechDictionaryAbbreviations`
The set of custom pronunciations for abbreviations.
Available in Mac OS X v10.5 and later.
Declared in SpeechSynthesis.h.

`kSpeechDictionaryEntrySpelling`
The spelling of an entry.
Available in Mac OS X v10.5 and later.
Declared in SpeechSynthesis.h.

`kSpeechDictionaryEntryPhonemes`
The phonemic representation of an entry.
Available in Mac OS X v10.5 and later.
Declared in SpeechSynthesis.h.

Discussion
The keys in a speech dictionary can determine how a synthesizer pronounces a word. After you've created a speech dictionary, you register it with a speech channel with the `UseSpeechDictionary` (page 1661) function.

Declared In
SpeechSynthesis.h

Error Callback User-Information String

Specifies the string to speak to the user when an error occurs.

```
CFStringRef kSpeechErrorCallbackSpokenString = CFSTR("SpokenString");
```

Constants

`kSpeechErrorCallbackSpokenString`

The string to speak to the user when an error occurs.

Available in Mac OS X v10.5 and later.

Declared in `SpeechSynthesis.h`.

Declared In

`SpeechSynthesis.h`

Result Codes

The most common result codes returned by Speech Synthesis Manager are listed below.

Result Code	Value	Description
`noSynthFound`	-240	Could not find the specified speech synthesizer Available in Mac OS X v10.0 and later.
`synthOpenFailed`	-241	Could not open another speech synthesizer channel Available in Mac OS X v10.0 and later.
`synthNotReady`	-242	Speech synthesizer is still busy speaking Available in Mac OS X v10.0 and later.
`bufTooSmall`	-243	Output buffer is too small to hold result Available in Mac OS X v10.0 and later.
`voiceNotFound`	-244	Voice resource not found Available in Mac OS X v10.0 and later.
`incompatibleVoice`	-245	Specified voice cannot be used with synthesizer Available in Mac OS X v10.0 and later.
`badDictFormat`	-246	Pronunciation dictionary format error Available in Mac OS X v10.0 and later.
`badInputText`	-247	Raw phoneme text contains invalid characters Available in Mac OS X v10.0 and later.

Gestalt Constants

You can check for version and feature availability information by using the Speech Synthesis Manager selectors defined in the Gestalt Manager. For more information see *Inside Mac OS X: Gestalt Manager Reference*.

Ticket Services Reference

Framework: ApplicationServices/ApplicationServices.h, Carbon/Carbon.h

Declared in PMTemplate.h
PMTicket.h

Overview

Ticket Services provides the functions and data types used to communicate printing information (page format and print settings) among the various modules in the printing system. Developers who write printing dialog extensions and printer modules need to use the functions described in this reference and also need to consult the *Printing Plug-in Interfaces Reference*. Developers who write applications do not need this reference; see the *Carbon Printing Manager Reference* instead.

Functions by Task

Managing Tickets

`PMTicketCreate` (page 1749)
Creates a new ticket.

`PMTicketValidate` (page 1795)
Validates a ticket against the constraint values specified in a job template.

`PMTicketRetain` (page 1774)
Increments the retention count of a ticket object.

`PMTicketRemoveTicket` (page 1773)
Removes a subticket from a ticket.

`PMTicketRelease` (page 1772)
Decrements the retention count of a ticket object.

`PMTicketReleaseAndClear` (page 1772)
Decrements the retention count of a ticket and sets the ticket reference to `NULL`.

`PMTicketCopy` (page 1747)
Copies a ticket.

`PMTicketCreateTemplate` (page 1749)
Retrieves a template from a ticket.

`PMTicketCopyItem` (page 1748)
Copies an item from one ticket to another ticket.

`PMTicketReleaseItem` (page 1773)
Removes an item from a ticket.

`PMTicketDeleteItem` (page 1750)
Makes an item in a ticket unavailable.

`PMTicketLockItem` (page 1770)
Locks an item in a ticket.

`PMTicketUnlockItem` (page 1794)
Unlocks an item in a ticket.

`PMTicketIsItemLocked` (page 1770)
Checks to see if an item in a ticket is locked.

`PMTicketConfirmTicket` (page 1746)
Checks whether a ticket appears to be valid.

`PMTicketContainsItem` (page 1746)
Checks whether an item exists in a ticket.

`PMTicketContainsTicket` (page 1747)
Checks whether a ticket is contained in another ticket.

`PMTicketFillFromArray` (page 1751)
Adds items defined in an array of ticket item structures to a ticket.

Setting Ticket Items

`PMTicketSetBoolean` (page 1774)
Writes an item of type `Boolean` to a ticket.

`PMTicketSetBytes` (page 1775)
Writes an item that's an array of type `UInt8` to a ticket.

`PMTicketSetCFArray` (page 1776)
Writes an item of type `CFArray` to a ticket.

`PMTicketSetCFBoolean` (page 1776)
Writes an item of type `CFBoolean` to a ticket.

`PMTicketSetCFData` (page 1777)
Writes an item of type `CFData` to a ticket.

`PMTicketSetCFDate` (page 1778)
Writes an item of type `CFDate` to a ticket.

`PMTicketSetCFDictionary` (page 1779)
Writes an item of type `CFDictionary` to a ticket.

`PMTicketSetCFNumber` (page 1779)
Writes an item of type `CFNumber` to a ticket.

`PMTicketSetCFString` (page 1780)
Writes an item of type `CFString` to a ticket.

`PMTicketSetCString` (page 1781)
Writes an item that's a C-style string to a ticket.

`PMTicketSetCStringArray` (page 1782)
Writes an item that's an array of C-style strings to a ticket.

PMTicketSetDouble (page 1782)
Writes an item of type double to a ticket.

PMTicketSetDoubleArray (page 1783)
Writes an item that's an array of values of type double to a ticket.

PMTicketSetItem (page 1784)
Writes an item of type CFType to a ticket.

PMTicketSetPMRect (page 1785)
Writes an item of type PMRect to a ticket.

PMTicketSetPMRectArray (page 1786)
Writes an item that's an array of values of type PMRect to a ticket.

PMTicketSetPMResolution (page 1787)
Writes an item of type PMResolution to a ticket.

PMTicketSetPMResolutionArray (page 1788)
Writes an item that's an array of data of type PMResolution to a ticket.

PMTicketSetPString (page 1789)
Writes an item that's a Pascal-style string to a ticket.

PMTicketSetSInt32 (page 1789)
Writes an item of type SInt32 to a ticket.

PMTicketSetSInt32Array (page 1790)
Writes an item that's an array of data of type SInt32 to a ticket.

PMTicketSetTemplate (page 1791)
Writes an item that's a job template to a ticket.

PMTicketSetTicket (page 1791)
Writes a subticket to a ticket.

PMTicketSetUInt32 (page 1792)
Writes an item of type UInt32 to a ticket.

PMTicketSetUInt32Array (page 1793)
Writes an item that's an array of data of type UInt32 to a ticket.

Getting Ticket Items

PMTicketGetAllocator (page 1751)
Obtains the allocator object used for allocating memory for a ticket.

PMTicketGetAPIVersion (page 1752)
Obtains the version of the application programming interface (API) used to created a ticket.

PMTicketGetBoolean (page 1752)
Obtains data for a ticket item of type Boolean.

PMTicketGetBytes (page 1753)
Obtains data for a ticket item that's an array of UInt8 values.

PMTicketGetCFArray (page 1754)
Obtains data for a ticket item that's a Core Foundation array.

PMTicketGetCFBoolean (page 1755)
Obtains data for a ticket item that's an array of CFBoolean values.

PMTicketGetCFData (page 1755)
Obtains data for a ticket item of type CFData.

PMTicketGetCFDate (page 1756)
Obtains data for a ticket item of type CFDate.

PMTicketGetCFDictionary (page 1757)
Obtains data for a ticket item of type CFDictionary.

PMTicketGetCFNumber (page 1758)
Obtains data for a ticket item of type CFNumber.

PMTicketGetCFString (page 1758)
Obtains data for a ticket item of type CFString.

PMTicketGetCString (page 1759)
Obtains data for a ticket item of that's a C-style string.

PMTicketGetDouble (page 1760)
Obtains data for a ticket item of type double.

PMTicketGetEnumType (page 1760)
Obtains a ticket's ticket type (job, paper, converter, and so on).

PMTicketGetIndexPMResolution (page 1761)
Obtains an indexed resolution for a ticket item that's an array of type PMResolution.

PMTicketGetItem (page 1762)
Obtains data for a ticket item of type CFType.

PMTicketGetLockedState (page 1762)
Obtains the lock state of a ticket.

PMTicketGetPMRect (page 1764)
Obtains data for a ticket item of type PMRect.

PMTicketGetPMResolution (page 1764)
Obtains data for a ticket item of type PMResolution.

PMTicketGetPPDDict (page 1765)
Obtains data for a ticket item that's a PostScript printer description (PPD) dictionary.

PMTicketGetPString (page 1766)
Obtains data for a ticket item that's a Pascal-style string.

PMTicketGetRetainCount (page 1767)
Obtains the retention count for a ticket.

PMTicketGetSInt32 (page 1767)
Obtains data for a ticket item of type SInt32.

PMTicketGetTicket (page 1768)
Obtains a subticket from a ticket.

PMTicketGetType (page 1769)
Obtains a value that specifies the ticket's type.

PMTicketGetUInt32 (page 1769)
Obtains an item of type UInt32 from a ticket.

Managing Templates

`PMTemplateCreate` (page 1714)
Creates a new job template.

`PMTemplateDelete` (page 1715)
Deletes an existing job template.

`PMTemplateMakeEntry` (page 1731)
Creates a new entry in a job template.

`PMTemplateMakeFullEntry` (page 1731)
Creates a new entry in a job template and sets the default and constraint values for the entry.

`PMTemplateMergeTemplates` (page 1732)
Merges the entries from one job template with entries from another job template.

`PMTemplateRemoveEntry` (page 1733)
Removes an entry from a job template.

`PMTemplateValidateItem` (page 1745)
Validates an item in a job template.

`PMTemplateIsLocked` (page 1729)
Checks to see if a job template is locked.

Setting Template Items

`PMTemplateSetBooleanDefaultValue` (page 1733)
Sets the default value for a job template entry of type `Boolean`.

`PMTemplateSetCFArrayConstraintValue` (page 1734)
Sets the constraint values for a job template entry of type `CFArray`.

`PMTemplateSetCFDataDefaultValue` (page 1734)
Sets the default value for a job template entry of type `CFDataRef`.

`PMTemplateSetCFDefaultValue` (page 1735)
Sets the default value for a job template entry of type `CFTypeRef`.

`PMTemplateSetCFRangeConstraint` (page 1735)
Sets a range of constraint values for a job template entry of type `CFTypeRef`.

`PMTemplateSetDoubleDefaultValue` (page 1736)
Sets the default value for a job template entry of type `double`.

`PMTemplateSetDoubleListConstraint` (page 1736)
Sets constraint values for a job template entry of type `double`.

`PMTemplateSetDoubleRangeDefaultValue` (page 1738)
Sets the default range of values for a job template entry of type `double`.

`PMTemplateSetDoubleRangeConstraint` (page 1737)
Sets a range of constraint values for a job template entry of type `double`.

`PMTemplateSetDoubleRangesConstraint` (page 1738)
Sets a range of constraint values for a job template entry that is a range of type `double`.

`PMTemplateSetPMRectDefaultValue` (page 1739)
Sets the default value for a job template entry of type `PMRect`.

PMTemplateSetPMRectListConstraint (page 1740)
Sets constraint values for a job template entry of type PMRect.

PMTemplateSetPMTicketDefaultValue (page 1741)
Sets the default value for a job template entry of type PMTicketRef.

PMTemplateSetPMTicketListConstraint (page 1741)
Sets constraint values for a job template entry of type PMTicketRef.

PMTemplateSetSInt32DefaultValue (page 1742)
Sets the default value for a job template entry of type SInt32.

PMTemplateSetSInt32ListConstraint (page 1742)
Sets constraint values for a job template entry of type SInt32.

PMTemplateSetSInt32RangeDefaultValue (page 1744)
Sets the default range of values for a job template entry of type SInt32.

PMTemplateSetSInt32RangeConstraint (page 1743)
Sets a range of constraint values for a job template entry of type SInt32.

PMTemplateSetSInt32RangesConstraint (page 1744)
Sets a range of constraint values for a job template entry that is a range of type SInt32.

Getting Template Items

PMTemplateGetValueType (page 1729)
Obtains the data type of a job template entry.

PMTemplateGetConstraintType (page 1718)
Obtains the constraint type for a job template entry.

PMTemplateGetBooleanDefaultValue (page 1715)
Obtains the default value for a job template entry of type Boolean.

PMTemplateGetCFArrayConstraintValue (page 1716)
Obtains an array of constraint values for a job template entry of type CFArrayRef.

PMTemplateGetCFDataDefaultValue (page 1716)
Obtains the default value for a job template entry of type CFDataRef.

PMTemplateGetCFDefaultValue (page 1717)
Obtains the default value for a job template entry of type CFTypeRef.

PMTemplateGetCFRangeConstraintValue (page 1717)
Obtains the range of constraint values for a job template entry of type CFTypeRef.

PMTemplateGetDoubleDefaultValue (page 1719)
Obtains the default value for a job template entry of type double.

PMTemplateGetDoubleRangeDefaultValue (page 1721)
Obtains the default range values for a job template entry of type double.

PMTemplateGetDoubleListConstraintValue (page 1719)
Obtains constraint values for a job template entry of type double.

PMTemplateGetDoubleRangeConstraintValue (page 1720)
Obtains the default range of values for a job template entry of type double.

PMTemplateGetDoubleRangesConstraintValue (page 1722)
Obtains a range for the minimum and maximum constraint values for a job template entry that is a range of type double.

PMTemplateGetPMRectDefaultValue (page 1723)
Obtains the default value for a job template entry of type PMRect.

PMTemplateGetPMRectListConstraintValue (page 1724)
Obtains constraint values for a job template entry of type PMRect.

PMTemplateGetPMTicketDefaultValue (page 1724)
Obtains the default value for a job template entry of type PMTicket.

PMTemplateGetListTicketConstraintValue (page 1722)
Obtains the constraint value for a job template entry that of type PMTicketRef.

PMTemplateGetSInt32DefaultValue (page 1725)
Obtains the default value for a job template entry of type SInt32.

PMTemplateGetSInt32RangeDefaultValue (page 1727)
Obtains the default range values for a job template entry of type SInt32.

PMTemplateGetSInt32ListConstraintValue (page 1726)
Obtains constraint values for a job template entry of type SInt32.

PMTemplateGetSInt32RangeConstraintValue (page 1726)
Obtains the default range of values for a job template entry of type SInt32.

PMTemplateGetSInt32RangesConstraintValue (page 1728)
Obtains a range of constraint values for a job template entry that is a range of type SInt32.

Converting To and From XML

PMTemplateCreateXML (page 1714)
Converts the data in a job template to data represented as XML.

PMTicketToXML (page 1794)
Converts the data in a ticket to XML.

PMTicketWriteXML (page 1795)
Converts a ticket to XML and then writes it to a file stream.

PMTicketWriteXMLToFile (page 1796)
Converts a ticket to XML and then writes it to a file.

PMXMLToTicket (page 1796)
Converts a ticket saved as XML to a ticket.

PMTemplateLoadFromXML (page 1730)
Restores a job template that was previously converted to XML.

PMTicketReadXMLFromFile (page 1771)
Restores a ticket previously converted to XML and saved as a file.

Deprecated Functions

PMTicketSetMetaItem (page 1785)
Writes an item that does not need to be stored in an XML-representation of a ticket.

PMTicketGetMetaItem (page 1763)
Obtains data for a item added with the function PMTicketSetMetaItem.

Functions

PMTemplateCreate

Creates a new job template.

```
OSStatus PMTemplateCreate (
   PMTemplateRef *newTemplate
);
```

Parameters

newTemplate

On return, points to a job template data structure allocated by the function.

Return Value

A result code. See "Ticket Services Result Codes" (page 1832).

Availability

Not available in CarbonLib.

Available in Mac OS X 10.0 and later.

Declared In

`PMTemplate.h`

PMTemplateCreateXML

Converts the data in a job template to data represented as XML.

```
OSStatus PMTemplateCreateXML (
   PMTemplateRef srcTemplate,
   CFDataRef *xmlData
);
```

Parameters

srcTemplate

A reference to a job template created by calling the function `PMTemplateCreate`.

xmlData

On return, points to a reference to an XML representation of the data in the job template specified by the `srcTemplate` parameter.

Return Value

A result code. See "Ticket Services Result Codes" (page 1832).

Availability

Not available in CarbonLib.

Available in Mac OS X 10.0 and later.

Declared In

`PMTemplate.h`

PMTemplateDelete

Deletes an existing job template.

```
OSStatus PMTemplateDelete (
   PMTemplateRef *oldTemplate
);
```

Parameters

oldTemplate

On input, a reference to a job template created by calling the function `PMTemplateCreate`. On return, points to `NULL`.

Return Value

A result code. See "Ticket Services Result Codes" (page 1832).

Availability

Not available in CarbonLib.

Available in Mac OS X 10.0 and later.

Declared In

`PMTemplate.h`

PMTemplateGetBooleanDefaultValue

Obtains the default value for a job template entry of type `Boolean`.

```
OSStatus PMTemplateGetBooleanDefaultValue (
   PMTemplateRef pmTemplate,
   CFStringRef key,
   Boolean *defaultValue
);
```

Parameters

pmTemplate

A reference to a job template. You can call the function `PMSessionGetDataFromSession` with the ticket type set to `kPDE_PMJobTemplateRef` to get a value that you can then cast to a job template reference.

key

A reference to a `CFString` object that uniquely identifies the data you want to retrieve from the template.

defaultValue

On return, points to the default value for the template entry specified by the `key` parameter.

Return Value

A result code. See "Ticket Services Result Codes" (page 1832).

Availability

Not available in CarbonLib.

Available in Mac OS X 10.0 and later.

Declared In

`PMTemplate.h`

PMTemplateGetCFArrayConstraintValue

Obtains an array of constraint values for a job template entry of type `CFArrayRef`.

```
OSStatus PMTemplateGetCFArrayConstraintValue (
   PMTemplateRef pmTemplate,
   CFStringRef key,
   CFArrayRef *constraintValue
);
```

Parameters

pmTemplate

A reference to a job template. You can call the function `PMSessionGetDataFromSession` with the ticket type set to `kPDE_PMJobTemplateRef` to get a value that you can then cast to a job template reference.

key

A reference to a `CFString` object that uniquely identifies the data you want to retrieve from the template.

constraintValue

On return, a poinrter to a Core Foundation array reference for the constraint values for the template entry specified by the `key` parameter.

Return Value

A result code. See "Ticket Services Result Codes" (page 1832).

Availability

Not available in CarbonLib.

Available in Mac OS X 10.0 and later.

Declared In

`PMTemplate.h`

PMTemplateGetCFDataDefaultValue

Obtains the default value for a job template entry of type `CFDataRef`.

```
OSStatus PMTemplateGetCFDataDefaultValue (
   PMTemplateRef pmTemplate,
   CFStringRef key,
   CFDataRef *defaultValue
);
```

Parameters

pmTemplate

A reference to a job template. You can call the function `PMSessionGetDataFromSession` with the ticket type set to `kPDE_PMJobTemplateRef` to get a value that you can then cast to a job template reference.

key

A reference to a `CFString` object that uniquely identifies the data you want to retrieve from the template.

defaultValue

On return, points to a Core Foundation data reference that specfies the default data for the template entry specified by the `key` parameter.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTemplate.h`

PMTemplateGetCFDefaultValue

Obtains the default value for a job template entry of type `CFTypeRef`.

```
OSStatus PMTemplateGetCFDefaultValue (
   PMTemplateRef pmTemplate,
   CFStringRef key,
   CFTypeRef *defaultValue
);
```

Parameters

pmTemplate
A reference to a job template. You can call the function `PMSessionGetDataFromSession` with the ticket type set to `kPDE_PMJobTemplateRef` to get a value that you can then cast to a job template reference.

key
A reference to a `CFString` object that uniquely identifies the data you want to retrieve from the template.

defaultValue
On return, points to a Core Foundation type reference that specifies the default data for the template entry specified by the `key` parameter.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTemplate.h`

PMTemplateGetCFRangeConstraintValue

Obtains the range of constraint values for a job template entry of type `CFTypeRef`.

```
OSStatus PMTemplateGetCFRangeConstraintValue (
   PMTemplateRef pmTemplate,
   CFStringRef key,
   CFTypeRef *min,
   CFTypeRef *max
);
```

Parameters

pmTemplate

A reference to a job template. You can call the function `PMSessionGetDataFromSession` with the ticket type set to `kPDE_PMJobTemplateRef` to get a value that you can then cast to a job template reference.

key

A reference to a `CFString` object that uniquely identifies the data you want to retrieve from the template.

min

On return, points to a Core Foundation type reference that specifies the minimum value to which the template entry specified by the `key` parameter is constrained.

max

On return, points to a Core Foundation type reference that specifies the maximum value to which the template entry specified by the `key` parameter is constrained.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTemplate.h`

PMTemplateGetConstraintType

Obtains the constraint type for a job template entry.

```
OSStatus PMTemplateGetConstraintType (
   PMTemplateRef pmTemplate,
   CFStringRef key,
   PMConstraintType *constraintType
);
```

Parameters

pmTemplate

A reference to a job template. You can call the function `PMSessionGetDataFromSession` with the ticket type set to `kPDE_PMJobTemplateRef` to get a value that you can then cast to a job template reference.

key

A reference to a `CFString` object that uniquely identifies the data whose constraint type you want to retrieve from the template.

constraintType

On return, points to the constraint type for the data specified by the `key` parameter. See "Constraint Types" (page 1802) for a list of the constraint types that can be returned.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTemplate.h`

PMTemplateGetDoubleDefaultValue

Obtains the default value for a job template entry of type `double`.

```
OSStatus PMTemplateGetDoubleDefaultValue (
   PMTemplateRef pmTemplate,
   CFStringRef key,
   double *defaultValue
);
```

Parameters

pmTemplate

A reference to a job template. You can call the function `PMSessionGetDataFromSession` with the ticket type set to `kPDE_PMJobTemplateRef` to get a value that you can then cast to a job template reference.

key

A reference to a `CFString` object that uniquely identifies the data you want to retrieve from the template.

defaultValue

On return, points to the default `double` value for the template entry specified by the `key` parameter.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTemplate.h`

PMTemplateGetDoubleListConstraintValue

Obtains constraint values for a job template entry of type `double`.

```
OSStatus PMTemplateGetDoubleListConstraintValue (
   PMTemplateRef pmTemplate,
   CFStringRef key,
   int *listSize,
   double *doubleList
);
```

Parameters

pmTemplate

A reference to a job template. You can call the function `PMSessionGetDataFromSession` with the ticket type set to `kPDE_PMJobTemplateRef` to get a value that you can then cast to a job template reference.

key

A reference to a `CFString` object that uniquely identifies the data you want to retrieve from the template.

listSize

A pointer to the number of items in the array specified by the parameter `doubleList`.

doubleList

On return, points to an array of `double` values to which the template entry specified by the `key` parameter is constrained.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Discussion
You need to call the function `PMTemplateGetDoubleListConstraintValue` twice. First, call the function to get the number of items in the array specified by the parameter `doubleList`. You should call the function again after you allocate space for the array.

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTemplate.h`

PMTemplateGetDoubleRangeConstraintValue

Obtains the default range of values for a job template entry of type `double`.

```
OSStatus PMTemplateGetDoubleRangeConstraintValue (
   PMTemplateRef pmTemplate,
   CFStringRef key,
   double *min,
   double *max
);
```

Parameters

pmTemplate

A reference to a job template. You can call the function `PMSessionGetDataFromSession` with the ticket type set to `kPDE_PMJobTemplateRef` to get a value that you can then cast to a job template reference.

key

A reference to a `CFString` object that uniquely identifies the data you want to retrieve from the template.

min

On return, points to the minimum value to which the template entry specified by the `key` parameter is constrained.

max

On return, points to the maximum value to which the template entry specified by the `key` parameter is constrained.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTemplate.h`

PMTemplateGetDoubleRangeDefaultValue

Obtains the default range values for a job template entry of type `double`.

```
OSStatus PMTemplateGetDoubleRangeDefaultValue (
   PMTemplateRef pmTemplate,
   CFStringRef key,
   double *min,
   double *max
);
```

Parameters

pmTemplate

A reference to a job template. You can call the function `PMSessionGetDataFromSession` with the ticket type set to `kPDE_PMJobTemplateRef` to get a value that you can then cast to a job template reference.

key

A reference to a `CFString` object that uniquely identifies the data you want to retrieve from the template.

min

On return, points to the minimum value to which the range is constrained for the template entry specified by the `key` parameter.

max

On return, points to the maximum value to which the range is constrained for the template entry specified by the `key` parameter.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
PMTemplate.h

PMTemplateGetDoubleRangesConstraintValue

Obtains a range for the minimum and maximum constraint values for a job template entry that is a range of type `double`.

```
OSStatus PMTemplateGetDoubleRangesConstraintValue (
   PMTemplateRef pmTemplate,
   CFStringRef key,
   double *minForMin,
   double *maxForMin,
   double *minForMax,
   double *maxForMax
);
```

Parameters

pmTemplate

A reference to a job template. You can call the function `PMSessionGetDataFromSession` with the ticket type set to `kPDE_PMJobTemplateRef` to get a value that you can then cast to a job template reference.

key

A reference to a `CFString` object that uniquely identifies the data you want to retrieve from the template.

minForMin

On return, points to the minimum value to which the minimum of the range is constrained for the template entry specified by the `key` parameter.

maxForMin

On return, points to the maximum value to which the minimum of the range is constrained for the template entry specified by the `key` parameter.

minForMax

On return, points to the minimum value to which the maximum of the range is constrained for the template entry specified by the `key` parameter.

maxForMax

On return, points to the maximum value to which the maximum of the range is constrained for the template entry specified by the `key` parameter.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
PMTemplate.h

PMTemplateGetListTicketConstraintValue

Obtains the constraint value for a job template entry that of type `PMTicketRef`.

```
OSStatus PMTemplateGetListTicketConstraintValue (
   PMTemplateRef pmTemplate,
   CFStringRef key,
   PMTicketRef *listTicket
);
```

Parameters

pmTemplate

A reference to a job template. You can call the function `PMSessionGetDataFromSession` with the ticket type set to `kPDE_PMJobTemplateRef` to get a value that you can then cast to a job template reference.

key

A reference to a `CFString` object that uniquely identifies the data you want to retrieve from the template.

listTicket

On return, points to a reference to the list ticket to which the template entry specified by the `key` parameter is constrained.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTemplate.h`

PMTemplateGetPMRectDefaultValue

Obtains the default value for a job template entry of type `PMRect`.

```
OSStatus PMTemplateGetPMRectDefaultValue (
   PMTemplateRef pmTemplate,
   CFStringRef key,
   PMRect *defaultValue
);
```

Parameters

pmTemplate

A reference to a job template. You can call the function `PMSessionGetDataFromSession` with the ticket type set to `kPDE_PMJobTemplateRef` to get a value that you can then cast to a job template reference.

key

A reference to a `CFString` object that uniquely identifies the data you want to retrieve from the template.

defaultValue

On return, points to the default `PMRect` data for the template entry specified by the `key` parameter.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTemplate.h`

PMTemplateGetPMRectListConstraintValue

Obtains constraint values for a job template entry of type `PMRect`.

```
OSStatus PMTemplateGetPMRectListConstraintValue (
   PMTemplateRef pmTemplate,
   CFStringRef key,
   int *listSize,
   PMRect *rectList
);
```

Parameters

pmTemplate
A reference to a job template. You can call the function `PMSessionGetDataFromSession` with the ticket type set to `kPDE_PMJobTemplateRef` to get a value that you can then cast to a job template reference.

key
A reference to a `CFString` object that uniquely identifies the data you want to retrieve from the template.

listSize
A pointer to the number of items in the array specified by the parameter `rectList`.

rectList
On return, points to an array of `PMRect` values to which the template entry specified by the `key` parameter is constrained.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Discussion
You need to call the function `PMTemplateGetPMRectListConstraintValue` twice. First, call the function to get the number of items in the array specified by the parameter `rectList`. You should call the function again after you allocate space for the array.

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTemplate.h`

PMTemplateGetPMTicketDefaultValue

Obtains the default value for a job template entry of type `PMTicket`.

```
OSStatus PMTemplateGetPMTicketDefaultValue (
   PMTemplateRef pmTemplate,
   CFStringRef key,
   PMTicketRef *defaultValue
);
```

Parameters

pmTemplate

A reference to a job template. You can call the function `PMSessionGetDataFromSession` with the ticket type set to `kPDE_PMJobTemplateRef` to get a value that you can then cast to a job template reference.

key

A reference to a `CFString` object that uniquely identifies the data you want to retrieve from the template.

defaultValue

On return, points to a reference to the default ticket for the template entry specified by the `key` parameter.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTemplate.h`

PMTemplateGetSInt32DefaultValue

Obtains the default value for a job template entry of type `SInt32`.

```
OSStatus PMTemplateGetSInt32DefaultValue (
   PMTemplateRef pmTemplate,
   CFStringRef key,
   SInt32 *defaultValue
);
```

Parameters

pmTemplate

A reference to a job template. You can call the function `PMSessionGetDataFromSession` with the ticket type set to `kPDE_PMJobTemplateRef` to get a value that you can then cast to a job template reference.

key

A reference to a `CFString` object that uniquely identifies the data you want to retrieve from the template.

defaultValue

On return, points to the default value for the template entry specified by the `key` parameter.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTemplate.h`

PMTemplateGetSInt32ListConstraintValue

Obtains constraint values for a job template entry of type `SInt32`.

```
OSStatus PMTemplateGetSInt32ListConstraintValue (
   PMTemplateRef pmTemplate,
   CFStringRef key,
   int *listSize,
   SInt32 *sint32List
);
```

Parameters

pmTemplate
A reference to a job template. You can call the function `PMSessionGetDataFromSession` with the ticket type set to `kPDE_PMJobTemplateRef` to get a value that you can then cast to a job template reference.

key
A reference to a `CFString` object that uniquely identifies the data you want to retrieve from the template.

listSize
On return, points to the number of items in the array specified by the parameter `sint32List`.

sint32List
On return, points to an array of `SInt32` values to which the template entry specified by the `key` parameter is constrained.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Discussion
You need to call the function `PMTemplateGetSInt32ListConstraintValue` twice. First, call the function to get the number of items in the array specified by the parameter `sint32List`. You should call the function again after you allocate space for the array.

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTemplate.h`

PMTemplateGetSInt32RangeConstraintValue

Obtains the default range of values for a job template entry of type `SInt32`.

```
OSStatus PMTemplateGetSInt32RangeConstraintValue (
   PMTemplateRef pmTemplate,
   CFStringRef key,
   SInt32 *min,
   SInt32 *max
);
```

Parameters

pmTemplate

A reference to a job template. You can call the function `PMSessionGetDataFromSession` with the ticket type set to `kPDE_PMJobTemplateRef` to get a value that you can then cast to a job template reference.

key

A reference to a `CFString` object that uniquely identifies the data you want to retrieve from the template.

min

On return, points to the minimum value to which the template entry specified by the `key` parameter is constrained.

max

On return, points to the maximum value to which the template entry specified by the `key` parameter is constrained.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTemplate.h`

PMTemplateGetSInt32RangeDefaultValue

Obtains the default range values for a job template entry of type `SInt32`.

```
OSStatus PMTemplateGetSInt32RangeDefaultValue (
   PMTemplateRef pmTemplate,
   CFStringRef key,
   SInt32 *min,
   SInt32 *max
);
```

Parameters

pmTemplate

A reference to a job template. You can call the function `PMSessionGetDataFromSession` with the ticket type set to `kPDE_PMJobTemplateRef` to get a value that you can then cast to a job template reference.

key

A reference to a `CFString` object that uniquely identifies the data you want to retrieve from the template.

min

On return, points to the minimum value to which the range is constrained for the template entry specified by the `key` parameter.

max

On return, points to the maximum value to which the range is constrained for the template entry specified by the `key` parameter.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTemplate.h`

PMTemplateGetSInt32RangesConstraintValue

Obtains a range of constraint values for a job template entry that is a range of type `SInt32`.

```
OSStatus PMTemplateGetSInt32RangesConstraintValue (
   PMTemplateRef pmTemplate,
   CFStringRef key,
   SInt32 *minForMin,
   SInt32 *maxForMin,
   SInt32 *minForMax,
   SInt32 *maxForMax
);
```

Parameters

pmTemplate

A reference to a job template. You can call the function `PMSessionGetDataFromSession` with the ticket type set to `kPDE_PMJobTemplateRef` to get a value that you can then cast to a job template reference.

key

A reference to a `CFString` object that uniquely identifies the data you want to retrieve from the template.

minForMin

On return, points to the minimum value to which the minimum of the range is constrained for the template entry specified by the `key` parameter.

maxForMin

On return, points to the maximum value to which the minimum of the range is constrained for the template entry specified by the `key` parameter.

minForMax

On return, points to the minimum value to which the maximum of the range is constrained for the template entry specified by the `key` parameter.

maxForMax

On return, points to the maximum value to which the maximum of the range is constrained for the template entry specified by the `key` parameter.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTemplate.h`

PMTemplateGetValueType

Obtains the data type of a job template entry.

```
OSStatus PMTemplateGetValueType (
   PMTemplateRef pmTemplate,
   CFStringRef key,
   PMValueType *valueType
);
```

Parameters

pmTemplate
A reference to a job template. You can call the function `PMSessionGetDataFromSession` with the ticket type set to `kPDE_PMJobTemplateRef` to get a value that you can then cast to a job template reference.

key
A reference to a `CFString` object that uniquely identifies the data you want to retrieve from the template.

valueType
On return, points to the value type for the template entry specified by the `key` parameter. See "PMTicketItemType" (page 1800) for a list of values that can be returned.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTemplate.h`

PMTemplateIsLocked

Checks to see if a job template is locked.

```
OSStatus PMTemplateIsLocked (
   PMTemplateRef srcTemplate,
   Boolean *locked
);
```

Parameters

srcTemplate

A reference to a job template created by calling the function `PMTemplateCreate`.

locked

On return, points to `true` if the job template is locked and `false` if the template is not locked.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Discussion
A job template cannot be modified unless it is unlocked.

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTemplate.h`

PMTemplateLoadFromXML

Restores a job template that was previously converted to XML.

```
OSStatus PMTemplateLoadFromXML (
   CFDataRef srcData,
   PMTemplateRef *destTemplate
);
```

Parameters

srcData

A reference to `CFData` that represents job template data. You obtain a `CFDataRef` by calling the function `PMTemplateCreateXML`.

destTemplate

A reference to a job template created by calling the function `PMTemplateCreate`. On return, the job template contains the entries specified by the XML data.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTemplate.h`

PMTemplateMakeEntry

Creates a new entry in a job template.

```
OSStatus PMTemplateMakeEntry (
   PMTemplateRef pmTemplate,
   CFStringRef key,
   PMValueType valueType,
   PMConstraintType constraintType
);
```

Parameters

pmTemplate

A reference to a job template created by calling the function `PMTemplateCreate`.

key

A reference to a `CFString` object that uniquely identifies the entry. You use the key to set and obtain the data for this entry.

valueType

The data type of the value associated with the entry. See "PMValueType" (page 1801) for a list of constants you can use to specify the data type.

constraintType

The type of constraint you want applied to the data associated with the entry. See "Constraint Types" (page 1802) for a list of constants you can use to specify the constraint type.

Return Value

A result code. See "Ticket Services Result Codes" (page 1832).

Discussion

After you call the function `PMTemplateMakeEntry`, you should set default and constraint values for the entry by calling the appropriate `PMTemplateSet` functions for the data type of the entry.

Availability

Not available in CarbonLib.

Available in Mac OS X 10.0 and later.

Declared In

`PMTemplate.h`

PMTemplateMakeFullEntry

Creates a new entry in a job template and sets the default and constraint values for the entry.

```
OSStatus PMTemplateMakeFullEntry (
   PMTemplateRef pmTemplate,
   CFStringRef key,
   PMValueType valueType,
   PMConstraintType constraintType,
   CFTypeRef defaultValue,
   CFTypeRef constraintValue
);
```

Parameters

pmTemplate

A reference to a job template created by calling the function `PMTemplateCreate`.

key

A reference to a `CFString` object that uniquely identifies the entry. You use the key to set and obtain the data for this entry.

valueType

The data type of the value associated with the entry. See "PMValueType" (page 1801) for a list of constants you can use to specify the data type.

constraintType

The type of constraint you want applied to the data associated with the entry. See "Constraint Types" (page 1802) for a list of constants you can use to specify the constraint type.

defaultValue

A reference to the default value for this entry.

constraintValue

A reference to the values used to constrain the data associated with this entry.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTemplate.h`

PMTemplateMergeTemplates

Merges the entries from one job template with entries from another job template.

```
OSStatus PMTemplateMergeTemplates (
   PMTemplateRef sourceTemplate,
   PMTemplateRef destTemplate
);
```

Parameters

sourceTemplate

A reference to the job template whose entries you want to merge with the destination template.

destTemplate

A reference to the job template into which you want to merge entries from the source template. Any entry in the destination template that has the same key as an entry in the source template is overwritten by the data from the source template.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTemplate.h`

PMTemplateRemoveEntry

Removes an entry from a job template.

```
OSStatus PMTemplateRemoveEntry (
   PMTemplateRef pmTemplate,
   CFStringRef key
);
```

Parameters

pmTemplate

A reference to a job template created by calling the function `PMTemplateCreate`.

key

A reference to a `CFString` object that uniquely identifies the entry you want to remove.

Return Value

A result code. See "Ticket Services Result Codes" (page 1832).

Availability

Not available in CarbonLib.

Available in Mac OS X 10.0 and later.

Declared In

`PMTemplate.h`

PMTemplateSetBooleanDefaultValue

Sets the default value for a job template entry of type `Boolean`.

```
OSStatus PMTemplateSetBooleanDefaultValue (
   PMTemplateRef pmTemplate,
   CFStringRef key,
   Boolean defaultValue
);
```

Parameters

pmTemplate

A reference to a job template created by calling the function `PMTemplateCreate`.

key

A reference to a `CFString` object that uniquely identifies the data whose default value you want to set.

defaultValue

A `Boolean` value that specifies the default value for template entry specified by the `key` parameter.

Return Value

A result code. See "Ticket Services Result Codes" (page 1832).

Availability

Not available in CarbonLib.

Available in Mac OS X 10.0 and later.

Declared In

`PMTemplate.h`

PMTemplateSetCFArrayConstraintValue

Sets the constraint values for a job template entry of type `CFArray`.

```
OSStatus PMTemplateSetCFArrayConstraintValue (
   PMTemplateRef pmTemplate,
   CFStringRef key,
   CFArrayRef constraintValue
);
```

Parameters

pmTemplate

A reference to a job template created by calling the function `PMTemplateCreate`.

key

A reference to a `CFString` object that uniquely identifies the data whose constraint values you want to set.

constraintValue

A reference to a Core Foundation array that contains the values to which the template entry specified by the `key` parameter is constrained.

Return Value

A result code. See "Ticket Services Result Codes" (page 1832).

Availability

Not available in CarbonLib.

Available in Mac OS X 10.0 and later.

Declared In

`PMTemplate.h`

PMTemplateSetCFDataDefaultValue

Sets the default value for a job template entry of type `CFDataRef`.

```
OSStatus PMTemplateSetCFDataDefaultValue (
   PMTemplateRef pmTemplate,
   CFStringRef key,
   CFDataRef defaultValue
);
```

Parameters

pmTemplate

A reference to a job template created by calling the function `PMTemplateCreate`.

key

A reference to a `CFString` object that uniquely identifies the data whose default value you want to set.

defaultValue

A reference to the default data for template entry specified by the `key` parameter.

Return Value

A result code. See "Ticket Services Result Codes" (page 1832).

Availability

Not available in CarbonLib.

Available in Mac OS X 10.0 and later.

Declared In
PMTemplate.h

PMTemplateSetCFDefaultValue

Sets the default value for a job template entry of type CFTypeRef.

```
OSStatus PMTemplateSetCFDefaultValue (
   PMTemplateRef pmTemplate,
   CFStringRef key,
   CFTypeRef defaultValue
);
```

Parameters

pmTemplate
A reference to a job template created by calling the function PMTemplateCreate.

key
A reference to a CFString object that uniquely identifies the data whose default value you want to set.

defaultValue
A reference to the default data for template entry specified by the key parameter.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
PMTemplate.h

PMTemplateSetCFRangeConstraint

Sets a range of constraint values for a job template entry of type CFTypeRef.

```
OSStatus PMTemplateSetCFRangeConstraint (
   PMTemplateRef pmTemplate,
   CFStringRef key,
   CFTypeRef min,
   CFTypeRef max
);
```

Parameters

pmTemplate
A reference to a job template created by calling the function PMTemplateCreate.

key
A reference to a CFString object that uniquely identifies the data whose range of constraint values you want to set.

min

A reference to the minimum value to which the template entry specified by the `key` parameter is constrained.

max

A reference to the maximum value to which the template entry specified by the `key` parameter is constrained.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTemplate.h`

PMTemplateSetDoubleDefaultValue

Sets the default value for a job template entry of type `double`.

```
OSStatus PMTemplateSetDoubleDefaultValue (
   PMTemplateRef pmTemplate,
   CFStringRef key,
   double defaultValue
);
```

Parameters

pmTemplate

A reference to a job template created by calling the function `PMTemplateCreate`.

key

A reference to a `CFString` object that uniquely identifies the data whose default value you want to set.

defaultValue

A `double` value that specifies the default value for template entry specified by the `key` parameter.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTemplate.h`

PMTemplateSetDoubleListConstraint

Sets constraint values for a job template entry of type `double`.

```
OSStatus PMTemplateSetDoubleListConstraint (
   PMTemplateRef pmTemplate,
   CFStringRef key,
   int listSize,
   double *doubleList
);
```

Parameters

pmTemplate

A reference to a job template created by calling the function `PMTemplateCreate`.

key

A reference to a `CFString` object that uniquely identifies the data whose constraint values you want to set.

listSize

The size of the array specified by the parameter `doubleList`.

doubleList

A pointer to an array of `double` values to which the template entry specified by the `key` parameter is constrained.

Return Value

A result code. See "Ticket Services Result Codes" (page 1832).

Availability

Not available in CarbonLib.

Available in Mac OS X 10.0 and later.

Declared In

`PMTemplate.h`

PMTemplateSetDoubleRangeConstraint

Sets a range of constraint values for a job template entry of type `double`.

```
OSStatus PMTemplateSetDoubleRangeConstraint (
   PMTemplateRef pmTemplate,
   CFStringRef key,
   double min,
   double max
);
```

Parameters

pmTemplate

A reference to a job template created by calling the function `PMTemplateCreate`.

key

A reference to a `CFString` object that uniquely identifies the data whose constraint values you want to set.

min

A `double` value that specifies the minimum value to which the template entry specified by the `key` parameter is constrained.

max

A `double` value that specifies the maximum value to which the template entry specified by the `key` parameter is constrained.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTemplate.h`

PMTemplateSetDoubleRangeDefaultValue

Sets the default range of values for a job template entry of type `double`.

```
OSStatus PMTemplateSetDoubleRangeDefaultValue (
   PMTemplateRef pmTemplate,
   CFStringRef key,
   double min,
   double max
);
```

Parameters

pmTemplate

A reference to a job template created by calling the function `PMTemplateCreate`.

key

A reference to a `CFString` object that uniquely identifies the data whose default values you want to set.

min

A `double` value that specifies the default minimum value for the template entry specified by the `key` parameter.

max

A `double` value that specifies the default maximum value for template entry specified by the `key` parameter.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTemplate.h`

PMTemplateSetDoubleRangesConstraint

Sets a range of constraint values for a job template entry that is a range of type `double`.

```
OSStatus PMTemplateSetDoubleRangesConstraint (
   PMTemplateRef pmTemplate,
   CFStringRef key,
   double minForMin,
   double maxForMin,
   double minForMax,
   double maxForMax
);
```

Parameters

pmTemplate

A reference to a job template created by calling the function `PMTemplateCreate`.

key

A reference to a `CFString` object that uniquely identifies the data whose range of constraint values you want to set.

minForMin

A `double` value that specifies the minimum value to which the minimum of the range is constrained for the template entry specified by the `key` parameter.

maxForMin

A `double` value that specifies the maximum value to which the minimum of the range is constrained for the template entry specified by the `key` parameter.

minForMax

A `double` value that specifies the minimum value to which the maximum of the range is constrained for the template entry specified by the `key` parameter.

maxForMax

A `double` value that specifies the maximum value to which the maximum of the range is constrained for the template entry specified by the `key` parameter.

Return Value

A result code. See "Ticket Services Result Codes" (page 1832).

Availability

Not available in CarbonLib.

Available in Mac OS X 10.0 and later.

Declared In

`PMTemplate.h`

PMTemplateSetPMRectDefaultValue

Sets the default value for a job template entry of type `PMRect`.

```
OSStatus PMTemplateSetPMRectDefaultValue (
   PMTemplateRef pmTemplate,
   CFStringRef key,
   PMRect *defaultValue
);
```

Parameters

pmTemplate

A reference to a job template created by calling the function `PMTemplateCreate`.

key

A reference to a `CFString` object that uniquely identifies the data whose default value you want to set.

defaultValue

A pointer to a `PMRect` that specifies the default rectangle for the template entry specified by the `key` parameter.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTemplate.h`

PMTemplateSetPMRectListConstraint

Sets constraint values for a job template entry of type `PMRect`.

```
OSStatus PMTemplateSetPMRectListConstraint (
   PMTemplateRef pmTemplate,
   CFStringRef key,
   int listSize,
   PMRect *rectList
);
```

Parameters

pmTemplate

A reference to a job template created by calling the function `PMTemplateCreate`.

key

A reference to a `CFString` object that uniquely identifies the data whose constraint values you want to set.

listSize

The size of the array specified by the parameter `rectList`.

rectList

A pointer to an array of `PMRect` values to which the template entry specified by the `key` parameter is constrained.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTemplate.h`

PMTemplateSetPMTicketDefaultValue

Sets the default value for a job template entry of type `PMTicketRef`.

```
OSStatus PMTemplateSetPMTicketDefaultValue (
   PMTemplateRef pmTemplate,
   CFStringRef key,
   PMTicketRef defaultValue
);
```

Parameters

pmTemplate

A reference to a job template created by calling the function `PMTemplateCreate`.

key

A reference to a `CFString` object that uniquely identifies the data whose default value you want to set.

defaultValue

A reference to a ticket that specifies the default ticket for the template entry specified by the `key` parameter.

Return Value

A result code. See "Ticket Services Result Codes" (page 1832).

Availability

Not available in CarbonLib.

Available in Mac OS X 10.0 and later.

Declared In

`PMTemplate.h`

PMTemplateSetPMTicketListConstraint

Sets constraint values for a job template entry of type `PMTicketRef`.

```
OSStatus PMTemplateSetPMTicketListConstraint (
   PMTemplateRef pmTemplate,
   CFStringRef key,
   PMTicketRef listTicket
);
```

Parameters

pmTemplate

A reference to a job template created by calling the function `PMTemplateCreate`.

key

A reference to a `CFString` object that uniquely identifies the data whose constraint values you want to set.

listTicket

A reference to a ticket that specifies the default list ticket for the template entry specified by the `key` parameter.

Return Value

A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTemplate.h`

PMTemplateSetSInt32DefaultValue

Sets the default value for a job template entry of type `SInt32`.

```
OSStatus PMTemplateSetSInt32DefaultValue (
   PMTemplateRef pmTemplate,
   CFStringRef key,
   SInt32 defaultValue
);
```

Parameters

`pmTemplate`
A reference to a job template created by calling the function `PMTemplateCreate`.

`key`
A reference to a `CFString` object that uniquely identifies the data whose default value you want to set.

`defaultValue`
An `SInt32` value that specifies the default value for the template entry specified by the `key` parameter.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTemplate.h`

PMTemplateSetSInt32ListConstraint

Sets constraint values for a job template entry of type `SInt32`.

```
OSStatus PMTemplateSetSInt32ListConstraint (
   PMTemplateRef pmTemplate,
   CFStringRef key,
   int listSize,
   SInt32 *sint32List
);
```

Parameters

`pmTemplate`
A reference to a job template created by calling the function `PMTemplateCreate`.

key

A reference to a `CFString` object that uniquely identifies the data whose constraint values you want to set.

listSize

The size of the array specified by the parameter `sint32List`.

sint32List

A pointer to an array of `SInt32` values to which the template entry specified by the `key` parameter is constrained.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTemplate.h`

PMTemplateSetSInt32RangeConstraint

Sets a range of constraint values for a job template entry of type `SInt32`.

```
OSStatus PMTemplateSetSInt32RangeConstraint (
   PMTemplateRef pmTemplate,
   CFStringRef key,
   SInt32 min,
   SInt32 max
);
```

Parameters

pmTemplate

A reference to a job template created by calling the function `PMTemplateCreate`.

key

A reference to a `CFString` object that uniquely identifies the data whose constraint values you want to set.

min

An `SInt32` value that specifies the minimum value to which the template entry specified by the `key` parameter is constrained.

max

An `SInt32` value that specifies the maximum value to which the template entry specified by the `key` parameter is constrained.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTemplate.h`

PMTemplateSetSInt32RangeDefaultValue

Sets the default range of values for a job template entry of type `SInt32`.

```
OSStatus PMTemplateSetSInt32RangeDefaultValue (
   PMTemplateRef pmTemplate,
   CFStringRef key,
   SInt32 min,
   SInt32 max
);
```

Parameters

pmTemplate

A reference to a job template created by calling the function `PMTemplateCreate`.

key

A reference to a `CFString` object that uniquely identifies the data whose default values you want to set.

min

An `SInt32` value that specifies the default minimum value for the template entry specified by the `key` parameter.

max

An `SInt32` value that specifies the default maximum value for the template entry specified by the `key` parameter.

Return Value

A result code. See "Ticket Services Result Codes" (page 1832).

Availability

Not available in CarbonLib.

Available in Mac OS X 10.0 and later.

Declared In

`PMTemplate.h`

PMTemplateSetSInt32RangesConstraint

Sets a range of constraint values for a job template entry that is a range of type `SInt32`.

```
OSStatus PMTemplateSetSInt32RangesConstraint (
   PMTemplateRef pmTemplate,
   CFStringRef key,
   SInt32 minForMin,
   SInt32 maxForMin,
   SInt32 minForMax,
   SInt32 maxForMax
);
```

Parameters

pmTemplate

A reference to a job template created by calling the function `PMTemplateCreate`.

key

A reference to a `CFString` object that uniquely identifies the data whose range of constraint values you want to set.

minForMin
An SInt32 value that specifies the minimum value to which the minimum of the range is constrained for the template entry specified by the key parameter.

maxForMin
An SInt32 value that specifies the maximum value to which the minimum of the range is constrained for the template entry specified by the key parameter.

minForMax
An SInt32 value that specifies the minimum value to which the maximum of the range is constrained for the template entry specified by the key parameter.

maxForMax
An SInt32 value that specifies the maximum value to which the maximum of the range is constrained for the template entry specified by the key parameter.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
PMTemplate.h

PMTemplateValidateItem

Validates an item in a job template.

```
OSStatus PMTemplateValidateItem (
   PMTemplateRef pmTemplate,
   CFStringRef key,
   CFTypeRef item,
   Boolean *validationResults
);
```

Parameters

pmTemplate
A reference to a job template created by calling the function PMTemplateCreate.

key
A reference to a CFString object that uniquely identifies the job template entry you want to validate.

item
A reference to the data you want to validate.

validationResults
On return, points to true is the item is validated and false if it is not validated.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
PMTemplate.h

PMTicketConfirmTicket

Checks whether a ticket appears to be valid.

```
OSStatus PMTicketConfirmTicket (
   PMTicketRef ticket
);
```

Parameters

ticket
A reference to a ticket created by calling the function PMTicketCreate.

Return Value
A result code. Returns noErr if the ticket appears to be valid. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
PMTicket.h

PMTicketContainsItem

Checks whether an item exists in a ticket.

```
Boolean PMTicketContainsItem (
   PMTicketRef ticket,
   UInt32 nodeIndex1,
   UInt32 nodeIndex2,
   CFStringRef key
);
```

Parameters

ticket
A reference to a ticket created by calling the function PMTicketCreate.

nodeIndex1
Reserved for future use. Currently, you must pass the constant kPMTopLevel.

nodeIndex2
Reserved for future use. Currently, you must pass the constant kPMTopLevel.

key
A reference to a CFString object that uniquely identifies the ticket item you want to check.

Return Value
Returns true if the item exists.

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
PMTicket.h

PMTicketContainsTicket

Checks whether a ticket is contained in another ticket.

```
OSStatus PMTicketContainsTicket (
   PMTicketRef ticket,
   CFStringRef requestedType,
   UInt32 index,
   Boolean *exists
);
```

Parameters

ticket
A reference to a ticket created by calling the function PMTicketCreate.

requestedType
A reference to a CFString object that specfies the ticket type of the ticket for which you want to check. See "Ticket Type Strings" (page 1831) for a list of constants you can pass.

index
Reserved for future use. Currently, you must pass the constant kPMTopLevel.

exists
On return, points to true if the ticket contains a subticket of the ticket type specified by the requestedType parameter.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
PMTicket.h

PMTicketCopy

Copies a ticket.

```
OSStatus PMTicketCopy (
   CFAllocatorRef allocator,
   PMTicketRef sourceTicket,
   PMTicketRef *destinationTicket
);
```

Parameters

allocator
A reference to the allocator object to be used for allocating memory. Pass a reference to a valid allocator or kCFAllocatorDefault to request the default allocator.

sourceTicket

A reference to a ticket created by calling the function `PMTicketCreate`. This is the ticket you want to copy.

destinationTicket

A pointer to a ticket reference. On return, points to a copy of the source ticket.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTicket.h`

PMTicketCopyItem

Copies an item from one ticket to another ticket.

```
OSStatus PMTicketCopyItem (
   PMTicketRef sourceTicket,
   PMTicketRef destTicket,
   CFStringRef clientID,
   CFStringRef key,
   Boolean locked
);
```

Parameters

sourceTicket

A reference to a ticket created by calling the function `PMTicketCreate`. This is the ticket from which you want to copy an item.

destTicket

A reference to a ticket created by calling the function `PMTicketCreate`. This is the ticket to which the item is copied.

clientID

A reference to a `CFString` object that uniquely identifies your application. The string should be in a format similar to a Java-style package name (think of it as a reverse URL), such as `CFSTR("com.myvendorname.myprintingcode")`.

key

A reference to a `CFString` object that uniquely identifies the ticket item you want to copy.

locked

A `Boolean` value. Pass `true` to lock the copied item or `false` to set the item's lock state to unlock. Locking the item prevents any subsequent modification of this item.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Discussion
If an item must be copied from one ticket to another, call the function `PMTicketCopyItem` to make the simple transfer. This updates the modification date and client ID for the item. The *locked* field determines if subsequent updates can be made.

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
PMTicket.h

PMTicketCreate

Creates a new ticket.

```
OSStatus PMTicketCreate (
   CFAllocatorRef allocator,
   CFStringRef ticketType,
   PMTicketRef *newTicket
);
```

Parameters

allocator

A reference to the allocator object to be used for allocating memory. Pass a reference to a valid allocator or `kCFAllocatorDefault` to request the default allocator.

ticketType

A reference to a `CFString` object that specfies the ticket type of the ticket you want to create. See "Ticket Type Strings" (page 1831) for a list of constants you can pass.

newTicket

On return, a reference to a ticket.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
PMTicket.h

PMTicketCreateTemplate

Retrieves a template from a ticket.

```
OSStatus PMTicketCreateTemplate (
   PMTicketRef ticket,
   UInt32 nodeIndex1,
   UInt32 nodeIndex2,
   CFStringRef key,
   PMTemplateRef *item
);
```

Parameters

ticket

A reference to a ticket created by calling the function `PMTicketCreate`.

nodeIndex1
Reserved for future use. Currently, you must pass the constant `kPMTopLevel`.

nodeIndex2
Reserved for future use. Currently, you must pass the constant `kPMTopLevel`.

key
A reference to a `CFString` object that uniquely identifies the template you want to retrieve.

item
On return, points to the template reference specified by the `key` parameter.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Discussion
The function `PMTicketCreateTemplate` retrieves the template data associated with the specified key. The template is stored in the ticket as flattened data. The function creates a template object from the flattened data.

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTicket.h`

PMTicketDeleteItem

Makes an item in a ticket unavailable.

```
OSStatus PMTicketDeleteItem (
   PMTicketRef ticket,
   CFStringRef clientID,
   CFStringRef key
);
```

Parameters

ticket
A reference to a ticket created by calling the function `PMTicketCreate`.

clientID
A reference to a `CFString` object that uniquely identifies your application. The string should be in a format similar to a Java-style package name (think of it as a reverse URL), such as `CFSTR("com.myvendorname.myprintingcode")`.

key
A reference to a `CFString` object that uniquely identifies the ticket item you want to make unavailable.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Discussion
After an item is deleted by calling the function `PMTicketDeleteItem`, the result code `kPMInvalidItem` is returned when anyone tries to access the item. The function `PMTicketDeleteItem` actually makes the item unavailable rather than deleting the item. The function adds information to the item's dictionary to record the history of the item and to indicate the item is unavailable. You should call the function `PMTicketReleaseItem` if you want to completely remove the item from the ticket.

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTicket.h`

PMTicketFillFromArray

Adds items defined in an array of ticket item structures to a ticket.

```
OSStatus PMTicketFillFromArray (
   PMTicketRef ticket,
   CFStringRef clientID,
   const PMTicketItemStruct *items,
   UInt32 itemCount
);
```

Parameters

ticket
A reference to a ticket created by calling the function `PMTicketCreate`.

clientID
A reference to a `CFString` object that uniquely identifies your application. The string should be in a format similar to a Java-style package name (think of it as a reverse URL), such as `CFSTR("com.myvendorname.myprintingcode")`.

items
A pointer to an array of ticket item structures.

itemCount
The number of items in the `items` array.

Return Value
A result code. If the result code is anything other than `noErr`, it's possible that not all of the items were added successfully. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTicket.h`

PMTicketGetAllocator

Obtains the allocator object used for allocating memory for a ticket.

```
OSStatus PMTicketGetAllocator (
   PMTicketRef ticket,
   CFAllocatorRef *allocator
);
```

Parameters

ticket

A reference to a ticket created by calling the function `PMTicketCreate`.

allocator

On return, a reference to the `CFAllocator` object associated with the ticket.

Return Value

A result code. See "Ticket Services Result Codes" (page 1832).

Availability

Not available in CarbonLib.

Available in Mac OS X 10.0 and later.

Declared In

`PMTicket.h`

PMTicketGetAPIVersion

Obtains the version of the application programming interface (API) used to created a ticket.

```
OSStatus PMTicketGetAPIVersion (
   PMTicketRef ticket,
   CFStringRef *apiVersion
);
```

Parameters

ticket

A reference to a ticket created by calling the function `PMTicketCreate`.

apiVersion

On return, a reference to a `CFString` object that specifies the version of the API used to create the ticket.

Return Value

A result code. See "Ticket Services Result Codes" (page 1832).

Availability

Not available in CarbonLib.

Available in Mac OS X 10.0 and later.

Declared In

`PMTicket.h`

PMTicketGetBoolean

Obtains data for a ticket item of type `Boolean`.

```
OSStatus PMTicketGetBoolean (
   PMTicketRef ticket,
   UInt32 nodeIndex1,
   UInt32 nodeIndex2,
   CFStringRef key,
   Boolean *value
);
```

Parameters

ticket

A reference to a ticket created by calling the function `PMTicketCreate`.

nodeIndex1

Reserved for future use. Currently, you must pass the constant `kPMTopLevel`.

nodeIndex2

Reserved for future use. Currently, you must pass the constant `kPMTopLevel`.

key

A reference to a `CFString` object that uniquely identifies the ticket item whose value you want to obtain. See the Base Services documentation for a description of the `CFStringRef` data type.

value

On return, points to the `Boolean` value for the item specified by the `key` parameter.

Return Value

A result code. See "Ticket Services Result Codes" (page 1832).

Availability

Not available in CarbonLib.

Available in Mac OS X 10.0 and later.

Declared In

`PMTicket.h`

PMTicketGetBytes

Obtains data for a ticket item that's an array of `UInt8` values.

```
OSStatus PMTicketGetBytes (
   PMTicketRef ticket,
   UInt32 nodeIndex1,
   UInt32 nodeIndex2,
   CFStringRef key,
   UInt8 *data,
   UInt32 *size
);
```

Parameters

ticket

A reference to a ticket created by calling the function `PMTicketCreate`.

nodeIndex1

Reserved for future use. Currently, you must pass the constant `kPMTopLevel`.

nodeIndex2

Reserved for future use. Currently, you must pass the constant `kPMTopLevel`.

key

A reference to a `CFString` object that uniquely identifies the ticket item whose value you want to obtain.

data

On return, points to an array of data of type `UInt8` for the item specified by the `key` parameter.

size

On input, pass the size of the buffer pointed to by the `data` parameter. On return, points to the number of bytes in the array.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Discussion
If you don't know the size of the data buffer, you need to call the function `PMTicketGetBytes` twice. First, call the function to get the number of items in the array specified by the parameter `data`. You should call the function again after you allocate space for the array.

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTicket.h`

PMTicketGetCFArray

Obtains data for a ticket item that's a Core Foundation array.

```
OSStatus PMTicketGetCFArray (
   PMTicketRef ticket,
   UInt32 nodeIndex1,
   UInt32 nodeIndex2,
   CFStringRef key,
   CFArrayRef *item
);
```

Parameters

ticket

A reference to a ticket created by calling the function `PMTicketCreate`.

nodeIndex1

Reserved for future use. Currently, you must pass the constant `kPMTopLevel`.

nodeIndex2

Reserved for future use. Currently, you must pass the constant `kPMTopLevel`.

key

A reference to a `CFString` object that uniquely identifies the ticket item whose value you want to obtain.

item

On return, points to a Core Foundation array reference for the item specified by the `key` parameter.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTicket.h`

PMTicketGetCFBoolean

Obtains data for a ticket item that's an array of `CFBoolean` values.

```
OSStatus PMTicketGetCFBoolean (
   PMTicketRef ticket,
   UInt32 nodeIndex1,
   UInt32 nodeIndex2,
   CFStringRef key,
   CFBooleanRef *item
);
```

Parameters

ticket
A reference to a ticket created by calling the function `PMTicketCreate`.

nodeIndex1
Reserved for future use. Currently, you must pass the constant `kPMTopLevel`.

nodeIndex2
Reserved for future use. Currently, you must pass the constant `kPMTopLevel`.

key
A reference to a `CFString` object that uniquely identifies the ticket item whose value you want to obtain.

item
On return, points to a Core Foundation Boolean reference for the item specified by the `key` parameter.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTicket.h`

PMTicketGetCFData

Obtains data for a ticket item of type `CFData`.

```
OSStatus PMTicketGetCFData (
   PMTicketRef ticket,
   UInt32 nodeIndex1,
   UInt32 nodeIndex2,
   CFStringRef key,
   CFDataRef *item
);
```

Parameters

ticket

A reference to a ticket created by calling the function `PMTicketCreate`.

nodeIndex1

Reserved for future use. Currently, you must pass the constant `kPMTopLevel`.

nodeIndex2

Reserved for future use. Currently, you must pass the constant `kPMTopLevel`.

key

A reference to a `CFString` object that uniquely identifies the ticket item whose value you want to obtain.

item

On return, points to a Core Foundation data reference for the item specified by the `key` parameter.

Return Value

A result code. See "Ticket Services Result Codes" (page 1832).

Availability

Not available in CarbonLib.

Available in Mac OS X 10.0 and later.

Declared In

`PMTicket.h`

PMTicketGetCFDate

Obtains data for a ticket item of type `CFDate`.

```
OSStatus PMTicketGetCFDate (
   PMTicketRef ticket,
   UInt32 nodeIndex1,
   UInt32 nodeIndex2,
   CFStringRef key,
   CFDateRef *item
);
```

Parameters

ticket

A reference to a ticket created by calling the function `PMTicketCreate`.

nodeIndex1

Reserved for future use. Currently, you must pass the constant `kPMTopLevel`.

nodeIndex2

Reserved for future use. Currently, you must pass the constant `kPMTopLevel`.

key

A reference to a `CFString` object that uniquely identifies the ticket item whose value you want to obtain.

item

On return, points to a Core Foundation date reference for the item specified by the `key` parameter.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTicket.h`

PMTicketGetCFDictionary

Obtains data for a ticket item of type `CFDictionary`.

```
OSStatus PMTicketGetCFDictionary (
   PMTicketRef ticket,
   UInt32 nodeIndex1,
   UInt32 nodeIndex2,
   CFStringRef key,
   CFDictionaryRef *item
);
```

Parameters

ticket

A reference to a ticket created by calling the function `PMTicketCreate`.

nodeIndex1

Reserved for future use. Currently, you must pass the constant `kPMTopLevel`.

nodeIndex2

Reserved for future use. Currently, you must pass the constant `kPMTopLevel`.

key

A reference to a `CFString` object that uniquely identifies the ticket item whose value you want to obtain.

item

On return, points to a Core Foundation dictionary reference for the item specified by the `key` parameter.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTicket.h`

PMTicketGetCFNumber

Obtains data for a ticket item of type `CFNumber`.

```
OSStatus PMTicketGetCFNumber (
   PMTicketRef ticket,
   UInt32 nodeIndex1,
   UInt32 nodeIndex2,
   CFStringRef key,
   CFNumberRef *item
);
```

Parameters

ticket

A reference to a ticket created by calling the function `PMTicketCreate`.

nodeIndex1

Reserved for future use. Currently, you must pass the constant `kPMTopLevel`.

nodeIndex2

Reserved for future use. Currently, you must pass the constant `kPMTopLevel`.

key

A reference to a `CFString` object that uniquely identifies the ticket item whose value you want to obtain.

item

On return, points to a Core Foundation number reference for the item specified by the `key` parameter.

Return Value

A result code. See "Ticket Services Result Codes" (page 1832).

Availability

Not available in CarbonLib.

Available in Mac OS X 10.0 and later.

Declared In

`PMTicket.h`

PMTicketGetCFString

Obtains data for a ticket item of type `CFString`.

```
OSStatus PMTicketGetCFString (
   PMTicketRef ticket,
   UInt32 nodeIndex1,
   UInt32 nodeIndex2,
   CFStringRef key,
   CFStringRef *item
);
```

Parameters

ticket

A reference to a ticket created by calling the function `PMTicketCreate`.

nodeIndex1

Reserved for future use. Currently, you must pass the constant `kPMTopLevel`.

nodeIndex2

Reserved for future use. Currently, you must pass the constant `kPMTopLevel`.

key

A reference to a `CFString` object that uniquely identifies the ticket item whose value you want to obtain.

item

On return, points to a Core Foundation string reference for the item specified by the `key` parameter.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTicket.h`

PMTicketGetCString

Obtains data for a ticket item of that's a C-style string.

```
OSStatus PMTicketGetCString (
   PMTicketRef ticket,
   UInt32 nodeIndex1,
   UInt32 nodeIndex2,
   CFStringRef key,
   UInt32 bufferSize,
   CFStringEncoding encoding,
   char *value
);
```

Parameters

ticket

A reference to a ticket created by calling the function `PMTicketCreate`.

nodeIndex1

Reserved for future use. Currently, you must pass the constant `kPMTopLevel`.

nodeIndex2

Reserved for future use. Currently, you must pass the constant `kPMTopLevel`.

key

A reference to a `CFString` object that uniquely identifies the ticket item whose value you want to obtain.

bufferSize

The size of the string specified by the `value` parameter.

encoding

The encoding of the string. You should supply one of the `CFStringBuiltInEncodings` constants defined in Core Foundation String Services.

value

On return, points to the C-style string for the item specified by the `key` parameter.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTicket.h`

PMTicketGetDouble

Obtains data for a ticket item of type `double`.

```
OSStatus PMTicketGetDouble (
   PMTicketRef ticket,
   UInt32 nodeIndex1,
   UInt32 nodeIndex2,
   CFStringRef key,
   double *value
);
```

Parameters

ticket
A reference to a ticket created by calling the function `PMTicketCreate`.

nodeIndex1
Reserved for future use. Currently, you must pass the constant `kPMTopLevel`.

nodeIndex2
Reserved for future use. Currently, you must pass the constant `kPMTopLevel`.

key
A reference to a `CFString` object that uniquely identifies the ticket item whose value you want to obtain.

value
On return, points to the `double` value for the item specified by the `key` parameter.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTicket.h`

PMTicketGetEnumType

Obtains a ticket's ticket type (job, paper, converter, and so on).

```
OSStatus PMTicketGetEnumType (
   PMTicketRef ticket,
   PMTicketType *ticketType
);
```

Parameters

ticket

A reference to a ticket created by calling the function `PMTicketCreate`.

ticketType

On return, points to a value of type `PMTicketType` that specifies a ticket's type.

Return Value

A result code. See "Ticket Services Result Codes" (page 1832).

Availability

Not available in CarbonLib.

Available in Mac OS X 10.0 and later.

Declared In

`PMTicket.h`

PMTicketGetIndexPMResolution

Obtains an indexed resolution for a ticket item that's an array of type `PMResolution`.

```
OSStatus PMTicketGetIndexPMResolution (
   PMTicketRef ticket,
   UInt32 nodeIndex1,
   UInt32 nodeIndex2,
   CFStringRef key,
   UInt32 index,
   PMResolution *res
);
```

Parameters

ticket

A reference to a ticket created by calling the function `PMTicketCreate`.

nodeIndex1

Reserved for future use. Currently, you must pass the constant `kPMTopLevel`.

nodeIndex2

Reserved for future use. Currently, you must pass the constant `kPMTopLevel`.

key

A reference to a `CFString` object that uniquely identifies the ticket item whose value you want to obtain.

index

The index of the resolution you want to obtain.

res

On return, points to the resolution (`PMResolution`) specified by the `index` parameter.

Return Value

A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTicket.h`

PMTicketGetItem

Obtains data for a ticket item of type `CFType`.

```
OSStatus PMTicketGetItem (
   PMTicketRef ticket,
   UInt32 nodeIndex1,
   UInt32 nodeIndex2,
   CFStringRef key,
   CFTypeRef *item
);
```

Parameters

ticket
A reference to a ticket created by calling the function `PMTicketCreate`.

nodeIndex1
Reserved for future use. Currently, you must pass the constant `kPMTopLevel`.

nodeIndex2
Reserved for future use. Currently, you must pass the constant `kPMTopLevel`.

key
A reference to a `CFString` object that uniquely identifies the ticket item whose value you want to obtain.

item
On return, point to a Core Foundation type reference for the item specified by the `key` parameter.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTicket.h`

PMTicketGetLockedState

Obtains the lock state of a ticket.

```
OSStatus PMTicketGetLockedState (
   PMTicketRef ticket,
   Boolean *lockedState
);
```

Parameters

ticket

A reference to a ticket created by calling the function `PMTicketCreate`.

lockedState

On return, points to `true` if the ticket is locked and `false` if the ticket is unlocked.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Discussion
Tickets can be locked by the printing system. If you try to modify a locked ticket the result code `kPMTicketLocked` is returned. You can call the function `PMTicketGetLockedState` before you call any other function that modifies the ticket.

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`PMTicketDeprecated.h`

PMTicketGetMetaItem

Obtains data for a item added with the function `PMTicketSetMetaItem`.

Not recommended.

```
OSStatus PMTicketGetMetaItem (
   PMTicketRef ticket,
   CFStringRef key,
   CFTypeRef *item
);
```

Parameters

ticket

A reference to a ticket created by calling the function `PMTicketCreate`.

key

A reference to a `CFString` object that uniquely identifies the ticket item whose value you want to obtain.

item

On return, a reference to the data for the item specified by the `key` parameter.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Not available to 64-bit applications.

Declared In
`PMTicketDeprecated.h`

PMTicketGetPMRect

Obtains data for a ticket item of type `PMRect`.

```
OSStatus PMTicketGetPMRect (
   PMTicketRef ticket,
   UInt32 nodeIndex1,
   UInt32 nodeIndex2,
   CFStringRef key,
   PMRect *value
);
```

Parameters

ticket
A reference to a ticket created by calling the function `PMTicketCreate`.

nodeIndex1
Reserved for future use. Currently, you must pass the constant `kPMTopLevel`.

nodeIndex2
Reserved for future use. Currently, you must pass the constant `kPMTopLevel`.

key
A reference to a `CFString` object that uniquely identifies the ticket item whose value you want to obtain.

value
On return, points to the `PMRect` data for the item specified by the `key` parameter.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTicket.h`

PMTicketGetPMResolution

Obtains data for a ticket item of type `PMResolution`.

```
OSStatus PMTicketGetPMResolution (
   PMTicketRef ticket,
   UInt32 nodeIndex1,
   UInt32 nodeIndex2,
   CFStringRef key,
   PMResolution *res
);
```

Parameters

ticket

A reference to a ticket created by calling the function `PMTicketCreate`.

nodeIndex1

Reserved for future use. Currently, you must pass the constant `kPMTopLevel`.

nodeIndex2

Reserved for future use. Currently, you must pass the constant `kPMTopLevel`.

key

A reference to a `CFString` object that uniquely identifies the ticket item whose value you want to obtain.

res

On return, points to the `PMResolution` data for the item specified by the `key` parameter.

Return Value

A result code. See "Ticket Services Result Codes" (page 1832).

Availability

Not available in CarbonLib.

Available in Mac OS X 10.0 and later.

Declared In

`PMTicket.h`

PMTicketGetPPDDict

Obtains data for a ticket item that's a PostScript printer description (PPD) dictionary.

```
OSStatus PMTicketGetPPDDict (
   PMTicketRef ticket,
   UInt32 nodeIndex1,
   UInt32 nodeIndex2,
   CFMutableDictionaryRef *dict
);
```

Parameters

ticket

A reference to a ticket created by calling the function `PMTicketCreate`.

nodeIndex1

Reserved for future use. Currently, you must pass the constant `kPMTopLevel`.

nodeIndex2

Reserved for future use. Currently, you must pass the constant `kPMTopLevel`.

dict

On return, points to a reference to the PostScript printer description (PPD) dictionary associated with the specified ticket. The dictionary holds pairs of PPD main and option keywords. The main keywords are specified as keys in the dictionary and the options keywords specify the value.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`PMTicketDeprecated.h`

PMTicketGetPString

Obtains data for a ticket item that's a Pascal-style string.

```
OSStatus PMTicketGetPString (
   PMTicketRef ticket,
   UInt32 nodeIndex1,
   UInt32 nodeIndex2,
   CFStringRef key,
   UInt32 bufferSize,
   CFStringEncoding encoding,
   StringPtr value
);
```

Parameters

ticket

A reference to a ticket created by calling the function `PMTicketCreate`.

nodeIndex1

Reserved for future use. Currently, you must pass the constant `kPMTopLevel`.

nodeIndex2

Reserved for future use. Currently, you must pass the constant `kPMTopLevel`.

key

A reference to a `CFString` object that uniquely identifies the ticket item whose value you want to obtain.

bufferSize

The size of the `value` parameter.

encoding

The encoding of the string. You should supply one of the `CFStringBuiltInEncodings` constants defined in Core Foundation String Services.

value

On return, points to the Pascal-style string value for the ticket item specified by the `key` parameter.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTicket.h`

PMTicketGetRetainCount

Obtains the retention count for a ticket.

```
OSStatus PMTicketGetRetainCount (
   PMTicketRef ticket,
   CFIndex *retainCount
);
```

Parameters

ticket
A reference to a ticket created by calling the function `PMTicketCreate`.

retainCount
On return, points to the retention count for the ticket.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Discussion
The function `PMTicketGetRetainCount` behaves similarly to the Core Foundation function `CFGetRetainCount`.

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTicket.h`

PMTicketGetSInt32

Obtains data for a ticket item of type `SInt32`.

```
OSStatus PMTicketGetSInt32 (
   PMTicketRef ticket,
   UInt32 nodeIndex1,
   UInt32 nodeIndex2,
   CFStringRef key,
   SInt32 *value
);
```

Parameters

ticket
A reference to a ticket created by calling the function `PMTicketCreate`.

nodeIndex1
Reserved for future use. Currently, you must pass the constant `kPMTopLevel`.

nodeIndex2

Reserved for future use. Currently, you must pass the constant `kPMTopLevel`.

key

A reference to a `CFString` object that uniquely identifies the ticket item whose value you want to obtain.

value

On return, points to the `SInt32` value for the ticket item specified by the `key` parameter.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTicket.h`

PMTicketGetTicket

Obtains a subticket from a ticket.

```
OSStatus PMTicketGetTicket (
   PMTicketRef ticket,
   CFStringRef requestedType,
   UInt32 index,
   PMTicketRef *retrievedTicket
);
```

Parameters

ticket

A reference to a ticket created by calling the function `PMTicketCreate`.

requestedType

A string that specifies the ticket type of the ticket you want to obtain. See "Ticket Type Strings" (page 1831) for a list of strings you can pass.

index

Reserved for future use. Currently, you must pass the constant `kPMTopLevel`.

retrievedTicket

On return, points to the ticket reference whose type you specified.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTicket.h`

PMTicketGetType

Obtains a value that specifies the ticket's type.

```
OSStatus PMTicketGetType (
   PMTicketRef ticket,
   CFStringRef *ticketType
);
```

Parameters

ticket

A reference to a ticket created by calling the function `PMTicketCreate`.

ticketType

On return, points to a string value that specifies the ticket's type. See "PMTicketType" (page 1801) for a list of constants that can be returned

Return Value

A result code. See "Ticket Services Result Codes" (page 1832).

Availability

Not available in CarbonLib.

Available in Mac OS X 10.0 and later.

Declared In

`PMTicket.h`

PMTicketGetUInt32

Obtains an item of type `UInt32` from a ticket.

```
OSStatus PMTicketGetUInt32 (
   PMTicketRef ticket,
   UInt32 nodeIndex1,
   UInt32 nodeIndex2,
   CFStringRef key,
   UInt32 *value
);
```

Parameters

ticket

A reference to a ticket created by calling the function `PMTicketCreate`.

nodeIndex1

Reserved for future use. Currently, you must pass the constant `kPMTopLevel`.

nodeIndex2

Reserved for future use. Currently, you must pass the constant `kPMTopLevel`.

key

A reference to a `CFString` object that uniquely identifies the ticket item whose value you want to obtain.

value

On return, points to `UInt32` value for the ticket item specified by the `key` parameter.

Return Value

A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTicket.h`

PMTicketIsItemLocked

Checks to see if an item in a ticket is locked.

```
OSStatus PMTicketIsItemLocked (
   PMTicketRef ticket,
   CFStringRef key,
   Boolean *locked
);
```

Parameters

ticket
A reference to a ticket created by calling the function `PMTicketCreate`.

key
A reference to a `CFString` object that uniquely identifies the ticket item you want to check.

locked
On return, points to `true` if the item is locked or `false` if the item is not locked.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Discussion
The function `PMTicketIsItemLocked` checks only those items stored in the top-level of the ticket. It does not check items in subtickets.

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`PMTicketDeprecated.h`

PMTicketLockItem

Locks an item in a ticket.

```
OSStatus PMTicketLockItem (
   PMTicketRef ticket,
   CFStringRef clientID,
   CFStringRef key
);
```

Parameters

ticket

A reference to a ticket created by calling the function `PMTicketCreate`.

clientID

A reference to a `CFString` object that uniquely identifies your application. The string should be in a format similar to a Java-style package name (think of it as a reverse URL), such as `CFSTR("com.myvendorname.myprintingcode")`.

key

A reference to a `CFString` object that uniquely identifies the ticket item you want to lock.

Return Value

A result code. See "Ticket Services Result Codes" (page 1832).

Discussion

The function `PMTicketLockItem` locks only those items stored in the top-level of the ticket. It does not lock items in sub-tickets.

Availability

Not available in CarbonLib.

Available in Mac OS X 10.0 and later.

Not available to 64-bit applications.

Declared In

`PMTicketDeprecated.h`

PMTicketReadXMLFromFile

Restores a ticket previously converted to XML and saved as a file.

```
OSStatus PMTicketReadXMLFromFile (
   CFAllocatorRef allocator,
   const char *path,
   PMTicketRef *ticket,
   CFStringRef *errorString
);
```

Parameters

allocator

A reference to the allocator object to be used for allocating memory. Pass a reference to a valid allocator or `kCFAllocatorDefault` to request the default allocator.

path

A string that specifies the path name of the XML file you want to read.

ticket

A reference to a ticket created by calling the function `PMTicketCreate`. On return, the ticket contains the entries specified by the XML file.

errorString
On return, a reference to a `CFString` object that contains an error message if an error occurred.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTicket.h`

PMTicketRelease

Decrements the retention count of a ticket object.

```
OSStatus PMTicketRelease (
   PMTicketRef ticket
);
```

Parameters
ticket
A reference to a ticket created by calling the function `PMTicketCreate`.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTicket.h`

PMTicketReleaseAndClear

Decrements the retention count of a ticket and sets the ticket reference to `NULL`.

```
OSStatus PMTicketReleaseAndClear (
   PMTicketRef *ticket
);
```

Parameters
ticket
A reference to a ticket created by calling the function `PMTicketCreate`.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
PMTicket.h

PMTicketReleaseItem

Removes an item from a ticket.

```
OSStatus PMTicketReleaseItem (
   PMTicketRef ticket,
   CFStringRef key
);
```

Parameters

ticket

A reference to a ticket created by calling the function PMTicketCreate.

key

A reference to a CFString object that uniquely identifies the ticket item you want to remove.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Discussion
An item can only be released if it is not locked. The function PMTicketReleaseItem works differently than the function PMTicketDeleteItem. The function PMTicketDeleteItem makes the item unavailable, but keeps information about the item in the ticket. The function PMTicketReleaseItem removes the item from the ticket.

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
PMTicket.h

PMTicketRemoveTicket

Removes a subticket from a ticket.

```
OSStatus PMTicketRemoveTicket (
   PMTicketRef ticket,
   CFStringRef typeToRemove,
   UInt32 index
);
```

Parameters

ticket

A reference to a ticket created by calling the function PMTicketCreate.

typeToRemove

A reference to a CFString object that specfies the ticket type of the ticket you want to create. See "Ticket Type Strings" (page 1831) for a list of constants you can pass.

index

Reserved for future use. Currently, you must pass the constant kPMTopLevel.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTicket.h`

PMTicketRetain

Increments the retention count of a ticket object.

```
OSStatus PMTicketRetain (
   PMTicketRef ticket
);
```

Parameters

ticket
A reference to a ticket created by calling the function `PMTicketCreate`.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTicket.h`

PMTicketSetBoolean

Writes an item of type `Boolean` to a ticket.

```
OSStatus PMTicketSetBoolean (
   PMTicketRef ticket,
   CFStringRef clientID,
   CFStringRef key,
   Boolean value,
   Boolean locked
);
```

Parameters

ticket
A reference to a ticket created by calling the function `PMTicketCreate`.

clientID
A reference to a `CFString` object that uniquely identifies your application. The string should be in a format similar to a Java-style package name (think of it as a reverse URL), such as `CFSTR("com.myvendorname.myprintingcode")`.

key
A reference to a `CFString` object that uniquely identifies the ticket item you want to set.

value
The `Boolean` value to which you want to set the ticket item entry specified by the `key` parameter.

locked
Pass `true` to set the item to locked; `false` to set it to unlocked.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTicket.h`

PMTicketSetBytes

Writes an item that's an array of type `UInt8` to a ticket.

```
OSStatus PMTicketSetBytes (
   PMTicketRef ticket,
   CFStringRef clientID,
   CFStringRef key,
   const UInt8 *data,
   UInt32 size,
   Boolean locked
);
```

Parameters

ticket
A reference to a ticket created by calling the function `PMTicketCreate`.

clientID
A reference to a `CFString` object that uniquely identifies your application. The string should be in a format similar to a Java-style package name (think of it as a reverse URL), such as `CFSTR("com.myvendorname.myprintingcode")`.

key
A reference to a `CFString` object that uniquely identifies the ticket item you want to set.

data
A pointer to the data to which you want to set the ticket item entry specified by the `key` parameter.

size
The size of the data, in bytes.

locked
Pass `true` to set the item to locked; `false` to set it to unlocked.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.

Available in Mac OS X 10.0 and later.

Declared In
`PMTicket.h`

PMTicketSetCFArray

Writes an item of type `CFArray` to a ticket.

```
OSStatus PMTicketSetCFArray (
   PMTicketRef ticket,
   CFStringRef clientID,
   CFStringRef key,
   CFArrayRef item,
   Boolean locked
);
```

Parameters

ticket
A reference to a ticket created by calling the function `PMTicketCreate`.

clientID
A reference to a `CFString` object that uniquely identifies your application. The string should be in a format similar to a Java-style package name (think of it as a reverse URL), such as `CFSTR("com.myvendorname.myprintingcode")`.

key
A reference to a `CFString` object that uniquely identifies the ticket item you want to set.

item
A reference to the Core Foundation array to which you want to set the ticket item entry specified by the `key` parameter.

locked
Pass `true` to set the item to locked; `false` to set it to unlocked.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTicket.h`

PMTicketSetCFBoolean

Writes an item of type `CFBoolean` to a ticket.

```
OSStatus PMTicketSetCFBoolean (
   PMTicketRef ticket,
   CFStringRef clientID,
   CFStringRef key,
   CFBooleanRef item,
   Boolean locked
);
```

Parameters

ticket

A reference to a ticket created by calling the function `PMTicketCreate`.

clientID

A reference to a `CFString` object that uniquely identifies your application. The string should be in a format similar to a Java-style package name (think of it as a reverse URL), such as `CFSTR("com.myvendorname.myprintingcode")`.

key

A reference to a `CFString` object that uniquely identifies the ticket item you want to set.

item

A reference to the `CFBoolean` value to which you want to set the ticket item entry specified by the `key` parameter.

locked

Pass `true` to set the item to locked; `false` to set it to unlocked.

Return Value

A result code. See "Ticket Services Result Codes" (page 1832).

Availability

Not available in CarbonLib.

Available in Mac OS X 10.0 and later.

Declared In

`PMTicket.h`

PMTicketSetCFData

Writes an item of type `CFData` to a ticket.

```
OSStatus PMTicketSetCFData (
   PMTicketRef ticket,
   CFStringRef clientID,
   CFStringRef key,
   CFDataRef item,
   Boolean locked
);
```

Parameters

ticket

A reference to a ticket created by calling the function `PMTicketCreate`.

clientID

A reference to a `CFString` object that uniquely identifies your application. The string should be in a format similar to a Java-style package name (think of it as a reverse URL), such as `CFSTR("com.myvendorname.myprintingcode")`.

key

A reference to a `CFString` object that uniquely identifies the ticket item you want to set.

item

A reference to the `CFData` to which you want to set the ticket item entry specified by the `key` parameter.

locked

Pass `true` to set the item to locked; `false` to set it to unlocked.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTicket.h`

PMTicketSetCFDate

Writes an item of type `CFDate` to a ticket.

```
OSStatus PMTicketSetCFDate (
   PMTicketRef ticket,
   CFStringRef clientID,
   CFStringRef key,
   CFDateRef item,
   Boolean locked
);
```

Parameters

ticket

A reference to a ticket created by calling the function `PMTicketCreate`.

clientID

A reference to a `CFString` object that uniquely identifies your application. The string should be in a format similar to a Java-style package name (think of it as a reverse URL), such as `CFSTR("com.myvendorname.myprintingcode")`.

key

A reference to a `CFString` object that uniquely identifies the ticket item you want to set.

item

A reference to the `CFDate` value to which you want to set the ticket item entry specified by the `key` parameter.

locked

Pass `true` to set the item to locked; `false` to set it to unlocked.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
PMTicket.h

PMTicketSetCFDictionary

Writes an item of type CFDictionary to a ticket.

```
OSStatus PMTicketSetCFDictionary (
   PMTicketRef ticket,
   CFStringRef clientID,
   CFStringRef key,
   CFDictionaryRef item,
   Boolean locked
);
```

Parameters

ticket
A reference to a ticket created by calling the function PMTicketCreate.

clientID
A reference to a CFString object that uniquely identifies your application. The string should be in a format similar to a Java-style package name (think of it as a reverse URL), such as CFSTR("com.myvendorname.myprintingcode").

key
A reference to a CFString object that uniquely identifies the ticket item you want to set.

item
A reference to the Core Foundation dictionary to which you want to set the ticket item entry specified by the key parameter.

locked
Pass true to set the item to locked; false to set it to unlocked.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
PMTicket.h

PMTicketSetCFNumber

Writes an item of type CFNumber to a ticket.

```
OSStatus PMTicketSetCFNumber (
   PMTicketRef ticket,
   CFStringRef clientID,
   CFStringRef key,
   CFNumberRef item,
   Boolean locked
);
```

Parameters

ticket

A reference to a ticket created by calling the function `PMTicketCreate`.

clientID

A reference to a `CFString` object that uniquely identifies your application. The string should be in a format similar to a Java-style package name (think of it as a reverse URL), such as `CFSTR("com.myvendorname.myprintingcode")`.

key

A reference to a `CFString` object that uniquely identifies the ticket item you want to set.

item

A reference to the `CFNumber` value to which you want to set the ticket item entry specified by the `key` parameter.

locked

Pass `true` to set the item to locked; `false` to set it to unlocked.

Return Value

A result code. See "Ticket Services Result Codes" (page 1832).

Availability

Not available in CarbonLib.

Available in Mac OS X 10.0 and later.

Declared In

`PMTicket.h`

PMTicketSetCFString

Writes an item of type `CFString` to a ticket.

```
OSStatus PMTicketSetCFString (
   PMTicketRef ticket,
   CFStringRef clientID,
   CFStringRef key,
   CFStringRef item,
   Boolean locked
);
```

Parameters

ticket

A reference to a ticket created by calling the function `PMTicketCreate`.

clientID

A reference to a `CFString` object that uniquely identifies your application. The string should be in a format similar to a Java-style package name (think of it as a reverse URL), such as `CFSTR("com.myvendorname.myprintingcode")`.

key

A reference to a `CFString` object that uniquely identifies the ticket item you want to set.

item

A reference to the `CFString` object to which you want to set the ticket item entry specified by the `key` parameter.

locked

Pass `true` to set the item to locked; `false` to set it to unlocked.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTicket.h`

PMTicketSetCString

Writes an item that's a C-style string to a ticket.

```
OSStatus PMTicketSetCString (
   PMTicketRef ticket,
   CFStringRef clientID,
   CFStringRef key,
   const char *value,
   Boolean locked
);
```

Parameters

ticket

A reference to a ticket created by calling the function `PMTicketCreate`.

clientID

A reference to a `CFString` object that uniquely identifies your application. The string should be in a format similar to a Java-style package name (think of it as a reverse URL), such as `CFSTR("com.myvendorname.myprintingcode")`.

key

A reference to a `CFString` object that uniquely identifies the ticket item you want to set.

value

The C-style string to which you want to set the ticket item entry specified by the `key` parameter. The string must use UTF-8 encoding.

locked

Pass `true` to set the item to locked; `false` to set it to unlocked.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
PMTicket.h

PMTicketSetCStringArray

Writes an item that's an array of C-style strings to a ticket.

```
OSStatus PMTicketSetCStringArray (
   PMTicketRef ticket,
   CFStringRef clientID,
   CFStringRef key,
   const char **cStringArray,
   UInt32 count,
   Boolean locked
);
```

Parameters

ticket
A reference to a ticket created by calling the function PMTicketCreate.

clientID
A reference to a CFString object that uniquely identifies your application. The string should be in a format similar to a Java-style package name (think of it as a reverse URL), such as CFSTR("com.myvendorname.myprintingcode").

key
A reference to a CFString object that uniquely identifies the ticket item you want to set.

cStringArray
The array of C-style strings to which you want to set the ticket item entry specified by the key parameter. The strings must use UTF-8 encoding.

count
The number of characters in the C-style string array.

locked
Pass true to set the item to locked; false to set it to unlocked.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
PMTicket.h

PMTicketSetDouble

Writes an item of type double to a ticket.

```
OSStatus PMTicketSetDouble (
   PMTicketRef ticket,
   CFStringRef clientID,
   CFStringRef key,
   double value,
   Boolean locked
);
```

Parameters

ticket

A reference to a ticket created by calling the function `PMTicketCreate`.

clientID

A reference to a `CFString` object that uniquely identifies your application. The string should be in a format similar to a Java-style package name (think of it as a reverse URL), such as `CFSTR("com.myvendorname.myprintingcode")`.

key

A reference to a `CFString` object that uniquely identifies the ticket item you want to set.

value

The `double` value to which you want to set the ticket item entry specified by the `key` parameter.

locked

Pass `true` to set the item to locked; `false` to set it to unlocked.

Return Value

A result code. See "Ticket Services Result Codes" (page 1832).

Availability

Not available in CarbonLib.

Available in Mac OS X 10.0 and later.

Declared In

`PMTicket.h`

PMTicketSetDoubleArray

Writes an item that's an array of values of type `double` to a ticket.

```
OSStatus PMTicketSetDoubleArray (
   PMTicketRef ticket,
   CFStringRef clientID,
   CFStringRef key,
   const double *array,
   UInt32 count,
   Boolean changeable
);
```

Parameters

ticket

A reference to a ticket created by calling the function `PMTicketCreate`.

clientID

A reference to a `CFString` object that uniquely identifies your application. The string should be in a format similar to a Java-style package name (think of it as a reverse URL), such as `CFSTR("com.myvendorname.myprintingcode")`.

key
A reference to a `CFString` object that uniquely identifies the ticket item you want to set.

doubleArray
A pointer to an array of `double` values to which you want to set the ticket item entry specified by the `key` parameter.

count
The number of values in the array specified by the `doubleArray` parameter.

changeable
Pass `true` to set the item to locked; `false` to set it to unlocked.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTicket.h`

PMTicketSetItem

Writes an item of type `CFType` to a ticket.

```
OSStatus PMTicketSetItem (
   PMTicketRef ticket,
   CFStringRef clientID,
   CFStringRef key,
   CFTypeRef item,
   Boolean locked
);
```

Parameters

ticket
A reference to a ticket created by calling the function `PMTicketCreate`.

clientID
A reference to a `CFString` object that uniquely identifies your application. The string should be in a format similar to a Java-style package name (think of it as a reverse URL), such as `CFSTR("com.myvendorname.myprintingcode")`.

key
A reference to a `CFString` object that uniquely identifies the ticket item you want to set.

item
A reference to the generic Core Foundation data to which you want to set the ticket item entry specified by the `key` parameter.

locked
Pass `true` to set the item to locked; `false` to set it to unlocked.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.

Available in Mac OS X 10.0 and later.

Declared In
`PMTicket.h`

PMTicketSetMetaItem

Writes an item that does not need to be stored in an XML-representation of a ticket.

Not recommended.

```
OSStatus PMTicketSetMetaItem (
   PMTicketRef ticket,
   CFStringRef key,
   CFTypeRef item
);
```

Parameters

ticket

A reference to a ticket created by calling the function `PMTicketCreate`.

key

A reference to a `CFString` object that uniquely identifies the ticket item you want to set.

item

A reference to the generic Core Foundation data to which you want to set the ticket item entry specified by the `key` parameter.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Discussion
You can use the function `PMTicketSetMetaItem` to add an item to a ticket when you don't want that item o be written to an XML-representation of the ticket. In other words, when you want to temporarily add an item to a ticket. Items added with this function cannot be locked.

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`PMTicketDeprecated.h`

PMTicketSetPMRect

Writes an item of type `PMRect` to a ticket.

```
OSStatus PMTicketSetPMRect (
   PMTicketRef ticket,
   CFStringRef clientID,
   CFStringRef key,
   PMRect *value,
   Boolean locked
);
```

Parameters

ticket

A reference to a ticket created by calling the function `PMTicketCreate`.

clientID

A reference to a `CFString` object that uniquely identifies your application. The string should be in a format similar to a Java-style package name (think of it as a reverse URL), such as `CFSTR("com.myvendorname.myprintingcode")`.

key

A reference to a `CFString` object that uniquely identifies the ticket item you want to set.

value

A pointer to the `PMRect` value to which you want to set the ticket item entry specified by the `key` parameter. A `PMRect` data type is an array of four `double` values.

locked

Pass `true` to set the item to locked; `false` to set it to unlocked.

Return Value

A result code. See "Ticket Services Result Codes" (page 1832).

Availability

Not available in CarbonLib.

Available in Mac OS X 10.0 and later.

Declared In

`PMTicket.h`

PMTicketSetPMRectArray

Writes an item that's an array of values of type `PMRect` to a ticket.

```
OSStatus PMTicketSetPMRectArray (
   PMTicketRef ticket,
   CFStringRef clientID,
   CFStringRef key,
   PMRect *pmRectArray,
   UInt32 count,
   Boolean locked
);
```

Parameters

ticket

A reference to a ticket created by calling the function `PMTicketCreate`.

clientID

A reference to a `CFString` object that uniquely identifies your application. The string should be in a format similar to a Java-style package name (think of it as a reverse URL), such as `CFSTR("com.myvendorname.myprintingcode")`.

key

A reference to a `CFString` object that uniquely identifies the ticket item you want to set.

pmRectArray

A pointer to an array of `PMRect` values to which you want to set the ticket item entry specified by the `key` parameter. A `PMRect` data type is an array of four `double` values.

count

The number of values in the array specified by the `pmRectArray` parameter.

locked

Pass `true` to set the item to locked; `false` to set it to unlocked.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTicket.h`

PMTicketSetPMResolution

Writes an item of type `PMResolution` to a ticket.

```
OSStatus PMTicketSetPMResolution (
   PMTicketRef ticket,
   CFStringRef clientID,
   CFStringRef key,
   PMResolution *value,
   Boolean locked
);
```

Parameters

ticket

A reference to a ticket created by calling the function `PMTicketCreate`.

clientID

A reference to a `CFString` object that uniquely identifies your application. The string should be in a format similar to a Java-style package name (think of it as a reverse URL), such as `CFSTR("com.myvendorname.myprintingcode")`.

key

A reference to a `CFString` object that uniquely identifies the ticket item you want to set.

value

A pointer to the `PMResolution` value to which you want to set the ticket item entry specified by the `key` parameter. A `PMResolution` data type is an array of two `double` values.

locked

Pass `true` to set the item to locked; `false` to set it to unlocked.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTicket.h`

PMTicketSetPMResolutionArray

Writes an item that's an array of data of type `PMResolution` to a ticket.

```
OSStatus PMTicketSetPMResolutionArray (
   PMTicketRef ticket,
   CFStringRef clientID,
   CFStringRef key,
   PMResolution *pmResolutionArray,
   UInt32 count,
   Boolean locked
);
```

Parameters

ticket
A reference to a ticket created by calling the function `PMTicketCreate`.

clientID
A reference to a `CFString` object that uniquely identifies your application. The string should be in a format similar to a Java-style package name (think of it as a reverse URL), such as `CFSTR("com.myvendorname.myprintingcode")`.

key
A reference to a `CFString` object that uniquely identifies the ticket item you want to set.

pmResolutionArray
A pointer to an array of the `PMResolution` values to which you want to set the ticket item entry specified by the `key` parameter. A `PMResolution` data type is an array of two `double` values.

count
The number of items in the array specified by the `pmResolutionArray` parameter.

locked
Pass `true` to set the item to locked; `false` to set it to unlocked.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTicket.h`

PMTicketSetPString

Writes an item that's a Pascal-style string to a ticket.

```
OSStatus PMTicketSetPString (
   PMTicketRef ticket,
   CFStringRef clientID,
   CFStringRef key,
   ConstStringPtr value,
   Boolean locked
);
```

Parameters

ticket

A reference to a ticket created by calling the function `PMTicketCreate`.

clientID

A reference to a `CFString` object that uniquely identifies your application. The string should be in a format similar to a Java-style package name (think of it as a reverse URL), such as `CFSTR("com.myvendorname.myprintingcode")`.

key

A reference to a `CFString` object that uniquely identifies the ticket item you want to set.

value

A pointer to the Pascal-style string to which you want to set the ticket item entry specified by the `key` parameter. The string must use MacRoman encoding.

locked

Pass `true` to set the item to locked; `false` to set it to unlocked.

Return Value

A result code. See "Ticket Services Result Codes" (page 1832).

Availability

Not available in CarbonLib.

Available in Mac OS X 10.0 and later.

Declared In

`PMTicket.h`

PMTicketSetSInt32

Writes an item of type `SInt32` to a ticket.

```
OSStatus PMTicketSetSInt32 (
   PMTicketRef ticket,
   CFStringRef clientID,
   CFStringRef key,
   SInt32 value,
   Boolean locked
);
```

Parameters

ticket

A reference to a ticket created by calling the function `PMTicketCreate`.

clientID

A reference to a `CFString` object that uniquely identifies your application. The string should be in a format similar to a Java-style package name (think of it as a reverse URL), such as `CFSTR("com.myvendorname.myprintingcode")`.

key

A reference to a `CFString` object that uniquely identifies the ticket item you want to set.

value

The `SInt32` value to which you want to set the ticket item entry specified by the `key` parameter.

locked

Pass `true` to set the item to locked; `false` to set it to unlocked.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTicket.h`

PMTicketSetSInt32Array

Writes an item that's an array of data of type `SInt32` to a ticket.

```
OSStatus PMTicketSetSInt32Array (
   PMTicketRef ticket,
   CFStringRef clientID,
   CFStringRef key,
   const SInt32 *sInt32Array,
   UInt32 count,
   Boolean locked
);
```

Parameters

ticket

A reference to a ticket created by calling the function `PMTicketCreate`.

clientID

A reference to a `CFString` object that uniquely identifies your application. The string should be in a format similar to a Java-style package name (think of it as a reverse URL), such as `CFSTR("com.myvendorname.myprintingcode")`.

key

A reference to a `CFString` object that uniquely identifies the ticket item you want to set.

sInt32Array

A pointer to an array of `SInt32` values to which you want to set the ticket item entry specified by the `key` parameter.

count

The number of values in the array specified by the `sInt32Array` parameter.

locked

Pass `true` to set the item to locked; `false` to set it to unlocked.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTicket.h`

PMTicketSetTemplate

Writes an item that's a job template to a ticket.

```
OSStatus PMTicketSetTemplate (
   PMTicketRef ticket,
   CFStringRef clientID,
   CFStringRef key,
   PMTemplateRef item,
   Boolean locked
);
```

Parameters

ticket
A reference to a ticket created by calling the function `PMTicketCreate`.

clientID
A reference to a `CFString` object that uniquely identifies your application. The string should be in a format similar to a Java-style package name (think of it as a reverse URL), such as `CFSTR("com.myvendorname.myprintingcode")`.

key
A reference to a `CFString` object that uniquely identifies the ticket item you want to set.

item
A reference to a job template created by calling the function `PMTemplateCreate`.

locked
Pass `true` to set the item to locked; `false` to set it to unlocked.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTicket.h`

PMTicketSetTicket

Writes a subticket to a ticket.

```
OSStatus PMTicketSetTicket (
   PMTicketRef ticket,
   PMTicketRef ticketToAdd,
   UInt32 index
);
```

Parameters

ticket

A reference to a ticket created by calling the function `PMTicketCreate`. This is the ticket to which you want to add a subticket. Any ticket can contain another ticket.

ticketToAdd

A reference to a ticket created by calling the function `PMTicketCreate`. This is the ticket you want to be a subticket.

index

Reserved for future use. Currently, you must pass the constant `kPMTopLevel`.

Return Value

A result code. See "Ticket Services Result Codes" (page 1832).

Availability

Not available in CarbonLib.

Available in Mac OS X 10.0 and later.

Declared In

`PMTicket.h`

PMTicketSetUInt32

Writes an item of type `UInt32` to a ticket.

```
OSStatus PMTicketSetUInt32 (
   PMTicketRef ticket,
   CFStringRef clientID,
   CFStringRef key,
   UInt32 value,
   Boolean locked
);
```

Parameters

ticket

A reference to a ticket created by calling the function `PMTicketCreate`.

clientID

A reference to a `CFString` object that uniquely identifies your application. The string should be in a format similar to a Java-style package name (think of it as a reverse URL), such as `CFSTR("com.myvendorname.myprintingcode")`.

key

A reference to a `CFString` object that uniquely identifies the ticket item you want to set.

value

The `UInt32` value to which you want to set the ticket item entry specified by the `key` parameter.

locked

Pass `true` to set the item to locked; `false` to set it to unlocked.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTicket.h`

PMTicketSetUInt32Array

Writes an item that's an array of data of type `UInt32` to a ticket.

```
OSStatus PMTicketSetUInt32Array (
   PMTicketRef ticket,
   CFStringRef clientID,
   CFStringRef key,
   const UInt32 *uInt32Array,
   UInt32 count,
   Boolean locked
);
```

Parameters

ticket
A reference to a ticket created by calling the function `PMTicketCreate`.

clientID
A reference to a `CFString` object that uniquely identifies your application. The string should be in a format similar to a Java-style package name (think of it as a reverse URL), such as `CFSTR("com.myvendorname.myprintingcode")`.

key
A reference to a `CFString` object that uniquely identifies the ticket item you want to set.

uInt32Array
A pointer to the array of `UInt32` values to which you want to set the ticket item entry specified by the `key` parameter.

count
The number of values in the array specified by the `uInt32Array` parameter.

locked
Pass `true` to set the item to locked; `false` to set it to unlocked.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTicket.h`

PMTicketToXML

Converts the data in a ticket to XML.

```
OSStatus PMTicketToXML (
   PMTicketRef ticket,
   CFDataRef *anXMLTicket
);
```

Parameters

ticket

A reference to a ticket created by calling the function `PMTicketCreate`.

anXMLTicket

On return, points to a Core Foundation data reference that represents job template data. You are responsible for releasing the `CFData` reference.

Return Value

A result code. See "Ticket Services Result Codes" (page 1832).

Discussion

If you want to write the XML data is to a file, use the function `PMTicketWriteXMLToFile`.

Availability

Not available in CarbonLib.

Available in Mac OS X 10.0 and later.

Declared In

`PMTicket.h`

PMTicketUnlockItem

Unlocks an item in a ticket.

```
OSStatus PMTicketUnlockItem (
   PMTicketRef ticket,
   CFStringRef clientID,
   CFStringRef key
);
```

Parameters

ticket

A reference to a ticket created by calling the function `PMTicketCreate`.

clientID

A reference to a `CFString` object that uniquely identifies your application. The string should be in a format similar to a Java-style package name (think of it as a reverse URL), such as `CFSTR("com.myvendorname.myprintingcode")`.

key

A reference to a `CFString` object that uniquely identifies the ticket item you want to unlock.

Return Value

A result code. See "Ticket Services Result Codes" (page 1832).

Discussion
The function `PMTicketUnlockItem` unlocks only those items stored in the top-level of the ticket. It does not unlock items in subtickets.

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`PMTicketDeprecated.h`

PMTicketValidate

Validates a ticket against the constraint values specified in a job template.

```
OSStatus PMTicketValidate (
   PMTicketRef ticket,
   PMTemplateRef verifyingTemplate,
   CFArrayRef *invalidItems
);
```

Parameters

ticket
A reference to a ticket created by calling the function `PMTicketCreate`.

verifyingTemplate
A reference to the job template against which you want to validate the ticket.

invalidItems
On return, points to an array of invalid items, should there be any. If there are no invalid items, and the function returns `noErr`, then the value of `invalidItems` is undefined.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Discussion
Only those items in the ticket that have corresponding entries in the job template are checked. In other words, a ticket item's key must match a template item's key for the ticket item to be validated.

Availability
Not available in CarbonLib.
Available in Mac OS X 10.0 and later.

Declared In
`PMTicket.h`

PMTicketWriteXML

Converts a ticket to XML and then writes it to a file stream.

```
OSStatus PMTicketWriteXML (
   PMTicketRef ticket,
   FILE *file
);
```

Parameters

ticket

A reference to a ticket created by calling the function `PMTicketCreate`.

xmlFile

On input, the file to which you want the XML data to be written.

Return Value

A result code. See "Ticket Services Result Codes" (page 1832).

Availability

Not available in CarbonLib.

Available in Mac OS X 10.0 and later.

Declared In

`PMTicket.h`

PMTicketWriteXMLToFile

Converts a ticket to XML and then writes it to a file.

```
OSStatus PMTicketWriteXMLToFile (
   PMTicketRef ticket,
   const char *path
);
```

Parameters

ticket

A reference to a ticket created by calling the function `PMTicketCreate`.

path

On input, the path of the file to which you want the XML data to be written. The function opens the file or creates one if one doesn't exist.

Return Value

A result code. See "Ticket Services Result Codes" (page 1832).

Availability

Not available in CarbonLib.

Available in Mac OS X 10.0 and later.

Declared In

`PMTicket.h`

PMXMLToTicket

Converts a ticket saved as XML to a ticket.

```
OSStatus PMXMLToTicket (
   CFAllocatorRef allocator,
   CFDataRef anXMLTicket,
   PMTicketRef *ticket,
   CFStringRef *conversionError
);
```

Parameters

allocator

A reference to the allocator object to be used for allocating memory. Pass a reference to a valid allocator or `kCFAllocatorDefault` to request the default allocator.

anXMLTicket

A reference to Core Foundation data that contains previously-converted job template data.

ticket

On return, a reference to a ticket that contains the data converted from the XML data specified by the `anXMLTicket` parameter.

conversionError

On return, a reference to a `CFString` object that specifies errors during the conversion process, if any. Pass `NULL` if you are not interested in getting the errors.

Return Value
A result code. See "Ticket Services Result Codes" (page 1832).

Availability
Not available in CarbonLib.

Available in Mac OS X 10.0 and later.

Declared In
`PMTicket.h`

Data Types

ConstCStrList

Represents a static list of C-string pointers.

```
typedef CStrList ConstCStrList;
```

Discussion
For more information see "CStrList" (page 1798).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`PMTicket.h`

ConstPMRectList

Represents a static list of `PMRect` data structures.

```
typedef PMRectList ConstPMRectList;
```

Discussion
For more information see "PMRectList" (page 1799).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`PMTicket.h`

ConstSInt32List

Represents a static list of `SInt32List` data structures.

```
typedef SInt32List ConstSInt32List;
```

Discussion
Form more information see "SInt32List" (page 1801).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`PMTicket.h`

CStrList

Contains an array of `CString` pointers and the number of pointers in the array.

```
struct CStrList {
    SInt32 count;
    char **strArray;
};
typedef struct CStrList CStrList;
```

Fields
`count`
The number of `CString` pointers in the array.
`strArray`
A pointer to an array of `CString` pointers.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`PMTicket.h`

PMPrintingPhaseType

Represents printing phases.

```
typedef UInt16 PMPrintingPhaseType;
```

Discussion
For more information see "Printing Phase Types" (page 1824).

Availability
Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared In
`PMTicket.h`

PMRectList

Contains a list of `PMRect` data structures.

```
struct PMRectList {
    SInt32 count;
    PMRect **pmRectArray;
};
typedef struct PMRectList PMRectList;
```

Fields

`count`
The number of `PMRect` pointers in the array.

`pmRectArray`
A pointer to a list of `PMRect` data structures.

Discussion
A `PMRect` data structure contains a set of four `double` values (top, left, bottom, and right). This structure is used to specify page and paper rectangles.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`PMTicket.h`

PMTemplateRef

Refers to a template object that contains private variables and functions necessary to represent a job template.

```
typedef struct OpaquePMTemplateRef* PMTemplateRef;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`PMTicket.h`

PMTicketErrors

Represents values that indicate error conditions.

```
typedef SInt16 PMTicketErrors;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`PMTicket.h`

PMTicketItemStruct

Contains information about a ticket item.

```
struct PMTicketItemStruct {
    char *key;
    PMTicketItemType itemType;
    Boolean locked;
    union {
        const   void *GenericData;
    const   char *cString;
      SInt32 sInt32;
      UInt32 boolean;
      ConstCStrList *cStrlist;
      PMRect *rect;
      ConstSInt32List *sInt32List;
      ConstPMRectList *pmRectList;
    } value;
};
```

Fields

`key`
A string that uniquely identifies the item.

`itemType`
The type of item defined in the union.

`locked`
The lock state of the item.

`value`
The data associated with the item.

Discussion
You can use this structure to define a static ticket item. An array of these structures can then be converted to a ticket by calling the function `PMTicketFillFromArray`.

PMTicketItemType

Represents a ticket item type.

```
typedef UInt16 PMTicketItemType;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`PMTicket.h`

PMTicketRef

Refers to a ticket object that contains private variables and functions necessary to represent a ticket.

```
typedef struct OpaquePMTicketRef* PMTicketRef;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`PMTicket.h`

PMTicketType

Represents a ticket type.

```
typedef SInt16 PMTicketType;
```

Discussion
For more information see "PMTicketType" (page 1801).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`PMTicket.h`

PMValueType

Represents a value type.

```
typedef SInt32 PMValueType;
```

Discussion
For more information see "Item Value Types" (page 1808).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`PMTemplate.h`

SInt32List

Contains an array of `SInt32` values.

```
struct SInt32List {
    SInt32 count;
    const SInt32 *sInt32Array;
};
typedef struct SInt32List SInt32List;
```

Fields

`count`

The number of signed 32-bit values in the array.

`sInt32Array`

A pointer to the array.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`PMTicket.h`

Constants

ColorSync Options

Defines strings and keys for items related to ColorSync options.

```
#define kPMColorDeviceIDStr kPMPrinterInfoPrelude "PMColorDeviceID"
#define kPMColorDeviceIDKey CFSTR(kPMColorDeviceIDStr)
#define kPMColorSyncProfilesStr kPMPrinterInfoPrelude "PMColorSyncProfiles"
#define kPMColorSyncProfilesKey CFSTR(kPMColorSyncProfilesStr)
```

Constants

`kPMColorDeviceIDStr`

The color device ID string.

`kPMColorDeviceIDKey`

The value of this key is a `CFString` representing a `CFUUID`; it must be unique per device.

`kPMColorSyncProfilesStr`

The ColorSync profiles sting.

`kPMColorSyncProfilesKey`

The value of this key is a `CFArray` of `CFDictionary` data structures, one `CFDictionary` data structure for each factory profile.

Constraint Types

Specify a constraint type for a job template entry.

```
typedef SInt32 PMConstraintType;
enum {
    kPMConstraintUndefined = 0,
    kPMConstraintRange = 1,
    kPMConstraintList = 2,
    kPMConstraintPrivate = 3
};
```

Constants

`kPMConstraintUndefined`
Values are not constrained.
Available in Mac OS X v10.0 and later.
Declared in `PMTemplate.h`.

`kPMConstraintRange`
Values are constrained by a range of two values, both of type `CFTypeRef`.
Available in Mac OS X v10.0 and later.
Declared in `PMTemplate.h`.

`kPMConstraintList`
Values are constrained by an array.
Available in Mac OS X v10.0 and later.
Declared in `PMTemplate.h`.

`kPMConstraintPrivate`
Values are constrained privately, and should not be checked by the system.
Available in Mac OS X v10.0 and later.
Declared in `PMTemplate.h`.

Converter Setup Ticket Keys

Defines strings and keys for items related to a converter setup ticket.

```
#define kPMConverterSetupPrelude "com.apple.print.ConverterSetup."
#define kPMBandingRequestedStr kPMConverterSetupPrelude "PMBandingRequested"
#define kPMBandingRequestedKey CFSTR(kPMBandingRequestedStr)
#define kPMRequiredBandHeightStr kPMConverterSetupPrelude "PMRequiredBandHeight"
#define kPMRequiredBandHeightKey CFSTR(kPMRequiredBandHeightStr)
#define kPMDepthSwitchingEnabledStr kPMConverterSetupPrelude "PMDepthSwitching"
#define kPMDepthSwitchingEnabledKey CFSTR(kPMDepthSwitchingEnabledStr)
#define kPMWhiteSkippingEnabledStr kPMConverterSetupPrelude "PMWhiteSpaceSkipping"
#define kPMWhiteSkippingEnabledKey CFSTR(kPMWhiteSkippingEnabledStr)
#define kPMConverterResHorizontalStr kPMConverterSetupPrelude
"PMConversionResHorizontal"
#define kPMConverterResHorizontalKey CFSTR(kPMConverterResHorizontalStr)
#define kPMConverterResVerticalStr kPMConverterSetupPrelude "PMConversionResVertcial"
#define kPMConverterResVerticalKey CFSTR(kPMConverterResVerticalStr)
#define kPMRequestedPixelFormatStr kPMConverterSetupPrelude "PMPixelFormat"
#define kPMRequestedPixelFormatKey CFSTR(kPMRequestedPixelFormatStr)
#define kPMRequestedPixelLayoutStr kPMConverterSetupPrelude "PMPixelLayout"
#define kPMRequestedPixelLayoutKey CFSTR(kPMRequestedPixelLayoutStr)
#define kPMCVColorSyncProfileIDKey CFSTR(kPMCVColorSyncProfileIDStr)
```

Constants

`kPMConverterSetupPrelude`
The converter-setup prelude sting.

`kPMBandingRequestedStr`
The banding-requested string.

`kPMBandingRequestedKey`
The value of this key is a `CFBoolean`; turns banding on if it's available.

`kPMRequiredBandHeightStr`
The banding-height string.

`kPMRequiredBandHeightKey`
The value of this key is a `CFNumber` value; specifies the number of scan lines needed for each band. If it specifies the whole page, banding is disabled.

`kPMDepthSwitchingEnabledStr`
The depth-switching-enabled string.

`kPMDepthSwitchingEnabledKey`
The value of this key is a `CFBoolean` value; `true` specifies the printer module requests the converter to switch between black & white and color bands when possible.

`kPMWhiteSkippingEnabledStr`
The white-skipping-enabled string.

`kPMWhiteSkippingEnabledKey`
The value of this key is a `CFBoolean`; `true` specifies the printer module requests the converter to skip over white space if possible.

`kPMConverterResHorizontalStr`
The horizontal rendering resolution string.

`kPMConverterResHorizontalKey`
The value of this key is a `CFNumber` of type `CFNumberDoubleType`; specifies the final horizontal rendering resolution.

`kPMConverterResVerticalStr`
The vertical resolution string.

`kPMConverterResVerticalKey`
The value of this key is a `CFNumber` of type `CFNumberDoubleType`; specifies the final vertical rendering resolution.

`kPMRequestedPixelFormatStr`
The pixel format string.

`kPMRequestedPixelFormatKey`
The value of this key is a `CFNumber` of type `CFNumberLongType`; specifies the pixel format requested of the converter.

`kPMRequestedPixelLayoutStr`
The pixel layout string.

`kPMRequestedPixelLayoutKey`
The value of this key is a `CFNumber` of type `CFNumberLongType`; specifies the pixel layout requested of the converter.

`kPMCVColorSyncProfileIDKey`
The value of this key is a `CFNumber` of type `kCFNumberSInt32Type`; specifies the profile ID for the ColorSync profile to be used with the print job.

Data Transmission Keys

Defines strings and keys for items related to data transmission.

```
#define kPMIsBinaryOKStr            kPMPrinterInfoPrelude "PMIsBinaryOK"
#define kPMIsBinaryOKKey            CFSTR(kPMIsBinaryOKStr)
#define kPM8BitCommStr            kPMPrinterInfoPrelude "PM8BitComm"
#define kPM8BitCommKey            CFSTR(kPM8BitCommStr)
#define kPMTransparentCommStr           kPMPrinterInfoPrelude "PMTransparentComm"
#define kPMTransparentCommKey            CFSTR(kPMTransparentCommStr)
```

Constants

`kPMIsBinaryOKStr`
The binary is okay string.

`kPMIsBinaryOKKey`
The value of this key is a `CFBoolean` representing the result of querying the PostScript printer about its ability to accept binary data. It is possible for the underlying communications to support binary data, both high bit characters and control characters, but for a spooler on the other end of the channel to not accept binary data. This value represents the spooler/printer's abilities.

`kPM8BitCommStr`
The 8-bit communication string.

`kPM8BitCommKey`
The value of this key is a `CFBoolean` indicating whether the communications channel can transmit characters in the range 0x80 -)xFF inclusive without them being damaged or interpreted as channel control characters.

`kPMTransparentCommStr`
The transparent communication string.

`kPMTransparentCommKey`
The value of this key is a `CFBoolean` indicating whether the communications channel can transmit characters in the range 0x00 - 0x1F inclusive without them being damaged or interpreted as channel control characters.

Document Ticket Keys

Defines strings and keys for items in a document ticket; currently not used.

```
#define kPMDocumentTicketPrelude "com.apple.print.DocumentTicket."
#define kPMSpoolFormatStr kPMDocumentTicketPrelude "PMSpoolFormat"
#define kPMSpoolFormatKey CFSTR(kPMSpoolFormatStr)
#define kPMPrinterModuleFormatStr kPMDocumentTicketPrelude "PMDocPMInputFormat"
#define kPMPrinterModuleFormatKey CFSTR(kPMPrinterModuleFormatStr)
```

Constants

`kPMDocumentTicketPrelude`
Currently not used.

`kPMSpoolFormatStr`
Currently not used.

`kPMSpoolFormatKey`
Currently not used.

`kPMPrinterModuleFormatStr`
Currently not used.

`kPMPrinterModuleFormatKey`
Currently not used.

Drawing Resolution Keys

Defines strings and keys for items in related to drawing resolution.

```
#define kPMPrinterSuggestedResStr kPMPrinterInfoPrelude
"PMPrinterSuggestedRes"
#define kPMPrinterSuggestedResKey CFSTR(kPMPrinterSuggestedResStr
        #define kPMPrinterMinResStr kPMPrinterInfoPrelude "PMPrinterMinRes"
#define kPMPrinterMinResKey CFSTR(kPMPrinterMinResStr)
#define kPMPrinterMaxResStr kPMPrinterInfoPrelude "PMPrinterMaxRes"
#define kPMPrinterMaxResKey CFSTR(kPMPrinterMaxResStr)
```

Constants

`kPMPrinterSuggestedResStr`
The suggested application drawing resolutions string.

`kPMPrinterSuggestedResKey`
The value of this key is the suggested application drawing resolutions key.

`kPMPrinterMinResStr`
The minimum drawing resolution string.

`kPMPrinterMinResKey`
The value of this key is the minimum range of resolutions for the printer; specified as a `CFArray` of two `CFNumber` values of type `kCFNumberDoubleType`.

`kPMPrinterMaxResStr`
The maximum printer resolution string.

`kPMPrinterMaxResKey`
The value of this key is the maximum range of resolutions for the printer; specified as a `CFArray` of two `CFNumber` values of type `kCFNumberDoubleType`.

Duplex Options

Specify values for the duplex options key (`kPMDuplexingKey`.)

```
enum {
    kPMDuplexNone = 1,
    kPMDuplexNoTumble = 2,
    kPMDuplexTumble = 3,
    kPMSimplexTumble = 4,
    kPMDuplexDefault = 1
};
```

Constants

`kPMDuplexNone`
Don't use duplex.
Available in Mac OS X v10.0 and later.
Declared in `PMDefinitions.h`.

`kPMDuplexNoTumble`
Print on both sides of the paper; flip pages from left to right.
Available in Mac OS X v10.0 and later.
Declared in `PMDefinitions.h`.

`kPMDuplexTumble`
Print on both sides of the paper; tumbling so pages flip top to bottom.
Available in Mac OS X v10.0 and later.
Declared in `PMDefinitions.h`.

`kPMSimplexTumble`
Print on only one side of the paper, but tumble the images while printing.
Available in Mac OS X v10.0 and later.
Declared in `PMDefinitions.h`.

`kPMDuplexDefault`
Don't use duplex; this option is the same as `kPMDuplexNone`.

Error Handling Options

Specify whether or not an error handler is available.

```
enum {
    kPSNoErrorHandler = 0,
    kPSErrorHandler = 1
};
```

Constants

`kPSNoErrorHandler`
Specifies that an error handler is not available.
Available in Mac OS X v10.0 and later.
Declared in `PMTicket.h`.

`kPSErrorHandler`
Specifies that an error handler is available.

Available in Mac OS X v10.0 and later.

Declared in `PMTicket.h`.

Fetch options

Specifies whether an item should be fetched.

```
#define kPMDontFetchItem NULL
```

Constants

`kPMDontFetchItem`
Don't fetch the item.

Installable Options

Defines a string and key for installable printer options.

```
#define kPMInstallableOptionStr kPMPrinterInfoPrelude
"PMInstallableOption"
#define kPMInstallableOptionKey CFSTR(kPMInstallableOptionStr)
```

Constants

`kPMInstallableOptionStr`
The installable options string.

`kPMInstallableOptionKey`
The value of this key is a packed array of Pascal strings that specifies the installable options in the PostScript printer description (PPD) file. The strings are as key-value pairs of PPD main and option keywords.

Item Value Types

Specify the data type of a ticket or template item.

```
typedef UInt16 PMTicketItemType;
enum {
    kPMItemInvalidType = 0,
    kPMItemCStringType = 1,
    kPMItemSInt32Type = 2,
    kPMItemBooleanType = 3,
    kPMItemCStrListType = 4,
    kPMItemPMRectType = 5,
    kPMItemSInt32ListType = 6,
    kPMItemPMRectListType = 7
};
```

Constants

`kPMItemInvalidType`
The type is not valid.
Available in Mac OS X v10.0 and later.
Declared in `PMTicket.h`.

`kPMItemCStringType`
A C-style string pointer.
Available in Mac OS X v10.0 and later.
Declared in `PMTicket.h`.

`kPMItemSInt32Type`
A signed 32-bit integer.
Available in Mac OS X v10.0 and later.
Declared in `PMTicket.h`.

`kPMItemBooleanType`
A `Boolean` value.
Available in Mac OS X v10.0 and later.
Declared in `PMTicket.h`.

`kPMItemCStrListType`
A list of C-style strings
Available in Mac OS X v10.0 and later.
Declared in `PMTicket.h`.

`kPMItemPMRectType`
A pointer to a `PMRect` data structure.
Available in Mac OS X v10.0 and later.
Declared in `PMTicket.h`.

`kPMItemSInt32ListType`
A pointer to an `SInt32List` data structure.
Available in Mac OS X v10.0 and later.
Declared in `PMTicket.h`.

`kPMItemPMRectListType`
A pointer to a `PMRectList` data structure.
Available in Mac OS X v10.0 and later.
Declared in `PMTicket.h`.

Job Ticket Keys

Defines strings and keys for items in a job ticket.

```
#define kPMJobTicketPrelude "com.apple.print.JobInfo."
#define kPMJobNameStr kPMJobTicketPrelude "PMJobName"
#define kPMJobNameKey CFSTR(kPMJobNameStr)
#define kPMApplicationNameStr kPMJobTicketPrelude "PMApplicationName"
#define kPMApplicationNameKey CFSTR(kPMApplicationNameStr)
#define kPMUserLanguageStr kPMJobTicketPrelude "PMUserLanguage"
#define kPMUserLanguageKey CFSTR(kPMUserLanguageStr)
#define kPMJobOwnerStr kPMJobTicketPrelude "PMJobOwner"
#define kPMJobOwnerKey CFSTR(kPMJobOwnerStr)
#define kPMJobTemplateStr kPMJobTicketPrelude "PMJobTemplate"
#define  CFSTR(kPMJobTemplateStr)
#define kPMPhaseStr kPMJobTicketPrelude "PMPrintingPhase"
#define kPMPhaseKey CFSTR(kPMPhaseStr)
#define kPMOutputTypeStr kPMJobTicketPrelude "PMOutputType"
#define kPMOutputTypeKey CFSTR(kPMOutputTypeStr)
```

Constants

`kPMJobTicketPrelude`
The job ticket prelude string.

`kPMJobNameStr`
The job name string.

`kPMJobNameKey`
The value of this key is a `CFString` that specifies the name of the job to be displayed in the print queue dialog.

`kPMApplicationNameStr`
The application name string.

`kPMApplicationNameKey`
The value of this key is a `CFString` that specifies the application's name.

`kPMUserLanguageStr`
The user language string.

`kPMUserLanguageKey`
The value of this key is a `CFNumber` of type `kCFNumberSInt32Type`.

`kPMJobOwnerStr`
The job owner string.

`kPMJobOwnerKey`
The value of this key is a `CFString` that specifies the name of the user who submitted the job.

`kPMJobTemplateStr`
The job template string.

`kPMJobTemplateKey`
The value of this key is a `CFDictionary` that is actually a `PMTemplateRef`.

`kPMPhaseStr`
The printing phase string.

`kPMPhaseKey`
The value of this key is a `CFNumber` of type `kCFNumberSInt32Type`; specifies an enumeration—Spooling, RIPing, and so forth.

`kPMOutputTypeStr`
The output type string.

`kPMOutputTypeKey`
The value of this key is a `CFString` that specifies a Mime type from the `kPMOutputTypeListKey` array generated by the printer module.

Default Copy/Collate Value

Specifies the default value for copy/collate.

```
enum {
    kPMCopyCollateDefault = 1
};
```

Constants

`kPMCopyCollateDefault`
Use the default value for copy/collate.

List Ticket Keys

Defines strings and keys for items in a list ticket.

```
#define kPMTicketListPrelude "com.apple.print.TicketList."
```

Constants

`kPMTicketListPrelude`
The list ticket prelude string.

Lock State

Specifies whether an item is locked or unlocked.

```
enum {
    kPMUnlocked = 0,
    kPMLocked = 1
};
```

Constants

`kPMUnlocked`
Indicates items is unlocked.

Available in Mac OS X v10.2 and later.

Declared in `PMDefinitions.h`.

`kPMLocked`
Indicates items is locked.

Available in Mac OS X v10.2 and later.

Not available to 64-bit applications.

Declared in `PMDefinitionsDeprecated.h`.

Memory Keys

Defines strings and keys for items related to printer memory.

```
#define kPMTotalMemInstalledStr kPMPrinterInfoPrelude
"PMTotalMemInstalled" #define kPMTotalMemInstalledKey
CFSTR(kPMTotalMemInstalledStr)
#define kPMTotalMemAvailableStr kPMPrinterInfoPrelude "PMTotalMemAvailable"
#define kPMTotalMemAvailableKey CFSTR(kPMTotalMemAvailableStr)
```

Constants

`kPMTotalMemInstalledStr`
The memory installed string.

`kPMTotalMemInstalledKey`
The value of this key is a `CFNumber` of type `kCFNumberSInt32Type`; specifies the memory installed in the printer.

`kPMTotalMemAvailableStr`
The total memory available string.

`kPMTotalMemAvailableKey`
The value of this key is a `CFNumber` of type `kCFNumberSInt32Type`; specifies the remaining memory available for use.

Page Format Ticket Keys

Defines strings and keys for items in a page format ticket.

```
#define kPMPageFormatPrelude "com.apple.print.PageFormat."
#define kPMAdjustedPaperRectStr kPMPageFormatPrelude "PMAdjustedPaperRect"
#define kPMAdjustedPaperRectKey CFSTR(kPMAdjustedPaperRectStr)
#define kPMAdjustedPageRectStr kPMPageFormatPrelude "PMAdjustedPageRect"
#define kPMAdjustedPageRectKey CFSTR(kPMAdjustedPageRectStr)
#define kPMDrawingResHorizontalStr kPMPageFormatPrelude "PMHorizontalRes"
#define kPMDrawingResHorizontalKey CFSTR(kPMDrawingResHorizontalStr)
#define kPMDrawingResVerticalStr kPMPageFormatPrelude "PMVerticalRes"
#define kPMDrawingResVerticalKey CFSTR(kPMDrawingResVerticalStr)
#define kPMPageScalingHorizontalStr kPMPageFormatPrelude "PMScaling"
#define kPMPageScalingHorizontalKey CFSTR(kPMPageScalingHorizontalStr)
#define kPMPageScalingVerticalStr kPMPageFormatPrelude "PMVerticalScaling"
#define kPMPageScalingVerticalKey CFSTR(kPMPageScalingVerticalStr)
#define kPMPageOrientationStr kPMPageFormatPrelude "PMOrientation"
#define kPMPageOrientationKey CFSTR(kPMPageOrientationStr)
#define kPMPageBackupRecordHdlStr kPMPageFormatPrelude "BackupPrintRecordHandle"
#define kPMPageBackupRecordHdlKey CFSTR(kPMPageBackupRecordHdlStr)
#define kPMPageBackupRecordDataStr kPMPageFormatPrelude "BackupPrintRecord"
#define kPMPageBackupRecordDataKey CFSTR kPMPageBackupRecordDataStr)
#define kPMPageCustomDialogHdlStr kPMPageFormatPrelude "CustomDialogRecord"
#define kPMPageCustomDialogHdlKey CFSTR(kPMPageCustomDialogHdlStr)
#define kPMFormattingPrinterStr kPMPageFormatPrelude "FormattingPrinter"
#define kPMFormattingPrinterKey CFSTR(kPMFormattingPrinterStr)
```

Constants

`kPMPageFormatPrelude`
The page format ticket prelude string.

`kPMAdjustedPaperRectStr`
The adjusted paper rectangle string.

`kPMAdjustedPaperRectKey`
The value of this key is a `CFArray` of four `CFNumbers` of type `kCFNumberDoubleType` for the adjusted paper rectangle, in points.

`kPMAdjustedPageRectStr`
The adjusted page rectangle string.

`kPMAdjustedPageRectKey`
The value of this key is a `CFArray` of four `CFNumbers` of type `kCFNumberDoubleType` for the adjusted page rectangle, in points.

`kPMDrawingResHorizontalStr`
The horizontal drawing resolution string.

`kPMDrawingResHorizontalKey`
The value of this key is a `CFNumber` of type `kCFNumberDoubleType`; the drawing resolution in horizontal direction.

`kPMDrawingResVerticalStr`
The vertical drawing resolution string.

`kPMDrawingResVerticalKey`
The value of this key is a `CFNumber` of type `kCFNumberDoubleType`; the drawing resolution in vertical direction.

`kPMPageScalingHorizontalStr`
The horizontal page scaling string.

`PMPageScalingHorizontalKey`
The value of this key is a `CFNumber` of type `kCFNumberDoubleType`; the horizontal scaling factor applied to original page size.

`kPMPageScalingVerticalStr`
The vertical page scaling string.

`kPMPageScalingVerticalKey`
The value of this key is a `CFNumber` of type `kCFNumberDoubleType`; the vertical scaling factor applied to original page size.

`kPMPageOrientationStr`
The page orientation string.

`kPMPageOrientationKey`
The value of this key is a `CFNumber` of type `kCFNumberSInt32Type`; `PMOrientation`, 1 = portrait, 2 = landscape, 3 = reverse portrait, 4 = reverse landscape.

`kPMPageBackupRecordHdlStr`
The page backup record handle string.

`kPMPageBackupRecordHdlKey`
The value of this key is a print record handle (`CFData`); not used when data is flattened. (Mac OS 8 and 9 only)

`kPMPageBackupRecordDataStr`
The page backup record data string.

`kPMPageBackupRecordDataKey`
The value of this key is a print record (`CFData`) stored in complete form; used when flattening ticket with the print record. ((Mac OS 8 and 9 only)

`kPMPageCustomDialogHdlStr`
The page custom dialog handle string.

`kPMPageCustomDialogHdlKey`
: The value of this key is a handle (`CFData`) to the print record using for custom dialog calls; not stored when flattened. (Mac OS 8 and 9 only)

`kPMFormattingPrinterStr`
: The formatting printer string.

`kPMFormattingPrinterKey`
: The value of this key is a `CFString` that specifies name of the formatting printer.

Page Ticket Key

Defines strings and keys for items in a page ticket; currently not used.

```
#define kPMPageTicketPrelude "com.apple.print.PageTicket."
```

Constants

`kPMPageTicketPrelude`
: Currently not used.

Paper Info Ticket Keys

Defines strings and keys for items in a paper info ticket.

```
#define kPMPaperInfoPrelude "com.apple.print.PaperInfo."
#define kPMPaperNameStr kPMPaperInfoPrelude "PMPaperName"
#define kPMPaperNameKey CFSTR(kPMPaperNameStr)
#define kPMUnadjustedPaperRectStr kPMPaperInfoPrelude "PMUnadjustedPaperRect"
#define kPMUnadjustedPaperRectKey CFSTR(kPMUnadjustedPaperRectStr)
#define kPMUnadjustedPageRectStr kPMPaperInfoPrelude "PMUnadjustedPageRect"
#define kPMUnadjustedPageRectKey CFSTR(kPMUnadjustedPageRectStr)
#define kPMMatchPaperStr kPMPaperInfoPrelude "PMMatchPaper"
#define kPMMatchPaperKey CFSTR(kPMMatchPaperStr)
```

Constants

`kPMPaperInfoPrelude`
: The paper info ticket prelude string.

`kPMPaperNameStr`
: The paper name string.

`kPMPaperNameKey`
: The paper name key specifies the name of the paper displayed in the user interface.

`kPMUnadjustedPaperRectStr`
: The unadjusted paper rectangle string.

`kPMUnadjustedPaperRectKey`
: The unadjusted paper rectangle key specifies the unadjusted paper rectangle.

`kPMUnadjustedPageRectStr`
: The unadjusted page rectangle string.

`kPMUnadjustedPageRectKey`
: The unadjusted page rectangle key specifies the unadjusted page rectangle.

`kPMMatchPaperStr`
: The paper match string.

`kPMMatchPaperKey`
The paper match key specifies how closely the printing system must match the specified paper.

PostScript Language Level Targets

Specify language-level targets for PostScript printing.

```
enum {
    kPMPSTargetLanguageLevel2and3 = -3,
    kPMPSTargetLanguageLevel1and2 = -2,
    kPMPSTargetLanguageLevelUnknown = -1,
    kPMPSTargetLanguageLevel1 = 1,
    kPMPSTargetLanguageLevel2 = 2,
    kPMPSTargetLanguageLevel3 = 3,
    kPMPSTargetLanguageLevelDefault = -1
};
```

Constants

`kPMPSTargetLanguageLevel2and3`
Level 2 compatible, may take advantage of Level 3 features.

Available in Mac OS X v10.1 and later.

Declared in `PMTicket.h`.

`kPMPSTargetLanguageLevel1and2`
Level 1 compatible, may take advantage of Lever 2 and 3 features.

Available in Mac OS X v10.1 and later.

Declared in `PMTicket.h`.

`kPMPSTargetLanguageLevelUnknown`
Language level of target is unknown.

Available in Mac OS X v10.1 and later.

Declared in `PMTicket.h`.

`kPMPSTargetLanguageLevel1`
Level 1.

Available in Mac OS X v10.1 and later.

Declared in `PMTicket.h`.

`kPMPSTargetLanguageLevel2`
Level 2.

Available in Mac OS X v10.1 and later.

Declared in `PMTicket.h`.

`kPMPSTargetLanguageLevel3`
Level 3.

Available in Mac OS X v10.1 and later.

Declared in `PMTicket.h`.

`kPMPSTargetLanguageLevelDefault`
Same as `kPMPSTargetLanguageLevelUnknown`.

Available in Mac OS X v10.1 and later.

Declared in `PMTicket.h`.

PostScript Printer Description Tags

Defines strings and keys for items related to PostScript printer description files.

```
#define kPMDescriptionFileStr kPMPrinterInfoPrelude
"PMDescriptionFile"
#define kPMDescriptionFileKey CFSTR(kPMDescriptionFileStr)
#define kPMCompiledPPDStr kPMPrinterInfoPrelude "PMCompiledPPD"
#define kPMCompiledPPDKey CFSTR(kPMCompiledPPDStr)
```

Constants

`kPMDescriptionFileStr`
The printer description file string.

`kPMDescriptionFileKey`
The value of this key is a `CFString`; specifies the PostScript printer description file name or other description file.

`kPMCompiledPPDStr`
The compiled PostScript printer description string.

`kPMCompiledPPDKey`
The value of this key is a compiled PostScript printer description (`CFData`).

PostScript Printer Driver Keys

Defines a string and key for a PostScript printer driver.

```
#define kPMPrinterIsPostScriptDriverStr kPMPrinterInfoPrelude "PMIsPostScriptDriver"
#define kPMPrinterIsPostScriptDriverKey CFSTR(kPMPrinterIsPostScriptDriverStr)
```

Constants

`kPMPrinterIsPostScriptDriverStr`
The PostScript printer driver string.

`kPMPrinterIsPostScriptDriverKey`
The value of this key is a `CFBoolean` value.

Print Settings Ticket Keys

Defines strings and keys for items in a print settings ticket.

```
#define kPMBorderStr kPMPrintSettingsPrelude "PMBorder"
#define kPMBorderKey CFSTR(kPMBorderStr)
#define kPMBorderTypeStr kPMPrintSettingsPrelude "PMBorderType"
#define kPMBorderTypeKey CFSTR(kPMBorderTypeStr)
#define kPMLayoutNUpStr kPMPrintSettingsPrelude "PMLayoutNUp"
#define kPMLayoutNUpKey CFSTR(kPMLayoutNUpStr
#define kPMLayoutRowsStr kPMPrintSettingsPrelude "PMLayoutRows"
#define kPMLayoutRowsKey CFSTR(kPMLayoutRowsStr)
#define kPMLayoutColumnsStr kPMPrintSettingsPrelude "PMLayoutColumns"
#define kPMLayoutColumnsKey CFSTR(kPMLayoutColumnsStr)
#define kPMLayoutDirectionStr kPMPrintSettingsPrelude "PMLayoutDirection"
#define kPMLayoutDirectionKey CFSTR(kPMLayoutDirectionStr)
#define kPMLayoutTileOrientationStr kPMPrintSettingsPrelude "PMLayoutTileOrientation"
#define kPMLayoutTileOrientationKey CFSTR(kPMLayoutTileOrientationStr)
#define kPMQualityStr kPMPrintSettingsPrelude "PMQuality"
#define kPMQualityKey CFSTR(kPMQualityStr)
#define kPMPaperTypeStr kPMPrintSettingsPrelude "PMPaperType"
#define kPMPaperTypeKey CFSTR(kPMPaperTypeStr)
#define kPMJobStateStr kPMPrintSettingsPrelude "PMJobState"
#define kPMJobStateKey CFSTR(kPMJobStateStr)
#define kPMJobHoldUntilTimeStr kPMPrintSettingsPrelude "PMJobHoldUntilTime"
#define kPMJobHoldUntilTimeKey CFSTR(kPMJobHoldUntilTimeStr)
#define kPMJobPriorityStr kPMPrintSettingsPrelude "PMJobPriority"
#define kPMJobPriorityKey CFSTR(kPMJobPriorityStr)
#define kPMPaperSourceStr kPMPrintSettingsPrelude "PMPaperSource"
#define kPMPaperSourceKey CFSTR(kPMPaperSourceStr)
#define kPMDuplexingStr kPMPrintSettingsPrelude "PMDuplexing"
#define kPMDuplexingKey CFSTR(kPMDuplexingStr)
#define kPMColorModeStr kPMPrintSettingsPrelude "PMColorMode"
#define kPMColorModeKey CFSTR(kPMColorModeStr)
#define kPMColorSyncProfileIDStr kPMPrintSettingsPrelude "PMColorSyncProfileID"
#define kPMColorSyncProfileIDKey            CFSTR(kPMColorSyncProfileIDStr)
#define kPMColorSyncSystemProfilePathStr    kPMPrintSettingsPrelude
"PMColorSyncSystemProfilePath"
#define kPMColorSyncSystemProfilePathKey CFSTR(kPMColorSyncSystemProfilePathStr)
#define kPMPrintScalingHorizontalStr kPMPrintSettingsPrelude "PMScaling"
#define kPMPrintScalingHorizontalKey CFSTR(kPMPrintScalingHorizontalStr)
#define kPMPrintScalingVerticalStr kPMPrintSettingsPrelude "PMVerticalScaling"
#define kPMPrintScalingVerticalKey CFSTR(kPMPrintScalingVerticalStr)
#define kPMPrintScalingAlignmentStr kPMPrintSettingsPrelude "PMScalingAlignment"
#define kPMPrintScalingAlignmentKey CFSTR(kPMPrintScalingAlignmentStr)
#define kPMPrintOrientationStr kPMPrintSettingsPrelude "PMOrientation"
#define kPMPrintOrientationKey CFSTR(kPMPrintOrientationStr)
#define kPMPreviewStr kPMPrintSettingsPrelude "PMPreview"
#define kPMPreviewKey CFSTR(kPMPreviewStr
#define kPMPrintBackupRecordHdlStr kPMPrintSettingsPrelude "BackupPrintRecordHandle"
#define kPMPrintBackupRecordHdlKey CFSTR(kPMPrintBackupRecordHdlStr)
#define kPMPrintBackupRecordDataStr kPMPrintSettingsPrelude "BackupPrintRecord"
#define kPMPrintBackupRecordDataKey CFSTR(kPMPrintBackupRecordDataStr)
#define kPMPrintCustomDialogHdlStr kPMPrintSettingsPrelude "CustomDialogRecord"
#define kPMPrintCustomDialogHdlKey CFSTR(kPMPrintCustomDialogHdlStr)
#define kPMPrimaryPaperFeedStr                kPMPrintSettingsPrelude
"PMPrimaryPaperFeed"
#define kPMPrimaryPaperFeedKey                CFSTR(kPMPrimaryPaperFeedStr)
#define kPMSecondaryPaperFeedStr            kPMPrintSettingsPrelude
"PMSecondaryPaperFeed"
#define kPMSecondaryPaperFeedKey            CFSTR(kPMSecondaryPaperFeedStr)
#define kPMPSErrorHandlerStr                kPMPrintSettingsPrelude
```

```
"PMPSErrorHandler"
#define kPMPSErrorHandlerKey                CFSTR(kPMPSErrorHandlerStr)
#define kPMPSErrorOnScreenStr                kPMPrintSettingsPrelude
"PMPSErrorOnScreen"
#define kPMPSErrorOnScreenKey                CFSTR(kPMPSErrorOnScreenStr)
#define kPMPSTraySwitchStr                    kPMPrintSettingsPrelude
"PMPSTraySwitch"
#define kPMPSTraySwitchKey                    CFSTR(kPMPSTraySwitchStr)
#define kPMPPDDictStr     kPMPrintSettingsPrelude "kPMPPDDictStr"
#define kPMPPDDictKey CFSTR(kPMPPDDictStr)
```

Constants

`kPMPrintSettingsPrelude`
The print settings ticket prelude string.

`kPMDestinationTypeStr`
The destination type string.

`kPMDestinationTypeKey`
The value of this key is a `CFNumber` of type `kCFNumberSInt32Type`; can be `kPMDestinationPrinter`, `kPMDestinationFile`, or `kPMDestinationFax`.

`kPMOutputFilenameStr`
The output filename string.

`kPMOutputFilenameKey`
The value of this key is a `CFString`; a URL that specifies the output filename.

`kPMCopiesStr`
The copies string.

`kPMCopiesKey`
The value of this key is a `CFNumber` of type `kCFNumberSInt32Type` that specifies number of copies to print.

`kPMCopyCollateStr`
The copy/collate string.

`kPMCopyCollateKey`
The value of this key is a `CFBoolean` value; used to turn collating on.

`kPMReverseOrderStr`
The reverse order string.

`kPMReverseOrderKey`
The value of this key is a `CFBoolean` value; `true` specifies to print sheets back to front. All layout options are unaffected by reverse order.

`kPMPageRangeStr`
The page range string.

`kPMPageRangeKey`
The value of this key is a `CFArray` of type `kCFNumberSInt32Type`; indicates valid range of pages that the application is able to print.

`kPMFirstPageStr`
The first page string.

`kPMFirstPageKey`
The value of this key is a `CFNumber` of type `kCFNumberSInt32Type`; the first page selected by user to print.

`kPMLastPageStr`
The last page string.

`kPMLastPageKey`
The value of this key is a `CFNumber` of type `kCFNumberSInt32Type`; the last page selected by user to print.

`kPMBorderStr`
The border string.

`kPMBorderKey`
The value of this key is a `CFBoolean`; `true` specifies to use borders.

`kPMBorderTypeStr`
The border type string.

`kPMBorderTypeKey`
The value of this key is a `CFNumber` of type `kCFNumberSInt32Type`; specifies an enumeration (`PMBorderType`).

`kPMLayoutNUpStr`
The layout string.

`kPMLayoutNUpKey`
The value of this key is a `CFBoolean` value; turns N-Up layout on.

`kPMLayoutRowsStr`
The layout rows string.

`kPMLayoutRowsKey`
The value of this key is a `CFNumber` of type `kCFNumberSInt32Type`; indicates number of layout rows.

`kPMLayoutColumnsStr`
The layout columns string.

`kPMLayoutColumnsKey`
The value of this key is a `CFNumber` of type `kCFNumberSInt32Type`; indicates number of layout columns.

`kPMLayoutDirectionStr`
The layout direction string.

`kPMLayoutDirectionKey`
The value of this key is a `CFNumber` of type `kCFNumberSInt32Type`; specifies an enumeration (`PMLayoutDirection`).

`kPMLayoutTileOrientationStr`
The layout tile orientation string.

`kPMLayoutTileOrientationKey`
The value of this key is a `CFNumber` of type `kCFNumberSInt32Type`; `PMOrientation`, 1 = portrait, 2 = landscape, etc.

`kPMQualityStr`
The print quality string.

`kPMQualityKey`
The value of this key is a `CFNumber` of type `kCFNumberSInt32Type`; specfies an enumeration—draft, normal, best.

`kPMPaperTypeStr`
The paper type string.

`kPMPaperTypeKey`
The value of this key is a `CFNumber` of type `kCFNumberSInt32Type`.

`kPMJobStateStr`
The job state string.

`kPMJobStateKey`
The value of this key is a `CFNumber` of type `kCFNumberSInt32Type`; specifies an enumeration—active = 0, pending, hold until, hold indefinitely, aborted, finished.

`kPMJobHoldUntilTimeStr`
The job hold until string.

`kPMJobHoldUntilTimeKey`
The value of this key is a `CFDate`; specifies time to print the job.

`kPMJobPriorityStr`
The job priority string.

`kPMJobPriorityKey`
The value of this key is a `CFNumber` of type `kCFNumberSInt32Type`; specifies an enumeration—Low = 0, normal, urgent.

`kPMPaperSourceStr`
The paper source string.

`kPMPaperSourceKey`
The value of this key is a `CFNumber` of type `kCFNumberSInt32Type`; specifies an enumeration of paper sources.

`kPMDuplexingStr`
The duplexing string.

`kPMDuplexingKey`
The value of this key is a `CFNumber` of type `kCFNumberSInt32Type`; specifies an enumeration—`kPMDuplexNone`, `kPMDuplexNoTumble`, `kPMDuplexTumble`, `kPMSimplexTumble`.

`kPMColorModeStr`
The color mode string.

`kPMColorModeKey`
The value of this key is a `CFNumber` of type `kCFNumberSInt32Type`; specifies an enumeration—Black and White, Grayscale, Color, HiFi Color.

`kPMColorSyncProfileIDStr`
The ColorSync Profile ID string.

`kPMColorSyncProfileIDKey`
The value of this key is a `CFNumber` of type `kCFNumberSInt32Type`; specifies the ID of the ColorSync profile to use.

`kPMColorSyncSystemProfilePathStr`
The ColorSync system profile path string.

`kPMColorSyncSystemProfilePathKey`
The value of this key is a `CFString`; specifies the path of system profile.

`kPMPrintScalingHorizontalStr`
The horizontal print scaling string.

`kPMPrintScalingHorizontalKey`
The value of this key is a `CFNumber` of type `kCFNumberDoubleType`; specifies the horizontal scaling factor applied to original page size.

`kPMPrintScalingVerticalStr`
The vertical print scaling string.

`kPMPrintScalingVerticalKey`
The value of this key is a `CFNumber` of type `kCFNumberDoubleType`; specifies the vertical scaling factor applied to original page size.

`kPMPrintScalingAlignmentStr`
The print scaling alignment string.

`kPMPrintScalingAlignmentKey`
The value of this key is a `CFNumber` of type `kCFNumberSInt32Type`; specifies an enumeration (`PMScalingAlignment`).

`kPMPrintOrientationStr`
The print orientation string.

`kPMPrintOrientationKey`
The value of this key is a `CFNumber` of type `kCFNumberSInt32Type`; specifies and enumeration—`PMOrientation`, 1 = portrait, 2 = landscape, etc.

`kPMPreviewStr`
The print preview string.

`kPMPreviewKey`
The value of this key is a `CFString`; "YES" indicates the user clicked the Preview button.

`kPMPrintBackupRecordHdlStr`
The print backup record handle string.

`kPMPrintBackupRecordHdlKey`
The value of this key is a print record handle (`CFData`); not used when data is flattened. (Mac OS 8 and 9 only)

`kPMPrintBackupRecordDataStr`
The print backup record data string.

`kPMPrintBackupRecordDataKey`
The value of this key is a print record (`CFData`) stored in complete form; used when flattening a ticket with the print record. (Mac OS 8 and 9 only)

`kPMPrintCustomDialogHdlStr`
The print custom dialog handle string.

`kPMPrintCustomDialogHdlKey`
The value of this key is a handle (`CFData`) to the print record using for custom dialog calls; not stored when data is flattened. (Mac OS 8 and 9 only)

`kPMPrimaryPaperFeedStr`
The primary paper feed string.

`kPMPrimaryPaperFeedKey`
The value of this key is a `CFArray`; the main and option PPD keywords for input paper feed.

`kPMSecondaryPaperFeedStr`
The secondary paper feed string.

`kPMSecondaryPaperFeedKey`
The value of this key is a `CFArray`; the main and option PPD keywords for input paper feed.

`kPMPSErrorHandlerStr`
The PostScript error handle string.

`kPMPSErrorHandlerKey`
The value of this key is a `CFNumber` of type `kCFNumberSInt32Type`.

`kPMPSErrorOnScreenStr`
The PostScript error on screen string.

`kPMPSErrorOnScreenKey`
The value of this key is a `CFBoolean`; turns PostScript error onscreen notification on.

`kPMPSTraySwitchStr`
The PostScript tray switch string.

`kPMPSTraySwitchKey`
The value of this key is a `CFArray`; the main and option PostScript printer description file keywords for tray switching.

`kPMPPDDictStr`
The PostScript printer description file string.

`kPMPPDDictKey`
The value of this key is a `CFDictionary`; the main and option PostScript printer description file keywords for additional features.

Printer Driver Creator Code Key

Defines a string and key for the printer driver creator code.

```
#define kPMDriverCreatorStr                    kPMPrinterInfoPrelude
"PMDriverCreator        "
#define kPMDriverCreatorKey                    CFSTR(kPMDriverCreatorStr)
```

Constants

`kPMDriverCreatorStr`
The printer driver creator string.

`kPMDriverCreatorKey`
The value of this key is a `CFNumber` of type `kCFNumberSInt32Type` that specifies the creator code for the printer driver.

Printer Font Keys

Defines a string and key for the printer fonts.

```
#define kPMPrinterFontStr kPMPrinterInfoPrelude "Printer
Fonts    "
#define kPMPrinterFontKey CFSTR(kPMPrinterFontStr)
```

Constants

`kPMPrinterFontStr`
The printer font string.

`kPMPrinterFontKey`
The value of this key is `CFData` that specifies the printer resident fonts.

Printer Info Ticket Keys

Defines strings and keys for items in a printer info ticket.

```
#define kPMPrinterInfoPrelude "com.apple.print.PrinterInfo."
#define kPMPrinterLongNameStr kPMPrinterInfoPrelude "PMPrinterLongName"
#define kPMPrinterLongNameKey CFSTR(kPMPrinterLongNameStr)
#define kPMPrinterShortNameStr kPMPrinterInfoPrelude "PMPrinterShortName"
#define kPMPrinterShortNameKey CFSTR(kPMPrinterShortNameStr)
#define kPMMakeAndModelNameStr kPMPrinterInfoPrelude "PMMakeAndModelName"

#define kPMInputFileTypeListKey CFSTR(kPMInputFileTypeListStr)
#define kPMOutputTypeListStr     kPMPrinterInfoPrelude "PMOutputTypeList"
#define kPMOutputTypeListKey     CFSTR(kPMOutputTypeListStr)
```

Constants

`kPMPrinterInfoPrelude`
The printer info ticket prelude string.

`kPMPrinterLongNameStr`
The printer long name string.

`kPMPrinterLongNameKey`
The value of this key is a `CFString`; specifies the full name of the printer.

`kPMPrinterShortNameStr`
The printer short name string.

`kPMPrinterShortNameKey`
The value of this key is a `CFString`; specifies a shortened version of the printer name.

`kPMMakeAndModelNameStr`
The printer make and model string.

`kPMMakeAndModelNameKey`
The value of this key is a `CFString`; specifies the product name used for the printer

`kPMPrinterAddressStr`
The printer address string.

`kPMPrinterAddressKey`
The value of this key is the product address (`CFData`).

`kPMSupportsColorStr`
The color supported string.

`kPMSupportsColorKey`
The value of this key is a `CFBoolean`; `true` if the printer supports color printing.

`kPMDoesCopiesStr`
The copies string.

`kPMDoesCopiesKey`
The value of this key is a `CFBoolean`; `true` if the printer supports copies.

`kPMDoesCopyCollateStr`
The collation string.

`kPMDoesCopyCollateKey`
The value of this key is a `CFBoolean`; `true` if the printer supports collation.

`kPMDoesReverseOrderStr`
The reverse-order string.

`kPMDoesReverseOrderKey`
The value of this key is a `CFBoolean`; `true` if the printer can print in reverse order.

`kPMInputFileTypeListStr`
The file type list string.

`kPMInputFileTypeListKey`
The value of this key is a `CFArray` of `CFString` data that indicates file types.

`kPMOutputTypeListStr`
The output type list string.

`kPMOutputTypeListKey`
The value of this key is a `CFArray` of `CFString` data that indicates the MIME types for the data that can be sent to an I/O module.

Printing Phase Types

Specify the phase of the printing process.

```
typedef UInt16 PMPrintingPhaseType;
enum {
    kPMPhaseUnknown = 0,
    kPMPhasePreDialog = 1,
    kPMPhaseDialogsUp = 2,
    kPMPhasePostDialogs = 3,
    kPMPhasePreAppDrawing = 4,
    kPMPhaseAppDrawing = 5,
    kPMPhasePostAppDrawing = 6,
    kPMPhasePreConversion = 7,
    kPMPhaseConverting = 8,
    kPMPhasePostConversion = 9,
    kPMPhasePrinting = 10
};
```

Constants

`kPMPhaseUnknown`
Phase unknown.

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in `PMTicket.h`.

`kPMPhasePreDialog`
Just before the code to open the dialog.

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in `PMTicket.h`.

`kPMPhaseDialogsUp`
A printing dialogs is open.

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in `PMTicket.h`.

`kPMPhasePostDialogs`
The printing dialogs have been opened and are now closed, but the job is not yet spooling.

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in `PMTicket.h`.

`kPMPhasePreAppDrawing`
The job is just about to spool.

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in `PMTicket.h`.

`kPMPhaseAppDrawing`
Drawing commands are now being spooled from the application.

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in `PMTicket.h`.

`kPMPhasePostAppDrawing`
Spooling is finished, not the job is not yet rendered or converted.

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in `PMTicket.h`.

`kPMPhasePreConversion`
The job is just about to be converted to its final format (PostScript, Raster, or other).

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in `PMTicket.h`.

`kPMPhaseConverting`
The job is being converted from the spool file to the final format.

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in `PMTicket.h`.

`kPMPhasePostConversion`
The data is ready for the printer and waiting for completion.

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in `PMTicket.h`.

`kPMPhasePrinting`
The job is waiting for the printer.

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in `PMTicket.h`.

Discussion
Printing phase types signal a shift from one printing phase to the next and are set by many parts of the printing system. You can check the phase by testing for greater-than and less-than conditions.

Rasterizer Options

Specify options for rasterizing.

```
enum {
    kPMPSTTRasterizerUnknown = 0,
    kPMPSTTRasterizerNone = 1,
    kPMPSTTRasterizerAccept68K = 2,
    kPMPSTTRasterizerType42 = 3
};
```

Constants

`kPMPSTTRasterizerUnknown`
Rasterizer unknown.
Available in Mac OS X v10.0 and later.
Declared in `PMTicket.h`.

`kPMPSTTRasterizerNone`
No rasterizer.
Available in Mac OS X v10.0 and later.
Declared in `PMTicket.h`.

`kPMPSTTRasterizerAccept68K`
Accepts 68 K.
Available in Mac OS X v10.0 and later.
Declared in `PMTicket.h`.

`kPMPSTTRasterizerType42`
Uses type 42.
Available in Mac OS X v10.0 and later.
Declared in `PMTicket.h`.

Template Entry Data Types

Specify the data type of a job template entry.

```
typedef SInt32 PMValueType;
enum {
    kPMValueUndefined = 0,
    kPMValueBoolean = 1,
    kPMValueData = 2,
    kPMValueString = 3,
    kPMValueSInt32 = 4,
    kPMValueSInt32Range = 5,
    kPMValueUInt32 = 6,
    kPMValueUInt32Range = 7,
    kPMValueDouble = 8,
    kPMValueDoubleRange = 9,
    kPMValuePMRect = 10,
    kPMValueDate = 11,
    kPMValueArray = 12,
    kPMValueDict = 13,
    kPMValueTicket = 14
};
```

Constants

`kPMValueUndefined`
Template entry is unknown or undefined.

Available in Mac OS X v10.0 and later.

Declared in `PMTemplate.h`.

`kPMValueBoolean`
A `CFBoolean` value.

Available in Mac OS X v10.0 and later.

Declared in `PMTemplate.h`.

`kPMValueData`
A `CFData` value. This is generic data converted to Core Foundation data. Template entries of this type should have a default value, but no other constraints.

Available in Mac OS X v10.0 and later.

Declared in `PMTemplate.h`.

`kPMValueString`
A `CFString` value. Template entries of this type should have a default value, but no other constraints.

Available in Mac OS X v10.0 and later.

Declared in `PMTemplate.h`.

`kPMValueSInt32`
A `CFNumber` value.

Available in Mac OS X v10.0 and later.

Declared in `PMTemplate.h`.

`kPMValueSInt32Range`
A pair of `CFNumber` values (`SInt32` data type).

Available in Mac OS X v10.0 and later.

Declared in `PMTemplate.h`.

`kPMValueUInt32`
A `CFNumber` value (unsigned long data types).

Available in Mac OS X v10.0 and later.

Declared in `PMTemplate.h`.

`kPMValueUInt32Range`
A pair of `CFNumber` values (`UInt32` values).

Available in Mac OS X v10.0 and later.

Declared in `PMTemplate.h`.

`kPMValueDouble`
A `CFNumber` value (`double` data type.)

Available in Mac OS X v10.0 and later.

Declared in `PMTemplate.h`.

`kPMValueDoubleRange`
A pair of `CFNumber` values (`double` data types).

Available in Mac OS X v10.0 and later.

Declared in `PMTemplate.h`.

`kPMValuePMRect`
A Core Foundation array that contains four `CFNumbers` values (`double` data types).

Available in Mac OS X v10.0 and later.

Declared in `PMTemplate.h`.

`kPMValueDate`
A `CFDate` value.

Available in Mac OS X v10.0 and later.

Declared in `PMTemplate.h`.

`kPMValueArray`
A Core Foundation array.

Available in Mac OS X v10.0 and later.

Declared in `PMTemplate.h`.

`kPMValueDict`
A `CFDictionary` data structure. Template entries of this type should have a default value, but no other constraints.

Available in Mac OS X v10.0 and later.

Declared in `PMTemplate.h`.

`kPMValueTicket`
A ticket.

Available in Mac OS X v10.0 and later.

Declared in `PMTemplate.h`.

Discussion
A template entry data type determines what other fields and functions are available for the entry.

Template Strings

Define a string associated with a template.

```
#define kPMTemplatePrelude     "com.apple.print.TemplateSpecific."
#define kPMPaperInfoListStr     "PMTemplatePaperInfoTicket"
#define kPMPaperInfoList CFSTR( kPMPaperInfoListStr )
```

Constants

`kPMTemplatePrelude`
A template prelude string.

`kPMPaperInfoListStr`
A paper info list string.

`kPMPaperInfoList`
A paper info list.

Ticket Levels

Specify the level of an item within a ticket.

```
enum {
    kPMTopLevel = 0
};
```

Constants

`kPMTopLevel`
Specifies the top level ticket.

Discussion

You should pass the constant `kPMTopLevel` to any function that has parameters to specify ticket level calls. No other options are currently available.

Ticket Types

Specify a ticket type, that is, a ticket kind.

```
typedef SInt16 PMTicketType;
enum {
    kPMTicketTypeUnknown = -1,
    kPMJobTicketType = 1,
    kPMDocumentTicketType = 2,
    kPMPageTicketType = 3,
    kPMPageFormatTicketType = 4,
    kPMPrintSettingsTicketType = 5,
    kPMPrinterInfoTicketType = 6,
    kPMDestinationTicketType = 7,
    kPMConverterSetupTicketType = 8,
    kPMModuleInfoTicketType = 9,
    kPMTicketListType = 10,
    kPMPaperInfoTicketType = 11
};
```

Constants

`kPMTicketTypeUnknown`
Specifies the ticket type is not know.

Available in Mac OS X v10.0 and later.

Declared in `PMTicket.h`.

`kPMJobTicketType`
Specifies a job ticket.
Available in Mac OS X v10.0 and later.
Declared in `PMTicket.h`.

`kPMDocumentTicketType`
Specifies a document ticket.
Available in Mac OS X v10.0 and later.
Declared in `PMTicket.h`.

`kPMPageTicketType`
Specifies a page ticket.
Available in Mac OS X v10.0 and later.
Declared in `PMTicket.h`.

`kPMPageFormatTicketType`
Specifies a page format ticket.
Available in Mac OS X v10.0 and later.
Declared in `PMTicket.h`.

`kPMPrintSettingsTicketType`
Specifies a print settings ticket.
Available in Mac OS X v10.0 and later.
Declared in `PMTicket.h`.

`kPMPrinterInfoTicketType`
Specifies a printer info ticket.
Available in Mac OS X v10.0 and later.
Declared in `PMTicket.h`.

`kPMDestinationTicketType`
Specifies a destination ticket.
Available in Mac OS X v10.0 and later.
Declared in `PMTicket.h`.

`kPMConverterSetupTicketType`
Specifies a converter setup ticket.
Available in Mac OS X v10.0 and later.
Declared in `PMTicket.h`.

`kPMModuleInfoTicketType`
Specifies a printer module info ticket.
Available in Mac OS X v10.0 and later.
Declared in `PMTicket.h`.

`kPMTicketListType`
Specifies a list ticket.
Available in Mac OS X v10.0 and later.
Declared in `PMTicket.h`.

`kPMPaperInfoTicketType`
Specifies a paper info ticket.

Available in Mac OS X v10.0 and later.

Declared in `PMTicket.h`.

Ticket Type Strings

Specify ticket types.

```
#define kPMJobTicket CFSTR("com.apple.print.JobTicket")
#define kPMDocumentTicket CFSTR("com.apple.print.DocumentTicket")
#define kPMPageTicket CFSTR("com.apple.print.PageTicket")
#define kPMPageFormatTicket CFSTR("com.apple.print.PageFormatTicket")
#define kPMPrintSettingsTicket CFSTR("com.apple.print.PrintSettingsTicket")
#define kPMDestinationTicket CFSTR("com.apple.print.DestinationTicket")
#define kPMConverterSetupTicket CFSTR("com.apple.print.ConverterSetupTicket")
#define kPMPrinterInfoTicket CFSTR("com.apple.print.PrinterInfoTicket")
#define kPMModuleInfoTicket CFSTR("com.apple.print.ModuleInfoTicket")
#define kPMTicketList CFSTR("com.apple.print.TicketList")
#define kPMPaperInfoTicket CFSTR("com.apple.print.PaperInfoTicket")
```

Constants

`kPMJobTicket`
Specifies a job ticket; the top-level ticket for a print job.

`kPMDocumentTicket`
Specifies a document ticket.

`kPMPageTicket`
Specifies a page ticket.

`kPMPageFormatTicket`
Specifies a page format ticket.

`kPMPrintSettingsTicket`
Specifies a print settings ticket.

`kPMDestinationTicket`
Specifies a destination ticket.

`kPMConverterSetupTicket`
Specifies a converter setup ticket.

`kPMPrinterInfoTicket`
Specifies a printer info ticket.

`kPMModuleInfoTicket`
Specifies a module info ticket.

`kPMTicketList`
Specifies a list ticket.

`kPMPaperInfoTicket`
Specifies a paper info ticket.

Discussion

Use these ticket type strings of ticket types to create a ticket.

Result Codes

This table lists result codes defined for Ticket Services.

Result Code	Value	Description
kPMTicketTypeNotFound	-9580	The ticket type was not found. Available in Mac OS X v10.0 and later.
kPMUpdateTicketFailed	-9581	Could not update the ticket. Available in Mac OS X v10.0 and later.
kPMValidateTicketFailed	-9582	Could not validate the ticket. Available in Mac OS X v10.0 and later.
kPMSubTicketNotFound	-9583	Could not find the subticket. Available in Mac OS X v10.0 and later.
kPMInvalidSubTicket	-9584	The subticket is invalid. Available in Mac OS X v10.0 and later.
kPMDeleteSubTicketFailed	-9585	Could not delete the subticket. Available in Mac OS X v10.0 and later.
kPMItemIsLocked	-9586	The item is locked. Available in Mac OS X v10.0 and later.
kPMTicketIsLocked	-9587	The ticket is locked. Available in Mac OS X v10.0 and later.
kPMTemplateIsLocked	-9588	The job template is locked. Available in Mac OS X v10.0 and later.
kPMKeyNotFound	-9589	Could not find the key. Available in Mac OS X v10.0 and later.
kPMKeyNotUnique	-9590	The key is not unique. Available in Mac OS X v10.0 and later.
kPMUnknownDataType	-9591	The data type is unknown. Available in Mac OS X v10.0 and later.

Overview

Apple Type Services for Unicode Imaging (ATSUI) enables the rendering of Unicode-encoded text with advanced typographic features. It automatically handles many of the complexities inherent in text layout, including the correct rendering of text in bidirectional and vertical script systems.

ATSUI may be useful to developers who are writing new text editors or word processing applications that render Unicode-encoded text. You can also use ATSUI if you want to modify your existing application to support Unicode text rendering.

This document describes the ATSUI application programming interface (API) through version 2.4. If you are a font designer or want more information about fonts, see the Apple font site: http://developer.apple.com/fonts/

Functions by Task

Creating and Initializing Style Objects

`ATSUCreateStyle` (page 1865)
Creates an opaque style object containing only default style attributes, font features, and font variations.

`ATSUCreateAndCopyStyle` (page 1863)
Creates a copy of a style object.

`ATSUCompareStyles` (page 1855)
Compares the attribute values of two style objects.

`ATSUClearStyle` (page 1854)
Restores default values to a style object.

`ATSUStyleIsEmpty` (page 1968)
Indicates whether a style object contains only default values.

`ATSUSetStyleRefCon` (page 1961)
Sets application-specific data for a style object.

`ATSUGetStyleRefCon` (page 1918)
Obtains application-specific data for a style object.

`ATSUDisposeStyle` (page 1876)
Disposes of the memory associated with a style object.

Manipulating Style Attributes

`ATSUSetAttributes` (page 1950)
Sets style attribute values in a style object.

`ATSUCopyAttributes` (page 1856)
Copies all style attribute settings from a source style object to a destination style object.

`ATSUOverwriteAttributes` (page 1944)
Copies to a destination style object the nondefault style attribute settings of a source style object.

`ATSUUnderwriteAttributes` (page 1972)
Copies to a destination style object only those nondefault style attribute settings of a source style object that are at default settings in the destination object.

`ATSUGetAllAttributes` (page 1886)
Obtains an array of style attribute tags and value sizes for a style object.

`ATSUGetAttribute` (page 1892)
Obtains a style attribute value for a style object.

`ATSUGetContinuousAttributes` (page 1893)
Obtains the style attribute values that are continuous over a given text range.

`ATSUClearAttributes` (page 1848)
Restores default values to the specified style attributes of a style object.

Manipulating Font Features

`ATSUSetFontFeatures` (page 1952)
Sets font features in a style object.

`ATSUGetAllFontFeatures` (page 1887)
Obtains the font features of a style object that are not at default settings.

`ATSUGetFontFeature` (page 1895)
Obtains the font feature corresponding to an index into an array of font features for a style object.

`ATSUClearFontFeatures` (page 1849)
Restores default settings to the specified font features of a style object.

`ATSUGetFontFeatureTypes` (page 1898)
Obtains the available feature types of a font.

`ATSUCountFontFeatureTypes` (page 1860)
Obtains the number of available feature types in a font.

ATSUGetFontFeatureSelectors (page 1897)
Obtains the available feature selectors for a given feature type in a font.

ATSUCountFontFeatureSelectors (page 1859)
Obtains the number of available feature selectors for a given feature type in a font.

Manipulating Font Variations

ATSUSetVariations (page 1967)
Sets font variation axes and values in a style object.

ATSUGetAllFontVariations (page 1888)
Obtains a style object's font variation values that are not at default settings.

ATSUGetFontVariationValue (page 1903)
Obtains the current value for a font variation axis in a style object.

ATSUClearFontVariations (page 1850)
Restores default values to the specified font variation axes of a style object.

ATSUGetIndFontVariation (page 1911)
Obtains a variation axis and its value range for a font.

ATSUCountFontVariations (page 1862)
Obtains the number of defined variation axes in a font.

ATSUGetFontInstance (page 1900)
Obtains the font variation axis values for a font instance.

ATSUCountFontInstances (page 1860)
Obtains the number of defined font instances in a font.

Creating and Initializing Text Layout Objects

ATSUCreateTextLayout (page 1866)
Creates an opaque text layout object containing only default text layout attributes.

ATSUCreateTextLayoutWithTextPtr (page 1869)
Creates an opaque text layout object containing default text layout attributes as well as associated text and text styles.

ATSUCreateAndCopyTextLayout (page 1863)
Creates a copy of a text layout object.

ATSUSetTextPointerLocation (page 1965)
Associates text with a text layout object or updates previously associated text.

ATSUGetTextLocation (page 1921)
Obtains information about the text associated with a text layout object.

ATSUSetRunStyle (page 1959)
Defines a style run by associating style information with a run of text.

ATSUGetRunStyle (page 1916)
Obtains style run information for a character offset in a run of text.

ATSUSetTextLayoutRefCon (page 1964)
Sets application-specific data for a text layout object.

`ATSUGetTextLayoutRefCon` (page 1921)
Obtains application-specific data for a text layout object.

`ATSUDisposeTextLayout` (page 1876)
Disposes of the memory associated with a text layout object.

Manipulating Text Layout Attributes

`ATSUSetLayoutControls` (page 1955)
Sets layout control attribute values in a text layout object.

`ATSUCopyLayoutControls` (page 1857)
Copies all layout control attribute settings from a source text layout object to a destination text layout object.

`ATSUGetAllLayoutControls` (page 1890)
Obtains an array of layout control attribute tags and value sizes for a text layout object.

`ATSUGetLayoutControl` (page 1912)
Obtains a layout control attribute value for a text layout object.

`ATSUClearLayoutControls` (page 1852)
Restores default values to the specified layout control attributes of a text layout object.

Manipulating Line Attributes

`ATSUSetLineControls` (page 1956)
Sets layout control attribute values for a single line in a text layout object.

`ATSUCopyLineControls` (page 1857)
Copies line control attribute settings from a line in a source text layout object to a line in a destination text layout object.

`ATSUGetAllLineControls` (page 1891)
Obtains an array of line control attribute tags and value sizes for a line in a text layout object.

`ATSUGetLineControl` (page 1913)
Obtains a line control attribute value for a line in a text layout object.

`ATSUClearLineControls` (page 1853)
Restores default values to the specified line control attributes of a line in a text layout object.

Manipulating Line Breaks

`ATSUBreakLine` (page 1846)
Calculates and, optionally, sets a soft line break in a range of text.

`ATSUBatchBreakLines` (page 1844)
Calculates soft line breaks for the text associated with a text layout object.

`ATSUSetSoftLineBreak` (page 1961)
Sets a soft line break that you specify.

`ATSUGetSoftLineBreaks` (page 1917)
Obtains soft line breaks in a range of text.

ATSUClearSoftLineBreaks (page 1854)
Removes soft line breaks from a range of text.

Substituting Fonts

ATSUMatchFontsToText (page 1936)
Examines a text range for characters that cannot be drawn with the current font and suggests a substitute font, if necessary.

ATSUSetTransientFontMatching (page 1967)
Turns automatic font substitution on or off for a text layout object.

ATSUGetTransientFontMatching (page 1922)
Obtains whether ATSUI automatically performs font substitution for a text layout object.

ATSUCreateFontFallbacks (page 1864)
Creates an opaque object that can be set to contain a font list and a font-search method.

ATSUSetObjFontFallbacks (page 1958)
Assigns a font list and a font-search method to a font fallback object.

ATSUGetObjFontFallbacks (page 1914)
Obtains the font list and font-search method associated with a font fallback object.

ATSUDisposeFontFallbacks (page 1875)
Disposes of the memory associated with a font fallback object.

Identifying Fonts

ATSUGetFontIDs (page 1899)
Obtains a list of all the ATSUI-compatible fonts installed on the user's system.

ATSUFontCount (page 1885)
Obtains the number of ATSUI-compatible fonts installed on a user's system.

ATSUFindFontName (page 1880)
Obtains a name string and index value for the first font in a name table that matches the specified ATSUI font ID, name code, platform, script, and/or language.

ATSUFindFontFromName (page 1879)
Obtains an ATSUI font ID for the first entry in a name table that matches the specified name string, name code, platform, script, and/or language.

ATSUGetIndFontName (page 1908)
Obtains a name string, name code, platform, script, and language for the font that matches an ATSUI font ID and name table index value.

ATSUCountFontNames (page 1861)
Obtains the number of font names that correspond to a given ATSUI font ID.

ATSUGetIndFontTracking (page 1910)
Obtains the name code and tracking value for the font tracking that matches an ASTUI font ID, glyph orientation, and tracking table index.

ATSUCountFontTracking (page 1861)
Obtains the number of entries in the font tracking table that correspond to a given ATSUI font ID and glyph orientation.

`ATSUGetFontFeatureNameCode` (page 1896)
Obtains the name code for a font's feature type or selector that matches an ASTUI font ID, feature type, and feature selector.

`ATSUGetFontVariationNameCode` (page 1902)
Obtains the name code for the font variation that matches an ASTUI font ID and font variation axis.

`ATSUGetFontInstanceNameCode` (page 1901)
Obtains the name code for the font instance that matches an ASTUI font ID and font instance index value.

Drawing and Highlighting Text

`ATSUDrawText` (page 1877)
Renders a range of text at a specified location in a QuickDraw graphics port or Quartz graphics context.

`ATSUHighlightText` (page 1931)
Renders a highlighted range of text at a specified location in a QuickDraw graphics port or Quartz graphics context.

`ATSUUnhighlightText` (page 1974)
Renders a previously highlighted range of text in an unhighlighted state.

`ATSUSetHighlightingMethod` (page 1953)
Sets the method ATSUI uses to highlight and unhighlight text for a text layout object.

`ATSUGetTextHighlight` (page 1919)
Obtains the highlight region for a range of text.

`ATSUHighlightInactiveText` (page 1930)
Highlights previously selected text using an alpha value of 0.5.

`ATSUClearLayoutCache` (page 1851)
Clears the layout cache of a line or an entire text layout object.

Supporting User Interaction With Onscreen Text

`ATSUTextInserted` (page 1970)
Informs ATSUI of the location and length of a text insertion.

`ATSUTextDeleted` (page 1969)
Informs ATSUI of the location and length of a text deletion.

`ATSUTextMoved` (page 1971)
Informs ATSUI of the new memory location of relocated text.

`ATSUPositionToOffset` (page 1946)
Obtains the memory offset for the glyph edge nearest a mouse-down event.

`ATSUOffsetToPosition` (page 1942)
Obtains the caret position(s) corresponding to a memory offset.

`ATSUNextCursorPosition` (page 1940)
Obtains the memory offset for the insertion point that follows the current insertion point in storage order, as determined by a move of the specified length.

ATSUPreviousCursorPosition (page 1948)
Obtains the memory offset for the insertion point that precedes the current insertion point in storage order, as determined by a move of the specified length.

ATSURightwardCursorPosition (page 1949)
Obtains the memory offset for the insertion point to the right of the high caret position, as determined by a move of the specified length at a line direction boundary.

ATSULeftwardCursorPosition (page 1933)
Obtains the memory offset for the insertion point to the left of the high caret position, as determined by a move of the specified length at a line direction boundary.

ATSUPositionToCursorOffset (page 1945)
Obtains the memory offset for the glyph edge nearest a mouse-down event, after a move of the specified length.

ATSUOffsetToCursorPosition (page 1941)
Obtains the caret position(s) corresponding to a memory offset, after a move of the specified length.

Obtaining Text Metrics

ATSUMeasureTextImage (page 1938)
Obtains the image bounding rectangle for a line of text after final layout.

ATSUGetUnjustifiedBounds (page 1923)
Obtains the typographic bounding rectangle for a line of text prior to final layout.

ATSUGetGlyphBounds (page 1904)
Obtains the typographic bounds of a line of glyphs after final layout.

ATSUCalculateBaselineDeltas (page 1847)
Obtains the optimal baseline positions for glyphs in a style run.

ATSUGlyphGetIdealMetrics (page 1927)
Obtains resolution-independent font metric information for glyphs associated with a given style object.

ATSUGlyphGetScreenMetrics (page 1929)
Obtains device-adjusted font metric information for glyphs associated with a given style object.

ATSUGetNativeCurveType (page 1914)
Obtains the type of outline path used for glyphs associated with a given style object.

ATSUGlyphGetCurvePaths (page 1926)
Obtains the outline paths for a glyph associated with a given style object.

ATSUGlyphGetCubicPaths (page 1925)
Obtains the cubic outline paths for a glyph.

ATSUGlyphGetQuadraticPaths (page 1928)
Obtains the quadratic outline paths for a glyph.

Working With Tabs

ATSUSetTabArray (page 1962)
Sets a tab ruler for a text layout object.

ATSUGetTabArray (page 1918)
Retrieves the tab ruler associated with a text layout object.

Accessing Glyph Data

ATSUDirectGetLayoutDataArrayPtrFromLineRef (page 1872)
Obtains the glyph data specified by a direct-data selector and for a specific line of text.

ATSUDirectGetLayoutDataArrayPtrFromTextLayout (page 1873)
Obtains a copy of the glyph data specified by a direct-data selector and for a specific line of text in a text layout object.

ATSUDirectReleaseLayoutDataArrayPtr (page 1874)
Releases a pointer to a direct-data array.

ATSUDirectAddStyleSettingRef (page 1871)
Looks up, and if necessary, adds a style setting to a line of text.

Flattening and Parsing Style Data

ATSUFlattenStyleRunsToStream (page 1882)
Flattens ATSUI style-run data so that it can be saved to disk or passed (through the pasteboard) to another application.

ATSUUnflattenStyleRunsFromStream (page 1972)
Unflattens previously-flattened ATSUI style run data so that it can be read from disk or accepted (through the pasteboard) from another application.

Creating, Calling, and Deleting Universal Procedure Pointers

NewATSUDirectLayoutOperationOverrideUPP (page 1989)
Creates a new universal procedure pointer (UPP) to a layout operation override callback.

InvokeATSUDirectLayoutOperationOverrideUPP (page 1984)
Calls your layout operation override callback.

DisposeATSUDirectLayoutOperationOverrideUPP (page 1979)
Disposes of a universal procedure pointer (UPP) to a layout operation override callback.

NewRedrawBackgroundUPP (page 1989)
Creates a new universal procedure pointer (UPP) to a redraw background callback.

InvokeRedrawBackgroundUPP (page 1984)
Invokes your redraw background callback.

DisposeRedrawBackgroundUPP (page 1980)
Disposes of a new universal procedure pointer (UPP) to a redraw background callback.

NewATSCubicMoveToUPP (page 1986)
Creates a new universal procedure pointer (UPP) to a cubic move-to callback.

InvokeATSCubicMoveToUPP (page 1981)
Calls your cubic move-to callback.

`DisposeATSCubicMoveToUPP` (page 1977)
Disposes of a universal procedure pointer (UPP) to a cubic move-to callback.

`NewATSCubicLineToUPP` (page 1986)
Creates a new universal procedure pointer (UPP) to a cubic line-to callback.

`InvokeATSCubicLineToUPP` (page 1981)
Calls your cubic line-to callback.

`DisposeATSCubicLineToUPP` (page 1977)
Disposes of a universal procedure pointer (UPP) to a cubic line-to callback.

`NewATSCubicCurveToUPP` (page 1985)
Creates a new universal procedure pointer (UPP) to a cubic curve-to callback.

`InvokeATSCubicCurveToUPP` (page 1980)
Calls your cubic curve-to callback.

`DisposeATSCubicCurveToUPP` (page 1976)
Disposes of a universal procedure pointer (UPP) to a cubic curve-to callback.

`NewATSCubicClosePathUPP` (page 1985)
Creates a new universal procedure pointer (UPP) to a cubic close-path callback.

`InvokeATSCubicClosePathUPP` (page 1980)
Calls your cubic close-path callback.

`DisposeATSCubicClosePathUPP` (page 1976)
Disposes of a universal procedure pointer (UPP) to a cubic close-path callback.

`NewATSQuadraticNewPathUPP` (page 1988)
Creates a new universal procedure pointer (UPP) to a quadratic new-path callback.

`InvokeATSQuadraticNewPathUPP` (page 1983)
Calls your quadratic new-path callback.

`DisposeATSQuadraticNewPathUPP` (page 1979)
Disposes of a universal procedure pointer (UPP) to a quadratic new-path callback.

`NewATSQuadraticLineUPP` (page 1988)
Creates a new universal procedure pointer (UPP) to a quadratic line callback.

`InvokeATSQuadraticLineUPP` (page 1983)
Calls your quadratic line callback.

`DisposeATSQuadraticLineUPP` (page 1978)
Disposes of a universal procedure pointer (UPP) to a quadratic line callback.

`NewATSQuadraticCurveUPP` (page 1987)
Creates a new universal procedure pointer (UPP) to a quadratic curve callback.

`InvokeATSQuadraticCurveUPP` (page 1982)
Calls your quadratic curve callback.

`DisposeATSQuadraticCurveUPP` (page 1978)
Disposes of a universal procedure pointer (UPP) to a quadratic curve callback.

`NewATSQuadraticClosePathUPP` (page 1987)
Creates a new universal procedure pointer (UPP) to a quadratic close-path callback.

`InvokeATSQuadraticClosePathUPP` (page 1982)
Calls your quadratic close-path callback.

`DisposeATSQuadraticClosePathUPP` (page 1978)
Disposes of a universal procedure pointer (UPP) to a quadratic close-path callback.

Not Recommended

`ATSUFONDtoFontID` (page 1884)
Finds the ATSUI font ID that corresponds to a font family number, if one exists. (Deprecated. There is no replacement because FONDs are a QuickDraw concept and QuickDraw is deprecated.)

`ATSUFontIDtoFOND` (page 1885)
Finds the font family number that corresponds to an ATSUI font ID, if one exists. (Deprecated. There is no replacement because FONDs are a QuickDraw concept and QuickDraw is deprecated.)

`ATSUMeasureText` (page 1938)
(Deprecated. Use `ATSUGetUnjustifiedBounds` (page 1923) instead.)

`ATSUDrawGlyphInfo` (page 1877) Deprecated in Mac OS X v10.3
Draws glyphs at the specified location, based on style and layout information specified for each glyph. (Deprecated. Use functions from "Accessing Glyph Data" (page 1842) instead.)

`ATSUGetFontFallbacks` (page 1894) Deprecated in Mac OS X v10.3
Obtains the global font list and search order that ATSUI uses when a font does not have the glyph needed to image a character. (Deprecated. Use font fallback objects instead.)

`ATSUGetGlyphInfo` (page 1906) Deprecated in Mac OS X v10.3
Obtains a copy of the style and layout information for each glyph in a line. (Deprecated. Use functions from "Accessing Glyph Data" (page 1842) instead.)

`ATSUSetFontFallbacks` (page 1952) Deprecated in Mac OS X v10.3
Sets, on a global scope, the font list and search order for ATSUI to use when a font does not have the glyph needed to image a character. (Deprecated. Use font fallback objects instead.)

`ATSUCopyToHandle` (page 1858) Deprecated in Mac OS X v10.1
Copies an ATSUI style to a handle. (Deprecated. Use `ATSUFlattenStyleRunsToStream` (page 1882) instead.)

`ATSUCreateTextLayoutWithTextHandle` (page 1867) Deprecated in Mac OS X v10.0
Creates an opaque text layout object containing default text layout attributes as well as associated text and text styles. (Deprecated. Use `ATSUCreateTextLayoutWithTextPtr` (page 1869) instead. See the Discussion for more details.)

`ATSUIdle` (page 1933) Deprecated in Mac OS X v10.0
Performs background processing. (Deprecated. There is no replacement because this function does nothing in Mac OS X.)

`ATSUSetTextHandleLocation` (page 1963) Deprecated in Mac OS X v10.0
Associates text with a text layout object. (Deprecated. Use `ATSUSetTextPointerLocation` (page 1965) instead. See the Discussion for more details.)

Functions

ATSUBatchBreakLines

Calculates soft line breaks for the text associated with a text layout object.

```
OSStatus ATSUBatchBreakLines (
   ATSUTextLayout iTextLayout,
   UniCharArrayOffset iRangeStart,
   UniCharCount iRangeLength,
   ATSUTextMeasurement iLineWidth,
   ItemCount *oBreakCount
);
```

Parameters

iTextLayout

The `ATSUTextLayout` for which you want to determine soft line breaks.

iRangeStart

A `UniCharArrayOffset` value specifying the offset from the beginning of the text layout object's text buffer to the first character of the text range to examine. To specify the beginning of the text buffer, pass the constant `kATSUFromTextBeginning`.

iRangeLength

The number of characters in which to consider in the determination of the soft line breaks.

iLineWidth

An `ATSUTextMeasurement` value specifying the line width for the text, as measured from the offset provided in the `iLineStart` parameter. You must pass a nonzero value. You should use the same width as the width layout control set for the text layout object since the final layout of each line is based on the controls set for the line or the entire text layout object. If no line width has been set for the line, `ATSUBatchBreakLines` uses the line width set for the text layout object; if this value is not set, `ATSUBatchBreakLines` returns `paramErr`.

Note that the value you pass for the `iLineWidth` parameter is used only for the line-breaking operation. For justification, flushness, and other operations to work properly you must also use this value as the line width for the text layout object. You can set the line width for the text layout object by calling the function `ATSUSetLineControls` or `ATSUSetLayoutControls` with the `kATSULineWidthTag` and the line width value.

oBreakCount

The number of soft line breaks found and set from the call. If you do not want to obtain the number of soft line breaks, then set this parameter to `NULL`.

Return Value

A result code. See "ATSUI Result Codes" (page 2068).

Discussion

The `ATSUBatchBreakLines` function is equivalent to repeatedly calling the `ATSUBreakLine` function with the parameter `iUseAsSoftLineBreak` set to `true`. However the `ATSUBatchBreakLines` function performs more efficiently than repeated call to the `ATSUBreakLine` function.

You must call the `ATSUGetSoftLineBreaks` function to obtain the actual soft line breaks that were determined and set by the `ATSUBatchBreakLines` function.

Availability

Available in Mac OS X v10.2 and later.

Not available to 64-bit applications.

Declared In

`ATSUnicodeDrawing.h`

ATSUBreakLine

Calculates and, optionally, sets a soft line break in a range of text.

```
OSStatus ATSUBreakLine (
   ATSUTextLayout iTextLayout,
   UniCharArrayOffset iLineStart,
   ATSUTextMeasurement iLineWidth,
   Boolean iUseAsSoftLineBreak,
   UniCharArrayOffset *oLineBreak
);
```

Parameters

iTextLayout

An `ATSUTextLayout` value specifying the text layout object to examine.

iLineStart

A `UniCharArrayOffset` value specifying the offset from the beginning of the text layout object's text buffer to the first character of the text range to examine. To specify the beginning of the text buffer, pass the constant `kATSUFromTextBeginning`. When calling `ATSUBreakLine` repeatedly to obtain all the soft line breaks for a given text range, in each subsequent call pass the value produced in the `oLineBreak` parameter by the immediately prior call to `ATSUBreakLine`.

iLineWidth

An `ATSUTextMeasurement` value specifying the line width for the text, as measured from the offset provided in the `iLineStart` parameter. You must pass a nonzero value. You can pass `kATSUUseLineControlWidth` to indicate that `ATSUBreakLine` should use the previously set line width attribute for the current line to determine how many characters can fit on the line. If no line width has been set for the line, `ATSUBreakLine` uses the line width set for the text layout object; if this value is not set, `ATSUBreakLine` returns `paramErr`.

Note that the value you pass for the `iLineWidth` parameter is used only for the line-breaking operation. For justification, flushness, and other operations to work properly you must also use this value as the line width for the text layout object. You can set the line width for the text layout object by calling the function `ATSUSetLineControls` or `ATSUSetLayoutControls` with the `kATSULineWidthTag` and the line width value.

iUseAsSoftLineBreak

A `Boolean` value indicating whether `ATSUBreakLine` should automatically set the line break produced in the `oLineBreak` parameter. If `true`, `ATSUBreakLine` sets the line break and clears any previously-set soft line breaks that precede the new break in the line but lie after the offset specified by `iLineStart`.

oLineBreak

A pointer to a `UniCharArrayOffset` value. On return, the value specifies the offset from the beginning of the text layout object's text buffer to the location of the calculated soft line break. If the value produced is the same value as specified in `iLineStart`, you have made an input parameter error. In this case, check to make sure that the line width specified in `iLineWidth` is big enough for `ATSUBreakLine` to perform line breaking. `ATSUBreakLine` does not return an error in this case. ATSUI usually calculates a soft line break to be at the beginning of the first word that does not fit on the line. But if `ATSUBreakLine` calculates the most optimal line break to be in the middle of a word, it returns the result code `kATSULineBreakInWord`. Note that ATSUI produces a line break in the middle of a word only as a last resort.

Return Value

A result code. See "ATSUI Result Codes" (page 2068).

Discussion
When the user inserts or deletes text or changes text layout attributes that affect how glyphs are laid out, you must determine whether the affected range of text still fits in the set line width, that is, whether the text needs to be rewrapped. You can use the `ATSUBreakLine` function to calculate a soft line break, based on the line width and text range you specify. If you pass `true` for `iUseAsSoftLineBreak`, `ATSUBreakLine` sets the soft line break it calculates and performs line layout on the characters.

If you need to calculate and set soft line breaks for a range of text and you want to use the same width for all lines in this range, you should call the function `ATSUBatchBreakLines` (page 1844). Calling `ATSUBatchBreakLines` is equivalent to repeatedly calling the `ATSUBreakLine` function with the parameter `iUseAsSoftLineBreak` set to true. However, the `ATSUBatchBreakLines` function performs more efficiently than repeated calls to the `ATSUBreakLine` function.

If you do choose to call the `ATSUBreakLine` function repeatedly to obtain all possible line breaks for a range of text it will produce the previously set soft line break(s) if there are no additional line breaks to be found, or if the user has altered the text range or its attributes in a way that does not affect glyph layout.

The `ATSUBreakLine` function suggests a soft line break each time it encounters a hard line break character such as a carriage return, line feed, form feed, line separator, or paragraph separator. If `ATSUBreakLine` does not encounter a hard line break, it uses the line width you specify to determine how many characters fit on a line and suggests soft line breaks accordingly.

If you pass `true` for `iUseAsSoftLineBreak`, `ATSUBreakLine` uses the soft line break it calculates to perform line layout on the characters. `ATSUBreakLine` then determines whether the characters still fit within the line, which is necessary due to end-of-line effects such as swashes. When `ATSUBreakLine` sets a soft line break, it clears any previously-set soft line breaks that precede the new break in the line but lie after the offset specified by `iLineStart`.

Before calculating soft line breaks, `ATSUBreakLine` turns off any previously set line justification, rotation, width, alignment, descent, and ascent values and treats the text as a single line. Additionally, `ATSUBreakLine` examines the text layout object to ensure that each of the characters in the range is assigned to a style run. If there are gaps between style runs, `ATSUBreakLine` assigns the characters in the gap to the style run that precedes (in storage order) the gap. If there is no style run at the beginning of the text range, `ATSUBreakLine` assigns these characters to the first style run it finds. If there no style run at the end of the text range, `ATSUBreakLine` assigns the remaining characters to the last style run it finds.

For optimal performance, you should use `ATSUBreakLine` or `ATSUBatchBreakLines` to both calculate and set soft line breaks in your text. You should typically only call the function `ATSUSetSoftLineBreak` (page 1961) to set soft line breaks when you are using your own line-breaking algorithm to calculate soft line breaks.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeDrawing.h`

ATSUCalculateBaselineDeltas

Obtains the optimal baseline positions for glyphs in a style run.

```
OSStatus ATSUCalculateBaselineDeltas (
   ATSUStyle iStyle,
   BslnBaselineClass iBaselineClass,
   BslnBaselineRecord oBaselineDeltas
);
```

Parameters

iStyle

An `ATSUStyle` value specifying the style object to examine.

iBaselineClass

A `BslnBaselineClass` constant identifying the primary baseline from which to measure other baselines. See `SFNTLayoutTypes.h` for an enumeration of possible values. Pass the constant `kBSLNNoBaselineOverride` to use the standard baseline value from the current font.

oBaselineDeltas

A `BslnBaselineRecord` array consisting of `Fixed` values. On return, the array contains baseline offsets, specifying distances measured in points, from the default baseline to each of the other baseline types in the style object. Positive values indicate baselines above the default baseline and negative values indicate baselines below it. See `SFNTLayoutTypes.h` for a description of the `BslnBaselineRecord` type.

Return Value

A result code. See "ATSUI Result Codes" (page 2068).

Discussion

Depending on the writing system, a baseline may be above, below, or through the centers of glyphs. In general, a style run has a default baseline, to which all glyphs are visually aligned when the text is laid out. For example, in a run of Roman text, the default baseline is the Roman baseline, upon which glyphs sit (except for descenders, which extend below the baseline).

You can call the `ATSUCalculateBaselineDeltas` function to obtain the distances from a specified baseline type to that of other baseline types for a given style object. `ATSUCalculateBaselineDeltas` takes into account font and text size when performing these calculations. ATSUI uses these distances to determine the cross-stream shifting to apply when aligning glyphs in a style run. You can use the resulting array to set or obtain the optimal baseline positions of glyphs in a style run. You can also set various baseline values to create special effects such as drop capitals.

The functions `ATSUSetLineControls` (page 1956) and `ATSUSetLayoutControls` (page 1955) allow you to set baseline offset values at the line or layout level, respectively, using the `kATSULineBaselineValuesTag` control attribute tag. For more information on `kATSULineBaselineValuesTag`, see "Attribute Tags" (page 2030).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`ATSUnicodeObjects.h`

ATSUClearAttributes

Restores default values to the specified style attributes of a style object.

```
OSStatus ATSUClearAttributes (
   ATSUStyle iStyle,
   ItemCount iTagCount,
   const ATSUAttributeTag iTag[]
);
```

Parameters

iStyle

An `ATSUStyle` value specifying the style object for which to restore default style attribute values.

iTagCount

An `ItemCount` value specifying the number of attributes to restore to default values. This value should correspond to the number of elements in the `iTag` array. To restore all style attributes in the specified style object, pass the constant `kATSUClearAll` in this parameter. In this case, the value in the `iTag` parameter is ignored.

iTag

A pointer to the initial `ATSUAttributeTag` constant in an array of attribute tags. Each tag should identify a style attribute to restore to its default value. See "Attribute Tags" (page 2030) for a description of the Apple-defined style attribute tag constants.

Return Value

A result code. See "ATSUI Result Codes" (page 2068).

Discussion

The `ATSUClearAttributes` function removes those style attribute values identified by the tag constants in the `iTag` array and replaces them with the default values described in "Attribute Tags" (page 2030). If you specify that any currently unset attribute values be removed, the function does not return an error.

To remove all previously set style attribute, font feature, and font variation values from a style object, call the function `ATSUClearStyle` (page 1854).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`ATSUnicodeObjects.h`

ATSUClearFontFeatures

Restores default settings to the specified font features of a style object.

```
OSStatus ATSUClearFontFeatures (
   ATSUStyle iStyle,
   ItemCount iFeatureCount,
   const ATSUFontFeatureType iType[],
   const ATSUFontFeatureSelector iSelector[]
);
```

Parameters

iStyle

An `ATSUStyle` value specifying the style object for which to restore default font feature settings.

iFeatureCount

An `ItemCount` value specifying the number of font features to restore to default settings. This value should correspond to the number of elements in the *iType* and *iSelector* arrays. To restore default settings to all the font features in the specified style object, pass the constant `kATSUClearAll` in this parameter. In this case, the values in the `iType` and `iSelector` parameters are ignored.

iType

A pointer to the initial `ATSUFontFeatureType` value in an array of feature types. Each value should identify a font feature to restore to its default setting. To obtain all previously set font features for a given style object, you can call the function `ATSUGetAllFontFeatures` (page 1887).

iSelector

A pointer to the initial `ATSUFontFeatureSelector` value in an array of feature selectors. Each element in the array must contain a valid feature selector corresponding to a font feature you provide in the *iType* parameter. To obtain all previously set feature selectors for a given style object, you can call the function `ATSUGetAllFontFeatures` (page 1887).

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The `ATSUClearFontFeatures` function removes those font features that are identified by the feature selector and type constants in the `iSelector` and `iType` arrays and replaces them with their font-defined default values. Note that if you pass `ATSUClearFontFeatures` a font feature and selector that are already at default settings, the function does not return an error.

To restore default font variations to a style object, call the function `ATSUClearFontVariations` (page 1850). To restore default style attributes to a style object, call `ATSUClearAttributes` (page 1848). To restore all default settings to a style object (for font features, variations, and style attributes), call the function `ATSUClearStyle` (page 1854).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeFonts.h`

ATSUClearFontVariations

Restores default values to the specified font variation axes of a style object.

```
OSStatus ATSUClearFontVariations (
   ATSUStyle iStyle,
   ItemCount iAxisCount,
   const ATSUFontVariationAxis iAxis[]
);
```

Parameters

iStyle

An `ATSUStyle` value specifying the style object for which to restore default font variation axis settings.

iAxisCount

An ItemCount value specifying the number of font variation axes to restore to default settings. This value should correspond to the number of elements in the *iAxis* array. To restore default values to all the font variation axes in the style object, pass the constant kATSUClearAll in this parameter. If you pass kATSUClearAll the value in the iAxis parameter is ignored.

iAxis

A pointer to the initial ATSUFontVariationAxis tag in an array of font variation axes. Each element in the array must contain a valid tag that corresponds to a font variation axis to restore to its default setting. You can obtain variation axis tags for a style object from the function ATSUGetAllFontVariations (page 1888).

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The ATSUClearFontVariations function removes those font variation axis values identified by variation axis tags in the iAxis array and replaces them with their font-defined default values. You can remove unset font variation values from a style object without a function error.

To restore default font features to a style object, call the function ATSUClearFontFeatures (page 1849). To restore default style attributes, call ATSUClearAttributes (page 1848). To restore all default settings to a style object (for font features, variations, and style attributes), call the function ATSUClearStyle (page 1854).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
ATSUnicodeFonts.h

ATSUClearLayoutCache

Clears the layout cache of a line or an entire text layout object.

```
OSStatus ATSUClearLayoutCache (
   ATSUTextLayout iTextLayout,
   UniCharArrayOffset iLineStart
);
```

Parameters

iTextLayout

An ATSUTextLayout value identifying the text layout object for which to clear a layout cache.

iLineStart

A UniCharArrayOffset value specifying the offset from the beginning of the text buffer to the beginning of the line for which to discard the layout cache. If the range of text spans multiple lines, you should call ATSUClearLayoutCache for each line, passing the offset corresponding to the beginning of the new line to draw with each call. To clear the layout cache of the entire text layout object, you can pass the constant kATSUFromTextBeginning.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The layout cache contains all the layout information ATSUI calculates and needs to draw a range of text in a text layout object. This includes caret positions, the memory locations of glyphs, and other information needed to lay out the glyphs. ATSUI uses information in the layout cache to avoid laying out the text again, thereby improving performance. When you clear the layout cache of a line or block of text, ATSUI takes longer to redraw a line, since it must perform the calculations that support glyph layout again.

You should call the function `ATSUClearLayoutCache` when you need to decrease the amount of memory your application uses. This function reclaims memory at the cost of optimal performance.

By default, the `ATSUClearLayoutCache` function removes the layout cache of a single line. To clear the layout cache for multiple lines, you should call `ATSUClearLayoutCache` for each line. To clear the layout cache of an entire text layout object, pass the constant `kATSUFromTextBeginning` in the `iLineStart` parameter. Note that `ATSUClearLayoutCache` does not produce a function error if lines do not have a layout cache.

The `ATSUClearLayoutCache` function flushes the layout cache but does not alter previously set text layout attributes, soft line break positions, or the text memory location. If you do not want to retain these values, you should dispose of the text layout object by calling the `ATSUDisposeTextLayout` (page 1876) function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSUnicodeObjects.h`

ATSUClearLayoutControls

Restores default values to the specified layout control attributes of a text layout object.

```
OSStatus ATSUClearLayoutControls (
   ATSUTextLayout iTextLayout,
   ItemCount iTagCount,
   const ATSUAttributeTag iTag[]
);
```

Parameters

iTextLayout
An `ATSUTextLayout` value specifying the text layout object for which to restore default layout control attribute values.

iTagCount
An `ItemCount` value specifying the number of layout control attributes to restore to default values. This value should correspond to the number of elements in the `iTag` array. To restore all layout control attributes in the specified text layout object, pass the constant `kATSUClearAll` in this parameter. In this case, the value in the `iTag` parameter is ignored.

iTag
A pointer to the initial `ATSUAttributeTag` constant in an array of attribute tags. Each tag should identify a layout control attribute to restore to its default value. See "Attribute Tags" (page 2030) for a description of the Apple-defined layout control attribute tag constants.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The `ATSUClearLayoutControls` function removes those layout control attribute values identified by the tag constants in the `iTag` array and replaces them with the default values described in "Attribute Tags" (page 2030). If you specify that any currently unset attribute values be removed, the function does not return an error.

To restore default values to line control attributes in a text layout object, call the function `ATSUClearLineControls` (page 1853).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeObjects.h`

ATSUClearLineControls

Restores default values to the specified line control attributes of a line in a text layout object.

```
OSStatus ATSUClearLineControls (
   ATSUTextLayout iTextLayout,
   UniCharArrayOffset iLineStart,
   ItemCount iTagCount,
   const ATSUAttributeTag iTag[]
);
```

Parameters

iTextLayout
An `ATSUTextLayout` value specifying the text layout object containing the line for which to restore default line control attribute values.

iLineStart
A `UniCharArrayOffset` value specifying the offset from the beginning of the text layout object's text buffer to the first character of the line for which to restore attribute values.

iTagCount
An `ItemCount` value specifying the number of line control attributes to restore to default values. This value should correspond to the number of elements in the `iTag` array. To restore all line control attributes of the specified line, pass the constant `kATSUClearAll` in this parameter. In this case, the value in the `iTag` parameter is ignored.

iTag
A pointer to the initial `ATSUAttributeTag` constant in an array of attribute tags. Each tag should identify a line control attribute to restore to its default value. See "Attribute Tags" (page 2030) for a description of the Apple-defined line control attribute tag constants.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The `ATSUClearLineControls` function removes those line control attribute values identified by the tag constants in the `iTag` array and replaces them with the default values described in "Attribute Tags" (page 2030). If you specify that any currently unset attribute values be removed, the function does not return an error.

To restore default values to layout control attributes in a text layout object, call the function `ATSUClearLayoutControls` (page 1852).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeObjects.h`

ATSUClearSoftLineBreaks

Removes soft line breaks from a range of text.

```
OSStatus ATSUClearSoftLineBreaks (
   ATSUTextLayout iTextLayout,
   UniCharArrayOffset iRangeStart,
   UniCharCount iRangeLength
);
```

Parameters

`iTextLayout`
An `ATSUTextLayout` value specifying the text layout object for which to remove line breaks.

`iRangeStart`
A `UniCharArrayOffset` value specifying the offset from the beginning of the text layout object's text buffer to the first character of the text range. To indicate that the specified text range starts at the beginning of the text buffer, you can pass the constant `kATSUFromTextBeginning`. To specify the entire text buffer, pass `kATSUFromTextBeginning` in this parameter and `kATSUToTextEnd` in the `iRangeLength` parameter.

`iRangeLength`
A `UniCharCount` value specifying the length of the text range. If you want the range of text to extend to the end of the text buffer, you can pass the constant `kATSUToTextEnd`.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The `ATSUClearSoftLineBreaks` function clears all previously set soft line breaks for the specified text range and clears any associated layout caches as well.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeDrawing.h`

ATSUClearStyle

Restores default values to a style object.

```
OSStatus ATSUClearStyle (
   ATSUStyle iStyle
);
```

Parameters

iStyle

An `ATSUStyle` value specifying the style object for which to restore default values.

Return Value

A result code. See "ATSUI Result Codes" (page 2068).

Discussion

The `ATSUClearStyle` function clears a style object of all style attributes (including any application-defined attributes), font features, and font variations and returns these values to their default settings. Default font variations and font features are defined by the font; default style attribute values are described in "Attribute Tags" (page 2030). `ATSUClearStyle` does not remove reference constants.

To restore only default style attributes to a style object, you should call the function `ATSUClearAttributes` (page 1848). To restore only font variations to a style object, call `ATSUClearFontVariations` (page 1850). To restore only font features, call `ATSUClearFontFeatures` (page 1849).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`ATSUnicodeObjects.h`

ATSUCompareStyles

Compares the attribute values of two style objects.

```
OSStatus ATSUCompareStyles (
   ATSUStyle iFirstStyle,
   ATSUStyle iSecondStyle,
   ATSUStyleComparison *oComparison
);
```

Parameters

iFirstStyle

An `ATSUStyle` value specifying the first style object to compare.

iSecondStyle

An `ATSUStyle` value specifying the second style object to compare.

oComparison

A pointer to an `ATSUStyleComparison` value. On return, the value contains the results of the comparison and indicates whether the two style objects are the same, different, or one a subset of the another. See "Style Comparison Options" (page 2063) for a description of possible values.

Return Value

A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The `ATSUCompareStyles` function compares the contents of two style objects, including their style attributes, font features, and font variations. It does not consider reference constants or application-defined style attributes in the comparison.

You can call `ATSUCompareStyles`, in conjunction with the function `ATSUGetAllAttributes` (page 1886), to implement style sheets and tables of style runs.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeObjects.h`

ATSUCopyAttributes

Copies all style attribute settings from a source style object to a destination style object.

```
OSStatus ATSUCopyAttributes (
   ATSUStyle iSourceStyle,
   ATSUStyle iDestinationStyle
);
```

Parameters

`iSourceStyle`
An `ATSUStyle` value specifying the style object from which to copy style attributes.

`iDestinationStyle`
An `ATSUStyle` value specifying the style object to set style attributes to.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The `ATSUCopyAttributes` function copies all style attributes to a destination style object from a source style object, including any default values (those values not set by your application) in the source object. Default values for style attributes are described in "Attribute Tags" (page 2030).

The `ATSUCopyAttributes` function does not copy the contents of memory referenced by pointers within custom style attributes or within reference constants. You are responsible for ensuring that this memory remains valid until both the source and destination style objects are disposed of.

To copy style attributes that are explicitly set in the source but not in the destination style object, call the function `ATSUUnderwriteAttributes` (page 1972). To copy all style attributes that are explicitly set in the source object into the destination object, whether or not the destination object has its own settings for these values, call the function `ATSUOverwriteAttributes` (page 1944).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeObjects.h`

ATSUCopyLayoutControls

Copies all layout control attribute settings from a source text layout object to a destination text layout object.

```
OSStatus ATSUCopyLayoutControls (
   ATSUTextLayout iSourceTextLayout,
   ATSUTextLayout iDestTextLayout
);
```

Parameters

iSourceTextLayout

An `ATSUTextLayout` value specifying the text layout object from which to copy layout control attributes.

iDestTextLayout

An `ATSUTextLayout` value specifying the text layout object for which to set layout control attributes.

Return Value

A result code. See "ATSUI Result Codes" (page 2068).

Discussion

The `ATSUCopyLayoutControls` function copies all layout control attribute values to a destination text layout object from a source text layout object, including any default (unset) values in the source object. Default values for unset layout control attributes are described in "Attribute Tags" (page 2030).

`ATSUCopyLayoutControls` does not copy the contents of memory referenced by pointers within reference constants. You are responsible for ensuring that this memory remains valid until both the source and destination text layout objects are disposed.

To copy line control attribute values from one text layout object to another, call the function `ATSUCopyLineControls` (page 1857).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`ATSUnicodeObjects.h`

ATSUCopyLineControls

Copies line control attribute settings from a line in a source text layout object to a line in a destination text layout object.

```
OSStatus ATSUCopyLineControls (
   ATSUTextLayout iSourceTextLayout,
   UniCharArrayOffset iSourceLineStart,
   ATSUTextLayout iDestTextLayout,
   UniCharArrayOffset iDestLineStart
);
```

Parameters

iSourceTextLayout

An `ATSUTextLayout` value specifying the text layout object from which to copy line control attributes.

iSourceLineStart
A `UniCharArrayOffset` value specifying the offset from the beginning of the text layout object's text buffer to the first character of the line from which to copy control attributes.

iDestTextLayout
An `ATSUTextLayout` value specifying the text layout object for which to set line control attributes. This can be the same text layout object passed in the `iSourceTextLayout` parameter if you want to copy line control attributes from one line to another within a text layout object.

iDestLineStart
A `UniCharArrayOffset` value specifying the offset from the beginning of the text layout object's text buffer to the first character of the line for which to set control attributes.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The `ATSUCopyLineControls` function copies all line control attribute values to a line in a destination text layout object from a line in a source text layout object, including any default (unset) values in the source line. Unset line control attributes are assigned the default values described in "Attribute Tags" (page 2030).

`ATSUCopyLineControls` does not copy the contents of memory referenced by pointers within reference constants. You are responsible for ensuring that this memory remains valid until the source text layout object is disposed.

To copy layout control attributes from one text layout object to another, call the function `ATSUCopyLayoutControls` (page 1857).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeObjects.h`

ATSUCopyToHandle

Copies an ATSUI style to a handle. (Deprecated in Mac OS X v10.1. Use `ATSUFlattenStyleRunsToStream` (page 1882) instead.)

Not Recommended

```
OSStatus ATSUCopyToHandle (
   ATSUStyle iStyle,
   Handle oStyleHandle
);
```

Parameters
iStyle
An `ATSUStyle` value.

oStyleHandle
A valid handle.

Return Value
A result code.

Discussion
The `ATSUCopyToHandle` function is not recommended for use, as this function does not produce the correct data format for the display of ATSUI style data. You should instead use the function `ATSUFlattenStyleRunsToStream` to flatten style data and the function `ATSUUnflattenStyleRunsFromStream` to unflatten style data. These functions read and write data using the `ustl` data specification. You can use a data block format of this type to copy and paste Unicode-encoded styled text between applications or within your application. The `ustl` data structure contains flattened text layout data, flattened style run data, and flattened style list data. For more information on the `ustl` data structure see *Inside Mac OS X: ATSUI Reference*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.1.
Not available to 64-bit applications.

Declared In
`ATSUnicodeFlattening.h`

ATSUCountFontFeatureSelectors

Obtains the number of available feature selectors for a given feature type in a font.

```
OSStatus ATSUCountFontFeatureSelectors (
   ATSUFontID iFontID,
   ATSUFontFeatureType iType,
   ItemCount *oSelectorCount
);
```

Parameters

iFont
An `ATSUFontID` value identifying the font to examine.

iType
An `ATSUFontFeatureType` value specifying one of the font's supported feature types. To obtain the available feature types for a font, call the function `ATSUGetFontFeatureTypes` (page 1898).

oSelectorCount
A pointer to an `ItemCount` value. On return, the value specifies the actual number of feature selectors defined for the feature type by the font.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The `ATSUCountFontFeatureSelectors` function obtains the total number of feature selectors defined for a given feature type in the font. You can use the count produced by `ATSUCountFontFeatureSelectors` to determine how much memory to allocate for the `oSelectors` array in the function `ATSUGetFontFeatureSelectors` (page 1897).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeFonts.h`

ATSUCountFontFeatureTypes

Obtains the number of available feature types in a font.

```
OSStatus ATSUCountFontFeatureTypes (
   ATSUFontID iFontID,
   ItemCount *oTypeCount
);
```

Parameters

iFont

An `ATSUFontID` value identifying the font to examine.

oTypeCount

A pointer to an `ItemCount` value. On return, the value specifies the actual number of feature types defined for the font.

Return Value

A result code. See "ATSUI Result Codes" (page 2068).

Discussion

The `ATSUCountFontFeatureTypes` function obtains the total number of feature types defined for a font. You can use the count produced by `ATSUCountFontFeatureTypes` to determine how much memory to allocate for the `oTypes` array in the function `ATSUGetFontFeatureTypes` (page 1898).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`ATSUnicodeFonts.h`

ATSUCountFontInstances

Obtains the number of defined font instances in a font.

```
OSStatus ATSUCountFontInstances (
   ATSUFontID iFontID,
   ItemCount *oInstances
);
```

Parameters

iFont

An `ATSUFontID` value identifying the font to examine.

oInstances

A pointer to an `ItemCount` value. On return, the value specifies the number of font instances defined for the font.

Return Value

A result code. See "ATSUI Result Codes" (page 2068).

Discussion

The `ATSUCountFontInstances` function obtains the total number of font instances defined in a font. You can use an index value derived from this count to get information about a specific font instance by calling the function `ATSUGetFontInstance` (page 1900).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeFonts.h`

ATSUCountFontNames

Obtains the number of font names that correspond to a given ATSUI font ID.

```
OSStatus ATSUCountFontNames (
   ATSUFontID iFontID,
   ItemCount *oFontNameCount
);
```

Parameters

iFontID

An `ATSUFontID` value specifying the font to examine.

oFontNameCount

A pointer to an `ItemCount` value. On return, the value specifies the number of entries in the font name table corresponding to the given ATSUI font ID.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The `ATSUCountFontNames` function obtains the number of font names defined in a font name table for a given ATSUI font ID. This number includes repetitions of the same name in different platforms, languages, and scripts; names of font features, variations, tracking settings, and instances for the font; and font names identified by name code constants.

You can pass an index value based on this count to the function `ATSUGetIndFontName` (page 1908) to obtain a name string, name code, platform, script, and language for a given ATSUI font ID.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeFonts.h`

ATSUCountFontTracking

Obtains the number of entries in the font tracking table that correspond to a given ATSUI font ID and glyph orientation.

```
OSStatus ATSUCountFontTracking (
   ATSUFontID iFontID,
   ATSUVerticalCharacterType iCharacterOrientation,
   ItemCount *oTrackingCount
);
```

Parameters

iFont

An `ATSUFontID` value specifying the font to examine.

iCharacterOrientation

An `ATSUVerticalCharacterType` constant identifying the glyph orientation of the font tracking entries, for example `kATSUStronglyHorizontal` or `kATSUStronglyVertical`. See "Vertical Character Types" (page 2068) for a description of possible values.

oTrackingCount

A pointer to an `ItemCount` value. On return, the value specifies the number of entries in the font tracking table corresponding to the given ATSUI font ID and glyph orientation.

Return Value

A result code. See "ATSUI Result Codes" (page 2068).

Discussion

The `ATSUCountFontTracking` function obtains the number of font tracking entries defined in a font tracking table for a given ATSUI font ID and glyph orientation. You can pass an index value based on this count to the function `ATSUGetIndFontTracking` (page 1910) to obtain the name code and tracking value of a font tracking.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`ATSUnicodeFonts.h`

ATSUCountFontVariations

Obtains the number of defined variation axes in a font.

```
OSStatus ATSUCountFontVariations (
   ATSUFontID iFontID,
   ItemCount *oVariationCount
);
```

Parameters

iFont

An `ATSUFontID` value identifying the font to examine.

oVariationCount

A pointer to an `ItemCount` value. On return, the value specifies the number of variation axes defined for the font.

Return Value

A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The `ATSUCountFontVariations` function obtains the total number of variation axes defined for a font. You can use the count produced by `ATSUCountFontVariations` to get information about a specific font variation axis from the function `ATSUGetIndFontVariation` (page 1911).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeFonts.h`

ATSUCreateAndCopyStyle

Creates a copy of a style object.

```
OSStatus ATSUCreateAndCopyStyle (
   ATSUStyle iStyle,
   ATSUStyle *oStyle
);
```

Parameters

`iStyle`
An `ATSUStyle` value specifying the style object to copy.

`oStyle`
A pointer to an `ATSUStyle` value. On return, the pointer refers to a newly created style object. This style object contains the same values for style attributes, font features, and font variations as those of the style object passed in the `iStyle` parameter.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The `ATSUCreateAndCopyStyle` function creates a new style object with values obtained from the source style object's style attributes, font features, and font variations. `ATSUCreateAndCopyStyle` does not copy reference constants.

To create a new style object without copying a source object, you can call the function `ATSUCreateStyle` (page 1865). Alternately, to copy the contents of a source style object into an existing style object, call the function `ATSUCopyAttributes` (page 1856).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeObjects.h`

ATSUCreateAndCopyTextLayout

Creates a copy of a text layout object.

```
OSStatus ATSUCreateAndCopyTextLayout (
   ATSUTextLayout iTextLayout,
   ATSUTextLayout *oTextLayout
);
```

Parameters

iTextLayout

An `ATSUTextLayout` value specifying the text layout object to copy.

oTextLayout

A pointer to an `ATSUTextLayout` value. On return, the pointer refers to a newly created text layout object containing the contents of the text layout object in the `iTextLayout` parameter.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The `ATSUCreateAndCopyTextLayout` function creates a copy of the source text layout object's style runs (including references to the associated text buffer and style objects), line attributes, layout attributes, and layout caches. `ATSUCreateAndCopyTextLayout` does not copy reference constants.

To create a text layout object without copying a source object, you can the function `ATSUCreateTextLayout` (page 1866) or the function `ATSUCreateTextLayoutWithTextPtr` (page 1869).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeObjects.h`

ATSUCreateFontFallbacks

Creates an opaque object that can be set to contain a font list and a font-search method.

```
OSStatus ATSUCreateFontFallbacks (
   ATSUFontFallbacks *oFontFallback
);
```

Parameters

oFontFallback

A pointer to an `ATSUFontFallbacks` value. On return, the pointer refers to a newly created font fallback object.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The `ATSUCreateFontFallbacks` function creates an "empty" font fallback object, which can be used to define ATSUI's search behavior when seeking substitute fonts for a text layout object. Font fallback objects are thread safe and can be shared among threads.

You set the font list and search method for the font fallback object by calling the function `ATSUSetObjFontFallbacks` (page 1958). To associate the font fallback object with a text layout object, call either of the functions `ATSUSetLayoutControls` (page 1955) or `ATSUSetLineControls` (page 1956). You pass these functions the control attribute value `kATSULineFontFallbacksTag` to set the font fallback object.

Similarly to a style object, a font fallback object can be used with any number of text layout objects. While it is innately more efficient to reuse font fallback objects, instead of repeatedly creating (and destroying) them, there is another reason to share a given font fallback object among text layout objects. That is, as a font fallback object is used, it continues to amass data about the system's fonts and which are best applied to the various ranges of Unicode. Therefore, for best performance, once you create a font fallback object, you should keep it and use it as often as needed.

You should dispose of a font fallback object only when it is no longer needed in your application. To dispose of the memory associated with a font fallback object, call the function `ATSUDisposeFontFallbacks` (page 1875).

Availability
Available in Mac OS X v10.1 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeObjects.h`

ATSUCreateStyle

Creates an opaque style object containing only default style attributes, font features, and font variations.

```
OSStatus ATSUCreateStyle (
   ATSUStyle *oStyle
);
```

Parameters

oStyle
A pointer to an `ATSUStyle` value. On return, the pointer refers to an empty style object.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The `ATSUCreateStyle` function creates a style object containing only default values for style attributes, font features, and font variations. The default values for the font features and variations are assigned by the font. The default style attribute values are described in "Attribute Tags" (page 2030).

To make changes to the default style attribute values, you can call the function `ATSUSetAttributes` (page 1950). To set font features and font variations, call the functions `ATSUSetFontFeatures` (page 1952) and `ATSUSetVariations` (page 1967), respectively. You can also use the function `ATSUCreateAndCopyStyle` (page 1863) to create a new style object by copying all the settings from an existing one.

For ATSUI to apply your selected character-style information, you must associate the style object with a text run in a text layout object. A text run consists of one or more characters that are contiguous in memory. If you associate these characters with a distinct style, you define a style run. You can use the function `ATSUSetRunStyle` (page 1959) to define a style run by associating a style object with a run of text in a text

layout object. Or, to create a text layout object and associate style objects with it at the same time, you can call the function `ATSUCreateTextLayoutWithTextPtr` (page 1869). In either case, each text run in a text layout object must be assigned a style object, which may or may not differ from other style objects assigned to other text runs in the text layout object.

Style objects are readily reusable and should be cached for later use, if possible. You can create a style object once and then use it for as many text layout objects as appropriate. Style objects are thread-safe starting with ATSUI version 2.3.

Note that you are responsible for disposing of the memory allocated for the style object. However, you should dispose of any text layout objects with which the style object is associated prior to disposing of the style object itself. To dispose of a style object, call the function `ATSUDisposeStyle` (page 1876).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSUnicodeObjects.h`

ATSUCreateTextLayout

Creates an opaque text layout object containing only default text layout attributes.

```
OSStatus ATSUCreateTextLayout (
   ATSUTextLayout *oTextLayout
);
```

Parameters

oTextLayout

A valid pointer to an `ATSUTextLayout` value. On return, the value refers to an empty text layout object.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The `ATSUCreateTextLayout` function creates a text layout object containing only the default text layout attributes described in "Attribute Tags" (page 2030). The resulting text layout object is associated with neither text nor style objects. However, most ATSUI functions that operate on text layout objects require that the objects be associated with style information and text. To associate style objects and text with an empty text layout object, you can call the functions `ATSUSetRunStyle` (page 1959) and `ATSUSetTextPointerLocation` (page 1965). Or, to create a text layout object and associate style objects and text with it at the same time, you can call the function `ATSUCreateTextLayoutWithTextPtr` (page 1869).

To provide nondefault line or layout attributes for a text layout object, you can call the functions `ATSUSetLineControls` (page 1956) or `ATSUSetLayoutControls` (page 1955). After setting text attributes, call `ATSUDrawText` (page 1877) to draw the text.

Text layout objects are readily reusable and should be cached for later use, if possible. You can reuse a text layout object even if the text associated with it is altered. Call the functions `ATSUSetTextPointerLocation` (page 1965), `ATSUTextDeleted` (page 1969), or `ATSUTextInserted` (page 1970) to manage the altered text.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeObjects.h`

ATSUCreateTextLayoutWithTextHandle

Creates an opaque text layout object containing default text layout attributes as well as associated text and text styles. (Deprecated in Mac OS X v10.0. Use `ATSUCreateTextLayoutWithTextPtr` (page 1869) instead. See the Discussion for more details.)

Not recommended.

```
OSStatus ATSUCreateTextLayoutWithTextHandle (
   UniCharArrayHandle iText,
   UniCharArrayOffset iTextOffset,
   UniCharCount iTextLength,
   UniCharCount iTextTotalLength,
   ItemCount iNumberOfRuns,
   const UniCharCount iRunLengths[],
   ATSUStyle iStyles[],
   ATSUTextLayout *oTextLayout
);
```

Parameters

iText

A handle of type `UniCharArrayHandle` referring to a text buffer containing UTF-16–encoded text. ATSUI associates this buffer with the new text layout object and analyzes the entire text of the buffer when obtaining the layout context for the current text range. Thus, for paragraph-format text, if you specify a buffer containing less than a complete paragraph, some of ATSUI's layout results are not guaranteed to be accurate. For example, with a buffer of less than a full paragraph, ATSUI can neither reliably obtain the context for bidirectional processing nor reliably generate accent attachments and ligature formations for Roman text.

iTextOffset

A `UniCharArrayOffset` value specifying the offset from the beginning of the text buffer to the first character of the range to include in the layout. To indicate that the specified text range starts at the beginning of the text buffer, you can pass the constant `kATSUFromTextBeginning`. To specify the entire text buffer, pass `kATSUFromTextBeginning` in this parameter and `kATSUToTextEnd` in the `iTextLength` parameter.

iTextLength

A `UniCharCount` value specifying the length of the text range. Note that `iTextOffset + iTextLength` must be less than or equal to the value of the *iTextTotalLength* parameter. If you want the range of text to extend to the end of the text buffer, you can pass the constant `kATSUToTextEnd`.

iTextTotalLength

A `UniCharCount` value specifying the length of the entire text buffer. This value should be greater than or equal to the range of text defined by the `iTextLength` parameter.

iNumberOfRuns

An `ItemCount` value specifying the number of text style runs you want to define within the text range. The number of style objects and style run lengths passed in the `iStyles` and `iRunLengths` parameters, respectively, should each be equal to the number of runs specified here.

iRunLengths

A pointer to a `UniCharCount` array specifying the lengths of each style run in the text layout object. You can pass `kATSUToTextEnd` for the last style run length if you want the style run to extend to the end of the text range. If the sum of the style run lengths is less than the total length of the text range, the remaining characters are assigned to the last style run.

iStyles

A pointer to the first element in an `ATSUStyle` array. Each element in the array must contain a valid style object that corresponds to a style run defined by the `iRunLengths` array.

oTextLayout

A valid pointer to an `ATSUTextLayout` value. On return, the value refers to the newly created text layout object.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
You should use the function `ATSUCreateTextLayoutWithTextPtr` (page 1869) instead of using the function `ATSUCreateTextLayoutWithTextHandle`.

The `ATSUCreateTextLayoutWithTextHandle` function creates a text layout object associated with style objects and text and containing the default text layout attributes described in "Attribute Tags" (page 2030). To provide nondefault line or layout attributes for a text layout object, you can call the functions `ATSUSetLineControls` (page 1956) or `ATSUSetLayoutControls` (page 1955). After setting text attributes, call `ATSUDrawText` (page 1877) to draw the text.

Because the only way that ATSUI interacts with text is via the memory references you associate with a text layout object, you are responsible for keeping these references updated, as in the following cases:

1. When the user deletes or inserts a subrange within a text buffer (but the buffer itself is not relocated), you should call the functions `ATSUTextDeleted` (page 1969) and `ATSUTextInserted` (page 1970), respectively.

2. When you relocate the entire text buffer (but no other changes have occurred that would affect the buffer's current subrange), you should call the function `ATSUTextMoved` (page 1971).

3. When both the buffer itself is relocated and a subrange of the buffer's text is deleted or inserted (that is, a combination of cases 1 and 2, above), you must use either the function `ATSUSetTextHandleLocation` (page 1963) or the function `ATSUSetTextPointerLocation` (page 1965) to inform ATSUI.

4. When you are associating an entirely different buffer with a text layout object, you must call either the function `ATSUSetTextHandleLocation` (page 1963) or the function `ATSUSetTextPointerLocation` (page 1965).

Note that, because ATSUI objects retain state information, doing superfluous calling can degrade performance. For example, you could call `ATSUSetTextHandleLocation` rather than `ATSUTextInserted` when the user inserts text, but there would be a performance penalty, as all the layout caches are flushed when you call `ATSUSetTextHandleLocation`, rather than just the affected ones.

Text layout objects are readily reusable and should themselves be cached for later use, if possible.

The `ATSUCreateTextLayoutWithTextHandle` function associates text with a text layout object via a handle, but ATSUI functions that need to access the text return the handle to its original state upon completion.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.0.
Not available to 64-bit applications.

Declared In
`ATSUnicodeObjects.h`

ATSUCreateTextLayoutWithTextPtr

Creates an opaque text layout object containing default text layout attributes as well as associated text and text styles.

```
OSStatus ATSUCreateTextLayoutWithTextPtr (
   ConstUniCharArrayPtr iText,
   UniCharArrayOffset iTextOffset,
   UniCharCount iTextLength,
   UniCharCount iTextTotalLength,
   ItemCount iNumberOfRuns,
   const UniCharCount iRunLengths[],
   ATSUStyle iStyles[],
   ATSUTextLayout *oTextLayout
);
```

Parameters

iText

A pointer of type `ConstUniCharArrayPtr`, referring to a text buffer containing UTF-16–encoded text. ATSUI associates this buffer with the new text layout object and analyzes the complete text of the buffer when obtaining the layout context for the current text range. Thus, for paragraph-format text, if you specify a buffer containing less than a complete paragraph, some of ATSUI's layout results are not guaranteed to be accurate. For example, with a buffer of less than a full paragraph, ATSUI can neither reliably obtain the context for bidirectional processing nor reliably generate accent attachments and ligature formations for Roman text.

iTextOffset

A `UniCharArrayOffset` value specifying the offset from the beginning of the text buffer to the first character of the range to include in the layout. To indicate that the specified text range starts at the beginning of the text buffer, you can pass the constant `kATSUFromTextBeginning`. To specify the entire text buffer, pass `kATSUFromTextBeginning` in this parameter and `kATSUToTextEnd` in the `iTextLength` parameter.

iTextLength

A `UniCharCount` value specifying the length of the text range. Note that `iTextOffset + iTextLength` must be less than or equal to the value of the *`iTextTotalLength`* parameter. If you want the range of text to extend to the end of the text buffer, you can pass the constant `kATSUToTextEnd`.

iTextTotalLength

A `UniCharCount` value specifying the length of the entire text buffer. This value should be greater than or equal to the range of text defined by the `iTextLength` parameter.

iNumberOfRuns

An `ItemCount` value specifying the number of text style runs you want to define within the overall text range. The number of style objects and style run lengths passed in the `iStyles` and `iRunLengths` parameters, respectively, should be equal to the number of runs specified here.

iRunLengths

A pointer to the first element in a `UniCharCount` array. This array provides ATSUI with the lengths of each of the text's style runs. You can pass `kATSUToTextEnd` for the last style run length if you want the style run to extend to the end of the text range. If the sum of the style run lengths is less than the total length of the text range, the remaining characters are assigned to the last style run.

iStyles

A pointer to the first element in an `ATSUStyle` array. Each element in the array must contain a valid style object that corresponds to a style run defined by the `iRunLengths` array.

oTextLayout

A valid pointer to an `ATSUTextLayout` value. On return, the value refers to the newly created text layout object.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The `ATSUCreateTextLayoutWithTextPtr` function creates a text layout object associated with style objects and text and containing the default text layout attributes described in "Attribute Tags" (page 2030). To provide nondefault line or layout attributes for a text layout object, you can call the functions `ATSUSetLineControls` (page 1956) or `ATSUSetLayoutControls` (page 1955). After setting text attributes, call `ATSUDrawText` (page 1877) to draw the text.

Because the only way that ATSUI interacts with text is via the memory references you associate with a text layout object, you are responsible for keeping these references updated, as in the following cases:

1. When the user deletes or inserts a subrange within a text buffer (but the buffer itself is not relocated), you should call the functions `ATSUTextDeleted` (page 1969) and `ATSUTextInserted` (page 1970), respectively.

2. When you relocate the entire text buffer (but no other changes have occurred that would affect the buffer's current subrange), you should call the function `ATSUTextMoved` (page 1971).

3. When both the buffer itself is relocated and a subrange of the buffer's text is deleted or inserted (that is, a combination of cases 1 and 2, above), you must use the function `ATSUSetTextPointerLocation` (page 1965) to inform ATSUI.

4. When you are associating an entirely different buffer with a text layout object, you must call the function `ATSUSetTextPointerLocation` (page 1965).

Note that, because ATSUI objects retain state information, doing superfluous calling can degrade performance. For example, you could call `ATSUSetTextPointerLocation` rather than `ATSUTextInserted` when the user inserts text, but there would be a performance penalty, as all the layout caches are flushed when you call `ATSUSetTextPointerLocation`, rather than just the affected ones.

Text layout objects are readily reusable and should themselves be cached for later use, if possible. Text objects are thread-safe starting with ATSUI version 2.4.

Availability
Available in Mac OS X v10.0 and later.

Declared In
ATSUnicodeObjects.h

ATSUDirectAddStyleSettingRef

Looks up, and if necessary, adds a style setting to a line of text.

```
OSStatus ATSUDirectAddStyleSettingRef (
   ATSULineRef iLineRef,
   ATSUStyleSettingRef iStyleSettingRef,
   UInt16 *oStyleIndex
);
```

Parameters

iLineRef

An ATSULineRef value that specifies the line of text to which you want to add a style setting. You should pass the same reference provided as a parameter to your ATSUDirectLayoutOperationOverrideProcPtr (page 1998) callback function.

iStyleSettingRef

An ATSUStyleSettingRef value that specifies the style setting you want ATSUI to look up or add to the text layout object referenced by the line starting at the offset iLineOffset.

oStyleIndex

On return, points to the index of the ATSUStyleSettingRef passed in iStyleSettingRef for the line referenced by iLineRef. If the ATSUStyleSettingRef does not exist in that context, ATSUI adds it and returns the index value.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The function ATSUDirectAddStyleSettingRef checks to see if a line of text has a specified style setting reference associated with it. If the style setting reference is not associated with the line of text, ATSUI adds the style setting reference.

You must call this function from within an ATSUDirectLayoutOperationOverrideProcPtr (page 1998) callback function. You can use the function ATSUDirectAddStyleSettingRef to replace or substitute glyphs. For example, you can check a line of text for a specific character, such as a whitespace character. When your application finds a whitespace character, it can call the function ATSUDirectAddStyleSettingRef to set style attributes that achieve the desired effect.

Do not call this function if you obtained an ATSUStyleSettingRef array for the line specified by iLineRef and have not yet disposed of the pointer to this array by calling the function ATSUDirectReleaseLayoutDataArrayPtr (page 1874), as the pointer is not guaranteed to be valid after you call the function ATSUDirectAddStyleSettingRef.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
ATSUnicodeDirectAccess.h

ATSUDirectGetLayoutDataArrayPtrFromLineRef

Obtains the glyph data specified by a direct-data selector and for a specific line of text.

```
OSStatus ATSUDirectGetLayoutDataArrayPtrFromLineRef (
   ATSULineRef iLineRef,
   ATSUDirectDataSelector iDataSelector,
   Boolean iCreate,
   void *oLayoutDataArrayPtr[],
   ItemCount *oLayoutDataCount
);
```

Parameters

iLineRef

An `ATSULineRef` value that specifies the line of text whose data you want to obtain. You should pass the same `ATSULineRef` value passed to the `ATSUDirectLayoutOperationOverrideProcPtr` (page 1998) callback function from which you are calling this function.

iDataSelector

A direct-data selector constant that specifies the data you want to obtain. You can pass any of the constants described in "Direct Data Selectors" (page 2044).

iCreate

A `Boolean` value that specifies whether to create an array if one does not already exist. Pass `true` if you want an array created. If the line referenced by the `iLineRef` parameter does not already have an array created that contains the data specified by the `iDataSelector` parameter, then ATSUI creates a zero-filled array and returns the array in the `oLayoutDataArray` parameter. The `iCreate` parameter has no effect for some data specified by the direct-data selector. See "Direct Data Selectors" (page 2044) for details.

oLayoutDataArrayPtr[]

On return, points to an array that contains the data specified by the `iDataSelector` parameter. The data is for the line of text referenced by the `iLineRef` parameter. If an array for the specified data does not exist, and if the `iCreate` is set to `false`, ATSUI returns `NULL`. If an array for the specified data does not exist, and if the `iCreate` is set to `true`, ATSUI creates a zero-filled array. You can pass `NULL` if you only want to obtain the number of entries in the array returned in the *oLayoutDataArray* array.

oLayoutDataCount

On return, the number of entries in the array returned in the *oLayoutDataArray* array.

Return Value

A result code. See "ATSUI Result Codes" (page 2068).

Discussion

The function `ATSUDirectGetLayoutDataArrayPtrFromLineRef` returns the data pointer specified by the `iDataSelector` parameter and referenced by the `iLineRef` parameter. You must call this function from within an `ATSUDirectLayoutOperationOverrideProcPtr` (page 1998) callback function. You must only release the data pointer by calling the function `ATSUDirectReleaseLayoutDataArrayPtr` (page 1874). When you call this function, it signals ATSUI that you are done with the data and that ATSUI can merge your modifications with the font's data. If you do not properly free the data by calling the function `ATSUDirectReleaseLayoutDataArrayPtr`, a memory leak may result.

The data you obtain is the actual data used by ATSUI in its layout process; it is not a copy. This function is very efficient because ATSUI does not need to allocate memory and copy data. Furthermore, because you obtain a pointer to the data that ATSUI uses for its layout, any modifications you make to the data effect the final layout.

Many of the data arrays you can request are created by ATSUI only when necessary. If you plan to alter the data in an array, make sure you set the `iCreate` parameter to true. This ensures that the array is created. If an arrays are not created, ATSUI assumes all entries in the array are zero.

The pointer returned by this function is only valid within the context of the `ATSUDirectLayoutOperationOverrideProcPtr` callback function. You must not retain it for later use.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`ATSUnicodeDirectAccess.h`

ATSUDirectGetLayoutDataArrayPtrFromTextLayout

Obtains a copy of the glyph data specified by a direct-data selector and for a specific line of text in a text layout object.

```
OSStatus ATSUDirectGetLayoutDataArrayPtrFromTextLayout (
   ATSUTextLayout iTextLayout,
   UniCharArrayOffset iLineOffset,
   ATSUDirectDataSelector iDataSelector,
   void *oLayoutDataArrayPtr[],
   ItemCount *oLayoutDataCount
);
```

Parameters

iTextLayout
An `ATSUTextLayout` value that specifies the text layout object whose data you want to obtain.

iLineOffset
The edge offset that corresponds to the beginning of the line of text whose data you want to obtain.

iDataSelector
A direct-data selector constant that specifies the data you want to obtain. You can pass any of the constants described in "Direct Data Selectors" (page 2044).

oLayoutDataArrayPtr[]
On return, points to an array that contains the data specified by the `iDataSelector` parameter. The data is for the line of text referenced by the `iLineOffset` parameter. If an array for the specified data does not exist, ATSUI returns `NULL`. You can pass `NULL` if you only want to obtain the number of entries in the array in the *oLayoutDataArray* array.

oLayoutDataCount
On return, the number of entries in the array `oLayoutDataArray`.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The function `ATSUDirectGetLayoutDataArrayPtrFromTextLayout` returns a pointer to the data specified by `iDataSelector` and referenced by `iTextLayout` for the line starting at `iLineOffset`. You must not call this function from within an `ATSUDirectLayoutOperationOverrideProcPtr` (page 1998)callback function.

You should only release the data pointer by calling the function `ATSUDirectReleaseLayoutDataArrayPtr`. When you call this function, it signals ATSUI that you are done with the data and that ATSUI can merge your modifications with the font's data. If you do not properly free the data by calling the function `ATSUDirectReleaseLayoutDataArrayPtr`, a memory leak may result.

The data you obtain is a copy of the data ATSUI uses for its layout processes. This means the following:

- Obtaining data through a copy operation takes more time than obtaining the actual data. This function returns in order-n time instead of in a constant time.
- Changing any of the data values has no effect on the layout.

Before you use this function, you should consider using the function`ATSUDirectGetLayoutDataArrayPtrFromLineRef` (page 1872) with the `kATSULayoutOperationPostLayoutAdjustment` selector.

If you use the function `ATSUDirectGetLayoutDataArrayPtrFromTextLayout` to obtain the `ATSUStyleSettingRef` array, the structures referenced by each element of the array are invalid after you call the function `ATSUDirectReleaseLayoutDataArrayPtr` to release the array. If want to retain one or more of the elements in the `ATSUStyleSettingRef` array for later use, you must not call the function `ATSUDirectReleaseLayoutDataArrayPtr` until all operations that use the elements in the `ATSUStyleSettingRef` in the array are complete. The elements in the `ATSUStyleSettingRef` array are valid only within the context of the callback from which they were obtained

Many of the requested data arrays are created by ATSUI only when necessary. This means that it's possible for the function `ATSUDirectGetLayoutDataArrayPtrFromTextLayout` to return a `NULL` pointer and a count of `0`. If this is case and if the function does not return an error, the array doesn't exist. You should interpret this result to mean that all values in the array are `0`.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeDirectAccess.h`

ATSUDirectReleaseLayoutDataArrayPtr

Releases a pointer to a direct-data array.

```
OSStatus ATSUDirectReleaseLayoutDataArrayPtr (
   ATSULineRef iLineRef,
   ATSUDirectDataSelector iDataSelector,
   void *iLayoutDataArrayPtr[]
);
```

Parameters

`iLineRef`

An `ATSULineRef` value that specifies the line of text whose data is pointed to by the `iLayoutDataArrayPtr` parameter. Pass `NULL` if you did not obtain the layout data array pointer using a `lineRef`.

iDataSelector

A direct-data selector constant that specifies the data pointed to by the `iLayoutDataArrayPtr` parameter. You can pass any of the constants described in "Direct Data Selectors" (page 2044).

iLayoutDataArrayPtr[]

A pointer to the layout data array of which you want to dispose.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
You must call the function `ATSUDirectReleaseLayoutDataArrayPtr` when you no longer need the direct-data pointer you obtained from the `ATSUDirectGetLayoutDataArrayPtrFromLineRef` (page 1872) or `ATSUDirectGetLayoutDataArrayPtrFromTextLayout` (page 1873) functions. You must dispose of the pointer to inform ATSUI you no longer need the data and to allow for ATSUI to make any internal adjustments prior to completing the layout process.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`ATSUnicodeDirectAccess.h`

ATSUDisposeFontFallbacks

Disposes of the memory associated with a font fallback object.

```
OSStatus ATSUDisposeFontFallbacks (
   ATSUFontFallbacks iFontFallbacks
);
```

Parameters

iFontFallbacks

An `ATSUFontFallbacks` value specifying the font fallback object to dispose. See the `ATSUFontFallbacks` data type.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The `ATSUDisposeFontFallbacks` function frees the memory associated with the specified font fallback object and its internal structures.

For best performance, once you create a font fallback object, you should keep it and use it as often as needed. You should dispose of the font fallback object only when it is no longer needed in your application.

Availability
Available in Mac OS X v10.1 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeObjects.h`

ATSUDisposeStyle

Disposes of the memory associated with a style object.

```
OSStatus ATSUDisposeStyle (
   ATSUStyle iStyle
);
```

Parameters

iStyle

An `ATSUStyle` value specifying the style object to dispose of.

Return Value

A result code. See "ATSUI Result Codes" (page 2068).

Discussion

The `ATSUDisposeStyle` function frees the memory associated with the specified style object and its internal structures, including style run attributes. It does not dispose of the memory pointed to by application-defined style run attributes or reference constants. You are responsible for doing so.

You should call this function after calling the function `ATSUDisposeTextLayout` (page 1876) to dispose of any text layout objects associated with the style object.

For best performance, once you create a style object, you should keep it and use it as often as needed. You should dispose of the style object only when it is no longer needed in your application.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`ATSUnicodeObjects.h`

ATSUDisposeTextLayout

Disposes of the memory associated with a text layout object.

```
OSStatus ATSUDisposeTextLayout (
   ATSUTextLayout iTextLayout
);
```

Parameters

iTextLayout

An `ATSUTextLayout` value specifying the text layout object to dispose of.

Return Value

A result code. See "ATSUI Result Codes" (page 2068).

Discussion

The `ATSUDisposeTextLayout` function frees the memory associated with the specified text layout object and its internal structures, including line and layout control attributes, style runs, and soft line breaks. `ATSUDisposeTextLayout` does not dispose of any memory that may be allocated for reference constants or style objects associated with the text layout object. You are responsible for doing so.

For best performance, text layout objects are readily reusable and should be cached for later use, if possible. You can reuse a text layout object even if the text associated with it is altered. Call the functions `ATSUSetTextPointerLocation` (page 1965), `ATSUTextDeleted` (page 1969), or `ATSUTextInserted` (page 1970) to manage the altered text, rather than disposing of the text layout object and creating a new one.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSUnicodeObjects.h`

ATSUDrawGlyphInfo

Draws glyphs at the specified location, based on style and layout information specified for each glyph. (Deprecated in Mac OS X v10.3. Use functions from "Accessing Glyph Data" (page 1842) instead.)

Not recommended.

```
OSStatus ATSUDrawGlyphInfo (
   ATSUGlyphInfoArray *iGlyphInfoArray,
   Float32Point iLocation
);
```

Parameters

iGlyphInfoArray

A pointer to an `ATSUGlyphInfoArray` structure containing the glyph information to draw. You can obtain an `ATSUGlyphInfoArray` structure from the function `ATSUGetGlyphInfo` (page 1906).

iLocation

A `Float32Point` data structure that contains the x and y coordinates at which to draw the glyph(s). Each coordinate in the `Float32Point` data structure is a `Float32` value.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
You must use `ATSUDrawGlyphInfo` to draw glyphs if you have previously called the function `ATSUGetGlyphInfo` (page 1906), and you have modified the glyph information. However, if you want to modify the glyph information you should use the functions `ATSUGlyphGetQuadraticPaths` (page 1928) or `ATSUGlyphGetCubicPaths` (page 1925) instead of calling the function `ATSUGetGlyphInfo`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.3.
Not available to 64-bit applications.

Declared In
`ATSUnicodeGlyphs.h`

ATSUDrawText

Renders a range of text at a specified location in a QuickDraw graphics port or Quartz graphics context.

```
OSStatus ATSUDrawText (
   ATSUTextLayout iTextLayout,
   UniCharArrayOffset iLineOffset,
   UniCharCount iLineLength,
   ATSUTextMeasurement iLocationX,
   ATSUTextMeasurement iLocationY
);
```

Parameters

iTextLayout

An `ATSUTextLayout` value identifying the text layout object for which to render text.

iLineOffset

A `UniCharArrayOffset` value specifying the offset from the beginning of the text buffer to the first character of the range to render. The function `ATSUDrawText` renders text to the first soft line break it encounters. If the range of text spans multiple lines, you should call `ATSUDrawText` for each line, passing the offset corresponding to the beginning of the new line to draw with each call. To indicate that the specified text range starts at the beginning of the text buffer, you can pass the constant `kATSUFromTextBeginning`. To specify the entire text buffer, pass `kATSUFromTextBeginning` in this parameter and `kATSUToTextEnd` in the `iLineLength` parameter.

iLineLength

A `UniCharCount` value specifying the length of the text range to render. If you want the range of text to extend to the end of the text buffer, you can pass the constant `kATSUToTextEnd`. Keep in mind that the function `ATSUDrawText` renders text one line at a time. If the range of text spans multiple lines, you must call `ATSUDrawText` for each line.

iLocationX

An `ATSUTextMeasurement` value specifying the x-coordinate of the origin (in either the current QuickDraw graphics port or in a Quartz graphics context) of the line containing the text range to render. Note that the `ATSUTextMeasurement` type is defined as a `Fixed` value, so you must ensure that your coordinates are converted to `Fixed` values before passing them to this function. Pass the constant `kATSUUseGrafPortPenLoc`, described in "Convenience Constants" (page 2043), to draw relative to the current pen location in the current graphics port.

iLocationY

An `ATSUTextMeasurement` value specifying the y-coordinate of the origin (in either the current graphics port or Quartz graphics context) of the line containing the text range to render. Note that the `ATSUTextMeasurement` type is defined as a `Fixed` value, so you must ensure that your coordinates are converted to `Fixed` values before passing them to this function. Pass the constant `kATSUUseGrafPortPenLoc`, described in "Convenience Constants" (page 2043), to draw relative to the current pen location in the current graphics port.

Return Value

A result code. See "ATSUI Result Codes" (page 2068).

Discussion

The `ATSUDrawText` function renders a range of text at a specified location in a QuickDraw graphics port or Quartz graphics context. This function renders text to the first soft line break it encounters. If you draw into a QuickDraw graphics port you get the best performance by using a bit depth of 16 bits. If you use bit depths of 1, 4, or 8, your application incurs a performance penalty.

You typically call the `ATSUDrawText` function every time you need to draw or redraw unhighlighted text. To draw highlighted text, call the function `ATSUHighlightText` (page 1931).

ATSUDrawText uses the transfer mode and resolution that are set in the graphics port or graphics context. If you explicitly set in the style object, then text color is taken from the style object, and the value in the graphics port/context is ignored. If the text color was not explicitly set in the style object, ATSUDrawText uses the graphics port/context setting.

ATSUDrawText examines the text layout object to ensure that each of the characters in the range is assigned to a style run. If there are gaps between style runs, ATSUI assigns the characters in the gap to the style run that precedes (in storage order) the gap. If there is no style run at the beginning of the text range, ATSUI assigns these characters to the first style run it finds. If there is no style run at the end of the text range, ATSUI assigns the remaining characters to the last style run it finds.

If you want to draw a range of text that spans multiple lines, you should call ATSUDrawText for each line of text to draw, even if all the lines are in the same text layout object. You should adjust the iLineOffset parameter to reflect the beginning of each line to be drawn.

Availability
Available in Mac OS X v10.0 and later.

Declared In
ATSUnicodeDrawing.h

ATSUFindFontFromName

Obtains an ATSUI font ID for the first entry in a name table that matches the specified name string, name code, platform, script, and/or language.

```
OSStatus ATSUFindFontFromName (
   const void *iName,
   ByteCount iNameLength,
   FontNameCode iFontNameCode,
   FontPlatformCode iFontNamePlatform,
   FontScriptCode iFontNameScript,
   FontLanguageCode iFontNameLanguage,
   ATSUFontID *oFontID
);
```

Parameters

iName

A string that specifies the font name whose ATSUI font ID you want to obtain. The string that you pass must be appropriate for the value you pass in the iFontNameCode parameter. For example, if the iFontNameCode parameter is kFontPostscriptName, then you would supply a string that specifies the PostScript name of the font.

iNameLength

A ByteCount value specifying the length of the font name string provided in the *iName* parameter.

iFontNameCode

The FontNameCode value of the font name for which to obtain an ATSUI font ID. The FontNameCode is a UInt32 data type, and it is defined in the SFNTTypes.h header file. You can supply any of the following constants, kFontCopyrightName, kFontFamilyName, kFontStyleName, kFontUniqueName, kFontFullName, kFontVersionName, kFontPostscriptName, kFontTrademarkName, kFontManufacturerName, kFontDesignerName, kFontDescriptionName, kFontVendorURLName, kFontDesignerURLName, kFontLicenseDescriptionName,or kFontLicenseInfoURLName.

iFontNamePlatform

A FontPlatformCode value specifying the encoding of the font name, for example, kFontUnicodePlatform (for UTF-16), kFontMacintoshPlatform, kFontReservedPlatform, kFontMicrosoftPlatform, or kFontCustomPlatform. If you pass the kFontNoPlatformCode constant, ATSUFindFontFromName produces the first font in the name table matching the other specified parameters. See the SFNTTypes.h header file for a definition of the FontPlatformCode type and a list of possible values.

iFontNameScript

A FontScriptCode value specifying the script code of the font name, for example, kFontRomanScript. Pass kFontNoScriptCode if you supplied the kFontUnicodePlatform constant for the iFontNamePlatform parameter. If you pass the kFontNoScriptCode constant, ATSUFindFontFromName produces the first font in the name table matching the other specified parameters. See the SFNTTypes.h header file for a definition of the FontScriptCode type and a list of possible values.

iFontNameLanguage

A FontLanguageCode value specifying the language of the font name, for example, kFontNorwegianLanguage. Pass kFontNoLanguageCode if you supplied the kFontUnicodePlatform constant for the iFontNamePlatform parameter. If you pass the kFontNoLanguageCode constant, ATSUFindFontFromName produces the first font in the name table matching the other specified parameters. See the SFNTTypes.h header file for a definition of the FontLanguageCode type and a list of possible values.

oFontID

On return, points to the unique identifier for the specified font that matches the specified name string, name code, platform, script, and/or language. Note that because Apple Type Services assigns ATSUFontID values systemwide at runtime, font IDs can change across system restarts.

Return Value

A result code. If no installed font matches the specified parameters, ATSUFindFontFromName produces the constant kATSUInvalidFontID and returns the result code kATSUInvalidFontErr. See "ATSUI Result Codes" (page 2068).

Discussion

The ATSUFindFontFromName function obtains an ATSUI font ID for the first font that matches the specified name string, name code, platform, script, and/or language. Because ATSUI cannot guarantee the uniqueness of names among installed fonts, ATSUFindFontFromName does not necessarily find the only font ID that matches these parameters. As a result, you may want to create a more sophisticated name-matching algorithm or guarantee the uniqueness of names among installed fonts.

To find a name string and index value for the first font in a name table that matches an ATSUI font ID and the specified font parameters, call the function ATSUFindFontName (page 1880).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

ATSUnicodeFonts.h

ATSUFindFontName

Obtains a name string and index value for the first font in a name table that matches the specified ATSUI font ID, name code, platform, script, and/or language.

```
OSStatus ATSUFindFontName (
   ATSUFontID iFontID,
   FontNameCode iFontNameCode,
   FontPlatformCode iFontNamePlatform,
   FontScriptCode iFontNameScript,
   FontLanguageCode iFontNameLanguage,
   ByteCount iMaximumNameLength,
   Ptr oName,
   ByteCount *oActualNameLength,
   ItemCount *oFontNameIndex
);
```

Parameters

iFontID

The `ATSUFontID` value of the font for which to obtain a name string. Note that because Apple Type Services assigns `ATSUFontID` values systemwide at runtime, font IDs can change across system restarts.

iFontNameCode

The `FontNameCode` value of the font for which to obtain a name string. The `FontNameCode` is a `UInt32` data type, and it is defined in the `SFNTTypes.h` header file.

iFontNamePlatform

A `FontPlatformCode` value specifying the encoding of the font, for example, `kFontUnicodePlatform`, `kFontMacintoshPlatform`, `kFontReservedPlatform`, `kFontMicrosoftPlatform`, or `kFontCustomPlatform`. If you pass the `kFontNoPlatformCode` constant, `ATSUFindFontName` produces the first font in the name table matching the other specified parameters. See the `SFNTTypes.h` header file for a definition of the `FontPlatformCode` type and a list of possible values.

iFontNameScript

A `FontScriptCode` value specifying the script code of the font, for example, `kFontRomanScript`. If you pass the `kFontNoScriptCode` constant, `ATSUFindFontName` produces the first font in the name table matching the other specified parameters. See the `SFNTTypes.h` header file for a definition of the `FontScriptCode` type and a list of possible values.

iFontNameLanguage

A `FontLanguageCode` value specifying the language of the font, for example, `kFontNorwegianLanguage`. If you pass the `kFontNoLanguageCode` constant, `ATSUFindFontName` produces the first font in the name table matching the other specified parameters. See the `SFNTTypes.h` header file for a definition of the `FontLanguageCode` type and a list of possible values.

iMaximumNameLength

A `ByteCount` value specifying the maximum length of the font name to obtain. Typically, this is equivalent to the size of the buffer that you have allocated in the `oName` parameter. To determine this length, see the Discussion.

oName

A pointer to a buffer. On return, the buffer contains the name string of the first font in the font name table matching your specified parameters. If the buffer you allocate is not large enough, `ATSUFindFontName` produces a partial string.

oActualNameLength

A pointer to a `ByteCount` value. On return, the value specifies the actual length of the complete name string. This may be greater than the value passed in the `iMaximumNameLength` parameter. You should check this value to ensure that you have allocated sufficient memory and therefore obtained the complete name string for the font.

oFontNameIndex

A pointer to an ItemCount value. On return, the value provides a 0-based index to the font name in the font name table.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The ATSUFindFontName function obtains a name string and index value for the first font in a name table that matches the specified ATSUI font ID, name code, platform, script, and/or language.

Typically you use the ATSUFindFontName function by calling it twice, as follows:

1. Pass NULL for the *oName* and *oFontNameIndex* parameters, 0 for the *iMaximumNameLength* parameter, and valid values for the other parameters. ATSUFindFontName returns the length of the font name string in the oActualNameLength parameter.

2. Allocate enough space for a buffer of the returned size, then call the function again, passing a valid pointer to the buffer in the oName parameter. On return, the buffer contains the font name string.

To obtain an ATSUI font ID for the first font in a name table that matches the specified name string, name code, platform, script, and/or language, call the function ATSUFindFontFromName (page 1879). To obtain the font name string, name code, platform, script, and language for the font that matches an ATSUI font ID and name table index, call the function ATSUGetIndFontName (page 1908).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
ATSUnicodeFonts.h

ATSUFlattenStyleRunsToStream

Flattens ATSUI style-run data so that it can be saved to disk or passed (through the pasteboard) to another application.

```
OSStatus ATSUFlattenStyleRunsToStream (
   ATSUFlattenedDataStreamFormat iStreamFormat,
   ATSUFlattenStyleRunOptions iFlattenOptions,
   ItemCount iNumberOfRunInfo,
   const ATSUStyleRunInfo iRunInfoArray[],
   ItemCount iNumberOfStyleObjects,
   const ATSUStyle iStyleArray[],
   ByteCount iStreamBufferSize,
   void *oStreamBuffer,
   ByteCount *oActualStreamBufferSize
);
```

Parameters

iStreamFormat

The format of the flattened data. There is only one format supported at this time, 'ustl' so you must pass the constant kATSUDataStreamUnicodeStyledText.

iFlattenOptions

The options you want to use to flatten the data. There are no options supported at this time, so you must pass the constant `kATSUFlattenOptionsNoOptionsMask`.

iNumberOfRunInfo

The number of style run information structures passed in the `iRunInfoArray` parameter. If you pass `0`, ATSUI assumes there is only one style for the entire text block passed in the `oStreamBuffer` parameter. The flattened data format passed to the `iStreamFormat` parameter must support the use of one style.

iRunInfoArray[]

An array of `ATSUStyleRunInfo` structures that describes the style runs to be flattened. This array must contain `iNumberOfRunInfo` entries. An `ATSUStyleRunInfo` structure contains an index into an array of unique ATSUI style objects (`ATSUStyle`) and the length of the run to which the style object applies. Each index in the `ATSUStyleRunInfo` structure must reference a valid `ATSUStyle` object passed in the `iStyleArray` parameter. You can pass `NULL`, only if `iNumberOfRunInfo` is set to zero.

iNumberOfStyleObjects

The number of `ATSUStyle` objects in the array passed to the `iStyleArray` parameter. You must pass a value that is greater than `0`.

iStyleArray[]

An array of `ATSUStyle` objects to be flattened. You cannot pass `NULL`.

iStreamBufferSize

The size of the stream buffer, pointed to by the `oStreamBuffer` parameter. You can pass `0` only if the `iStreamBufferSize` parameter is set to `NULL`. If you are uncertain of the size of the array, see the Discussion.

oStreamBuffer

On input, a pointer to the data you want to flatten. On return, points to the flattened data. If you pass `NULL` for this parameter, no data is flattened. Instead, the size of the buffer is calculated by ATSUI and returned in `oActualStreamSize` parameter. See the Discussion for more details. You are responsible for allocating the text buffer passed in the `oStreamBuffer` parameter.

oActualStreamBufferSize

On return, the size of the data written to the `oStreamBuffer` parameter. You can pass `NULL` only if the `oStreamBuffer` parameter is not `NULL`.

Return Value

A result code. See "ATSUI Result Codes" (page 2068). This function can also return `paramErr` if you pass invalid values for any of the parameters.

Discussion

The function `ATSUFlattenStyleRunsToStream` takes an array of `ATSUStyle` objects and style run information and flattens the data to the specified format. The style runs must all reference the same block of Unicode text (usually passed separately as text in the `'utxt'` format). The style runs must also be in ascending order relative to the text in the text block.

Typically you use the function `ATSUFlattenStyleRunsFromStream` by calling it twice, as follows:

1. Provide appropriate values for the `iStreamFormat`, `iFlattenOptions`, `iNumberOfRunInfo`, `iRunInfoArray`, `iNumberOfStyleObjects`, and `iStyleArray` parameters. Set `iStreamBufferSize` to `0`, `oStreamBuffer` to `NULL`, and pass a valid reference to a `ByteCount` variable in the `oActualStreamBufferSize` parameter. Call the function `ATSUFlattenStyleRunsToStream`. On return, `oActualStreamBufferSize` points to the size needed for the buffer.

2. Allocate an appropriately-sized buffer for the `oStreamBuffer` parameter and then call the function `ATSUFlattenStyleRunsToStream` a second time.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeFlattening.h`

ATSUFONDtoFontID

Finds the ATSUI font ID that corresponds to a font family number, if one exists. (**Deprecated.** There is no replacement because FONDs are a QuickDraw concept and QuickDraw is deprecated.)

Not recommended.

```
OSStatus ATSUFONDtoFontID (
   short iFONDNumber,
   Style iFONDStyle,
   ATSUFontID *oFontID
);
```

Parameters

iFONDNumber
The font family number of the ATSUI-compatible font for which to obtain an ATSUI font ID.

iFONDStyle
The font family style of the font, if any. Style identifiers exist only for fonts that split a font family into subgroups.

oFontID
A pointer to a `ATSUFontID` value. On return, the value provides a unique identifier for the specified font family number and style.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The function `ATSUFONDtoFontID` is not recommended for use. Instead, use the Font Manager functions that translate font family numbers to `FMFont` values, which are equivalent to `ATSUFontID` values. Font family numbers were used by QuickDraw to represent fonts to the Font Manager. Some of these fonts, even if compatible with ATSUI, may not have font IDs.

Note that Apple Type Services assigns `ATSUFontID` values systemwide at runtime. As a result, these font IDs can change when the system is restarted.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeFonts.h`

ATSUFontCount

Obtains the number of ATSUI-compatible fonts installed on a user's system.

```
OSStatus ATSUFontCount (
   ItemCount *oFontCount
);
```

Parameters

oFontCount

A pointer to an `ItemCount` value. On return, the value specifies the current number of ATSUI-compatible fonts installed on the user's system.

Return Value

A result code. See "ATSUI Result Codes" (page 2068).

Discussion

The `ATSUFontCount` function obtains the number of fonts on a user's system that are compatible with ATSUI. Incompatible fonts include those that cannot be used to represent Unicode, the missing-character glyph font, and fonts whose names begin with a period or a percent sign. You can use the count produced in the `oFontCount` parameter to determine the amount of memory to allocate for the `oFontIDs` array in the function `ATSUGetFontIDs` (page 1899).

It is important to note that the set of installed ATSUI-compatible fonts may change while your application is running. In Mac OS X, the set of installed fonts may change at any time. Although in Mac OS 9, fonts cannot be removed from the Fonts folder while an application other than the Finder is running, they can be removed from other locations, and it is possible for fonts to be added.

Additionally, just because the number of fonts stays the same between two successive calls to `ATSUFontCount`, this does not mean that the font lists are the same. It is possible for a font to be added and another removed between two successive calls to `ATSUFontCount`, leaving the total number unchanged.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`ATSUnicodeFonts.h`

ATSUFontIDtoFOND

Finds the font family number that corresponds to an ATSUI font ID, if one exists. (**Deprecated.** There is no replacement because FONDs are a QuickDraw concept and QuickDraw is deprecated.)

Not recommended.

```
OSStatus ATSUFontIDtoFOND (
   ATSUFontID iFontID,
   short *oFONDNumber,
   Style *oFONDStyle
);
```

Parameters

iFontID

The `ATSUFontID` value of the font for which to obtain a font family number. Note that because Apple Type Services assigns `ATSUFontID` values systemwide at runtime, font IDs can change across system restarts.

oFONDNumber

A pointer to a signed sixteen-bit integer. On return, the value identifies the font family number corresponding to the specified ATSUI font ID.

oFONDStyle

A pointer to a `Style` value. On return, the value identifies the font family style of the font, if any. Style identifiers exist only for fonts that split a font family into subgroups.

Return Value

A result code. See "ATSUI Result Codes" (page 2068).

Discussion

The function `ATSUFontIDtoFOND` is not recommended for use. Instead, use the Font Manager functions that translate `FMFont` values, which are equivalent to `ATSUFontID` values, to font family numbers. Font family numbers were used by QuickDraw to represent fonts to the Font Manager. Some of these fonts, even if compatible with ATSUI, may not have font IDs.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`ATSUnicodeFonts.h`

ATSUGetAllAttributes

Obtains an array of style attribute tags and value sizes for a style object.

```
OSStatus ATSUGetAllAttributes (
   ATSUStyle iStyle,
   ATSUAttributeInfo oAttributeInfoArray[],
   ItemCount iTagValuePairArraySize,
   ItemCount *oTagValuePairCount
);
```

Parameters

iStyle

An `ATSUStyle` value specifying the style object to examine.

oAttributeInfoArray

A pointer to memory you have allocated for an array of `ATSUAttributeInfo` values. On return, the array contains pairs of tags and value sizes for any of the object's style attributes that are not at default values. If you are uncertain of how much memory to allocate for this array, see the Discussion.

iTagValuePairArraySize

An ItemCount value specifying the maximum number of tag and value size pairs to obtain for the style object. Typically, this is equivalent to the number of ATSUAttributeInfo structures for which you have allocated memory in the oAttributeInfoArray parameter. To determine this value, see the Discussion.

oTagValuePairCount

A pointer to an ItemCount value. On return, the value specifies the actual number of ATSUAttributeInfo structures in the style object. This may be greater than the value you specified in the iTagValuePairArraySize parameter.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The ATSUGetAllAttributes function obtains all nondefault style attribute tags and values sizes for a style object. You can pass a tag and value-size pair obtained from ATSUGetAllAttributes to the function ATSUGetAttribute (page 1892) to determine the corresponding attribute value.

Typically you use the function ATSUGetAllAttributes by calling it twice, as follows:

1. Pass a reference to the style object to examine in the iStyle parameter, a valid pointer to an ItemCount value in the *oTagValuePairCount* parameter, NULL for the oAttributeInfoArray parameter, and 0 for the *iTagValuePairArraySize* parameter. ATSUGetAllAttributes returns the size of the tag and value-size arrays in the oTagValuePairCount parameter.

2. Allocate enough space for an array of the returned size, then call the ATSUGetAllAttributes function again, passing a valid pointer in the oAttributeInfoArray parameter. On return, the pointer refers to an array of the style attribute tag and value-size pairs contained in the style object.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
ATSUnicodeObjects.h

ATSUGetAllFontFeatures

Obtains the font features of a style object that are not at default settings.

```
OSStatus ATSUGetAllFontFeatures (
   ATSUStyle iStyle,
   ItemCount iMaximumFeatureCount,
   ATSUFontFeatureType oFeatureType[],
   ATSUFontFeatureSelector oFeatureSelector[],
   ItemCount *oActualFeatureCount
);
```

Parameters

iStyle

An ATSUStyle value specifying the style object to examine.

iMaximumFeatureCount

An ItemCount value specifying the maximum number of feature types and selectors to obtain for the style object. Typically, this is equivalent to the number of ATSUFontFeatureType and ATSUFontFeatureSelector values for which you have allocated memory in the oFeatureType and oFeatureSelector parameters, respectively. To determine this value, see the Discussion.

oFeatureType

A pointer to memory you have allocated for an array of ATSUFontFeatureType values. On return, the array contains constants identifying each type of font feature that is at a nondefault setting in the style object. If you are uncertain of how much memory to allocate for this array, see the Discussion.

oFeatureSelector

A pointer to memory you have allocated for an array of ATSUFontFeatureSelector values. On return, the array contains constants identifying the feature selectors that are at nondefault settings in the style object. Each selector determines the setting for a corresponding feature type produced in the *oFeatureType* parameter. If you are uncertain of how much memory to allocate for this array, see the Discussion.

oActualFeatureCount

A pointer to an ItemCount value. On return, the value specifies the actual number of font feature types and selectors in the style object. This may be greater than the value you specified in the iMaximumFeatureCount parameter.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The ATSUGetAllFontFeatures function obtains all of a style object's font features that are not at default settings. Font features are grouped into categories called feature types, within which individual feature selectors define particular feature settings. The arrays produced by ATSUGetAllFontFeatures contain constants identifying the object's font types and their corresponding font selectors.

Typically you use the function ATSUGetAllFontFeatures by calling it twice, as follows:

1. Pass a reference to the style object to examine in the iStyle parameter, a valid pointer to an ItemCount value in the *oActualFeatureCount* parameter, NULL for the oFeatureType and oFeatureSelector parameters, and 0 for the *iMaximumFeatureCount* parameter. ATSUGetAllFontFeatures returns the size in the oActualFeatureCount parameter to use for the feature type and selector arrays.

2. Allocate enough space for arrays of the returned size, then call ATSUGetAllFontFeatures again, passing a pointer to the arrays in the oFeatureType and oFeatureSelector parameters. On return, the arrays contain the font feature types and selectors, respectively, for the style object.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
ATSUnicodeFonts.h

ATSUGetAllFontVariations

Obtains a style object's font variation values that are not at default settings.

```
OSStatus ATSUGetAllFontVariations (
   ATSUStyle iStyle,
   ItemCount iVariationCount,
   ATSUFontVariationAxis oVariationAxes[],
   ATSUFontVariationValue oFontVariationValues[],
   ItemCount *oActualVariationCount
);
```

Parameters

iStyle

An `ATSUStyle` value specifying the style object to examine.

iVariationCount

An `ItemCount` value specifying the maximum number of font variation values to obtain for the style object. Typically, this is equivalent to the number of `ATSUFontVariationAxis` and `ATSUFontVariationValue` values for which you have allocated memory in the `oVariationAxes` and `oFontVariationValues` parameters, respectively. To determine this value, see the Discussion.

oVariationAxes

A pointer to memory you have allocated for an array of `ATSUFontVariationAxis` values. On return, the array contains tags identifying those font variation axes in the style object that are not at default values. If you are uncertain of how much memory to allocate for this array, see the Discussion.

oFontVariationValues

A pointer to memory you have allocated for an array of `ATSUFontVariationValue` values. On return, the array contains the current font variation values for the font variation axes produced in the `oVariationAxes` array. If you are uncertain of how much memory to allocate for this array, see the Discussion.

oActualVariationCount

A pointer to an `ItemCount` value. On return, the value specifies the actual number of nondefault font variation values in the style object. This may be greater than the value you passed in the `iVariationCount` parameter.

Return Value

A result code. See "ATSUI Result Codes" (page 2068).

Discussion

The `ATSUGetAllFontVariations` function obtains all of a style object's font variation axes that are not at default settings, as well as the current values for the axes.

Typically you use the function `ATSUGetAllFontVariations` by calling it twice, as follows:

1. Pass a reference to the style object to examine in the `iStyle` parameter, a pointer to an `ItemCount` value in the *oActualVariationCount* parameter, `NULL` for the `oVariationAxes` and `oFontVariationValues` parameters, and 0 for the *iVariationCount* parameter. `ATSUGetAllFontVariations` returns the size to use for the variation axes and value arrays in the `oActualVariationCount` parameter.

2. Allocate enough space for arrays of the returned size, then call `ATSUGetAllFontVariations` again, passing a pointer to the arrays in the `oVariationAxes` and `oFontVariationValues` parameters. On return, the arrays contain the font variation axes and their corresponding values, respectively, for the style object.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In
ATSUnicodeFonts.h

ATSUGetAllLayoutControls

Obtains an array of layout control attribute tags and value sizes for a text layout object.

```
OSStatus ATSUGetAllLayoutControls (
   ATSUTextLayout iTextLayout,
   ATSUAttributeInfo oAttributeInfoArray[],
   ItemCount iTagValuePairArraySize,
   ItemCount *oTagValuePairCount
);
```

Parameters

iTextLayout

An ATSUTextLayout value specifying the text layout object to examine.

oAttributeInfoArray

A pointer to memory you have allocated for an array of ATSUAttributeInfo values. On return, the array contains pairs of tags and value sizes for the object's layout control attributes that are not at default values. If you are uncertain of how much memory to allocate for this array, see the Discussion.

iTagValuePairArraySize

An ItemCount value specifying the maximum number of tag and value size pairs to obtain for the text layout object. Typically, this is equivalent to the number of ATSUAttributeInfo structures for which you have allocated memory in the oAttributeInfoArray parameter. To determine this value, see the Discussion.

oTagValuePairCount

A pointer to an ItemCount value. On return, the value specifies the actual number of ATSUAttributeInfo structures in the text layout object. This may be greater than the value you specified in the iTagValuePairArraySize parameter.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The ATSUGetAllLayoutControls function obtains all nondefault layout control attribute tags and their values sizes for a text layout object. You can pass a tag and value size pair obtained from ATSUGetAllLayoutControls to the function ATSUGetLayoutControl (page 1912) to determine the corresponding attribute value.

Typically you use the function ATSUGetAllLayoutControls by calling it twice, as follows:

1. Pass a reference to the text layout object to examine in the iTextLayout parameter, NULL for the oAttributeInfoArray parameter, a pointer to an ItemCount value in the *oTagValuePairCount* parameter, and 0 for the *iTagValuePairArraySize* parameter. ATSUGetAllLayoutControls returns the size of the tag and value size arrays in the oTagValuePairCount parameter.

2. Allocate enough space for an array of the returned size, then call the ATSUGetAllLayoutControls function again, passing a valid pointer in the oAttributeInfoArray parameter. On return, the pointer refers to an array of the layout control attribute tag and value size pairs contained in the text layout object.

To obtain the nondefault line control attribute tags and value sizes for a text layout object, call the function `ATSUGetAllLineControls` (page 1891).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeObjects.h`

ATSUGetAllLineControls

Obtains an array of line control attribute tags and value sizes for a line in a text layout object.

```
OSStatus ATSUGetAllLineControls (
   ATSUTextLayout iTextLayout,
   UniCharArrayOffset iLineStart,
   ATSUAttributeInfo oAttributeInfoArray[],
   ItemCount iTagValuePairArraySize,
   ItemCount *oTagValuePairCount
);
```

Parameters

iTextLayout
An `ATSUTextLayout` value specifying the text layout object to examine.

iLineStart
A `UniCharArrayOffset` value specifying the offset from the beginning of the text layout object's text buffer to the first character of the line for which to obtain line control attribute values.

oAttributeInfoArray
A pointer to memory you have allocated for an array of `ATSUAttributeInfo` values. On return, the array contains pairs of tags and value sizes for the object's line control attributes that are not at default values. If you are uncertain of how much memory to allocate for this array, see the Discussion.

iTagValuePairArraySize
An `ItemCount` value specifying the maximum number of tag and value size pairs to obtain for the line. Typically, this is equivalent to the number of `ATSUAttributeInfo` structures for which you have allocated memory in the `oAttributeInfoArray` parameter. To determine this value, see the Discussion.

oTagValuePairCount
A pointer to an `ItemCount` value. On return, the value specifies the actual number of `ATSUAttributeInfo` structures in the line. This may be greater than the value you specified in the `iTagValuePairArraySize` parameter.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The `ATSUGetAllLineControls` function obtains all nondefault line control attribute tags and their values sizes for a line in a text layout object. You can pass a tag and value size pair obtained from `ATSUGetAllLineControls` to the function `ATSUGetLineControl` (page 1913) to determine the corresponding attribute value.

Typically you use the function `ATSUGetAllLineControls` by calling it twice, as follows:

1. Pass a reference to the text layout object to examine in the `iTextLayout` parameter, the appropriate `UniCharArrayOffset` value in the *`iLineStart`* parameter, `NULL` for the `oAttributeInfoArray` parameter, a pointer to an `ItemCount` value in the *`oTagValuePairCount`* parameter, and 0 for the *`iTagValuePairArraySize`* parameter. `ATSUGetAllLineControls` returns the size of the tag and value size arrays in the `oTagValuePairCount` parameter.

2. Allocate enough space for an array of the returned size, then call the `ATSUGetAllLineControls` function again, passing a valid pointer in the `oAttributeInfoArray` parameter. On return, the pointer refers to an array of the line control attribute tag and value size pairs contained in the specified line.

To obtain the nondefault layout control attribute tags and value sizes for a text layout object, call the function `ATSUGetAllLayoutControls` (page 1890).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeObjects.h`

ATSUGetAttribute

Obtains a style attribute value for a style object.

```
OSStatus ATSUGetAttribute (
   ATSUStyle iStyle,
   ATSUAttributeTag iTag,
   ByteCount iExpectedValueSize,
   ATSUAttributeValuePtr oValue,
   ByteCount *oActualValueSize
);
```

Parameters

`iStyle`
An `ATSUStyle` value specifying the style object for which to obtain an attribute value.

`iTag`
An `ATSUAttributeTag` constant identifying the attribute value to obtain. See "Attribute Tags" (page 2030) for a description of the Apple-defined style attribute tag constants.

`iExpectedValueSize`
The expected size (in bytes) of the value to obtain. To determine the size of an application-defined style attribute value, see the Discussion.

`oValue`
An `ATSUAttributeValuePtr` value, identifying the memory you have allocated for the attribute value. If you are uncertain of how much memory to allocate, see the Discussion. On return, *`oValue`* contains a valid pointer to the actual attribute value.

`oActualValueSize`
A pointer to a `ByteCount` value. On return, the value contains the actual size (in bytes) of the attribute value. You should examine this parameter if you are unsure of the size of the attribute value being obtained, as in the case of custom style run attributes.

Return Value
A result code. See "ATSUI Result Codes" (page 2068). Note that if the attribute value you want to obtain is not set, `ATSUGetAttribute` produces the default value in the `oValue` parameter and returns the result code `kATSUNotSetErr`.

Discussion
The `ATSUGetAttribute` function obtains the value of a specified style attribute for a given style object.

Before calling `ATSUGetAttribute`, you should call the function `ATSUGetAllAttributes` (page 1886) to obtain an array of nondefault style attribute tags and value sizes for the style object. You can then pass `ATSUGetAttribute` the tag and value size for the attribute value to obtain.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeObjects.h`

ATSUGetContinuousAttributes

Obtains the style attribute values that are continuous over a given text range.

```
OSStatus ATSUGetContinuousAttributes (
   ATSUTextLayout iTextLayout,
   UniCharArrayOffset iOffset,
   UniCharCount iLength,
   ATSUStyle oStyle
);
```

Parameters

iTextLayout
An `ATSUTextLayout` value specifying the text layout object to examine.

iOffset
A `UniCharArrayOffset` value specifying the offset from the beginning of the text buffer to the first character of the text range to examine. To indicate that the specified text range starts at the beginning of the text buffer, you can pass the constant `kATSUFromTextBeginning`. To specify the entire text buffer, pass `kATSUFromTextBeginning` in this parameter and `kATSUToTextEnd` in the `iLength` parameter.

iLength
A `UniCharCount` value specifying the length of the text range to examine. If you want the range of text to extend to the end of the text buffer, you can pass the constant `kATSUToTextEnd`.

oStyle
An `ATSUStyle` value. On return, the style object contains those attributes that are the same for the entire text range specified by the `iOffset` and `iLength` parameters.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The `ATSUGetContinuousAttributes` function examines the specified text range to obtain the style attribute values (including those at default values) that remain consistent for the entire text range. You should call `ATSUGetContinuousAttributes` to determine the style information that remains constant over text that has been selected by the user.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeObjects.h`

ATSUGetFontFallbacks

Obtains the global font list and search order that ATSUI uses when a font does not have the glyph needed to image a character. (Deprecated in Mac OS X v10.3. Use font fallback objects instead.)

Not recommended.

```
OSStatus ATSUGetFontFallbacks (
   ItemCount iMaxFontFallbacksCount,
   ATSUFontID oFontIDs[],
   ATSUFontFallbackMethod *oFontFallbackMethod,
   ItemCount *oActualFallbacksCount
);
```

Parameters

iMaxFontFallbacksCount
An `ItemCount` value specifying the maximum number of fonts that you want to obtain. Typically, this is equivalent to the size of the array allocated in the `oFontIDs` parameter. To determine this value, see the Discussion.

oFontIDs
A pointer to memory you have allocated for an array of `ATSUFontID` values. If you are uncertain of how much memory to allocate, see the Discussion. On return, the array contains font IDs identifying the fonts ATSUI searches when seeking a substitute font.

oFontFallbackMethod
A pointer to an `ATSUFontFallbackMethod` value. On return, the value identifies the order in which ATSUI searches fonts. See "Font Fallback Methods" (page 2048) for a description of possible values.

oActualFallbacksCount
A pointer to an `ItemCount` value. On return, the value specifies the actual number of fonts that ATSUI searches. This value may be greater than that passed in the `iMaxFontFallbacksCount` parameter.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
You should not use this function because it operates on a global scope and may not be available in future versions of ATSUI. You should instead use the function `ATSUGetObjFontFallbacks` (page 1914) with a font fallback object that has been associated with a text layout object. See *Inside Mac OS X: Rendering Unicode Text With ATSUI* for step-by-step instructions on creating a font fallback object and associating it with a text layout object.

Special Considerations

Global font fallback settings can be changed by any ATSUI client, so they can be changed unexpectedly. The only way to ensure that ATSUI uses your preferred font fallback settings for your text is to create a font fallback object and associated it with a text layout object. See the Discussion for more details.

Version Notes

Available beginning with ATSUI 1.1.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.3.

Not available to 64-bit applications.

Declared In

`ATSUnicodeObjects.h`

ATSUGetFontFeature

Obtains the font feature corresponding to an index into an array of font features for a style object.

```
OSStatus ATSUGetFontFeature (
   ATSUStyle iStyle,
   ItemCount iFeatureIndex,
   ATSUFontFeatureType *oFeatureType,
   ATSUFontFeatureSelector *oFeatureSelector
);
```

Parameters

iStyle

An `ATSUStyle` value specifying the style object to examine.

iFeatureIndex

An `ItemCount` value specifying an index into the array of font features for the style object. This index identifies the font feature to examine. Because this index is zero-based, you must pass a value between 0 and one less than the value produced in the `oActualFeatureCount` parameter of the function `ATSUGetAllFontFeatures` (page 1887).

oFeatureType

A pointer to memory you have allocated for an `ATSUFontFeatureType` value. On return, the value identifies the font feature type corresponding to the index passed in the `iFeatureIndex` parameter.

oFeatureSelector

A pointer to memory you have allocated for an `ATSUFontFeatureSelector` value. On return, the value identifies the font feature selector that corresponds to the feature type produced in the *oFeatureType* parameter.

Return Value

A result code. Note that if the index specifies a font feature that is not set, `ATSUGetFontFeature` produces the font-specified default value for the feature and returns the result code `kATSUNotSetErr`. See "ATSUI Result Codes" (page 2068).

Discussion
The `ATSUGetFontFeature` function obtains the setting for a specified font feature in a style object. You might typically call `ATSUGetFontFeature` if you need to obtain one previously set feature after another within your program's processing loop. To obtain all previously set font features for a given style object, you can call the function `ATSUGetAllFontFeatures` (page 1887).

Before calling `ATSUGetFontFeature`, you should call the function `ATSUGetAllFontFeatures` (page 1887) to obtain a count of the font features that are set in the style object. You can then pass the index for the feature whose setting you want to obtain in the `iTag` and `iMaximumValueSize` parameters of `ATSUGetFontFeature`.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeFonts.h`

ATSUGetFontFeatureNameCode

Obtains the name code for a font's feature type or selector that matches an ASTUI font ID, feature type, and feature selector.

```
OSStatus ATSUGetFontFeatureNameCode (
   ATSUFontID iFontID,
   ATSUFontFeatureType iType,
   ATSUFontFeatureSelector iSelector,
   FontNameCode *oNameCode
);
```

Parameters

iFont
The `ATSUFontID` value of the font for which to obtain the name code for a feature type or selector. Note that because Apple Type Services assigns `ATSUFontID` values systemwide at runtime, font IDs can change across system restarts.

iType
An `ATSUFontFeatureType` constant identifying a valid feature type. To obtain the valid feature types for a font, call the function `ATSUGetFontFeatureTypes` (page 1898).

iSelector
An `ATSUFontFeatureSelector` constant identifying a valid feature selector that corresponds to the feature type passed in the `iType` parameter. If you pass the constant `kATSUNoSelector`, the name code produced by `ATSUGetFontFeatureNameCode` is that of the feature type, not the feature selector. To obtain the valid feature selectors for a font, call the function`ATSUGetFontFeatureSelectors` (page 1897).

oNameCode
A pointer to a `FontNameCode` value. On return, the value contains the name code for the font feature selector or type. The `FontNameCode` is a `UInt32` data type, and it is defined in the `SFNTTypes.h` header file.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The `ATSUGetFontFeatureNameCode` function obtains the name code for a font's feature type or selector that matches an ASTUI font ID, feature type and feature selector values. By default, `ATSUGetFontFeatureNameCode` function obtains the name code of a feature selector. To determine the name code of a feature type, pass the constant `kATSUNoSelector` in the `iSelector` parameter.

You can use the function `ATSUFindFontName` (page 1880) to obtain the localized name string for the name code produced by `ATSUGetFontFeatureNameCode`.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeFonts.h`

ATSUGetFontFeatureSelectors

Obtains the available feature selectors for a given feature type in a font.

```
OSStatus ATSUGetFontFeatureSelectors (
   ATSUFontID iFontID,
   ATSUFontFeatureType iType,
   ItemCount iMaximumSelectors,
   ATSUFontFeatureSelector oSelectors[],
   Boolean oSelectorIsOnByDefault[],
   ItemCount *oActualSelectorCount,
   Boolean *oIsMutuallyExclusive
);
```

Parameters

iFont
An `ATSUFontID` value identifying the font to examine.

iType
An `ATSUFontFeatureType` value specifying one of the font's supported feature types. To obtain the available feature types for a font, call the function `ATSUGetFontFeatureTypes` (page 1898).

iMaximumSelectors
An `ItemCount` value specifying the maximum number of feature selectors to obtain for the font's specified feature type. Typically, this is equivalent to the number of elements in the `oSelectors` array.

oSelectors
A pointer to memory you have allocated for an array of `ATSUFontFeatureSelector` values. You can call the function `ATSUCountFontFeatureSelectors` (page 1859) to obtain the number of available feature selectors for a given font feature type and thus determine the amount of memory to allocate. On return, the array contains constants identifying each available feature selector for the given feature type. The constants that represent font feature selectors are defined in the header file `SFNTLayoutTypes.h` and are described in *Inside Mac OS X: Rendering Unicode Text With ATSUI*.

oSelectorIsOnByDefault
A pointer to memory you have allocated for an array of `Boolean` values. The number of elements in this array should correspond to the number of elements in the *oSelectors* array. On return, the array contains `Boolean` values indicating whether the corresponding feature selector in the *oSelectors* array is on or off. If `true`, the feature selector is on by default; if false, off.

oActualSelectorCount

A pointer to an `ItemCount` value. On return, the value specifies the actual number of feature selectors defined for the given feature type. This value may be greater than the value you specify in the `iMaximumSelectors` parameter.

oIsMutuallyExclusive

A pointer to a `Boolean` value. On return, the value indicates whether the feature selectors for the given feature type are exclusive or nonexclusive. If a feature type is exclusive you can choose only one of its available feature selectors at a time, such as whether to display numbers as proportional or fixed-width. If a feature type is nonexclusive, you can enable any number of feature selectors at once. If `true`, the feature type is exclusive and only one selector can be used at a time.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
A given font may not support all possible feature types and selectors. If you select features that are not available in a font, you won't see a change in the glyph's appearance. To determine the available features of a font, you can call the functions `ATSUGetFontFeatureTypes` (page 1898) and `ATSUGetFontFeatureSelectors`.

The `ATSUGetFontFeatureSelectors` function reads the font data table for the specified font and obtains its supported feature selectors for the given feature types. You can then use this information both to present the user a list of font features from which to select and to call such functions as `ATSUSetFontFeatures` (page 1952) with more accuracy.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeFonts.h`

ATSUGetFontFeatureTypes

Obtains the available feature types of a font.

```
OSStatus ATSUGetFontFeatureTypes (
   ATSUFontID iFontID,
   ItemCount iMaximumTypes,
   ATSUFontFeatureType oTypes[],
   ItemCount *oActualTypeCount
);
```

Parameters

iFont

An `ATSUFontID` value identifying the font to examine.

iMaximumTypes

An `ItemCount` value specifying the maximum number of feature types to obtain for the font. Typically, this is equivalent to the number of elements in the `oTypes` array.

oTypes

A pointer to memory you have allocated for an array of `ATSUFontFeatureType` values. You can call the function `ATSUCountFontFeatureTypes` (page 1860) to obtain the number of available feature types for a given font and thus determine the amount of memory to allocate. On return, the array contains constants identifying each type of feature that is defined for the font. The constants that represent font feature types are defined in the header file `SFNTLayoutTypes.h` and are described in *Inside Mac OS X: Rendering Unicode Text With ATSUI*.

oActualTypeCount

A pointer to an `ItemCount` value. On return, the value specifies the actual number of feature types defined in the font. This may be greater than the value you specify in the `iMaximumTypes` parameter.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
A given font may not support all possible feature types and selectors. If you select features that are not available in a font, you won't see a change in the glyph's appearance. To determine the available features of a font, you can call the functions `ATSUGetFontFeatureTypes` and `ATSUGetFontFeatureSelectors` (page 1897).

The `ATSUGetFontFeatureTypes` function reads the font data table for the specified font and obtains its supported feature types. You can then use this information both to present the user a list of font features from which to select and to call such functions as `ATSUSetFontFeatures` (page 1952) with more accuracy.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeFonts.h`

ATSUGetFontIDs

Obtains a list of all the ATSUI-compatible fonts installed on the user's system.

```
OSStatus ATSUGetFontIDs (
   ATSUFontID oFontIDs[],
   ItemCount iArraySize,
   ItemCount *oFontCount
);
```

Parameters

oFontIDs

A pointer to memory you have allocated for an array of `ATSUFontID` values. On return, the array contains unique identifiers for each of the ATSUI-compatible fonts installed on the user's system. You should allocate enough memory to contain an array the size of the count produced by the function `ATSUFontCount` (page 1885).

iArraySize

An `ItemCount` value specifying the maximum number of fonts to obtain. Typically, this is equivalent to the number of `ATSUFontID` values for which you have allocated memory in the `oFontIDs` parameter.

oFontCount

A pointer to an `ItemCount` value. On return, the value specifies the actual number of ATSUI-compatible fonts installed on the user's system. This may be greater than the value you specified in the `iArraySize` parameter.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The `ATSUGetFontIDs` function obtains the IDs of all the fonts on the user's system except for the last-resort font. It is important to note that the set of installed ATSUI-compatible fonts may change while your application is running. In Mac OS X, the set of installed fonts may change at any time. Although in Mac OS 9, fonts cannot be removed from the Fonts folder while an application other than the Finder is running, they can be removed from other locations, and it is possible for fonts to be added.

To ensure an accurate representation of the set of installed ATSUI-compatible fonts, you should call `ATSUGetFontIDs` to rebuild your font menu each time your application is brought to the foreground.

Finally, note that Apple Type Services assigns `ATSUFontID` values systemwide at runtime. As a result, these font IDs can change across system restarts.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeFonts.h`

ATSUGetFontInstance

Obtains the font variation axis values for a font instance.

```
OSStatus ATSUGetFontInstance (
   ATSUFontID iFontID,
   ItemCount iFontInstanceIndex,
   ItemCount iMaximumVariations,
   ATSUFontVariationAxis oAxes[],
   ATSUFontVariationValue oValues[],
   ItemCount *oActualVariationCount
);
```

Parameters

iFont

An `ATSUFontID` value identifying the font to examine.

iFontInstanceIndex

An `ItemCount` value specifying an index into an array of instances for the font. This index identifies the font instance to examine. Because this index is zero-based, you must pass a value between 0 and one less than the value produced in the `oInstances` parameter of the function `ATSUCountFontInstances` (page 1860).

iMaximumVariations

An ItemCount value specifying the maximum number of font variation axes to obtain for the font instance. Typically, this is equivalent to the number of ATSUFontVariationAxis and ATSUFontVariationValue values for which you have allocated memory in the oAxes and oValues parameters, respectively. To determine this value, see the Discussion.

oAxes

A pointer to memory you have allocated for an array of ATSUFontVariationAxis values. On return, the array contains tags identifying the font variation axes that constitute the font instance. If you are uncertain of how much memory to allocate for this array, see the Discussion.

oValues

A pointer to memory you have allocated for an array of ATSUFontVariationValue values. On return, the array contains the defined values for the font variation axes produced in the oAxes array. If you are uncertain of how much memory to allocate for this array, see the Discussion.

oActualVariationCount

A pointer to an ItemCount value. On return, the value specifies the actual number of font variation axes that constitute the font instance. This may be greater than the value you passed in the iMaximumVariations parameter.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
A font instance consists of a named set of values for each variation axis in a font. For example, suppose a font has the variation axis 'wght' with a minimum value of 0.0, a default of 0.5, and a maximum of 1.0. Additionally, the variation axis 'wdth' is also defined for the font, with a similar value range. The type designer can then choose to declare a font instance for a set of specific values within these axes, such as "Demibold" for a value of 0.8 for the 'wght' axis and 0.5 for the 'wdth' axis. By calling the function ATSUGetFontInstance, you can obtain the variation axis values for a given index into an array of font instances.

Typically you use the function ATSUGetFontInstance by calling it twice, as follows:

1. Pass the ID of the font to examine in the iFont parameter, a valid pointer to an ItemCount value in the *oActualVariationCount* parameter, NULL for the oAxes and oValues parameters, and 0 for the other parameters. ATSUGetFontInstance returns the size to use for the oAxes and oValues arrays in the oActualVariationCount parameter.

2. Allocate enough space for arrays of the returned size, then call the ATSUGetFontInstance again, passing pointers to the arrays in the oAxes and oValues parameters. On return, the arrays contain the font variation axes and their corresponding values, respectively, for the font instance.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
ATSUnicodeFonts.h

ATSUGetFontInstanceNameCode

Obtains the name code for the font instance that matches an ASTUI font ID and font instance index value.

```
OSStatus ATSUGetFontInstanceNameCode (
   ATSUFontID iFontID,
   ItemCount iInstanceIndex,
   FontNameCode *oNameCode
);
```

Parameters

iFont

The `ATSUFontID` value of the font for which to obtain a font instance name code. Note that because Apple Type Services assigns `ATSUFontID` values systemwide at runtime, font IDs can change across system restarts.

iInstanceIndex

An `ItemCount` value providing an index to the font instance for which to obtain a name code. Because this index must be 0-based, you should pass a value between 0 and one less than the count produced by the function `ATSUCountFontInstances` (page 1860).

oNameCode

A pointer to a `FontNameCode` value. On return, the value contains the name code for the font instance. The `FontNameCode` is a `UInt32` data type, and it is defined in the `SFNTTypes.h` header file.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
A font instance consists of a named set of values for each variation axis in a font. The `ATSUGetFontInstanceNameCode` function obtains the name code for the font instance that matches an ASTUI font ID and font instance index value.

You can use the function `ATSUFindFontName` (page 1880) to obtain the localized name string for the name code produced by `ATSUGetFontInstanceNameCode`. You can obtain the font variation axis values for a font instance by calling the function`ATSUGetFontInstance` (page 1900).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeFonts.h`

ATSUGetFontVariationNameCode

Obtains the name code for the font variation that matches an ASTUI font ID and font variation axis.

```
OSStatus ATSUGetFontVariationNameCode (
   ATSUFontID iFontID,
   ATSUFontVariationAxis iAxis,
   FontNameCode *oNameCode
);
```

Parameters

iFont

The `ATSUFontID` value of the font for which to obtain a font variation name code. Note that because Apple Type Services assigns `ATSUFontID` values systemwide at runtime, font IDs can change across system restarts.

iAxis

An `ATSUFontVariationAxis` value representing a valid variation axis tag. To obtain a valid variation axis tag for a font, you can call the functions`ATSUGetIndFontVariation` (page 1911) or `ATSUGetFontInstance` (page 1900).

oNameCode

A pointer to a `FontNameCode` value. On return, the value contains the name code for the font variation. The `FontNameCode` is a `UInt32` data type, and it is defined in the `SFNTTypes.h` header file.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The `ATSUGetFontVariationNameCode` function obtains the name code for the font variation that matches an ASTUI font ID and font variation axis tag. You can use the function `ATSUFindFontName` (page 1880) to obtain the localized name string for the name code produced by `ATSUGetFontVariationNameCode`.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeFonts.h`

ATSUGetFontVariationValue

Obtains the current value for a font variation axis in a style object.

```
OSStatus ATSUGetFontVariationValue (
   ATSUStyle iStyle,
   ATSUFontVariationAxis iFontVariationAxis,
   ATSUFontVariationValue *oFontVariationValue
);
```

Parameters

iStyle

An `ATSUStyle` value specifying the style object to examine.

iFontVariationAxis

An `ATSUFontVariationAxis` tag specifying the style object's variation axis to examine. You can obtain variation axis tags for a style object from the function `ATSUGetAllFontVariations` (page 1888).

oFontVariationValue

A pointer to memory you have allocated for an `ATSUFontVariationValue` value. On return, `ATSUGetFontVariationValue` produces the currently set value for the style object's specified variation axis. If this value has not been set, `ATSUGetFontVariationValue` produces the font-defined default value.

Return Value
A result code. Note that if no value has been set for the specified variation axis, `ATSUGetFontVariationValue` produces the font-defined default value and returns the result code `kATSUNotSetErr`. See "ATSUI Result Codes" (page 2068).

Discussion
The `ATSUGetFontVariationValue` function obtains the setting for a specified font variation axis in a style object. You might typically call `ATSUGetFontVariationValue` if you need to obtain one previously set variation axis value after another within your program's processing loop. To obtain all nondefault font variation axis values for a given style object, you can call the function `ATSUGetAllFontVariations` (page 1888).

Before calling `ATSUGetFontVariationValue`, call the function ATSUGetAllFontVariations (page 1888) to obtain the font variation axes that are set for the style object.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeFonts.h`

ATSUGetGlyphBounds

Obtains the typographic bounds of a line of glyphs after final layout.

```
OSStatus ATSUGetGlyphBounds (
   ATSUTextLayout iTextLayout,
   ATSUTextMeasurement iTextBasePointX,
   ATSUTextMeasurement iTextBasePointY,
   UniCharArrayOffset iBoundsCharStart,
   UniCharCount iBoundsCharLength,
   UInt16 iTypeOfBounds,
   ItemCount iMaxNumberOfBounds,
   ATSTrapezoid oGlyphBounds[],
   ItemCount *oActualNumberOfBounds
);
```

Parameters

`iTextLayout`
An `ATSUTextLayout` value specifying the text layout object to examine.

`iTextBasePointX`
An `ATSUTextMeasurement` value specifying the x-coordinate of the origin of the line containing the glyphs in the current graphics port or Quartz graphics context. Pass the constant `kATSUUseGrafPortPenLoc`, described in "Convenience Constants" (page 2043), to obtain the glyph bounds relative to the current pen location in the current graphics port or graphics context. You can pass 0 to obtain only the dimensions of the bounds relative to one another, not their actual onscreen position.

`iTextBasePointY`
An `ATSUTextMeasurement` value specifying the y-coordinate of the origin of the line containing the glyphs in the current graphics port or Quartz graphics context. Pass the constant `kATSUUseGrafPortPenLoc`, described in "Convenience Constants" (page 2043), to obtain the glyph bounds relative to the current pen location in the current graphics port or graphics context. You can pass `0` to obtain only the dimensions of the bounds relative to one another, not their actual onscreen position.

iBoundsCharStart

A `UniCharArrayOffset` value specifying the offset from the beginning of the text buffer to the character corresponding to the first glyph to measure. To indicate that the text range starts at the beginning of the text buffer, you can pass the constant `kATSUFromTextBeginning`.

iBoundsCharLength

A `UniCharCount` value specifying the length of the text range to measure. If you want the range to extend to the end of the text buffer, you can pass the constant `kATSUToTextEnd`.

iTypeOfBounds

A glyph bounds constant indicating whether the width of the resulting typographic glyph bounds is determined using the caret origin (midway between two characters), the glyph origin in device space, or the glyph origin in fractional absolute positions (uncorrected for device display). See "Glyph Origin Selectors" (page 2049) for a description of possible values.

iMaxNumberOfBounds

An `ItemCount` value specifying the maximum number of bounding trapezoids to obtain. Typically, this is equivalent to the number of bounds in the `oGlyphBounds` array. To determine this value, see the Discussion.

oGlyphBounds

A pointer to memory you have allocated for an array of `ATSTrapezoid` values. On return, the array contains a trapezoid representing the typographic bounds for glyphs in the text range. If the specified range of text encloses nested bidirectional text, `ATSUGetGlyphBounds` produces multiple trapezoids defining these regions.In ATSUI 1.1, the maximum number of enclosing trapezoids that can be returned is 31; in ATSUI 1.2, the maximum number is 127. If you pass a range that covers an entire line, `ATSUGetGlyphBounds` returns 1 trapezoid. If you are uncertain of how much memory to allocate for this array, see the Discussion.

oActualNumberOfBounds

A pointer to an `ItemCount` value. On return, the value specifies the actual number of enclosing trapezoids bounding the specified characters. This may be greater than the value you provide in the `iMaxNumberOfBounds` parameter.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
There are two kinds of bounds that your application may typically want to obtain for a block of text: typographic bounds and image bounds. The image bounds define the smallest rectangle that completely encloses the filled or framed parts of a block of text—that is, the text's "inked" glyphs. Because of the potential differences in glyph height in a text block, your application may instead need to determine the typographic bounds. The typographic bounding rectangle contains the extra space above and below the image bounding rectangle where characters with ascenders or descenders would be drawn (even if none currently are).

The `ATSUGetGlyphBounds` function produces the enclosing trapezoid(s) that represent the typographic bounds for glyphs in a final, laid-out range of text. You typically call this function when you need to obtain an enclosing trapezoid for a line, taking rotation and all other layout attributes into account.

ATSUI determines the height of each trapezoid by examining any line ascent and descent attribute values you may have set for the line. If you have not set these attributes for the line, the `ATSUGetGlyphBounds` function uses any line ascent and descent values you may have set for the text layout object containing the line. If these are not set, `ATSUGetGlyphBounds` uses the font's natural line ascent and descent values for the line. If these are previously set, `ATSUGetGlyphBounds` uses the `ATSUStyle` ascent and or descent/leading values.

Depending on the value you pass in the `iTypeOfBounds` parameter, the width of the resulting trapezoid(s) is determined using one of the following values:

- the caret origin, located halfway between two characters, which should be used when performing your own highlighting
- the glyph origin in device space, which is useful for obtaining bounds adjusted for specific rendering and device constraints
- the glyph origin in fractional (or "ideal") absolute positions, uncorrected for device display

Note that the coordinates produced for the trapezoid(s) are offset by the amount specified in the `iTextBasePointX` and `iTextBasePointY` parameters. If your goal in calling the `ATSUGetGlyphBounds` function is to obtain metrics for drawing the typographic bounds on the screen, pass the position of the origin of the line in the current graphics port or graphics context in these parameters. This enables `ATSUGetGlyphBounds` to match the trapezoids to their onscreen image.

Before calculating the typographic glyph bounds for the given text range, the `ATSUGetGlyphBounds` function examines the text layout object to make sure that the style runs cover the entire range of text. If there are gaps between style runs, `ATSUGetGlyphBounds` assigns the characters in the gap to the style run following the gap. If there is no style run at the beginning of the range of text, `ATSUGetGlyphBounds` assigns these characters to the first style run it can find. If there is no style run at the end of the range of text, `ATSUGetGlyphBounds` assigns the remaining characters to the last style run it can find.

Typically you use the `ATSUGetGlyphBounds` function by calling it twice, as follows:

1. Pass `NULL` for the `oGlyphBounds` parameter, `0` for the *`iMaxNumberOfBounds`* parameter, and valid values for the other parameters. The `ATSUGetGlyphBounds` function returns the actual number of trapezoids needed to enclose the glyphs in the `oActualNumberOfBounds` parameter.
2. Allocate enough space for a buffer of the returned size, then call the function again, passing a valid pointer to the buffer in the `oGlyphBounds` parameter. On return, the buffer contains the trapezoids for the glyphs' typographic bounds.

To obtain the typographic bounds of a line of text prior to line layout, call the function `ATSUGetUnjustifiedBounds` (page 1923). To calculate the image bounding rectangle for a final laid-out line, call the function `ATSUMeasureTextImage` (page 1938).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSUnicodeDrawing.h`

ATSUGetGlyphInfo

Obtains a copy of the style and layout information for each glyph in a line. (Deprecated in Mac OS X v10.3. Use functions from "Accessing Glyph Data" (page 1842) instead.)

Not recommended.

```
OSStatus ATSUGetGlyphInfo (
   ATSUTextLayout iTextLayout,
   UniCharArrayOffset iLineStart,
   UniCharCount iLineLength,
   ByteCount *ioBufferSize,
   ATSUGlyphInfoArray *oGlyphInfoPtr
);
```

Parameters

iTextLayout

An `ATSUTextLayout` value specifying the text layout object to examine.

iLineStart

A `UniCharArrayOffset` value specifying the offset from the beginning of the text buffer to the first character of the line to examine. To indicate that the line starts at the beginning of the text buffer, you can pass the constant `kATSUFromTextBeginning`. To specify the entire text buffer, pass `kATSUFromTextBeginning` in this parameter and `kATSUToTextEnd` in the `iLineLength` parameter.

iLineLength

A `UniCharCount` value specifying the length of the line. If you want the line to extend to the end of the text buffer, you can pass the constant `kATSUToTextEnd`.

ioBufferSize

A pointer to a `ByteCount` value specifying the size of the buffer you have allocated for the `ATSUGlyphInfoArray` structure produced in the *oGlyphInfoPtr* parameter. On return, the value specifies the actual size of the `ATSUGlyphInfoArray` structure.

oGlyphInfoPtr

A pointer to an `ATSUGlyphInfoArray` structure. On return, the structure contains values identifying the text layout object, the number of glyphs in the specified line, and an array of `ATSUGlyphInfo` structures for each of the glyphs. Each `ATSUGlyphInfo` structure contains information identifying the glyph, the style object with which it is associated, and other related layout values.

Return Value

A result code. See "ATSUI Result Codes" (page 2068).

Discussion

The `ATSUGetGlyphInfo` function obtains a copy of the style and layout information for each glyph in a line of text. Copying can be slow, so it's best to use this function only if you do not plan to modify the glyph information. If you do modify the glyph information, you can only draw the modified glyphs by calling the function `ATSUDrawGlyphInfo` (page 1877). Because you are working with a copy of the glyph data and not the actual data that ATSUI has, if you try to draw text by calling the `ATSUDrawText` (page 1877) function, none of the changes you make to the glyph information will be reflected in the drawn text.

Note that is you obtain glyph information with the function `ATSUGetGlyphInfo` and then draw glyphs using `ATSUDrawGlyphInfo`, ATSUI does not take synthetic styles into account when it draw. This means that font substitution will not work.

If you want to modify glyph information you should instead use the ATSUI direct-access functions `ATSUGlyphGetQuadraticPaths` (page 1928) or `ATSUGlyphGetCubicPaths` (page 1925). You use each of these functions along with callback functions you supply for drawing the glyphs. When you modify and draw glyphs using ATSUI's direct-access functions, you obtain access to the same information as that supplied by the function `ATSUGetGlyphInfo`, but in a way that allows font substitution to work. For more information on retrieving and drawing glyph outlines, see *Inside Mac OS X: Rendering Unicode Text With ATSUI*.

The Unicode characters in the text layout object (`ATSUTextLayout`) and the glyphs returned by the function `ATSUGetGlyphInfo` do not necessarily have a one-to-one correspondence. For example, the accented Latin character é can be represented by an e with a combining ´ accent. In this case, two characters map to one glyph.

Common ligatures such as fi also form automatically for some fonts, causing two characters to map to one glyph. Right-to-left scripts such as Arabic, and complex scripts such as Devanagari or Thai have even more complicated mappings from characters to glyphs.

For this reason it's best to use the high level ATSUI functions whenever possible, and to associate a paragraph of text with a text layout object. Your application is then completely insulated from such issues.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.3.
Not available to 64-bit applications.

Declared In
`ATSUnicodeGlyphs.h`

ATSUGetIndFontName

Obtains a name string, name code, platform, script, and language for the font that matches an ATSUI font ID and name table index value.

```
OSStatus ATSUGetIndFontName (
   ATSUFontID iFontID,
   ItemCount iFontNameIndex,
   ByteCount iMaximumNameLength,
   Ptr oName,
   ByteCount *oActualNameLength,
   FontNameCode *oFontNameCode,
   FontPlatformCode *oFontNamePlatform,
   FontScriptCode *oFontNameScript,
   FontLanguageCode *oFontNameLanguage
);
```

Parameters

`iFontID`

The `ATSUFontID` value of the font for which to obtain information. Note that because Apple Type Services assigns `ATSUFontID` values systemwide at runtime, font IDs can change across system restarts.

`iFontNameIndex`

An `ItemCount` value providing an index to the font for which to obtain information. Because this index must be 0-based, you should pass a value between 0 and one less than the count produced by the function `ATSUCountFontNames` (page 1861).

`iMaximumNameLength`

A `ByteCount` value specifying the maximum length of the font name string to obtain. Typically, this is equivalent to the size of the buffer that you have allocated in the `oName` parameter. To determine this length, see the Discussion.

oName

A pointer to a buffer. On return, the buffer contains the name string of the font matching the ATSUI font ID and name table index value being passed. If the buffer you allocate is not large enough to contain the name string, `ATSUGetIndFontName` produces a partial string.

oActualNameLength

A pointer to a `ByteCount` value. On return, the value specifies the actual length of the complete name string. This may be greater than the value passed in the `iMaximumNameLength` parameter. You should check this value to ensure that you have allocated sufficient memory and therefore obtained the complete name string for the font.

oFontNameCode

A pointer to a `FontNameCode` value. On return, the value contains the name code for the font. The `FontNameCode` is a `UInt32` data type, and it is defined in the `SFNTTypes.h` header file. ATSUI can return any of the following constants, `kFontCopyrightName`, `kFontFamilyName`, `kFontStyleName`, `kFontUniqueName`, `kFontFullName`, `kFontVersionName`, `kFontPostscriptName`, `kFontTrademarkName`, `kFontManufacturerName`, `kFontDesignerName`, `kFontDescriptionName`, `kFontVendorURLName`, `kFontDesignerURLName`, `kFontLicenseDescriptionName`, or `kFontLicenseInfoURLName`.

oFontNamePlatform

A pointer to a `FontPlatformCode` value. On return, this value specifies the encoding of the font, for example, `kFontUnicodePlatform`, `kFontMacintoshPlatform`, `kFontReservedPlatform`, `kFontMicrosoftPlatform`, or `kFontCustomPlatform`. See the `SFNTTypes.h` header file for a definition of the `FontPlatformCode` type and a list of possible values.

oFontNameScript

A pointer to a `FontScriptCode` value. On return, this value specifies the script code of the font, for example, `kFontRomanScript`. See the `SFNTTypes.h` header file for a definition of the `FontScriptCode` type and a list of possible values.

oFontNameLanguage

A pointer to a `FontLanguageCode` value. On return, this value specifies the language of the font, for example, `kFontNorwegianLanguage`. See the `SFNTTypes.h` header file for a definition of the `FontLanguageCode` type and a list of possible values.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The `ATSUGetIndFontName` function obtains a name string, name code, language code, script code, and platform code for the font that matches the specified ATSUI font ID and name table index value.

Typically you use the `ATSUGetIndFontName` function by calling it twice, as follows:

1. Pass valid values for the *iFontID*, *iFontNameIndex*, and *oActualNameLength* parameters, 0 for the *iMaximumNameLength* parameter, and `NULL` for the other parameters. `ATSUGetIndFontName` returns the length of the font name string in the `oActualNameLength` parameter.

2. Allocate enough space for a buffer of the returned size, then call the function again, passing a valid pointer to the buffer in the `oName` parameter. On return, the buffer contains the font name string.

To find a name string and index value for the first font in a name table that matches an ATSUI font ID and the specified font parameters, call the function `ATSUFindFontName` (page 1880). To obtain an ATSUI font ID for the first font in a name table that matches the specified name string, name code, platform, script, and/or language, call the function `ATSUFindFontFromName` (page 1879).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeFonts.h`

ATSUGetIndFontTracking

Obtains the name code and tracking value for the font tracking that matches an ASTUI font ID, glyph orientation, and tracking table index.

```
OSStatus ATSUGetIndFontTracking (
   ATSUFontID iFontID,
   ATSUVerticalCharacterType iCharacterOrientation,
   ItemCount iTrackIndex,
   Fixed *oFontTrackingValue,
   FontNameCode *oNameCode
);
```

Parameters

iFont

The `ATSUFontID` value of the font tracking for which to obtain a name code and tracking value. Note that because Apple Type Services assigns `ATSUFontID` values systemwide at runtime, font IDs can change across system restarts.

iCharacterOrientation

An `ATSUVerticalCharacterType` constant identifying the glyph orientation of the font tracking value to obtain, for example `kATSUStronglyHorizontal` or `kATSUStronglyVertical`. See "Vertical Character Types" (page 2068) for a description of possible values.

iTrackIndex

An `ItemCount` value providing an index to the font tracking for which to obtain information. Because this index must be 0-based, you should pass a value between 0 and one less than the count produced by the function `ATSUCountFontTracking` (page 1861).

oFontTrackingValue

A pointer to a `Fixed` value. On return, the value contains the font tracking value.

oNameCode

A pointer to a `FontNameCode` value. On return, the value contains the name code for the font tracking. The `FontNameCode` is a `UInt32` data type, and it is defined in the `SFNTTypes.h` header file.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
You can call the `ATSUGetIndFontTracking` function to obtain the name code and tracking value that matches the specified ATSUI font ID, glyph orientation, and tracking table index value.

You can use the function `ATSUFindFontName` (page 1880) to obtain the localized name string for the name code produced by `ATSUGetIndFontTracking`.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
ATSUnicodeFonts.h

ATSUGetIndFontVariation

Obtains a variation axis and its value range for a font.

```
OSStatus ATSUGetIndFontVariation (
   ATSUFontID iFontID,
   ItemCount iVariationIndex,
   ATSUFontVariationAxis *oATSUFontVariationAxis,
   ATSUFontVariationValue *oMinimumValue,
   ATSUFontVariationValue *oMaximumValue,
   ATSUFontVariationValue *oDefaultValue
);
```

Parameters

iFont

An ATSUFontID value identifying the font to examine.

iVariationIndex

An ItemCount value specifying an index into the array of variation axes for the font. This index identifies the font variation axis to examine. Because this index is zero-based, you must pass a value between 0 and one less than the value produced in the oVariationCount parameter of the function ATSUCountFontVariations (page 1862).

oATSUFontVariationAxis

A pointer to an ATSUFontVariationAxis value. On return, the value provides a four-character code identifying the font variation axis corresponding to the specified index.

oMinimumValue

A pointer to an ATSUFontVariationValue value. On return, the value identifies the variation axis minimum.

oMaximumValue

A pointer to an ATSUFontVariationValue value. On return, the value identifies the variation axis maximum.

oDefaultValue

A pointer to an ATSUFontVariationValue value. On return, the value identifies the variation axis default.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
By calling the function ATSUGetIndFontVariation, you can obtain a variation axis and its maximum, minimum, and default values for a font.

If you supply font variation axes and values to the function ATSUSetVariations (page 1967), you can change the appearance of a style object's font accordingly.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
ATSUnicodeFonts.h

ATSUGetLayoutControl

Obtains a layout control attribute value for a text layout object.

```
OSStatus ATSUGetLayoutControl (
   ATSUTextLayout iTextLayout,
   ATSUAttributeTag iTag,
   ByteCount iExpectedValueSize,
   ATSUAttributeValuePtr oValue,
   ByteCount *oActualValueSize
);
```

Parameters

iTextLayout

An ATSUTextLayout value specifying the text layout object for which to obtain a layout control attribute value.

iTag

An ATSUAttributeTag constant identifying the attribute value to obtain. See "Attribute Tags" (page 2030) for a description of the Apple-defined attribute tag constants.

iExpectedValueSize

The expected size (in bytes) of the value to obtain. To determine the size of an application-defined style attribute value, see the Discussion.

oValue

An ATSUAttributeValuePtr pointer, identifying the memory you have allocated for the attribute value. If you are uncertain of how much memory to allocate, see the Discussion. On return, *oValue* contains a valid pointer to the actual attribute value. If the value is unset, ATSUGetLayoutControl produces the default value in this parameter.

oActualValueSize

A pointer to a ByteCount value. On return, the value contains the actual size (in bytes) of the attribute value. You should examine this parameter if you are unsure of the size of the attribute value being obtained.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The ATSUGetLayoutControl function obtains the value of a specified layout control attribute for a given text layout object.

Before calling ATSUGetLayoutControl, you should call the function ATSUGetAllLayoutControls (page 1890) to obtain an array of nondefault layout control attribute tags and value sizes for the text layout object. You can then pass the tag and value size for the attribute value to obtain to ATSUGetLayoutControl.

Typically you use the function ATSUGetLayoutControl by calling it twice, as follows:

1. Pass a reference to the text layout object to examine in the iTextLayout parameter, NULL for the oValue parameter, 0 for the iExpectedValueSize parameter. ATSUGetLayoutControl returns the actual size of the attribute value in the oActualValueSize parameter.

2. Allocate enough space for an array of the returned size, then call the `ATSUGetLayoutControl` function again, passing a valid pointer in the `oValue` parameter. On return, the pointer refers to the actual attribute value contained in the text layout object.

To obtain the value of a line control attribute value for a text layout object, call the function `ATSUGetLineControl` (page 1913).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeObjects.h`

ATSUGetLineControl

Obtains a line control attribute value for a line in a text layout object.

```
OSStatus ATSUGetLineControl (
   ATSUTextLayout iTextLayout,
   UniCharArrayOffset iLineStart,
   ATSUAttributeTag iTag,
   ByteCount iExpectedValueSize,
   ATSUAttributeValuePtr oValue,
   ByteCount *oActualValueSize
);
```

Parameters

iTextLayout
An `ATSUTextLayout` value specifying the text layout object for which to obtain a line control attribute value.

iLineStart
A `UniCharArrayOffset` value specifying the offset from the beginning of the text layout object's text buffer to the first character of the line for which to obtain a line control attribute value.

iTag
An `ATSUAttributeTag` constant identifying the attribute value to obtain. See "Attribute Tags" (page 2030) for a description of the Apple-defined attribute tag constants.

iExpectedValueSize
The expected size (in bytes) of the value to obtain.

oValue
An `ATSUAttributeValuePtr` pointer, identifying the memory you have allocated for the attribute value. If you are uncertain of how much memory to allocate, see the Discussion. On return, *oValue* contains a valid pointer to the actual attribute value. If the value is unset, `ATSUGetLineControl` produces the default value in this parameter.

oActualValueSize
A pointer to a `ByteCount` value. On return, the value contains the actual size (in bytes) of the attribute value. You should examine this parameter if you are unsure of the size of the attribute value being obtained.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The `ATSUGetLineControl` function obtains the value of a specified line control attribute for a given line of text in a text layout object.

Before calling `ATSUGetLineControl`, you should call the function `ATSUGetAllLineControls` (page 1891) to obtain an array of nondefault line control attribute tags and value sizes for the line. You can then pass the tag and value size for the attribute value to obtain to `ATSUGetLineControl`.

To obtain the value of a layout control attribute value for a text layout object, call the function `ATSUGetLayoutControl` (page 1912).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeObjects.h`

ATSUGetNativeCurveType

Obtains the type of outline path used for glyphs associated with a given style object.

```
OSStatus ATSUGetNativeCurveType (
   ATSUStyle iATSUStyle,
   ATSCurveType *oCurveType
);
```

Parameters

iATSUStyle
An `ATSUStyle` value specifying the style object to examine.

oCurveType
A pointer to an `ATSCurveType` value. On return, the value provides a constant specifying the type of outline path being used. Possible values include `kATSCubicCurveType`, `kATSQuadCurveType`, and `kATSOtherCurveType`.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
You can call the `ATSUGetNativeCurveType` function to obtain the type of outline path used for glyphs associated with a given style object.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeGlyphs.h`

ATSUGetObjFontFallbacks

Obtains the font list and font-search method associated with a font fallback object.

```
OSStatus ATSUGetObjFontFallbacks (
   ATSUFontFallbacks iFontFallbacks,
   ItemCount iMaxFontFallbacksCount,
   ATSUFontID oFonts[],
   ATSUFontFallbackMethod *oFontFallbackMethod,
   ItemCount *oActualFallbacksCount
);
```

Parameters

iFontFallbacks

An `ATSUFontFallbacks` value specifying the font fallback object to examine.

iMaxFontFallbacksCount

An `ItemCount` value specifying the maximum number of fonts that you want to obtain. Typically, this is equivalent to the size of the array allocated in the `oFonts` parameter. To determine this value, see the Discussion.

oFonts

A pointer to memory you have allocated for an array of `ATSUFontID` values. If you are uncertain of how much memory to allocate, see the Discussion. On return, the array contains font IDs identifying the fonts in the font list associated with the font fallback object.

oFontFallbackMethod

A pointer to an `ATSUFontFallbackMethod` value. On return, the value identifies the font-search method associated with the font fallback object. See "Font Fallback Methods" (page 2048) for a description of possible values.

oActualFallbacksCount

A pointer to an `ItemCount` value. On return, the value specifies the actual number of fonts in the font list associated with the text layout object. This value may be greater than that passed in the `iMaxFontFallbacksCount` parameter.

Return Value

A result code. See "ATSUI Result Codes" (page 2068).

Discussion

The `ATSUGetObjFontFallbacks` function obtains the list of fonts and the search order associated with a given font fallback object.

Typically you use the function `ATSUGetObjFontFallbacks` by calling it twice, as follows:

1. Pass valid values for the *iFontFallbacks* and *oActualFallbacksCount* parameters, `NULL` for the `oFonts` and *oFontFallbackMethod* parameters and `0` for the *iMaxFontFallbacksCount* parameter. `ATSUGetObjFontFallbacks` returns the size of the font array in the `oActualFallbacksCount` parameter.

2. Allocate enough space for an array of the returned size, then call the function again, passing a valid pointer in the `oFonts` parameter. On return, the array contains the font list associated with the font fallback object.

You set the font list and search method for a font fallback object by calling the function `ATSUSetObjFontFallbacks` (page 1958).

Availability

Available in Mac OS X v10.1 and later.

Not available to 64-bit applications.

Declared In
ATSUnicodeObjects.h

ATSUGetRunStyle

Obtains style run information for a character offset in a run of text.

```
OSStatus ATSUGetRunStyle (
   ATSUTextLayout iTextLayout,
   UniCharArrayOffset iOffset,
   ATSUStyle *oStyle,
   UniCharArrayOffset *oRunStart,
   UniCharCount *oRunLength
);
```

Parameters

iTextLayout

An ATSUTextLayout value specifying the text layout object for which to obtain style run information.

iOffset

A pointer to a UniCharArrayOffset value. This value should specify the offset from the beginning of the text buffer to the character for which to obtain style run information. To specify the beginning of the text buffer, you can pass the constant kATSUFromTextBeginning.

oStyle

A pointer to an ATSUStyle value. On return, the value specifies the style object assigned to the range of text containing the character at *iOffset*. Note that if you pass an offset in the iOffset parameter that is at a style run boundary, ATSUGetRunStyle produces style run information for the following, not preceding, style run.

oRunStart

A pointer to a UniCharArrayOffset value. On return, the value specifies the offset from the beginning of the text buffer to the first character of the style run containing the character at iOffset. Note that the entire style run does not necessarily share the same unset attribute values as the character at iOffset.

oRunLength

A pointer to a UniCharCount value. On return, the value specifies the length of the style run containing the character at iOffset.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
You can use the ATSUGetRunStyle function to obtain the style object assigned to a given text offset. ATSUGetRunStyle also produces the encompassing text range that shares the style object with the offset.

Note that the style object contains those previously set style attributes, font features, and font variations that are continuous for the range of text that includes the specified text offset. If you want to obtain all shared style information for a style run, including any unset attributes, call the function ATSUGetContinuousAttributes (page 1893) instead.

If only one style run is set in the text layout object, and it does not cover the entire text layout object, ATSUGetRunStyle uses the style run information for the iOffset parameter to set the style run information for the remaining text.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeObjects.h`

ATSUGetSoftLineBreaks

Obtains soft line breaks in a range of text.

```
OSStatus ATSUGetSoftLineBreaks (
   ATSUTextLayout iTextLayout,
   UniCharArrayOffset iRangeStart,
   UniCharCount iRangeLength,
   ItemCount iMaximumBreaks,
   UniCharArrayOffset oBreaks[],
   ItemCount *oBreakCount
);
```

Parameters

iTextLayout

An `ATSUTextLayout` value specifying the text layout object to examine.

iRangeStart

A `UniCharArrayOffset` value specifying the offset from the beginning of the text layout object's text buffer to the first character of the text range to examine. To indicate that the specified text range starts at the beginning of the text buffer, you can pass the constant `kATSUFromTextBeginning`, To specify the entire text buffer, pass `kATSUFromTextBeginning` in this parameter and `kATSUToTextEnd` in the `iRangeLength` parameter.

iRangeLength

A `UniCharCount` value specifying the length of the text range. If you want the range of text to extend to the end of the text buffer, you can pass the constant `kATSUToTextEnd`.

iMaximumBreaks

An `ItemCount` value specifying the maximum number of soft line breaks to obtain. Typically, this is equivalent to the number of `UniCharArrayOffset` values for which you have allocated memory in the `oBreaks` array. To determine this value, see the Discussion.

oBreaks

A pointer to memory you have allocated for an array of `UniCharArrayOffset` values. On return, the array contains offsets from the beginning of the text buffer to each of the soft line breaks in the text range. If you are uncertain of how much memory to allocate for this array, see the Discussion.

oBreakCount

A pointer to an `ItemCount` value. On return, the value specifies the actual number of soft line breaks in the range of text. This may be greater than the value you specified in the `iMaximumBreaks` parameter.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The `ATSUGetSoftLineBreaks` function obtains the soft line breaks that are currently set in a given text range.

Typically you use the function `ATSUGetSoftLineBreaks` by calling it twice, as follows:

1. Pass valid values for the *`iTextLayout`*, *`iRangeStart`*, *`iRangeLength`*, and *`oBreakCount`* parameters. Pass `NULL` for the `oBreaks` parameter and 0 for the *`iMaximumBreaks`* parameter. On return, the value of the `oBreakCount` parameter specifies the number of items in the offset array.

2. Allocate enough space for an array of the appropriate size (number of items in the array multiplied by 4 bytes per item), then call the function again, passing a valid pointer in the `oBreaks` parameter. On return, the pointer refers to an array containing the text range's soft line breaks.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeDrawing.h`

ATSUGetStyleRefCon

Obtains application-specific data for a style object.

```
OSStatus ATSUGetStyleRefCon (
   ATSUStyle iStyle,
   URefCon *oRefCon
);
```

Parameters

`iStyle`
An `ATSUStyle` value specifying the style object for which to obtain application-specific data.

`oRefCon`
A pointer to a 32-bit value. On return, the value contains or refers to application-specific style data.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The `ATSUGetStyleRefCon` function obtains a reference constant (that is, application-specific data) associated with a style object. To associate a reference constant with a style object, call the function `ATSUSetStyleRefCon` (page 1961).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeObjects.h`

ATSUGetTabArray

Retrieves the tab ruler associated with a text layout object.

```
OSStatus ATSUGetTabArray (
   ATSUTextLayout iTextLayout,
   ItemCount iMaxTabCount,
   ATSUTab oTabs[],
   ItemCount *oTabCount
);
```

Parameters

iTextLayout

An `ATSUTextLayout` value specifying the text layout object whose tab ruler you want to obtain.

iMaxTabCount

The maximum number of tabs that can be written to the `iTabs` array.

oTabs[]

An array of `ATSUTab` values. On return, this array contains the current tab values in order of position along the line from left to right. Pass `NULL` if you want to retrieve the number of tabs, but not the tab values.

oTabCount

The number of tabs set for the text layout object.

Return Value

A result code. See "ATSUI Result Codes" (page 2068).

Discussion

This function can be used to retrieve all the tabs that were previously set for a text layout object, using the function `ATSUSetTabArray`. All the returned tabs will be in order of position along the line.Typically you use the `ATSUGetTabArray` function by calling it twice, as follows:

1. Pass `NULL` for the `oTabs` parameter, `0` for the *iMaxTabCount* parameter, and valid values for the other parameters. The `ATSUGetTabArray` function returns the actual number of tabs in the `oTabCount` parameter.

2. Allocate enough space for a buffer of the returned size, then call the function again, passing a valid pointer to the buffer in the `oTabs` parameter. On return, the buffer contains the tab values in order of position along the line from left to right.

Availability

Available in Mac OS X v10.2 and later.

Not available to 64-bit applications.

Declared In

`ATSUnicodeObjects.h`

ATSUGetTextHighlight

Obtains the highlight region for a range of text.

```
OSStatus ATSUGetTextHighlight (
   ATSUTextLayout iTextLayout,
   ATSUTextMeasurement iTextBasePointX,
   ATSUTextMeasurement iTextBasePointY,
   UniCharArrayOffset iHighlightStart,
   UniCharCount iHighlightLength,
   RgnHandle oHighlightRegion
);
```

Parameters

iTextLayout

An `ATSUTextLayout` value identifying the text layout object containing the text range.

iTextBasePointX

An `ATSUTextMeasurement` value specifying the x-coordinate of the origin (in either the current graphics port or in a Quartz graphics context) of the line containing the text range. Pass the constant `kATSUUseGrafPortPenLoc`, described in "Convenience Constants" (page 2043), to obtain the highlight region relative to the current pen location in the current graphics port.

iTextBasePointY

An `ATSUTextMeasurement` value specifying the y-coordinate of the origin (in either the current graphics port or graphics context) of the line containing the text range. Pass the constant `kATSUUseGrafPortPenLoc`, described in "Convenience Constants" (page 2043), to obtain the highlight region relative to the current pen location in the current graphics port.

iHighlightStart

A `UniCharArrayOffset` value specifying the offset from the beginning of the text buffer to the first character of the range. If the range of text spans multiple lines, you should call `ATSUGetTextHighlight` for each line, passing the offset corresponding to the beginning of the new line with each call. To indicate that the specified text range starts at the beginning of the text buffer, you can pass the constant `kATSUFromTextBeginning`. To specify the entire text buffer, pass `kATSUFromTextBeginning` in this parameter and `kATSUToTextEnd` in the `iHighlightLength` parameter.

iHighlightLength

A `UniCharCount` value specifying the length of the text range. If you want the text range to extend to the end of the text buffer, you can pass the constant `kATSUToTextEnd`.

oHighlightRegion

A valid `RgnHandle` value. On return, `ATSUGetTextHighlight` produces a `MacRegion` structure containing the highlight region for the specified range of text. In the case of discontinuous highlighting, the region consists of multiple components, with `MacRegion.rgnBBox` specifying the bounding box around the entire area of discontinuous highlighting.

Return Value

A result code. See "ATSUI Result Codes" (page 2068).

Discussion

The `ATSUGetTextHighlight` function obtains the highlight region for a range of text. To highlight text, call the function `ATSUHighlightText` (page 1931).

The `ATSUGetTextHighlight` function uses the previously set line ascent and descent values to calculate the height of the highlight region. If these values have not been set for the line, `ATSUGetTextHighlight` uses the line ascent and descent values set for the text layout object containing the line. If these are not set, it uses the default values.

Version Notes
When there are discontinuous highlighting regions, the structure produced in the `oHighlightRegion` parameter is made up of multiple components. In ATSUI 1.1, the maximum number of components that can be produced is 31. In ATSUI 1.2, the maximum number of components is 127.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeDrawing.h`

ATSUGetTextLayoutRefCon

Obtains application-specific data for a text layout object.

```
OSStatus ATSUGetTextLayoutRefCon (
   ATSUTextLayout iTextLayout,
   URefCon *oRefCon
);
```

Parameters

iTextLayout
An `ATSUTextLayout` value specifying the text layout object for which to obtain application-specific data.

oRefCon
A pointer to a 32-bit value. On return, the value contains or refers to application-specific text layout data.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The `ATSUGetTextLayoutRefCon` function obtains a reference constant (that is, application-specific data) associated with a text layout object. To associate a reference constant with a text layout object, call the function `ATSUSetTextLayoutRefCon` (page 1964).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeObjects.h`

ATSUGetTextLocation

Obtains information about the text associated with a text layout object.

```
OSStatus ATSUGetTextLocation (
   ATSUTextLayout iTextLayout,
   void **oText,
   Boolean *oTextIsStoredInHandle,
   UniCharArrayOffset *oOffset,
   UniCharCount *oTextLength,
   UniCharCount *oTextTotalLength
);
```

Parameters

iTextLayout

An `ATSUTextLayout` value specifying the text layout object to examine.

oText

A pointer to data of any type. On return, the pointer is set to either a pointer or a handle that refers to the text buffer for the specified text layout object.

oTextIsStoredInHandle

A pointer to a `Boolean` value. On return, the value is set to `true` if the text buffer in the `oText` parameter is accessed by a handle; if `false`, a pointer.

oOffset

A pointer to a `UniCharArrayOffset` value. On return, the value specifies the offset from the beginning of the text buffer to the first character of the layout's current text range.

oTextLength

A pointer to a `UniCharCount` value. On return, the value specifies the length of the text range.

oTextTotalLength

A pointer to a `UniCharCount` value. On return, the value specifies the length of the entire text buffer.

Return Value

A result code. See "ATSUI Result Codes" (page 2068).

Discussion

When you call the `ATSUGetTextLocation` function for a given text layout object, ATSUI obtains the location of the text layout object's associated text in physical memory, the length of the text range and its text buffer, and whether the text is accessed by a pointer or handle.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`ATSUnicodeObjects.h`

ATSUGetTransientFontMatching

Obtains whether ATSUI automatically performs font substitution for a text layout object.

```
OSStatus ATSUGetTransientFontMatching (
   ATSUTextLayout iTextLayout,
   Boolean *oTransientFontMatching
);
```

Parameters

iTextLayout

An `ATSUTextLayout` value specifying the text layout object to examine.

oTransientFontMatching

A pointer to a `Boolean` value. On return, the value indicates whether ATSUI performs automatic font substitution for the text layout object. If `true`, ATSUI automatically performs font substitution for the text range associated with the text layout object.

Return Value

A result code. See "ATSUI Result Codes" (page 2068).

Discussion

You can call the `ATSUGetTransientFontMatching` function to find out whether ATSUI automatically performs font substitution for a given text layout object when a character cannot be drawn with the assigned font. To turn automatic font substitution on or off for a text layout object, call the function `ATSUSetTransientFontMatching` (page 1967).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`ATSUnicodeObjects.h`

ATSUGetUnjustifiedBounds

Obtains the typographic bounding rectangle for a line of text prior to final layout.

```
OSStatus ATSUGetUnjustifiedBounds (
   ATSUTextLayout iTextLayout,
   UniCharArrayOffset iLineStart,
   UniCharCount iLineLength,
   ATSUTextMeasurement *oTextBefore,
   ATSUTextMeasurement *oTextAfter,
   ATSUTextMeasurement *oAscent,
   ATSUTextMeasurement *oDescent
);
```

Parameters

iTextLayout

An `ATSUTextLayout` value specifying the text layout object to examine.

iLineStart

A `UniCharArrayOffset` value specifying the offset from the beginning of the text buffer to the first character of the line. To indicate that the line starts at the beginning of the text buffer, you can pass the constant `kATSUFromTextBeginning`. To specify the entire text buffer, pass `kATSUFromTextBeginning` in this parameter and `kATSUToTextEnd` in the `iLineLength` parameter.

iLineLength

A `UniCharCount` value specifying the length of the line. If you want the line to extend to the end of the text buffer, you can pass the constant `kATSUToTextEnd`.

oTextBefore

A pointer to an `ATSUTextMeasurement` value. On return, the value specifies the starting point of the typographic bounds for the line, relative to the origin (0,0) of the line and taking into account cross-stream shifting. Note that the `ATSUMeasureText` function might produce negative values for the typographic starting point of the line if, for example, the initial character of the line is allowed to hang into the margin. For horizontal text, this value corresponds to the left side of the bounding rectangle.

oTextAfter

A pointer to an `ATSUTextMeasurement` value. On return, the value specifies the end point of the typographic bounds for the line, relative to the origin (0,0) of the line and taking into account cross-stream shifting. For horizontal text, this value corresponds to the right side of the bounding rectangle.

oAscent

A pointer to an `ATSUTextMeasurement` value. On return, the value specifies the ascent of the typographic bounds for the line, relative to the origin (0,0) of the line and taking into account cross-stream shifting. For horizontal text, this value corresponds to the top side of the bounding rectangle.

oDescent

A pointer to an `ATSUTextMeasurement` value. On return, the value specifies the descent of the typographic bounds for the line, relative to the origin (0,0) of the line and taking into account cross-stream shifting. For horizontal text, this value corresponds to the bottom side of the bounding rectangle.

Return Value

A result code. See "ATSUI Result Codes" (page 2068).

Discussion

There are two kinds of bounds that your application may typically want to obtain for a block of text: typographic bounds and image bounds. The image bounds define the smallest rectangle that completely encloses the filled or framed parts of a block of text—that is, the text's "inked" glyphs. Because of the potential differences in glyph height in a text block, your application may instead need to determine the typographic bounds. The typographic bounding rectangle contains the extra space above and below the image bounding rectangle where characters with ascenders or descenders would be drawn (even if none currently are).

The `ATSUGetUnjustifiedBounds` function calculates the typographic bounds (in coordinates independent of the rendering device) for a line of text. Note that `ATSUGetUnjustifiedBounds` calculates these bounds prior to the text's final layout, and therefore, the calculated bounds might not reflect those of the final laid-out line. To obtain the typographic bounds of a line after it is laid out, you can call the function `ATSUGetGlyphBounds` (page 1904).

The `ATSUGetUnjustifiedBounds` function ignores any previously set line attributes such as line rotation, flushness, justification, ascent, and descent in its calculations. You typically only call `ATSUGetUnjustifiedBounds` when you need to find out what the width of a line is without these attributes, such as for determining your own line breaks or the leading and line spacing to impose on a line.

The `ATSUGetUnjustifiedBounds` function treats the specified text range as a single line. That is, if the range of text you specify is less than a line, it nevertheless treats the initial character in the range as the start of a line, for measuring purposes. If the range of text extends beyond a line, `ATSUGetUnjustifiedBounds` ignores soft line breaks, again, treating the text as a single line.

Before calculating the typographic bounds for the text range, the `ATSUGetUnjustifiedBounds` function examines the text layout object to ensure that each of the characters in the range is assigned to a style run. If there are gaps between style runs, `ATSUGetUnjustifiedBounds` assigns the characters in the gap to the style run that precedes (in storage order) the gap. If there is no style run at the beginning of the text range, `ATSUGetUnjustifiedBounds` assigns these characters to the first style run it finds. If there is no style run at the end of the text range, `ATSUGetUnjustifiedBounds` assigns the remaining characters to the last style run it finds.

To obtain the image bounding rectangle of a laid-out line, call the function `ATSUMeasureTextImage` (page 1938).

Version Notes
As of ASTUI version 2.4, this function replaces the `ATSUMeasureText` function.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeDrawing.h`

ATSUGlyphGetCubicPaths

Obtains the cubic outline paths for a glyph.

```
OSStatus ATSUGlyphGetCubicPaths (
   ATSUStyle iATSUStyle,
   GlyphID iGlyphID,
   ATSCubicMoveToUPP iMoveToProc,
   ATSCubicLineToUPP iLineToProc,
   ATSCubicCurveToUPP iCurveToProc,
   ATSCubicClosePathUPP iClosePathProc,
   void *iCallbackDataPtr,
   OSStatus *oCallbackResult
);
```

Parameters

iATSUStyle
An `ATSUStyle` value specifying the style object to examine.

iGlyphID
A `GlyphID` value identifying the glyph for which to obtain an outline path.

iMoveToProc
A pointer to your callback function for handling the pen move-to operation.

iLineToProc
A pointer to your callback function for handling the line-to operation.

iCurveToProc
A pointer to your callback function for handling the curve-to operation.

iClosePathProc
A pointer to your callback function for handling the close-path operation.

iCallbackDataPtr

A pointer to any data your callback functions need. This pointer is passed through to your callback functions.

oCallbackResult

On output, a value that indicates the status of your callback function. When a callback function returns any value other than `0`, the `ATSGlyphGetCubicPaths` function stops parsing the glyph path outline and returns the result `kATSOutlineParseAbortedErr`.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The glyph outlines that are returned are the hinted outlines at the font size specified in the style object. If you want to use unhinted outlines, set the font size to a very large size, (for example, 1000 points) and then scale down the returned curves to the desired size.

As of Mac OS X version 10.1, the curves returned by this function are derived from quadratic curves, irrespective of the native curve type of the font.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeGlyphs.h`

ATSUGlyphGetCurvePaths

Obtains the outline paths for a glyph associated with a given style object.

```
OSStatus ATSUGlyphGetCurvePaths (
   ATSUStyle iATSUStyle,
   GlyphID iGlyphID,
   ByteCount *ioBufferSize,
   ATSUCurvePaths *oPaths
);
```

Parameters

iATSUStyle

An `ATSUStyle` value specifying the style object to examine.

iGlyphID

A `GlyphID` value identifying the glyph for which to obtain an outline path.

ioBufferSize

A pointer to a `ByteCount` value specifying the size of the buffer you have allocated for the `ATSUCurvePaths` structure in the *oPaths* parameter. On return, the value provides the actual size of buffer needed to contain the produced `ATSUCurvePaths` structure.

oPaths

A pointer to an `ATSUCurvePaths` structure. On return, the `ATSUCurvePaths` structure contains a value specifying the number of contours that comprise the glyph's outline, as well as an array of `ATSUCurvePath` structures, each of which defines a contour.

Return Value
A result code. See "ATSUI Result Codes" (page 2068). If the font is a protected font, returns `kATSUInvalidFontErr`.

Discussion
This function only returns quadratic paths. The glyph outlines that are returned are the hinted outlines at the font size specified in the style object. If you want to obtain unhinted outlines, set the font size to a very large size, (for example, 1000 points) and then scale down the returned curves to the desired size. More typically, however, you would use the functions `ATSUGlyphGetCubicPaths` (page 1925) and `ATSUGlyphGetQuadraticPaths` (page 1928) when drawing curves.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeGlyphs.h`

ATSUGlyphGetIdealMetrics

Obtains resolution-independent font metric information for glyphs associated with a given style object.

```
OSStatus ATSUGlyphGetIdealMetrics (
   ATSUStyle iATSUStyle,
   ItemCount iNumOfGlyphs,
   GlyphID iGlyphIDs[],
   ByteOffset iInputOffset,
   ATSGlyphIdealMetrics oIdealMetrics[]
);
```

Parameters

iATSUStyle
An `ATSUStyle` value specifying the style object to examine.

iNumOfGlyphs
An `ItemCount` value specifying the number of glyphs to examine. This value should be the same as the number of glyph IDs being passed in the *iGlyphIDs* parameter and the number of `ATSGlyphIdealMetrics` structures for which memory is allocated in the *oIdealMetrics* parameter.

iGlyphIDs
A pointer to the first `GlyphID` value in an array of glyph IDs. Each ID should identify a glyph for which to obtain font metric information.

iInputOffset
A `ByteOffset` value specifying the offset in bytes between glyph IDs in the *iGlyphIDs* array.

oIdealMetrics
A pointer to memory you have allocated for an array of `ATSGlyphIdealMetrics` structures. On return, each structure contains advance and side-bearing values for a glyph.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The advance width is the full horizontal width of the glyph as measured from its origin to the origin of the next glyph on the line, including the left-side and right-side bearings. For vertical text, the advance height is the sum of the top-side bearing, the bounding-box height, and the bottom-side bearing.

You can call the `ATSUGlyphGetIdealMetrics` function to obtain an array of `ATSGlyphIdealMetrics` structures containing values for the specified glyphs' advance and side bearings. `ATSUGlyphGetIdealMetrics` can analyze both horizontal and vertical text, automatically producing the appropriate bearing values (oriented for width or height, respectively) for each.

You should call `ATSUGlyphGetIdealMetrics` to obtain resolution-independent glyph metrics. To obtain device-adjusted (that is, resolution-dependent) glyph metrics, call the function `ATSUGlyphGetScreenMetrics` (page 1929).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeGlyphs.h`

ATSUGlyphGetQuadraticPaths

Obtains the quadratic outline paths for a glyph.

```
OSStatus ATSUGlyphGetQuadraticPaths (
   ATSUStyle iATSUStyle,
   GlyphID iGlyphID,
   ATSQuadraticNewPathUPP iNewPathProc,
   ATSQuadraticLineUPP iLineProc,
   ATSQuadraticCurveUPP iCurveProc,
   ATSQuadraticClosePathUPP iClosePathProc,
   void *iCallbackDataPtr,
   OSStatus *oCallbackResult
);
```

Parameters

iATSUStyle
An `ATSUStyle` value specifying the style object to examine.

iGlyphID
A `GlyphID` value identifying the glyph for which to obtain an outline path.

iNewPathProc
A pointer to your callback function for handling the new-path operation.

iLineProc
A pointer to your callback function for handling the line operation.

iCurveProc
A pointer to your callback function for handling the curve operation.

iClosePathProc
A pointer to your callback function for handling the close-path operation.

iCallbackDataPtr
A pointer to any data your callback functions need. This pointer is passed through to your callback functions.

oCallbackResult
On output, a value that indicates the status of your callback function. When a callback function returns any value other than 0, the ATSGlyphGetQuadraticPaths function stops parsing the path outline and returns the result kATSOutlineParseAbortedErr.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The glyph outlines that are returned are the hinted outlines at the font size specified in the style object. If you want to use unhinted outlines, set the font size to a very large size, (for example, 1000 points) and then scale down the returned curves to the desired size.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
ATSUnicodeGlyphs.h

ATSUGlyphGetScreenMetrics

Obtains device-adjusted font metric information for glyphs associated with a given style object.

```
OSStatus ATSUGlyphGetScreenMetrics (
   ATSUStyle iATSUStyle,
   ItemCount iNumOfGlyphs,
   GlyphID iGlyphIDs[],
   ByteOffset iInputOffset,
   Boolean iForcingAntiAlias,
   Boolean iAntiAliasSwitch,
   ATSGlyphScreenMetrics oScreenMetrics[]
);
```

Parameters

iATSUStyle
An ATSUStyle value specifying the style object to examine.

iNumOfGlyphs
An ItemCount value specifying the number of glyphs to examine. This value should be the same as the number of glyph IDs being passed in the *iGlyphIDs* parameter and the number of ATSGlyphScreenMetrics structures for which memory is allocated in the *oScreenMetrics* parameter.

iGlyphIDs
A pointer to the first GlyphID value in an array of glyph IDs. Each ID should identify a glyph for which to obtain font metric information.

iInputOffset
A ByteOffset value specifying the offset in bytes between glyph IDs in the *iGlyphIDs* array.

iForcingAntiAlias
A Boolean value indicating whether anti-aliasing is forced for the style object.

iAntiAliasSwitch
A Boolean value indicating whether anti-aliasing is currently on or off.

oScreenMetrics

A pointer to memory you have allocated for an array of `ATSGlyphScreenMetrics` structures. On return, each structure contains device-adjusted metrics for a glyph, including advance and side bearings, but also values for the top left, height, and width of the glyph.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
You can call the `ATSUGlyphGetScreenMetrics` function to obtain an array of `ATSGlyphScreenMetrics` structures containing values for the specified glyphs' advance and side bearings, top left, height, and width.

You should call `ATSUGlyphGetScreenMetrics` to obtain device-adjusted (that is, resolution-dependent) glyph metrics. To obtain resolution-independent glyph metrics, call the function `ATSUGlyphGetIdealMetrics` (page 1927).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeGlyphs.h`

ATSUHighlightInactiveText

Highlights previously selected text using an alpha value of 0.5.

```
OSStatus ATSUHighlightInactiveText (
   ATSUTextLayout iTextLayout,
   ATSUTextMeasurement iTextBasePointX,
   ATSUTextMeasurement iTextBasePointY,
   UniCharArrayOffset iHighlightStart,
   UniCharCount iHighlightLength
);
```

Parameters

iTextLayout

An `ATSUTextLayout` value identifying the text layout object containing the text range.

iTextBasePointX

An `ATSUTextMeasurement` value specifying the x-coordinate of the origin (in either the current graphics port or in a Quartz graphics context) of the line containing the text range. Pass the constant `kATSUUseGrafPortPenLoc`, described in "Convenience Constants" (page 2043), to obtain the highlight region relative to the current pen location in the current graphics port.

iTextBasePointY

An `ATSUTextMeasurement` value specifying the y-coordinate of the origin (in either the current graphics port or graphics context) of the line containing the text range. Pass the constant `kATSUUseGrafPortPenLoc`, described in "Convenience Constants" (page 2043), to obtain the highlight region relative to the current pen location in the current graphics port.

iHighlightStart

A `UniCharArrayOffset` value specifying the offset from the beginning of the text buffer to the first character of the range. If the range of text spans multiple lines, you should call `ATSUGetTextHighlight` for each line, passing the offset corresponding to the beginning of the new line with each call. To indicate that the specified text range starts at the beginning of the text buffer, you can pass the constant `kATSUFromTextBeginning`. To specify the entire text buffer, pass `kATSUFromTextBeginning` in this parameter and `kATSUToTextEnd` in the `iHighlightLength` parameter.

iHighlightLength

A `UniCharCount` value specifying the length of the text range. If you want the text range to extend to the end of the text buffer, you can pass the constant `kATSUToTextEnd`.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeDrawing.h`

ATSUHighlightText

Renders a highlighted range of text at a specified location in a QuickDraw graphics port or Quartz graphics context.

```
OSStatus ATSUHighlightText (
   ATSUTextLayout iTextLayout,
   ATSUTextMeasurement iTextBasePointX,
   ATSUTextMeasurement iTextBasePointY,
   UniCharArrayOffset iHighlightStart,
   UniCharCount iHighlightLength
);
```

Parameters

iTextLayout

An `ATSUTextLayout` value identifying the text layout object for which to render highlighted text.

iTextBasePointX

An `ATSUTextMeasurement` value specifying the x-coordinate of the origin (in either the current graphics port or in a Quartz graphics context) of the line containing the text range to highlight. Pass the constant `kATSUUseGrafPortPenLoc`, described in "Convenience Constants" (page 2043), to draw relative to the current pen location in the current graphics port.

iTextBasePointY

An `ATSUTextMeasurement` value specifying the y-coordinate of the origin (in either the current graphics port or graphics context) of the line containing the text range to highlight. Pass the constant `kATSUUseGrafPortPenLoc`, described in "Convenience Constants" (page 2043), to draw relative to the current pen location in the current graphics port.

iHighlightStart

A UniCharArrayOffset value specifying the offset from the beginning of the text buffer to the first character of the range to highlight. If the range of text spans multiple lines, you should call ATSUHighlightText for each line, passing the offset corresponding to the beginning of the new line to draw with each call. To indicate that the specified text range starts at the beginning of the text buffer, you can pass the constant kATSUFromTextBeginning. To specify the entire text buffer, pass kATSUFromTextBeginning in this parameter and kATSUToTextEnd in the iHighlightLength parameter.

iHighlightLength

A UniCharCount value specifying the length of the text range to highlight. If you want the range of text to extend to the end of the text buffer, you can pass the constant kATSUToTextEnd.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
When the user selects a series of glyphs, the characters in memory corresponding to the glyphs make up the selection range and should be highlighted to indicate where the next editing operation is to occur. The characters in a selection range are always contiguous in memory, but their corresponding glyphs are not necessarily so onscreen. If the selection range crosses a direction boundary, it is appropriate to display discontinuous highlighting.

The ATSUHighlightText function renders a highlighted range of text at a specified location in a QuickDraw graphics port or Quartz graphics context, using the highlight information in the graphics port or context. ATSUHighlightText automatically produces discontinuous highlighting, if needed. You typically call the ATSUHighlightText function every time you need to draw or redraw highlighted text.

If you provide your own CGContextRef (for example, one created by calling the function QDBeginCGContext) for an ATSUTextLayout, highlighting performed by calling the function ATSUHighlightText will not work unless you first call the function ATSUSetHighlightingMethod with the *iMethod* parameter set to kRedrawHighlighting and a pointer to an ATSUUnhighlightData structure as the iUnhighlightData parameter.

Before drawing the highlighted text, ATSUHighlightText examines the text layout object to ensure that each of the characters in the range is assigned to a style run. If there are gaps between style runs, ATSUI assigns the characters in the gap to the style run that precedes (in storage order) the gap. If there is no style run at the beginning of the text range, ATSUI assigns these characters to the first style run it finds. If there is no style run at the end of the text range, ATSUI assigns the remaining characters to the last style run it finds.

ATSUHighlightText uses the previously set line ascent and descent values to calculate the height of the highlighted region. If these values have not been set for the line, ATSUHighlightText uses the line ascent and descent values set for the text layout object containing the line. If these are not set, it uses the default values.

To draw a highlighted text range that spans multiple lines, you should call ATSUHighlightText for each line of the text range, even if all the lines are in the same text layout object. You should adjust the iHighlightStart parameter to reflect the beginning of each line to be drawn.

After calling ATSUHighlightText, to properly redraw the unhighlighted text and background, you should always call the function ATSUUnhighlightText (page 1974).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
ATSUnicodeDrawing.h

ATSUIdle

Performs background processing. (Deprecated in Mac OS X v10.0. There is no replacement because this function does nothing in Mac OS X.)

Not recommended.

```
OSStatus ATSUIdle (
   ATSUTextLayout iTextLayout
);
```

Parameters

iTextLayout

A reference to the text layout object in which you want ATSUI to perform background processing.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The function ATSUIdle is not recommended. Current versions of ATSUI do not implement background processing for text layout objects. In Mac OS X, the function ATSUIdle does nothing.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.0.
Not available to 64-bit applications.

Declared In
ATSUnicodeObjects.h

ATSULeftwardCursorPosition

Obtains the memory offset for the insertion point to the left of the high caret position, as determined by a move of the specified length at a line direction boundary.

```
OSStatus ATSULeftwardCursorPosition (
   ATSUTextLayout iTextLayout,
   UniCharArrayOffset iOldOffset,
   ATSUCursorMovementType iMovementType,
   UniCharArrayOffset *oNewOffset
);
```

Parameters

iTextLayout

An ATSUTextLayout value identifying the text layout object to examine.

iOldOffset

A `UniCharArrayOffset` value specifying the memory offset corresponding to the current caret position. To specify the beginning of the text buffer, pass the constant `kATSUFromTextBeginning`. For bidirectional text, you can specify the previous layout by passing the constant `kATSUFromPreviousLayout` and the following layout by passing the constant `kATSUFromFollowingLayout`. See the Discussion for example code that shows how to use these constants.

iMovementType

An `ATSUCursorMovementType` constant identifying the unit of movement. See "Caret Movement Types" (page 2042) for a description of possible values (which range from a single Unicode character to a Unicode word in length). Note that ATSUI may not be able to move the caret by a single Unicode character in some cases, since doing so might place the insertion point in the middle of a surrogate pair.

oNewOffset

A pointer to a `UniCharArrayOffset` value. On return, the value provides the memory offset corresponding to the new insertion point. This offset may be outside the initial text buffer.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
Line direction boundaries can occur on the trailing edges of two glyphs, the leading edges of two glyphs, or at the beginning or end of a text segment. At direction boundaries, a single insertion point in memory can require two caret positions onscreen, one for text entry in each direction. The two separate carets (known as a split caret or a dual caret) consist of a high caret and a low caret. The high (primary) caret is displayed at the caret position for inserting text whose direction corresponds to the line direction (the dominant direction for the overall line of text). The low (secondary) caret is displayed at the caret position for inserting text whose direction is counter to the overall line direction.

The `ATSURightwardCursorPosition` function obtains the memory offset for the insertion point to the left of the high caret position, as determined by a move of the specified length at a line direction boundary.

You should use the `ATSULeftwardCursorPosition` function or the function `ATSURightwardCursorPosition` (page 1949) to determine caret position when the user presses the right and left arrow keys.

Except in the case of Indic text (and other cases where the font rearranges the glyphs), for left-to-right text, calling the function `ATSULeftwardCursorPosition` has the same effect as calling `ATSUPreviousCursorPosition` (page 1948). For right-to-left text, calling the function `ATSULeftwardCursorPosition` has the same effect as calling `ATSUNextCursorPosition` (page 1940).

The following code shows how to use the constants `kATSUFromPreviousLayout` and `kATSUFromFollowingLayout` with the function `ATSULeftwardCursorPosition`:

```
typedef struct TLayoutWithEndOffset
{
    ATSUTextLayout      layout;
    UInt32              endOffset;
};

typedef struct TLayoutsWithEndOffsets
{
    UInt32                  count;
    TLayoutWithEndOffset    layouts[];
}
```

```
UniCharArrayOffset MyAbsoluteToRelativeOffset (
                TLayoutsWithEndOffsets * iLayouts,
                UniCharArrayOffset iAbsoluteOffset );
UniCharArrayOffset MyRelativeToAbsoluteOffset (
                TLayoutsWithEndOffsets * iLayouts,
                UInt32 iLayoutIndex,
                UniCharArrayOffset iRelativeOffset );
UniCharArrayOffset MyGetLayoutEndOffset (
                TLayoutsWithEndOffsets * iLayouts,
                UInt32 iLayoutIndex );

/* Passing in current offset relative to the beginning of */
/* the entire text buffer (absolute), */
/* not just the current paragraph. This returns the new (absolute)  */
/* offset relative to the beginning of the entire text buffer.*/
UniCharArrayOffset
MyLeftwardCursorPosition ( TLayoutsWithEndOffsets * iLayouts,
                    UInt32 iLayoutIndex,
                    UniCharArrayOffset iAbsoluteOffset,
                    ATSUCursorMovementType iType )
{
    OSStatus            status;
    UInt32              newLayoutIndex = iLayoutIndex;
    UniCharArrayOffset  newRelativeOffset;

    status = ATSULeftwardCursorPosition(
                iLayouts->layouts[iLayoutIndex].layout,
                MyAbsoluteToRelativeOffset (iLayouts, iAbsoluteOffset  ),
                iType, &newRelativeOffset );

    if ( status == noErr )
    {
        /* If the API returns the same value as */
        /* that passed in then we're at */
        /* the edge of the layout so need to move */
        /* to the adjacent layout. f */
        /* If that value is zero then we're moving to the previous  layout. */
        /* (This is left-to-right text.) */
        if ( (newRelativeOffset == iRelativeOffset) &&
                (iRelativeOffset == 0) )
        {
            /* Don't want to move before the first layout! */
            if ( iLayoutIndex != 0 )
            {
                /* Pass kATSUFromFollowingLayout to the previous  */
                /* ATSUTextLayout. */
                /* Note that the returned offset is relative to
                /* the ATSUTextLayout passed in here.*/
                newLayoutIndex--;
                status = ATSULeftwardCursorPosition(
                            iLayouts[newLayoutIndex],
                            kATSUFromFollowingLayout,
                            iType &newRelativeOffset );
            }
        }
        else
        {
```

```
            UniCharArrayOffset  endAbsoluteOffset = MyGetLayoutEndOffset(
                            iLayouts, iLayoutIndex );

            /* We've moved to the very end of this layout */
            /* (past the trailing carriage return presumably) */
            /* so we're moving to the following layout. */
            /* Make sure we aren't at the */
            /* end of the text buffer. (This is right-to-left text.)  */
            if ( (newRelativeOffset == MyAbsoluteToRelativeOffset  (
                        iLayouts, endAbsoluteOffset )) &&
                       (iLayoutIndex != iLayouts->count) )
            {
                newLayoutIndex++;
                status = ATSULeftwardCursorPosition(
                            iLayouts->layouts[newLayoutIndex],
                            kATSUFromPreviousLayout, iType,
                            &newRelativeOffset );

                /* If we're moving from one paragraph to the following  one */
                /* and we aren't at the beginning of the layout  means
                /* that we're moving to a left-to-right */
                /* paragraph and we must back up one so that*/
                /* we're just before the line ending whitespace
                /* (space or <CR>), unless the */
                /* following layout is the last one. */
                if ( (newRelOffset > 0) && (newLayoutIndex  !=
                         iLayouts->count) )
                    newRelativeOffset--;
            }
        }
    }
    return MyRelativeToAbsoluteOffset( iLayouts, newLayoutIndex,
                        newRelativeOffset );
}
```

ATSUMatchFontsToText

Examines a text range for characters that cannot be drawn with the current font and suggests a substitute font, if necessary.

```
OSStatus ATSUMatchFontsToText (
   ATSUTextLayout iTextLayout,
   UniCharArrayOffset iTextStart,
   UniCharCount iTextLength,
   ATSUFontID *oFontID,
   UniCharArrayOffset *oChangedOffset,
   UniCharCount *oChangedLength
);
```

Parameters

iTextLayout

An `ATSUTextLayout` value specifying the text layout object to examine.

iTextStart

A `UniCharArrayOffset` value specifying the offset from the beginning of the text layout object's text buffer to the first character of the range to examine. To start at the beginning of the text buffer, pass the constant `kATSUFromTextBeginning`.

iTextLength

A `UniCharCount` value specifying the length of the text range to examine. If you want the range of text to extend to the end of the text buffer, you can pass the constant `kATSUToTextEnd`.

oFontID

A pointer to a `ATSUFontID` value. On return, the value provides a font ID for the suggested substitute font or `kATSUInvalidFontID`, if no substitute font is available.

oChangedOffset

A pointer to a `UniCharArrayOffset` value. On return, this value specifies the offset from the beginning of the text buffer to the first character that cannot be drawn with the current font.

oChangedLength

A pointer to a `UniCharCount` value. On return, this value specifies the length of the text range that cannot be drawn with the current font.

Return Value

A result code. See "ATSUI Result Codes" (page 2068). The result code `noErr` indicates that all the characters in the given range can be rendered with their current font(s) and no font substitution is needed. If you receive either of the result codes `kATSUFontsMatched` or `kATSUFontsNotMatched`, you should update the input range and call `ATSUMatchFontsToText` again to ensure that all the characters in the range can be drawn.

Discussion

When you call the `ATSUMatchFontsToText` function, ATSUI scans the given range of text for characters that cannot be drawn with the currently assigned font. When ATSUI finds such a character, it identifies a substitute font for drawing the character. ATSUI then continues scanning the text range for subsequent characters that cannot be drawn, stopping when it

- finds a character that can be drawn with the currently assigned font, or
- finds a character that cannot be drawn with either the currently assigned font or the substitute font, or
- reaches the end of the text range you have specified

ATSUI's default behavior for finding a substitute font is to recommend the first valid font that it finds when scanning the fonts in the user's system. ATSUI first searches in the standard application fonts for various languages. If that fails, ATSUI searches through the remaining fonts on the system in the order in which the Font Manager returns the fonts. After ATSUI has searched all the fonts in the system, any unmatched text is drawn using the last-resort font. That is, missing glyphs are represented by and empty box to indicate to the

user that a valid font for that character is not installed on their system. You can alter ATSUI's default search behavior by calling the function `ATSUCreateFontFallbacks` (page 1864) and defining your own font fallback settings for the text layout object.

So, for example, if the subrange of text for which you wanted to perform font substitution was the text "abcde", and the characters 'c' and 'd' could not be drawn with the current font, but could be drawn with font X, and the character 'e' either could be drawn with the current font or could not be drawn with font X, then `ATSUMatchFontsToText` produces the ID of font X in the `oFont` parameter and sets the `oChangedOffset` parameter to 2 and the `oChangedLength` parameter to 2.

Because ATSUI does not necessarily completely scan the text range you specify with each call to `ATSUMatchFontsToText`, if ATSUI does find any characters that cannot be rendered with their current font, you should call `ATSUMatchFontsToText` again and update the input range to check that all the subsequent characters in the range can be drawn. For that reason, you should call `ATSUMatchFontsToText` from within a loop to assure that the entire range of text is checked.

Note that calling `ATSUMatchFontsToText` does not cause the suggested font substitution to be performed. If you want ATSUI to perform font substitution for you, you can call the function `ATSUSetTransientFontMatching` (page 1967).

ATSUMeasureTextImage

Obtains the image bounding rectangle for a line of text after final layout.

```
OSStatus ATSUMeasureTextImage (
   ATSUTextLayout iTextLayout,
   UniCharArrayOffset iLineOffset,
   UniCharCount iLineLength,
   ATSUTextMeasurement iLocationX,
   ATSUTextMeasurement iLocationY,
   Rect *oTextImageRect
);
```

Parameters

iTextLayout

An `ATSUTextLayout` value specifying the text layout object to examine.

iLineOffset

A `UniCharArrayOffset` value specifying the offset from the beginning of the text buffer to the first character of the line to examine. To indicate that the specified line starts at the beginning of the text buffer, you can pass the constant `kATSUFromTextBeginning`. To specify the entire text buffer, pass `kATSUFromTextBeginning` in this parameter and `kATSUToTextEnd` in the `iLineLength` parameter.

iLineLength

A `UniCharCount` value specifying the length of the text range. If you want the range of text to extend to the end of the text buffer, you can pass the constant `kATSUToTextEnd`. However, the image bounds is restricted to the line in which `iLineOffset` resides.

iLocationX

An `ATSUTextMeasurement` value specifying the x-coordinate of the line's origin in the current graphics port or Quartz graphics context. Pass the constant `kATSUUseGrafPortPenLoc`, described in "Convenience Constants" (page 2043), for the dimensions of the bounds relative to the current pen location in the current graphics port or graphics context. You can pass `0` to obtain only the dimensions of the bounding rectangle relative to one another, not their actual onscreen position.

iLocationY

An `ATSUTextMeasurement` value specifying the y-coordinate of the line's origin in the current graphics port or Quartz graphics context. Pass the constant `kATSUUseGrafPortPenLoc`, described in "Convenience Constants" (page 2043), for the dimensions of the bounds relative to the current pen location in the current graphics port or graphics context. You can pass `0` to obtain only the dimensions of the bounding rectangle relative to one another, not their actual onscreen position.

oTextImageRect

A pointer to a `Rect` structure. On return, the structure contains the dimensions of the image bounding rectangle for the text, offset by the values specified in the `iLocationX` and `iLocationY` parameters. If the line is rotated, the sides of the rectangle are parallel to the coordinate axis.

Return Value

A result code. See "ATSUI Result Codes" (page 2068).

Discussion

The `ATSUMeasureTextImage` function obtains the image bounds of a laid-out line of text. These bounds are described by the smallest rectangle that completely encloses the filled or framed parts of a block of text—that is, the text's "inked" glyphs.

In measuring the line, the `ATSUMeasureTextImage` function takes into account line rotation, alignment, and justification, as well as other characteristics that affect layout, such as hanging punctuation. (If the line is rotated, the sides of the rectangle are parallel to the coordinate axes and encompass the rotated line.) If no attributes are set for the line, `ATSUMeasureTextImage` uses the global attributes set for the text layout object.

Because the height of the image bounding rectangle is determined by the actual device metrics, `ATSUMeasureTextImage` ignores any previously set line ascent and descent values for the line it is measuring.

Before calculating the image bounds for the text range, the `ATSUMeasureTextImage` function examines the text layout object to ensure that each of the characters in the range is assigned to a style run. If there are gaps between style runs, `ATSUMeasureTextImage` assigns the characters in the gap to the style run that precedes (in storage order) the gap. If there is no style run at the beginning of the text range, the `ATSUMeasureTextImage` function assigns these characters to the first style run it finds. If there is no style run at the end of the text range, `ATSUMeasureTextImage` assigns the remaining characters to the last style run it finds.

To obtain the final typographic bounds of a line, call the function `ATSUGetGlyphBounds` (page 1904). To calculate the unjustified typographic bounds of a line, call the function `ATSUGetUnjustifiedBounds` (page 1923).

`ATSUnicodeDrawing.h`

ATSUNextCursorPosition

Obtains the memory offset for the insertion point that follows the current insertion point in storage order, as determined by a move of the specified length.

```
OSStatus ATSUNextCursorPosition (
   ATSUTextLayout iTextLayout,
   UniCharArrayOffset iOldOffset,
   ATSUCursorMovementType iMovementType,
   UniCharArrayOffset *oNewOffset
);
```

Parameters

iTextLayout
An `ATSUTextLayout` value identifying the text layout object to examine.

iOldOffset
A `UniCharArrayOffset` value specifying the memory offset corresponding to the current caret position. To specify the beginning of the text buffer, pass the constant `kATSUFromTextBeginning`.

iMovementType
An `ATSUCursorMovementType` constant identifying the unit of movement. See "Caret Movement Types" (page 2042) for a description of possible values (which range from a single Unicode character to a Unicode word in length). Note that ATSUI may not be able to move the caret by a single Unicode character in some cases, since doing so might place the insertion point in the middle of a surrogate pair.

oNewOffset
A pointer to a `UniCharArrayOffset` value. On return, the value provides the memory offset corresponding to the following insertion point. This offset may be outside the initial text buffer.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The `ATSUNextCursorPosition` function obtains the memory offset for the insertion point that follows the current insertion point in storage order, as determined by a move of the specified length.

You should use the `ATSUNextCursorPosition` function or the function `ATSUPreviousCursorPosition` (page 1948) to determine caret position when the initial memory offset is not at a line direction boundary. If the initial offset is at a line direction boundary, you should instead use the functions `ATSURightwardCursorPosition` (page 1949) or `ATSULeftwardCursorPosition` (page 1933).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeDrawing.h`

ATSUOffsetToCursorPosition

Obtains the caret position(s) corresponding to a memory offset, after a move of the specified length.

```
OSStatus ATSUOffsetToCursorPosition (
   ATSUTextLayout iTextLayout,
   UniCharArrayOffset iOffset,
   Boolean iIsLeading,
   ATSUCursorMovementType iMovementType,
   ATSUCaret *oMainCaret,
   ATSUCaret *oSecondCaret,
   Boolean *oCaretIsSplit
);
```

Parameters

iTextLayout
An `ATSUTextLayout` value identifying the text layout object to examine.

iOffset
A `UniCharArrayOffset` value specifying the memory offset corresponding to the glyph edge nearest the event, after a movement of the specified type. You can obtain this value by examining the offset produced in the `ioPrimaryOffset` parameter of the function `ATSUPositionToCursorOffset` (page 1945).

iIsLeading
A `Boolean` value indicating whether the specified offset corresponds to the leading or trailing edge of the glyph. You can obtain this information from the function `ATSUPositionToCursorOffset` (page 1945). This value is relevant if the offset occurs at a line direction boundary or within a glyph cluster.

iMovementType
An `ATSUCursorMovementType` constant identifying the unit of cursor movement. See "Caret Movement Types" (page 2042) for a description of possible values (which range from a single Unicode character to a Unicode word in length). Note that ATSUI may not be able to move the cursor by a single Unicode character in some cases, since doing so might place the cursor in the middle of a surrogate pair.

oMainCaret
A pointer to an `ATSUCaret` structure. On return, the structure contains the starting and ending pen locations of the high caret if the value produced in the `oCaretIsSplit` parameter is `true`. If the value is `false`, the structure contains the starting and ending pen locations of the main caret.

oSecondCaret

A pointer to an `ATSUCaret` structure. On return, the structure contains the starting and ending pen locations of the low caret if the value passed back in the `oCaretIsSplit` parameter is `true`. If the value is `false`, the structure contains the starting and ending pen locations of the main caret (that is, the same values as the `oMainCaret` parameter).

oCaretIsSplit

A pointer to a `Boolean` value. On return, the value indicates whether the offset specified in the `iOffset` parameter occurs at a line direction boundary. If `true`, the offset occurs at a line direction boundary; otherwise, `false`.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeDrawing.h`

ATSUOffsetToPosition

Obtains the caret position(s) corresponding to a memory offset.

```
OSStatus ATSUOffsetToPosition (
   ATSUTextLayout iTextLayout,
   UniCharArrayOffset iOffset,
   Boolean iIsLeading,
   ATSUCaret *oMainCaret,
   ATSUCaret *oSecondCaret,
   Boolean *oCaretIsSplit
);
```

Parameters

iTextLayout

An `ATSUTextLayout` value identifying the text layout object to examine.

iOffset

A `UniCharArrayOffset` value specifying the memory offset for which to obtain the corresponding caret position. To respond to a mouse-down event, pass the offset produced in the `ioPrimaryOffset` parameter of the function `ATSUPositionToOffset` (page 1946)—that is, the offset corresponding to the glyph edge closest to the event.

iIsLeading

A `Boolean` value indicating whether the offset corresponds to the leading or trailing edge of the glyph. You can obtain this information from the function `ATSUPositionToOffset` (page 1946). This value is relevant if the offset occurs at a line direction boundary or within a glyph cluster.

oMainCaret

A pointer to an `ATSUCaret` structure. On return, the structure contains the starting and ending pen locations of the high caret if the value produced in `oCaretIsSplit` is `true`. If the value is `false`, the structure contains the starting and ending pen locations of the main caret.

oSecondCaret

A pointer to an `ATSUCaret` structure. On return, the structure contains the starting and ending pen locations of the low caret if the value passed back in the `oCaretIsSplit` parameter is `true`. If the value is `false`, the structure contains the starting and ending pen locations of the main caret (that is, the same values as the `oMainCaret` parameter).

oCaretIsSplit

A pointer to a `Boolean` value. On return, the value indicates whether the offset specified in the `iOffset` parameter occurs at a line direction boundary. If `true`, the offset occurs at a line direction boundary; otherwise, `false`.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The process of hit-testing text obtains the location of a mouse-down event relative both to the position of onscreen glyphs and to the corresponding offset between character codes in memory. You can then use the location information obtained by hit-testing to set the insertion point (that is, the caret) or selection range (for highlighting).

Hit-testing text is complicated by the fact that a given line of text may be bidirectional. Therefore, the onscreen order of glyphs may not readily correspond to the storage order of the corresponding character codes. And the concept of which glyph comes "first" in a line of text cannot always be limited to the visual terms "left" and "right." Because of these complexities, it is more accurate to speak in terms of "leading" and "trailing" edges to glyphs. A "leading edge" is defined as the edge of a glyph that you first encounter when you read the text that includes that glyph. For example, when reading Roman text, you first encounter the left edge of a Roman glyph. Similarly, the "trailing edge" is defined as the edge of the glyph encountered last.

ATSUI can translate the location of a mouse click into an onscreen position, as well as to a memory offset. When you use ATSUI for hit-testing, ATSUI takes into account the glyph edge (whether leading or trailing) nearest to where the click occurred, thus providing positional information in complex situations, such as at line direction boundaries or within glyph clusters.

Line direction boundaries can occur on the trailing edges of two glyphs, the leading edges of two glyphs, or at the beginning or end of a text segment. At direction boundaries, a single insertion point in memory can require two caret positions onscreen, one for text entry in each direction. The two separate carets (known as a split caret or a dual caret) consist of a high caret and a low caret. The high (primary) caret is displayed at the caret position for inserting text whose direction corresponds to the line direction (the dominant direction for the overall line of text). The low (secondary) caret is displayed at the caret position for inserting text whose direction is counter to the overall line direction.

The first step in obtaining the caret position(s) for a mouse-down event is to pass the location (in local coordinates, relative to the line origin) of the event to the function `ATSUPositionToOffset` (page 1946). The `ATSUPositionToOffset` function produces the memory offset corresponding to the glyph edge nearest the event. If the mouse-down event occurs at a line direction boundary or within a glyph cluster, the `ATSUPositionToOffset` function produces two offsets. You can then provide the offset(s) to the `ATSUOffsetToPosition` function, to obtain the actual caret position(s) for the event.

The `ATSUOffsetToPosition` function produces two structures of type `ATSUCaret`. These structures contain the pen positioning information needed to draw the caret(s) for the event, specified relative to the origin of the line in the current graphics port or graphics context. Specifically, the `ATSUCaret` structures contain x-y coordinates for both the caret's starting and ending pen positions (the latter taking into account line rotation, caret slanting, and split-caret appearances).

If the memory offset you pass to `ATSUOffsetToPosition` is at a line boundary, the structure produced in the `oMainCaret` parameter contains the starting and ending pen locations for the high caret, while the `oSecondCaret` parameter contains the corresponding values for the low caret. If the offset is not at a line boundary, both parameters contain the starting and ending pen locations of the main caret.

Because you provide the `ATSUOffsetToPosition` function an offset relative to the origin of the line where the hit occurred, `ATSUOffsetToPosition` produces positioning information that is also relative. Therefore, you must transform the positions produced by the `ATSUOffsetToPosition` function before drawing the caret(s). To transform the caret location(s), add the starting and ending caret coordinates to the coordinates of the origin of the line in which the hit occurred. For example, if `ATSUOffsetToPosition` produces starting and ending pen locations of (25,0), (25,25) in the `oMainCaret` parameter (and the `oSecondCaret` parameter contains the same coordinates, meaning that the caret was not split), you would add these to the position of the origin of the line in the graphics port or context. If the position of the line origin was at (50,50), then the starting and ending pen locations of the caret would be (75,50), (75,75).

Availability

`ATSUnicodeDrawing.h`

ATSUOverwriteAttributes

Copies to a destination style object the nondefault style attribute settings of a source style object.

```
OSStatus ATSUOverwriteAttributes (
   ATSUStyle iSourceStyle,
   ATSUStyle iDestinationStyle
);
```

Parameters

`iSourceStyle`
An `ATSUStyle` value specifying the style object from which to copy nondefault style attributes.

`iDestinationStyle`
An `ATSUStyle` value specifying the style object containing the style attributes to be overwritten.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The `ATSUOverwriteAttributes` function copies all nondefault style attribute values from a source style object to a destination style object. The source object's nondefault values are applied to the destination object whether or not the destination object also has nondefault values for the copied attributes. All other settings in the destination style object are left unchanged.

`ATSUOverwriteAttributes` does not copy the contents of memory referenced by pointers within custom style attributes or within reference constants. You are responsible for ensuring that this memory remains valid until both the source and destination style objects are disposed of.

To create a style object that contains all the contents of another style object, call the function `ATSUCreateAndCopyStyle` (page 1863). To copy all the style attributes (including any default settings) of a style object into an existing style object, call the function `ATSUCopyAttributes` (page 1856). To copy style attributes that are set in the source but not in the destination style object, call the function `ATSUUnderwriteAttributes` (page 1972).

ATSUPositionToCursorOffset

Obtains the memory offset for the glyph edge nearest a mouse-down event, after a move of the specified length.

```
OSStatus ATSUPositionToCursorOffset (
   ATSUTextLayout iTextLayout,
   ATSUTextMeasurement iLocationX,
   ATSUTextMeasurement iLocationY,
   ATSUCursorMovementType iMovementType,
   UniCharArrayOffset *ioPrimaryOffset,
   Boolean *oIsLeading,
   UniCharArrayOffset *oSecondaryOffset
);
```

Parameters

iTextLayout
An `ATSUTextLayout` value identifying the text layout object in which the mouse-down event occurred.

iLocationX
An `ATSUTextMeasurement` value specifying the x-coordinate of the event, in local coordinates, relative to the origin of the line where the event occurred. That is, to specify the x-coordinate value, you should subtract the x-coordinate of the line origin from the x-coordinate of the event (in local coordinates). You can pass the constant `kATSUUseGrafPortPenLoc`, described in "Convenience Constants" (page 2043), for the location of the mouse-down event relative to the current pen location in the current graphics port.

iLocationY
An `ATSUTextMeasurement` value specifying the y-coordinate of the event, in local coordinates, relative to the origin of the line where the event occurred. That is, to specify the y-coordinate value, you should subtract the y-coordinate of the line origin from the y-coordinate of the event (in local coordinates). You can pass the constant `kATSUUseGrafPortPenLoc`, described in "Convenience Constants" (page 2043), for the location of the mouse-down event relative to the current pen location in the current graphics port.

iMovementType
An `ATSUCursorMovementType` constant identifying the unit of movement. See "Caret Movement Types" (page 2042) for a description of possible values (which range from a single Unicode character to a Unicode word in length). Note that ATSUI may not be able to move the caret by a single Unicode character in some cases, since doing so might place the insertion point in the middle of a surrogate pair.

ioPrimaryOffset

A pointer to a `UniCharArrayOffset` value specifying the offset corresponding to the beginning of the line where the event occurred. On return, the value specifies the offset corresponding to the glyph edge nearest the event, after a movement of the specified type. This offset corresponds to where the insertion point would be placed after the move. To determine whether this offset indicates the leading or trailing edge of the glyph, you can examine the value produced in the *oIsLeading* parameter.

oIsLeading

A pointer to a `Boolean` value. On return, the value indicates whether the offset produced in the `ioPrimaryOffset` parameter is leading or trailing. The `ATSUPositionToOffset` function produces a value of `true` if the offset is leading (that is, more closely associated with the subsequent character in memory). It produces a value of `false` if the offset is trailing (that is, more closely associated with the preceding character in memory).

oSecondaryOffset

A pointer to a `UniCharArrayOffset` value. On return, the value typically specifies the same offset as that produced in the *ioPrimaryOffset* parameter, unless the event occurred within a glyph cluster or at a line direction boundary. If so, the value specifies the secondary offset, for the glyph edge furthest from the event.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The `ATSUPositionToCursorOffset` function produces the memory offset for the glyph edge nearest a mouse-down event, after a move of the specified length. This offset corresponds to where an insertion point would be placed after the move.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeDrawing.h`

ATSUPositionToOffset

Obtains the memory offset for the glyph edge nearest a mouse-down event.

```
OSStatus ATSUPositionToOffset (
   ATSUTextLayout iTextLayout,
   ATSUTextMeasurement iLocationX,
   ATSUTextMeasurement iLocationY,
   UniCharArrayOffset *ioPrimaryOffset,
   Boolean *oIsLeading,
   UniCharArrayOffset *oSecondaryOffset
);
```

Parameters

iTextLayout

An `ATSUTextLayout` value identifying the text layout object in which the mouse-down event occurred.

iLocationX

An `ATSUTextMeasurement` value specifying the x-coordinate of the event, in local coordinates, relative to the origin of the line where the event occurred. That is, to specify the x-coordinate value, you should subtract the x-coordinate of the line origin from the x-coordinate of the hit point (in local coordinates). You can pass the constant `kATSUUseGrafPortPenLoc`, described in "Convenience Constants" (page 2043), for the location of the mouse-down event relative to the current pen location in the current graphics port.

iLocationY

An `ATSUTextMeasurement` value specifying the y-coordinate of the event, in local coordinates, relative to the origin of the line where the event occurred. That is, to specify the y-coordinate value, you should subtract the y-coordinate of the line origin from the y-coordinate of the hit point (in local coordinates). You can pass the constant `kATSUUseGrafPortPenLoc`, described in "Convenience Constants" (page 2043), for the location of the mouse-down event relative to the current pen location in the current graphics port.

ioPrimaryOffset

A pointer to a `UniCharArrayOffset` value specifying the offset corresponding to the beginning of the line where the event occurred. On return, the value specifies the offset corresponding to the glyph edge that is visually closest to the event. To determine whether this offset indicates the leading or trailing edge of the glyph, you can examine the value produced in the *oIsLeading* parameter.

oIsLeading

A pointer to a `Boolean` value. On return, the value indicates whether the offset produced in the `ioPrimaryOffset` parameter is leading or trailing. The function `ATSUPositionToOffset` produces a value of `true` if the offset is leading (that is, more closely associated with the subsequent character in memory). It produces a value of `false` if the offset is trailing (that is, more closely associated with the preceding character in memory).

oSecondaryOffset

A pointer to a `UniCharArrayOffset` value. On return, the value typically specifies the same offset as that produced in the *ioPrimaryOffset* parameter, unless the event occurred within a glyph cluster or at a line direction boundary. If so, the value specifies a secondary offset. The secondary offset is associated with the glyph that has a different direction from the primary line direction.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The process of hit-testing text obtains the location of a mouse-down event relative both to the position of onscreen glyphs and to the corresponding offset between character codes in memory. You can then use the location information obtained by hit-testing to set the insertion point (that is, the caret) or selection range (for highlighting).

Hit-testing text is complicated by the fact that a given line of text may be bidirectional. Therefore, the onscreen order of glyphs may not readily correspond to the storage order of the corresponding character codes. And the concept of which glyph comes "first" in a line of text cannot always be limited to the visual terms "left" and "right." Because of these complexities, it is more accurate to speak in terms of "leading" and "trailing" edges to glyphs. A "leading edge" is defined as the edge of a glyph that you first encounter when you read the text that includes that glyph. For example, when reading Roman text, you first encounter the left edge of a Roman glyph. Similarly, the "trailing edge" is defined as the edge of the glyph encountered last.

ATSUI can translate the location of a mouse click into an onscreen position, as well as to a memory offset. When you use ATSUI for hit-testing, ATSUI takes into account the glyph edge (whether leading or trailing) nearest to where the click occurred, thus providing positional information in complex situations, such as at line direction boundaries or within glyph clusters.

The first step in obtaining the caret position(s) for a mouse-down event is to pass the location (in local coordinates, relative to the line origin) of the event to the function `ATSUPositionToOffset`. For example, if you have a mouse-down event whose position in local coordinates is (75,50), you would subtract this value from the position of the origin of the line in the current graphics port. If the position of the origin of the line in the current graphics port is (50,50), then the relative position of the event that you would pass in the `iLocationX` and `iLocationY` parameters is (25,0).

The `ATSUPositionToOffset` function produces the memory offset corresponding to the glyph edge nearest the event. If the mouse-down event occurs at a line direction boundary or within a glyph cluster, `ATSUPositionToOffset` produces two offsets. You can then provide the offset(s) to the `ATSUOffsetToPosition` (page 1942) function, to obtain the actual caret position(s) for the event.

When you call the `ATSUPositionToOffset` function, ATSUI examines the Unicode directionality of the character corresponding to the event location. The `ATSUPositionToOffset` function produces a value of `true` in the *`oIsLeading`* parameter if the offset is leading (that is, more closely associated with the subsequent character in memory and therefore indicative of a left-to-right line direction). It produces a value of `false` if the offset is trailing (that is, more closely associated with the preceding character in memory and indicative of a right-to-left line direction).

Finally, note that when the event occurs beyond the leftmost or rightmost caret positions of the line (not taking into account line rotation), such that no glyph corresponds to the location of the hit, the `ATSUPositionToOffset` function produces the primary offset of the closest edge of the line to the input location. The `oIsLeading` flag depends on the directionality of the closest glyph and the side of the line to which the input location is closest. In this case, the secondary offset is equal to the primary offset, since no glyph was hit.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSUnicodeDrawing.h`

ATSUPreviousCursorPosition

Obtains the memory offset for the insertion point that precedes the current insertion point in storage order, as determined by a move of the specified length.

```
OSStatus ATSUPreviousCursorPosition (
   ATSUTextLayout iTextLayout,
   UniCharArrayOffset iOldOffset,
   ATSUCursorMovementType iMovementType,
   UniCharArrayOffset *oNewOffset
);
```

Parameters

`iTextLayout`

An `ATSUTextLayout` value identifying the text layout object to examine.

`iOldOffset`

A `UniCharArrayOffset` value specifying the memory offset corresponding to the current caret position. To specify the beginning of the text buffer, pass the constant `kATSUFromTextBeginning`,

iMovementType

An `ATSUCursorMovementType` constant identifying the unit of movement. See "Caret Movement Types" (page 2042) for a description of possible values (which range from a single Unicode character to a Unicode word in length). Note that ATSUI may not be able to move the caret by a single Unicode character in some cases, since doing so might place the insertion point in the middle of a surrogate pair.

oNewOffset

A pointer to a `UniCharArrayOffset` value. On return, the value provides the memory offset corresponding to the preceding insertion point. This offset may be outside the initial text buffer.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The `ATSUPreviousCursorPosition` function obtains the memory offset for the insertion point that precedes the current insertion point in storage order, as determined by a move of the specified length.

You should use the `ATSUPreviousCursorPosition` function or the function `ATSUNextCursorPosition` (page 1940) to determine caret position when the initial offset is not at a line direction boundary. If the initial offset is at a line direction boundary, you should instead use the functions `ATSURightwardCursorPosition` (page 1949) or `ATSULeftwardCursorPosition` (page 1933).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeDrawing.h`

ATSURightwardCursorPosition

Obtains the memory offset for the insertion point to the right of the high caret position, as determined by a move of the specified length at a line direction boundary.

```
OSStatus ATSURightwardCursorPosition (
   ATSUTextLayout iTextLayout,
   UniCharArrayOffset iOldOffset,
   ATSUCursorMovementType iMovementType,
   UniCharArrayOffset *oNewOffset
);
```

Parameters

iTextLayout

An `ATSUTextLayout` value identifying the text layout object to examine.

iOldOffset

A `UniCharArrayOffset` value specifying the memory offset corresponding to the current caret position. To specify the beginning of the text buffer, pass the constant `kATSUFromTextBeginning`. For bidirectional text, you can specify the previous layout by passing the constant `kATSUFromPreviousLayout` and the following layout by passing the constant `kATSUFromFollowingLayout`. See the Discussion for the function `ATSULeftwardCursorPosition` (page 1933) for an example of how these constants can be used.

iMovementType

An `ATSUCursorMovementType` constant identifying the unit of movement. See "Caret Movement Types" (page 2042) for a description of possible values (which range from a single Unicode character to a Unicode word in length). Note that ATSUI may not be able to move the caret by a single Unicode character in some cases, since doing so might place the insertion point in the middle of a surrogate pair.

oNewOffset

A pointer to a `UniCharArrayOffset` value. On return, the value provides the memory offset corresponding to the new insertion point. This offset may be outside the initial text buffer.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
Line direction boundaries can occur on the trailing edges of two glyphs, the leading edges of two glyphs, or at the beginning or end of a text segment. At direction boundaries, a single insertion point in memory can require two caret positions onscreen, one for text entry in each direction. The two separate carets (known as a split caret or a dual caret) consist of a high caret and a low caret. The high (primary) caret is displayed at the caret position for inserting text whose direction corresponds to the line direction (the dominant direction for the overall line of text). The low (secondary) caret is displayed at the caret position for inserting text whose direction is counter to the overall line direction.

The `ATSURightwardCursorPosition` function obtains the memory offset for the insertion point to the right of the high caret position, as determined by a move of the specified length at a line direction boundary.

You should use the `ATSURightwardCursorPosition` function or the function `ATSULeftwardCursorPosition` (page 1933) to determine caret position when the user presses the right and left arrow keys.

Except in the case of Indic text (and other cases where the font rearranges the glyphs), for left-to-right text, calling the function `ATSURightwardCursorPosition` has the same effect as calling `ATSUNextCursorPosition` (page 1940). For right-to-left text, calling the function `ATSURightwardCursorPosition` has the same effect as calling `ATSUPreviousCursorPosition` (page 1948).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeDrawing.h`

ATSUSetAttributes

Sets style attribute values in a style object.

```
OSStatus ATSUSetAttributes (
   ATSUStyle iStyle,
   ItemCount iAttributeCount,
   const ATSUAttributeTag iTag[],
   const ByteCount iValueSize[],
   const ATSUAttributeValuePtr iValue[]
);
```

Parameters

iStyle

An `ATSUStyle` value specifying the style object for which to set attributes.

iAttributeCount

An `ItemCount` value specifying the number of attributes to set. This value should correspond to the number of elements in the `iTag` and `iValueSize` arrays.

iTag

A pointer to the initial `ATSUAttributeTag` value in an array of attribute tags. Each element in the array must contain a valid style attribute tag that corresponds to the style attribute value to set. Note that an attribute tag cannot be used in versions of the Mac OS that are earlier than the version in which the tag was introduced. For example, a tag available in Mac OS version 10.2 cannot be used in Mac OS version 10.1 or earlier. You can call the function Gestalt to check version information for ATSUI. See "Attribute Tags" (page 2030) for a description of the Apple-defined style attribute tag constants and for availability information.

iValueSize

A pointer to the initial `ByteCount` value in an array of attribute value sizes. Each element in the array must contain the size (in bytes) of the corresponding style run attribute value being set. `ATSUSetAttributes` sets style attributes after confirming the sizes in the array.

iValue

A pointer to the initial `ATSUAttributeValuePtr` value in an array of attribute value pointers. Each pointer in the array must reference an attribute value corresponding to a tag in the `iTag` array. The value referenced by the pointer must be legal for that tag.

Return Value

A result code. See "ATSUI Result Codes" (page 2068). If there is a function error, `ATSUSetAttributes` does not set any attributes in the style object.

Discussion

Style attributes are a collection of values and settings that override the font-specified behavior for displaying and formatting text in a style run. To specify a style attribute, ATSUI uses a "triple" consisting of (1) an attribute tag, (2) a value for that tag, and (3) the size of the value.

The `ATSUSetAttributes` function enables you to set multiple style attribute values for a style object. When you call `ATSUSetAttributes`, any style attributes that you do not set retain their previous values. To set font features and font variations, call the functions `ATSUSetFontFeatures` (page 1952) and `ATSUSetVariations` (page 1967), respectively.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`ATSUnicodeObjects.h`

ATSUSetFontFallbacks

Sets, on a global scope, the font list and search order for ATSUI to use when a font does not have the glyph needed to image a character. (Deprecated in Mac OS X v10.3. Use font fallback objects instead.)

Not recommended.

```
OSStatus ATSUSetFontFallbacks (
   ItemCount iFontFallbacksCount,
   const ATSUFontID iFontIDs[],
   ATSUFontFallbackMethod iFontFallbackMethod
);
```

Parameters

iFontFallbacksCount

An `ItemCount` value specifying the number of fonts to be searched. This value should be equivalent to the number of elements in the `iFontIDs` array.

iFontIDs

A pointer to the first `ATSUFontID` value in the array of fonts to be searched.

iFontFallbackMethod

An `ATSUFontFallbackMethod` value specifying the order in which ATSUI is to search the fonts. See "Font Fallback Methods" (page 2048) for a description of possible search orders.

Return Value

A result code. See "ATSUI Result Codes" (page 2068).

Discussion

When you call `ATSUSetFontFallbacks`, any settings you apply are global to the process and are used by all ATSUI clients in the process. Therefore, any ATSUI clients in the process can change these global font fallback settings unexpectedly. Other application threads can modify the font fallbacks settings, as well. The only way to ensure that ATSUI uses your preferred font fallback settings for your text is to create a font fallback object and associated it with a text layout object.

You create a font fallback object by calling the function `ATSUCreateFontFallbacks` (page 1864). You define settings for the object by calling the function `ATSUSetObjFontFallbacks` (page 1958). To associate the font fallback object with a text layout object, call either of the functions `ATSUSetLayoutControls` (page 1955) or `ATSUSetLineControls` (page 1956). See *Inside Mac OS X: Rendering Unicode Text With ATSUI* for step-by-step instructions on creating a font fallback object and associating it with a text layout object.

Special Considerations

You should not use this function because it operates on a global scope and may not be available in future versions of ATSUI. Instead, use font fallback objects as described in the Discussion.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.3.

Not available to 64-bit applications.

Declared In

`ATSUnicodeObjects.h`

ATSUSetFontFeatures

Sets font features in a style object.

```
OSStatus ATSUSetFontFeatures (
   ATSUStyle iStyle,
   ItemCount iFeatureCount,
   const ATSUFontFeatureType iType[],
   const ATSUFontFeatureSelector iSelector[]
);
```

Parameters

iStyle

An `ATSUStyle` value specifying the style object for which to set font features.

iFeatureCount

An `ItemCount` value specifying the number of font features to set. This value should correspond to the number of elements in the `iType` and `iSelector` arrays.

iType

A pointer to the initial `ATSUFontFeatureType` value in an array of feature types. Each element in the array must contain a valid feature type that corresponds to a feature selector in the `iSelector` array. To obtain the valid feature types for a font, call the function `ATSUGetFontFeatureTypes` (page 1898).

iSelector

A pointer to the initial `ATSUFontFeatureSelector` value in an array of feature selectors. Each element in the array must contain a valid feature selector that corresponds to a feature type in the `iType` array. To obtain the valid feature selectors for a font, call the function `ATSUGetFontFeatureSelectors` (page 1897).

Return Value

A result code. See "ATSUI Result Codes" (page 2068).

Discussion

The `ATSUSetFontFeatures` function enables you to set multiple font features for a style object. Any unset font features retain their font-defined default values. To set style attributes and font variations for a style object, call the functions `ATSUSetAttributes` (page 1950) and `ATSUSetVariations` (page 1967), respectively.

The constants that represent font feature types are defined in the header file `SFNTLayoutTypes.h`. When you use ATSUI to access and set font features, you must use the constants defined in this header file, which are described in *Inside Mac OS X: Rendering Unicode Text With ATSUI*. As feature types can be added at any time, you should check Apple's font feature registry website for the most up-to-date list of font feature types and selectors: http://developer.apple.com/fonts/Registry/index.html.

Version Notes

Prior to ATSUI 1.2, `ATSUSetFontFeatures` does not remove contradictory font features. You are responsible for maintaining your own list and removing contradictory settings when they occur. Beginning with ATSUI 1.2, `ATSUSetFontFeatures` removes contradictory font features if they are set.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`ATSUnicodeFonts.h`

ATSUSetHighlightingMethod

Sets the method ATSUI uses to highlight and unhighlight text for a text layout object.

```
OSStatus ATSUSetHighlightingMethod (
   ATSUTextLayout iTextLayout,
   ATSUHighlightMethod iMethod,
   const ATSUUnhighlightData *iUnhighlightData
);
```

Parameters

iTextLayout

An `ATSUTextLayout` value identifying the text layout object for which to set the highlighting method.

iMethod

An `ATSUHighlightMethod` value specifying the type of highlighting for ATSUI to use (`kInvertHighlighting` or `kRedrawHighlighting`). The default highlighting method, if you do not call `ATSUSetHighlightingMethod`, is inversion. See "Highlight Methods" (page 2053) for a description of available values.

iUnhighlightData

A pointer to an `ATSUUnhighlightData` structure if you are setting the *iMethod* parameter to `kRedrawHighlighting` or `NULL` if setting `iMethod` to `kInvertHighlighting`. Before calling `ATSUSetHighlightingMethod`, you should set the `ATSUUnhighlightData` structure to contain the data needed (either a color or a UPP for a background drawing callback) to redraw the background.

Return Value

A result code. See "ATSUI Result Codes" (page 2068).

Discussion

In Mac OS 9 and by default in Mac OS X (except with Cocoa applications—see below), ATSUI highlights text by "inverting" the region containing the text, that is, its background color. Although inversion provides satisfactory highlighting in most cases, it does not always provide the best result for grayscale text. (Mac OS X sets a lower threshold for antialiasing, while in Mac OS 9 grayscale text can be turned off by the user.)

In Mac OS X, when using a Quartz graphics context, you can instruct ATSUI to use the redraw method of highlighting, rather than simple inversion. (Note that Cocoa applications always use the redraw method of highlighting.) The redraw method allows for accurate highlighting of more complex backgrounds, such as those containing multiple colors, patterns, or pictures. To set redrawing on, call the `ATSUSetHighlightingMethod` function and specify that the redraw method be used (by passing `kRedrawHighlighting` in the *iMethod* parameter).

If you specify the redraw method of highlighting when you call `ATSUSetHighlightingMethod`, then you must also specify how the background is to be redrawn when the function `ATSUUnhighlightText` (page 1974) is called. ATSUI can restore the desired background in one of two ways, depending on the background's complexity:

- When the background is a single color (such as white), ATSUI can readily unhighlight the background. In such a case, you specify the background color that ATSUI uses by calling `ATSUSetHighlightingMethod` and setting `iUnhighlightData.dataType` to `kATSUBackgroundColor` and providing the background color in `iUnhighlightData.unhighlightData`. With these settings defined, when you call `ATSUUnhighlightText`, ATSUI simply calculates the previously highlighted area, repaints it with the specified background color, and then redraws the text.
- When the background is more complex (containing, for example, multiple colors, patterns, or pictures), you must provide a redraw background callback function when you call `ATSUSetHighlightingMethod`. You do this by setting `iUnhighlightData.dataType` to `kATSUBackgroundCallback` and providing a `RedrawBackgroundUPP` in `iUnhighlightData.unhighlightData`. Then when you call `ATSUUnhighlightText` and ATSUI calls your callback, you are responsible for redrawing the background

of the unhighlighted area. If you choose to also redraw the text, then your callback should return `false` as a function result. If your callback returns `true` ATSUI redraws any text that needs to be redrawn. See `RedrawBackgroundProcPtr` (page 1999) for additional information.

Version Notes
Mac OS 9 applications cannot use the redraw method of highlighting and must use the inversion method, instead.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeDrawing.h`

ATSUSetLayoutControls

Sets layout control attribute values in a text layout object.

```
OSStatus ATSUSetLayoutControls (
   ATSUTextLayout iTextLayout,
   ItemCount iAttributeCount,
   const ATSUAttributeTag iTag[],
   const ByteCount iValueSize[],
   const ATSUAttributeValuePtr iValue[]
);
```

Parameters

`iTextLayout`
An `ATSUTextLayout` value specifying the text layout object for which to set layout control attributes.

`iAttributeCount`
An `ItemCount` value specifying the number of attributes to set. This value should correspond to the number of elements in the `iTag` and `iValueSize` arrays.

`iTag`
A pointer to the initial `ATSUAttributeTag` value in an array of layout control attribute tags. Each element in the array must contain a valid tag that corresponds to the layout control attribute to set. See "Attribute Tags" (page 2030) for a description of the Apple-defined layout control attribute tag constants.

`iValueSize`
A pointer to the initial `ByteCount` value in an array of attribute value sizes. Each element in the array must contain the size (in bytes) of the corresponding layout control attribute being set. `ATSUSetLayoutControls` sets layout attributes after confirming the sizes in the array.

`iValue`
A pointer to the initial `ATSUAttributeValuePtr` value in an array of attribute value pointers. Each value in the array must correspond to a tag in the `iTag` array and be a legal value for that tag.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
When you use ATSUI to image your text, you can control the text's display and formatting at a number of different levels.

One level is that of the entire text range associated with your text layout object, also known as the "layout level." To affect display and formatting on this level, you can specify various layout control attributes using the `ATSUSetLayoutControls` function. These attributes affect the width of the text area from margin to margin, the alignment of the text, its justification, rotation, and direction, as well as other layout options.

Another level is that of a single line of text, that is, the "line level." To affect display and formatting on this level, you specify various line control attributes via the function `ATSUSetLineControls` (page 1956). These attributes are similar to those that you can apply on a full-layout basis, but each affects only an individual text line.

Given that ATSUI allows you to control similar aspects of the display and formatting of your text at either the line level or the layout level (or both, or neither), it is up to you to decide how much layout control to take. However, you should note the following:

- Setting layout control attributes overrides the corresponding default layout-level settings for a text layout object. Any layout attributes that you do not set retain the default values described in "Attribute Tags" (page 2030).
- Setting line control attributes overrides the corresponding layout-level settings (whether set or at default values) for a text layout object. This is true even if you set the layout-level attributes subsequently to the line-level ones.
- From a performance standpoint, it is preferable to work from the layout level and not specify layout line by line unless necessary.

Finally, it is also possible to control the display and formatting of your text at the level of an individual character or "run" of characters. At this level, you customize layout by manipulating style settings in a style object. Among the character-level aspects you can control are style attributes (such as font size and color), font features (such as ligatures), and font variations (such as continually varying font weights or widths). However, there are certain line control attributes (specified via the `ATSLineLayoutOptions` flags) that can override style attributes applied to the same text.

Similarly to style attributes, you use a "triple" to specify a line or layout control attribute. That is, an attribute tag, the value of the attribute it sets, and the size (in bytes) of the attribute value. Attribute tags are constants supplied by ATSUI. Attribute values may be a scalar, a structure, or a pointer.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSUnicodeObjects.h`

ATSUSetLineControls

Sets layout control attribute values for a single line in a text layout object.

```
OSStatus ATSUSetLineControls (
   ATSUTextLayout iTextLayout,
   UniCharArrayOffset iLineStart,
   ItemCount iAttributeCount,
   const ATSUAttributeTag iTag[],
   const ByteCount iValueSize[],
   const ATSUAttributeValuePtr iValue[]
);
```

Parameters

iTextLayout

An `ATSUTextLayout` value specifying the text layout object for which to set line control attribute values.

iLineStart

A `UniCharArrayOffset` value specifying the offset from the beginning of the text layout object's text buffer to the first character of the line for which to set control attributes.

iAttributeCount

An `ItemCount` value specifying the number of attributes to set. This value should correspond to the number of elements in the `iTag` and `iValueSize` arrays.

iTag

A pointer to the initial `ATSUAttributeTag` value in an array of line control attribute tags. Each element in the array must contain a valid tag that corresponds to the line control attribute to set. See "Attribute Tags" (page 2030) for a description of the Apple-defined line control attribute tag constants.

iValueSize

A pointer to the initial `ByteCount` value in an array of attribute value sizes. Each element in the array must contain the size (in bytes) of the corresponding line control attribute being set. `ATSUSetLineControls` sets line attributes after confirming the sizes in the array.

iValue

A pointer to the initial `ATSUAttributeValuePtr` value in an array of attribute value pointers. Each value in the array must correspond to a tag in the `iTag` array and be a legal value for that tag.

Return Value

A result code. See "ATSUI Result Codes" (page 2068).

Discussion

When you use ATSUI to image your text, you can control the text's display and formatting at a number of different levels. One level is that of the entire text range associated with your text layout object, also known as the "layout level." To affect display and formatting on this level, you can specify various layout control attributes using the `ATSUSetLayoutControls` (page 1955) function. These attributes affect the width of the text area from margin to margin, the alignment of the text, its justification, rotation, and direction, as well as other layout options.

Another level is that of a single line of text, that is, the "line level." To affect display and formatting on the line level, you specify various line control attributes using the function `ATSUSetLineControls`. These attributes are similar to those that you can apply on a full-layout basis, but each affects only an individual text line.

You can break text into lines by calling the functions `ATSUBatchBreakLines` (page 1844) or `ATSUBreakLine` (page 1846). You can define separate lines of text by specifying soft breaks either by

- calling the function `ATSUBatchBreakLines`
- calling the function `ATSUBreakLine` with the `iUseAsSoftBreak` parameter set to `true`

- specifying the soft line breaks using the function `ATSUSetSoftLineBreak`

Given that ATSUI allows you to control similar aspects of the display and formatting of your text at either the line level or the layout level (or both, or neither), it is up to you to decide how much layout control to take. However, you should note the following:

- Setting layout control attributes overrides the corresponding default layout-level settings for a text layout object. Any layout attributes that you do not set retain the default values described in "Attribute Tags" (page 2030).
- Setting line control attributes overrides the corresponding layout-level settings (whether set or at default values) for a text layout object. This is true even if you set the layout-level attributes subsequently to the line-level ones. Any line attributes that you do not set retain their default values.
- From a performance standpoint, it is preferable to work from the layout level and not specify layout line by line unless necessary.

Finally, it is also possible to control the display and formatting of your text at the level of an individual character or "run" of characters. At this level, you customize layout by manipulating style settings in a style object. Among the character-level aspects you can control are style attributes (such as font size and color), font features (such as ligatures), and font variations (such as continually varying font weights or widths). However, there are certain line control attributes (specified via the `ATSLineLayoutOptions` flags) that can override style attributes applied to the same text.

Similarly to style attributes, you use a "triple" to specify a line or layout control attribute. That is, an attribute tag, the value of the attribute it sets, and the size (in bytes) of the attribute value. Attribute tags are constants supplied by ATSUI. Attribute values may be a scalar, a structure, or a pointer.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

`ATSUnicodeObjects.h`

ATSUSetObjFontFallbacks

Assigns a font list and a font-search method to a font fallback object.

```
OSStatus ATSUSetObjFontFallbacks (
   ATSUFontFallbacks iFontFallbacks,
   ItemCount iFontFallbacksCount,
   const ATSUFontID iFonts[],
   ATSUFontFallbackMethod iFontFallbackMethod
);
```

Parameters

`iFontFallbacks`
An `ATSUFontFallbacks` value specifying the font fallback object for which to define settings.

`iFontFallbacksCount`
An `ItemCount` value specifying the number of fonts that ATSUI is to search. This value is typically equal to the number of font IDs you are providing in the *`iFonts`* array.

iFonts

A pointer to the first `ATSUFontID` value in an array of font IDs identifying the fonts ATSUI is to search.

iFontFallbackMethod

An `ATSUFontFallbackMethod` value identifying the order in which ATSUI is to search. See "Font Fallback Methods" (page 2048) for a description of possible values.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The `ATSUSetObjFontFallbacks` function defines the settings for a font fallback object. These settings determine the font list and search order that ATSUI uses when seeking substitute fonts for the text layout object with which the font fallback object is associated.

Creating, defining settings for, and associating a font fallback object with a text layout object is the only way to ensure that ATSUI uses your preferred font fallback settings for your text. To create a font fallback object, you first call the function `ATSUCreateFontFallbacks` (page 1864). You then define settings for the object by calling the `ATSUSetObjFontFallbacks` function. To associate the font fallback object with a text layout object call the function `ATSUSetLayoutControls` (page 1955). You pass these functions the control attribute value `kATSULineFontFallbacksTag` to set the font fallback object.

If you do not call `ATSUSetObjFontFallbacks` to change ATSUI's default search behavior, ATSUI searches all the fonts on the system sequentially and uses the first valid font it finds for a substitute. If you are careful in ordering the fonts that you supply to `ATSUSetObjFontFallbacks`, you can minimize the time ATSUI needs to find a substitute font.

Font fallback settings affect the behavior of the function `ATSUMatchFontsToText` (page 1936) and of font selection during layout and drawing when the function `ATSUSetTransientFontMatching` (page 1967) is set to on.

To obtain the font list and font-search method associated with a font fallback object, call the function `ATSUGetObjFontFallbacks` (page 1914).

Availability
Available in Mac OS X v10.1 and later.
Not available to 64-bit applications.

`ATSUnicodeObjects.h`

ATSUSetRunStyle

Defines a style run by associating style information with a run of text.

```
OSStatus ATSUSetRunStyle (
   ATSUTextLayout iTextLayout,
   ATSUStyle iStyle,
   UniCharArrayOffset iRunStart,
   UniCharCount iRunLength
);
```

Parameters

iTextLayout

An `ATSUTextLayout` value specifying a text layout object with an associated text buffer. `ATSUSetRunStyle` assigns a style object to a run of text in this buffer.

iStyle

An `ATSUStyle` value specifying the style object to associate with the text run.

iRunStart

A `UniCharArrayOffset` value specifying the offset from the beginning of the text buffer to the first character of the text run.

iRunLength

A `UniCharCount` value specifying the length of the text run.

Return Value

A result code. See "ATSUI Result Codes" (page 2068).

Discussion

A text run consists of one or more characters that are contiguous in memory. If you associate these characters with a distinct style, you define a style run. You can use the `ATSUSetRunStyle` function to define a style run, by associating a style object with a run of text in a text layout object. There is a limit of 64K different styles for each ATSUI text layout object. Each text run must be assigned its own style object, which may or may not differ from other style objects assigned to other text runs in a given text layout object.

You can create a new style object containing only default settings by calling the function `ATSUCreateStyle` (page 1865). To make changes to the default style attributes, you can call the function `ATSUSetAttributes` (page 1950). To set font features and font variations, call the functions `ATSUSetFontFeatures` (page 1952) and `ATSUSetVariations` (page 1967), respectively.

Note that if you call `ATSUSetRunStyle` on a text run that is already associated with a style object, the style set by `ATSUSetRunStyle` overrides the previous style. Additionally, upon completion, `ATSUSetRunStyle` adjusts the lengths of any style runs on either side of the affected style run.

For example, you may currently have a run of text, 40 characters long, that is assigned a single style, styleA. If you call `ATSUSetRunStyle`, you can reassign characters at offset 10–29 to a new style, styleB. If you do so, you would then have three style runs, where there once was one: characters at offset 0–9 (styleA), 10–29 (styleB), and 30–39 (styleA).

After calling `ATSUSetRunStyle`, you can call the function `ATSUDrawText` (page 1877) to display the styled text. When you call `ATSUDrawText`, if you have not previously assigned styles to all the characters you request to be drawn, ATSUI automatically does so. Specifically, ATSUI extends the first style it locates immediately prior (in storage order) to the unstyled characters to include those unassigned characters. If the unstyled characters are at the beginning of the text stream, ATSUI finds the first style run in the stream and extends it backward to the first character.

You should call `ATSUSetRunStyle` whenever you create a new text layout object without any associated styles, as by using the function `ATSUCreateTextLayout` (page 1866). You should also call `ATSUSetRunStyle` to assign a style to a text run in response to a user action, such as when the user selects a run of text and changes the font.

You do not need to call `ATSUSetRunStyle` when you change style attributes or text layout attributes. In such cases, ATSUI automatically updates the layout of the text as appropriate.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSUnicodeObjects.h`

ATSUSetSoftLineBreak

Sets a soft line break that you specify.

```
OSStatus ATSUSetSoftLineBreak (
   ATSUTextLayout iTextLayout,
   UniCharArrayOffset iLineBreak
);
```

Parameters

iTextLayout
An `ATSUTextLayout` value specifying the text layout object for which to set a line break.

iLineBreak
A `UniCharArrayOffset` value specifying the offset from the beginning of the text layout object's text buffer to the line break to set.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The `ATSUSetSoftLineBreak` function enables you to set a soft line break in a text range. You should typically only call `ATSUSetSoftLineBreak` to set line breaks when you are using your own line-breaking algorithm to calculate these breaks. For optimal performance, you should use `ATSUBatchBreakLines` (page 1844) to both calculate and set soft line breaks in your text.

After calling `ATSUSetSoftLineBreak`, you should call the function `ATSUGetUnjustifiedBounds` (page 1923) to determine whether the characters still fit within the line, which is necessary due to end-of-line effects such as swashes.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeDrawing.h`

ATSUSetStyleRefCon

Sets application-specific data for a style object.

```
OSStatus ATSUSetStyleRefCon (
   ATSUStyle iStyle,
   URefCon iRefCon
);
```

Parameters

iStyle

An `ATSUStyle` value specifying the style object for which to set application-specific data.

iRefCon

A 32-bit value containing or referring to application-specific style data.

Return Value

A result code. See "ATSUI Result Codes" (page 2068).

Discussion

The `ATSUSetStyleRefCon` function associates a reference constant (that is, application-specific data) with a style object. If you copy or clear a style object that contains a reference constant, the reference constant is neither copied nor removed. To obtain application-specific data for a style object, call the function `ATSUGetStyleRefCon` (page 1918).

When you dispose of a style object that contains a reference constant, you are responsible for freeing any memory allocated for the reference constant. Calling the function `ATSUDisposeStyle` (page 1876) does not do so.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`ATSUnicodeObjects.h`

ATSUSetTabArray

Sets a tab ruler for a text layout object.

```
OSStatus ATSUSetTabArray (
   ATSUTextLayout iTextLayout,
   const ATSUTab iTabs[],
   ItemCount iTabCount
);
```

Parameters

iTextLayout

An `ATSUTextLayout` value specifying the text layout object for which you want to set a tab ruler.

iTabs[]

An array of the tab values you want applied to the text layout object. This tab ruler is applied to all lines in the text layout object. You can pass `NULL` if `iTabCount` equals `0`. Passing `NULL` effectively deletes any tab ruler that was set previously.

iTabCount

The number of tabs in the given `iTabs` array. If value is `0`, any previously-set tab ruler is cleared from the text layout object.

Return Value

A result code. See "ATSUI Result Codes" (page 2068).

Discussion
When a tab ruler is set for a text layout object, ATSUI automatically aligns text such that any tabs in the text are laid out to follow the tab ruler's specifications. If you want to use tabs in your text and you also want to use the function `ATSUBatchBreakLines`, then you must set tabs by calling the function `ATSUSetTabArray`.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeObjects.h`

ATSUSetTextHandleLocation

Associates text with a text layout object. (Deprecated in Mac OS X v10.0. Use `ATSUSetTextPointerLocation` (page 1965) instead. See the Discussion for more details.)

Not recommended.

```
OSStatus ATSUSetTextHandleLocation (
   ATSUTextLayout iTextLayout,
   UniCharArrayHandle iText,
   UniCharArrayOffset iTextOffset,
   UniCharCount iTextLength,
   UniCharCount iTextTotalLength
);
```

Parameters

iTextLayout
An `ATSUTextLayout` value specifying the text layout object with which to associate text.

iText
A handle of type `UniCharArrayHandle`, referring to a text buffer containing UTF-16–encoded text. ATSUI associates this buffer with the text layout object and analyzes the complete text of the buffer when obtaining the layout context for the current text range. Thus, for paragraph-format text, if you specify a buffer containing less than a complete paragraph, some of ATSUI's layout results are not guaranteed to be accurate. For example, with a buffer of less than a full paragraph, ATSUI can neither reliably obtain the context for bidirectional processing nor reliably generate accent attachments and ligature formations for Roman text.

iTextOffset
A `UniCharArrayOffset` value specifying the offset from the beginning of the text buffer to the first character of the range to include in the layout. To indicate that the specified text range starts at the beginning of the text buffer, you can pass the constant `kATSUFromTextBeginning`,. To specify the entire text buffer, pass `kATSUFromTextBeginning` in this parameter and `kATSUToTextEnd` in the `iTextLength` parameter.

iTextLength
A `UniCharCount` value specifying the length of the text range. Note that `iTextOffset + iTextLength` must be less than or equal to the value of the *iTextTotalLength* parameter. If you want the range of text to extend to the end of the text buffer, you can pass the constant `kATSUToTextEnd`.

iTextTotalLength

A UniCharCount value specifying the length of the entire text buffer. This value should be greater than or equal to the range of text defined by the iTextLength parameter.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
You should use the function ATSUSetTextPointerLocation (page 1965) instead of the function ATSUSetTextHandleLocation.

For ATSUI to render your text, you must associate the text with both a text layout object and style information. Some functions, such as ATSUCreateTextLayoutWithTextPtr (page 1869), create a text layout object and associate text with it concurrently. However, if you use the function ATSUCreateTextLayout (page 1866) to create a layout object, you must assign text to the text layout object prior to attempting most ATSUI operations.

You can use either of the functions ATSUSetTextHandleLocation or ATSUSetTextPointerLocation (page 1965) to associate text with a text layout object. When you call these functions, you are both assigning a text buffer to a text layout object and specifying the current text subrange within the buffer to include in the layout.

If there is already text associated with a text layout object, calling ATSUSetTextHandleLocation or ATSUSetTextPointerLocation overrides the previously associated text, as well as clearing the object's layout caches. You would typically only call these functions for a text layout object with existing associated text if either (a) both the buffer itself is relocated and a subrange of the buffer's text is deleted or inserted or (b) when associating an entirely different buffer with a text layout object.

Note that, because ATSUI objects retain state, doing superfluous calling can degrade performance. For example, you could call ATSUSetTextHandleLocation rather than ATSUTextInserted (page 1970) when the user simply inserts a subrange of text within a text buffer, but there would be a performance penalty, as all the layout caches are flushed by ATSUSetTextHandleLocation, rather than just the affected ones.

Similarly, you should not call ATSUSetTextHandleLocation, when an entire text buffer associated with a text layout object is relocated, but no other changes have occurred that would affect the buffer's current subrange. Instead, you should call ATSUTextMoved (page 1971), which is a more focused function and therefore more efficient.

After associating text with the text layout object, use ATSUSetRunStyle (page 1959) to associate style information with the text. You can then call the function ATSUDrawText (page 1877) to display the text.

Note that while ATSUSetTextHandleLocation associates text with a text layout object via a handle, ATSUI functions that need to access the text return the handle to its original state upon function completion.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.0.
Not available to 64-bit applications.

Declared In
ATSUnicodeObjects.h

ATSUSetTextLayoutRefCon

Sets application-specific data for a text layout object.

```
OSStatus ATSUSetTextLayoutRefCon (
   ATSUTextLayout iTextLayout,
   URefCon iRefCon
);
```

Parameters

iTextLayout

An `ATSUTextLayout` value specifying the text layout object for which to set application-specific data.

iRefCon

A 32-bit value containing or referring to application-specific text layout data.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The `ATSUSetTextLayoutRefCon` function associates a reference constant (that is, application-specific data) with a text layout object. You might typically use `ATSUSetTextLayoutRefCon` to track user preferences that can effect layout, for example.

If you copy or clear a text layout object containing a reference constant, the reference constant is not copied or removed. When you dispose of a text layout object that contains a reference constant, you are responsible for freeing any memory allocated for the reference constant. Calling the function `ATSUDisposeTextLayout` (page 1876) does not do so.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSUnicodeObjects.h`

ATSUSetTextPointerLocation

Associates text with a text layout object or updates previously associated text.

```
OSStatus ATSUSetTextPointerLocation (
   ATSUTextLayout iTextLayout,
   ConstUniCharArrayPtr iText,
   UniCharArrayOffset iTextOffset,
   UniCharCount iTextLength,
   UniCharCount iTextTotalLength
);
```

Parameters

iTextLayout

An `ATSUTextLayout` value specifying the text layout object for which to set text.

iText

A pointer of type `ConstUniCharArrayPtr`, referring to a text buffer containing UTF-16–encoded text. ATSUI associates this buffer with the text layout object and analyzes the complete text of the buffer when obtaining the layout context for the current text range. Thus, for paragraph-format text, if you specify a buffer containing less than a complete paragraph, some of ATSUI's layout results are not guaranteed to be accurate. For example, with a buffer of less than a full paragraph, ATSUI can neither reliably obtain the context for bidirectional processing nor reliably generate accent attachments and ligature formations.

iTextOffset

A UniCharArrayOffset value specifying the offset from the beginning of the text buffer to the first character of the range to include in the layout. To indicate that the specified text range starts at the beginning of the text buffer, you can pass the constant kATSUFromTextBeginning. To specify the entire text buffer, pass kATSUFromTextBeginning in this parameter and kATSUToTextEnd in the iTextLength parameter.

iTextLength

A UniCharCount value specifying the length of the text range. Note that iTextOffset + iTextLength must be less than or equal to the value of the *iTextTotalLength* parameter. If you want the range of text to extend to the end of the text buffer, you can pass the constant kATSUToTextEnd.

iTextTotalLength

A UniCharCount value specifying the length of the entire text buffer. This value should be greater than or equal to the range of text defined by the iTextLength parameter.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
For ATSUI to render your text, you must associate the text with both a text layout object and style information. Some functions, such as ATSUCreateTextLayoutWithTextPtr (page 1869), create a text layout object and associate text with it concurrently. However, if you use the function ATSUCreateTextLayout (page 1866) to create a text layout object, you must assign text to the object prior to attempting most ATSUI operations.

You can use the function ATSUSetTextPointerLocation or to associate text with a text layout object. When you call this function, you are both assigning a text buffer to a text layout object and specifying the current text subrange within the buffer to include in the layout.

If there is already text associated with a text layout object, calling ATSUSetTextPointerLocation overrides the previously associated text, as well as clearing the object's layout caches. You would typically only call this function for a text layout object with existing associated text if either (a) both the buffer itself is relocated and a subrange of the buffer's text is deleted or inserted or (b) when associating an entirely different buffer with a text layout object.

Note that, because ATSUI objects retain state, doing superfluous calling can degrade performance. For example, you could call ATSUSetTextPointerLocation rather than ATSUTextInserted (page 1970) when the user simply inserts a subrange of text within a text buffer, but there would be a performance penalty, as all the layout caches are flushed by ATSUSetTextPointerLocation, rather than just the affected ones.

Similarly, you should not call ATSUSetTextPointerLocation, when an entire text buffer associated with a text layout object is relocated, but no other changes have occurred that would affect the buffer's current subrange. Instead, you should call ATSUTextMoved (page 1971), which is a more focused function and therefore more efficient.

After associating text with a text layout object, use ATSUSetRunStyle (page 1959) to associate style information with the text. You can then call the function ATSUDrawText (page 1877) to display the text or a subrange of the text.

Not available to 64-bit applications.

Declared In
ATSUnicodeObjects.h

ATSUSetTransientFontMatching

Turns automatic font substitution on or off for a text layout object.

```
OSStatus ATSUSetTransientFontMatching (
   ATSUTextLayout iTextLayout,
   Boolean iTransientFontMatching
);
```

Parameters

iTextLayout

An `ATSUTextLayout` value specifying the text layout object for which to set automatic font substitution on or off.

iTransientFontMatching

A `Boolean` value indicating whether ATSUI is to perform automatic font substitution for the text layout object. If you pass `true`, ATSUI performs automatic font substitution for the text range associated with the text layout object.

Return Value

A result code. See "ATSUI Result Codes" (page 2068).

Discussion

Calling the `ATSUSetTransientFontMatching` function sets ATSUI's automatic font substitution to on or off for a given text layout object. When automatic font substitution is on, ATSUI scans the text range associated with specified text layout object looking for undrawable characters whenever a layout is performed, for example, when text is measured or drawn. When ATSUI finds a character that cannot be drawn with the currently assigned font, it identifies a valid font for the character and draws the character. ATSUI continues scanning the text range for characters in need of substitute fonts, replacing the font and redrawing the characters as needed. ATSUI stops scanning when it reaches the end of the text range associated with the text layout object.

ATSUI's default behavior for finding a substitute font is to use the first valid font that it finds when sequentially scanning the fonts in the user's system. However, you can alter this behavior by calling the function `ATSUCreateFontFallbacks` (page 1864) and defining your own font fallback settings for the text layout object. If ATSUI cannot find any suitable replacement fonts, it substitutes the missing-character glyph—that is, a glyph representing an empty box—to indicate to the user that a valid font is not installed on their system.

Note that when `ATSUSetTransientFontMatching` performs font substitution, it does not change the font attribute in the associated style object. That is, the font attribute for the style object associated with the redrawn character(s) remains set to the invalid font—not the valid substitute font— just as it was prior to calling `ATSUSetTransientFontMatching`.

If you want ATSUI to identify a substitute font, but you do not want ATSUI to automatically perform the font substitution, you can call the function `ATSUMatchFontsToText` (page 1936).

Availability

Available in Mac OS X v10.0 and later.

`ATSUnicodeObjects.h`

ATSUSetVariations

Sets font variation axes and values in a style object.

```
OSStatus ATSUSetVariations (
   ATSUStyle iStyle,
   ItemCount iVariationCount,
   const ATSUFontVariationAxis iAxes[],
   const ATSUFontVariationValue iValue[]
);
```

Parameters

iStyle

An `ATSUStyle` value specifying the style object for which to set font variation values.

iVariationCount

An `ItemCount` value specifying the number of font variation values to set. This value should correspond to the number of elements in the `iAxes` and `iValue` arrays.

iAxes

A pointer to the initial `ATSUFontVariationAxis` value in an array of font variation axes. Each element in the array must represent a valid variation axis tag that corresponds to a variation value in the *iValue* array. To obtain a valid variation axis tag for a font, you can call the functions `ATSUGetIndFontVariation` (page 1911) or `ATSUGetFontInstance` (page 1900).

iValue

A pointer to the initial `ATSUFontVariationValue` value in an array of font variation values. Each element in the array must contain a value that is valid for the corresponding variation axis in the `iAxes` parameter. You can obtain a font's maximum, minimum, and default values for a given variation axis by calling the function `ATSUGetIndFontVariation` (page 1911). You can obtain the font variation axis values for a font instance by calling `ATSUGetFontInstance` (page 1900).

Return Value

A result code. See "ATSUI Result Codes" (page 2068).

Discussion

If you supply font variation axes and values to the `ATSUSetVariations` function, you can change the appearance of a style object's font accordingly. You may specify any number of variation axes and values in a style object. Any of the font's variations that you do not set retain their font-defined default values.

You can also use the `ATSUSetVariations` function to supply your own value within any variation axes defined for the font. However, if the font does not support the variation axis you specify, your custom variation has no visual effect.

By calling the function `ATSUGetIndFontVariation` (page 1911), you can obtain a variation axis and its maximum, minimum, and default values for a font.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`ATSUnicodeFonts.h`

ATSUStyleIsEmpty

Indicates whether a style object contains only default values.

```
OSStatus ATSUStyleIsEmpty (
   ATSUStyle iStyle,
   Boolean *oIsClear
);
```

Parameters

iStyle

An `ATSUStyle` value specifying the style object to examine.

oIsClear

A pointer to a `Boolean` value. On return, the value is set to `true` if the style object contains only default values for style attributes, font features, and font variations. If `false`, the style object contains one or more nondefault values for style attributes, font features, or font variations.

Return Value

A result code. See "ATSUI Result Codes" (page 2068).

Discussion

You can call the `ATSUStyleIsEmpty` function to determine whether a style object contains only default values for style attributes, font features, and font variations. `ATSUStyleIsEmpty` does not consider reference constants in its evaluation.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`ATSUnicodeObjects.h`

ATSUTextDeleted

Informs ATSUI of the location and length of a text deletion.

```
OSStatus ATSUTextDeleted (
   ATSUTextLayout iTextLayout,
   UniCharArrayOffset iDeletedRangeStart,
   UniCharCount iDeletedRangeLength
);
```

Parameters

iTextLayout

An `ATSUTextLayout` value specifying the text layout object containing the deleted text.

iDeletedRangeStart

A `UniCharArrayOffset` value specifying the offset from the beginning of the text buffer to the memory location of the deleted text. To specify a deletion point at the beginning of the text buffer, you can pass the constant `kATSUFromTextBeginning`. To specify that the entire text buffer has been deleted, pass `kATSUFromTextBeginning` in this parameter and `kATSUToTextEnd` in the `iDeletedRangeLength` parameter.

iIDeletedRangeLength

A `UniCharCount` value specifying the length of the deleted text. To specify a deletion length extending to the end of the text buffer, you can pass the constant `kATSUToTextEnd`.

Return Value

A result code. See "ATSUI Result Codes" (page 2068).

Discussion
When you call the `ATSUTextDeleted` function to inform ATSUI of a text deletion, it shortens the style run(s) containing the deleted text by the amount of the deletion. If a style run corresponds entirely to a range of deleted text, that style run is removed. If the deletion point is between two style runs, the first style run is shortened (or removed).

The `ATSUTextDeleted` function also shortens the total length of the text buffer containing the deleted text by the amount of the deletion. That is, it shifts the memory location of the text following the deleted text by `iDeletedRangeLength`. `ATSUTextDeleted` also removes any soft line breaks that fall within the deleted text and updates affected drawing caches.

The `ATSUTextDeleted` function does not change the actual memory location of the affected text. You are responsible for deleting the corresponding text is from the text buffer. You are also responsible for calling the function `ATSUDisposeStyle` (page 1876) to dispose of the memory associated with any style runs that have been removed.

Note that calling the function `ATSUTextDeleted` automatically removes previously-set soft line breaks if the line breaks are within the range of text that is deleted.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ATSUnicodeObjects.h`

ATSUTextInserted

Informs ATSUI of the location and length of a text insertion.

```
OSStatus ATSUTextInserted (
   ATSUTextLayout iTextLayout,
   UniCharArrayOffset iInsertionLocation,
   UniCharCount iInsertionLength
);
```

Parameters
iTextLayout
An `ATSUTextLayout` value specifying the text layout object containing the inserted text.
iInsertionLocation
A `UniCharArrayOffset` value specifying the offset from the beginning of the text buffer to the memory location of the inserted text. To specify an insertion point at the beginning of the text buffer, you can pass the constant `kATSUFromTextBeginning`.
iInsertionLength
A `UniCharCount` value specifying the length of the inserted text.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
When you call the `ATSUTextInserted` function to inform ATSUI of a text insertion, it extends the style run containing the insertion point by the amount of the inserted text. If the insertion point is between two style runs, the first style run is extended to include the new text.

The ATSUTextInserted function also extends the total length of the text buffer containing the inserted text by the amount of the inserted text. That is, it shifts the memory location of the text following the inserted text by iInsertionLength. ATSUTextInserted then updates drawing caches.

Note that the ATSUTextInserted function does not change the actual memory location of the inserted text. You are responsible for placing the inserted text into the text buffer at the appropriate location.

The ATSUTextInserted function does not insert style runs or line breaks; to do so, call the functions ATSUSetRunStyle (page 1959) and ATSUSetSoftLineBreak (page 1961), respectively. Break line operations should be redone after you call ATSUTextInserted.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
ATSUnicodeObjects.h

ATSUTextMoved

Informs ATSUI of the new memory location of relocated text.

```
OSStatus ATSUTextMoved (
   ATSUTextLayout iTextLayout,
   ConstUniCharArrayPtr iNewLocation
);
```

Parameters

iTextLayout
An ATSUTextLayout value identifying the text layout object associated with the relocated text.

iNewLocation
A ConstUniCharArrayPtr specifying the new memory location of the moved text.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
You should call the ATSUTextMoved function when a range of text consisting of less than an entire text buffer has been moved. The ATSUTextMoved function informs ATSUI of the new memory location of the text. You are responsible for moving the text. The text buffer should remain otherwise unchanged.

When a range of text consisting of an entire text buffer has been moved, you should:

- Call the function ATSUSetTextPointerLocation (page 1965) to update the text buffer's location.
- Call the function ATSUSetRunStyle (page 1959) to update the corresponding style runs for the text buffer.
- Call the function ATSUDrawText (page 1877) to display the updated text.

Availability
Available in Mac OS X v10.0 and later.

Declared In
ATSUnicodeObjects.h

ATSUUnderwriteAttributes

Copies to a destination style object only those nondefault style attribute settings of a source style object that are at default settings in the destination object.

```
OSStatus ATSUUnderwriteAttributes (
   ATSUStyle iSourceStyle,
   ATSUStyle iDestinationStyle
);
```

Parameters

iSourceStyle

An `ATSUStyle` value specifying the style object from which to copy nondefault style attributes.

iDestinationStyle

An `ATSUStyle` value specifying the style object containing style attribute values to be set.

Return Value

A result code. See "ATSUI Result Codes" (page 2068).

Discussion

The `ATSUUnderwriteAttributes` function copies to a destination style object only those nondefault style attribute values of a source style object that are not currently set in a destination style object. Note that the corresponding value in the destination object must not be set in order for a copied value to be applied. All other quantities in the destination style object are left unchanged.

`ATSUUnderwriteAttributes` does not copy the contents of memory referenced by pointers within custom style attributes or within reference constants. You are responsible for ensuring that this memory remains valid until both the source and destination style objects are disposed of.

To create a style object that contains all the contents of another style object, call the function `ATSUCreateAndCopyStyle` (page 1863). To copy all the style attributes (including any default settings) of a style object into an existing style object, call the function `ATSUCopyAttributes` (page 1856). To copy style attributes that are set in the source whether or not they are set in the destination style object, call the function `ATSUOverwriteAttributes` (page 1944).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`ATSUnicodeObjects.h`

ATSUUnflattenStyleRunsFromStream

Unflattens previously-flattened ATSUI style run data so that it can be read from disk or accepted (through the pasteboard) from another application.

```
OSStatus ATSUUnflattenStyleRunsFromStream (
   ATSUFlattenedDataStreamFormat iStreamFormat,
   ATSUUnFlattenStyleRunOptions iUnflattenOptions,
   ByteCount iStreamBufferSize,
   const void *iStreamBuffer,
   ItemCount iNumberOfRunInfo,
   ItemCount iNumberOfStyleObjects,
   ATSUStyleRunInfo oRunInfoArray[],
   ATSUStyle oStyleArray[],
   ItemCount *oActualNumberOfRunInfo,
   ItemCount *oActualNumberOfStyleObjects
);
```

Parameters

iStreamFormat

The format of the flattened data. There is only one format supported at this time (`'ustl'`) so you must pass the constant `kATSUDataStreamUnicodeStyledText`.

iUnflattenOptions

The options you want to use to unflatten the data. There are no options supported at this time, so you must pass the constant `kATSUUnflattenOptionsNoOptionsMask`.

iStreamBufferSize

The size of the buffer pointed to by the `iStreamBuffer` parameter. You must pass a value greater than `0`.

iStreamBuffer

A pointer to the buffer that contains the flattened data. The data must be of the format specified by the `iStreamFormat` parameter and must be of size specified by the `iStreamBufferSize` parameter. You cannot pass `NULL`.

iNumberOfRunInfo

The number of style run information structures passed in the `iRunInfoArray` parameter. If you are uncertain of the number of style run information structures, see the Discussion.

iNumberOfStyleObjects

The number of `ATSUStyle` objects in the array passed into the `iStyleArray` parameter. If you are uncertain of the number of `ATSUStyle` objects, see the Discussion.

oRunInfoArray[]

On return, points to an array of style run information structures. Each structure contains a style run length and index into the `oStyleArray` array. If you are uncertain of how much memory to allocate for this array, see the Discussion. You are responsible for disposing of the array when you no longer need it.

oStyleArray[]

On return, a pointer to an array of the unique ATSUI style objects (`ATSUStyle`) obtained from the flattened data. The indices returned in the array `oRunInfoArray` are indices into this array. If you are uncertain of how much memory to allocate for this array, see the Discussion. You are responsible for disposing of the array and the ATSUI style objects in the array when you no longer need the array.

oActualNumberOfRunInfo

On return, points to the actual number of `ATSUStyleRunInfo` structures obtained from the flattened data. The actual number of structures is the number of entries added to the array `oRunInfoArray`. You can pass `NULL` if you to not want to obtain this value.

oActualNumberOfStyleObjects

On return, points to the actual number of unique ATSUI style objects (ATSUStyle) obtained from the flattened data. The actual number is the number of entries added to the oStyleArray array. You can pass NULL if you do no want to obtain this value.

Return Value
A result code. See "ATSUI Result Codes" (page 2068). This function can also return paramErr if you pass invalid values for any of the parameters.

Discussion
The function ATSUUnflattenStyleRunsFromStream extracts the ATSUI style run information from previously-flattened data. The style objects and style run information structures are returned in two separate arrays—the array oStyleArray and the array oRunInfoArray. These arrays are not parallel. Each ATSUStyle object in the oStyleArray is a unique ATSUStyle object. To figure out which ATSUStyle object belongs to which text run, the caller must parse the array of ATSUStyleRunInfo structures. These structures contain the style run lengths and an index into the oStyleArray.

Typically you use the function ATSUUnflattenStyleRunsFromStream by calling it twice, as follows:

1. Provide appropriate values for the iStreamFormat, iUnflattenOptions, and iStreamBuffer parameters. Pass 0 for the iNumberOfRunInfo and iNumberOfStyleObjects parameters, NULL for the oRunInfoArray and oStyleArray, parameters and valid ItemCount references for the oActualNumberOfRunInfo and oActualNumberOfStyleObjects parameters. On return, oActualNumberOfRunInfo and oActualNumberOfStyleObjects point to the sizes needed to allocate these arrays.

2. Allocate appropriately-sized arrays of ATSUStyleRunInfo data structures and ATSUStyle objects. Call the function ATSUUnflattenStyleRunsFromStream a second time, passing the newly allocated arrays in the oRunInfoArray and oStyleArray parameters, with the iNumberOfRunInfo and iNumberOfStyleObjects parameters set to the values you obtained from the first call.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
ATSUnicodeFlattening.h

ATSUUnhighlightText

Renders a previously highlighted range of text in an unhighlighted state.

```
OSStatus ATSUUnhighlightText (
   ATSUTextLayout iTextLayout,
   ATSUTextMeasurement iTextBasePointX,
   ATSUTextMeasurement iTextBasePointY,
   UniCharArrayOffset iHighlightStart,
   UniCharCount iHighlightLength
);
```

Parameters
iTextLayout

An ATSUTextLayout value identifying the text layout object for which to render unhighlighted text.

iTextBasePointX

An ATSUTextMeasurement value specifying the x-coordinate of the origin (in either the current graphics port or in a Quartz graphics context) of the line containing the text range. Pass the constant kATSUUseGrafPortPenLoc, described in "Convenience Constants" (page 2043), to draw relative to the current pen location in the current graphics port.

iTextBasePointY

An ATSUTextMeasurement value specifying the y-coordinate of the origin (in either the current graphics port or in a Quartz graphics context) of the line containing the text range. Pass the constant kATSUUseGrafPortPenLoc, described in "Convenience Constants" (page 2043), to draw relative to the current pen location in the current graphics port.

iHighlightStart

A UniCharArrayOffset value specifying the offset from the beginning of the text buffer to the first character of the text range. If the text range spans multiple lines, you should call ATSUUnhighlightText for each line, passing the offset corresponding to the beginning of the new line to draw with each call. To indicate that the specified text range starts at the beginning of the text buffer, you can pass the constant kATSUFromTextBeginning. To specify the entire text buffer, pass kATSUFromTextBeginning in this parameter and kATSUToTextEnd in the iHighlightLength parameter.

iHighlightLength

A UniCharCount value specifying the length of the text range. To indicate that the text range extends to the end of the text buffer, pass the constant kATSUToTextEnd.

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
The ATSUUnhighlightText function renders a previously highlighted range of text in an unhighlighted state. You should always call ATSUUnhighlightText after calling the function ATSUHighlightText (page 1931), to properly redraw the unhighlighted text and background.

If the inversion method of highlighting was used, when you call ATSUUnhighlightText, it merely undoes the inversion and renders the text.

If the redraw method of highlighting was used, ATSUUnhighlightText turns off the highlighting and restores the desired background. Depending on the complexity of the background, ATSUI restores the background in one of two ways:

- When the background is a single color (such as white), ATSUI can readily unhighlight the background. In such a case, you specify the background color that ATSUI uses by calling the function ATSUSetHighlightingMethod (page 1953) and setting iMethod to kRedrawHighlighting and iUnhighlightData.dataType to kATSUBackgroundColor and providing the background color in iUnhighlightData.unhighlightData. With these settings defined, when you call ATSUUnhighlightText, ATSUI simply calculates the previously highlighted area, repaints it with the specified background color, and then redraws the text.
- When the background is more complex (containing, for example, multiple colors, patterns, or pictures), you must provide a redraw background callback function when you call ATSUSetHighlightingMethod. You do this by setting iUnhighlightData.dataType to kATSUBackgroundCallback and providing a RedrawBackgroundUPP in iUnhighlightData.unhighlightData. When ATSUI calls your callback, you are responsible for redrawing the background of the unhighlighted area. If you choose to also redraw the text, then your callback should return false as a function result. If your callback returns true ATSUI redraws any text that needs to be redrawn. See RedrawBackgroundProcPtr (page 1999) for additional information.

Before calculating the dimensions of the area to unhighlight, `ATSUUnhighlightText` examines the text layout object to ensure that each of the characters in the range is assigned to a style run. If there are gaps between style runs, ATSUI assigns the characters in the gap to the style run that precedes (in storage order) the gap. If there is no style run at the beginning of the text range, ATSUI assigns these characters to the first style run it finds. If there is no style run at the end of the text range, ATSUI assigns the remaining characters to the last style run it finds.

The `ATSUUnhighlightText` function uses the previously set line ascent and descent values to calculate the height of the region to unhighlight. If these values have not been set for the line, `ATSUUnhighlightText` uses the line ascent and descent values set for the text layout object containing the line. If these are not set, it uses the default values.

If you want to remove highlighting from a text range that spans multiple lines, you should call `ATSUUnhighlightText` for each line of text that is being unhighlighted, even if all the lines belong to the same text layout object. You should adjust the `iHighlightStart` parameter to reflect the beginning of each line to be unhighlighted.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

`ATSUnicodeDrawing.h`

DisposeATSCubicClosePathUPP

Disposes of a universal procedure pointer (UPP) to a cubic close-path callback.

```
void DisposeATSCubicClosePathUPP (
   ATSCubicClosePathUPP userUPP
);
```

Parameters

userUPP

The universal procedure pointer.

Discussion
See the callback `ATSCubicClosePathProcPtr` (page 1990) for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSUnicodeGlyphs.h`

DisposeATSCubicCurveToUPP

Disposes of a universal procedure pointer (UPP) to a cubic curve-to callback.

```
void DisposeATSCubicCurveToUPP (
   ATSCubicCurveToUPP userUPP
);
```

Parameters

userUPP

The universal procedure pointer.

Discussion
See the callback `ATSCubicCurveToProcPtr` (page 1991) for more information.

Availability
Available in Mac OS X v10.0 and later.

DisposeATSQuadraticLineUPP

Disposes of a universal procedure pointer (UPP) to a quadratic line callback.

```
void DisposeATSQuadraticLineUPP (
   ATSQuadraticLineUPP userUPP
);
```

Parameters

userUPP

The universal procedure pointer.

Discussion
See the callback `ATSQuadraticLineProcPtr` (page 1996) for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSUnicodeGlyphs.h`

DisposeATSQuadraticNewPathUPP

Disposes of a universal procedure pointer (UPP) to a quadratic new-path callback.

```
void DisposeATSQuadraticNewPathUPP (
   ATSQuadraticNewPathUPP userUPP
);
```

Parameters

userUPP

The universal procedure pointer.

Discussion
See the callback `ATSQuadraticNewPathProcPtr` (page 1997) for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSUnicodeGlyphs.h`

DisposeATSUDirectLayoutOperationOverrideUPP

Disposes of a universal procedure pointer (UPP) to a layout operation override callback.

```
void DisposeATSUDirectLayoutOperationOverrideUPP (
   ATSUDirectLayoutOperationOverrideUPP userUPP
);
```

Parameters

userUPP

The universal procedure pointer.

Discussion
See the callback `ATSUDirectLayoutOperationOverrideProcPtr` (page 1998) for more information.

Availability
Available in Mac OS X v10.2 and later.

Declared In
ATSLayoutTypes.h

DisposeRedrawBackgroundUPP

Disposes of a new universal procedure pointer (UPP) to a redraw background callback.

```
void DisposeRedrawBackgroundUPP (
   RedrawBackgroundUPP userUPP
);
```

Parameters

userUPP
The universal procedure pointer.

Discussion
See the callback RedrawBackgroundProcPtr (page 1999) for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
ATSUnicodeTypes.h

InvokeATSCubicClosePathUPP

Calls your cubic close-path callback.

```
OSStatus InvokeATSCubicClosePathUPP (
   void *callBackDataPtr,
   ATSCubicClosePathUPP userUPP
);
```

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
You should not need to use the function InvokeATSCubicClosePathUPP, as ATSUI calls your cubic close-path callback for you. See the callback ATSCubicClosePathProcPtr (page 1990) for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
ATSUnicodeGlyphs.h

InvokeATSCubicCurveToUPP

Calls your cubic curve-to callback.

```
OSStatus InvokeATSCubicCurveToUPP (
   const Float32Point *pt1,
   const Float32Point *pt2,
   const Float32Point *pt3,
   void *callBackDataPtr,
   ATSCubicCurveToUPP userUPP
);
```

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
You should not need to use the function `InvokeATSCubicCurveToUPP`, as ATSUI calls your cubic curve-to callback for you. See the callback `ATSCubicCurveToProcPtr` (page 1991) for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSUnicodeGlyphs.h`

InvokeATSCubicLineToUPP

Calls your cubic line-to callback.

```
OSStatus InvokeATSCubicLineToUPP (
   const Float32Point *pt,
   void *callBackDataPtr,
   ATSCubicLineToUPP userUPP
);
```

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
You should not need to use the function `InvokeATSCubicLineToUPP`, as ATSUI calls your cubic line-to callback for you. See the callback `ATSCubicLineToProcPtr` (page 1992) for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSUnicodeGlyphs.h`

InvokeATSCubicMoveToUPP

Calls your cubic move-to callback.

```
OSStatus InvokeATSCubicMoveToUPP (
   const Float32Point *pt,
   void *callBackDataPtr,
   ATSCubicMoveToUPP userUPP
);
```

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
You should not need to use the function `InvokeATSCubicMoveToUPP`, as ATSUI calls your cubic move-to callback for you. See the callback `ATSCubicMoveToProcPtr` (page 1993) for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSUnicodeGlyphs.h`

InvokeATSQuadraticClosePathUPP

Calls your quadratic close-path callback.

```
OSStatus InvokeATSQuadraticClosePathUPP (
   void *callBackDataPtr,
   ATSQuadraticClosePathUPP userUPP
);
```

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
You should not need to use the function `InvokeATSQuadraticClosePathUPP`, as ATSUI calls your quadratic close-path callback for you. See the callback `ATSQuadraticClosePathProcPtr` (page 1994) for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSUnicodeGlyphs.h`

InvokeATSQuadraticCurveUPP

Calls your quadratic curve callback.

```
OSStatus InvokeATSQuadraticCurveUPP (
   const Float32Point *pt1,
   const Float32Point *controlPt,
   const Float32Point *pt2,
   void *callBackDataPtr,
   ATSQuadraticCurveUPP userUPP
);
```

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
You should not need to use the function `InvokeATSQuadraticCurveUPP`, as ATSUI calls your quadratic curve callback for you. See the callback `ATSQuadraticCurveProcPtr` (page 1995) for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSUnicodeGlyphs.h`

InvokeATSQuadraticLineUPP

Calls your quadratic line callback.

```
OSStatus InvokeATSQuadraticLineUPP (
   const Float32Point *pt1,
   const Float32Point *pt2,
   void *callBackDataPtr,
   ATSQuadraticLineUPP userUPP
);
```

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
You should not need to use the function `InvokeATSQuadraticLineUPP`, as ATSUI calls your quadratic line callback for you. See the callback `ATSQuadraticLineProcPtr` (page 1996) for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSUnicodeGlyphs.h`

InvokeATSQuadraticNewPathUPP

Calls your quadratic new-path callback.

```
OSStatus InvokeATSQuadraticNewPathUPP (
   void *callBackDataPtr,
   ATSQuadraticNewPathUPP userUPP
);
```

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
You should not need to use the function `InvokeATSQuadraticNewPathUPP`, as ATSUI calls your quadratic new-path callback for you. See the callback `ATSQuadraticNewPathProcPtr` (page 1997) for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSUnicodeGlyphs.h`

InvokeATSUDirectLayoutOperationOverrideUPP

Calls your layout operation override callback.

```
OSStatus InvokeATSUDirectLayoutOperationOverrideUPP (
   ATSULayoutOperationSelector iCurrentOperation,
   ATSULineRef iLineRef,
   URefCon iRefCon,
   void *iOperationCallbackParameterPtr,
   ATSULayoutOperationCallbackStatus *oCallbackStatus,
   ATSUDirectLayoutOperationOverrideUPP userUPP
);
```

Return Value
A result code. See "ATSUI Result Codes" (page 2068).

Discussion
You should not need to use the function `InvokeATSUDirectLayoutOperationOverrideUPP`, as ATSUI calls your layout operation override callback for your. See the callback `ATSUDirectLayoutOperationOverrideProcPtr` (page 1998) for more information.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`ATSLayoutTypes.h`

InvokeRedrawBackgroundUPP

Invokes your redraw background callback.

```
Boolean InvokeRedrawBackgroundUPP (
   ATSUTextLayout iLayout,
   UniCharArrayOffset iTextOffset,
   UniCharCount iTextLength,
   ATSTrapezoid iUnhighlightArea[],
   ItemCount iTrapezoidCount,
   RedrawBackgroundUPP userUPP
);
```

Return Value
A `Boolean` value that indicates whether or not the callback was invoked successfully .

Discussion
You should not need to use the function `InvokeRedrawBackgroundUPP`, as ATSUI calls your redraw background callback for you. See the callback `RedrawBackgroundProcPtr` (page 1999) for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSUnicodeTypes.h`

NewATSCubicClosePathUPP

Creates a new universal procedure pointer (UPP) to a cubic close-path callback.

```
ATSCubicClosePathUPP NewATSCubicClosePathUPP (
   ATSCubicClosePathProcPtr userRoutine
);
```

Parameters

userRoutine
A pointer to your cubic close-path callback.

Return Value
On return, a UPP to the cubic close-path callback.

Discussion
See the callback `ATSCubicClosePathProcPtr` (page 1990) for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSUnicodeGlyphs.h`

NewATSCubicCurveToUPP

Creates a new universal procedure pointer (UPP) to a cubic curve-to callback.

```
ATSCubicCurveToUPP NewATSCubicCurveToUPP (
   ATSCubicCurveToProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your cubic curve-to callback.

Return Value
On return, a UPP to the cubic curve-to callback.

Discussion
See the callback `ATSCubicCurveToProcPtr` (page 1991) for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSUnicodeGlyphs.h`

NewATSCubicLineToUPP

Creates a new universal procedure pointer (UPP) to a cubic line-to callback.

```
ATSCubicLineToUPP NewATSCubicLineToUPP (
   ATSCubicLineToProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your cubic line-to callback.

Return Value
On return, a UPP to the cubic line-to callback.

Discussion
See the callback `ATSCubicLineToProcPtr` (page 1992) for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSUnicodeGlyphs.h`

NewATSCubicMoveToUPP

Creates a new universal procedure pointer (UPP) to a cubic move-to callback.

```
ATSCubicMoveToUPP NewATSCubicMoveToUPP (
   ATSCubicMoveToProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your cubic move-to callback.

Return Value
On return, a UPP to the cubic move-to callback.

Discussion
See the callback `ATSCubicMoveToProcPtr` (page 1993) for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSUnicodeGlyphs.h`

NewATSQuadraticClosePathUPP

Creates a new universal procedure pointer (UPP) to a quadratic close-path callback.

```
ATSQuadraticClosePathUPP NewATSQuadraticClosePathUPP (
   ATSQuadraticClosePathProcPtr userRoutine
);
```

Parameters

userRoutine
A pointer to your quadratic close-path callback.

Return Value
On return, a UPP to the quadratic close-path callback.

Discussion
See the callback `ATSQuadraticClosePathProcPtr` (page 1994) for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSUnicodeGlyphs.h`

NewATSQuadraticCurveUPP

Creates a new universal procedure pointer (UPP) to a quadratic curve callback.

```
ATSQuadraticCurveUPP NewATSQuadraticCurveUPP (
   ATSQuadraticCurveProcPtr userRoutine
);
```

Parameters

userRoutine
A pointer to your quadratic curve callback.

Return Value
On return, a UPP to the quadratic curve callback.

Discussion
See the callback `ATSQuadraticCurveProcPtr` (page 1995) for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSUnicodeGlyphs.h`

NewATSQuadraticLineUPP

Creates a new universal procedure pointer (UPP) to a quadratic line callback.

```
ATSQuadraticLineUPP NewATSQuadraticLineUPP (
   ATSQuadraticLineProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your quadratic line callback.

Return Value
On return, a UPP to the quadratic line callback.

Discussion
See the callback `ATSQuadraticLineProcPtr` (page 1996) for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSUnicodeGlyphs.h`

NewATSQuadraticNewPathUPP

Creates a new universal procedure pointer (UPP) to a quadratic new-path callback.

```
ATSQuadraticNewPathUPP NewATSQuadraticNewPathUPP (
   ATSQuadraticNewPathProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your quadratic new-path callback.

Return Value
On return, a UPP to the quadratic new-path callback.

Discussion
See the callback `ATSQuadraticNewPathProcPtr` (page 1997) for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSUnicodeGlyphs.h`

NewATSUDirectLayoutOperationOverrideUPP

Creates a new universal procedure pointer (UPP) to a layout operation override callback.

```
ATSUDirectLayoutOperationOverrideUPP NewATSUDirectLayoutOperationOverrideUPP (
   ATSUDirectLayoutOperationOverrideProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your layout operation override callback.

Return Value

On return, a UPP to the layout operation override callback.

Discussion

See the callback `ATSUDirectLayoutOperationOverrideProcPtr` (page 1998) for more information.

Availability

Available in Mac OS X v10.2 and later.

Declared In

`ATSLayoutTypes.h`

NewRedrawBackgroundUPP

Creates a new universal procedure pointer (UPP) to a redraw background callback.

```
RedrawBackgroundUPP NewRedrawBackgroundUPP (
   RedrawBackgroundProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your redraw background callback.

Return Value

On return, a UPP to the redraw background callback.

Discussion

See the callback `RedrawBackgroundProcPtr` (page 1999) for more information.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`ATSUnicodeTypes.h`

Callbacks

ATSCubicClosePathProcPtr

Defines a pointer to a cubic close-path callback for drawing glyphs that overrides ATSUI's cubic close-path operation for drawing glyphs.

```
typedef OSStatus(* ATSCubicClosePathProcPtr)
(
    void *callBackDataPtr
);
```

If you name your function `MyATSCubicClosePathCallback`, you would declare it like this:

```
OSStatus MyATSCubicClosePathCallback (
    void *callBackDataPtr
);
```

Parameters

`callBackDataPtr`

A pointer to any data your callback function needs. You pass this pointer to the function `ATSUGlyphGetCurvePaths` (page 1926). Then, ATSUI passes the pointer through to your callback function when your callback function is invoked.

Return Value

A value that indicates the status of your callback function. When a callback function returns any value other than `0`, the `ATSGlyphGetCubicPaths` function stops parsing the path outline and returns the result `kATSOutlineParseAbortedErr`.

Discussion

You supply a pointer to your customized cubic close-path callback as a parameter to the function `ATSUGlyphGetCubicPaths` (page 1925).

To provide a pointer to your cubic close-path callback, you create a universal procedure pointer (UPP) of type `ATSCubicClosePathUPP`, using the function `NewATSCubicClosePathUPP` (page 1985). You can do so with code similar to the following:

```
ATSCubicClosePathUPP MyCubicClosePathUPP;
MyCubicClosePathUPP = NewATSCubicClosePathUPP (&MyATSCubicClosePathCallback);
```

When you no longer need to use your cubic close-path callback, you should use the function `DisposeATSCubicClosePathUPP` (page 1976) to dispose of the universal procedure pointer associated with the callback.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`ATSUnicodeGlyphs.h`

ATSCubicCurveToProcPtr

Defines a pointer to a cubic curve-to callback for drawing glyphs that overrides ATSUI's cubic curve-to operation for drawing glyphs.

```
typedef OSStatus(* ATSCubicCurveToProcPtr)
(
    const Float32Point *pt1,
    const Float32Point *pt2,
    const Float32Point *pt3,
    void *callBackDataPtr
);
```

If you name your function `MyATSCubicCurveToCallback`, you would declare it like this:

```
OSStatus MyATSCubicCurveToCallback (
    const Float32Point *pt1,
    const Float32Point *pt2,
    const Float32Point *pt3,
    void *callBackDataPtr
);
```

Parameters

pt1

A `Float32Point` data structure that contains the x and y coordinates for the relative point that defines the first off-curve point for this segment of the glyph.

pt2

A `Float32Point` data structure that contains the x and y coordinates for the relative point that defines the second off-curve point for this segment of the glyph.

pt3

A `Float32Point` data structure that contains the x and y coordinates for the relative point that defines the end of the curve (an on-curve point) for this segment of the glyph.

callBackDataPtr

A pointer to any data your callback function needs. You pass this pointer to the function `ATSUGlyphGetCurvePaths` (page 1926). Then, ATSUI passes the pointer through to your callback function when your callback function is invoked.

Return Value

A value that indicates the status of your callback function. When a callback function returns any value other than `0`, the `ATSGlyphGetCubicPaths` function stops parsing the path outline and returns the result `kATSOutlineParseAbortedErr`.

Discussion

You supply a pointer to your customized cubic curve-to function as a parameter to the function `ATSUGlyphGetCubicPaths` (page 1925).

To provide a pointer to your cubic curve-to callback, you create a universal procedure pointer (UPP) of type `ATSCubicCurveToUPP`, using the function `NewATSCubicCurveToUPP` (page 1985). You can do so with code similar to the following:

```
ATSCubicCurveToUPP MyCubicCurveToUPP;
MyCubicCurveToUPP = NewATSCubicCurveToUPP (&MyATSCubicCurveToCallback);
```

When you no longer need to use your cubic curve-to callback, you should use the function `DisposeATSCubicCurveToUPP` (page 1976) to dispose of the universal procedure pointer associated with the callback.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSUnicodeGlyphs.h`

ATSCubicLineToProcPtr

Defines a pointer to a cubic line-to callback for drawing glyphs that overrides ATSUI's cubic line-to operation for drawing glyphs.

```
typedef OSStatus(* ATSCubicLineToProcPtr)
(
    const Float32Point *pt,
    void *callBackDataPtr
);
```

If you name your function `MyATSCubicLineToCallback`, you would declare it like this:

```
OSStatus MyATSCubicLineToCallback (
    const Float32Point *pt,
    void *callBackDataPtr
);
```

Parameters

pt

A `Float32Point` data structure that contains the x and y coordinates for the relative point to which the pen should draw a line.

callBackDataPtr

A pointer to any data your callback function needs. You pass this pointer to the function `ATSUGlyphGetCurvePaths` (page 1926). Then, ATSUI passes the pointer through to your callback function when your callback function is invoked.

Return Value
A value that indicates the status of your callback function. When a callback function returns any value other than `0`, the `ATSGlyphGetCubicPaths` function stops parsing the path outline and returns the result `kATSOutlineParseAbortedErr`.

Discussion
You supply a pointer to your customized cubic line-to callback as a parameter to the function `ATSUGlyphGetCubicPaths` (page 1925).

To provide a pointer to your cubic line-to callback, you create a universal procedure pointer (UPP) of type `ATSCubicLineToUPP`, using the function `NewATSCubicLineToUPP` (page 1986). You can do so with code similar to the following:

```
ATSCubicLineToUPP MyCubicLineToUPP;
MyCubicLineToUPP = NewATSCubicLineToUPP (&MyATSCubicLineToCallback);
```

When you no longer need to use your cubic line-to callback, you should use the function `DisposeATSCubicLineToUPP` (page 1977) to dispose of the universal procedure pointer associated with the callback.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSUnicodeGlyphs.h`

ATSCubicMoveToProcPtr

Defines a pointer to a cubic move-to function for drawing glyphs that overrides ATSUI's cubic move-to operation for drawing glyphs.

```
typedef OSStatus(* ATSCubicMoveToProcPtr)
(
    const Float32Point *pt,
    void *callBackDataPtr
);
```

If you name your function `MyATSCubicMoveToCallback`, you would declare it like this:

```
OSStatus MyATSCubicMoveToCallback (
    const Float32Point *pt,
    void *callBackDataPtr
);
```

Parameters

pt

A `Float32Point` data structure that contains the x and y coordinates for the relative point to which the pen should move before it begins drawing this segment of the glyph.

callBackDataPtr

A pointer to any data your callback function needs. You pass this pointer to the function `ATSUGlyphGetCurvePaths` (page 1926). Then, ATSUI passes the pointer through to your callback function when your callback function is invoked.

Return Value
A value that indicates the status of your callback function. When a callback function returns any value other than `0`, the `ATSGlyphGetCubicPaths` function stops parsing the path outline and returns the result `kATSOutlineParseAbortedErr`.

Discussion
You supply a pointer to your customized cubic move-to callback as a parameter to the function `ATSUGlyphGetCubicPaths` (page 1925).

To provide a pointer to your cubic move-to callback, you create a universal procedure pointer (UPP) of type `ATSCubicMoveToUPP`, using the function `NewATSCubicMoveToUPP` (page 1986). You can do so with code similar to the following:

```
ATSCubicMoveToUPP MyCubicMoveToUPP;
MyCubicMoveToUPP = ATSCubicMoveToUPP (&MyATSCubicMoveToCallback);
```

When you no longer need to use your cubic move-to callback, you should use the function `DisposeATSCubicMoveToUPP` (page 1977) to dispose of the universal procedure pointer associated with the callback.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSUnicodeGlyphs.h`

ATSQuadraticClosePathProcPtr

Defines a pointer to a quadratic close-path callback for drawing glyphs that overrides ATSUI's quadratic close-path operation for drawing glyphs.

```
typedef OSStatus(* ATSQuadraticClosePathProcPtr)
(
    void *callBackDataPtr
);
```

If you name your function `MyATSQuadraticClosePathCallback`, you would declare it like this:

```
OSStatus MyATSQuadraticClosePathCallback
(
    void *callBackDataPtr
);
```

Parameters

`callBackDataPtr`

A pointer to any data your callback function needs. You pass this pointer to the function `ATSUGlyphGetQuadraticPaths` (page 1928). Then, ATSUI passes the pointer through to your callback function when your callback function is invoked.

Return Value
A value that indicates the status of your callback function. When a callback function returns any value other than `0`, the `ATSGlyphGetQuadraticPaths` function stops parsing the path outline and returns the result `kATSOutlineParseAbortedErr`.

Discussion
You supply a pointer to your customized quadratic close-path callback as a parameter to the function `ATSUGlyphGetQuadraticPaths` (page 1928).

To provide a pointer to your quadratic close-path callback, you create a universal procedure pointer (UPP) of type `ATSQuadraticClosePathUPP`, using the function `NewATSQuadraticClosePathUPP` (page 1987). You can do so with code similar to the following:

```
ATSQuadraticClosePathUPP MyQuadraticClosePathUPP;
MyQuadraticClosePathUPP = NewATSQuadraticClosePathUPP
(&MyATSQuadraticClosePathCallback);
```

When you no longer need to use your quadratic close-path callback, you should use the function `DisposeATSQuadraticClosePathUPP` (page 1978) to dispose of the universal procedure pointer associated with the callback.

Availability
Available in Mac OS X v10.0 and later.

Declared In

ATSQuadraticCurveProcPtr

Defines a pointer to a quadratic curve callback for drawing glyphs that overrides ATSUI's quadratic curve operation for drawing glyphs.

```
typedef OSStatus(* ATSQuadraticCurveProcPtr)
(
    const Float32Point *pt1,
    const Float32Point *controlPt,
    const Float32Point *pt2,
    void *callBackDataPtr
);
```

If you name your function `MyATSQuadraticCurveCallback`, you would declare it like this:

```
OSStatus MyATSQuadraticCurveCallback (
    const Float32Point *pt1,
    const Float32Point *controlPt,
    const Float32Point *pt2,
    void *callBackDataPtr
);
```

Parameters

pt1

A `Float32Point` data structure that contains the x and y coordinates for the relative point that defines the start of the curve (an on-curve point) for this segment of the glyph.

controlPt

A `Float32Point` data structure that contains the x and y coordinates for the relative point that defines the control point (an off-curve point) for this segment of the glyph.

pt2

A `Float32Point` data structure that contains the x and y coordinates for the relative point that defines the end of the curve (an on-curve point) for this segment of the glyph.

callBackDataPtr

A pointer to any data your callback function needs. You pass this pointer to the function `ATSUGlyphGetQuadraticPaths` (page 1928). Then, ATSUI passes the pointer through to your callback function when your callback function is invoked.

Return Value
A value that indicates the status of your callback function. When a callback function returns any value other than `0`, the `ATSGlyphGetQuadraticPaths` function stops parsing the path outline and returns the result `kATSOutlineParseAbortedErr`.

Discussion
You supply a pointer to your customized quadratic curve callback as a parameter to the function `ATSUGlyphGetQuadraticPaths` (page 1928).

To provide a pointer to your quadratic curve callback, you create a universal procedure pointer (UPP) of type `ATSQuadraticCurveUPP`, using the function `NewATSQuadraticCurveUPP` (page 1987). You can do so with code similar to the following:

```
ATSQuadraticCurveUPP MyQuadraticCurveUPP;
MyQuadraticCurveUPP = NewATSQuadraticCurveUPP (&MyATSQuadraticCurveCallback);
```

When you no longer need to use your quadratic curve callback, you should use the function `DisposeATSQuadraticCurveUPP` (page 1978) to dispose of the universal procedure pointer associated with the callback.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSUnicodeGlyphs.h`

ATSQuadraticLineProcPtr

Defines a pointer to a quadratic line callback for drawing glyphs that overrides ATSUI's quadratic line operation for drawing glyphs.

```
typedef OSStatus(* ATSQuadraticLineProcPtr)
(
    const Float32Point *pt1,
    const Float32Point *pt2,
    void *callBackDataPtr
);
```

If you name your function `MyATSQuadraticLineCallback`, you would declare it like this:

```
OSStatus MyATSQuadraticLineCallback (
    const Float32Point *pt1,
    const Float32Point *pt2,
    void *callBackDataPtr
);
```

Parameters

pt1
A `Float32Point` data structure that contains the x and y coordinates for the relative point that defines the start of the line for this segment of the glyph.

pt2
A `Float32Point` data structure that contains the x and y coordinates for the relative point that defines the end of the line for this segment of the glyph.

callBackDataPtr
A pointer to any data your callback function needs. You pass this pointer to the function `ATSUGlyphGetQuadraticPaths` (page 1928). Then, ATSUI passes the pointer through to your callback function when your callback function is invoked.

Return Value
A value that indicates the status of your callback function. When a callback function returns any value other than `0`, the `ATSGlyphGetQuadraticPaths` function stops parsing the path outline and returns the result `kATSOutlineParseAbortedErr`.

Discussion
You supply a pointer to your customized quadratic line callback as a parameter to the function `ATSUGlyphGetQuadraticPaths` (page 1928).

To provide a pointer to your quadratic line callback, you create a universal procedure pointer (UPP) of type `ATSQuadraticLineUPP`, using the function `NewATSQuadraticLineUPP` (page 1988). You can do so with code similar to the following:

```
ATSQuadraticLineUPP MyQuadraticLineUPP;
MyQuadraticLineUPP = NewATSQuadraticLineUPP (&MyATSQuadraticLineCallback);
```

When you no longer need to use your quadratic line callback, you should use the function `DisposeATSQuadraticLineUPP` (page 1978) to dispose of the universal procedure pointer associated with the callback.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSUnicodeGlyphs.h`

ATSQuadraticNewPathProcPtr

Defines a pointer to a quadratic new-path callback for drawing glyphs that overrides ATSUI's quadratic new-path operation for drawing glyphs.

```
typedef OSStatus(* ATSQuadraticNewPathProcPtr)
(
    void *callBackDataPtr
);
```

If you name your function `MyATSQuadraticNewPathCallback`, you would declare it like this:

```
OSStatus MyATSQuadraticNewPathCallback
(
    void *callBackDataPtr
);
```

Parameters

`callBackDataPtr`

A pointer to any data your callback function needs. You pass this pointer to the function `ATSUGlyphGetQuadraticPaths` (page 1928). Then, ATSUI passes the pointer through to your callback function when your callback function is invoked.

Return Value
A value that indicates the status of your callback function. When a callback function returns any value other than `0`, the `ATSGlyphGetQuadraticPaths` function stops parsing the path outline and returns the result `kATSOutlineParseAbortedErr`.

Discussion
You supply a pointer to your customized quadratic new-path callback as a parameter to the function `ATSUGlyphGetQuadraticPaths` (page 1928).

To provide a pointer to your quadratic new-path callback, you create a universal procedure pointer (UPP) of type `ATSQuadraticNewPathUPP`, using the function `NewATSQuadraticNewPathUPP` (page 1988). You can do so with code similar to the following:

```
ATSQuadraticNewPathUPP MyQuadraticNewPathUPP;
MyQuadraticNewPathUPP = NewATSQuadraticNewPathUPP
(&MyATSQuadraticNewPathCallback);
```

When you no longer need to use your quadratic new-path callback, you should use the function `DisposeATSQuadraticNewPathUPP` (page 1979) to dispose of the universal procedure pointer associated with the callback.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSUnicodeGlyphs.h`

ATSUDirectLayoutOperationOverrideProcPtr

Defines a pointer to a layout operation callback that overrides an ATSUI layout operation.

```
typedef CALLBACK_API_C (OSStatus, ATSUDirectLayoutOperationOverrideProcPtr
)
    ATSULayoutOperationSelector iCurrentOperation,
    ATSULineRef iLineRef,
    UInt32 iRefCon,
    void *iOperationCallbackParameterPtr,
    ATSULayoutOperationCallbackStatus *oCallbackStatus
);
```

If you name your function `MyLayoutOperationOverrideCallback`, you would declare it like this:

```
OSStatus MyLayoutOperationOverrideCallback
(
    ATSULayoutOperationSelector iCurrentOperation,
    ATSULineRef iLineRef,
    UInt32 iRefCon,
    void *iOperationCallbackParameterPtr,
    ATSULayoutOperationCallbackStatus *oCallbackStatus
);
```

Parameters

iCurrentOperation
The operation that triggered the callback. This value is passed to your callback by ATSUI. If you write a callback that handles more than one layout operation, you can use this value to determine which operation you should handle.

iLineRef
An `ATSULineRef` value that specifies the line of text on which your callback will operation. Your callback gets called for each line of text associated with the text layout object on which you installed the callback.

iRefCon

An unsigned 32-bit integer. This is an optional value. You can use this value to specify any data your application needs, such as user preference data.

iOperationCallbackParameterPtr

A pointer. This is currently unused and should be set to `NULL`.

oCallbackStatus

A layout callback status value. On output, you must supply a status value to indicate to ATSUI whether or not your callback handled the operation. See "Layout Callback Status Values" (page 2055) for a list of the constants you can supply.

Discussion

ATSUI calls your layout operation override function each time the layout operation you specify is invoked. You associate a universal procedure pointer with a text layout object by treating the callback as a layout attribute. That is, you set up a triple (tag, size, value) to specify the layout operation your callback handles, then you call the function `ATSUSetLayoutControls` (page 1955) to associate the triple with the text layout object whose layout operation you want to override. The attribute tag you specify is `kATSULayoutOperationOverrideTag`. The attribute value you specify is an `ATSULayoutOperationOverrideSpecifier` structure that contains a selector for a layout operation and a pointer to your callback function.

To provide a pointer to your layout operation override callback, you create a universal procedure pointer (UPP) of type `ATSUDirectLayoutOperationOverrideUPP`, using the function `NewATSUDirectLayoutOperationOverrideUPP` (page 1989). You can do so with code similar to the following:

```
ATSUDirectLayoutOperationOverrideUPP MyLayoutOperationOverrideUPP;
MyLayoutOperationOverrideUPP = NewATSUDirectLayoutOperationOverrideUPP
                                (&MyLayoutOperationOverrideCallback);
```

When your layout operation is completed, you should use the function `DisposeATSUDirectLayoutOperationOverrideUPP` (page 1979) to dispose of the universal procedure pointer associated with your layout operation override function. However, if you plan to use the same layout operation override function in subsequent layout operations, you can reuse the same UPP, rather than dispose of it and later create a new UPP.

You are limited to the ATSUI functions you can call from within your callback. You can call only those functions that have do not trigger ATSUI to perform the layout operation again. Otherwise, you run the risk of causing infinite recursion. Most functions that use "create", "get", or "copy" semantics are safe to use within your callback. If you call one of the restricted functions, the function returns immediately with the error `kATSUInvalidCallInsideCallbackErr`.

Availability

Available in Mac OS X v10.2 and later.

Declared In

`ATSLayoutTypes.h`

RedrawBackgroundProcPtr

Defines a pointer to a redraw-background callback that overrides ATSUI's highlighting method for drawing backgrounds.

```
typedef Boolean (* RedrawBackgroundProcPtr)
(
    ATSUTextLayout iLayout,
    UniCharArrayOffset iTextOffset,
    UniCharCount iTextLength,
    ATSTrapezoid *iUnhighlightArea,
    ItemCount iTrapezoidCount
);
```

If you name your function `MyRedrawBackgroundCallback`, you would declare it like this:

```
Boolean MyRedrawBackgroundCallback (
    ATSUTextLayout iLayout,
    UniCharArrayOffset iTextOffset,
    UniCharCount iTextLength,
    ATSTrapezoid *iUnhighlightArea,
    ItemCount iTrapezoidCount
);
```

Parameters

iLayout

An `ATSUTextLayout` value that specifies the text layout object on which your callback will operate.

iTextOffset

The offset of the text to be highlighted.

iTextLength

The length of the text to be highlighted.

iUnhighlightArea

An array of `ATSTrapezoid` data structures that describe the boundaries of the highlight area. The boundary values in this array are always specified in QuickDraw coordinates.

iTrapezoidCount

The number of `ATSTrapezoid` data structures in the `iUnhighlightArea` array.

Return Value

A `Boolean` value that indicates whether ATSUI should redraw the text. If your function redraws the text, your callback should return `false`, otherwise you callback should return `true` to have ATSUI redraw any text that needs to be redrawn.

Discussion

ATSUI calls your customized redraw-background callback when it needs to redraw complex backgrounds (and optionally the text as well). For ATSUI to use your callback, you must first call the `ATSUSetHighlightingMethod` (page 1953) function with the `iMethod` parameter set to `kRedrawHighlighting`. You must also pass an `ATSUUnhighlightData` data structure as a parameter to the `ATSUSetHighlightingMethod` function. This structure should contain a pointer to your redraw background callback.

To provide a pointer to your redraw background callback, you create a universal procedure pointer (UPP) of type `RedrawBackgroundUPP`, using the function `NewRedrawBackgroundUPP` (page 1989). You can do so with code similar to the following:

```
RedrawBackgroundUPP gMyRedrawBackgroundUPP;
gMyRedrawBackgroundUPP = NewRedrawBackgroundUPP
                            (&MyRedrawBackgroundCallback);
```

For ATSUI to invoke your callback function, you must also pass the `RedrawBackgroundUPP` in the `unhighlightData.backgroundUPP` field of the `iUnhighlightData` parameter for the function `ATSUSetHighlightingMethod`. When finished, you must call the function `DisposeRedrawBackgroundUPP` (page 1980) to dispose of the `RedrawBackgroundUPP`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSUnicodeTypes.h`

Data Types

Core Data Types

ATSUAttributeInfo

Contains an attribute tag and the size of the attribute.

```
struct ATSUAttributeInfo {
    ATSUAttributeTag fTag;
    ByteCount fValueSize;
};
```

Fields

`fTag`

Identifies a particular style run or text attribute value. For a description of the Apple-defined style run and text layout attribute tag constants, see "Attribute Tags" (page 2030).

`fValueSize`

The size (in bytes) of the style run or text layout attribute value.

Discussion
Several ATSUI functions pass back an array of structures of this type. The function `ATSUGetAllAttributes` (page 1886) passes back an array of `ATSUAttributeInfo` structures to represent the data sizes of all previously set style run attribute values and the corresponding style run attribute tags that identify those style run attribute values. The function `ATSUGetAllLayoutControls` (page 1890) passes back an array of `ATSUAttributeInfo` structures to represent the data sizes of all previously set text layout attribute values for an entire text layout object and the corresponding text layout attribute tags that identify those text layout attribute values. The function `ATSUGetAllLineControls` (page 1891) passes back an array of `ATSUAttributeInfo` structures to represent the data sizes of all previously set text layout attribute values for a single line in a text layout object and the corresponding text layout attribute tags that identify those text layout attribute values.

ATSLayoutRecord

Contains basic layout information for a single glyph.

```
struct ATSLayoutRecord {
    ATSGlyphRef         glyphID;
    ATSGlyphInfoFlags   flags;
    ByteCount           originalOffset;
    Fixed               realPos;
};
typedef struct ATSLayoutRecord ATSLayoutRecord;
```

Fields

`glyphID`

A reference to a glyph ID.

`flags`

A flag that specifies the glyph's properties. See "Glyph Property Flags" (page 2051) for the constants you can use.

`originalOffset`

The byte offset of the character with which this glyph is associated.

`realPos`

A `Fixed` value that specifies the real position of the glyph. This is the x-coordinate of the glyph.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`ATSLayoutTypes.h`

ATSUStyleSettingRef

A reference to an opaque style setting object.

```
typedef struct LLCStyleInfo*         ATSUStyleSettingRef;
```

Discussion
You can obtain a style setting reference by calling the functions `ATSUDirectGetLayoutDataArrayPtrFromLineRef` (page 1872) or `ATSUDirectGetLayoutDataArrayPtrFromTextLayout` (page 1873) with the selector set to `kATSUDirectDataStyleSettingATSUStyleSettingRefArray`. You can move a style setting reference from one text layout object to another by calling the function `ATSUDirectAddStyleSettingRef` (page 1871).

Availability
Available in Mac OS X v10.2 and later.

Declared In
`ATSUnicodeDirectAccess.h`

ATSUAttributeValuePtr

Represents a pointer to a style run or text layout attribute value of unknown size.

```
typedef void* ATSUAttributeValuePtr;
```

Discussion
Each attribute value pointed to by `ATSUAttributeValuePtr` is identified by an attribute tag and the size (in bytes) of the attribute value.

You pass the `ATSUAttributeValuePtr` type to functions that set or clear attribute values in style and text layout objects. The `ATSUAttributeValuePtr` type is passed back by functions that query style and text layout objects for their attribute values. You must dereference this pointer and cast it to the appropriate data type to obtain the actual attribute value.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSUnicodeTypes.h`

ConstATSUAttributeValuePtr

A pointer to a constant attribute value pointer (`ATSUAttributeValuePtr`).

```
typedef const void* ConstATSUAttributeValuePtr;
```

Discussion
An `ATSUAttributeValuePtr` data type provides generic access to storage of attribute values which vary in size.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSUnicodeTypes.h`

ATSURGBAlphaColor

Contains color information that includes alpha channel information.

```
struct ATSURGBAlphaColor {
    float               red;
    float               green;
    float               blue;
    float               alpha;
};
typedef struct ATSURGBAlphaColor        ATSURGBAlphaColor;
```

Fields

`red`
A value that specifies the red component of the background color.

`green`
A value that specifies the green component of the background color.

`blue`
A value that specifies the blue component of the background color.

`alpha`
A value that specifies thee alpha channel component of the background color.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`ATSUnicodeTypes.h`

ATSUBackgroundColor

Redefines the `ATSUBackgroundColor` data type to be an `ATSURGBAlphaColor` data type.

```
typedef ATSURGBAlphaColor ATSUBackgroundColor;
```

Discussion
Prior to Mac OS X version 10.2, the `ATSUBackgroundColor` data type did not include an alpha channel.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSUnicodeTypes.h`

ATSUBackgroundData

A union that contains a background color or a universal procedure pointer to a callback that redraws the background.

```
union ATSUBackgroundData {
    ATSUBackgroundColor backgroundColor;
    RedrawBackgroundUPP backgroundUPP;
};
```

Fields
`backgroundColor`
A structure that specifies the background color.

`backgroundUPP`
A universal procedure pointer to a callback function for redrawing complex backgrounds. See `RedrawBackgroundUPP` (page 2030) for more information.

ATSUCaret

Contains the coordinates needed to draw a caret.

```
struct ATSUCaret {
    Fixed fX;
    Fixed fY;
    Fixed fDeltaX;
    Fixed fDeltaY;
};
```

Fields

`fX`

Represents the x-coordinate of the caret's starting pen position relative to the position of the origin of the line in the current graphics port in which the hit occurred.

`fY`

Represents the y-coordinate of the caret's starting pen position relative to the position of the origin of the line in the current graphics port in which the hit occurred.

`fDeltaX`

Represents the x-coordinate of the caret's ending pen position relative to the position of the origin of the line in the current graphics port in which the hit occurred. This position takes into account line rotation. You do not have to rotate it yourself.

`fDeltaY`

Represents the y-coordinate of the caret's ending pen position relative to the position of the origin of the line in the current graphics port in which the hit occurred. This position takes into account line rotation. You do not have to rotate it yourself.

Discussion

The function `ATSUOffsetToPosition` (page 1942) passes back two structures of type `ATSUCaret` to represent the caret position relative to the origin of the line in the current graphics port, corresponding to a specified edge offset. If the edge offset is at a line boundary, the structure passed back in `oMainCaret` contains the starting and ending pen locations of the high caret, while `oSecondCaret` contains the low caret. If the offset is not at a line boundary, both parameters contain the same structure. This structure contains the starting and ending pen locations of the main caret.

You can use the information in this structure to draw a caret by calling the `MoveTo` and `LineTo` functions. For example.

```
MoveTo (fX, fY);
LineTo (fDeltaX, fDeltaY);
```

ATSUFontFeatureType

Represents the attributes of a particular font feature.

```
typedef UInt16 ATSUFontFeatureType;
```

Discussion

Font features are typographic and layout capabilities that you can select or deselect and which control many aspects of glyph selection, ordering, and positioning. Font features include fundamental controls such as whether your text is drawn with contextual forms, as well as details of appearance such as whether you want alternate forms of glyphs to be used at the beginning of a word. To a large extent, how text looks when it is laid out is a function of the number and kinds of font features you choose.

Font vendors create tables that implement the specific set of features which are included in a font by the font designer. Note that only a few feature types and selectors may be available with a given font. If you select features that are not available in a font, you won't see a change in the glyph's appearance. To determine the available features of a font, you can call the functions `ATSUGetFontFeatureTypes` (page 1898) and `ATSUGetFontFeatureSelectors` (page 1897).

For a complete discussion of font features, the selectors you use to access them, and illustrations of the features, see *Inside Mac OS X: Rendering Unicode Text With ATSUI*.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSUnicodeTypes.h`

ATSUFontFeatureSelector

Represents the state (on or off) of a particular feature type.

```
typedef UInt16 ATSUFontFeatureSelector;
```

Discussion
You pass the `ATSUFontFeatureSelector` type to functions that set or clear font feature selectors in a style run. The `ATSUFontFeatureSelector` type is passed back by functions that obtain font feature selectors in a style run. For a complete discussion of font feature selectors, see *Inside Mac OS X: Rendering Unicode Text With ATSUI*.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSUnicodeTypes.h`

ATSUFontVariationAxis

Represents a stylistic attribute and the range of values that the font can use to express this attribute.

```
typedef FourCharCode ATSUFontVariationAxis;
```

Discussion
Font variations allow your application to produce a range of type styles algorithmically. You can obtain a a variation axis and its maximum, minimum, and default values for a font by calling the function `ATSUGetIndFontVariation` (page 1911). For a complete discussion of font variations, see *Inside Mac OS X: Rendering Unicode Text With ATSUI*.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSUnicodeTypes.h`

ATSUFontVariationValue

Represents the range of values that the font can use for a particular font variation.

```
typedef Fixed ATSUFontVariationValue;
```

Discussion
You pass the `ATSUFontVariationValue` type to functions that set and clear font variations in a style run. The `ATSUFontVariationValue` type is passed back by functions that query a style run for font variations.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSUnicodeTypes.h`

ATSUFontFallbacks

An opaque structure that contains a font fallback list and font fallback cache information.

```
typedef struct OpaqueATSUFontFallbacks *ATSUFontFallbacks;
```

Availability
Available in Mac OS X v10.1 and later.

Declared In
`ATSUnicodeTypes.h`

ATSUFontID

Represents the unique identifier of a font to the font management system in ATSUI.

```
typedef FMFont ATSUFontID;
```

Discussion
You pass the `ATSUFontID` type with functions that set and obtain font information. The `ATSUFontID` type is passed back by functions that count fonts installed on a user's system. The `ATSUFontID` type can be also used to set and get the font in a style run; see "Attribute Tags" (page 2030).

An `ATSUFontID` specifies a font family and instance. This value is not guaranteed to remain constant if the system is restarted. You should obtain the font's unique name and store that information in documents for which you need persistent font information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSUnicodeTypes.h`

ATSUGlyphInfo

Contains information about a glyph.

```
struct ATSUGlyphInfo {
    GlyphID glyphID;
    UInt16 reserved;
    UInt32 layoutFlags;
    UniCharArrayOffset charIndex;
    ATSUStyle style;
    Float32 deltaY;
    Float32 idealX;
    SInt16 screenX;
    SInt16 caretX;
};
```

Fields

`glyphID`
A glyph ID. This is unique to the associated font.

`reserved`
Reserved for Apple's use.

`layoutFlags`
The layout flags associated with this glyph.

`charIndex`
The index of the character in the Unicode character stream from which this glyph is derived.

`style`
An `ATSUStyle` value that specifies the style object associated with this glyph.

`deltaY`
The cross-stream shift value for this glyph.

`idealX`
The ideal with-stream offset from the origin of this layout.

`screenX`
The device-adjusted with-stream offset from the origin of this layout.

`caretX`
The position in device coordinates where a trailing caret for this glyph intersects the baseline.

Discussion

This data structure is used by ATSUI to return the glyph information associated with one glyph.

ATSUGlyphInfoArray

Contains text layout information for an array of glyphs.

```
struct ATSUGlyphInfoArray {
    ATSUTextLayout layout;
    ItemCount numGlyphs;
    ATSUGlyphInfo glyphs[1];
};
```

Fields

`layout`
An `ATSUTextLayout` value that specifies the text layout object associated with the glyphs.

`numGlyphs`
The number of glyphs associated with the text layout object.

`glyphs`
An array of glyph information structures.

Discussion
This data structure is used by ATSUI to return the glyph information associated with the glyphs in a text layout object.

ATSUGlyphSelector

Contains information that directs ATSUI to use a specific glyph instead of the one ATSUI normally derives.

```
struct ATSUGlyphSelector {
    GlyphCollection     collection;
    GlyphID             glyphID;
};
typedef struct ATSUGlyphSelector        ATSUGlyphSelector;
```

Fields
`collection`
A value that represents the collection of glyphs you want ATSUI to use. See "Glyph Collection Types" (page 2050) for possible values you can supply.

`glyphID`
A glyph ID value or a collection ID (CID) value. Supply a glyph ID when the collection type is `kGlyphCollectionGID`. Otherwise supply a CID.

Discussion
The `ATSUGlyphSelector` structure along with the attribute tag `kATSUGlyphSelectorTag` allow display of glyphs that do not have an explicit Unicode character. You can use the `kATSUGlyphSelectorTag` to access characters in fonts that otherwise would not be accessible. You can choose the variant glyph by font-specific glyph ID or CID. For more information on CID conventions, see go to http://www.adobe.com. You can get the variant glyph information from an input method through the Text Services Manager using the Carbon event key `kEventParamTextInputGlyphInfoArray`.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`ATSUnicodeTypes.h`

ATSJustPriorityWidthDeltaOverrides

Contains justification width delta override structures, one for each priority-level override.

```
typedef ATSJustWidthDeltaEntryOverride ATSJustPriorityWidthDeltaOverrides[4];
```

Discussion
For more information see `ATSJustWidthDeltaEntryOverride` (page 2010).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSLayoutTypes.h`

ATSJustWidthDeltaEntryOverride

Contains values that specify the amount of space that can be added to or removed from the right and left sides of each of the glyphs of a given justification priority.

```
struct ATSJustWidthDeltaEntryOverride {
    Fixed beforeGrowLimit;
    Fixed beforeShrinkLimit;
    Fixed afterGrowLimit;
    Fixed afterShrinkLimit;
    JustificationFlags growFlags;
    JustificationFlags shrinkFlags;
};
typedef struct ATSJustWidthDeltaEntryOverride ATSJustWidthDeltaEntryOverride;
```

Fields

`beforeGrowLimit`
The proportion by which a glyph can expand on the left side (top side for vertical text). For example, a value of 0.2 means that a 24-point glyph can have by no more than 4.8 points (0.2 x 24 = 4.8) of extra space added on the left side (top side for vertical text).

`beforeShrinkLimit`
The proportion by which a glyph can shrink on the left side (top side for vertical text). If specified, this value should be negative.

`afterGrowLimit`
The proportion by which a glyph can expand on the right side (bottom side for vertical text).

`afterShrinkLimit`
The proportion by which a glyph can shrink on the right side (bottom side for vertical text). If specified, this value should be negative.

`growFlags`
Mask constants that indicate whether ATSUI should apply the limits defined in the `beforeGrowLimit` and `afterGrowLimit` fields. See "Justification Override Mask Constants" in the Font Manager for a description of possible values. These mask constants also control whether unlimited gap absorption should be applied to the priority of glyphs specified in the given width delta override structure. You can use these mask constants to selectively override the grow case only, while retaining default behavior for other cases.

`shrinkFlags`
Mask constants that indicate whether ATSUI should apply the limits defined in the `beforeShrinkLimit` and `afterShrinkLimit` fields. See "Justification Override Mask Constants" in the Font Manager for a description of possible values. These mask constants also control whether unlimited gap absorption should be applied to the priority of glyphs specified in the given width delta override structure. You can use these mask constants to selectively override the shrink case only, while retaining default behavior for other cases.

Discussion

The `JustWidthDeltaEntryOverride` structure specifies proportions for justification growth and shrinkage, both on the left and the right sides. The growth and shrinkage values override the font-specified widths, such as those specified by the font for kashidas.

It also contains justification flags. The `ATSJustWidthDeltaEntryOverride` data type can be used to set and get justification behavior and priority override weighting; see "Attribute Tags" (page 2030).

If you need to access other `'just'` table constants and structures from the `'sfnt'` resource, see the header file SFNTLayoutTypes.h.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSLayoutTypes.h`

ATSULayoutOperationOverrideSpecifier

Contains an layout operation selector and a pointer to a layout operation override callback.

```
struct ATSULayoutOperationOverrideSpecifier {
    ATSULayoutOperationSelector  operationSelector;
    ATSUDirectLayoutOperationOverrideUPP  overrideUPP;
};
typedef struct ATSULayoutOperationOverrideSpecifier
ATSULayoutOperationOverrideSpecifier;
```

Fields

`operationSelector`

A layout operation selector that specifies the operation for which the callback should be invoked. See "Layout Operation Selectors" (page 2055) for the selectors you can specify.

`overrideUPP`

A universal procedure pointer to a layout operation override callback.

Discussion
You can pass this structure as an attribute value for the layout attribute tag `kATSULayoutOperationOverrideTag`.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`ATSLayoutTypes.h`

ATSULineRef

Represents a reference to a structure that specifies a line of text.

```
typedef struct ATSGlyphVector *ATSULineRef;
```

Discussion
You get an ATSUI line reference from ATSUI when your layout operation override callback is invoked. The line reference refers to the line that ATSUI is in the process of laying out.

From within your callback, you pass an ATSUI line reference to the function `ATSUDirectGetLayoutDataArrayPtrFromLineRef` to obtain layout data for that line. The only way you can obtain an ATSUI line reference is from inside your layout operation override callback. An ATSUI line reference is not valid is outside of the callback.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`ATSLayoutTypes.h`

ATSUStyle

Represents a reference to an opaque structure that contains information about a style object.

```
typedef struct OpaqueATSUStyle *ATSUStyle;
```

Discussion
A style object is an opaque structure encapsulating the following character-level style settings

- style attributes: including font ID, font size, font color, kerning control, optical alignment, verticality, and with-stream (left-right) and cross-stream (up-down) shifting (as for superscripts and subscripts)
- font features: including ligatures, swashes, and alternate glyph forms
- font variations: such as continually varying font weight, width, or slant

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSUnicodeTypes.h`

ATSUStyleRunInfo

Contains information for a style run.

```
struct ATSUStyleRunInfo {
    UniCharCount        runLength;
    ItemCount           styleObjectIndex;
};
typedef struct ATSUStyleRunInfo         ATSUStyleRunInfo;
```

Fields
`runLength`
The length of the style run.
`styleObjectIndex`
An index into an array of unique style objects.

Discussion
This structure is used by the function `ATSUUnflattenStyleRunsFromStream` (page 1972) to return style run information.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`ATSUnicodeFlattening.h`

ATSUTab

Contains tab settings.

```
struct ATSUTab {
    ATSUTextMeasurement  tabPosition;
    ATSUTabType                         tabType;
};
typedef struct ATSUTab ATSUTab;
```

Fields

`tabPosition`

Specifies a tab position.

`tabType`

Specifies a type of tab stop. See "Tab Positioning Options" (page 2066).

Discussion

You can set tabs for a text layout object by calling the function `ATSUSetTabArray` (page 1962). You can obtain tab settings by calling the function `ATSUGetTabArray` (page 1918).

Availability

Available in Mac OS X v10.2 and later.

Declared In

`ATSUnicodeTypes.h`

ATSUTextLayout

Represents a reference to an opaque text layout structure that contains information about a text layout.

```
typedef struct OpaqueATSUTextLayout* ATSUTextLayout;
```

Discussion

The basic building block upon which ATSUI operates is a text layout object (`ATSUTextLayout`). A text layout object ties one or more paragraphs of text together with style attributes that may apply to characters, lines, or the entire layout. The text layout object itself contains information about line and layout attributes, including justification, rotation, direction, and others. Character style information is contained in a style object, which is only associated with, not contained by, a text layout object. For more information on text layout objects, see *Inside Mac OS X: Rendering Unicode Text With ATSUI*.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`ATSUnicodeTypes.h`

ATSUTextMeasurement

Represents measurements needed by ATSUI to lay out text, such as outline metrics and line width, ascent, descent.

```
typedef Fixed ATSUTextMeasurement;
```

Discussion

The `ATSUTextMeasurement` type is defined as a `Fixed` value, with a limit of 32K. You must ensure that your measurements are converted to `Fixed` values before passing them to ATSUI functions that use this type.

ATSUI uses fractional `Fixed` values instead of `short` values used in QuickDraw Text. Fractional `Fixed` values provide exact outline metrics and line specifications such as line width, ascent, descent, and so on.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSUnicodeTypes.h`

ATSTrapezoid

Contains the coordinates of the typographic bounding trapezoid for the final layout of a line a text.

```
struct ATSTrapezoid {
    FixedPoint upperLeft;
    FixedPoint upperRight;
    FixedPoint lowerRight;
    FixedPoint lowerLeft;
};
```

Fields

`upperLeft`
A structure of type `FixedPoint` that contains the upper left coordinates (assuming a horizontal line of text) of the typographic glyph bounds.

`upperRight`
A structure of type `FixedPoint` that contains the upper right coordinates (assuming a horizontal line of text) of the typographic glyph bounds.

`lowerRight`
A structure of type `FixedPoint` that identifies the lower right coordinates (assuming a horizontal line of text) of the typographic glyph bounds.

`lowerLeft`
A structure of type `FixedPoint` that identifies the lower left coordinates (assuming a horizontal line of text) of the typographic glyph bounds.

Discussion
The dimensions of the resulting trapezoid are relative to the coordinates specified in the `iTextBasePointX` and `iTextBasePointY` parameters. The width of the glyph bounds is determined based on the value passed in the `iTypeOfBounds` parameter.

The function `ATSUGetGlyphBounds` (page 1904) passes back an array of structures of type `ATSTrapezoid` to specify the enclosing trapezoid(s) of a final laid-out line of text. If the range of text spans directional boundaries, `ATSUGetGlyphBounds` produces multiple trapezoids defining these regions.

Version Notes
In ATSUI 1.1, the function `ATSUGetGlyphBounds` can pass back a maximum of 31 bounding trapezoids. In ATSUI 1.2, `ATSUGetGlyphBounds` can pass back as many as 127 bounding trapezoids.

ATSUUnhighlightData

Contains data needed to redraw the background.

```
struct ATSUUnhighlightData {
    ATSUBackgroundDataType dataType;
    ATSUBackgroundData unhighlightData;
};
```

Fields

`dataType`

The data type of the background—a color or a callback.

`unhighlightData`

A background color or a universal procedure pointer to a callback that redraws the background.

USTL Data Structure Data Types

The data types in this section define the `'ustl'` data structure, which is the data structure used by ATSUI to contain flattened data. The `'ustl'` data structure has four blocks. The Block 1 structure defines is a header for the entire `'ustl'` data structure. Block 2 structures define flattened text layout data. (Note that Block 2 structures are not currently used by the functions `ATSUFlattenStyleRunsToStream` (page 1882) and `ATSUUnflattenStyleRunsFromStream` (page 1972).) Block 3 structures define flattened style run data. Block 4 structures define flattened style data.

The `'ustl'` data structure can accommodate any ATSUI text layout and style run data associated with a document. That is, the `'ustl'` data structure can contain data for multiple text layout objects, multiple style runs, and multiple style objects. Within each block (text layout, style run, and style) you must specify the number structures in that block.

ATSFlatDataMainHeaderBlock

Contains the `'ustl'` data structure version and size and provides offsets to the text layout, style run, and style list data blocks.

```
struct ATSFlatDataMainHeaderBlock {
    UInt32              version;
    ByteCount           sizeOfDataBlock;
    ByteCount           offsetToTextLayouts;
    ByteCount           offsetToStyleRuns;
    ByteCount           offsetToStyleList;
};
typedef struct ATSFlatDataMainHeaderBlock ATSFlatDataMainHeaderBlock;
```

Fields

`version`

The version number of the `'ustl'` data structure. You must make sure this number is the first item in the data block, otherwise the data may not be readable by code written to parse earlier versions of `'ustl'` data.

`sizeOfDataBlock`

The total size of the data in bytes, including the four bytes needed for the version number.

`offsetToTextlayouts`

The offset from the beginning of the data block to the flattened text layout data. You can set this value to `0` if there is no text layout data. This value specifies the offset to the `ATSFlatDataTextLayoutDataHeader` (page 2016) structure.

`offsetToStyleRuns`

The offset from the beginning of the data to the flattened style run data. You can set this value to `0` if there is no flattened style run data. This value specifies the offset to the `ATSFlatDataStyleRunDataHeader` (page 2020) structure.

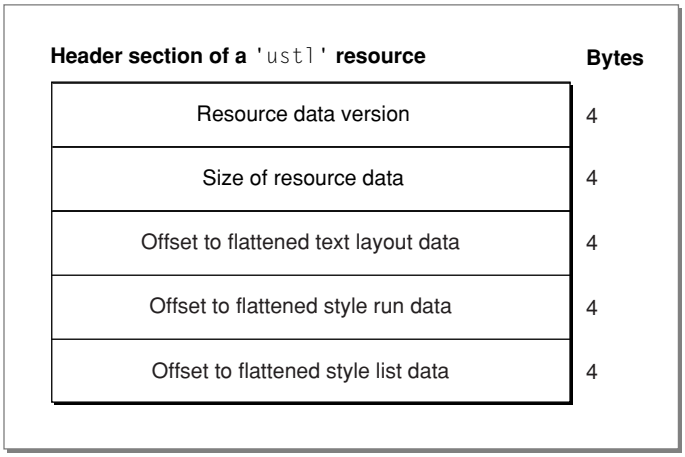
`offsetToStyleList`

The offset to the flattened style list data. You can set this value to `0` if there is no flattened style list data. This value specifies the offset to the `ATSFlatDataStyleListHeader` (page 2021) structure.

Discussion

The structure `ATSFlatDataMainHeaderBlock` is Block 1 of the `'ustl'` data structure. This structure contains information about the rest of the `'ustl'` data structure and provides offsets to each of the other three data blocks. Figure 46-1 illustrates the main header structure.

Figure 46-1 The main header for the ustl data structure



Per the `'ustl'` specification, all data blocks with the `'ustl'` data structure must maintain 4-byte alignment. For such items as font names, which have a variable width, you must add padding bytes to ensure the 4-byte alignment is always maintained.

Availability

Available in Mac OS X v10.2 and later.

Declared In

`ATSUnicodeFlattening.h`

ATSFlatDataTextLayoutDataHeader

Contains size, length, and offset information for a text layout data block.

```
struct ATSFlatDataTextLayoutDataHeader {
        ByteCount           sizeOfLayoutData;
        ByteCount           textLayoutLength;
        ByteCount           offsetToLayoutControls;
        ByteCount           offsetToLineInfo;
};
typedef struct ATSFlatDataTextLayoutDataHeader ATSFlatDataTextLayoutDataHeader;
```

Fields

`sizeOfLayoutData`

The size of the flattened text layout data. This value must include any bytes that have been added to maintain the required 4-byte alignment.

`textLayoutLength`

The number of characters to which the flattened text layout data applies.

`offsetLayoutControls`

The offset to the flattened layout control data. This offset is relative to the start of the text layout data block, and specifies the offset to the `ATSFlatDataLayoutControlsDataHeader` (page 2019) structure. The offset can be set to zero if there are no layout controls.

`offsetToLineLength`

The offset to the flattened line info data. This offset is relative to the start of the text layout data block, and specifies the offset to the `ATSFlatDataLineInfoHeader` (page 2019) structure. The offset can be set to zero if there is no line info in this layout.

Discussion

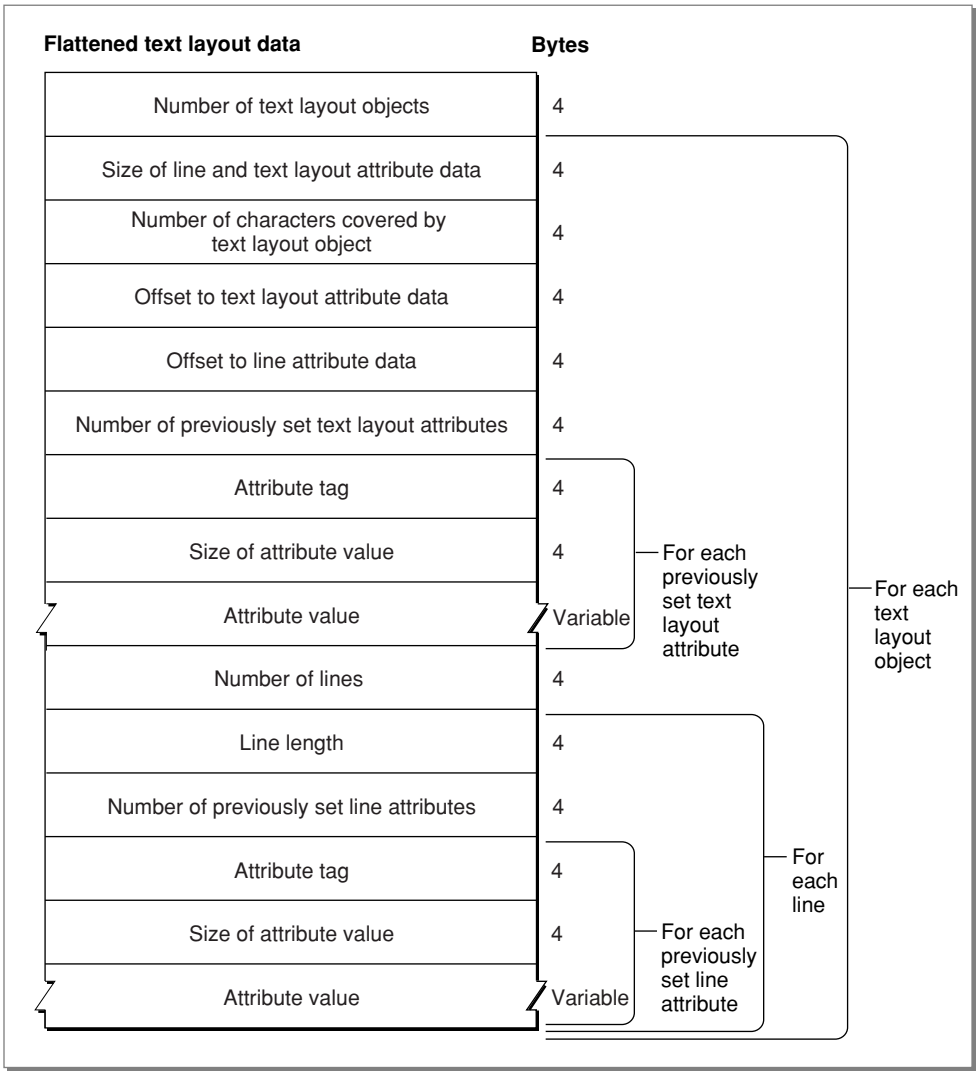
The `ATSFlatDataTextLayoutDataHeader` structure is a block 2 data structure and it is the main header for text layout data. If you have text layout data to flatten or unflatten, you must have one of these structures. for each text layout object whose data you want to flatten.

Note that the `ATSFlatDataTextLayoutDataHeader` data structure(s) must be preceded by an `ItemCount` value that specifies the number of `ATSFlatDataTextLayoutDataHeader` data structures included in the flattened data. Although the `ItemCount` value is not part of any `'ustl'` data structure, you need to include this 4-byte value when you flatten your text layout data so that you can successfully parse the flattened data at a later time.

The `offsetToTextLayouts` field in the `ATSFlatDataMainHeaderBlock` (page 2015) structure specifies the offset to the structure `ATSFlatDataTextLayoutDataHeader`.

Figure 46-2 depicts the flattened text layout data. At the top of the figure is the information contained in the data header (`ATSFlatDataTextLayoutDataHeader`). Following the header are layout controls data (see `ATSFlatDataLayoutControlsDataHeader` (page 2019)) and line length data (see `ATSFlatDataLineInfoHeader` (page 2019) and `ATSFlatDataLineInfoData` (page 2020)).

Figure 46-2 Flattened text layout data



If the `offsetToLayoutControls` value is not zero, there must be a `ATSFlatDataLayoutControlsDataHeader` (page 2019) structure that contains a count of the number of layout controls and an array of layout control attribute data.

If the `offsetToLineInfo` is not zero, then following the flattened layout controls data you must have an `ATSFlatDataLineInfoHeader` (page 2019) structure.

This and other Block 2 structures are not currently used by the functions `ATSUFlattenStyleRunsToStream` (page 1882) and `ATSUUnflattenStyleRunsFromStream` (page 1972).

Availability
Available in Mac OS X v10.2 and later.

Declared In
`ATSUnicodeFlattening.h`

ATSFlatDataLayoutControlsDataHeader

Contains the number of flattened layout controls and an array of layout control attribute data.

```
struct ATSFlatDataLayoutControlsDataHeader {
        ItemCount           numberOfLayoutControls;
        ATSUAttributeInfo   controlArray[1];
};typedef struct ATSFlatDataLayoutControlsDataHeader
ATSFlatDataLayoutControlsDataHeader;
```

Fields

`numberOfLayoutControls`

The number of flattened layout controls. There should be at least one layout control that specifies the line direction of the layout.

`controlArray[1]`

The first entry in an array of ATSUI attribute information. There should be `numberOfLayoutControls` entries in this array. If necessary, each ATSUI attribute info structure in the array should be followed by padding bytes to maintain the required 4-byte alignment. The value in the `fValueSize` field of each `ATSUAttributeInfo` structure must specify the size of the attribute value, and must not reflect any padding bytes you added.

Discussion

The `ATSFlatDataLayoutControlsDataHeader` structure is the header for the flattened layout controls structure. The `offsetToLayoutControls` field in the `ATSFlatDataTextLayoutDataHeader` (page 2016) structure specifies the offset to the structure `ATSFlatDataLayoutControlsDataHeader`. If there are no layout controls, you do not need the `ATSFlatDataLayoutControlsDataHeader` structure.

This and other Block 2 structures are not currently used by the functions `ATSUFlattenStyleRunsToStream` (page 1882) and `ATSUUnflattenStyleRunsFromStream` (page 1972).

Availability

Available in Mac OS X v10.2 and later.

Declared In

`ATSUnicodeFlattening.h`

ATSFlatDataLineInfoHeader

Contains the number of lines and an array of line information data.

```
struct ATSFlatDataLineInfoHeader {
        ItemCount           numberOfLines;
        ATSFlatDataLineInfoData  lineInfoArray[1];
};
typedef struct ATSFlatDataLineInfoHeader ATSFlatDataLineInfoHeader;
```

Fields

`numberOfLines`

The number of flattened line info structures that are stored in this block. This value should be greater than zero and equal to the number of soft line breaks in the layout plus one.

`lineInfoArray[1]`

The first entry in a array of `ATSFlatDataLineInfoData` (page 2020) structures. There should be `numberOfLines` entries in this array.

Discussion
The `ATSFlatDataLineInfoHeader` structure is the main data header for the flattened line info data. The value `offsetToLineInfo` in the `ATSFlatDataTextLayoutDataHeader` (page 2016) specifies the offset to the `ATSFlatDataLineInfoHeader` structure.

This and other Block 2 structures are not currently used by the functions `ATSUFlattenStyleRunsToStream` (page 1882) and `ATSUUnflattenStyleRunsFromStream` (page 1972).

Availability
Available in Mac OS X v10.2 and later.

Declared In
`ATSUnicodeFlattening.h`

ATSFlatDataLineInfoData

Contains a line length and the number of line controls for a line of flattened text.

```
struct ATSFlatDataLineInfoData {
        UniCharCount        lineLength;
        ItemCount           numberOfLineControls;
};
typedef struct ATSFlatDataLineInfoData  ATSFlatDataLineInfoData;
```

Fields

`lineLength`
The number of `UniChars` characters in the line.

`numberOfLineControls`
The number of line controls applied to the line. You can set this value to zero if there are no line controls applied to this line.

Discussion
If the `numberOfLineControls` is not zero, then you must supply an array of `ATSUAttributeInfo` structures that contains `numberOfLineControls` elements.

This and other Block 2 structures are not currently used by the functions `ATSUFlattenStyleRunsToStream` (page 1882) and `ATSUUnflattenStyleRunsFromStream` (page 1972).

Availability
Available in Mac OS X v10.2 and later.

Declared In
`ATSUnicodeFlattening.h`

ATSFlatDataStyleRunDataHeader

Contains the number of style runs and style run information for the style run data block.

```
struct ATSFlatDataStyleRunDataHeader {
    ItemCount           numberOfStyleRuns;
    ATSUStyleRunInfo    styleRunArray[1];
};
typedef struct ATSFlatDataStyleRunDataHeader ATSFlatDataStyleRunDataHeader;
```

Fields

`numberOfStyleRuns`

The number of style run data structures stored in this block.

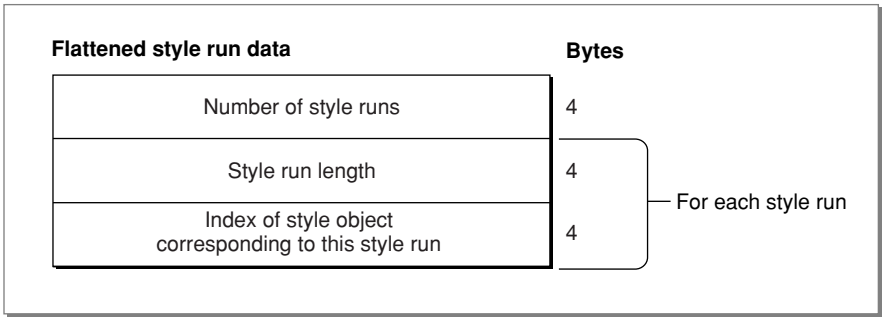
`styleRunArray[1]`

The first entry in a array of `ATSUStyleRunInfo` structures. There should be `numberOfStyleRuns` entries in this array.

Discussion

The `ATSFlatDataStyleRunDataHeader` structure precedes style run data structures. The `offsetToStyleRuns` field in the `ATSFlatDataMainHeaderBlock` (page 2015) specifies the offset to the structure `ATSFlatDataStyleRunDataHeader`.

Figure 46-3 Flattened style run data



This is a Block 3 structure. Block 3 structures are used by ATSUI style run flattening and parsing functions, `ATSUFlattenStyleRunsToStream` (page 1882) and `ATSUUnflattenStyleRunsFromStream` (page 1972), to represent flattened style run information. These structures work together with Block 4 structures.

Availability

Available in Mac OS X v10.2 and later.

Declared In

`ATSUnicodeFlattening.h`

ATSFlatDataStyleListHeader

Contains the number of styles and the first item in the style list style data header.

```
struct ATSFlatDataStyleListHeader {
        ItemCount           numberOfStyles;
        ATSFlatDataStyleListStyleDataHeader  styleDataArray[1];
};
typedef struct ATSFlatDataStyleListHeader ATSFlatDataStyleListHeader;
```

Fields

`numberOfStyles`

The number of flattened style objects in this block.

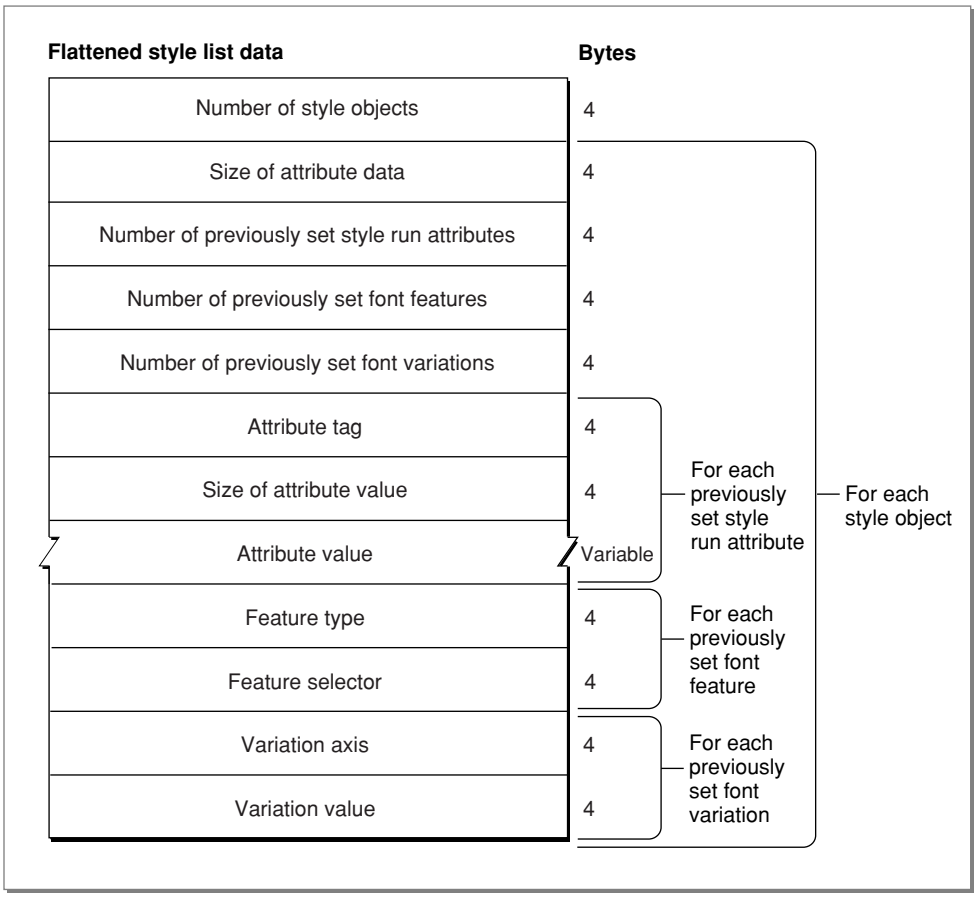
`styleDataArray[1]`

The first item in an array of `ATSFlatDataStyleListStyleDataHeader` (page 2023) structures. There should be `numberOfStyles` entries in this array. Note that the data stored in these structures can be of variable sizes.

Discussion

The `ATSFlatDataStyleListHeader` structure is the main header for Block 4. The `offsetToStyleList` field in the `ATSFlatDataMainHeaderBlock` (page 2015) specifies the offset to the structure `ATSFlatDataStyleListHeader`.

Figure 46-4 Flattened style list data



Availability

Available in Mac OS X v10.2 and later.

Declared In
ATSUnicodeFlattening.h

ATSFlatDataStyleListStyleDataHeader

Contains size information and the number of attributes, features, and variations for the style list data block.

```
struct ATSFlatDataStyleListStyleDataHeader {
            ByteCount           sizeOfStyleInfo;
            ItemCount           numberOfSetAttributes;
            ItemCount           numberOfSetFeatures;
            ItemCount           numberOfSetVariations;
};
typedef struct ATSFlatDataStyleListStyleDataHeader
ATSFlatDataStyleListStyleDataHeader;
```

Fields

`sizeOfStyleInfo`
The size of the flattened style object. This value should include the four bytes for this field (`sizeOfStyleInfo`) and any padding bytes you add to end of the structure to maintain the required 4-byte alignment.

`numberOfSetAttributes`
The number of attributes in the flattened style object. You should have at least one attribute for the font data, although you can set this value to `0` if you do not want to specify font data.

`numberOfSetFeatures`
The number of font features in the flattened style object. You can set this value to `0` if there are no font features in the style object.

`numberOfSetVariations`
The number of font variations in the flattened style object. You can set this value to `0` if there are no font variations in the style object.

Discussion
The `ATSFlatDataStyleListStyleDataHeader` structure forms the beginning of an individually flattened `ATSUStyle` object. This structure precedes the following data:

1. If the value `numberOfSetAttributes` is non-zero, there must be an array of `ATSUAttributeInfo` structures immediately following the `ATSFlatDataStyleListStyleDataHeader` structure to store the style attributes. This is a variable-size array. The number of `ATSUAttributeInfo` structures must be equal to the value `numberOfSetAttributes`, one structure for each attribute.

   If the value `numberOfSetAttributes` is zero, you do not need an array of `ATSUAttributeInfo` structures.

2. If the value `numberOfSetFeatures` is non-zero, there must be an array of `ATSFlatDataStyleListFeatureData` structures. These structures must appear immediately following the `ATSUAttributeInfo` array above (if there is such an array). The number of `ATSFlatDataStyleListFeatureData` structures must be equal to the value `numberOfSetFeatures`, one structure for each feature.

   If the value `numberOfSetFeatures` is zero, you do not need an array of `ATSFlatDataStyleListFeatureData` structures.

3. If the value `numberOfSetVariations` is non-zero, there must be an array of `ATSFlatDataStyleListVariationData` structures immediately following the `ATSFlatDataStyleListFeatureData` array (if there is such an array). The number of `ATSFlatDataStyleListVariationData` structures must be equal to the value `numberOfSetVariations`, one structure for each variation.

This is a Block 4 structure. Block 4 structures store flattened `ATSUStyle` objects and are currently used by the ATSUI style run flattening and parsing functions, `ATSUFlattenStyleRunsToStream` (page 1882) and `ATSUUnflattenStyleRunsFromStream` (page 1972).

Availability
Available in Mac OS X v10.2 and later.

Declared In
`ATSUnicodeFlattening.h`

ATSFlatDataStyleListFeatureData

Contains flattened font feature data.

```
struct ATSFlatDataStyleListFeatureData {
            ATSUFontFeatureType  theFeatureType;
            ATSUFontFeatureSelector  theFeatureSelector;
};
typedef struct ATSFlatDataStyleListFeatureData ATSFlatDataStyleListFeatureData;
```

Fields

`theFeatureType`
A font feature type.

`theFeatureSelector`
A font feature selector.

Discussion
This is a Block 4 structure. The structure `ATSFlatDataStyleListFeatureData` stores flattened font feature data. If the value `numberOfSetFeatures` in the `ATSFlatDataStyleListStyleDataHeader` (page 2023) structure is non-zero, an array of these structure must follow the array of font data attributes (if such an array exists) if the `numberOfSetFeatures` is non-zero. The number of `ATSFlatDataStyleListFeatureData` structures must be equal to the value `numberOfSetFeatures`.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`ATSUnicodeFlattening.h`

ATSFlatDataStyleListVariationData

Contains flattened font variation axis data.

```
struct ATSFlatDataStyleListVariationData {
            ATSUFontVariationAxis  theVariationAxis;
            ATSUFontVariationValue  theVariationValue;
};
typedef struct ATSFlatDataStyleListVariationData ATSFlatDataStyleListVariationData;
```

Fields

`theVariationAxis`

A font variation axis.

`theVariationValue`

A font variation value.

Discussion

This is a Block 4 structure. The structure `ATSFlatDataStyleListVariationData` stores flattened font variation data. If the value `numberOfSetVariations` in the `ATSFlatDataStyleListStyleDataHeader` (page 2023) structure is non-zero, an array of these structure must follow the array of font features (if such an array exists) if the `numberOfSetVariations` is non-zero. The number of `ATSFlatDataStyleListVariationData` structures must be equal to the value `numberOfSetVariations`.

Availability

Available in Mac OS X v10.2 and later.

Declared In

`ATSUnicodeFlattening.h`

ATSFlatDataFontNameDataHeader

Contains font name information.

```
struct ATSFlatDataFontNameDataHeader {
        ATSFlatDataFontSpeciferType  nameSpecifierType;
        ByteCount           nameSpecifierSize;
};
typedef struct ATSFlatDataFontNameDataHeader ATSFlatDataFontNameDataHeader;
```

Fields

`nameSpecifierType`

A font specifier for the type of the font name data you plan to supply. See "Flattened Data Font Type Selectors" (page 2046) for a list of the font specifiers you can supply. The font name data must follow the `ATSFlatDataFontNameDataHeader` structure.

`nameSpecifierSize`

The size of the flattened font name data. This value must not include any padding bytes that may be necessary to achieve the required 4-byte alignment, unless the padding bytes are specified as part of structure, such as with the `ATSFlatDataFontSpecRawNameData` structure.

Discussion

Font information can be recorded in an `ATSUStyle` object using the attribute tag `kATSUFontTag` and an attribute value that is of type `ATSUFontID`. Unfortunately, a font ID can vary between systems or system startups, which means you cannot ensure that the font used when the style is flattened is the same font that will be used with the style is unflattened. To preserve font information, you must flatten font name data. You specify font information using the structure `ATSFlatDataFontNameDataHeader`. You store this structure as a style attribute value. You must make sure this structure maintains the required 4-byte alignment.

Following the `ATSFlatDataFontNameDataHeader` structure must be the flattened font name data of the type specified by the `nameSpecifierType` field. For instance, if the value of the `nameSpecType` field is `kATSFlattenedFontNameSpecifierRawNameData`, the structure that immediately follows should be a `ATSFlatDataFontSpecRawNameDataHeader` (page 2026) structure.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`ATSUnicodeFlattening.h`

ATSFlatDataFontSpecRawNameDataHeader

Contains raw font name data.

```
struct ATSFlatDataFontSpecRawNameDataHeader {
            ItemCount           numberOfFlattenedNames;
            ATSFlatDataFontSpecRawNameData  nameDataArray[1];
};
typedef struct ATSFlatDataFontSpecRawNameDataHeader
ATSFlatDataFontSpecRawNameDataHeader;
```

Fields

`numberOfFlattenedNames`
The number of flattened font names. There must be at least one flattened font name, otherwise the structure is malformed.

`nameDataArray[1]`
The first element in an array of raw font name data.

Discussion
The function `ATSUUnflattenStyleRunsFromStream` (page 1972) searches for fonts that match the font data provides in the `nameDataArray`. ATSUI obtains matches for all the font name specifiers in the structure. You must supply at least one entry in the `nameDataArray`, but you may want to supply more than one entry to ensure a specific match. For example, the default ATSUI implementation is to use two name specifiers—the full name of the font (`kFontFullName`) and the font manufacturer's name (`kFontManufacturerName`).

The `ATSFlatDataFontSpecRawNameDataHeader` structure must be followed by one or more `ATSFlatDataFontSpecRawNameData` structures. The number of structures must match the value specified by the `numberOfFlattenedName` field.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`ATSUnicodeFlattening.h`

ATSFlatDataFontSpecRawNameData

Contains data for a font name.

```
struct ATSFlatDataFontSpecRawNameData {
            FontNameCode        fontNameType;
            FontPlatformCode    fontNamePlatform;
            FontScriptCode      fontNameScript;
            FontLanguageCode    fontNameLanguage;
            ByteCount           fontNameLength;
};
typedef struct ATSFlatDataFontSpecRawNameData ATSFlatDataFontSpecRawNameData;
```

Fields

`fontNameType`

The type of font name. You must supply this parameter.

`fontNamePlatform`

The platform type of the font name. You should specify this if you know it (Unicode, Mac, and so forth). If you do not know the platform type, then specify `kFontNoPlatform`. In this case all matching is done by ATSUI based on the first font in the name table that matches the other parameters in this structure.

`fontNameScript`

The script code of the font name based on the platform specified in the `fontNamePlatform` field. If you set this to `kFontNoScript`, the name is matched based on the first font in the name table that matches the other font name parameters in this structure.

`fontNameLanguage`

The language of the font name. If you set this to `kFontNoLanguage`, the name is matched based on the first font in the name table that matches the other font name parameters in this structure.

`fontNameLength`

The length of the font name. The length should include any padding bytes needed to maintain the required 4-byte alignment.

Discussion

The `ATSFlatDataFontSpecRawNameData` structure is the structure in which raw font name data is actually stored. This structure is used only when the value of the `nameSpecifierType` field in the `ATSFlatDataFontNameDataHeader` (page 2025) structure is `kATSFlattenedFontSpecifierRawNameData`. The structure stores multiple font name table entries for the purposes of reconstructing an `ATSUFontID` value for the same font at some time in the future.

When the ATSUI parsing function `ATSUUnflattenStyleRunsFromStream` searches for fonts to match the font data in this structure, it obtains matches for all the font name specifiers in the structure. The default ATSUI implementation is to use two name specifiers—the full name of the font (`kFontFullName`) and the font manufacturer's name (`kFontManufacturerName`).

Availability

Available in Mac OS X v10.2 and later.

    kATSULanguageTag = 264L,
    kATSUMaxATSUITagValue = 65535L
};
```

Constants

`kATSULineWidthTag`

Specifies the desired width of a line of text, in typographic points, of the line when drawn as justified or right-aligned text. The associated value is of type `ATSUTextMeasurement` (page 2013) and has a default value of `0`.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSULineRotationTag`

Specifies the angle by which the entire line should be rotated. The associated value is a `Fixed` value that specifies degrees in a right-hand coordinate system, and has a default value of `0`.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSULineDirectionTag`

Specifies a left-to-right or right-to-left direction for the glyphs in a text layout object, regardless of their natural direction as specified in the font. The associated value is `Boolean` (`kATSURightToLeftBaseDirection` or `kATSULeftToRightBaseDirection`) and has a default value of `GetSysDirection()`. See "Glyph Direction Selectors" (page 2051) for more information on the values that can be associated with this tag.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSULineJustificationFactorTag`

Specifies how ATSUI should typographically fit a line of text to a given width (or height, in the case of vertical text). The associated value is a `Fract` value between 0 and 1 and has a default value of `kATSUNoJustification`. See "Line Justification Selectors" (page 2058) for information on the values that can be associated with this tag.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSULineFlushFactorTag`

Specifies how ATSUI should place text in relation to one or both margins, which are the left and right sides (or top and bottom sides) of the text area. The associated value is a `Fract` value between 0 and 1 and has a default value of `kATSUStartAlignment`. See "Line Alignment Selectors " (page 2057) for information on the values that can be associated with this tag.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSULineBaselineValuesTag`
Specifies the positions of different baseline types with respect to one another in a line of text. The associated value is of type `BslnBaselineRecord` and contains default values all of which are `0`. The values are calculated from other style attributes such as font and point size.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSULineLayoutOptionsTag`
Specifies how ATSUI should manipulate basic attributes of a line or the text layout object, such as whether a line should have optical hangers or whether the last line of a text layout object should be justified. The associated value is of type `ATSLineLayoutOptions` and has a default value of `kATSLineNoLayoutOptions`. See "Line Layout Attribute Tags" (page 2058) for information on the values that can be associated with this tag.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSULineAscentTag`
Specifies line ascent. The associated value is of type `ATSUTextMeasurement` (page 2013) and has a default value of `kATSUseLineHeight`. See "Line Height and Font Tracking Selectors" (page 2057) for information on the values that can be associated with this tag.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSULineDescentTag`
Specifies line descent. The associated value is of type `ATSUTextMeasurement` (page 2013) and has a default value of `kATSUseLineHeight`. See "Line Height and Font Tracking Selectors" (page 2057) for information on the values that can be associated with this tag.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSULineLangRegionTag`
Specifies line language region. The associated value is a region code (see the Script Manager reference for a list of region codes) and has a default value of `kTextRegionDontCare`.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSULineTextLocatorTag`
Specifies line text location. The associated value is of type `TextBreakLocatorRef` and has a default value of `NULL`.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSULineTruncationTag`
Specifies where in a line truncation should occur. The associated value is of type `ATSULineTruncation` and has a default value of `kATSUTruncateNone`. See "Line Truncation Selectors" (page 2054) for the values that can be associated with the line truncation tag.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSULineFontFallbacksTag`
Specifies line font fallbacks. The associated value is of type `ATSUFontFallbacks` (page 2007). See "Font Fallback Methods" (page 2048) for information on the values that can be associated with this tag.

Available in Mac OS X v10.1 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSULineDecimalTabCharacterTag`
Specifies the current setting for the decimal separator, and affects the behavior of decimal tabs for a text layout (not an individual line). The associated value is of type `CFStringRef`. The CFString object (`CFStringRef`) is retained by the style object in which it is set. The default value is the user setting in System Preferences.

Declared in `ATSUnicodeTypes.h`.

Available in Mac OS X version 10.3 and later.

`kATSULineHighlightCGColorTag`
Specifies the current setting of the highlight color and opacity. The associated value is of type `CGColorRef`. This can be set as a line or layout control. The CGColor object (CGColorRef) is retained by the text layout object in which it is set.

Available in Mac OS X version 10.3 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSULayoutOperationOverrideTag`
Specifies to override a layout operation. The associated value is of type `ATSULayoutOperationOverrideSpecifier` and has a default value of `NULL`.

Available starting with Mac OS X version 10.2.

Declared in `ATSUnicodeTypes.h`.

`kATSUMaxLineTag`
A convenience tag that specifies the upper limit of the text layout attribute tags.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSULineLanguageTag`
Not recommended. Instead use `kATSULineLangRegionTag`.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSUCGContextTag`
Specifies to use a Quartz context. When you use this tag to set up a Quartz context, ATSUI uses an 8-bit, sub-pixel rendering. This method of rendering positions glyph origins on fractional points, which results in superior rendering compared to ATSUI's default 4-bit pixel-aligned rendering. The attribute has a default value of `NULL`; you must provide a pointer to a `CGContext`. The `CGContext` is not retained by the text layout object; if the context is destroyed, the text layout contains an invalid `CGContext`. Available only in Mac OS X.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSUQDBoldfaceTag`
Specifies a boldface text style. Text style attribute tags are included for compatibility with the `Style` type used by the QuickDraw function `TextFace`. If a font variant for this text style exists, ATSUI uses that variant. Otherwise, the variant is generated algorithmically. The associated value is of type `Boolean` and has a default value of `false`.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSUQDItalicTag`
Specifies an italic text style. Text style attribute tags are included for compatibility with the `Style` type used by the QuickDraw function `TextFace`. If a font variant for this text style exists, ATSUI uses that variant. Otherwise, the variant is generated. The associated value is of type `Boolean` and has a default value of `false`.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSUQDUnderlineTag`
Specifies an underline text style. Text style attribute tags are included for compatibility with the `Style` type used by the QuickDraw function `TextFace`. If a font variant for this text style exists, ATSUI uses that variant. Otherwise, the variant is generated. The associated value is of type `Boolean` and has a default value of `false`.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSUQDCondensedTag`
Specifies a condensed text style. Text style attribute tags are included for compatibility with the `Style` type used by the QuickDraw function `TextFace`. If a font variant for this text style exists, ATSUI uses that variant. Otherwise, the variant is generated. The associated value is of type `Boolean` and has a default value of `false`.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSUQDExtendedTag`
Specifies an extended text style. Text style attribute tags are included for compatibility with the `Style` type used by the QuickDraw function `TextFace`. If a font variant for this text style exists, ATSUI uses that variant. Otherwise, the variant is generated The associated value is of type `Boolean` and has a default value of `false`.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSUFontTag`
Specifies a unique value that identifies a font to the font management system. The associated value is of type `ATSUFontID` (page 2007) and has a default value of `GetScriptVariable (smSystemScript, smScriptAppFond)`.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSUSizeTag`

Specifies the font size of the text in the style run. The associated value, in typographic points (72 per inch), is of type `Fixed` and has a default value of `GetScriptVariable (smSystemScript, smScriptAppFondSize)`.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSUColorTag`

Specifies the color of the glyphs in a style run. The associated value is of type `RGBColor` and has a default value of `(0,0,0)`.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSULangRegionTag`

Specifies a language region. The associated value is a region code (see the Script Manager reference for a list of region codes) and has a default value of `GetScriptManagerVariable (smRegionCode)`.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSUVerticalCharacterTag`

Specifies which direction (vertical or horizontal) glyphs should be drawn. The associated value is of type `ATSUVerticalCharacterType` and has a default value of `kATSUStronglyHorizontal`. See "Vertical Character Types" (page 2068) for more information on the values that can be associated with this tag.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSUImposeWidthTag`

Specifies an imposed width. The associated value is of type `ATSUTextMeasurement` (page 2013) and has a default value of `0`; all glyphs use their own font defined advance widths.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSUBeforeWithStreamShiftTag`

Specifies a uniform shift parallel to the baseline of the positions of individual pairs or sets of glyphs in the style run that's applied before (to the left) the glyphs of the style run. The associated value is of type `Fixed` and has a default value of `0`. Starting with Mac OS version 10.3, glyphs cannot be negatively shifted such that later glyphs appear before earlier glyphs. In other words, ATSUI limits the shift to a value that is, at most, the advance of the previous glyph.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSUAfterWithStreamShiftTag`

Specifies a uniform shift parallel to the baseline of the positions of individual pairs or sets of glyphs in the style run that's applied after (to the right) the glyphs of the style run. The associated value is of type `Fixed` and has a default value of `0`. Starting with Mac OS version 10.3, glyphs cannot be negatively shifted such that later glyphs appear before earlier glyphs. In other words, ATSUI limits the shift to a value that is, at most, the advance of the current glyph.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSUCrossStreamShiftTag`

Specifies the distance to raise or lower glyphs in the style run perpendicular to the text stream. This shift is vertical for horizontal text and horizontal for vertical text. The associated value (in points, 72 per inch) is of type `Fixed` and has a default value of `0`.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSUTrackingTag`

Specifies the relative proportion of font-defined adjustments to apply to interglyph positions. The associated value is of type `Fixed` and has a default value of `kATSNoTracking`. See "Line Height and Font Tracking Selectors" (page 2057) for information on the values that can be associated with this tag.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSUHangingInhibitFactorTag`

Specifies to what degree punctuation glyphs can hang beyond the end of a line for justification purposes. The associated value is a `Fract` value between `0` and `1` and has a default value of `0`.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSUKerningInhibitFactorTag`

Specifies how much to inhibit kerning; that is, the increase or decrease the space between glyphs. The associated value is a `Fract` value between `0` and `1` and has a default value of `0`.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSUDecompositionFactorTag`

Specifies the fractional adjustment to the font-specified threshold at which ligature decomposition occurs during justification. The associated value is a `Fract` value between `-1.0` and `1.0` and has a default value of `0` (no adjustment to the font-specified threshold).

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSUBaselineClassTag`

Specifies the preferred baseline (such as Roman, hanging, or ideographic centered) to use for text of a given font in a style run. The associated value is of type `BslnBaselineClass` (see SFNTLayoutTypes.h) and has a default value of `kBSLNRomanBaseline`. You can set the value to `kBSLNNoBaselineOverride` to use intrinsic baselines.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSUPriorityJustOverrideTag`

Specifies the degree to which ATSUI should override justification behavior for glyphs in the style run. The associated value is of type `ATSJustWidthDeltaEntryOverride` (page 2010). The default values in this structure are all `0`.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSUNoLigatureSplitTag`
Specifies whether or not ligatures and compound characters in a style have divisible components. The associated value is a `Boolean` and has a default value of `false`; ligatures and compound characters have divisible components.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSUNoCaretAngleTag`
Specifies whether the text caret or edges of a highlighted area are always parallel to the slant of the style run's text or always perpendicular to the baseline. The associated value is a `Boolean` and has a default value of `false`; use the character's angularity to determine its boundaries.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSUSuppressCrossKerningTag`
Specifies whether or not to suppress cross kerning. The associated value is a `Boolean` and has a default value of `false`; do not suppress automatic cross kerning (defined by font).

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSUNoOpticalAlignmentTag`
Specifies the amount to which ATSUI should adjust glyph positions at the ends of lines to give a more even visual appearance to margins. The associated value is a `Boolean` and has a default value of `false`; do not suppress character's automatic optical positional alignment

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSUForceHangingTag`
Specifies to treat glyphs in a style run as hanging punctuation, whether or not the font designer intended them to be. The associated value is a `Boolean` and has a default value of `false`; do not force the character's to hang beyond the line boundaries

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSUNoSpecialJustificationTag`
Specifies whether processes (such as glyph stretching and ligature decomposition) that occur at the end of the justification process should be applied. The associated value is a `Boolean` and has a default value of `false`; perform post-compensation justification if needed

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSUStyleTextLocatorTag`
Specifies style text locator. The associated value is of type `TextBreakLocatorRef` and has a default value of `NULL`—region derived locator or the default Text Utilities locator.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSUStyleRenderingOptionsTag`
: Specifies style rendering options. The associated value is of type `ATSUStyleRenderingOptions` and has a default value of `kATSStyleApplyHints`—ATS glyph rendering uses hinting. See "Style Rendering Options" (page 2065) for more information on the values that can be associated with this tag.

  Available in Mac OS X v10.0 and later.

  Declared in `ATSUnicodeTypes.h`.

`kATSUAscentTag`
: Specifies the ascent value of a style's font. The associated value is of type `ATSUTextMeasurement` (page 2013) and has a default value of the ascent value of the style object's font with the current point size.

  Available starting with Mac OS X version 10.2.

  Declared in `ATSUnicodeTypes.h`.

`kATSUDescentTag`
: Specifies the descent value of a style's font. The associated value is of type `ATSUTextMeasurement` (page 2013) and has a default value of the descent value of the style object's font with the current point size. The leading value is not included as par of the descent.

  Declared in `ATSUnicodeTypes.h`.

  Available starting with Mac OS X version 10.2.

`kATSULeadingTag`
: Specifies the leading value of a style's font. The associated value is of type `ATSUTextMeasurement` (page 2013) and has a default value of the leading value of the style object's font with the current point size.

  Available starting with Mac OS X version 10.2.

  Declared in `ATSUnicodeTypes.h`.

`kATSUGlyphSelectorTag`
: Specifies a glyph collection. The associated value is an address to an `ATSUGlyphSelector` (page 2009) data structure. Using this tag allows you access to characters in the fonts that otherwise would not be accessible. You can choose the variant glyph by providing a font-specific glyph ID or a CID. For more information on CID conventions, see http://www.adobe.com. You can get the variant glyph information from an input method through the Text Services Manager using the Carbon event key, `kEventParamTextInputGlyphInfoArray`.

  Declared in `ATSUnicodeTypes.h`.

  Available starting with Mac OS X version 10.2.

`kATSURGBAlphaColorTag`
: Specifies RGB color with an alpha channel. The associated value is of type `ATSURGBAlphaColor` and has a default value of (0,0,0,1).

  Available starting with Mac OS X version 10.2.

  Declared in `ATSUnicodeTypes.h`.

`kATSUFontMatrixTag`

Specifies a font transformation matrix. The associated value is of type `CGAffineTransform`. (See the Quartz 2D reference documentation for more information on this data type.) You can use a font matrix to achieve effects through ATSUI at a style-run level that were previously available only by changing settings directly in a `CGContext`. When you use the tag `kATSUFontMatrixTag`, you associate a font transformation matrix with an `ATSUStyle` object. You can set the values in the font transformation matrix to achieve such effects as reversing glyphs across the X-axes and rotating glyphs Note that ATSUI's layout uses the transformed metrics so layout will be effected and in some cases the effects might be unexpected. For example, for a transformation that mirrors the glyph across the Y-axes the metrics are in reverse and glyphs are rendered on top of each other.

Declared in `ATSUnicodeTypes.h`.

Available starting with Mac OS X version 10.2.

`kATSUStyleUnderlineCountOptionTag`

Specifies the number of strokes to be drawn for an underline. The associated value is of type `ATSUStyleLineCountType`. The default value is `kATSUStyleSingleLineCount`. May be set as a style attribute.

Available in Mac OS X version 10.3 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSUStyleUnderlineColorOptionTag`

Specifies the color of the strokes to draw for an underlined run of text. The associated value is of type `CGColorRef`. The default value is `NULL`. If `NULL`, the text color is used. The CGColor object (`CGColorRef`) is retained by the style object in which it is set. May be set as a style attribute.

Declared in `ATSUnicodeTypes.h`.

Available in Mac OS X version 10.3 and later.

`kATSUStyleStrikeThroughTag`

Specifies strikethrough style. The associated value is of type `Boolean`. The default value is `false`. May be set as a style attribute.

Available in Mac OS X version 10.3 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSUStyleStrikeThroughCountOptionTag`

Specifies the number of strokes to be drawn for a strikethrough. The associated value is of type `ATSUStyleLineCountType`. The default value is `kATSUStyleSingleLineCount`. May be set as a style attribute.

Available in Mac OS X version 10.3 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSUStyleStrikeThroughColorOptionTag`

Specifies the color of the strokes to draw for a strikethrough style. The associated value is of type `CGColorRef`. The CGColor object (`CGColorRef`) is retained by the style object in which it is set. The default value is `NULL`. If `NULL`, the text color is used. May be set as a style attribute.

Declared in `ATSUnicodeTypes.h`.

Available in Mac OS X version 10.3 and later.

`kATSUStyleDropShadowTag`
Specifies the text should be drawn with a drop shadow. The associated value is of type `Boolean`. The default value is `false`. Only takes effect if a CGContext is used for drawing. If you set this style attribute, you also need to set the drop shadow color using the tag `kATSUStyleDropShadowColorOptionTag`.

Declared in `ATSUnicodeTypes.h`.

Available in Mac OS X version 10.3 and later.

`kATSUStyleDropShadowBlurOptionTag`
Specifies the amount of blur for a drop shadow. The associated value is of type `float`. The default value is `0.0`. May be set as a style attribute.

Available in Mac OS X version 10.3 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSUStyleDropShadowColorOptionTag`
Specifies the color and opacity of a drop shadow. The associated value is of type `CGColorRef`. The default value is `NULL`. You need to set the `CGColorRef` to a value other than `NULL` if you want to see the drop shadow. May be set as a style attribute.

Available in Mac OS X version 10.3 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSUStyleDropShadowOffsetOptionTag`
Specifies the amount of offset from the text to be used when drawing a drop shadow. The associated value is of type `CGSize`. The default value is (`3.0`, `-3.0`). May be set as a style attribute.

Available in Mac OS X version 10.3 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSUMaxStyleTag`
A convenience tag that specifies the upper limit of style attribute tags.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSULanguageTag`
This tag is obsolete. Instead use `kATSULangRegionTag`.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSUMaxATSUITagValue`
Specifies this maximum Apple ATSUI reserved tag value. If you define a tag, it must have a value larger than the value of this tag.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

Discussion
An attribute tag cannot be used in versions of the Mac OS that are earlier than the version in which the tag was introduced. For example, a tag available in Mac OS version 10.2 cannot be used in Mac OS version 10.1 or earlier. You can call the function `Gestalt` to check version information for ATSUI.

Attribute tags indicates the particular type of attribute under consideration: font, size, color, and so on. Each style run may have at most one attribute with a given attribute tag (that is, a style run can't have more than one font or size) but may have none.

Some of the constants specify attributes that are applied to a style run, while other attributes are applied to an entire text layout object or to just a line in a text layout object. The constant descriptions assume horizontal text. If you set or get the an attribute that has been set for vertical text, you should interpret the constant descriptions accordingly.

Most of the constants in this section are described in further detail in *Inside Mac OS X: Rendering Unicode Text With ATSUI*. Where appropriate, that document provides illustrations that show the effect of applying an attribute. It also describes how to write code that sets style, line, and layout attributes.

A style run may have at most one style attribute with a given attribute tag. That is, a style run can't have more than one font or size attribute set but the style run does not need to have any attribute set explicitly.

When you set an attribute value for a line, the value overrides the attribute value set for the text layout object that contains the line. This is true even if you set line attributes before you set attributes for the entire text layout object that contains the line.

You can create your own attribute tag as long as your tag is outside those values reserved by Apple— 0 to 65,535 (0 to 0x0000FFFF). See *Rendering Unicode Text With ATSUI* for information on creating and registering your own attribute tags.

Background Data Types

Specify the data type of the background—a color or a callback.

```
typedef UInt32 ATSUBackgroundDataType;
enum {
    kATSUBackgroundColor = 0,
    kATSUBackgroundCallback = 1
};
```

Constants

`kATSUBackgroundColor`

Specifies the data type of the text background is a color.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSUBackgroundCallback`

Specifies the data type of the text background is a callback.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

Caret Movement Types

Specify the unit distance by which the caret moves.

```
typedef UInt16 ATSUCursorMovementType;
enum {
    kATSUByCharacter = 0,
    kATSUByTypographicCluster = 1,
    kATSUByWord = 2,
    kATSUByCharacterCluster = 3,
    kATSUByCluster = 1
};
```

Constants

`kATSUByCharacter`
Specifies to move the caret by a units based on single characters.
Available in Mac OS X v10.0 and later.
Declared in `ATSUnicodeTypes.h`.

`kATSUByTypographicCluster`
Specifies to move the caret by units of clusters based on characters or ligatures.
Available in Mac OS X v10.0 and later.
Declared in `ATSUnicodeTypes.h`.

`kATSUByWord`
Specifies to move the caret by units based on words.
Available in Mac OS X v10.0 and later.
Declared in `ATSUnicodeTypes.h`.

`kATSUByCharacterCluster`
Specifies to move the caret by units based only on clusters of characters.
Available only in Mac OS X and in CarbonLib versions 1.3 and later.
Declared in `ATSUnicodeTypes.h`.

`kATSUByCluster`
An obsolete name for the constant `kATSUByTypographicCluster`.
Available in Mac OS X v10.0 and later.
Declared in `ATSUnicodeTypes.h`.

Discussion

A caret movement type is used to indicate the unit (character, word, and so on) by which to move the caret. You use these constants when you call the ATSUI caret movement functions. Functions that use caret movement types use this information to calculate the edge offset in memory that corresponds to the resulting cursor position.

Convenience Constants

Specify whether to clear values or whether drawing, measuring, or hit-testing should be done relative to the current pen location in the current graphics port.

```
enum {
    kATSUUseGrafPortPenLoc = (unsigned long)0xFFFFFFFF,
    kATSUClearAll = (unsigned long)0xFFFFFFFF
};
```

Constants

`kATSUUseGrafPortPenLoc`

Indicates that drawing, measuring, or hit-testing should be done relative to the current pen location in the current graphics port.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSUClearAll`

Removes all previously set values from a style object, a single line, or a text layout object.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

Discussion

You can pass the `kATSUUseGrafPortPenLoc` constant to functions that operate on text layout objects to indicate that drawing, measuring, or hit-testing should be done relative to the current pen location in the current graphics port.

You can pass the `kATSUClearAll` constant to the following functions to remove previously set values from a style object: to `ATSUClearAttributes` (page 1848) to remove style run attributes, to `ATSUClearFontFeatures` (page 1849) to remove font features, and to `ATSUClearFontVariations` (page 1850) to remove font variations.

You can also use the `kATSUClearAll` constant to remove previously set text layout attributes: to `ATSUClearLineControls` (page 1853), to remove text layout attributes from a single line of a text layout object, and to `ATSUClearLayoutControls` (page 1852) to remove text layout attributes from every line in a text layout object.

Direct Data Selectors

Specify the layout data to obtain when calling the functions `ATSUDirectGetLayoutDataArrayPtrFromLineRef` or `ATSUDirectGetLayoutDataArrayPtrFromTextLayout`.

```
typedef UInt32 ATSUDirectDataSelector;
enum {
    kATSUDirectDataAdvanceDeltaFixedArray = 0L,
    kATSUDirectDataBaselineDeltaFixedArray = 1L,
    kATSUDirectDataDeviceDeltaSInt16Array = 2L,
    kATSUDirectDataStyleIndexUInt16Array = 3L,
    kATSUDirectDataStyleSettingATSUStyleSettingRefArray = 4L,
    kATSUDirectDataLayoutRecordATSLayoutRecordVersion1 = 100L,
    kATSUDirectDataLayoutRecordATSLayoutRecordCurrent =
            kATSUDirectDataLayoutRecordATSLayoutRecordVersion1
};
```

Constants

`kATSUDirectDataAdvanceDeltaFixedArray`

Specifies the parallel advance delta (delta X) array, which is an array of `Fixed` values. This array is created only on demand. If you plan to modify the data in this array, you should set the `iCreate` parameter to `true` when you call the functions `ATSUDirectGetLayoutDataArrayPtrFromLineRef` (page 1872) or `ATSUDirectGetLayoutDataArrayPtrFromTextLayout` (page 1873) to obtain this array.

Available in Mac OS X v10.2 and later.

Declared in `ATSUnicodeDirectAccess.h`.

`kATSUDirectDataBaselineDeltaFixedArray`

Specifies the parallel baseline delta (delta Y) array, which is an array of `Fixed` values. This array is created only on demand. If you plan to modify the data in this array, you should set the `iCreate` parameter to `true` when you call the functions `ATSUDirectGetLayoutDataArrayPtrFromLineRef` (page 1872) or `ATSUDirectGetLayoutDataArrayPtrFromTextLayout` (page 1873) to obtain this array.

Available in Mac OS X v10.2 and later.

Declared in `ATSUnicodeDirectAccess.h`.

`kATSUDirectDataDeviceDeltaSInt16Array`

Specifies the parallel device delta array, which is an array of `SInt16` values used to adjust truncated fractional values for devices that do not accept fractional positioning. The array specified by this selector is also used to provide precise positioning for connected scripts. This array is created only on demand. If you plan to modify the data in this array, you should set the `iCreate` parameter to `true` when you call the functions `ATSUDirectGetLayoutDataArrayPtrFromLineRef` (page 1872) or `ATSUDirectGetLayoutDataArrayPtrFromTextLayout` (page 1873) to obtain this array.

Available in Mac OS X v10.2 and later.

Declared in `ATSUnicodeDirectAccess.h`.

`kATSUDirectDataStyleIndexUInt16Array`

Specifies the parallel style index array, which is an array of (`UInt16`) values. The values in this array are indexes into the style setting reference (`ATSUStyleSettingRef`) array. This array is created only on demand. If you plan to modify the data in this array, you should set the `iCreate` parameter to `true` when you call the functions `ATSUDirectGetLayoutDataArrayPtrFromLineRef` (page 1872) or `ATSUDirectGetLayoutDataArrayPtrFromTextLayout` (page 1873) to obtain this array.

Available in Mac OS X v10.2 and later.

Declared in `ATSUnicodeDirectAccess.h`.

`kATSUDirectDataStyleSettingATSUStyleSettingRefArray`
Specifies the style setting reference (`ATSUStyleSettingRef`) array. This array is always available if the text layout object has any text associated with it. Setting the `iCreate` parameter when you call the functions `ATSUDirectGetLayoutDataArrayPtrFromLineRef` (page 1872) or `ATSUDirectGetLayoutDataArrayPtrFromTextLayout` (page 1873) to obtain this array has no effect.

Available in Mac OS X v10.2 and later.

Declared in `ATSUnicodeDirectAccess.h`.

`kATSUDirectDataLayoutRecordATSLayoutRecordVersion1`
Specifies the `ATSLayoutRecord` array, with the version 1 of the `ATSLayoutRecord` data structure. You should not use this selector. Instead use the selector `kATSUDirectDataLayoutRecordATSLayoutRecordCurrent` to ensure that your code uses the most current version of the `ATSLayoutRecord` data structure. ATSUI performs the most efficient processing only for the latest version of `ATSLayoutRecord` data structure. This array is always available if the text layout object has any text associated with it. Setting the `iCreate` parameter when you call the functions `ATSUDirectGetLayoutDataArrayPtrFromLineRef` (page 1872) or `ATSUDirectGetLayoutDataArrayPtrFromTextLayout` (page 1873) to obtain this array has no effect.

Available in Mac OS X v10.2 and later.

Declared in `ATSUnicodeDirectAccess.h`.

`kATSUDirectDataLayoutRecordATSLayoutRecordCurrent`
Specifies the `ATSLayoutRecord` array, with the current version of the `ATSLayoutRecord` data structure. Always use this selector to get the array of `ATSLayoutRecord` data structures. This array is always available if the text layout object has any text associated with it. Setting the `iCreate` parameter when you call the functions `ATSUDirectGetLayoutDataArrayPtrFromLineRef` (page 1872) or `ATSUDirectGetLayoutDataArrayPtrFromTextLayout` (page 1873) to obtain this array has no effect.

Available in Mac OS X v10.2 and later.

Declared in `ATSUnicodeDirectAccess.h`.

Discussion
You can provide direct data selectors to the functions `ATSUDirectGetLayoutDataArrayPtrFromLineRef` (page 1872) or `ATSUDirectGetLayoutDataArrayPtrFromTextLayout` (page 1873).

Flattened Data Font Type Selectors

Specifies the data type for flattened font name data.

```
typedef UInt32 ATSFlatDataFontSpeciferType;
enum {
    kATSFlattenedFontSpecifierRawNameData = 'namd'
};
```

Constants
`kATSFlattenedFontSpecifierRawNameData`
Specifies to use the font name as the flattened font name.

Available in Mac OS X v10.2 and later.

Declared in `ATSUnicodeFlattening.h`.

Flattened Data Format Selectors

Specify the format to use when flattening or unflattening data.

```
typedef UInt32 ATSUFlattenedDataStreamFormat;
enum {
    kATSUDataStreamUnicodeStyledText = 'ustl'
};
```

Constants

`kATSUDataStreamUnicodeStyledText`
Specifies to use the `'ustl'` data specification when flattening or unflattening data.

Available in Mac OS X v10.2 and later.

Declared in `ATSUnicodeFlattening.h`.

Flattened Style Run Data Options

Specify options to use when flattening ATSUI style run data.

```
typedef UInt32 ATSUFlattenStyleRunOptions;
enum {
        kATSUFlattenOptionNoOptionsMask = 0x00000000
};
```

Constants

`kATSUFlattenOptionNoOptionsMask`
Specifies that no options are to be used.

Available in Mac OS X v10.2 and later.

Declared in `ATSUnicodeFlattening.h`.

Discussion
Additional options may be added in the future.

Flattened Data Version Numbers

Specify versions of the `'ustl'` specification.

```
enum {
    kATSFlatDataUstlVersion0      = 0,
    kATSFlatDataUstlVersion1      = 1,
    kATSFlatDataUstlVersion2      = 2,
    kATSFlatDataUstlCurrentVersion = kATSFlatDataUstlVersion2};
```

Constants

`kATSFlatDataUstlVersion0`
Specifies version 0. This version is obsolete.

Available in Mac OS X v10.2 and later.

Declared in `ATSUnicodeFlattening.h`.

`kATSFlatDataUstlVersion1`
Specifies version 1. This version is obsolete.

Available in Mac OS X v10.2 and later.

Declared in `ATSUnicodeFlattening.h`.

`kATSFlatDataUstlVersion2`
Specifies version 2.

Available in Mac OS X v10.2 and later.

Declared in `ATSUnicodeFlattening.h`.

`kATSFlatDataUstlCurrentVersion`
Specifies the current version.

Available in Mac OS X v10.2 and later.

Declared in `ATSUnicodeFlattening.h`.

Discussion
The ATSUI functions `ATSUFlattenStyleRunsToStream` and `ATSUUnflattenStyleRunsFromStream` operate on data that conform to version 2 of the `'ustl'` specification.

Font Fallback Methods

Specify the method by which ATSUI tries to find an appropriate font for a character if the assigned font does not contain the needed glyphs.

```
typedef UInt16 ATSUFontFallbackMethod;
enum {
    kATSUDefaultFontFallbacks = 0,
    kATSULastResortOnlyFallback = 1,
    kATSUSequentialFallbacksPreferred = 2,
    kATSUSequentialFallbacksExclusive = 3
};
```

Constants
`kATSUDefaultFontFallbacks`
Specifies to use ATSUI's default font search method. ATSUI searches through all available fonts on the system for one that matches any text that cannot be drawn with the font specified in the current ATSU style object (`ATSUStyle`). ATSUI first searches in the standard application fonts for various languages. If that fails, it searches through the remaining fonts on the system in whatever order the Font Manager returns them. After ATSUI has searched all the fonts in the system, any unmatched text is drawn with the last-resort font.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSULastResortOnlyFallback`
Specifies that ATSUI should use the last resort font if the assigned font does not contain the needed glyphs.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSUSequentialFallbacksPreferred`
Specifies that ATSUI should first search sequentially through the list of supplied fonts before it searching through all available fonts on the system.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSUSequentialFallbacksExclusive`
Specifies that ATSUI should search exclusively through the list of supplied fonts. ATSUI use the last-resort font if it does not find a match in the list of supplied fonts.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

Glyph Origin Selectors

Specify which glyph origin to use to determine the width of the typographic glyph bounds.

```
enum {
    kATSUseCaretOrigins           = 0,
    kATSUseDeviceOrigins          = 1,
    kATSUseFractionalOrigins      = 2,
    kATSUseOriginFlags            = 3
};
```

Constants

`kATSUseCaretOrigins`
Specifies to use the caret origin to determine the width of the typographic glyph bounds. The caret origin is halfway between two characters.

Available in Mac OS X v10.0 and later.

Declared in `ATSLayoutTypes.h`.

`kATSUseDeviceOrigins`
Specifies to use the glyph origin in device space to determine the width of the typographic glyph bounds. This is useful if you need to adjust text on the screen.

Available in Mac OS X v10.0 and later.

Declared in `ATSLayoutTypes.h`.

`kATSUseFractionalOrigins`
Specifies to use the glyph origin in fractional absolute positions (which are uncorrected for display device) to determine the width of the typographic glyph bounds. This provides the ideal position of laid-out text and is useful if you need to scale text on the screen. The glyph origin is also used to obtain the width of the typographic bounding rectangle when you call the function `ATSUMeasureText`.

Available in Mac OS X v10.0 and later.

Declared in `ATSLayoutTypes.h`.

`kATSUseOriginFlags`
The number of glyph origin selectors.

Available in Mac OS X v10.0 and later.

Declared in `ATSLayoutTypes.h`.

Discussion
You can pass a glyph bounds selector in the `iTypeOfBounds` parameter of the function `ATSUGetGlyphBounds` (page 1904) to indicate whether the width of the resulting typographic glyph bounds is determined using the caret origin, glyph origin in device space, or glyph origin in fractional absolute positions.

Glyph Collection Types

Specify a character set.

```
typedef UInt16 GlyphCollection;
enum {
    kGlyphCollectionGID           = 0,
    kGlyphCollectionAdobeCNS1     = 1,
    kGlyphCollectionAdobeGB1      = 2,
    kGlyphCollectionAdobeJapan1   = 3,
    kGlyphCollectionAdobeJapan2   = 4,
    kGlyphCollectionAdobeKorea1   = 5,
    kGlyphCollectionUnspecified   = 0xFF
};
```

Constants

`kGlyphCollectionGID`
Indicates that the glyph value represents the actual glyph ID of a specific font.
Available in Mac OS X v10.2 and later.
Declared in `ATSUnicodeTypes.h`.

`kGlyphCollectionAdobeCNS1`
Specifies Adobe CNS1 CID-keyed fonts.
Available in Mac OS X v10.2 and later.
Declared in `ATSUnicodeTypes.h`.

`kGlyphCollectionAdobeGB1`
Specifies Adobe GB1 CID-keyed fonts.
Available in Mac OS X v10.2 and later.
Declared in `ATSUnicodeTypes.h`.

`kGlyphCollectionAdobeJapan1`
Specifies Adobe Japan1 CID-keyed fonts.
Available in Mac OS X v10.2 and later.
Declared in `ATSUnicodeTypes.h`.

`kGlyphCollectionAdobeJapan2`
Specifies Adobe Japan2 CID-keyed fonts.
Available in Mac OS X v10.2 and later.
Declared in `ATSUnicodeTypes.h`.

`kGlyphCollectionAdobeKorea1`
Specifies Adobe Korea1 CID-keyed fonts.
Available in Mac OS X v10.2 and later.
Declared in `ATSUnicodeTypes.h`.

`kGlyphCollectionUnspecified`
Indicates that the glyph collection is not specified.

Available in Mac OS X v10.2 and later.

Declared in `ATSUnicodeTypes.h`.

Discussion
A CID-keyed font is a PostScript font that uses a font file format developed by Adobe for fonts that have large character sets, such as Chinese, Japanese, and Korean fonts. For more information on CID-keyed fonts, see the Adobe website:

http://partners.adobe.com/

Glyph Direction Selectors

Specify a glyph direction.

```
enum {
    kATSULeftToRightBaseDirection = 0,
    kATSURightToLeftBaseDirection = 1
};
```

Constants
`kATSULeftToRightBaseDirection`
Imposes left-to-right direction on glyphs in a line of horizontal text; for vertical text, imposes top-to-bottom direction.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSURightToLeftBaseDirection`
Imposes right-to-left direction on glyphs in a line of horizontal text; for vertical text, imposes bottom-to-top direction.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

Discussion
These constants specify values for the `kATSULineDirectionTag` attribute tag. You can use one of these constants to set or obtain glyph direction in a line of text or an entire text layout object, regardless of their font-specified direction; see the functions `ATSUSetLayoutControls` (page 1955), `ATSUSetLineControls` (page 1956), `ATSUGetLayoutControl` (page 1912), and `ATSUGetLineControl` (page 1913).

Glyph Property Flags

Specify properties for a glyph.

```
typedef UInt32 ATSGlyphInfoFlags;
enum {
    kATSGlyphInfoAppleReserved    = 0x1FFBFFE8,
    kATSGlyphInfoIsAttachment     = (unsigned long)0x80000000,
    kATSGlyphInfoIsLTHanger       = 0x40000000,
    kATSGlyphInfoIsRBHanger       = 0x20000000,
    kATSGlyphInfoTerminatorGlyph  = 0x00080000,
    kATSGlyphInfoIsWhiteSpace     = 0x00040000,
    kATSGlyphInfoHasImposedWidth  = 0x00000010,
    kATSGlyphInfoByteSizeMask     = 0x00000007
};
```

Constants

`kATSGlyphInfoAppleReserved`
This flag is reserved by Apple. If you try to use it you may get an invalid value error.

Available in Mac OS X v10.2 and later.

Declared in `ATSLayoutTypes.h`.

`kATSGlyphInfoIsAttachment`
Specifies that the glyph attaches to another glyph.

Available in Mac OS X v10.2 and later.

Declared in `ATSLayoutTypes.h`.

`kATSGlyphInfoIsLTHanger`
Specifies that the glyph can hang off the left or top edge of a line.

Available in Mac OS X v10.2 and later.

Declared in `ATSLayoutTypes.h`.

`kATSGlyphInfoIsRBHanger`
Specifies that the glyph can hang off the right or bottom edge of a line.

Available in Mac OS X v10.2 and later.

Declared in `ATSLayoutTypes.h`.

`kATSGlyphInfoTerminatorGlyph`
Specifies that the glyph is not truly a glyph, but an end-marker to allow the calculation of the previous glyph's advance.

Available in Mac OS X v10.2 and later.

Declared in `ATSLayoutTypes.h`.

`kATSGlyphInfoIsWhiteSpace`
Specifies that the glyph is a whitespace glyph.

Available in Mac OS X v10.2 and later.

Declared in `ATSLayoutTypes.h`.

`kATSGlyphInfoHasImposedWidth`
Specifies that the glyph has an imposed width (that is, an advance width) specified by the style.

Available in Mac OS X v10.2 and later.

Declared in `ATSLayoutTypes.h`.

`kATSGlyphInfoByteSizeMask`
Specifies the size of the character that spawned the glyph. This is a three-bit mask that you can use to obtain the size of the original character that spawned a glyph. If you perform a logical `and` operation between this mask and an `ATSGlyphInfoFlags` flag, you obtain the size in bytes of the original character (0 - 7 bytes).

Available in Mac OS X v10.2 and later.

Declared in `ATSLayoutTypes.h`.

Discussion
Glyph information flags are set in the individual `ATSLayoutRecord` structure and apply only to the `ATSGlyphRef` reference in that structure. The flags are used by the ATSUI to tag a glyph with one or more specific properties.

Highlight Methods

Specify a text highlighting method.

```
typedef UInt32 ATSUHighlightMethod;
enum {
    kInvertHighlighting = 0,
    kRedrawHighlighting = 1
};
```

Constants
`kInvertHighlighting`
Specifies to use inversion for highlighting. You can use this when the background is a single color.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kRedrawHighlighting`
Specifies to use your callback for highlighting. You should use this when the background is complex (containing, for example, multiple colors, patterns, or pictures).

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

Discussion
You set the highlighting method by calling the function `ATSUSetHighlightingMethod` (page 1953).

Invalid Font ID Constant

Specifies a Font ID is not valid.

```
enum {
    kATSUInvalidFontID = 0
};
```

Constants
`kATSUInvalidFontID`
Indicates that the font ID is invalid.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

Discussion
The functions `ATSUFONDtoFontID` (page 1884), `ATSUFindFontFromName` (page 1879), and `ATSUMatchFontsToText` (page 1936) pass back this constant to indicate an invalid font ID. This constant is available with ATSUI 1.0.

Line Truncation Selectors

Specify where in a line truncation should occur.

```
typedef UInt32 ATSULineTruncation;
enum {
    kATSUTruncateNone = 0,
    kATSUTruncateStart = 1,
    kATSUTruncateEnd = 2,
    kATSUTruncateMiddle = 3,
    kATSUTruncateSpecificationMask = 7,
    kATSUTruncFeatNoSquishing = 8
};
```

Constants

`kATSUTruncateNone`
Specifies not to truncate the line.
Available in Mac OS X v10.0 and later.
Declared in `ATSUnicodeTypes.h`.

`kATSUTruncateStart`
Specifies to truncate the line at the beginning.
Available in Mac OS X v10.0 and later.
Declared in `ATSUnicodeTypes.h`.

`kATSUTruncateEnd`
Specifies to truncate the line at the end.
Available in Mac OS X v10.0 and later.
Declared in `ATSUnicodeTypes.h`.

`kATSUTruncateMiddle`
Specifies to truncate the line in the middle
Available in Mac OS X v10.0 and later.
Declared in `ATSUnicodeTypes.h`.

`kATSUTruncateSpecificationMask`
Reserved for the truncation specification (0 - 7).
Available in Mac OS X v10.1 and later.
Declared in `ATSUnicodeTypes.h`.

`kATSUTruncFeatNoSquishing`
Specifies not to perform any negative justification in lieu of truncation.
Available in Mac OS X v10.1 and later.
Declared in `ATSUnicodeTypes.h`.

Discussion
Line truncation options specify values for the `kATSULineTruncation` attribute tag. You can add any line truncation option to the option `kATSUTruncateSpecificationMask`. For example, adding `kATSUTruncateEnd` and `kATSUTruncFeatNoSquishing` to the mask `kATSUTruncateSpecificationMask` results in the value `0x0000000A`.

Layout Callback Status Values

Specify the status of a layout operation override callback.

```
typedef UInt32 ATSULayoutOperationCallbackStatus;
enum {
    kATSULayoutOperationCallbackStatusHandled = 0x00000000,
    kATSULayoutOperationCallbackStatusContinue = 0x00000001
};
```

Constants

`kATSULayoutOperationCallbackStatusHandled`
Specifies that your callback function has handled the operation which triggered the callback. This indicates to ATSUI that it does not need to perform any further processing for the layout operation.

Available in Mac OS X v10.2 and later.

Declared in `ATSLayoutTypes.h`.

`kATSULayoutOperationCallbackStatusContinue`
Specifies that your callback function has not handled the operation which triggered the callback. This indicates to ATSUI that needs to perform its own processing for the layout operation.

Available in Mac OS X v10.2 and later.

Declared in `ATSLayoutTypes.h`.

Discussion
You must return one of these status values from your `ATSUDirectLayoutOperationOverrideProcPtr` (page 1998) callback function to indicate to ATSUI whether or not your callback handled the layout operation.

Layout Operation Selectors

Specify a layout operation.

```
typedef UInt32 ATSULayoutOperationSelector;
enum {
    kATSULayoutOperationNone      = 0x00000000,
    kATSULayoutOperationJustification = 0x00000001,
    kATSULayoutOperationMorph     = 0x00000002,
    kATSULayoutOperationKerningAdjustment = 0x00000004,
    kATSULayoutOperationBaselineAdjustment = 0x00000008,
    kATSULayoutOperationTrackingAdjustment = 0x00000010,
    kATSULayoutOperationPostLayoutAdjustment = 0x00000020,
    kATSULayoutOperationAppleReserved = (unsigned long)0xFFFFFFC0
};
```

Constants

`kATSULayoutOperationNone`
Specifies that no layout operation is currently selected.
Available in Mac OS X v10.2 and later.
Declared in `ATSLayoutTypes.h`.

`kATSULayoutOperationJustification`
Specifies the justification operation.
Available in Mac OS X v10.2 and later.
Declared in `ATSLayoutTypes.h`.

`kATSULayoutOperationMorph`
Specifies the character-morphing operation.
Available in Mac OS X v10.2 and later.
Declared in `ATSLayoutTypes.h`.

`kATSULayoutOperationKerningAdjustment`
Specifies the kerning-adjustment operation.
Available in Mac OS X v10.2 and later.
Declared in `ATSLayoutTypes.h`.

`kATSULayoutOperationBaselineAdjustment`
Specifies the baseline-adjustment operation.
Available in Mac OS X v10.2 and later.
Declared in `ATSLayoutTypes.h`.

`kATSULayoutOperationTrackingAdjustment`
Specifies the tracking-adjustment operation.
Available in Mac OS X v10.2 and later.
Declared in `ATSLayoutTypes.h`.

`kATSULayoutOperationPostLayoutAdjustment`
Specifies the period of time after ATSUI has completed its layout operations.
Available in Mac OS X v10.2 and later.
Declared in `ATSLayoutTypes.h`.

`kATSULayoutOperationAppleReserved`
This selector is reserved for future use.
Available in Mac OS X v10.2 and later.
Declared in `ATSLayoutTypes.h`.

Discussion
You can use layout operation selectors to specify to ATSUI which operations to override. These selectors can also be passed from ATSUI to your application to indicate which operation is currently in progress.

Line Alignment Selectors

Specify the alignment of text relative to the margins in a line of text or in an entire text layout object.

```
#define kATSUStartAlignment ((Fract) 0x00000000L)
#define kATSUEndAlignment ((Fract) 0x40000000L)
#define kATSUCenterAlignment ((Fract) 0x20000000L)
```

Constants

`kATSUStartAlignment`
Specifies that horizontal text should be drawn to the right of the left margin (that is, its left edge coincides with the text layout object's position plus text width). Vertical text should be drawn below the top margin.

`kATSUEndAlignment`
Specifies that horizontal text should be drawn to the left of the right margin. Vertical text should be drawn above the bottom margin.

`kATSUCenterAlignment`
Specifies that horizontal text should be drawn between the left and right margins with an equal amount of space on either side. Vertical text should be drawn between the top and bottom margins with an equal amount of space on either side.

Discussion
You can use one of these constants to set or obtain the alignment of text relative to the margins in a line of text or in an entire text layout object; see the functions `ATSUSetLayoutControls` (page 1955), `ATSUSetLineControls` (page 1956), `ATSUGetLayoutControl` (page 1912), and `ATSUGetLineControl` (page 1913), respectively.

Line Height and Font Tracking Selectors

Specify how to determine line height and whether to turn off font tracking.

```
enum {
    kATSUseGlyphAdvance = 0x7FFFFFFF,
    kATSUseLineHeight = 0x7FFFFFFF,
    kATSNoTracking = (long)0x80000000
};
```

Constants

`kATSUseGlyphAdvance`
Specifies that ATSUI use the natural glyph advance value in a line or entire text layout object.

Available in Mac OS X v10.2 and later.

Declared in `ATSLayoutTypes.h`.

`kATSUseLineHeight`
Specifies that ATSUI use the natural line ascent and descent values dictated by the font and pixel size to determine line ascent and descent in a line or entire text layout object.

Available in Mac OS X v10.0 and later.

Declared in `ATSLayoutTypes.h`.

`kATSNoTracking`
A value of type `negativeInfinity` that indicates that font tracking should be off.

Available in Mac OS X v10.0 and later.

Declared in `ATSLayoutTypes.h`.

Discussion
You use line height selectors to set line ascent and descent text layout attributes. You can set the line ascent text layout attribute for a line or an entire text layout object by passing the `kATSULineAscentTag` tag to the functions `ATSUSetLineControls` (page 1956) and `ATSUSetLayoutControls` (page 1955), respectively. You can set the line descent text layout attribute for a line or an entire text layout object by passing the `kATSULineDescentTag` tag to the functions `ATSUSetLineControls` (page 1956) and `ATSUSetLayoutControls` (page 1955), respectively.

Line Justification Selectors

Specify the degree of line justification for a single line or an entire text layout object.

```
#define kATSUNoJustification        ((Fract) 0x00000000L)
#define kATSUFullJustification      ((Fract) 0x40000000L)
```

Constants
`kATSUNoJustification`
Indicates no justification.

`kATSUFullJustification`
Full justification between the text margins. White space is “stretched” to make the line extend to both text margins.

Discussion
You can set the line justification text layout attribute for a line or an entire text layout object by passing the `kATSULineJustificationFactorTag` tag the functions `ATSUSetLineControls` (page 1956) and `ATSUSetLayoutControls` (page 1955), respectively.

Line Layout Attribute Tags

Specify line layout attributes to be applied at the line level.

```
typedef UInt32 ATSLineLayoutOptions;
enum {
    kATSLineNoLayoutOptions       = 0x00000000,
    kATSLineIsDisplayOnly         = 0x00000001,
    kATSLineHasNoHangers          = 0x00000002,
    kATSLineHasNoOpticalAlignment = 0x00000004,
    kATSLineKeepSpacesOutOfMargin = 0x00000008,
    kATSLineNoSpecialJustification = 0x00000010,
    kATSLineLastNoJustification   = 0x00000020,
    kATSLineFractDisable          = 0x00000040,
    kATSLineImposeNoAngleForEnds  = 0x00000080,
    kATSLineFillOutToWidth        = 0x00000100,
    kATSLineTabAdjustEnabled      = 0x00000200,
    kATSLineIgnoreFontLeading     = 0x00000400,
    kATSLineApplyAntiAliasing     = 0x00000800,
    kATSLineNoAntiAliasing        = 0x00001000,
    kATSLineDisableNegativeJustification = 0x00002000,
    kATSLineDisableAutoAdjustDisplayPos = 0x00004000,
    kATSLineUseQDRendering        = 0x00008000,
    kATSLineDisableAllJustification = 0x00010000,
    kATSLineDisableAllGlyphMorphing = 0x00020000,
    kATSLineDisableAllKerningAdjustments = 0x00040000,
    kATSLineDisableAllBaselineAdjustments = 0x00080000,
    kATSLineDisableAllTrackingAdjustments = 0x00100000,
    kATSLineDisableAllLayoutOperations = kATSLineDisableAllJustification
|
        kATSLineDisableAllGlyphMorphing |
        kATSLineDisableAllKerningAdjustments |
        kATSLineDisableAllBaselineAdjustments |
        kATSLineDisableAllTrackingAdjustments,
    kATSLineUseDeviceMetrics      = 0x01000000,
    kATSLineBreakToNearestCharacter = 0x02000000,
    kATSLineAppleReserved         = (unsigned long)0xFCE00000};
```

Constants

`kATSLineNoLayoutOptions`

Specifies not to apply any options.

Available i n ATSUI 1.0 and later.

Declared in `ATSLayoutTypes.h`.

`kATSLineIsDisplayOnly`

This line option is no longer used. Instead use `kATSLineUseDeviceMetrics`.

Available in Mac OS X v10.0 and later.

Declared in `ATSLayoutTypes.h`.

`kATSLineHasNoHangers`

Specifies not to form hanging punctuation on the line. If the bit specified by this mask is set, the automatic hanging punctuation in the text layout object is overridden. The value in this bit overrides any adjustment to hanging punctuation set for a style run inside the text layout object using the style run attribute tags `kATSUForceHangingTag` or `kATSUHangingInhibitFactorTag`.

Declared in `ATSLayoutTypes.h`.

Available in ATSUI 1.0 and later.

`kATSLineHasNoOpticalAlignment`
Specifies not to perform optical alignment on the line. Optical alignment adjusts characters at the text margin so that they appear to be properly aligned; strict alignment can often cause the illusion of a ragged edge. The value in this bit overrides any adjustment to optical alignment set for a style run inside the text layout object using the style run attribute tag `kATSUNoOpticalAlignmentTag`.

Declared in `ATSLayoutTypes.h`.

Available in ATSUI 1.0 and later.

`kATSLineKeepSpacesOutOfMargin`
Specifies that the trailing white spaces at the end of a line of justified text should be placed outside the margin.

Available in ATSUI 1.0 and later.

Declared in `ATSLayoutTypes.h`.

`kATSLineNoSpecialJustification`
Specifies not to perform post-compensation justification on the line, even if such processing is necessary. This flag cannot be set for a single line of a text layout object. The value in this bit overrides any adjustment to the postcompensation actions set for a style run using the style run attribute tag `kATSUNoSpecialJustificationTag`.

Declared in `ATSLayoutTypes.h`.

Available in ATSUI 1.0 and later.

`kATSLineLastNoJustification`
Specifies not to justify a line if it is the last line of a justified text layout object. This flag is meaningless when setting a line's text layout attributes.

Available in ATSUI 1.0 and later.

Declared in `ATSLayoutTypes.h`.

`kATSLineFractDisable`
Specifies to position of the text in the line or text layout object relative to fractional absolute positions, which are uncorrected for device display. This provides the ideal position of laid-out text and is useful for scaling text onscreen. This origin is also used to get the width of the typographic bounding rectangle when you call the function `ATSUGetUnjustifiedBounds` (page 1923).

Declared in `ATSLayoutTypes.h`.

Available in ATSUI 1.1 and later.

`kATSLineImposeNoAngleForEnds`
Specifies to draw the carets on the far right and left sides of an unrotated line as vertical, no matter what the angle of text.

Available in ATSUI 1.1 and later.

Declared in `ATSLayoutTypes.h`.

`kATSLineFillOutToWidth`
Specifies to extend highlighting to both ends of a line, regardless of caret locations. This option does not effect the caret locations. This is provided for your convenience to extend your highlighting to the full width of the line.

Available in ATSUI 1.1 and later.

Declared in `ATSLayoutTypes.h`.

`kATSLineTabAdjustEnabled`
Specifies to automatically adjust the tab character width so that it fits the specified line width. If you are using ATSUI's tab functions—`ATSUSetTabArray` (page 1962) and `ATSUGetTabArray` (page 1918) to define a tab rule you do not need to use this selector. The selector is useful if you are handling your own tabs and only applies if the tab is at the end of a line (backing store). You must set this bit to ensure that highlighting is done correctly across tab stops. To ensure this, you should also set the bit specified by the `kATSLineImposeNoAngleForEnds` mask constant.

Declared in `ATSLayoutTypes.h`.

Available in ATSUI 1.2 and later.

`kATSLineIgnoreFontLeading`
Specifies to ignore any leading value specified by a font.

Available in ATSUI 2.3 and later.

Declared in `ATSLayoutTypes.h`.

`kATSLineApplyAntiAliasing`
Specifies that Apple Type Services should produce antialiased glyph images even if system preferences or Quartz settings indicate otherwise.

Available in Mac OS X v10.2 and later.

Declared in `ATSLayoutTypes.h`.

`kATSLineNoAntiAliasing`
Specifies that Apple Type Services should turn-off antialiasing glyph imaging even if system preferences or Quartz settings indicate otherwise. This option negates the `kATSLineApplyAntiAliasing` bit if it is set.

Available in Mac OS X v10.2 and later.

Declared in `ATSLayoutTypes.h`.

`kATSLineDisableNegativeJustification`
Specifies to allow glyph positions to extend beyond the line's assigned width if the line width is not sufficient to hold all its glyphs. This ensures that negative justification is not used.

Available in Mac OS X v10.2 and later.

Declared in `ATSLayoutTypes.h`.

`kATSLineDisableAutoAdjustDisplayPos`
Specifies not to automatically adjust individual character positions when rendering lines that have any integer glyph positioning, whether the integer glyph positioning is due to non-antialiased characters or though the use of the selector `kATSLineFractDisable`.

Available in Mac OS X v10.2 and later.

Declared in `ATSLayoutTypes.h`.

`kATSLineUseQDRendering`
Specifies to use QuickDraw to render a line of text instead of the default ATSUI rendering. With Mac OS X version 10.2, ATSUI renders text through Quartz, even if you do not attach a `CGContext` to a text layout object. In the default case, ATSUI retrieves the internal canonical `CGContext` of the current port, and renders to that port using Quartz at an antialiasing setting that simulates QuickDraw rendering. That is, a 4-bit pixel-aligned antialiasing. Because the default setting gives you simulated QuickDraw rendering, you should use the tag `kATSLineUseQDRendering` only if you must have backward compatibility. With Mac OS X version 10.3, this option no longer does anything different from not declaring a `CGContext`.

Available in Mac OS X v10.2 and later.

Declared in `ATSLayoutTypes.h`.

`kATSLineDisableAllJustification`
Specifies not to perform any justification operations on the line.

Available in Mac OS X v10.2 and later.

Declared in `ATSLayoutTypes.h`.

`kATSLineDisableAllGlyphMorphing`
Specifies not to perform any glyph-morphing operations on the line.

Available in Mac OS X v10.2 and later.

Declared in `ATSLayoutTypes.h`.

`kATSLineDisableAllKerningAdjustments`
Specifies not to perform any kerning-adjustment operations on the line.

Available in Mac OS X v10.2 and later.

Declared in `ATSLayoutTypes.h`.

`kATSLineDisableAllBaselineAdjustments`
Specifies not to perform any baseline-adjustment operations on the line.

Available in Mac OS X v10.2 and later.

Declared in `ATSLayoutTypes.h`.

`kATSLineDisableAllTrackingAdjustments`
Specifies not to perform any tracking-adjustment operations on the line.

Available in Mac OS X v10.2 and later.

Declared in `ATSLayoutTypes.h`.

`kATSLineDisableAllLayoutOperations`
Specifies to turn off all layout adjustments for this line.

Available in Mac OS X v10.2 and later.

Declared in `ATSLayoutTypes.h`.

`kATSLineUseDeviceMetrics`
Specifies to used rounded device metrics instead of fractional path metrics. This optimizes display of text and should be used only in cases in which the text is displayed onscreen as opposed to printed or output to PDF. If you use this option to display text onscreen as well as to print or create a PDF, you will get different results between the two types of output. This attribute is not recommended for Quartz antialiased text.

Available in Mac OS X v10.2 and later.

Declared in `ATSLayoutTypes.h`.

`kATSLineBreakToNearestCharacter`
Specifies that line breaking should occur at the nearest character, not word. This could cause a word to be split over multiple lines.

Available in Mac OS X version 10.3 and later.

Declared in `ATSLayoutTypes.h`.

`kATSLineAppleReserved`
This selector is reserved by Apple. If you try to use it, ATSUI returns the `kATSUInvalidAttributeValueEr` result code.

Available in ATSUI 1.1 and later.

Declared in `ATSLayoutTypes.h`.

Discussion
You can use a constant of type `ATSLineLayoutOptions` to set or obtain the line layout options in a line of text or for an entire text layout object; see the functions `ATSUSetLineControls` (page 1956) and `ATSUSetLayoutControls` (page 1955), respectively.

Line Layout Width Selector

Specifies a line width.

```
enum {
    kATSUUseLineControlWidth = 0X7FFFFFFF
};
```

Constants
`kATSUUseLineControlWidth`
Indicates that the functions `ATSUBreakLine` or `ATSUBatchBreakLines` should use the previously set line width attribute for the current line to determine how many characters can fit on the line. If no line width has been set for the line, these functions use the line width set for the text layout object; if not set, these functions use the default line width value.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

Discussion
You can pass this constant to the functions `ATSUBreakLine` (page 1846) or `ATSUBatchBreakLines` (page 1844) to indicate that the function should use the line width previously set for that line to calculate the soft line break. If no line width has been set for the line, these functions use the line width set for the text layout object.

No Selectors Option

Specifies no selectors are chosen.

```
enum {
    kATSUNoSelector = 0x0000FFFF
};
```

Constants
`kATSUNoSelector`
Specifies no selectors are chosen.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

Style Comparison Options

Specify how two style objects compare to each other.

```
typedef UInt16 ATSUStyleComparison;
enum {
    kATSUStyleUnequal = 0,
    kATSUStyleContains = 1,
    kATSUStyleEquals = 2,
    kATSUStyleContainedBy = 3
};
```

Constants

`kATSUStyleUnequal`
Specifies that styles are unequal.
Available in Mac OS X v10.0 and later.
Declared in `ATSUnicodeTypes.h`.

`kATSUStyleContains`
Specifies that style 1 contains style 2 as a proper subset.
Available in Mac OS X v10.0 and later.
Declared in `ATSUnicodeTypes.h`.

`kATSUStyleEquals`
Specifies that style 1 equals style 2.
Available in Mac OS X v10.0 and later.
Declared in `ATSUnicodeTypes.h`.

`kATSUStyleContainedBy`
Specifies that style 1 is contained by style 2.
Available in Mac OS X v10.0 and later.
Declared in `ATSUnicodeTypes.h`.

Discussion
The function `ATSUCompareStyles` (page 1855) returns a constant of type `ATSUStyleComparison` to indicate whether two style objects are the same, different, or a subset of one another.

Style Line Count Types

Specifies how many lines to draw for a given style type.

```
typedef UInt16 ATSUStyleLineCountType;
enum {
    kATSUStyleSingleLineCount     = 1,
    kATSUStyleDoubleLineCount     = 2
};
```

Constants

`kATSUStyleSingleLineCount`
Specifies to use a single line.
Available in Mac OS X v10.3 and later.
Declared in `ATSUnicodeTypes.h`.

`kATSUStyleDoubleLineCount`
Specifies to use a double line.
Available in Mac OS X v10.3 and later.
Declared in `ATSUnicodeTypes.h`.

Discussion
These constants are available in Mac OS X version 10.3 and later. Currently only the underline and strike through styles support this type.

Style Rendering Options

Specify rendering options for a style object.

```
typedef UInt32 ATSStyleRenderingOptions;
enum {
    kATSStyleNoOptions            = 0x00000000,
    kATSStyleNoHinting            = 0x00000001,
    kATSStyleApplyAntiAliasing    = 0x00000002,
    kATSStyleNoAntiAliasing       = 0x00000004,
    kATSStyleAppleReserved        = (unsigned long)0xFFFFFFF8,
    kATSStyleApplyHints           = kATSStyleNoOptions
};
```

Constants

`kATSStyleNoOptions`
Specifies no options are set.

Available in Mac OS X v10.0 and later.

Declared in `ATSLayoutTypes.h`.

`kATSStyleNoHinting`
Specifies that Apple Type Services (ATS) should produce unhinted glyph outlines. The default behavior is for ATS to produce is hinted glyph outlines.

Available in Mac OS X v10.2 and later.

Declared in `ATSLayoutTypes.h`.

`kATSStyleApplyAntiAliasing`
Specifies that Apple Type Services should produce antialiased glyph images even if system preferences or Quartz 2D settings indicate otherwise.

Available in Mac OS X v10.2 and later.

Declared in `ATSLayoutTypes.h`.

`kATSStyleNoAntiAliasing`
Specifies that Apple Type Services should turn-off antialiasing glyph imaging even if system preferences or Quartz 2D settings indicate otherwise. This selector negates the `kATSStyleApplyAntiAliasing` selector if is set.

Available in Mac OS X v10.2 and later.

Declared in `ATSLayoutTypes.h`.

`kATSStyleAppleReserved`
This selector is reserved by Apple. If you try to use it, you will get an invalid value error.

Available in Mac OS X v10.0 and later.

Declared in `ATSLayoutTypes.h`.

`kATSStyleApplyHints`
Specifies that Apple Type Services should produce hinted glyph outlines. This selector is obsolete; do not use it. It is listed here only for backwards compatibility.

Available in Mac OS X v10.0 and later.

Declared in `ATSLayoutTypes.h`.

Discussion
You can set style rendering attributes for a style object (`ATSUStyle`) by using the `kATSUStyleRenderingOptionsTag` attribute tag and calling the function `ATSUSetAttributes` (page 1950). Style rendering options provide fine control over how a style is rendered.

Tab Positioning Options

Specify text positioning for ATSUI tab stops.

```
typedef UInt16 ATSUTabType;
enum {
    kATSULeftTab                    = 0,
    kATSUCenterTab                  = 1,
    kATSURightTab                   = 2,
    kATSUDecimalTab                 = 3,
    kATSUNumberTabTypes             = 4
};
```

Constants

`kATSULeftTab`
Specifies that the left side of the tabbed text should be flush against the tab stop.
Available in Mac OS X v10.2 and later.
Declared in `ATSUnicodeTypes.h`.

`kATSUCenterTab`
Specifies that the tabbed text should be centered on the tab stop.
Available in Mac OS X v10.2 and later.
Declared in `ATSUnicodeTypes.h`.

`kATSURightTab`
Specifies that the right side of the tabbed text should be flush against the tab stop.
Available in Mac OS X v10.2 and later.
Declared in `ATSUnicodeTypes.h`.

`kATSUDecimalTab`
Specifies that the decimal point of a value should be centered on the tab stop. To set a decimal tab, use the tag `kATSULineDecimalTabCharacterTag`. This tag specifies the current setting for the decimal separator, and affects the behavior of decimal tabs for a text layout (not an individual line). The default character that is used as a separator is set by the user in System Preferences.
Declared in `ATSUnicodeTypes.h`.
Available in Mac OS X version 10.3 and later.

`kATSUNumberTabTypes`
Specifies the number of valid tab types.
Available in Mac OS X v10.2 and later.
Declared in `ATSUnicodeTypes.h`.

Discussion
You can use tab type constants to set a tab ruler. The default value is the user setting in System Preferences.

Text Buffer Convenience Constants

Refer to the beginning or end of a text buffer.

```
enum {
    kATSUFromTextBeginning = (unsigned long)0xFFFFFFFF,
    kATSUToTextEnd = (unsigned long)0xFFFFFFFF,
    kATSUFromPreviousLayout = (unsigned long)0xFFFFFFFE,
    kATSUFromFollowingLayout      = (unsigned long)0xFFFFFFFD
};
```

Constants

`kATSUFromTextBeginning`

Indicates that the range of text to be operated on should start at the beginning of the text layout object's text buffer.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSUToTextEnd`

Indicates that the range of text to be operated on should span to the end of the text layout object's text buffer.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSUFromPreviousLayout`

Used for bidirectional cursor movement between paragraphs in the functions `ATSURightwardCursorPosition` and `ATSULeftwardCursorPosition`.

Available in Mac OS X v10.3 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSUFromFollowingLayout`

Used for bidirectional cursor movement between paragraphs in the functions `ATSURightwardCursorPostion` and `ATSULeftwardCursorPosition`.

Available in Mac OS X v10.3 and later.

Declared in `ATSUnicodeTypes.h`.

Discussion

Do not pass these constants to functions which do not explicitly state they will accept them.

ATSUI functions that draw, highlight, measure, or otherwise operate on text do so to a range of text, not the entire text buffer (unless you specify the entire buffer). You specify the beginning of this range with an edge offset of type `UniCharArrayOffset`, and demarcate the end of the range by indicating a length of type `UniCharCount`.

If you want the range to start at the beginning of the text buffer, you should pass the constant `kATSUFromTextBeginning`. If you want the range to span the end of the text buffer, you should pass the constant `kATSUToTextEnd`. If you want the range to span the entire text buffer, pass `kATSUFromTextBeginning` in conjunction with the constant `kATSUToTextEnd`. For bidirectional text, you can specify the previous layout by passing the constant `kATSUFromPreviousLayout` and the following layout by passing the constant `kATSUFromFollowingLayout`.

Unflattened Style Run Data Options

Specify options to use when unflattening ATSUI style run data.

```
typedef UInt32 ATSUUnflattenStyleRunOptions;
enum {
    kATSUUnflattenOptionNoOptionsMask = 0x00000000
};
```

Constants
`kATSUUnflattenOptionNoOptionsMask`
Specifies that no options are to be used.

Discussion
Additional options may be added in the future.

Vertical Character Types

Specify the glyph orientation of font tracking settings or a style run.

```
typedef UInt16 ATSUVerticalCharacterType;
enum {
    kATSUStronglyHorizontal = 0,
    kATSUStronglyVertical = 1
};
```

Constants
`kATSUStronglyHorizontal`
Specifies a horizontal orientation.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

`kATSUStronglyVertical`
Specifies a vertical orientation.

Available in Mac OS X v10.0 and later.

Declared in `ATSUnicodeTypes.h`.

Discussion
You can pass a constant of type `ATSUVerticalCharacterType` to the functions `ATSUCountFontTracking` (page 1861) and `ATSUGetIndFontTracking` (page 1910) to specify the glyph orientation of font tracking settings, since font tracking settings differ depending upon glyph orientations.

You can also use one of these constants to set or obtain the glyph orientation of a style run; see the functions `ATSUSetAttributes` (page 1950) and `ATSUGetAttribute` (page 1892), respectively.

Result Codes

The most common result codes returned by Apple Type Services for Unicode Imaging are listed below.

Result Code	Value	Description
`kATSUInvalidTextLayoutErr`	-8790	The ATSUI text layout object is not initialized or is in an otherwise invalid state. Available beginning with ATSUI 1.0.

Result Code	Value	Description
kATSUInvalidStyleErr	-8791	The ATSUI style object is not initialized or in an otherwise invalid state. Available beginning with ATSUI 1.0.
kATSUInvalidTextRangeErr	-8792	The text range extends beyond the limits of the text layout object's text range. Available beginning with ATSUI 1.0.
kATSUFontsMatched	-8793	One or more characters cannot be rendered with the assigned font, but can be rendered with a substitute font from among those currently active. Available beginning with ATSUI 1.0.
kATSUFontsNotMatched	-8794	One or more characters can neither be rendered with the assigned font nor with any other currently active font. Available beginning with ATSUI 1.0.
kATSUNoCorrespondingFontErr	-8795	The font ID corresponds to an existing font that isn't available to ATSUI. Available beginning with ATSUI 1.0.
kATSUInvalidFontErr	-8796	The font ID does not correspond to any installed font or ATSUI is unable to obtain the font data (as in the case of a protected font). Available beginning with ATSUI 1.0.
kATSUInvalidAttributeValueErr	-8797	The attribute value is invalid or undefined. Available beginning with ATSIU 1.0.
kATSUInvalidAttributeSizeErr	-8798	The allocated attribute value size is less than required. Available beginning with ATSUI 1.0.
kATSUInvalidAttributeTagErr	-8799	The tag is an ATSUI-reserved value or the wrong type of attribute tag (that is, a style run attribute tag instead of text layout attribute tag and vice versa). Available beginning with ATSUI 1.0.
kATSUInvalidCacheErr	-8800	Indicates an attempt to read style data from an invalid cache (that is, the format of the cached data does not match that used by ATSUI or the cached data is corrupt). Available beginning with ATSUI 1.0.

Result Code	Value	Description
kATSUNotSetErr	-8801	The ATSUI style object's attribute, font feature, font variation is not set; the ATSUI text layout object or single line's attribute is not set; or a font name is not set. Available beginning with ATSUI 1.0.
kATSUNoStyleRunsAssignedErr	-8802	No style runs are assigned to the ATSUI text layout object. Available beginning with ATSUI 1.1.
kATSUQuickDrawTextErr	-8803	The QuickDraw function DrawText encountered an error rendering or measuring a line of text. Available beginning with ATSUI 1.1.
kATSULowLevelErr	-8804	Apple Type Services (ATS) encountered an error while performing an operation requested by ATSUI. Available beginning with ATSUI 1.1.
kATSUNoFontCmapAvailableErr	-8805	The 'CMAP' table cannot be accessed or synthesized for a font. Available beginning with ATSUI 1.1.
kATSUNoFontScalerAvailableErr	-8806	There is no font scaler available for a font. Available beginning with ATSUI 1.1.
kATSUCoordinateOverflowErr	-8807	The coordinate values passed to the function caused a coordinate overflow (greater than 32 KB). Available beginning with ATSUI 1.1.
kATSULineBreakInWord	-8808	The function ATSUBreakLine performed a line break within a word. Available beginning with ATSUI 1.2.
kATSUBusyObjectErr	-8809	An ATSUI object is being used by another thread. Available in Mac OS X v10.1 and later.
kATSUInvalidFontFallbacksErr	-8900	The ATSUFontFallback object is not initialized or is otherwise in an in valid state. Available in Mac OS X v10.1 and later.
kATSUUnsupportedStreamFormatErr	-8901	The data-flattening format is invalid or is not supported by this version of ATSUI. Available in Mac OS X v10.2 and later.
kATSUBadStreamErr	-8902	The data is not formatted as specified by the data-flattening format constant, or the data is corrupt. Available in Mac OS X v10.2 and later.

Result Code	Value	Description
kATSUOutputBufferTooSmallErr	-8903	The output buffer is too small to contain the data output by the function. Available in Mac OS X v10.2 and later.
kATSUInvalidCallInsideCallbackErr	-8904	Your callback is making a call that could cause an infinite recursion. Available in Mac OS X v10.2 and later.
kATSULastErr	-8959	No ATSUI-related result codes may exceed this value. Result code values between kATSUInvalidTextLayoutErr and kATSULastErr are reserved. Available beginning with ATSUI 1.0.

Gestalt Constants

You can check for version and feature availability information by using the ATSUI attribute and version selectors defined in the Gestalt Manager. For more information see Gestalt Manager Reference.

Carbon Accessibility Reference

Framework: ApplicationServices/HIServices.h, Carbon/HIToolbox.h

Overview

This document describes the Carbon accessibility API. You use this API to make your Carbon application accessible to assistive applications and technologies, a process called access enabling.

Who Should Read This Document?

All Carbon application developers should read this document for information on specific functions and constants they may need to access-enable their applications. If you're unsure which parts of the Carbon accessibility API you need, or if you're new to accessibility in Mac OS X, be sure to read the documents listed in "See Also" (page 2073).

Organization of This Document

This document contains API reference in the following sections:

- "Accessibility Object Functions" (page 2074) documents the functions some Carbon applications use to create and manipulate accessibility objects.
- "Accessibility Constants" (page 2081) documents accessibility Carbon events and the constants that define the accessibility event parameters, object attributes, and notifications.
- "Carbon Accessibility Result Codes" (page 2121) describes some of the error codes returned by the Carbon accessibility implementation.

See Also

For more information on accessibility in general and access enabling Carbon applications in particular, you should read the following documents:

- Getting Started With Accessibility
- Accessibility Overview
- Accessibility Programming Guidelines for Carbon

Functions

This section describes the functions some Carbon developers may need to use to access-enable their applications.

AXNotificationHIObjectNotify

Posts a notification for an accessibility object.

```
void AXNotificationHIObjectNotify (
   CFStringRef inNotification,
   HIObjectRef inHIObject,
   UInt64 inIdentifier
);
```

Parameters

inNotification

The string containing the name of the notification to broadcast.

inHIObject

The `HIObjectRef` portion of the accessibility object for which this notification applies.

inIdentifier

The 64-bit identifier portion of the accessibility object for which this notification applies.

Discussion

You use the `AXNotificationHIObjectNotify` function to broadcast changes in an accessibility object to assistive applications. For example, an accessibility object may want to broadcast that the window it represents has moved, or that an attribute value has changed. See "Notifications" (page 2117) for a list of possible notification constants. Note that accessibility objects representing standard user interface elements automatically send out notifications. In general, you do not need to post your own notifications unless you implement custom user interface elements.

Availability

Available in Mac OS X version 10.2 and later.

Not available to 64-bit applications.

Declared In

`HIAccessibility.h`

AXUIElementCreateWithHIObjectAndIdentifier

Creates an accessibility object that represents a user interface element.

```
AXUIElementRef AXUIElementCreateWithHIObjectAndIdentifier (
   HIObjectRef inHIObject,
   UInt64 inIdentifier
);
```

Parameters

inHIObject

A reference to the user interface element this accessibility object represents. You must pass one of the following reference types: `WindowRef`, `ControlRef`, `MenuRef`, or an `HIObjectRef`.

inIdentifier
A 64-bit identifier to uniquely identify the accessibility object within the user interface element. Pass `0` to indicate the base object identified by the `inHIObject` parameter.

Return Value
The newly created accessibility object.

Discussion
If the accessibility object represents part of the substructure of a user interface element, then you must assign it a unique, nonzero identifier value. If the accessibility object represents a complex user interface object as a whole, you must give it the identifier value `0`. For example, a segmented view containing five buttons can have six accessibility objects associated with it:

- The segmented view as a whole, identified by its control reference (`ControlRef`) and identifier value `0`.
- The five button elements, identified by the segmented view reference and identifiers `1` through `5`, respectively.

The accessibility object is a `CFTypeRef` object. You can use `CFEqual` to compare two accessibility objects. You must call `CFRelease` on the accessibility object when you no longer need it.

Availability
Available in Mac OS X version 10.2 and later.
Not available to 64-bit applications.

Declared In
`HIAccessibility.h`

AXUIElementGetHIObject

Gets the user interface element the given accessibility object represents.

```
HIObjectRef AXUIElementGetHIObject (
   AXUIElementRef inUIElement
);
```

Parameters
inHIAccObj
The accessibility object whose user interface element you want to get.

Return Value
A reference to the user interface element associated with the passed-in accessibility object (or `NULL` if `inHIAccObj` is not a valid accessibility object).

Availability
Available in Mac OS X version 10.2 and later.
Not available to 64-bit applications.

Declared In
`HIAccessibility.h`

AXUIElementGetIdentifier

Gets the unique identifier associated with an accessibility object.

```
void AXUIElementGetIdentifier (
   AXUIElementRef inUIElement,
   UInt64 *outIdentifier
);
```

Parameters

inHIAccObj

The accessibility object whose identifier you want to get.

outIdentifier

A pointer to a 64-bit integer. On return, `outIdentifier` contains the accessibility object's identifier. If `inHIAccObj` is not a valid accessibility object, this function returns 0. Note that 0 is a valid identifier value, so you should not assume that `inHIAccObj` is invalid if you receive a 0 result.

Discussion

If you create your own accessibility objects to represent custom user interface elements or subviews, you can use the identifier this function returns to identify which accessibility object is being referenced.

Availability

Available in Mac OS X version 10.2 and later.

Not available to 64-bit applications.

Declared In

`HIAccessibility.h`

HICopyAccessibilityActionDescription

Returns the system-defined action description string for a standard action.

```
CFStringRef HICopyAccessibilityActionDescription (
   CFStringRef inAction
);
```

Parameters

inAction

The action for which you want the system-defined description. See "Actions" (page 2115) for the action strings you can use.

Return Value

The system-defined description for the action. When you are finished with the CFString containing the description, you must use `CFRelease` to release it. If you pass in an unsupported action, the results are undefined.

Discussion

The `HICopyAccessibilityActionDescription` function is a convenience function you can use to get the current, system-defined action description for a given action. If you create an accessibility object that supports an action, you must supply the action description. Using this function allows you to take advantage of any changes or enhancements Apple might make.

Availability

Available in Mac OS X version 10.4 and later.

Not available to 64-bit applications.

Declared In
HIAccessibility.h

HICopyAccessibilityRoleDescription

Returns the system-defined role description string for a standard role or role-subrole pair.

```
CFStringRef HICopyAccessibilityRoleDescription (
   CFStringRef inRole,
   CFStringRef inSubrole
);
```

Parameters

inRole

The role for which you want the system-defined description. See "Roles" (page 2087) for the role strings you can use.

inSubrole

The subrole for which you want the system-defined description. See "Subroles" (page 2093) for the subrole strings you can use. Pass `NULL` if your accessible object does not have a subrole.

Return Value
The system-defined description for the role or role-subrole pair. When you are finished with the CFString containing the description, you must use `CFRelease` to release it. If there is no system-defined role description associated with the role or role-subrole pair you pass in, this function returns `NULL`. If you pass in an unknown role or an unknown subrole, this function returns `NULL`.

Discussion
The `HICopyAccessibilityRoleDescription` function is a convenience function you can use if you have to provide the role description for an accessibility object you create. Instead of hard-coding a role description for an accessibility object, you should use this function to get the current, system-defined role description. This allows you to take advantage of any changes or enhancements Apple might make.

Availability
Available in Mac OS X version 10.4 and later.
Not available to 64-bit applications.

Declared In
HIAccessibility.h

HIObjectIsAccessibilityIgnored

Returns whether the given HIObject is marked as ignored for accessibility purposes.

```
Boolean HIObjectIsAccessibilityIgnored (
   HIObjectRef inObject
);
```

Parameters

inObject

The object whose accessibility ignored state you wish to query.

Return Value
A Boolean value indicating whether the HIObject is ignored for accessibility purposes.

Availability
Available in Mac OS X version 10.2 and later.
Not available to 64-bit applications.

Declared In
`HIAccessibility.h`

HIObjectOverrideAccessibilityContainment

Allows you to override the accessibility objects an HIObject would usually supply as the values of its `kAXParentAttribute`, `kAXWindowAttribute`, and `kAXTopLevelUIElementAttribute` attributes.

```
OSStatus HIObjectOverrideAccessibilityContainment (
   HIObjectRef inHIObject,
   AXUIElementRef inDesiredParent,
   AXUIElementRef inDesiredWindow,
   AXUIElementRef inDesiredTopLevelUIElement
);
```

Parameters

inHIObject
The `HIObjectRef` whose parent attribute you want to override.

inDesiredParent
The `AXUIElementRef` that you want the given HIObject to return as the value of its `kAXParentAttribute` attribute. This function makes a copy of the `AXUIElementRef` and you must release the *inDesiredParent* parameter after you call this function. Passing `NULL` in this parameter indicates you do not want the HIObject to override the value of its `kAXParentAttribute` attribute.

inDesiredWindow
The `AXUIElementRef` that you want the given HIObject to return as the value of its `kAXWindowAttribute` attribute. This function makes a copy of the `AXUIElementRef` and you must release the *inDesiredWindow* parameter after you call this function. Passing `NULL` in this parameter indicates you do not want the HIObject to override the value of its `kAXWindowAttribute` attribute (if the value exists).

inDesiredTopLevelUIElement
The `AXUIElementRef` that you want the given HIObject to return as the value of its `kAXTopLevelUIElementAttribute` attribute. This function makes a copy of the `AXUIElementRef` and you must release the *inDesiredTopLevelUIElement* parameter after you call this function. Passing `NULL` in this parameter indicates you do not want the HIObject to override the value of its `kAXTopLevelUIElementAttribute` attribute (if the value exists).

Return Value
An OSStatus result code. If the `HIObjectRef` is invalid, this function returns `paramErr`.

Discussion
This function allows you to change the parent that the given HIObject would usually supply to the accessibility hierarchy. For example, you might call this function on the menu of a pop-up control to ensure that the menu returns the pop-up control as its parent (rather than the application). Optionally, this function also allows you to change the window and top-level accessibility object the given HIObject would supply.

If the input HIObject is a standard toolbox object, such as an HIView or a menu, the input HIObject will not be included as an accessibility child of its normal parent. In all other cases, it is the client's responsibility to ensure that the input HIObject is not included as an accessibility child of its normal parent.

If the desired `AXUIElementRef` parent represents an HIView, a menu, or a window, the input HIObject will be included automatically as an accessibility child of the specified parent. In all other cases, it is the client's responsibility to manually include the input HIObject as an accessibility child of the specified parent. To represent an HIView, a menu, or a window, an `AXUIElementRef` must contain the appropriate `HIObjectRef`, as well as an identifier value of 0.

Note that similar rules don't apply to the handling of the window and top-level element attributes, because those attributes don't represent two-way relationships.

Not every type of HIObject supports a containment override; currently, HIViews, menus, and windows support containment overrides.

Availability
Available in Mac OS X version 10.4 and later.
Not available to 64-bit applications.

Declared In
`HIAccessibility.h`

HIObjectSetAccessibilityIgnored

Marks an HIObject as ignored or unignored for accessibility purposes.

```
OSStatus HIObjectSetAccessibilityIgnored (
   HIObjectRef inObject,
   Boolean inIgnored
);
```

Parameters

inObject
The object whose accessibility ignored state you wish to change.

inIgnored
A Boolean value indicating whether to ignore the object (`TRUE`) or not (`FALSE`).

Return Value
An OSStatus signifying success or failure.

Discussion
An ignored HIObject is not shown to an assistive application that uses the accessibility APIs to examine the interface of your application. Your application's accessibility implementation should still report an ignored HIObject as usual. The Carbon accessibility implementation automatically hides ignored HIObjects from assistive applications.

Note: By default, an HIObject is *not* ignored.

Availability
Available in Mac OS X version 10.2 and later.
Not available to 64-bit applications.

Declared In
`HIAccessibility.h`

HIObjectSetAuxiliaryAccessibilityAttribute

Associates an additional accessibility attribute with an accessibility object (a UIElement) that is used to represent a given HIObject or part thereof.

```
OSStatus HIObjectSetAuxiliaryAccessibilityAttribute (
   HIObjectRef inHIObject,
   UInt64 inIdentifier,
   CFStringRef inAttributeName,
   CFTypeRef inAttributeData
);
```

Parameters

inHIObject

The `HIObjectRef` portion of the object-identifier pair to which the attribute data is associated.

inIdentifier

The 64-bit identifier portion of the object-identifier pair to which the attribute data is associated. Pass 0 in this parameter when you want to associate the attribute data to the HIObject as a whole. You might do this if, for example, you want to give a description attribute to the object representing a button.

inAttributeName

A `CFStringRef` of the name of the attribute. This string is retained before it is added to the auxiliary attribute storage area.

inAttributeData

A `CFTypeRef` containing the data supplied for the attribute's value. This data is retained before it is added to the auxiliary attribute storage area; you may release this data after calling this function. If you pass `NULL` in this parameter, it indicates that the named auxiliary attribute should no longer be associated with the object-identifier pair and any named attribute data previously associated with the object-identifier pair will be released.

Return Value

An OSStatus result code. The function returns `noErr` if it was able to associate the attribute data with the HIObject. If the `HIObjectRef` is invalid, `paramErr` is returned.

Discussion

This function allows your application to provide the name of and data for an accessibility attribute you want to add to the UIElement that represents a given HIObject-identifier pair. Normally, accessibility attributes are only supplied dynamically through Carbon events, but this function allows you to supply them statically.

This function only allows you to associate attributes whose values never change. If you need to supply attribute whose values are determined dynamically or whose values are settable, you must install the necessary Carbon accessibility event handlers. See Accessibility Programming Guidelines for Carbon for more information about how this works.

This function is particularly useful for supplying the values of the `kAXDescriptionAttribute`, `kAXTitleUIElementAttribute`, `kAXServesAsTitleForUIElementsAttribute`, `kAXLinkedUIElementsAttribute` attributes and other attributes whose values are specific to the layout and usage of your application.

The auxiliary attribute store (containing attribute values you supply using this function) is consulted during the HIObject's default handling of the Carbon accessibility attribute events. Therefore, any programmatic handling of a given accessibility attribute has the opportunity to override or block the consultation of the store. In general, if the toolbox or a Carbon event handler can provide the attribute value some other way, the store is not consulted.

Availability
Available in Mac OS X version 10.4 and later.
Not available to 64-bit applications.

Declared In
`HIAccessibility.h`

Constants

This section describes the constants that define accessibility events and aspects of accessibility objects. The accessibility event constants are defined in `CarbonEvents.h` in the Carbon framework. The accessibility object constants are defined in header files in the ApplicationServices framework.

Accessibility Events

Accessibility Event Constants

Define accessibility events (`kEventClassAccessibility`).

```
enum
{
    kEventAccessibleGetChildAtPoint = 1,
    kEventAccessibleGetFocusedChild = 2,
    kEventAccessibleGetAllAttributeNames = 21,
    kEventAccessibleGetAllParameterizedAttributeNames = 25,
    kEventAccessibleGetNamedAttribute = 22,
    kEventAccessibleSetNamedAttribute = 23,
    kEventAccessibleIsNamedAttributeSettable = 24,
    kEventAccessibleGetAllActionNames = 41,
    kEventAccessiblePerformNamedAction = 42,
    kEventAccessibleGetNamedActionDescription = 44
};
```

Constants
`kEventAccessibleGetChildAtPoint`

A request sent by an assistive application to get the accessible child of the given accessibility object that contains the given point. The `kEventParamMouseLocation` parameter contains the location in global coordinates.

If you handle this event, you use the `kEventParamAccessibleChild` parameter to return an accessible first-order child of the accessibility object receiving the event. If there is no child at the given point, your handler should leave the `kEventParamAccessibleChild` parameter empty and return `noErr`. You must not set the `kEventParamAccessibleChild` parameter to a grandchild or more distant descendant of the accessible object receiving this event.

Declared in `HIAccessibility.h`.

Available in Mac OS X version 10.2 and later.

`kEventAccessibleGetFocusedChild`

A request sent by an assistive application to get the accessible child of the given accessibility object that is part of the focus chain.

If you handle this event, you set the `kEventParamAccessibleChild` parameter to a first-order, accessible child that is focused or is the ancestor of a focused object. If there is no child in the focus chain, your handler should leave the `kEventParamAccessibleChild` parameter empty and return `noErr`. You must not set the `kEventParamAccessibleChild` parameter to a grandchild or more distant descendant of the accessible object receiving this event.

Declared in `HIAccessibility.h`.

Available in Mac OS X version 10.2 and later.

`kEventAccessibleGetAllAttributeNames`

A request sent by an assistive application to get the names of all attributes the given accessibility object supports.

If you handle this event, you create a CFString object for the name of each non-parameterized attribute and add it to the mutable array in the `kEventParamAccessibleAttributeNames` parameter. If the accessibility object receiving the event supports parameterized attributes, you return them in the handler for the `kEventAccessibleGetAllParameterizedAttributeNames` event.

Declared in `HIAccessibility.h`.

Available in Mac OS X version 10.2 and later.

`kEventAccessibleGetAllParameterizedAttributeNames`

A request sent by an assistive application to get the names of all parameterized attributes the given accessibility object supports.

If you handle this event, you create a CFString object for the name of each parameterized attribute and add it to the mutable array in the `kEventParamAccessibleAttributeNames` parameter. You must not return any regular, non-parameterized attribute names with this event. Instead, return regular attribute names in the handler for the `kEventAccessibleGetAllAttributeNames` event.

Declared in `HIAccessibility.h`.

Available in Mac OS X version 10.3 and later.

`kEventAccessibleGetNamedAttribute`

A request sent by an assistive application to get the value of the given attribute.

If you handle this event, you determine if the given accessibility object supports the attribute named in the `kEventParamAccessibleAttributeName` parameter. If it does, you return the attribute's value in the `kEventParamAccessibleAttributeValue` parameter. If the accessibility object does not support the attribute, return the `eventNotHandledErr` error. The type of the `kEventParamAccessibleAttributeValue` parameter varies with the type of the attribute's value.

This event may also include the optional `kEventParamAccessibleAttributeParameter` parameter that describes the parameters of a parameterized attribute. Note that parameterized attributes were introduced in Mac OS X version 10.3.

Declared in `HIAccessibility.h`.

Available in Mac OS X version 10.2 and later.

`kEventAccessibleSetNamedAttribute`

A request sent by an assistive application to set the value of the given attribute to the passed-in value.

If you handle this event, you determine if the given accessibility object supports the attribute named in the `kEventParamAccessibleAttributeName` parameter and if the attribute is settable. Then, you set the named attribute's value to the value supplied in the `kEventParamAccessibleAttributeValue` parameter. If you cannot handle this event (because, for example, the accessibility object does not support this attribute, the attribute is not settable, or the value is not appropriate), return the `eventNotHandledErr` error.

Declared in `HIAccessibility.h`.

Available in Mac OS X version 10.2 and later.

`kEventAccessibleIsNamedAttributeSettable`

A request sent by an assistive application to find out if the given attribute's value can be changed.

If you handle this event, you determine if the accessibility object supports the given attribute. If it does, you return a Boolean value in the `kEventParamAccessibleAttributeSettable` parameter that indicates whether the attribute's value can be changed.

Declared in `HIAccessibility.h`.

Available in Mac OS X version 10.2 and later.

`kEventAccessibleGetAllActionNames`

Sent by an assistive application to find out which actions the given accessibility object supports.

If you handle this event, you create a CFString object for the name of each action the given accessibility object supports and add it to the mutable array in the `kEventParamAccessibleActionNames` parameter.

Declared in `HIAccessibility.h`.

Available in Mac OS X version 10.2 and later.

`kEventAccessiblePerformNamedAction`

Sent by an assistive application when it wants the given accessibility object to perform the given action.

If you handle this event, you determine if the accessibility object supports the action named in the `kEventParamAccessibleActionName` parameter. If it does, you perform it.

In Mac OS X version 10.3 and later, this event includes the `kEventParamAccessibilityEventQueued` parameter, which indicates whether the event was queued. You check the value of this parameter before you perform an action that might result in a call to a routine that may not return immediately. If the event is queued, you can perform such an action without the possibility of causing an assistive application to receive a time-out error waiting for the action to complete. If the event is not queued, your handler can return the `eventDeferAccessibilityEventErr` to request that it be queued and sent to you later.

In versions of Mac OS X prior to 10.3, events are always directly dispatched and you should perform a requested action even if it might cause an assistive application to receive a time-out error.

Declared in `HIAccessibility.h`.

Available in Mac OS X version 10.2 and later.

`kEventAccessibleGetNamedActionDescription`

Sent by an assistive application to get the human-intelligible name of the given action.

If you handle this event, you determine if the given accessibility object supports the given action. If it does, you return the value of the action's description property in the `kEventParamAccessibleActionDescription` parameter. To do this, you do not create a CFString object for the action description. Instead, you must modify the mutable string object in the `kEventParamAccessibleActionDescription` parameter to contain the action description.

Declared in `HIAccessibility.h`.

Available in Mac OS X version 10.2 and later.

Discussion

Table 47-1 (page 2084) shows the parameters related to accessibility events.

Table 47-1 Parameter names and types for accessibility event kinds

Event kind	Parameter name	Parameter type
`kEventAccessible-GetChildAtPoint`	`kEventParamAccessibleObject`	`typeCFTypeRef` (an `AXUIElementRef`)
	`kEventParamAccessibleMouse-Location`	`typeHIPoint`
	`kEventParamAccessibleChild`	`typeCFTypeRef`
`kEventAccessible-GetFocusedChild`	`kEventParamAccessibleObject`	`typeCFTypeRef` (an `AXUIElementRef`)
	`kEventParamAccessibleChild`	`typeCFTypeRef`
`kEventAccessibleGet-AllAttributeNames`	`kEventParamAccessibleObject`	`typeCFTypeRef` (an `AXUIElementRef`)
	`kEventParamAccessibleAttribute-Names`	`typeCFMutableArrayRef`
`kEventAccessibleGet-AllParameterized-AttributeNames`	`kEventParamAccessibleObject`	`typeCFTypeRef` (an `AXUIElementRef`)
	`kEventParamAccessibleAttribute-Names`	`typeCFMutableArrayRef`
`kEventAccessibleGet-NamedAttribute`	`kEventParamAccessibleObject`	`typeCFTypeRef` (an `AXUIElementRef`)
	`kEventParamAccessibleAttribute-Name`	`typeCFStringRef`
	`kEventParamAccessibleAttribute-Parameter` (Optional; introduced in Mac OS X version 10.3)	`typeCFTypeRef`

Event kind	Parameter name	Parameter type
	kEventParamAccessibleAttribute-Value	typeCFTypeRef (Varies with the type of the attribute value)
kEventAccessibleSet-NamedAttribute	kEventParamAccessibleObject	typeCFTypeRef (an AXUIElementRef)
	kEventParamAccessibleAttribute-Name	typeCFStringRef
	kEventParamAccessibleAttribuute-Value	typeCFTypeRef (Varies with the type of the attribute value)
kEventAccessible-IsNamedAttribute-Settable	kEventParamAccessibleObject	typeCFTypeRef (an AXUIElementRef)
	kEventParamAccessibleAttribute-Name	typeCFStringRef
	kEventParamAccessibleAttribute-Settable	typeBoolean
kEventAccessibleGet-AllActionNames	kEventParamAccessibleObject	typeCFTypeRef
	kEventParamAccessibleActionNames	typeCFMutableArrayRef
kEventAccessible-PerformNamedAction	kEventParamAccessibleObject	typeCFTypeRef (an AXUIElementRef)
	kEventParamAccessibleActionName	typeCFStringRef
	kEventParamAccessibleEventQueued (Only in Mac OS X version 10.3 and later)	typeBoolean
kEventAccessible-GetNamedAction-Description	kEventParamAccessibleObject	typeCFTypeRef (an AXUIElementRef)
	kEventParamAccessibleActionName	typeCFStringRef
	kEventParamAccessibleAction-Description	typeCFMutableStringRef

Accessibility Event Parameters

Define parameters related to accessibility events.

```
enum
{
    kEventParamAccessibleObject = 'aojb',
    kEventParamAccessibleChild = 'achl',
    kEventParamAccessibleAttributeName = 'atnm',
    kEventParamAccessibleAttributeNames = 'atns',
    kEventParamAccessibleAttributeValue = 'atvl',
    kEventParamAccessibleAttributeSettable = 'atst',
    kEventParamAccessibleAttributeParameter = 'atpa',
    kEventParamAccessibleActionName = 'acnm',
    kEventParamAccessibleActionNames = 'acns',
    kEventParamAccessibleActionDescription = 'acds',
    kEventParamAccessibleEventQueued = 'aequ'
};
```

Constants

`kEventParamAccessibleObject`
Specifies an accessibility object. The parameter type is `typeCFTypeRef`, and the data must be of type `AXUIElementRef`.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`kEventParamAccessibleChild`
Specifies the child accessibility object. The parameter type is `typeCFTypeRef`, and the data must be of type `AXUIElementRef`.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`kEventParamAccessibleAttributeName`
Specifies an attribute name. The parameter type is `typeCFStringRef`.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`kEventParamAccessibleAttributeNames`
Specifies an array of attribute names (each of type `CFStringRef`). The parameter type is `typeCFMutableArrayRef`.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`kEventParamAccessibleAttributeValue`
Specifies the value of an attribute. The parameter type varies according to the attribute. However, this value must be one of the flat data types, such as point, rectangle, integer, float, or any CFType, and must be able to be packaged in a CFPropertyList. In particular, the data should not be a pointer, because you cannot be sure how long an assistive application will retain the value, or in what way it will interpret the value.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`kEventParamAccessibleAttributeSettable`
Specifies whether an attribute is settable. The parameter type is `typeBoolean`.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`kEventParamAccessibleAttributeParameter`
Specifies the parameters of a parameterized attribute. The parameter type is `typeCFTypeRef`.

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

`kEventParamAccessibleActionName`
Specifies an action name. The parameter type is `typeCFStringRef`.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`kEventParamAccessibleActionNames`
Specifies an array of action names (each of type `CFStringRef`) . The parameter type is `typeCFMutableArrayRef`.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`kEventParamAccessibleActionDescription`
Specifes the description of an action. The parameter type is `typeCFMutableStringRef`.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`kEventParamAccessibleEventQueued`
Specifies whether the event has been queued. The parameter type is `typeBoolean`.

Accessibility Event Class

Defines the event class for accessibility events.

```
enum
{
    kEventClassAccessibility = 'acce',
};
```

Constants

`kEventClassAccessibility`
Pass this value for the event class when registering for accessibility events.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

Accessibility Object Constants

Roles

Define the values an accessibility object's role attribute can have.

```
#define kAXApplicationRole  CFSTR("AXApplication")
#define kAXSystemWideRole   CFSTR("AXSystemWide")
#define kAXWindowRole       CFSTR("AXWindow")
#define kAXSheetRole        CFSTR("AXSheet")
#define kAXDrawerRole       CFSTR("AXDrawer")
#define kAXGrowAreaRole     CFSTR("AXGrowArea")
#define kAXImageRole        CFSTR("AXImage")
#define kAXUnknownRole      CFSTR("AXUnknown")
#define kAXButtonRole       CFSTR("AXButton")
#define kAXRadioButtonRole  CFSTR("AXRadioButton")
#define kAXCheckBoxRole     CFSTR("AXCheckBox")
#define kAXPopUpButtonRole  CFSTR("AXPopUpButton")
#define kAXMenuButtonRole   CFSTR("AXMenuButton")
#define kAXTabGroupRole     CFSTR("AXTabGroup")
#define kAXTableRole        CFSTR("AXTable")
#define kAXColumnRole       CFSTR("AXColumn")
#define kAXRowRole          CFSTR("AXRow")
#define kAXOutlineRole      CFSTR("AXOutline")
#define kAXBrowserRole      CFSTR("AXBrowser")
#define kAXScrollAreaRole   CFSTR("AXScrollArea")
#define kAXScrollBarRole    CFSTR("AXScrollBar")
#define kAXRadioGroupRole   CFSTR("AXRadioGroup")
#define kAXListRole         CFSTR("AXList")
#define kAXGroupRole        CFSTR("AXGroup")
#define kAXValueIndicatorRole CFSTR ("AXValueIndicator")
#define kAXComboBoxRole     CFSTR("AXComboBox")
#define kAXSliderRole       CFSTR("AXSlider")
#define kAXIncrementorRole  CFSTR("AXIncrementor")
#define kAXBusyIndicatorRole CFSTR ("AXBusyIndicator")
#define kAXProgressIndicatorRole  CFSTR("AXProgressIndicator")
#define kAXRelevanceIndicatorRole CFSTR("AXRelevanceIndicator")
#define kAXToolbarRole      CFSTR("AXToolbar")
#define kAXDisclosureTriangleRole CFSTR("AXDisclosureTriangle")
#define kAXTextFieldRole CFSTR("AXTextField")
#definekAXTextAreaRole      CFSTR("AXTextArea")
#define kAXStaticTextRole   CFSTR("AXStaticText")
#define kAXMenuBarRole      CFSTR("AXMenuBar")
#define kAXMenuBarItemRole  CFSTR("AXMenuBarItem")
#define kAXMenuRole         CFSTR("AXMenu")
#define kAXMenuItemRole     CFSTR("AXMenuItem")
#define kAXSplitGroupRole   CFSTR("AXSplitGroup")
#define kAXSplitterRole     CFSTR("AXSplitter")
#define kAXColorWellRole    CFSTR("AXColorWell")
#define kAXTimeFieldRole    CFSTR("AXTimeField")
#define kAXDateFieldRole    CFSTR("AXDateField")
#define kAXHelpTagRole      CFSTR("AXHelpTag")
#define kAXMatteRole        CFSTR("AXMatteRole")
#define kAXDockItemRole     CFSTR("AXDockItem")
```

Constants

`kAXApplicationRole`

An application.

Available in Mac OS X v10.2 and later.

Declared in `AXRoleConstants.h`.

`kAXSystemWideRole`
The system-wide accessibility object.
Available in Mac OS X v10.2 and later.
Declared in `AXRoleConstants.h`.

`kAXWindowRole`
A window.
Available in Mac OS X v10.2 and later.
Declared in `AXRoleConstants.h`.

`kAXSheetRole`
A sheet.
Available in Mac OS X v10.2 and later.
Declared in `AXRoleConstants.h`.

`kAXDrawerRole`
A drawer.
Available in Mac OS X v10.2 and later.
Declared in `AXRoleConstants.h`.

`kAXGrowAreaRole`
A grow control.
Available in Mac OS X v10.2 and later.
Declared in `AXRoleConstants.h`.

`kAXImageRole`
An image.
Available in Mac OS X v10.2 and later.
Declared in `AXRoleConstants.h`.

`kAXUnknownRole`
Generic role value for an unknown accessibility object.
Available in Mac OS X v10.2 and later.
Declared in `AXRoleConstants.h`.

`kAXButtonRole`
A button.
Available in Mac OS X v10.2 and later.
Declared in `AXRoleConstants.h`.

`kAXRadioButtonRole`
A radio button.
Available in Mac OS X v10.2 and later.
Declared in `AXRoleConstants.h`.

`kAXCheckBoxRole`
A check box.
Available in Mac OS X v10.2 and later.
Declared in `AXRoleConstants.h`.

`kAXPopUpButtonRole`
A pop-up button.

Available in Mac OS X v10.2 and later.

Declared in `AXRoleConstants.h`.

`kAXMenuButtonRole`
A menu button.

Available in Mac OS X v10.2 and later.

Declared in `AXRoleConstants.h`.

`kAXTabGroupRole`
A tab view.

Available in Mac OS X v10.2 and later.

Declared in `AXRoleConstants.h`.

`kAXTableRole`
A table.

Available in Mac OS X v10.2 and later.

Declared in `AXRoleConstants.h`.

`kAXColumnRole`
A column.

Available in Mac OS X v10.2 and later.

Declared in `AXRoleConstants.h`.

`kAXRowRole`
A row.

Available in Mac OS X v10.2 and later.

Declared in `AXRoleConstants.h`.

`kAXOutlineRole`
An accessibility object that displays row-based, hierarchically structured data, such as the list view in a Finder window.

Available in Mac OS X v10.2 and later.

Declared in `AXRoleConstants.h`.

`kAXBrowserRole`
An accessibility object that displays column-based, hierarchically structured data, such as the column view in a Finder window.

Available in Mac OS X v10.2 and later.

Declared in `AXRoleConstants.h`.

`kAXScrollAreaRole`
An accessibility object that displays data managed by scrolling controls.

Available in Mac OS X v10.2 and later.

Declared in `AXRoleConstants.h`.

`kAXScrollBarRole`
A scroll bar control.

Available in Mac OS X v10.2 and later.

Declared in `AXRoleConstants.h`.

`kAXRadioGroupRole`
A set of radio buttons.

Available in Mac OS X v10.2 and later.

Declared in `AXRoleConstants.h`.

`kAXListRole`
A list view.

Available in Mac OS X v10.2 and later.

Declared in `AXRoleConstants.h`.

`kAXGroupRole`
A group box. This role can also be used to group other views without any visual indication of the grouping.

Available in Mac OS X v10.2 and later.

Declared in `AXRoleConstants.h`.

`kAXValueIndicatorRole`
A control that indicates the value of an accessibility object, such as the scroller of a scroll bar control

Available in Mac OS X v10.2 and later.

Declared in `AXRoleConstants.h`.

`kAXComboBoxRole`
A combo box control.

Available in Mac OS X v10.2 and later.

Declared in `AXRoleConstants.h`.

`kAXSliderRole`
A slider control.

Available in Mac OS X v10.2 and later.

Declared in `AXRoleConstants.h`.

`kAXIncrementorRole`
A stepper control (also known as the “little arrows”).

Available in Mac OS X v10.2 and later.

Declared in `AXRoleConstants.h`.

`kAXBusyIndicatorRole`
An asynchronous progress indicator.

Available in Mac OS X v10.2 and later.

Declared in `AXRoleConstants.h`.

`kAXProgressIndicatorRole`
A determinate or indeterminate progress indicator.

Available in Mac OS X v10.2 and later.

Declared in `AXRoleConstants.h`.

`kAXRelevanceIndicatorRole`
A relevance indicator.

Available in Mac OS X v10.2 and later.

Declared in `AXRoleConstants.h`.

`kAXToolbarRole`
A toolbar.
Available in Mac OS X v10.2 and later.
Declared in `AXRoleConstants.h`.

`kAXDisclosureTriangleRole`
A disclosure triangle control.
Available in Mac OS X v10.4 and later.
Declared in `AXRoleConstants.h`.

`kAXTextFieldRole`
A text field.
Available in Mac OS X v10.2 and later.
Declared in `AXRoleConstants.h`.

`kAXTextAreaRole`
The editable text area in a control or window.
Available in Mac OS X v10.2 and later.
Declared in `AXRoleConstants.h`.

`kAXStaticTextRole`
A string of static text displayed in a window that is not part of any control.
Available in Mac OS X v10.2 and later.
Declared in `AXRoleConstants.h`.

`kAXMenuBarRole`
A menu bar.
Available in Mac OS X v10.2 and later.
Declared in `AXRoleConstants.h`.

`kAXMenuBarItemRole`
A menu bar item.
Available in Mac OS X v10.3 and later.
Declared in `AXRoleConstants.h`.

`kAXMenuRole`
A menu.
Available in Mac OS X v10.2 and later.
Declared in `AXRoleConstants.h`.

`kAXMenuItemRole`
A menu item.
Available in Mac OS X v10.2 and later.
Declared in `AXRoleConstants.h`.

`kAXSplitGroupRole`
A split view.
Available in Mac OS X v10.2 and later.
Declared in `AXRoleConstants.h`.

`kAXSplitterRole`
A splitter bar control.

Available in Mac OS X v10.2 and later.

Declared in `AXRoleConstants.h`.

`kAXColorWellRole`
A color well.

Available in Mac OS X v10.2 and later.

Declared in `AXRoleConstants.h`.

`kAXTimeFieldRole`
A field that displays time.

Available in Mac OS X v10.3 and later.

Declared in `AXRoleConstants.h`.

`kAXDateFieldRole`
A field that displays dates.

Available in Mac OS X v10.3 and later.

Declared in `AXRoleConstants.h`.

`kAXHelpTagRole`
A help tag.

Available in Mac OS X v10.4 and later.

Declared in `AXRoleConstants.h`.

`kAXMatteRole`
The outer view that represents the entire contents, including the view through the matte hole, the contents hidden by the matte frame, and the resizing and repositioning controls. An example of an object with a matte role is the iChat icon scaling window.

Available in Mac OS X v10.4 and later.

Declared in `AXRoleConstants.h`.

`kAXDockItemRole`
An icon that represents an item in the Dock.

Available in Mac OS X v10.4 and later.

Declared in `AXRoleConstants.h`.

Discussion
The value of the role attribute describes what the object is, not what it does. See the "Roles and Associated Attributes" appendix in Accessibility Overview for more information on which attributes are associated with each role.

Subroles

Define the values for an accessibility object's subrole attribute.

```
#define kAXCloseButtonSubrole       CFSTR("AXCloseButton")
#define kAXMinimizeButtonSubrole    CFSTR("AXMinimizeButton")
#define kAXZoomButtonSubrole        CFSTR("AXZoomButton")
#define kAXToolbarButtonSubrole     CFSTR("AXToolbarButton")
#define kAXSecureTextFieldSubrole   CFSTR("AXSecureTextField")
#define kAXTableRowSubrole          CFSTR("AXTableRow")
#define kAXOutlineRowSubrole        CFSTR("AXOutlineRow")
#define kAXUnknownSubrole           CFSTR("AXUnknown")
#define kAXStandardWindowSubrole    CFSTR("AXStandardWindow")
#define kAXDialogSubrole            CFSTR("AXDialog")
#define kAXSystemDialogSubrole      CFSTR("AXSystemDialog")
#define kAXFloatingWindowSubrole    CFSTR("AXFloatingWindow")
#define kAXSystemFloatingWindowSubrole CFSTR("AXSystemFloatingWindow")
#define kAXIncrementArrowSubrole    CFSTR("AXIncrementArrow")
#define kAXDecrementArrowSubrole    CFSTR("AXDecrementArrow")
#define kAXIncrementPageSubrole     CFSTR("AXIncrementPage")
#define kAXDecrementPageSubrole     CFSTR("AXDecrementPage")
#define kAXSortButtonSubrole        CFSTR("AXSortButton")
#define kAXSearchFieldSubrole       CFSTR("AXSearchField")
#define kAXApplicationDockItemSubrole CFSTR("AXApplicationDockItem")
#define kAXDocumentDockItemSubrole  CFSTR("AXDocumentDockItem")
#define kAXFolderDockItemSubrole    CFSTR("AXFolderDockItem")
#define kAXMinimizedWindowDockItemSubrole CFSTR("AXMinimizedWindowDockItem")
#define kAXURLDockItemSubrole       CFSTR("AXURLDockItem")
#define kAXDockExtraDockItemSubrole CFSTR("AXDockExtraDockItem")
#define kAXTrashDockItemSubrole     CFSTR("AXTrashDockItem")
#define kAXProcessSwitcherListSubrole CFSTR("AXProcessSwitcherList")
```

Constants

`kAXCloseButtonSubrole`

A close button (that is, the red button in a window's title bar that closes the window).

Available in Mac OS X v10.2 and later.

Declared in `AXRoleConstants.h`.

`kAXMinimizeButtonSubrole`

A minimize button (that is, the yellow button in a window's title bar that minimizes the window into the Dock).

Available in Mac OS X v10.2 and later.

Declared in `AXRoleConstants.h`.

`kAXZoomButtonSubrole`

A zoom button (that is, the green button in a window's title bar that adjusts the window's size).

Available in Mac OS X v10.2 and later.

Declared in `AXRoleConstants.h`.

`kAXToolbarButtonSubrole`

A toolbar button (that is, the button in a window's title bar that hides and reveals the toolbar).

Available in Mac OS X v10.2 and later.

Declared in `AXRoleConstants.h`.

`kAXSecureTextFieldSubrole`

A text field intended to contain sensitive data and that displays the user's input as a series of bullets.

Available in Mac OS X v10.2 and later.

Declared in `AXRoleConstants.h`.

`kAXTableRowSubrole`
A row in a table.

Available in Mac OS X v10.2 and later.

Declared in `AXRoleConstants.h`.

`kAXOutlineRowSubrole`
A row in an outline view (see `kAXOutlineRole` for a description of an outline view).

Available in Mac OS X v10.2 and later.

Declared in `AXRoleConstants.h`.

`kAXUnknownSubrole`
A subrole for an unknown type of window. A window should include a subrole to further define its type. If your window does not conform to an existing subrole, you can use the unknown subrole. Alternatively, you can return the `eventNotHandledErr` error when your window is asked for its subrole.

Available in Mac OS X v10.2 and later.

Declared in `AXRoleConstants.h`.

`kAXStandardWindowSubrole`
A standard window that includes a title bar (that is, not an inspector window or a sheet).

Available in Mac OS X v10.3 and later.

Declared in `AXRoleConstants.h`.

`kAXDialogSubrole`
A dialog window, such as an alert.

Available in Mac OS X v10.3 and later.

Declared in `AXRoleConstants.h`.

`kAXSystemDialogSubrole`
A system-generated dialog window that floats on the top layer, regardless of which application is frontmost. Use this subrole only when a dialog or alert applies to the system as a whole, such as a shutdown dialog.

Available in Mac OS X v10.3 and later.

Declared in `AXRoleConstants.h`.

`kAXFloatingWindowSubrole`
A utility window.

Available in Mac OS X v10.3 and later.

Declared in `AXRoleConstants.h`.

`kAXSystemFloatingWindowSubrole`
A system-generated utility window.

Available in Mac OS X v10.3 and later.

Declared in `AXRoleConstants.h`.

`kAXIncrementArrowSubrole`
The up arrow of a scroll bar.

Available in Mac OS X v10.3 and later.

Declared in `AXRoleConstants.h`.

`kAXDecrementArrowSubrole`
The down arrow of a scroll bar.
Available in Mac OS X v10.3 and later.
Declared in `AXRoleConstants.h`.

`kAXIncrementPageSubrole`
The increment area in the scroll track of a scroll bar.
Available in Mac OS X v10.3 and later.
Declared in `AXRoleConstants.h`.

`kAXDecrementPageSubrole`
The decrement area in the scroll track of a scroll bar.
Available in Mac OS X v10.3 and later.
Declared in `AXRoleConstants.h`.

`kAXSortButtonSubrole`
A column heading button in a list or column view.
Available in Mac OS X v10.4 and later.
Declared in `AXRoleConstants.h`.

`kAXSearchFieldSubrole`
A search field.
Available in Mac OS X v10.4 and later.
Declared in `AXRoleConstants.h`.

`kAXApplicationDockItemSubrole`
An icon in the Dock that represents an application.
Available in Mac OS X v10.4 and later.
Declared in `AXRoleConstants.h`.

`kAXDocumentDockItemSubrole`
An icon in the Dock that represents a document.
Available in Mac OS X v10.4 and later.
Declared in `AXRoleConstants.h`.

`kAXFolderDockItemSubrole`
An icon in the Dock that represents a folder.
Available in Mac OS X v10.4 and later.
Declared in `AXRoleConstants.h`.

`kAXMinimizedWindowDockItemSubrole`
An icon in the Dock that represents a minimized window.
Available in Mac OS X v10.4 and later.
Declared in `AXRoleConstants.h`.

`kAXURLDockItemSubrole`
An icon in the Dock that represents a URL.
Available in Mac OS X v10.4 and later.
Declared in `AXRoleConstants.h`.

`kAXDockExtraDockItemSubrole`
: An icon in the Dock that represents a Dock Extra.

  Available in Mac OS X v10.4 and later.

  Declared in `AXRoleConstants.h`.

`kAXTrashDockItemSubrole`
: The icon in the Dock that represents the Trash.

  Available in Mac OS X v10.4 and later.

  Declared in `AXRoleConstants.h`.

`kAXProcessSwitcherListSubrole`
: The display of running applications (processes) that appears when a user presses Command-Tab.

  Available in Mac OS X v10.4 and later.

  Declared in `AXRoleConstants.h`.

Discussion
A subrole provides a more specific description of an accessibility object's role. If an accessibility object is of a well-defined subtype, it can include the subrole attribute to provide additional information to an assistive application.

Attributes

Define the attributes available for accessibility objects.

```
//General attributes
#define kAXRoleAttribute                    CFSTR("AXRole")
#define kAXSubroleAttribute                 CFSTR("AXSubrole")
#define kAXRoleDescriptionAttribute         CFSTR("AXRoleDescription")
#define kAXHelpAttribute                    CFSTR("AXHelp")
#define kAXTitleAttribute                   CFSTR("AXTitle")
#define kAXValueAttribute                   CFSTR("AXValue")
#define kAXMinValueAttribute                CFSTR("AXMinValue")
#define kAXMaxValueAttribute                CFSTR("AXMaxValue")
#define kAXValueIncrementAttribute          CFSTR("AXValueIncrement")
#define kAXAllowedValuesAttribute           CFSTR("AXAllowedValues")
#define kAXEnabledAttribute                 CFSTR("AXEnabled")
#define kAXFocusedAttribute                 CFSTR("AXFocused")
#define kAXParentAttribute                  CFSTR("AXParent")
#define kAXChildrenAttribute                CFSTR("AXChildren")
#define kAXSelectedChildrenAttribute        CFSTR("AXSelectedChildren")
#define kAXVisibleChildrenAttribute         CFSTR("AXVisibleChildren")
#define kAXWindowAttribute                  CFSTR("AXWindow")
#define kAXTopLevelUIElementAttribute       CFSTR("AXTopLevelUIElement")
#define kAXPositionAttribute                CFSTR("AXPosition")
#define kAXSizeAttribute                    CFSTR("AXSize")
#define kAXOrientationAttribute             CFSTR("AXOrientation")
#define kAXDescriptionAttribute             CFSTR("AXDescription")
```

```
// Text-specific attributes
#define kAXSelectedTextAttribute            CFSTR("AXSelectedText")
#define kAXVisibleCharacterRangeAttribute CFSTR("AXVisibleCharacterRange")
#define kAXSelectedTextRangeAttribute       CFSTR("AXSelectedTextRange")
#define kAXNumberOfCharactersAttribute      CFSTR("AXNumberOfCharacters")
#define kAXSharedTextUIElementsAttribute    CFSTR("AXSharedTextUIElements")
#define kAXSharedCharacterRangeAttribute    CFSTR("AXSharedCharacterRange")

// Window-specific attributes
#define kAXMainAttribute                    CFSTR("AXMain")
#define kAXMinimizedAttribute               CFSTR("AXMinimized")
#define kAXCloseButtonAttribute             CFSTR("AXCloseButton")
#define kAXZoomButtonAttribute              CFSTR("AXZoomButton")
#define kAXMinimizeButtonAttribute          CFSTR("AXMinimizeButton")
#define kAXToolbarButtonAttribute           CFSTR("AXToolbarButton")
#define kAXGrowAreaAttribute                CFSTR("AXGrowArea")
#define kAXProxyAttribute                   CFSTR("AXProxy")
#define kAXModalAttribute                   CFSTR("AXModal")
#define kAXDefaultButtonAttribute           CFSTR("AXDefaultButton")
#define kAXCancelButtonAttribute            CFSTR("AXCancelButton")

// Menu-specific attributes
#define kAXMenuItemCmdCharAttribute         CFSTR("AXMenuItemCmdChar")
#define kAXMenuItemCmdVirtualKeyAttribute
                                    CFSTR("AXMenuItemCmdVirtualKey")
#define kAXMenuItemCmdGlyphAttribute        CFSTR("AXMenuItemCmdGlyph")
#define kAXMenuItemCmdModifiersAttribute
                                       CFSTR("AXMenuItemCmdModifiers")
#define kAXMenuItemMarkCharAttribute    CFSTR("AXMenuItemMarkChar")
#define kAXMenuItemPrimaryUIElementAttribute CFSTR("AXMenuItemPrimaryUIElement")

// Application-specific attributes
#define kAXMenuBarAttribute                     CFSTR("AXMenuBar")
#define kAXWindowsAttribute                     CFSTR("AXWindows")
#define kAXFrontmostAttribute                   CFSTR("AXFrontmost")
#define kAXHiddenAttribute                      CFSTR("AXHidden")
#define kAXMainWindowAttribute                  CFSTR("AXMainWindow")
#define kAXFocusedWindowAttribute               CFSTR("AXFocusedWindow")
#define kAXFocusedUIElementAttribute        CFSTR("AXFocusedUIElement")
```

```
// Miscellaneous attributes
#define kAXHeaderAttribute                  CFSTR("AXHeader")
#define kAXEditedAttribute                  CFSTR("AXEdited")
#define kAXValueWrapsAttribute              CFSTR("AXValueWraps")
#define kAXTabsAttribute                    CFSTR("AXTabs")
#define kAXTitleUIElementAttribute          CFSTR("AXTitleUIElement")
#define kAXHorizontalScrollBarAttribute     CFSTR("AXHorizontalScrollBar")
#define kAXVerticalScrollBarAttribute       CFSTR("AXVerticalScrollBar")
#define kAXOverflowButtonAttribute          CFSTR("AXOverflowButton")
#define kAXFilenameAttribute                CFSTR("AXFilename")
#define kAXExpandedAttribute                CFSTR("AXExpanded")
#define kAXSelectedAttribute                CFSTR("AXSelected")
#define kAXSplittersAttribute               CFSTR("AXSplitters")
#define kAXNextContentsAttribute            CFSTR("AXNextContents")
#define kAXDocumentAttribute                CFSTR("AXDocument")
#define kAXDecrementButtonAttribute         CFSTR("AXDecrementButton")
#define kAXIncrementButtonAttribute         CFSTR("AXIncrementButton")
#define kAXPreviousContentsAttribute        CFSTR("AXPreviousContents")
#define kAXContentsAttribute                CFSTR("AXContents")
#define kAXIncrementorAttribute             CFSTR("AXIncrementor")
#define kAXHourFieldAttribute               CFSTR("AXHourField")
#define kAXMinuteFieldAttribute             CFSTR("AXMinuteField")
#define kAXSecondFieldAttribute             CFSTR("AXSecondField")
#define kAXAMPMFieldAttribute               CFSTR("AXAMPMField")
#define kAXDayFieldAttribute                CFSTR("AXDayField")
#define kAXMonthFieldAttribute              CFSTR("AXMonthField")
#define kAXYearFieldAttribute               CFSTR("AXYearField")
#define kAXColumnTitleAttribute             CFSTR("AXColumnTitles")
#define kAXURLAttribute                     CFSTR("AXURL")
#define kAXLabelUIElementsAttribute         CFSTR("AXLabelUIElements")
#define kAXLabelValueAttribute              CFSTR("AXLabelValue")
#define kAXShownMenuUIElementAttribute      CFSTR("AXShownMenuUIElement")
#define kAXServesAsTitleForUIElementsAttribute
CFSTR("AXServesAsTitleForUIElements")
#define kAXLinkedUIElementsAttribute CFSTR("AXLinkedUIElements")

// Table and outline view attributes
#define kAXRowsAttribute                    CFSTR("AXRows")
#define kAXVisibleRowsAttribute             CFSTR("AXVisibleRows")
#define kAXSelectedRowsAttribute            CFSTR("AXSelectedRows")
#define kAXColumnsAttribute                 CFSTR("AXColumns")
#define kAXVisibleColumnsAttribute          CFSTR("AXVisibleColumns")
#define kAXSelectedColumnsAttribute         CFSTR("AXSelectedColumns")
#define kAXSortDirectionAttribute           CFSTR("AXSortDirection")
#define kAXColumnHeaderUIElementsAttribute CFSTR("AXColumnHeaderUIElements")
#define kAXIndexAttribute                   CFSTR("AXIndex")
#define kAXDisclosingAttribute              CFSTR("AXDisclosing")
#define kAXDisclosedRowsAttribute           CFSTR("AXDisclosedRows")
#define kAXDisclosedByRowAttribute          CFSTR("AXDisclosedByRow")

// Matte attributes
#define kAXMatteHoleAttribute               CFSTR("AXMatteHole")
#define kAXMatteContentUIElementAttribute CFSTR("AXMatteContentUIElement")

// Dock attributes
#define kAXIsApplicationRunningAttribute CFSTR("AXIsApplicationRunning")
```

```
// System-wide attributes
#define kAXFocusedApplicationAttribute      CFSTR("AXFocusedApplication")
```

Constants

`kAXRoleAttribute`

The role, or type, of this accessibility object (for example, `AXButton`). This string is for identification purposes only and does not need to be localized. All accessibility objects must include this attribute.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXSubroleAttribute`

The subrole of this accessibility object (for example, `AXCloseButton`). The subrole provides additional information about the accessibility object to an assistive application. This string is for identification purposes only and does not need to be localized. This attribute is necessary only for an accessibility object whose `AXRole` attribute does not adequately describe its meaning.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXRoleDescriptionAttribute`

A localized string describing the role (for example, "button"). This string must be readable by (or speakable to) the user. All accessibility objects must include this attribute. To get the system-defined role description string for a given role, use the `HICopyAccessibilityRoleDescription` (page 2077) function.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXHelpAttribute`

A localized string containing help text for this accessibility object. An accessibility object that provides help information should include this attribute.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXTitleAttribute`

The title associated with this accessibility object. A title is text that the object displays as part of its visual interface, such as the text "OK" on an OK button. This string must be localizable and human-intelligible. This attribute is required for all accessibility objects that display a string in their visual interfaces.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXValueAttribute`

The value associated with this accessibility object (for example, a scroller value). The value of an accessibility object is user-modifiable and represents the setting of the associated user interface element, such as the contents of an editable text field or the position of a scroller. This attribute is required if an accessibility object's value state conveys information to the user or if the user can define the value of the object.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXMinValueAttribute`

The minimum value this accessibility object can display (for example, the minimum value of a scroller control). This attribute is used only in conjunction with the `AXValue` attribute.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXMaxValueAttribute`

The maximum value this accessibility object can display (for example, the maximum value of a scroller control). This attribute is used only in conjunction with the `AXValue` attribute.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXValueIncrementAttribute`

The amount an accessibility object's value changes as the result of a single action (for example, how far a scroller travels with one mouse click). This attribute is used only in conjunction with the `AXValue` attribute.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXAllowedValuesAttribute`

An array of the allowed values for an accessibility object. This attribute indicates the subset of values to which an accessibility object can be set. For example, a slider control displays a large range of values, but the accessibility object representing the slider can be set to only a few specific values within that range. This attribute is used only in conjunction with the `AXValue` attribute.

Available in Mac OS X v10.4 and later.

Declared in `AXAttributeConstants.h`.

`kAXEnabledAttribute`

Indicates whether the user can interact with the accessibility object. For example, the `AXEnabled` attribute of a disabled button is `false`. This attribute is required for accessibility objects that represent views, menus, and menu items. This attribute is not required for accessibility objects that represent windows.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXFocusedAttribute`

Indicates whether the accessibility object currently has the keyboard focus. Note that you can set the value of the `AXFocused` attribute to `true` to accept keyboard focus. This attribute is required for all accessibility objects representing elements that can receive keyboard focus.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXParentAttribute`

This accessibility object's parent object in the accessibility hierarchy. This attribute is required for all accessibility objects except the application-level accessibility object.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXChildrenAttribute`

An array of the first-order accessibility objects contained by this accessibility object. An accessibility object may be a member of only one `AXChildren` array. This attribute is required for all accessibility objects that contain accessible child objects.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXSelectedChildrenAttribute`

An array of selected first-order accessibility objects contained by this accessibility object. For example, the selected subelements of a list view are contained in the `AXSelectedChildren` array of the list view's accessibility object. The members of the `AXSelectedChildren` array are a subset of the members of this accessibility object's `AXChildren` array. This attribute is required for accessibility objects that contain selectable child objects.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXVisibleChildrenAttribute`

An array of first-order accessibility objects contained by this accessibility object that are visible to a sighted user. For example, a list view's `AXVisibleChildren` array would contain the list's subelements that are currently scrolled into view. The members of the `AXVisibleChildren` array are a subset of the members of this accessibility object's `AXChildren` array. This attribute is recommended for accessibility objects whose child objects can be scrolled out of view or otherwise obscured.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXWindowAttribute`

The window element that contains this accessibility object. An accessibility object that is contained in a window includes this attribute so an assistive application easily can find the window without having to step through all intervening objects in the accessibility hierarchy. Note that the value of the `AXWindow` attribute must be an accessibility object that represents a window, not a sheet or drawer. For a similar attribute that is less restrictive, see `kAXTopLevelUIElementAttribute`. The `AXWindow` attribute is required for all accessibility elements whose parent or more distant ancestor represents a window.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXPositionAttribute`

The global screen coordinates of the top-left corner of this accessibility object. Note that the coordinates `0,0` represent the top-left corner of the screen that displays the menu bar. All accessibility objects that have a screen position (in other words, are visible on the screen) should include this attribute.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXTopLevelUIElementAttribute`

The window, sheet, or drawer element that contains this accessibility object. An accessibility object that is contained in a window, sheet, or drawer includes this attribute so an assistive application easily can find that element without having to step through all intervening objects in the accessibility hierarchy. This attribute is required for all accessibility objects whose parent or more distant ancestor represents a window, drawer, or sheet.

Available in Mac OS X v10.4 and later.

Declared in `AXAttributeConstants.h`.

`kAXSizeAttribute`

The vertical and horizontal dimensions of this accessibility object. This attribute is required for all accessibility objects that are visible on the screen.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXOrientationAttribute`

Indicates whether this accessibility object is displayed or interacted with in a vertical or a horizontal manner. The interpretation of an element, such as a slider, can change depending on whether it is oriented vertically or horizontally. Using the value of this attribute, an assistive application can communicate this information to the user. This attribute is required for any accessibility object, such as a scroller or slider, whose semantic meaning varies with the object's orientation.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXDescriptionAttribute`

The purpose of this accessibility object. The description string must be localizable and human-intelligible and it must be all lower case and include no punctuation. The string should briefly describe this accessibility object's purpose, without including the object's role description. This attribute is required for all accessibility objects that do not provide enough descriptive information in the title attribute.

Available in Mac OS X v10.4 and later.

Declared in `AXAttributeConstants.h`.

`kAXSelectedTextAttribute`

The currently selected text within this accessibility object. This attribute is required for all accessibility objects that represent editable text elements.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXSelectedTextRangeAttribute`

Indicates the range of characters (not bytes) that defines the currently selected text within this accessibility object. This attribute is required for all accessibility objects that represent editable text elements.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXVisibleCharacterRangeAttribute`

Indicates the range of characters (not bytes) that are scrolled into view within this accessibility object. This attribute is required only for accessibility objects that represent an editable text area (objects of role `AXTextArea`), not for any other text-related accessibility objects.

Available in Mac OS X v10.3 and later.

Declared in `AXAttributeConstants.h`.

`kAXNumberOfCharactersAttribute`

The total number of characters (not bytes) in the editable text element represented by this accessibility object. This attribute is required for all accessibility objects that represent editable text elements.

Available in Mac OS X v10.3 and later.

Declared in `AXAttributeConstants.h`.

`kAXSharedTextUIElementsAttribute`

An array of accessibility objects with which the text of this accessibility object is shared. In a multi-column document, for example, each column may be represented by a separate accessibility object. However, the text in the document may flow from one column to the other. You get the value of this attribute if you need to know with which accessibility object this accessibility object shares its text. This attribute is recommended for sets of accessibility objects that share text in a single window. (See `kAXSharedCharacterRange` for a related attribute.)

Available in Mac OS X v10.4 and later.

Declared in `AXAttributeConstants.h`.

`kAXSharedCharacterRangeAttribute`

The portion of shared text this accessibility object currently displays. In a multi-column document, for example, each column may be represented by a separate accessibility object. However, the text in the document may flow from one column to the other. Get the value of this attribute if you need to know the specific range of characters this accessibility object currently displays. This attribute is recommended for sets of accessibility objects that share text in a single window. (See `kAXSharedTextUIElementsAttribute` for a related attribute.)

Available in Mac OS X v10.4 and later.

Declared in `AXAttributeConstants.h`.

`kAXMainAttribute`

Indicates whether the window represented by this accessibility object is the main application window. Note that a window can be main even though it does not have keyboard focus. This attribute is recommended for all accessibility objects that represent windows.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXMinimizedAttribute`

Indicates whether the window represented by this accessibility object is currently minimized in the Dock. This attribute is recommended for all accessibility objects that represent windows that can be minimized.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXCloseButtonAttribute`

The close button of the window represented by this accessibility object. An accessibility object includes this attribute to help an assistive application easily find a window's close button, without having to traverse the accessibility hierarchy. This attribute is recommended for all accessibility objects that represent windows that contain a close button.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXZoomButtonAttribute`

The zoom button of the window represented by this accessibility object. An accessibility object includes this attribute to help an assistive application easily find a window's zoom button, without having to traverse the accessibility hierarchy. This attribute is recommended for all accessibility objects that represent windows that contain a zoom button.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXMinimizeButtonAttribute`

The minimize button of the window represented by this accessibility object. An accessibility object includes this attribute to help an assistive application easily find a window's minimize button, without having to traverse the accessibility hierarchy. This attribute is recommended for all accessibility objects that represent windows that contain a minimize button.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXToolbarButtonAttribute`

The toolbar button of the window represented by this accessibility object. An accessibility object includes this attribute to help an assistive application easily find a window's toolbar button, without having to traverse the accessibility hierarchy. This attribute is recommended for all accessibility objects that represent windows that contain a toolbar button.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXGrowAreaAttribute`

The grow area of the window represented by this accessibility object. An accessibility object includes this attribute to help an assistive application easily find a window's grow area, without having to traverse the accessibility hierarchy. This attribute is recommended for all accessibility objects that represent windows that contain a grow area.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXProxyAttribute`

The document proxy of the window represented by this accessibility object. An accessibility object includes this attribute to help an assistive application easily find a window's document proxy, without having to traverse the accessibility hierarchy. This attribute is recommended for all accessibility objects that represent windows that display a document proxy.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXModalAttribute`

Indicates whether the window represented by this accessibility object is modal. This attribute is recommended for all accessibility objects that represent windows.

Available in Mac OS X v10.3 and later.

Declared in `AXAttributeConstants.h`.

`kAXDefaultButtonAttribute`

The default button of the window represented by this accessibility object. An accessibility object includes this attribute to help an assistive application easily find a window's default button, without having to traverse the accessibility hierarchy. This attribute is recommended for all accessibility objects that represent windows that contain a default button.

Available in Mac OS X v10.3 and later.

Declared in `AXAttributeConstants.h`.

`kAXCancelButtonAttribute`

The cancel button of the window represented by this accessibility object. An accessibility object includes this attribute to help an assistive application easily find a window's cancel button, without having to traverse the accessibility hierarchy. This attribute is recommended for all accessibility objects that represent windows that contain a cancel button.

Available in Mac OS X v10.3 and later.

Declared in `AXAttributeConstants.h`.

`kAXMenuItemCmdCharAttribute`

The primary key in the keyboard shortcut for the command represented by this accessibility object. For example, "O" is the primary key in the keyboard shortcut for the Open command.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXMenuItemCmdVirtualKeyAttribute`

The key code associated with the physical key in the keyboard shortcut for the command represented by this accessibility object. For example, Return and Enter are different physical keys that can produce the same character. If an assistive application needs to be able to distinguish between them, it can view the virtual key codes.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXMenuItemCmdGlyphAttribute`

The glyph displayed for a physical key in the keyboard shortcut for the command represented by this accessibility object, if it is different from the visible result of pressing the key. The Delete key, for example, produces an invisible character, but it is associated with a visible glyph.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXMenuItemCmdModifiersAttribute`

An integer mask that represents the modifier keys held down in the keyboard shortcut for the command represented by this accessibility object.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXMenuItemMarkCharAttribute`

The symbol displayed to the left of the menu item represented by this accessibility object. For example, in the Window menu, a checkmark appears next to the active document's name. For more information on the standard symbols that can appear next to menu items, see *Apple Human Interface Guidelines*.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXMenuItemPrimaryUIElementAttribute`

The accessibility object representing the primary menu item in a group of dynamic menu items. Dynamic menu item are commands that change when the user presses a modifier key, such as Minimize Window and Minimize All Windows. Within each group, each dynamic menu item's accessibility object includes this attribute and in each case the attribute's value is the accessibility object representing the primary menu item.

Available in Mac OS X v10.4 and later.

Declared in `AXAttributeConstants.h`.

`kAXMenuBarAttribute`

The accessibility object representing the menu bar of this application. The application-level accessibility object includes this attribute to help an assistive application easily find the menu bar. This attribute is recommended for all application-level accessibility objects.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXWindowsAttribute`

An array of accessibility objects representing this application's windows. This attribute is recommended for all application-level accessibility objects.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXFrontmostAttribute`

Indicates whether the application represented by this accessibility object is active. This attribute is recommended for all application-level accessibility objects.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXHiddenAttribute`

Indicates whether the application represented by this accessibility object is hidden. This attribute is recommended for all application-level accessibility objects.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXMainWindowAttribute`

The accessibility object representing this application's main window. This attribute is recommended for all application-level accessibility objects.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXFocusedWindowAttribute`

The accessibility object that represents the currently focused window of this application. This attribute is recommended for all application-level accessibility objects.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXFocusedUIElemenAttribute`

The accessibility object that represents the currently focused user interface element in this application. This attribute is recommended for all application-level accessibility objects.

`kAXHeaderAttribute`

The accessibility object representing the header element of this accessibility object. For example, a table or an outline view can have a header element that displays column or row headers. An accessibility object includes this attribute to help an assistive application easily find embedded header information. This attribute is recommended for all accessibility objects that represent elements that display header information.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXEditedAttribute`

Indicates whether the user interface element represented by this accessibility object has been edited. For example, a document window indicates it has been edited by displaying a black dot in its close button. This attribute is recommended for all accessibility objects that represent editable user interface elements.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXTitleUIElementAttribute`

An accessibility object that represents a static text title associated with another accessibility object.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXValueWrapsAttribute`

Indicates whether the value displayed in the user interface element represented by this accessibility object wraps around.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXTabsAttribute`

An array of accessibility objects representing the tabs this accessibility object displays. An accessibility object includes this attribute to help an assistive application easily distinguish a tab view's tabs from its other children. This attribute is recommended for all accessibility objects that represent tab views.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXHorizontalScrollBarAttribute`

The horizontal scroll bar displayed by the user interface element this accessibility object represents. This is a convenience attribute an assistive application can use easily to find the scroll bar without traversing the accessibility hierarchy. This attribute is recommended for all accessibility objects that display a horizontal scroll bar.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXVerticalScrollBarAttribute`

The vertical scroll bar displayed by the user interface element this accessibility object represents. This is a convenience attribute an assistive application can use easily to find the scroll bar without traversing the accessibility hierarchy. This attribute is recommended for all accessibility objects that display a vertical scroll bar.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXOverflowButtonAttribute`

Identifies which child of an accessibility object representing a toolbar is the overflow button (if any). This attribute is optional.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXFilenameAttribute`

The filename associated with this accessibility object. This attribute is optional.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXExpandedAttribute`

Indicates whether the menu displayed by the combo box or pop-up menu represented by this accessibility object is currently expanded. This attribute is recommended for all accessibility objects that display a pop-up menu.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXSelectedAttribute`

Indicates whether the row or column element represented by this accessibility object is selected. This attribute is recommended for all accessibility objects that represent selectable rows or columns.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXSplittersAttribute`

An array of views and splitter bar elements displayed by the split view represented by this accessibility object. This is a convenience attribute that helps an assistive application easily find these elements.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXNextContentsAttribute`

The group of accessibility objects representing the elements on one side of a splitter bar. (Which side of the splitter bar is considered "next" is determined by the value of the splitter bar's orientation attribute.) This attribute is recommended for an accessibility object that represents the splitter bar in a split view.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXPreviousContentsAttribute`

The group of accessibility objects representing the elements on one side of a splitter bar. (Which side of the splitter bar is considered "previous" is determined by the value of the splitter bar's orientation attribute.) This attribute is recommended for an accessibility object that represents the splitter bar in a split view.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXDocumentAttribute`

The URL of the open document represented by this accessibility object. This attribute represents the URL as a string object.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXIncrementButtonAttribute`

The increment element associated with the user interface object this accessibility object represents. This attribute can be used to provide convenient access to the increment area of a custom user interface object. To refer to the increment button associated with a date or time field, see `kAXIncrementorAttribute`.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXDecrementButtonAttribute`

The decrement element associated with the user interface object this accessibility object represents. This attribute can be used to provide convenient access to the decrement area of a custom user interface object.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXContentsAttribute`

Content-containing accessibility objects that are children of this accessibility object. For example, a tab view contains children that represent both the tab controls and the content displayed for each tab. The accessibility object representing a tab view can include only the content-display children in its `AXContents` attribute to help an assistive application provide more targeted information to the user. This attribute is recommended for any accessibility object whose children represent both content and control elements.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXIncrementorAttribute`

The incrementor of a time or date field represented by this accessibility object. This attribute is required for accessibility objects that represent time or date field elements that display an incrementor.

Available in Mac OS X v10.3 and later.

Declared in `AXAttributeConstants.h`.

`kAXHourFieldAttribute`

The hour field of a time field represented by this accessibility object. This attribute is required for accessibility objects that represent time fields that display hours.

Available in Mac OS X v10.3 and later.

Declared in `AXAttributeConstants.h`.

`kAXMinuteFieldAttribute`

The minute field of a time field represented by this accessibility object. This attribute is required for accessibility objects that represent time fields that display minutes.

Available in Mac OS X v10.3 and later.

Declared in `AXAttributeConstants.h`.

`kAXSecondFieldAttribute`

The second field of a time field represented by this accessibility object. This attribute is required for accessibility objects that represent time fields that display seconds.

Available in Mac OS X v10.3 and later.

Declared in `AXAttributeConstants.h`.

`kAXAMPMFieldAttribute`

The AM/PM field of a time field represented by this accessibility object. This attribute is required for accessibility objects that represent time fields that display AM/PM settings.

Available in Mac OS X v10.3 and later.

Declared in `AXAttributeConstants.h`.

`kAXDayFieldAttribute`

The day field of a time field represented by this accessibility object. This attribute is required for accessibility objects that represent time fields that display days.

Available in Mac OS X v10.3 and later.

Declared in `AXAttributeConstants.h`.

`kAXMonthFieldAttribute`

The month field of a time field represented by this accessibility object. This attribute is required for accessibility objects that represent time fields that display months.

Available in Mac OS X v10.3 and later.

Declared in `AXAttributeConstants.h`.

`kAXYearFieldAttribute`

The year field of a time field represented by this accessibility object. This attribute is required for accessibility objects that represent time fields that display years.

Available in Mac OS X v10.3 and later.

Declared in `AXAttributeConstants.h`.

`kAXColumnTitleAttribute`

The title of the column element represented by this accessibility object. Note that, because column titles are sometimes the children of a separate header element, the value of this attribute can refer to an element that is not a child of the column accessibility object.

Available in Mac OS X v10.4 and later.

Declared in `AXAttributeConstants.h`.

`kAXURLAttribute`

The URL that describes the location of the document or application represented by this accessibility object.

Available in Mac OS X v10.3 and later.

Declared in `AXAttributeConstants.h`.

`kAXLabelUIElementsAttribute`

An array of accessibility objects representing the labels displayed near the control represented by this accessibility object. For example, a slider control might display labels that indicate the range of values the slider can represent. Because these labels are not displayed as part of the slider's visual interface, an assistive application does not know they are associated with the slider. By including accessibility objects representing the labels in this attribute, you make this association explicit.

Available in Mac OS X v10.4 and later.

Declared in `AXAttributeConstants.h`.

`kAXLabelValueAttribute`

The value of the label represented by this accessibility object. This attribute is required for all accessibility objects that represent labels.

Available in Mac OS X v10.4 and later.

Declared in `AXAttributeConstants.h`.

`kAXShownMenuUIElementAttribute`

An array of accessibility objects that represent the contextual or Dock menus provided by this accessibility object.

Available in Mac OS X v10.4 and later.

Declared in `AXAttributeConstants.h`.

`kAXServesAsTitleForUIElementsAttribute`

An array of accessibility objects for which this accessibility object serves as the title. For example, a piece of static text can serve as a title for one or more user interface elements. Because this static text string is not displayed as part of any user interface element's visual interface, an assistive application does not know the title is associated with user interface elements. By including this attribute in the accessibility object representing the title, you specify the accessibility objects with which this title is associated.

Available in Mac OS X v10.4 and later.

Declared in `AXAttributeConstants.h`.

`kAXLinkedUIElementsAttribute`

An array of accessibility objects with which this accessibility object is related. For example, the contents of a list item can be displayed in another pane or window. The list item and the separately displayed contents are related, but this relationship may not be apparent to an assistive application. To make such a relationship explicit, you include this attribute in the accessibility objects representing the related user interface elements.

Available in Mac OS X v10.4 and later.

Declared in `AXAttributeConstants.h`.

`kAXRowsAttribute`

An array of the accessibility objects representing the rows in this table or outline view.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXVisibleRowsAttribute`

An array of the accessibility objects representing the currently visible rows in this table or outline view.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXSelectedRowsAttribute`

An array of the accessibility objects representing the currently selected rows in this table or outline view.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXColumnsAttribute`

An array of the accessibility objects representing the columns in this browser view.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXVisibleColumnsAttribute`

An array of the accessibility objects representing the currently visible columns in this browser view.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXSelectedColumnsAttribute`

An array of the accessibility objects representing the currently selected columns in this browser view.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXSortDirectionAttribute`
The sort direction of this accessibility object's contents. For example, a list view's contents may be sorted in ascending or descending order.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXColumnHeaderUIElementsAttribute`
An array of accessibility objects representing the column headers of this table or browser view.

Available in Mac OS X v10.4 and later.

Declared in `AXAttributeConstants.h`.

`kAXIndexAttribute`
The index of the row or column represented by this accessibility object.

Available in Mac OS X v10.4 and later.

Declared in `AXAttributeConstants.h`.

`kAXDisclosingAttribute`
Indicates whether a row in an outline view represented by this accessibility object has an open or closed disclosure triangle. `true` indicates an open disclosure triangle; `false` indicates a closed disclosure triangle.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXDisclosedRowsAttribute`
An array of accessibility objects representing the disclosed rows of this user interface element.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXDisclosedByRowAttribute`
The accessibility object representing the disclosing row.

Available in Mac OS X v10.2 and later.

Declared in `AXAttributeConstants.h`.

`kAXMatteHoleAttribute`
The accessibility object that represents the area available to the user through the matte hole.

Available in Mac OS X v10.4 and later.

Declared in `AXAttributeConstants.h`.

`kAXMatteContentUIElementAttribute`
The accessibility object clipped by the matte.

Available in Mac OS X v10.4 and later.

Declared in `AXAttributeConstants.h`.

`kAXIsApplicationRunningAttribute`
Indicates if the application represented by the Dock icon this accessibility object represents is currently running.

Available in Mac OS X v10.4 and later.

Declared in `AXAttributeConstants.h`.

`kAXFocusedApplicationAttribute`
: Indicates the application element that is currently accepting keyboard input. This attribute is supported by the system-wide accessibility object to help an assistive application quickly determine the application that is accepting keyboard input. After the assistive application gets the accessibility object representing this application, it can send a message to the application asking for its focused accessibility object.

  Available in Mac OS X v10.2 and later.

  Declared in `AXAttributeConstants.h`.

`kAXInsertionPointLineNumberAttribute`
: The line number of the insertion point in the text associated with this accessibility object.

  Available in Mac OS X v10.4 and later.

  Declared in `AXAttributeConstants.h`.

Discussion
See the "Roles and Associated Attributes" appendix in Accessibility Overview for more information on which attributes are associated with a specific role.

Parameterized Attributes

Define the parameterized attributes an accessibility object can have.

```
// Text-suite parameterized attributes
#define kAXLineForIndexParameterizedAttribute CFSTR("AXLineForIndex")
#define kAXRangeForLineParameterizedAttribute          CFSTR("AXRangeForLine")
#define kAXStringForRangeParameterizedAttribute         CFSTR("AXStringForRange")
#define kAXRangeForPositionParameterizedAttribute CFSTR("AXRangeForPosition")
#define kAXRangeForIndexParameterizedAttribute CFSTR("AXRangeForIndex")
#define kAXBoundsForRangeParameterizedAttribute CFSTR("AXBoundsForRange")
#define kAXRTFForRangeParameterizedAttribute CFSTR("AXRTFForRange")
#define kAXAttributedStringForRangeParameterizedAttribute
CFSTR("AXAttributedStringForRange")
#define kAXStyleRangeForIndexParameterizedAttribute CFSTR("AXStyleRangeForIndex")
#define kAXInsertionPointLineNumberAttribute CFSTR("AXInsertionPointLineNumber")
```

Constants
`kAXLineForIndexParameterizedAttribute`
: Given an indexed character, the line number of the text associated with this accessibility object that contains the character.

  Available in Mac OS X v10.3 and later.

  Declared in `AXAttributeConstants.h`.

`kAXRangeForLineParameterizedAttribute`
: Given a line number, the range of characters of the text associated with this accessibility object that contains the line number.

  Available in Mac OS X v10.3 and later.

  Declared in `AXAttributeConstants.h`.

`kAXStringForRangeParameterizedAttribute`
: A substring of the text associated with this accessibility object that is specified by the given character range.

  Available in Mac OS X v10.3 and later.

  Declared in `AXAttributeConstants.h`.

`kAXRangeForPositionParameterizedAttribute`
: The composed character range in the text associated with this accessibility object that is specified by the given screen coordinates. This parameterized attribute returns the complete range of characters (including surrogate pairs of multi-byte glyphs) at the given screen coordinates.

  Available in Mac OS X v10.3 and later.

  Declared in `AXAttributeConstants.h`.

`kAXRangeForIndexParameterizedAttribute`
: The composed character range in the text associated with this accessibility object that is specified by the given index value. This parameterized attribute returns the complete range of characters (including surrogate pairs of multi-byte glyphs) at the given index.

  Available in Mac OS X v10.3 and later.

  Declared in `AXAttributeConstants.h`.

`kAXBoundsForRangeParameterizedAttribute`
: The bounding rectangle of the text associated with this accessibility object that is specified by the given range. This is the bounding rectangle a sighted user would see on the display screen, in pixels.

  Available in Mac OS X v10.3 and later.

  Declared in `AXAttributeConstants.h`.

`kAXRTFForRangeParameterizedAttribute`
: The RTF representation of the text associated with this accessibility object that is specified by the given range.

  Available in Mac OS X v10.3 and later.

  Declared in `AXAttributeConstants.h`.

`kAXAttributedStringForRangeParameterizedAttribute`
: The CFAttributedStringType representation of the text associated with this accessibility object that is specified by the given range.

  Available in Mac OS X v10.4 and later.

  Declared in `AXAttributeConstants.h`.

`kAXStyleRangeForIndexParameterizedAttribute`
: Given a character index, the range of text associated with this accessibility object over which the style in effect at that character index applies.

  Available in Mac OS X v10.3 and later.

  Declared in `AXAttributeConstants.h`.

Discussion
Parameterized attributes allow you to pass in additional values to get more specific information about the text associated with an accessibility object.

Availability
Available in Mac OS X version 10.3 and later.

Actions

Define the actions an accessibility object can perform.

```
// Accessibility actions.
#define kAXPressAction          CFSTR("AXPress")
#define kAXIncrementAction      CFSTR("AXIncrement")
#define kAXDecrementAction      CFSTR("AXDecrement")
#define kAXConfirmAction        CFSTR("AXConfirm")
#define kAXCancelAction         CFSTR("AXCancel")
#define kAXRaiseAction          CFSTR("AXRaise")
#define kAXShowMenuAction       CFSTR("AXShowMenu")
```

Constants

`kAXPressAction`

Simulates a single click, such as on a button.

Available in Mac OS X v10.2 and later.

Declared in `AXActionConstants.h`.

`kAXIncrementAction`

Increments the value of the accessibility object. The amount the value is incremented by is determined by the value of the `kAXValueIncrementAttribute` attribute.

Available in Mac OS X v10.2 and later.

Declared in `AXActionConstants.h`.

`kAXDecrementAction`

Decrements the value of the accessibility object. The amount the value is decremented by is determined by the value of the `kAXValueIncrementAttribute` attribute.

Available in Mac OS X v10.2 and later.

Declared in `AXActionConstants.h`.

`kAXConfirmAction`

Simulates pressing the Return key.

Available in Mac OS X v10.2 and later.

Declared in `AXActionConstants.h`.

`kAXCancelAction`

Simulates pressing a Cancel button.

Available in Mac OS X v10.2 and later.

Declared in `AXActionConstants.h`.

`kAXRaiseAction`

Causes a window to become as frontmost as is allowed by the containing application's circumstances. Note that an application's floating windows (such as inspector windows) might remain above a window that performs the raise action.

Available in Mac OS X v10.3 and later.

Declared in `AXActionConstants.h`.

`kAXShowMenuAction`

Simulates the opening of a contextual menu in the element represented by this accessibility object. This action can also be used to simulate the display of a menu that is preassociated with an element, such as the menu that displays when a user clicks Safari's back button slowly.

Available in Mac OS X v10.4 and later.

Declared in `AXActionConstants.h`.

Notifications

Define the notifications that can be broadcast by an accessibility object.

```
// Focus notifications
#define kAXMainWindowChangedNotification CFSTR("AXMainWindowChanged")
#define kAXFocusedWindowChangedNotification CFSTR("AXFocusedWindowChanged")
#define kAXFocusedUIElementChangedNotification
CFSTR("AXFocusedUIElementChanged")

// Application notifications
#define kAXApplicationActivatedNotification CFSTR("AXApplicationActivated")
#define kAXApplicationDeactivatedNotification CFSTR("AXApplicationDeactivated")
#define kAXApplicationHiddenNotification CFSTR("AXApplicationHidden")
#define kAXApplicationShownNotification CFSTR("AXApplicationShown")

// Window notifications
#define kAXWindowCreatedNotification    CFSTR("AXWindowCreated")
#define kAXWindowMovedNotification      CFSTR("AXWindowMoved")
#define kAXWindowResizedNotification    CFSTR("AXWindowResized")
#define kAXWindowMiniaturizedNotification CFSTR("AXWindowMiniaturized")
#define kAXWindowDeminiaturizedNotification CFSTR("AXWindowDeminiaturized")

// New drawer, sheet, and help tag notifications
#define kAXDrawerCreatedNotification    CFSTR("AXDrawerCreated")
#define kAXSheetCreatedNotification     CFSTR("AXSheetCreated")
#define kAXHelpTagCreatedNotification   CFSTR("AXHelpTagCreated")

// Element notifications
#define kAXValueChangedNotification     CFSTR("AXValueChanged")
#define kAXUIElementDestroyedNotification       CFSTR("AXUIElementDestroyed")

// Menu notifications
#define kAXMenuOpenedNotification       CFSTR("AXMenuOpened")
#define kAXMenuClosedNotification       CFSTR("AXMenuClosed")
#define kAXMenuItemSelectedNotification CFSTR("AXMenuItemSelected")

// Table and outline view notifications
#define kAXRowCountChangedNotification  CFSTR("AXRowCountChanged")

// Miscellaneous notifications
#define kAXSelectedChildrenChangedNotification
CFSTR("AXSelectedChildrenChanged")
#define kAXResizedNotification          CFSTR("AXResized")
#define kAXMovedNotification            CFSTR("AXMoved")
#define kAXCreatedNotification          CFSTR("AXCreated")
```

Constants

`kAXMainWindowChangedNotification`

The main window has changed.

Available in Mac OS X v10.2 and later.

Declared in `AXNotificationConstants.h`.

`kAXFocusedWindowChangedNotification`

The focused window has changed.

Available in Mac OS X v10.2 and later.

Declared in `AXNotificationConstants.h`.

`kAXFocusedUIElementChangedNotification`
The focused accessibility object has changed.

Available in Mac OS X v10.2 and later.

Declared in `AXNotificationConstants.h`.

`kAXApplicationActivatedNotification`
The application was activated (that is, brought to front).

Available in Mac OS X v10.2 and later.

Declared in `AXNotificationConstants.h`.

`kAXApplicationDeactivatedNotification`
The application was deactivated.

Available in Mac OS X v10.2 and later.

Declared in `AXNotificationConstants.h`.

`kAXApplicationHiddenNotification`
The application was hidden.

Available in Mac OS X v10.2 and later.

Declared in `AXNotificationConstants.h`.

`kAXApplicationShownNotification`
The application was shown (that is, a hidden application is now visible).

Available in Mac OS X v10.2 and later.

Declared in `AXNotificationConstants.h`.

`kAXWindowCreatedNotification`
A window was created. Carbon automatically sends this notification when window is created, as long as the window is implemented using Carbon window mechanisms.

Available in Mac OS X v10.2 and later.

Declared in `AXNotificationConstants.h`.

`kAXWindowMovedNotification`
The window was moved (this notification is sent at the end of the window-move operation, not during it).

Available in Mac OS X v10.2 and later.

Declared in `AXNotificationConstants.h`.

`kAXWindowResizedNotification`
The window was resized (this notification is sent at the end of the window-resize operation, not during it).

Available in Mac OS X v10.2 and later.

Declared in `AXNotificationConstants.h`.

`kAXWindowMiniaturizedNotification`
The application was minimized (that is, moved into the Dock).

Available in Mac OS X v10.2 and later.

Declared in `AXNotificationConstants.h`.

`kAXWindowDeminiaturizedNotification`
The window was moved out of the Dock.

Available in Mac OS X v10.2 and later.

Declared in `AXNotificationConstants.h`.

`kAXDrawerCreatedNotification`
A drawer was created (that is, a drawer now extends from this window).

Available in Mac OS X v10.3 and later.

Declared in `AXNotificationConstants.h`.

`kAXSheetCreatedNotification`
A sheet was created (that is, a modal dialog now extends from this window).

Available in Mac OS X v10.3 and later.

Declared in `AXNotificationConstants.h`.

`kAXHelpTagCreatedNotification`
A help tag is now visible for this accessibility object.

Available in Mac OS X v10.4 and later.

Declared in `AXNotificationConstants.h`.

`kAXValueChangedNotification`
The value of an accessibility object's value attribute was changed.

Available in Mac OS X v10.2 and later.

Declared in `AXNotificationConstants.h`.

`kAXUIElementDestroyedNotification`
An accessibility object was disposed of.

Available in Mac OS X v10.2 and later.

Declared in `AXNotificationConstants.h`.

`kAXMenuOpenedNotification`
A menu was opened.

Available in Mac OS X v10.2 and later.

Declared in `AXNotificationConstants.h`.

`kAXMenuClosedNotification`
A menu was closed.

Available in Mac OS X v10.2 and later.

Declared in `AXNotificationConstants.h`.

`kAXMenuItemSelectedNotification`
A menu item was selected.

Available in Mac OS X v10.2 and later.

Declared in `AXNotificationConstants.h`.

`kAXRowCountChangedNotification`
The number of rows in this table was changed.

Available in Mac OS X v10.4 and later.

Declared in `AXNotificationConstants.h`.

`kAXSelectedChildrenChangedNotification`
A different subset of this accessibility object's children were selected.

Available in Mac OS X v10.4 and later.

Declared in `AXNotificationConstants.h`.

`kAXResizedNotification`
The window has changed size.

Available in Mac OS X v10.4 and later.

Declared in `AXNotificationConstants.h`.

`kAXMovedNotification`
The position of this accessibility object was changed.

Available in Mac OS X v10.4 and later.

Declared in `AXNotificationConstants.h`.

`kAXCreatedNotification`
An accessibility object was created.

Available in Mac OS X v10.4 and later.

Declared in `AXNotificationConstants.h`.

Orientations and Sort Directions

Define the values for the orientation and sort-direction attributes of some accessibility objects.

```
// Orientations
#define kAXHorizontalOrientationValue CFSTR("AXHorizontalOrientation")
#define kAXVerticalOrientationValue CFSTR("AXVerticalOrientation")
#define kAXUnknownOrientationValue  CFSTR("AXUnknownOrientation")

// Sort directions
#define kAXAscendingSortDirectionValue CFSTR("AXAscendingSortDirection")
#define kAXDescendingSortDirectionValue CFSTR("AXDescendingSortDirection")
#define kAXUnknownSortDirectionValue CFSTR("AXUnknownSortDirection")
```

Constants

`kAXHorizontalOrientationValue`
This object is oriented horizontally.

Available in Mac OS X v10.2 and later.

Declared in `AXValueConstants.h`.

`kAXVerticalOrientationValue`
This object is oriented vertically.

Available in Mac OS X v10.2 and later.

Declared in `AXValueConstants.h`.

`kAXUnknownOrientationValue`
The orientation of this object is unknown.

Available in Mac OS X v10.4 and later.

Declared in `AXValueConstants.h`.

`kAXAscendingSortDirectionValue`
This object's contents are sorted in ascending order.

Available in Mac OS X v10.4 and later.

Declared in `AXValueConstants.h`.

`AXDescendingSortDirection`
This object's contents are sorted in descending order.

`kAXUnknownSortDirectionValue`
The sort order of this object is unknown.

Available in Mac OS X v10.4 and later.

Declared in `AXValueConstants.h`.

Discussion
See `kAXOrientationAttribute` and `kAXSortDirectionAttribute` for more information on the attributes for which you can use these values.

Result Codes

The result codes returned by the Carbon accessibility implementation are listed below. Other result codes defined in `AXError.h` are of use only to assistive applications.

Result Code	Value	Description
`kAXErrorIllegalArgument`	-25201	The value received in this event is an invalid value for this attribute. This also applies for invalid parameters in parameterized attributes. Available in Mac OS X v10.2 and later.
`kAXErrorInvalidUIElement`	-25202	The accessibility object received in this event is invalid. Available in Mac OS X v10.2 and later.
`kAXErrorInvalidUIElementObserver`	-25203	The observer for the accessibility object received in this event is invalid. Available in Mac OS X v10.2 and later.
`kAXErrorCannotComplete`	-25204	A fundamental error has occurred, such as a failure to allocate memory during processing. Available in Mac OS X v10.2 and later.
`kAXErrorAttributeUnsupported`	-25205	The referenced attribute is not supported. Alternatively, you can return the `eventNotHandledErr` error. Available in Mac OS X v10.2 and later.
`kAXErrorActionUnsupported`	-25206	The referenced action is not supported. Alternatively, you can return the `eventNotHandledErr` error. Available in Mac OS X v10.2 and later.
`kAXErrorAPIDisabled`	-25211	Assistive applications are not enabled in System Preferences. Available in Mac OS X v10.2 and later.

Result Code	Value	Description
`kAXErrorParameterizedAttributeUnsupported`	-25213	The parameterized attribute is not supported. Alternatively, you can return the `eventNotHandledErr` error. Available in Mac OS X v10.3 and later.

Core Printing Reference

Framework:	ApplicationServices/ApplicationServices.h
Declared in	PMCore.h PMCoreDeprecated.h PMDefinitions.h PMDefinitionsDeprecated.h

Overview

Core Printing is a C API that Mac OS X applications and command line tools can use to perform printing tasks that don't display a user interface. Core Printing defines a set of opaque types and a rich set of operations on instances of these types. The Core Printing opaque types include:

- `PMPrintSession` for general information about a print job
- `PMPrintSettings` for print job parameters
- `PMPageFormat` for the page format of a printed document
- `PMPaper` for information about a type of paper
- `PMPrinter` for information about a printer

In Carbon applications, Core Printing is used together with Carbon Printing to implement printing features. For more information about Carbon Printing, see *Carbon Printing Reference*.

In Cocoa applications, Core Printing can be used to extend the functionality in the Cocoa printing classes. The `NSPrintInfo` class provides direct access to some Core Printing objects.

Note: Core Printing is available to 64-bit applications, except for functions, data types, and constants that have been deprecated.

Functions by Task

Releasing and Retaining Printing Objects

`PMRelease` (page 2214)
Releases a printing object by decrementing its reference count.

`PMRetain` (page 2215)
Retains a printing object by incrementing its reference count.

Creating and Using Page Format Objects

`PMCreatePageFormat` (page 2143)
Creates a new page format object.

`PMCreatePageFormatWithPMPaper` (page 2144)
Creates a page format object with a specified paper.

`PMCopyPageFormat` (page 2141)
Copies the settings from one page format object into another.

`PMSessionDefaultPageFormat` (page 2225)
Assigns default parameter values to a page format object used in the specified printing session.

`PMSessionValidatePageFormat` (page 2248)
Updates the values in a page format object and validates them against the current formatting printer.

`PMSessionCreatePageFormatList` (page 2223)
Obtains a list of page format objects, each of which describes a paper size available on the specified printer.

`PMPageFormatCreateDataRepresentation` (page 2174)
Creates a data representation of a page format object.

`PMPageFormatCreateWithDataRepresentation` (page 2175)
Creates a page format object from a data representation.

`PMFlattenPageFormatToCFData` (page 2149)
Flattens a page format object into a Core Foundation data object for storage in a user document. (Deprecated. Use `PMPageFormatCreateDataRepresentation` (page 2174) instead.)

`PMFlattenPageFormat` (page 2149) Deprecated in Mac OS X v10.5
Flattens a page format object into a Memory Manager handle for storage in a user document. (Deprecated. Use `PMPageFormatCreateDataRepresentation` (page 2174) instead.)

`PMFlattenPageFormatToURL` (page 2150) Deprecated in Mac OS X v10.5
Flattens a page format object into a file for storage in a user document. (Deprecated. Use `PMPageFormatCreateDataRepresentation` (page 2174) and write the resulting data to your destination.)

`PMUnflattenPageFormat` (page 2265) Deprecated in Mac OS X v10.5
Rebuilds a page format object from a Memory Manager handle that contains flattened page format data. (Deprecated. Use `PMPageFormatCreateWithDataRepresentation` (page 2175) instead.)

`PMUnflattenPageFormatWithCFData` (page 2266) Deprecated in Mac OS X v10.5
Rebuilds a page format object from a Core Foundation data object that contains flattened page format data. (Deprecated. Use `PMPageFormatCreateWithDataRepresentation` (page 2175) instead.)

`PMUnflattenPageFormatWithURL` (page 2266) Deprecated in Mac OS X v10.5
Rebuilds a page format object from a file system URL that contains flattened page format data. (Deprecated. Instead read the data into a CFData object and use `PMPageFormatCreateWithDataRepresentation` (page 2175).)

Accessing Data in Page Format Objects

`PMGetPageFormatExtendedData` (page 2164)
Obtains extended page format data previously stored by your application.

`PMSetPageFormatExtendedData` (page 2258)
Stores your application-specific data in a page format object.

`PMGetPageFormatPaper` (page 2164)
Obtains the paper associated with a page format object.

`PMPageFormatGetPrinterID` (page 2175)
Obtains the identifier of the formatting printer for a page format object.

`PMGetOrientation` (page 2163)
Obtains the current setting for page orientation.

`PMSetOrientation` (page 2257)
Sets the page orientation for printing.

`PMGetScale` (page 2170)
Obtains the scaling factor currently applied to the page and paper rectangles.

`PMSetScale` (page 2263)
Sets the scaling factor for the page and paper rectangles.

`PMGetAdjustedPageRect` (page 2153)
Obtains the imageable area or page rectangle, taking into account orientation, application drawing resolution, and scaling settings.

`PMGetAdjustedPaperRect` (page 2154)
Obtains the rectangle defining the paper size, taking into account orientation, application drawing resolution, and scaling settings.

`PMGetUnadjustedPageRect` (page 2170)
Obtains the imageable area or page rectangle, unaffected by orientation, resolution, or scaling.

`PMGetUnadjustedPaperRect` (page 2171)
Obtains the paper rectangle, unaffected by rotation, resolution, or scaling.

`PMGetResolution` (page 2169) Deprecated in Mac OS X v10.5
Obtains the current application's drawing resolution. (Deprecated. Draw using Quartz 2D and call `CGContextScaleCTM` (page 105) instead.)

`PMSetAdjustedPageRect` (page 2250) Deprecated in Mac OS X v10.5
Requests a particular page size, adjusted for the current rotation, resolution, or scaling settings. (Deprecated. To set a particular paper size and margins, obtain or create a `PMPaper` (page 2275) object and call `PMCreatePageFormatWithPMPaper` (page 2144).)

`PMSetResolution` (page 2263) Deprecated in Mac OS X v10.5
Sets the application drawing resolution. (Deprecated. Draw using Quartz 2D and call `CGContextScaleCTM` (page 105) instead.)

`PMSetUnadjustedPaperRect` (page 2264) Deprecated in Mac OS X v10.5
Requests a particular paper size, unaffected by rotation, resolution, or scaling. (Deprecated. To set a particular paper size, obtain or create a `PMPaper` (page 2275) object and call `PMCreatePageFormatWithPMPaper` (page 2144).)

Creating and Using Print Settings Objects

`PMCreatePrintSettings` (page 2144)
Creates a new print settings object.

`PMSessionDefaultPrintSettings` (page 2225)
Assigns default parameter values to a print settings object for the specified printing session.

PMSessionValidatePrintSettings (page 2249)
Validates a print settings object within the context of the specified printing session.

PMPrintSettingsCreateDataRepresentation (page 2208)
Creates a data representation of a print settings object.

PMPrintSettingsCreateWithDataRepresentation (page 2209)
Creates a print settings object from a data representation.

PMCopyPrintSettings (page 2142)
Copies the settings from one print settings object into another.

PMPrintSettingsToOptions (page 2213)
Converts print settings into a CUPS options string.

PMPrintSettingsToOptionsWithPrinterAndPageFormat (page 2213)
Converts print settings and page format data into a CUPS options string for a specified printer.

PMFlattenPrintSettings (page 2150) Deprecated in Mac OS X v10.5
Flattens a print settings object into a Memory Manager handle for storage in a user document. (Deprecated. Use PMPrintSettingsCreateDataRepresentation (page 2208) instead.)

PMFlattenPrintSettingsToCFData (page 2151) Deprecated in Mac OS X v10.5
Flattens a print settings object into a Core Foundation data object for storage in a user document. (Deprecated. Use PMPrintSettingsCreateDataRepresentation (page 2208) instead.)

PMFlattenPrintSettingsToURL (page 2152) Deprecated in Mac OS X v10.5
Flattens a print settings object into a URL for storage in a user document. (Deprecated. Instead use PMPrintSettingsCreateDataRepresentation (page 2208) and write the resulting data to your destination.)

PMUnflattenPrintSettings (page 2267) Deprecated in Mac OS X v10.5
Rebuilds a print settings object from a Memory Manager handle that contains flattened print settings data. (Deprecated. Use PMPrintSettingsCreateWithDataRepresentation (page 2209) instead.)

PMUnflattenPrintSettingsWithCFData (page 2268) Deprecated in Mac OS X v10.5
Rebuilds a print settings object from a Core Foundation data object that contains flattened print settings data. (Deprecated. Use PMPrintSettingsCreateWithDataRepresentation (page 2209) instead.)

PMUnflattenPrintSettingsWithURL (page 2268) Deprecated in Mac OS X v10.5
Rebuilds a print settings object from a file that contains flattened print settings data. (Deprecated. Instead read the data into a CFData object and use PMPrintSettingsCreateWithDataRepresentation (page 2209).)

Accessing Data in Print Settings Objects

PMGetPrintSettingsExtendedData (page 2168)
Obtains extended print settings data previously stored by your application.

PMSetPrintSettingsExtendedData (page 2261)
Stores your application-specific data in a print settings object.

PMGetFirstPage (page 2159)
Obtains the number of the first page to be printed.

PMSetFirstPage (page 2254)
Sets the default page number of the first page to be printed.

`PMGetLastPage` (page 2162)
Obtains the number of the last page to be printed.

`PMSetLastPage` (page 2257)
Sets the page number of the last page to be printed.

`PMGetPageRange` (page 2165)
Obtains the valid range of pages that can be printed.

`PMSetPageRange` (page 2259)
Sets the valid range of pages that can be printed.

`PMPrintSettingsGetJobName` (page 2210)
Obtains the name of a print job.

`PMPrintSettingsSetJobName` (page 2211)
Specifies the name of a print job.

`PMGetCopies` (page 2155)
Obtains the number of copies that the user requests to be printed.

`PMSetCopies` (page 2252)
Sets the initial value for the number of copies to be printed.

`PMGetCollate` (page 2154)
Obtains a Boolean value that indicates whether the job collate option is selected.

`PMSetCollate` (page 2251)
Specifies whether the job collate option is selected.

`PMGetDuplex` (page 2158)
Obtains the selected duplex mode.

`PMSetDuplex` (page 2253)
Sets the duplex mode.

`PMPrintSettingsGetValue` (page 2210)
Obtains the value of a setting in a print settings object.

`PMPrintSettingsSetValue` (page 2212)
Stores the value of a setting in a print settings object.

`PMPrintSettingsCopyAsDictionary` (page 2207)
Creates a dictionary that contains the settings in a print settings object.

`PMPrintSettingsCopyKeys` (page 2207)
Obtains the keys for items in a print settings object.

`PMGetJobNameCFString` (page 2161) Deprecated in Mac OS X v10.5
Obtains the name of the print job. (Deprecated. Use `PMPrintSettingsGetJobName` (page 2210) instead.)

`PMSetJobNameCFString` (page 2256) Deprecated in Mac OS X v10.5
Specifies the name of a print job. (Deprecated. Use `PMPrintSettingsSetJobName` (page 2211) instead.)

Creating Printing Session Objects

`PMCreateSession` (page 2145)
Creates and initializes a printing session object and creates a context for printing operations.

Accessing Data in Printing Session Objects

`PMSessionGetDataFromSession` (page 2231)
Obtains application-specific data previously stored in a printing session object.

`PMSessionSetDataInSession` (page 2242)
Stores your application-specific data in a printing session object.

`PMSessionGetCurrentPrinter` (page 2231)
Obtains the current printer associated with a printing session.

`PMSessionSetCurrentPMPrinter` (page 2241)
Changes the current printer for a printing session.

`PMSessionGetCGGraphicsContext` (page 2230)
Obtains the Quartz graphics context for the current page in a printing session.

`PMSessionError` (page 2229)
Obtains the result code for any error returned by the printing session.

`PMSessionSetError` (page 2246)
Sets the value of the current result code for the specified printing session.

`PMSessionGetGraphicsContext` (page 2234) Deprecated in Mac OS X v10.5
Obtains the graphics context for the current page in a printing session. (Deprecated. Use `PMSessionGetCGGraphicsContext` (page 2230) instead.)

`PMSessionGeneral` (page 2229) Deprecated in Mac OS X v10.4
Maintains compatibility with the `PrGeneral` function in the classic Printing Manager. (Deprecated. Use `PMPrinterGetCommInfo` (page 2190) instead.)

`PMSessionGetDocumentFormatGeneration` (page 2233) Deprecated in Mac OS X v10.4
Obtains the spool file formats that can be generated for the specified printing session. (Deprecated. If you're drawing using Quartz 2D instead of QuickDraw, use `PMSessionBeginCGDocument` or `PMSessionBeginCGDocumentNoDialog` (page 2217); for submitting PostScript data, use `PMPrinterPrintWithFile` (page 2203) or `PMPrinterPrintWithProvider` (page 2204); to draw EPS data, use `PMCGImageCreateWithEPSDataProvider` (page 2139).)

`PMSessionSetCurrentPrinter` (page 2242) Deprecated in Mac OS X v10.4
Changes the current printer for a printing session to a printer specified by name. (Deprecated. Use `PMSessionSetCurrentPMPrinter` (page 2241) instead.)

`PMSessionSetDocumentFormatGeneration` (page 2244) Deprecated in Mac OS X v10.4
Requests a specified spool file format and supplies the graphics context type to use for drawing pages within the print loop. (Deprecated. If you're drawing using Quartz 2D instead of QuickDraw, use `PMSessionBeginCGDocument` or `PMSessionBeginCGDocumentNoDialog` (page 2217); for submitting PostScript data, use `PMPrinterPrintWithFile` (page 2203) or `PMPrinterPrintWithProvider` (page 2204); to draw EPS data, use `PMCGImageCreateWithEPSDataProvider` (page 2139).)

Using Printer Presets

`PMPresetCopyName` (page 2185)
Obtains the localized name for a preset.

`PMPresetCreatePrintSettings` (page 2186)
Creates a print settings object with settings that correspond to a preset.

`PMPresetGetAttributes` (page 2187)
Obtains the attributes of a preset.

Creating and Using Paper Objects

`PMPaperCreate` (page 2176)
: Creates a paper object. (Deprecated. Use `PMPrinterGetPaperList` (page 2198) to find the built-in papers available for a given printer or use `PMPaperCreateCustom` (page 2177) to create a custom paper.)

`PMPaperCreateCustom` (page 2177)
: Creates a custom paper object.

`PMPaperIsCustom` (page 2183)
: Returns a Boolean value indicating whether a specified paper is a custom paper.

Accessing Data in Paper Objects

`PMPaperGetID` (page 2179)
: Obtains the identifier of a paper object.

`PMPaperGetName` (page 2180)
: Obtains the name for a given paper.

`PMPaperGetWidth` (page 2182)
: Obtains the width of the sheet of paper represented by a paper object.

`PMPaperGetHeight` (page 2179)
: Obtains the height of the sheet of paper represented by a paper object.

`PMPaperGetMargins` (page 2180)
: Obtains the margins describing the unprintable area of the sheet represented by a paper object.

`PMPaperCreateLocalizedName` (page 2178)
: Obtains the localized name for a given paper.

`PMPaperGetPrinterID` (page 2182)
: Obtains the printer ID of the printer to which a given paper corresponds.

`PMPaperGetPPDPaperName` (page 2181)
: Obtains the PPD paper name for a given paper.

Print Loop Functions

`PMSessionBeginCGDocumentNoDialog` (page 2217)
: Begins a print job that draws into a Quartz graphics context and suppresses the printing status dialog.

`PMSessionEndDocumentNoDialog` (page 2227)
: Ends a print job started by calling the function `PMSessionBeginCGDocumentNoDialog` (page 2217) or `PMSessionBeginDocumentNoDialog` (page 2218).

`PMSessionBeginPageNoDialog` (page 2219)
: Starts a new page for printing in the specified printing session and suppresses the printing status dialog.

`PMSessionEndPageNoDialog` (page 2228)
: Indicates the end of drawing the current page for the specified printing session.

PMSessionBeginDocumentNoDialog (page 2218) Deprecated in Mac OS X v10.5
Begins a print job that, by default, draws into a QuickDraw graphics port, and suppresses the printing status dialog. (Deprecated. Use PMSessionBeginCGDocumentNoDialog (page 2217) instead.)

PMSessionSetIdleProc (page 2247) Deprecated in Mac OS X v10.4
Installs an idle callback function in your print loop. (Deprecated. There is no replacement; this function was included to facilitate porting legacy applications to Mac OS X, but it serves no useful purpose.)

Accessing the Print Job Destination

PMSessionSetDestination (page 2243)
Sets the destination location, format, and type for a print job.

PMSessionGetDestinationType (page 2232)
Obtains the output destination for a print job.

PMSessionCopyDestinationFormat (page 2221)
Obtains the destination format for a print job.

PMSessionCopyDestinationLocation (page 2221)
Obtains a destination location for a print job.

PMSessionCopyOutputFormatList (page 2222)
Obtains an array of destination formats supported by the current print destination.

Creating Printer Objects

PMServerLaunchPrinterBrowser (page 2216)
Launches the printer browser to browse the printers available for a print server.

PMServerCreatePrinterList (page 2215)
Creates a list of printers available to a print server.

PMSessionCreatePrinterList (page 2224)
Creates a list of printers available in the specified printing session.

PMPrinterCreateFromPrinterID (page 2190)
Creates a printer object from a print queue identifier.

PMCreateGenericPrinter (page 2143)
Creates a generic printer object.

Accessing Information About a Printer

PMPrinterCopyDescriptionURL (page 2187)
Obtains the URL of the description file for a given printer.

PMPrinterCopyDeviceURI (page 2188)
Obtains the device URI of a given printer.

PMPrinterCopyHostName (page 2188)
Obtains the name of the server hosting the print queue for a given printer.

PMPrinterCopyPresets (page 2189)
Obtains a list of print settings presets for a printer.

PMPrinterGetCommInfo (page 2190)
Obtains information about the communication channel for a printer.

PMPrinterGetDeviceURI (page 2192)
Obtains a copy of a printer's device URI. (Deprecated. Use PMPrinterCopyDeviceURI (page 2188) instead.)

PMPrinterGetDriverCreator (page 2192)
Obtains the creator of the driver associated with the specified printer.

PMPrinterGetDriverReleaseInfo (page 2193)
Obtains version information for the driver associated with the specified printer.

PMPrinterGetID (page 2193)
Returns the unique identifier of a printer.

PMPrinterGetLanguageInfo (page 2194)
Obtains information about the imaging language for the specified printer.

PMPrinterGetLocation (page 2195)
Returns the location of a printer.

PMPrinterGetMakeAndModelName (page 2195)
Obtains the manufacturer and model name of the specified printer.

PMPrinterGetMimeTypes (page 2196)
Obtains a list of MIME content types supported by a printer using the specified print settings.

PMPrinterGetName (page 2197)
Returns the human-readable name of a printer.

PMPrinterGetOutputResolution (page 2197)
Obtains the printer hardware output resolution for the specified print settings.

PMPrinterSetOutputResolution (page 2205)
Sets the print settings to reflect the specified printer hardware output resolution.

PMPrinterGetPaperList (page 2198)
Obtains the list of papers available for a printer.

PMPrinterGetPrinterResolutionCount (page 2199)
Obtains the number of resolution settings supported by the specified printer.

PMPrinterGetIndexedPrinterResolution (page 2194)
Obtains a resolution setting based on an index into the range of settings supported by the specified printer.

PMPrinterGetState (page 2200)
Obtains the current state of the print queue for a printer.

PMPrinterSetDefault (page 2205)
Sets the default printer for the current user.

PMPrinterIsDefault (page 2200)
Returns a Boolean value indicating whether a printer is the default printer for the current user.

PMPrinterIsFavorite (page 2201)
Returns a Boolean value indicating whether a printer is in the user's list of favorite printers.

PMPrinterIsPostScriptCapable (page 2201)
Returns a Boolean value indicating whether a printer is PostScript capable.

PMPrinterIsPostScriptPrinter (page 2202)
Determines whether a printer is a PostScript printer.

PMPrinterIsRemote (page 2202)
Indicates whether a printer is hosted by a remote print server.

PMPrinterGetPrinterResolution (page 2199) Deprecated in Mac OS X v10.5
Obtains a resolution setting for the specified printer. (Deprecated. Use PMPrinterGetPrinterResolutionCount (page 2199) and PMPrinterGetIndexedPrinterResolution (page 2194) to examine the available printer resolutions.)

PMPrinterGetDescriptionURL (page 2191) Deprecated in Mac OS X v10.4
Obtains a reference to the specified printer's description file. (Deprecated. Use PMPrinterCopyDescriptionURL (page 2187) instead.)

Submitting a Print Job to a Printer

PMPrinterPrintWithFile (page 2203)
Submits a print job to a specified printer using a file that contains print data.

PMPrinterPrintWithProvider (page 2204)
Submits a print job to a specified printer using a Quartz data provider to obtain the print data.

Accessing PostScript Printer Description Files

PMCopyAvailablePPDs (page 2140)
Obtains the list of PostScript printer description (PPD) files in a PPD domain.

PMCopyLocalizedPPD (page 2140)
Obtains a localized PostScript printer description (PPD) file.

PMCopyPPDData (page 2142)
Obtains the uncompressed PPD data for a PostScript printer description (PPD) file.

Printing with PostScript Data

PMCGImageCreateWithEPSDataProvider (page 2139)
Creates an image that references both the PostScript contents of EPS data and a preview (proxy) image for the data.

PMPrinterWritePostScriptToURL (page 2206)
Converts an input file of the specified MIME type to printer-ready PostScript for a destination printer.

PMSessionPostScriptBegin (page 2237) Deprecated in Mac OS X v10.4
Puts the current printer driver into PostScript mode, ready to accept PostScript data instead of QuickDraw data. (Deprecated. Use PMPrinterPrintWithFile (page 2203), PMPrinterPrintWithProvider (page 2204), or PMCGImageCreateWithEPSDataProvider (page 2139) instead.)

PMSessionPostScriptData (page 2238) Deprecated in Mac OS X v10.4
Passes PostScript data, referenced by a pointer, to the current printer driver. (Deprecated. Use PMPrinterPrintWithFile (page 2203), PMPrinterPrintWithProvider (page 2204), or PMCGImageCreateWithEPSDataProvider (page 2139) instead.)

PMSessionPostScriptEnd (page 2239) Deprecated in Mac OS X v10.4
: Restores the current driver to QuickDraw mode, ready to accept QuickDraw data instead of PostScript data. (Deprecated. Use PMPrinterPrintWithFile (page 2203), PMPrinterPrintWithProvider (page 2204), or PMCGImageCreateWithEPSDataProvider (page 2139) instead.)

PMSessionPostScriptFile (page 2239) Deprecated in Mac OS X v10.4
: Passes the PostScript data, contained in a file, to the current printer driver. (Deprecated. Use PMPrinterPrintWithFile (page 2203), PMPrinterPrintWithProvider (page 2204), or PMCGImageCreateWithEPSDataProvider (page 2139) instead.)

PMSessionPostScriptHandle (page 2240) Deprecated in Mac OS X v10.4
: Passes the PostScript data, referenced by a Memory Manager handle, to the current printer driver. (Deprecated. Use PMPrinterPrintWithFile (page 2203), PMPrinterPrintWithProvider (page 2204), or PMCGImageCreateWithEPSDataProvider (page 2139) instead.)

PMSessionSetPSInjectionData (page 2247) Deprecated in Mac OS X v10.4
: Specifies a set of PostScript code injection points and the PostScript data to be injected. (Deprecated. Use PMPrinterPrintWithFile (page 2203) or PMPrinterPrintWithProvider (page 2204) instead.)

Using PDF Workflow Items

PMWorkflowCopyItems (page 2270)
: Obtains an array of the available PDF workflow items.

PMWorkflowSubmitPDFWithOptions (page 2271)
: Submits a PDF file for workflow processing using the specified CUPS options string.

PMWorkflowSubmitPDFWithSettings (page 2272)
: Submits a PDF file for workflow processing using the specified print settings.

Matching Color With ColorSync

PMSessionDisableColorSync (page 2226) Deprecated in Mac OS X v10.5
: Disables use of a custom ColorSync profile previously enabled by the function PMSessionEnableColorSync (page 2226). (Deprecated. There is no replacement; draw using Quartz 2D instead.)

PMSessionEnableColorSync (page 2226) Deprecated in Mac OS X v10.5
: Enables use of a custom ColorSync profile previously set by the function PMSetProfile (page 2262). (Deprecated. There is no replacement; draw using Quartz 2D instead.)

PMSetProfile (page 2262) Deprecated in Mac OS X v10.5
: Embeds a color profile during printing. (Deprecated. There is no replacement; draw using Quartz 2D instead.)

Converting and Saving Old Print Records

PMSessionConvertOldPrintRecord (page 2220) Deprecated in Mac OS X v10.4
: Creates new page format and print settings objects from an old-style print record created for the classic Printing Manager. (Deprecated. There is no replacement; during the transition from Mac OS 9 to Mac OS X, this function facilitated the migration of print records saved in documents created in Mac OS 9, but the function no longer serves any useful purpose in Mac OS X.)

`PMSessionMakeOldPrintRecord` (page 2236) Deprecated in Mac OS X v10.4
Creates an old-style print record from page format and print settings objects. (Deprecated. There is no replacement; old-style print records are obsolete and serve no useful purpose in Mac OS X.)

Creating, Calling, and Deleting Universal Procedure Pointers

`DisposePMIdleUPP` (page 2137) Deprecated in Mac OS X v10.4
Disposes of a universal procedure pointer (UPP) to an idle callback. (Deprecated. There is no replacement; this function was included to facilitate porting legacy applications to Mac OS X, but it serves no useful purpose.)

`InvokePMIdleUPP` (page 2137) Deprecated in Mac OS X v10.4
Calls an idle callback. (Deprecated. There is no replacement; this function was included to facilitate porting legacy applications to Mac OS X, but it serves no useful purpose.)

`NewPMIdleUPP` (page 2138) Deprecated in Mac OS X v10.4
Creates a new universal procedure pointer (UPP) to an idle callback. (Deprecated. There is no replacement; this function was included to facilitate porting legacy applications to Mac OS X, but it serves no useful purpose.)

Legacy Core Printing Functions

`PMGetDestination` (page 2156) Deprecated in Mac OS X v10.5
Obtains the output destination of a print job. (Deprecated. Use `PMSessionGetDestinationType` (page 2232), `PMSessionCopyDestinationFormat` (page 2221), or `PMSessionCopyDestinationLocation` (page 2221) instead.)

`PMBegin` (page 2138) Deprecated in Mac OS X v10.4
Prepares Core Printing for use. (Deprecated. Use `PMCreateSession` (page 2145) instead.)

`PMConvertOldPrintRecord` (page 2139) Deprecated in Mac OS X v10.4
Creates a new `PMPageFormat` object and a new `PMPrintSettings` object from a print record created by the classic Printing Manager. (Deprecated. There is no replacement; during the transition from Mac OS 9 to Mac OS X, this function facilitated the migration of print records saved in documents created in Mac OS 9, but the function no longer serves any useful purpose in Mac OS X.)

`PMDefaultPageFormat` (page 2145) Deprecated in Mac OS X v10.4
Assigns default parameter values to an existing `PMPageFormat` object, for the current printer. (Deprecated. Use `PMSessionDefaultPageFormat` (page 2225) instead.)

`PMDefaultPrintSettings` (page 2146) Deprecated in Mac OS X v10.4
Assigns default parameter values to a `PMPrintSettings` object. (Deprecated. Use `PMSessionDefaultPrintSettings` (page 2225) instead.)

`PMDisableColorSync` (page 2146) Deprecated in Mac OS X v10.4
Disables ColorSync color matching for the current page. (Deprecated. There is no replacement; draw using Quartz 2D instead.)

`PMDisposePageFormat` (page 2147) Deprecated in Mac OS X v10.4
Releases memory previously allocated for a `PMPageFormat` object. (Deprecated. Use `PMRelease` (page 2214) instead.)

`PMDisposePrintSettings` (page 2147) Deprecated in Mac OS X v10.4
Releases memory previously allocated for a `PMPrintSettings` object. (Deprecated. Use `PMRelease` (page 2214) instead.)

PMEnableColorSync (page 2148) Deprecated in Mac OS X v10.4
Enables ColorSync color matching for the current page. (Deprecated. There is no replacement; draw using Quartz 2D instead.)

PMEnd (page 2148) Deprecated in Mac OS X v10.4
Closes Core Printing and releases its allocated memory. (Deprecated. Use PMRelease (page 2214) to release a PMPrintSession (page 2277) object instead.)

PMError (page 2148) Deprecated in Mac OS X v10.4
Obtains the result code from the last printing function called by your application. (Deprecated. Use PMSessionError (page 2229) instead.)

PMGeneral (page 2152) Deprecated in Mac OS X v10.4
Maintains compatibility with the PrGeneral function in the classic Printing Manager. (Deprecated. Use PMPrinterGetCommInfo (page 2190) instead.)

PMGetColorMode (page 2155) Deprecated in Mac OS X v10.4
Obtains the color mode for the print job. (Deprecated. There is no replacement; this function was included to facilitate porting legacy applications to Mac OS X, but it serves no useful purpose.)

PMGetDriverCreator (page 2157) Deprecated in Mac OS X v10.4
Obtains the creator of the driver associated with the current printer. (Deprecated. Use PMPrinterGetDriverCreator (page 2192) instead.)

PMGetDriverReleaseInfo (page 2157) Deprecated in Mac OS X v10.4
Obtains release information for the driver associated with the current printer. (Deprecated. Use PMPrinterGetDriverReleaseInfo (page 2193) instead.)

PMGetGrafPtr (page 2159) Deprecated in Mac OS X v10.4
Obtains the printing port from an opaque printing context. (Deprecated. Use PMSessionGetCGGraphicsContext (page 2230) instead.)

PMGetIndexedPrinterResolution (page 2160) Deprecated in Mac OS X v10.4
Obtains a resolution setting based on an index into the range of settings supported by the current printer. (Deprecated. Use PMPrinterGetIndexedPrinterResolution (page 2194) instead.)

PMGetJobName (page 2160) Deprecated in Mac OS X v10.4
Obtains the name of the print job. (Deprecated. Use PMPrintSettingsGetJobName (page 2210) instead.)

PMGetLanguageInfo (page 2162) Deprecated in Mac OS X v10.4
Obtains information about the current printer's imaging language. (Deprecated. Use PMPrinterGetLanguageInfo (page 2194) instead.)

PMGetPhysicalPageSize (page 2166) Deprecated in Mac OS X v10.4
Obtains the size of the imageable area in points, unaffected by rotation, resolution, or scaling. (Deprecated. Use PMGetUnadjustedPageRect (page 2170) or examine the paper returned by PMGetPageFormatPaper (page 2164).)

PMGetPhysicalPaperSize (page 2166) Deprecated in Mac OS X v10.4
Obtains the size of the paper in points, unaffected by rotation, resolution, or scaling. (Deprecated. Use PMGetUnadjustedPaperRect (page 2171) or examine the paper returned by PMGetPageFormatPaper (page 2164).)

PMGetPrinterResolution (page 2167) Deprecated in Mac OS X v10.4
Obtains the resolution setting for the current printer according to the tag parameter. (Deprecated. Use PMPrinterGetPrinterResolutionCount (page 2199) and PMPrinterGetIndexedPrinterResolution (page 2194) to examine the available printer resolutions.)

PMGetPrinterResolutionCount (page 2168) Deprecated in Mac OS X v10.4
Obtains the number of resolution settings supported by the current printer. (Deprecated. Use PMPrinterGetPrinterResolutionCount (page 2199) instead.)

PMIsPostScriptDriver (page 2172) Deprecated in Mac OS X v10.4
Reports whether the current printer driver supports the PostScript language. (Deprecated. Use PMPrinterIsPostScriptCapable (page 2201) or PMPrinterIsPostScriptPrinter (page 2202) instead.)

PMMakeOldPrintRecord (page 2172) Deprecated in Mac OS X v10.4
Creates an old-style print record from a PMPageFormat and a PMPrintSettings object. (Deprecated. There is no replacement; old-style print records are obsolete and serve no useful purpose in Mac OS X.)

PMNewPageFormat (page 2173) Deprecated in Mac OS X v10.4
Creates a new PMPageFormat object. (Deprecated. Use PMCreatePageFormat (page 2143) instead.)

PMNewPrintSettings (page 2173) Deprecated in Mac OS X v10.4
Creates a new PMPrintSettings object. (Deprecated. Use PMCreatePrintSettings (page 2144) instead.)

PMPostScriptBegin (page 2183) Deprecated in Mac OS X v10.4
Puts the current driver into PostScript mode, ready to accept PostScript data instead of QuickDraw data. (Deprecated. Use PMPrinterPrintWithFile (page 2203), PMPrinterPrintWithProvider (page 2204), or PMCGImageCreateWithEPSDataProvider (page 2139) instead.)

PMPostScriptData (page 2183) Deprecated in Mac OS X v10.4
Passes PostScript data, referenced by a pointer, to the current printer driver. (Deprecated. Use PMPrinterPrintWithFile (page 2203), PMPrinterPrintWithProvider (page 2204), or PMCGImageCreateWithEPSDataProvider (page 2139) instead.)

PMPostScriptEnd (page 2184) Deprecated in Mac OS X v10.4
Restores the current driver to QuickDraw mode, ready to accept QuickDraw data instead of PostScript data. (Deprecated. Use PMPrinterPrintWithFile (page 2203), PMPrinterPrintWithProvider (page 2204), or PMCGImageCreateWithEPSDataProvider (page 2139) instead.)

PMPostScriptFile (page 2184) Deprecated in Mac OS X v10.4
Passes PostScript data, contained in a file, to the current printer driver. (Deprecated. Use PMPrinterPrintWithFile (page 2203), PMPrinterPrintWithProvider (page 2204), or PMCGImageCreateWithEPSDataProvider (page 2139) instead.)

PMPostScriptHandle (page 2185) Deprecated in Mac OS X v10.4
Passes PostScript data, referenced by a handle, to the current printer driver. (Deprecated. Use PMPrinterPrintWithFile (page 2203), PMPrinterPrintWithProvider (page 2204), or PMCGImageCreateWithEPSDataProvider (page 2139) instead.)

PMSessionGetDocumentFormatSupported (page 2234) Deprecated in Mac OS X v10.4
Obtains the spool file formats that are accepted by the current printer driver. (Deprecated. Use PMPrinterPrintWithFile (page 2203), PMPrinterPrintWithProvider (page 2204), or PMCGImageCreateWithEPSDataProvider (page 2139) instead.)

PMSessionIsDocumentFormatSupported (page 2235) Deprecated in Mac OS X v10.4
Reports whether the current printer driver supports a specified spool file format. (Deprecated. Use PMPrinterPrintWithFile (page 2203), PMPrinterPrintWithProvider (page 2204), or PMCGImageCreateWithEPSDataProvider (page 2139) instead.)

PMSetColorMode (page 2251) Deprecated in Mac OS X v10.4
Sets the desired color mode for the print job. (Deprecated. There is no replacement; this function was included to facilitate porting legacy applications to Mac OS X, but it serves no useful purpose.)

`PMSetError` (page 2253) Deprecated in Mac OS X v10.4
: Sets the value of the current result code. (Deprecated. Use `PMSessionSetError` (page 2246) instead.)

`PMSetIdleProc` (page 2255) Deprecated in Mac OS X v10.4
: Installs an idle callback function in your print loop. (Deprecated. There is no replacement; this function was included to facilitate porting legacy applications to Mac OS X, but it serves no useful purpose.)

`PMSetJobName` (page 2255) Deprecated in Mac OS X v10.4
: Specifies the name of the print job. (Deprecated. Use `PMPrintSettingsSetJobName` (page 2211) instead.)

`PMSetPhysicalPaperSize` (page 2260) Deprecated in Mac OS X v10.4
: Requests a particular paper size, unaffected by rotation, resolution, or scaling. (Deprecated. Use `PMCreatePageFormatWithPMPaper` (page 2144) instead.)

`PMValidatePageFormat` (page 2269) Deprecated in Mac OS X v10.4
: Obtains a valid `PMPageFormat` object. (Deprecated. Use `PMSessionValidatePageFormat` (page 2248) instead.)

`PMValidatePrintSettings` (page 2270) Deprecated in Mac OS X v10.4
: Obtains a valid `PMPrintSettings` object. (Deprecated. Use `PMSessionValidatePrintSettings` (page 2249) instead.)

Functions

DisposePMIdleUPP

Disposes of a universal procedure pointer (UPP) to an idle callback. (Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Mac OS X, but it serves no useful purpose.)

```
void DisposePMIdleUPP (
   PMIdleUPP userUPP
);
```

Discussion

You do not need this function in Mac OS X. Instead, use the standard idle proc. See the `PMIdleProcPtr` (page 2273) callback function.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`PMCoreDeprecated.h`

InvokePMIdleUPP

Calls an idle callback. (Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Mac OS X, but it serves no useful purpose.)

```
void InvokePMIdleUPP (
   PMIdleUPP userUPP
);
```

Discussion
You do not need this function in Mac OS X. Instead, use the standard idle proc. See the `PMIdleProcPtr` (page 2273) callback function.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`PMCoreDeprecated.h`

NewPMIdleUPP

Creates a new universal procedure pointer (UPP) to an idle callback. (Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Mac OS X, but it serves no useful purpose.)

```
PMIdleUPP NewPMIdleUPP (
   PMIdleProcPtr userRoutine
);
```

Discussion
You do not need this function in Mac OS X. Instead, use the standard idle proc. See the `PMIdleProcPtr` (page 2273) callback function.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`PMCoreDeprecated.h`

PMBegin

Prepares Core Printing for use. (Deprecated in Mac OS X v10.4. Use `PMCreateSession` (page 2145) instead.)

```
OSStatus PMBegin ();
```

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
Do not nest calls to `PMBegin`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`PMCoreDeprecated.h`

PMCGImageCreateWithEPSDataProvider

Creates an image that references both the PostScript contents of EPS data and a preview (proxy) image for the data.

```
CGImageRef PMCGImageCreateWithEPSDataProvider (
   CGDataProviderRef epsDataProvider,
   CGImageRef epsPreview
);
```

Parameters

epsDataProvider

A Quartz data provider that supplies the PostScript contents of the EPS file. The EPS data must begin with the EPSF required header and bounding box DSC (Document Structuring Conventions) comments.

epsPreview

A Quartz image that serves as the proxy image for the EPS file. When the image returned by this function is rendered onscreen or sent to a printer that cannot render PostScript, this proxy image is drawn instead.

Return Value

An image capable of rendering either the EPS content or the proxy image, depending upon the capabilities of the destination printer.

Discussion

It is likely that data will not be read from the EPS data provider until after this function returns. You should be careful not to free the underlying EPS data until the data provider's release function is invoked. Similarly, do not free the preview image data until the image data provider's release function is invoked. You are responsible for releasing the data providers for the EPS image and the EPS preview image.

Note that in Mac OS X v10.3 and later, Quartz can convert EPS data into PDF data. Using this feature and then using Quartz to draw the resulting PDF data may produce superior results for your application. See *CGPSConverter Reference* for details.

Availability

Available in Mac OS X v10.1 and later.

Declared In

`PMCore.h`

PMConvertOldPrintRecord

Creates a new `PMPageFormat` object and a new `PMPrintSettings` object from a print record created by the classic Printing Manager. (Deprecated in Mac OS X v10.4. There is no replacement; during the transition from Mac OS 9 to Mac OS X, this function facilitated the migration of print records saved in documents created in Mac OS 9, but the function no longer serves any useful purpose in Mac OS X.)

```
OSStatus PMConvertOldPrintRecord (
    Handle printRecordHandle,
    PMPrintSettings *printSettings,
    PMPageFormat *pageFormat
);
```

Parameters

printRecordHandle

A handle to a print record created by the classic Printing Manager.

printSettings
On return, a validated `PMPrintSettings` object.

pageFormat
On return, a validated `PMPageFormat` object.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
Valid after calling `PMBegin`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`PMCoreDeprecated.h`

PMCopyAvailablePPDs

Obtains the list of PostScript printer description (PPD) files in a PPD domain.

```
OSStatus PMCopyAvailablePPDs (
   PMPPDDomain domain,
   CFArrayRef *ppds
);
```

Parameters

domain
The PPD domain to search. See "PostScript Printer Description File Domains" (page 2292) for a description of the constants you can use to specify the domain.

ppds
A pointer to your `CFArrayRef` variable. On return, the variable refers to a Core Foundation array of PPD files in the specified domain. Each element in the array is a Core Foundation URL object that specifies the location of a PPD file or a compressed PPD file. You are responsible for releasing the array. If the specified domain is not valid, the variable is set to `NULL`.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Availability
Available in Mac OS X v10.3 and later.

Declared In
`PMCore.h`

PMCopyLocalizedPPD

Obtains a localized PostScript printer description (PPD) file.

```
OSStatus PMCopyLocalizedPPD (
   CFURLRef ppd,
   CFURLRef *localizedPPD
);
```

Parameters

ppd

A Core Foundation URL object for a PPD file. You can obtain a PPD URL using the function `PMCopyAvailablePPDs` (page 2140).

localizedPPD

A pointer to your `CFURLRef` variable. On return, the variable refers to a Core Foundation URL object. The URL specifies the location of a PPD file or a compressed PPD file that has been localized for the current user's language preference. You are responsible for releasing the URL. If the *ppd* parameter is not valid, the variable is set to `NULL`.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
To access the data in the PPD file, you can use the function `PMCopyPPDData` (page 2142).

Special Considerations

In Mac OS X v10.5 and later, the printing system supports globalized PPD files as defined in CUPS version 1.2 and later. A globalized PPD file contains multiple localizations within a single file. If a globalized PPD file exists, this function returns the URL to this file and it is up to the application to obtain the correct localized data. For more information, see CUPS PPD Extensions.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`PMCore.h`

PMCopyPageFormat

Copies the settings from one page format object into another.

```
OSStatus PMCopyPageFormat (
   PMPageFormat formatSrc,
   PMPageFormat formatDest
);
```

Parameters

formatSrc

The page format object to duplicate.

formatDest

The page format object to receive the copied settings. On return, this object contains the same settings as the `formatSrc` object.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Availability
Available in Mac OS X v10.0 and later.

Declared In
PMCore.h

PMCopyPPDData

Obtains the uncompressed PPD data for a PostScript printer description (PPD) file.

```
OSStatus PMCopyPPDData (
   CFURLRef ppd,
   CFDataRef *data
);
```

Parameters

ppd

A URL for a PPD or compressed PPD file. You can obtain a PPD URL using the function PMCopyAvailablePPDs (page 2140) or PMCopyLocalizedPPD (page 2140).

data

A pointer to your CFDataRef variable. On return, the variable refers to a Core Foundation data object containing the uncompressed PPD data from the specified PPD file. You are responsible for releasing the data object. If the *ppd* parameter does not reference a PPD file, the variable is set to NULL.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Availability
Available in Mac OS X v10.3 and later.

Declared In
PMCore.h

PMCopyPrintSettings

Copies the settings from one print settings object into another.

```
OSStatus PMCopyPrintSettings (
   PMPrintSettings settingSrc,
   PMPrintSettings settingDest
);
```

Parameters

settingSrc

The print settings object to duplicate.

settingDest

The print settings object to receive the copied settings. On return, this object contains the same settings as the settingSrc object.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Availability
Available in Mac OS X v10.0 and later.

Declared In
PMCore.h

PMCreateGenericPrinter

Creates a generic printer object.

```
OSStatus PMCreateGenericPrinter (
    PMPrinter *printer
);
```

Parameters

printer

A pointer to your PMPrinter (page 2276) variable. On return, the variable refers to a new printer object that represents the generic formatting printer. You are responsible for releasing the printer object with the function PMRelease (page 2214).

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
This function provides a way to create a PMPrinter object that represents the generic formatting printer.

Availability
Available in Mac OS X v10.5 and later.

Declared In
PMCore.h

PMCreatePageFormat

Creates a new page format object.

```
OSStatus PMCreatePageFormat (
   PMPageFormat *pageFormat
);
```

Parameters

pageFormat

A pointer to your PMPageFormat (page 2275) variable. On return, the variable refers to a new page format object. You are responsible for releasing the page format object with the function PMRelease (page 2214).

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
This function allocates memory for a new page format object in your application's memory space and sets its reference count to 1. The new page format object is empty and unusable until you call PMSessionDefaultPageFormat (page 2225) or PMCopyPageFormat (page 2141).

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
CarbonSketch

Declared In
PMCore.h

PMCreatePageFormatWithPMPaper

Creates a page format object with a specified paper.

```
OSStatus PMCreatePageFormatWithPMPaper (
   PMPageFormat *pageFormat,
   PMPaper paper
);
```

Parameters

pageFormat

A pointer to your PMPageFormat (page 2275) variable. On return, the variable refers to a new page format object that represents the specified paper. You are responsible for releasing the page format object with the function PMRelease (page 2214).

paper

The type of paper for the new page format object.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Availability
Available in Mac OS X v10.3 and later.

Declared In
PMCore.h

PMCreatePrintSettings

Creates a new print settings object.

```
OSStatus PMCreatePrintSettings (
   PMPrintSettings *printSettings
);
```

Parameters

printSettings

A pointer to your PMPrintSettings (page 2277) variable. On return, the variable refers to a new print settings object. You are responsible for releasing the print settings object with the function PMRelease (page 2214).

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
This function allocates memory for a new print settings object in your application's memory space and sets its reference count to 1. The new print settings object is empty and unusable until you call PMSessionDefaultPrintSettings (page 2225) or PMCopyPrintSettings (page 2142).

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
CarbonSketch

Declared In
`PMCore.h`

PMCreateSession

Creates and initializes a printing session object and creates a context for printing operations.

```
OSStatus PMCreateSession (
   PMPrintSession *printSession
);
```

Parameters

printSession

A pointer to your `PMPrintSession` (page 2277) variable. On return, the variable refers to a new printing session object. You are responsible for releasing the printing session object with the function `PMRelease` (page 2214).

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
This function allocates memory for a new printing session object in your application's memory space and sets its reference count to 1. The new printing session object is initialized with information that the printing system uses for a print job.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
CarbonSketch

Declared In
`PMCore.h`

PMDefaultPageFormat

Assigns default parameter values to an existing `PMPageFormat` object, for the current printer. (Deprecated in Mac OS X v10.4. Use `PMSessionDefaultPageFormat` (page 2225) instead.)

```
OSStatus PMDefaultPageFormat (
    PMPageFormat pageFormat
);
```

Parameters

pageFormat

On return, a `PMPageFormat` object containing default parameter values.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
Valid after calling `PMBegin` and creating a page format object.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`PMCoreDeprecated.h`

PMDefaultPrintSettings

Assigns default parameter values to a `PMPrintSettings` object. (Deprecated in Mac OS X v10.4. Use `PMSessionDefaultPrintSettings` (page 2225) instead.)

```
OSStatus PMDefaultPrintSettings (
    PMPrintSettings printSettings
);
```

Parameters
printSettings
A `PMPrintSettings` object. On return, the object contains default parameter values.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
Valid after calling `PMBegin` and creating a print settings object.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`PMCoreDeprecated.h`

PMDisableColorSync

Disables ColorSync color matching for the current page. (Deprecated in Mac OS X v10.4. There is no replacement; draw using Quartz 2D instead.)

```
OSStatus PMDisableColorSync ();
```

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
Valid between calls to `PMBeginPage` and `PMEndPage`.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In
PMCoreDeprecated.h

PMDisposePageFormat

Releases memory previously allocated for a `PMPageFormat` object. (Deprecated in Mac OS X v10.4. Use `PMRelease` (page 2214) instead.)

```
OSStatus PMDisposePageFormat (
    PMPageFormat pageFormat
);
```

Parameters

pageFormat

On return, an invalidated `PMPageFormat` object.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
Valid after calling `PMBegin` and creating a page format object.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
PMCoreDeprecated.h

PMDisposePrintSettings

Releases memory previously allocated for a `PMPrintSettings` object. (Deprecated in Mac OS X v10.4. Use `PMRelease` (page 2214) instead.)

```
OSStatus PMDisposePrintSettings (
    PMPrintSettings printSettings
);
```

Parameters

printSettings

On return, an invalidated `PMPrintSettings` reference.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
Valid after calling `PMBegin` and creating a print settings object.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
PMCoreDeprecated.h

PMEnableColorSync

Enables ColorSync color matching for the current page. (Deprecated in Mac OS X v10.4. There is no replacement; draw using Quartz 2D instead.)

```
OSStatus PMEnableColorSync ();
```

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
Valid between calls to `PMBeginPage` and `PMEndPage`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
PMCoreDeprecated.h

PMEnd

Closes Core Printing and releases its allocated memory. (Deprecated in Mac OS X v10.4. Use `PMRelease` (page 2214) to release a `PMPrintSession` (page 2277) object instead.)

```
OSStatus PMEnd (void);
```

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
PMCoreDeprecated.h

PMError

Obtains the result code from the last printing function called by your application. (Deprecated in Mac OS X v10.4. Use `PMSessionError` (page 2229) instead.)

```
OSStatus PMError ();
```

Return Value
A result code. The result code `kPMCancel` indicates the user canceled the current print job.

Discussion
Valid after calling `PMBegin`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`PMCoreDeprecated.h`

PMFlattenPageFormat

Flattens a page format object into a Memory Manager handle for storage in a user document. (Deprecated in Mac OS X v10.5. Use `PMPageFormatCreateDataRepresentation` (page 2174) instead.)

```
OSStatus PMFlattenPageFormat (
   PMPageFormat pageFormat,
   Handle *flatFormat
);
```

Parameters

pageFormat

The page format object to flatten.

flatFormat

A pointer to your `Handle` variable. On return, the variable refers to a Memory Manager handle that contains the flattened page format object. The handle is allocated by the function. You are responsible for disposing of the handle.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Related Sample Code
CarbonSketch

Declared In
`PMCoreDeprecated.h`

PMFlattenPageFormatToCFData

Flattens a page format object into a Core Foundation data object for storage in a user document. (Deprecated in Mac OS X v10.5. Use `PMPageFormatCreateDataRepresentation` (page 2174) instead.)

```
OSStatus PMFlattenPageFormatToCFData (
   PMPageFormat pageFormat,
   CFDataRef *flatFormat
);
```

Parameters

pageFormat

The page format object to flatten.

flatFormat

A pointer to your `CFDataRef` variable. On return, the variable refers to a Core Foundation data object containing a flattened representation of the specified page format object. You are responsible for releasing the data object.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Availability
Available in Mac OS X v10.4 and later.
Deprecated in Mac OS X v10.5.

See Also
`PMUnflattenPageFormatWithCFData` (page 2266)

Declared In
`PMCoreDeprecated.h`

PMFlattenPageFormatToURL

Flattens a page format object into a file for storage in a user document. (Deprecated in Mac OS X v10.5. Use `PMPageFormatCreateDataRepresentation` (page 2174) and write the resulting data to your destination.)

```
OSStatus PMFlattenPageFormatToURL (
   PMPageFormat pageFormat,
   CFURLRef flattenFileURL
);
```

Parameters

pageFormat

The page format object to flatten.

flatFormat

A Core Foundation URL specifying a file to contain a flattened representation of the specified page format object. If the file already exists, it is overwritten. Only file-based URLs are supported.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Availability
Available in Mac OS X v10.4 and later.
Deprecated in Mac OS X v10.5.

See Also
`PMUnflattenPageFormatWithURL` (page 2266)

Declared In
`PMCoreDeprecated.h`

PMFlattenPrintSettings

Flattens a print settings object into a Memory Manager handle for storage in a user document. (Deprecated in Mac OS X v10.5. Use `PMPrintSettingsCreateDataRepresentation` (page 2208) instead.)

```
OSStatus PMFlattenPrintSettings (
   PMPrintSettings printSettings,
   Handle *flatSettings
);
```

Parameters

printSettings

The print settings object to flatten.

flatSettings

A pointer to your `Handle` variable. On return, the variable refers to a Memory Manager handle that contains a flattened print settings object. The handle is allocated by the function. You are responsible for disposing of the handle.

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Discussion

There are no scoping requirements as to when you may use this function.

Apple recommends that you do not reuse the print settings information if the user prints the document again. The information supplied by the user in the Print dialog should pertain to the document only while the document prints, so there is no need to save the print settings object.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`PMCoreDeprecated.h`

PMFlattenPrintSettingsToCFData

Flattens a print settings object into a Core Foundation data object for storage in a user document. (Deprecated in Mac OS X v10.5. Use `PMPrintSettingsCreateDataRepresentation` (page 2208) instead.)

```
OSStatus PMFlattenPrintSettingsToCFData (
   PMPrintSettings printSettings,
   CFDataRef *flatSetting
);
```

Parameters

printSettings

The print settings object to flatten.

flatSetting

A pointer to your `CFDataRef` variable. On return, the variable refers to a Core Foundation data object that contains a flattened representation of the specified print settings object. You are responsible for releasing the data object.

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Availability

Available in Mac OS X v10.4 and later.

Deprecated in Mac OS X v10.5.

See Also
PMUnflattenPrintSettingsWithCFData (page 2268)

Declared In
PMCoreDeprecated.h

PMFlattenPrintSettingsToURL

Flattens a print settings object into a URL for storage in a user document. (Deprecated in Mac OS X v10.5. Instead use PMPrintSettingsCreateDataRepresentation (page 2208) and write the resulting data to your destination.)

```
OSStatus PMFlattenPrintSettingsToURL (
   PMPrintSettings printSettings,
   CFURLRef flattenFileURL
);
```

Parameters

printSettings

The print settings object to flatten.

flattenFileURL

A Core Foundation URL specifying a file to contain a flattened representation of the specified print settings object. If the file already exists, it is overwritten. Only file-based URLs are supported.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Availability
Available in Mac OS X v10.4 and later.
Deprecated in Mac OS X v10.5.

See Also
PMUnflattenPrintSettingsWithURL (page 2268)

Declared In
PMCoreDeprecated.h

PMGeneral

Maintains compatibility with the PrGeneral function in the classic Printing Manager. (Deprecated in Mac OS X v10.4. Use PMPrinterGetCommInfo (page 2190) instead.)

```
OSStatus PMGeneral (
    Ptr pData
);
```

Parameters

pData

A pointer to a PrGeneral data structure.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
Valid after calling `PMBegin`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`PMCoreDeprecated.h`

PMGetAdjustedPageRect

Obtains the imageable area or page rectangle, taking into account orientation, application drawing resolution, and scaling settings.

```
OSStatus PMGetAdjustedPageRect (
   PMPageFormat pageFormat,
   PMRect *pageRect
);
```

Parameters

pageFormat
The page format object whose adjusted page rectangle you want to obtain.

pageRect
A pointer to your `PMRect` (page 2277) structure. On return, the structure contains the current imageable area, in points, taking into account scaling, rotation, and application resolution settings. The page rectangle is the area of the page to which an application can draw. The coordinates for the upper-left corner of the page rectangle are (0,0). See *Supporting Printing in Your Carbon Application* for more information on page and paper rectangles.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
Before using this function, you must call `PMSessionValidatePageFormat` (page 2248) to ensure that the values for the adjusted page rectangle correctly account for scaling, rotation, and application resolution settings.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
CarbonSketch

Declared In
`PMCore.h`

PMGetAdjustedPaperRect

Obtains the rectangle defining the paper size, taking into account orientation, application drawing resolution, and scaling settings.

```
OSStatus PMGetAdjustedPaperRect (
   PMPageFormat pageFormat,
   PMRect *paperRect
);
```

Parameters

pageFormat

The page format object whose adjusted paper rectangle you want to obtain.

paperRect

A pointer to your `PMRect` (page 2277) structure. On return, the structure describes the current paper size, in points, taking into account scaling, rotation, and application resolution settings. The coordinates of the upper-left corner of the paper rectangle are specified relative to the page rectangle. The coordinates of the upper-left corner of the page rectangle are always (0,0), which means the coordinates of the upper-left corner of the paper rectangle are always negative or (0,0). See *Supporting Printing in Your Carbon Application* for more information on page and paper rectangles.

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Discussion

Before using this function, you must call the function `PMSessionValidatePageFormat` (page 2248) to ensure that the values for the adjusted paper rectangle correctly account for scaling, rotation, and application resolution settings.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`PMCore.h`

PMGetCollate

Obtains a Boolean value that indicates whether the job collate option is selected.

```
OSStatus PMGetCollate (
   PMPrintSettings printSettings,
   Boolean *collate
);
```

Parameters

printSettings

The print settings object you're querying to determine whether the job collate option is selected.

collate

A pointer to your Boolean variable. On return, `true` if the job collate option is selected; otherwise, `false`.

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Discussion
The Collated checkbox is displayed in the Copies & Pages pane of the Print dialog. This option determines how printed material is organized. For example, if you have a document that is three pages long and you are printing multiple copies with the Collated option selected, the job prints pages 1, 2, and 3 in that order and then repeats. However, if the Collated option is not selected and you're printing multiple copies of those same three pages, the job prints copies of page 1, then copies of page 2, and finally copies of page 3.

Availability
Available in Mac OS X v10.2 and later.

See Also
`PMSetCollate` (page 2251)

Declared In
`PMCore.h`

PMGetColorMode

Obtains the color mode for the print job. (Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Mac OS X, but it serves no useful purpose.)

```
OSStatus PMGetColorMode (
   PMPrintSettings printSettings,
   PMColorMode *colorMode
);
```

Parameters

printSettings

The print settings object whose color mode you want to obtain.

colorMode

On return, a pointer to a value that represents the color mode setting. See "Color Modes" (page 2298) for a list of possible return values.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
This function is not recommended. It doesn't do anything in Mac OS X and in general is no longer appropriate for applications to call.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`PMCoreDeprecated.h`

PMGetCopies

Obtains the number of copies that the user requests to be printed.

```
OSStatus PMGetCopies (
   PMPrintSettings printSettings,
   UInt32 *copies
);
```

Parameters

printSettings

The print settings object whose number of copies you want to obtain.

copies

A pointer to your `UInt32` variable. On return, the variable contains the number of copies requested by the user.

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Availability

Available in Mac OS X v10.0 and later.

See Also

`PMSetCopies` (page 2252)

Declared In

`PMCore.h`

PMGetDestination

Obtains the output destination of a print job. (Deprecated in Mac OS X v10.5. Use `PMSessionGetDestinationType` (page 2232), `PMSessionCopyDestinationFormat` (page 2221), or `PMSessionCopyDestinationLocation` (page 2221) instead.)

```
OSStatus PMGetDestination (
   PMPrintSettings printSettings,
   PMDestinationType *destType,
   CFURLRef *fileURL
);
```

Parameters

printSettings

The print settings object whose destination you want to obtain.

destType

A pointer to your `PMDestinationType` variable. On return, the variable indicates the destination for the print job. See "Destination Types" (page 2281).

fileURL

A pointer to your `CFURLRef` variable. On return, the variable refers to a Core Foundation URL that contains the location of the print job destination.

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Discussion

For print jobs that are sent to disk, as opposed a printer, you can use this function to obtain the location of the destination file. Valid within a printing session after creating a print settings object.

Before using this function you must call `PMSessionValidatePrintSettings` or `PMValidatePrintSettings` to ensure that the print settings object is valid.

Special Considerations

This function does not take a print session parameter and therefore cannot indicate whether preview has been selected as the destination.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`PMCoreDeprecated.h`

PMGetDriverCreator

Obtains the creator of the driver associated with the current printer. (Deprecated in Mac OS X v10.4. Use `PMPrinterGetDriverCreator` (page 2192) instead.)

```
OSStatus PMGetDriverCreator (
    OSType *creator
);
```

Parameters

creator
On return, the 4-byte creator type of the driver (for example, `'APPL'` for an Apple printer driver).

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
Valid after calling `PMBegin`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`PMCoreDeprecated.h`

PMGetDriverReleaseInfo

Obtains release information for the driver associated with the current printer. (Deprecated in Mac OS X v10.4. Use `PMPrinterGetDriverReleaseInfo` (page 2193) instead.)

```
OSStatus PMGetDriverReleaseInfo (
    VersRec *release
);
```

Parameters

release

On return, a pointer to a `VersRec` data structure containing the driver's short and long version strings and country code.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
Valid after calling `PMBegin`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`PMCoreDeprecated.h`

PMGetDuplex

Obtains the selected duplex mode.

```
OSStatus PMGetDuplex (
   PMPrintSettings printSettings,
   PMDuplexMode *duplexSetting
);
```

Parameters

printSettings

The print settings object whose duplex mode you want to obtain.

duplexSetting

A pointer to your `PMDuplexMode` variable. On return, the variable contains the duplex mode setting in the current print job. Possible values include:

- `kPMDuplexNone` (one-sided printing)
- `kPMDuplexNoTumble` (two-sided printing)
- `kPMDuplexTumble` (two-sided printing with tumbling)

See "Duplex Modes" (page 2282) for a full description of the duplex mode constants.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
Duplex printing is a print job that prints on both sides of the paper. The Two-Sided printing control is displayed in the Layout pane of the Print dialog.

Availability
Available in Mac OS X v10.4 and later.

Declared In
PMCore.h

PMGetFirstPage

Obtains the number of the first page to be printed.

```
OSStatus PMGetFirstPage (
   PMPrintSettings printSettings,
   UInt32 *first
);
```

Parameters

printSettings

The print settings object whose first page number you want to obtain.

first

A pointer to your UInt32 variable. On return, the variable contains the page number of the first page to print. The default first page number is 1.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
You can use this function to obtain the page number entered by the user in the From field of the Print dialog. If the user selects the All button, the function returns a value of 1. If the user did not enter a value, the function returns the value of the previous call to PMSetFirstPage, if any, or the default value of 1.

Availability
Available in Mac OS X v10.0 and later.

See Also
PMSetFirstPage (page 2254)

Related Sample Code
CarbonSketch

Declared In
PMCore.h

PMGetGrafPtr

Obtains the printing port from an opaque printing context. (Deprecated in Mac OS X v10.4. Use PMSessionGetCGGraphicsContext (page 2230) instead.)

```
OSStatus PMGetGrafPtr (
    PMPrintContext printContext,
    GrafPtr *grafPort
);
```

Parameters

printContext

A PMPrintContext object.

grafPort
On return, a pointer to a `grafPort` defining the current printing port.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
Valid after calling `PMBegin` and creating a printing context.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`PMCoreDeprecated.h`

PMGetIndexedPrinterResolution

Obtains a resolution setting based on an index into the range of settings supported by the current printer. (Deprecated in Mac OS X v10.4. Use `PMPrinterGetIndexedPrinterResolution` (page 2194) instead.)

```
OSStatus PMGetIndexedPrinterResolution (
    UInt32 index,
    PMResolution *res
);
```

Parameters
index
An index into the range of resolution settings supported by the specified printer. Index values begin at 1.

res
On return, the printer resolution setting.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
Valid after calling `PMBegin`. You must first use the `PMGetPrinterResolutionCount` function to obtain the number of resolution settings supported by the current printer.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`PMCoreDeprecated.h`

PMGetJobName

Obtains the name of the print job. (Deprecated in Mac OS X v10.4. Use `PMPrintSettingsGetJobName` (page 2210) instead.)

```
OSStatus PMGetJobName (
   PMPrintSettings printSettings,
   StringPtr name
);
```

Parameters

printSettings

A `PMPrintSettings` object.

name

On return, the name of the print job.

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Discussion

Valid after calling `PMBegin` and creating a print settings object. Before using this function you must call `PMValidatePrintSettings` to ensure that the print settings object is valid.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`PMCoreDeprecated.h`

PMGetJobNameCFString

Obtains the name of the print job. (Deprecated in Mac OS X v10.5. Use `PMPrintSettingsGetJobName` (page 2210) instead.)

```
OSStatus PMGetJobNameCFString (
   PMPrintSettings printSettings,
   CFStringRef *name
);
```

Parameters

printSettings

The print settings object whose job name you want to obtain.

name

A pointer to your `CFStringRef` variable. On return, the variable refers to a string that contains the name of the print job. Despite what its name implies, the function `PMGetJobNameCFString` has Create/Copy semantics which means your application must release the string returned to it.

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

See Also

`PMSetJobNameCFString` (page 2256)

Declared In
PMCoreDeprecated.h

PMGetLanguageInfo

Obtains information about the current printer's imaging language. (Deprecated in Mac OS X v10.4. Use PMPrinterGetLanguageInfo (page 2194) instead.)

```
OSStatus PMGetLanguageInfo (
    PMLanguageInfo *info
);
```

Parameters

info

On return, a pointer to a data structure containing the printer's language level, version and release. The format of the returned data is based on the PostScript language.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
Valid after calling PMBegin. PMGetLanguageInfo is useful for PostScript printers but may be irrelevant for other types of printers.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
PMCoreDeprecated.h

PMGetLastPage

Obtains the number of the last page to be printed.

```
OSStatus PMGetLastPage (
   PMPrintSettings printSettings,
   UInt32 *last
);
```

Parameters

printSettings

The print settings object whose last page number you want to obtain.

last

A pointer to your UInt32 variable. On return, the variable contains the page number of the last page to print.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
You use this function to obtain the page number entered by the user in the To field of the Print dialog. If the user did not enter a value, the function returns the value of the previous call to PMSetLastPage, if any, or a default value.

You should not look for the constant `kPMPrintAllPages`. That constant is used only with the `PMSetLastPage` and `PMSetPageRange` functions to specify a last page. It is not returned by the `PMGetLastPage` function.

Availability
Available in Mac OS X v10.0 and later.

See Also
`PMSetLastPage` (page 2257)

Related Sample Code
CarbonSketch

Declared In
`PMCore.h`

PMGetOrientation

Obtains the current setting for page orientation.

```
OSStatus PMGetOrientation (
   PMPageFormat pageFormat,
   PMOrientation *orientation
);
```

Parameters

`pageFormat`

The page format object whose orientation you want to obtain.

`orientation`

A pointer to your `PMOrientation` variable. On return, the variable contains a constant value indicating the page orientation. Supported values are:

- `kPMPortrait`
- `kPMLandscape`
- `kPMReversePortrait` (supported in Mac OS X v10.5 and later)
- `kPMReverseLandscape`

See "Page Orientation Constants" (page 2283) for a complete description of the page orientation constants.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Availability
Available in Mac OS X v10.0 and later.

See Also
`PMSetOrientation` (page 2257)

Declared In
`PMCore.h`

PMGetPageFormatExtendedData

Obtains extended page format data previously stored by your application.

```
OSStatus PMGetPageFormatExtendedData (
   PMPageFormat pageFormat,
   OSType dataID,
   UInt32 *size,
   void *extendedData
);
```

Parameters

pageFormat

The page format object that contains your extended data.

dataID

A 4-character code that identifies your data. This is typically your application's creator code. If your creator code is outside the ASCII 7-bit character range 0x20–0x7F, you need to use a different 4-character code.

size

A pointer to a value that specifies the size of the buffer you have allocated for the extended page format data. On return, this variable contains the number of bytes read into the buffer or the size of the extended data. You can pass the constant `kPMDontWantSize` if you do not need this information. (See "Data Not Wanted Constants" (page 2279) for more information.)

extendedData

A pointer to a buffer to receive the extended data. Pass the constant `kPMDontWantData` if you do not want to read the data. (See "Data Not Wanted Constants" (page 2279) for more information.)

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Discussion

Your application typically needs to call the function `PMGetPageFormatExtendedData` two times in order to retrieve the extended page format data. The first time, pass the constant `kPMDontWantData` in the parameter *extendedData* to obtain the buffer size required for the extended data. Then allocate the buffer and call the function a second time to read the extended data into your buffer.

If you write a printing dialog extension for your application that stores data in the page format object, you use the function `PMGetPageFormatExtendedData` to retrieve the data associated with it.

Availability

Available in Mac OS X v10.0 and later.

See Also

`PMSetPageFormatExtendedData` (page 2258)

Declared In

`PMCore.h`

PMGetPageFormatPaper

Obtains the paper associated with a page format object.

```
OSStatus PMGetPageFormatPaper (
   PMPageFormat format,
   PMPaper *paper
);
```

Parameters

pageFormat

The page format object whose paper you want to obtain.

paper

A pointer to your `PMPaper` (page 2275) variable. On return, the variable refers to a paper object that represents the paper associated with the specified page format. You should not release the paper object without first retaining it.

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Availability

Available in Mac OS X v10.3 and later.

Declared In

`PMCore.h`

PMGetPageRange

Obtains the valid range of pages that can be printed.

```
OSStatus PMGetPageRange (
   PMPrintSettings printSettings,
   UInt32 *minPage,
   UInt32 *maxPage
);
```

Parameters

printSettings

The print settings object whose page range you want to obtain.

minPage

A pointer to your `UInt32` variable. On return, the variable contains the minimum page number allowed.

maxPage

A pointer to your `UInt32` variable. On return, the variable contains the maximum page number allowed.

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Discussion

The page range returned by the function `PMGetPageRange` is independent of the first and last page values returned by `PMGetFirstPage` (page 2159) and `PMGetLastPage` (page 2162). See `PMSetPageRange` for more information.

Availability

Available in Mac OS X v10.0 and later.

See Also
PMSetPageRange (page 2259)

Declared In
PMCore.h

PMGetPhysicalPageSize

Obtains the size of the imageable area in points, unaffected by rotation, resolution, or scaling. (Deprecated in Mac OS X v10.4. Use PMGetUnadjustedPageRect (page 2170) or examine the paper returned by PMGetPageFormatPaper (page 2164).)

```
OSStatus PMGetPhysicalPageSize (
   PMPageFormat pageFormat,
   PMRect *pageSize
);
```

Parameters

pageFormat

A PMPageFormat object previously created by your application.

pageSize

On return, a rectangle describing the physical page size where your application can draw.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
PMCoreDeprecated.h

PMGetPhysicalPaperSize

Obtains the size of the paper in points, unaffected by rotation, resolution, or scaling. (Deprecated in Mac OS X v10.4. Use PMGetUnadjustedPaperRect (page 2171) or examine the paper returned by PMGetPageFormatPaper (page 2164).)

```
OSStatus PMGetPhysicalPaperSize (
   PMPageFormat pageFormat,
   PMRect *paperSize
);
```

Parameters

pageFormat

A PMPageFormat object previously created by your application.

paperSize

On return, a rectangle describing the physical size of the paper. Units are in 1/72 inch. Thus a 8.5 x 11 sheet of paper returns for its individual components:

top - 0.0

left - 0.0

bottom - 792.0

right - 612.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`PMCoreDeprecated.h`

PMGetPrinterResolution

Obtains the resolution setting for the current printer according to the tag parameter. (Deprecated in Mac OS X v10.4. Use `PMPrinterGetPrinterResolutionCount` (page 2199) and `PMPrinterGetIndexedPrinterResolution` (page 2194) to examine the available printer resolutions.)

```
OSStatus PMGetPrinterResolution (
    PMTag tag,
    PMResolution *res
);
```

Parameters

tag

Specifies the kind of resolution information required.

res

The printer resolution setting.

Return Value
A result code. . The result code `kPMNotImplemented` indicates that the printer driver does not support multiple resolution settings.

Discussion
Valid after calling `PMBegin`.

The following resolution tag constants are recognized:

`kPMMinRange`

The minimum resolution supported by the printer.

`kPMMaxRange`

The maximum resolution supported by the printer.

`kPMMinSquareResolution`

The minimum resolution setting for which the horizontal and vertical resolutions are equal.

`kPMMaxSquareResolution`
The maximum resolution setting for which the horizontal and vertical resolutions are equal.

`kPMDefaultResolution`
The default resolution setting for the printer (typically 72 dpi).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`PMCoreDeprecated.h`

PMGetPrinterResolutionCount

Obtains the number of resolution settings supported by the current printer. (Deprecated in Mac OS X v10.4. Use `PMPrinterGetPrinterResolutionCount` (page 2199) instead.)

```
OSStatus PMGetPrinterResolutionCount (
    UInt32 *count
);
```

Parameters

count
On return, the number of supported printing resolutions.

Return Value
A result code. The result code `kPMNotImplemented` indicates that the printer driver does not support multiple resolution settings.

Discussion
Valid after calling `PMBegin`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`PMCoreDeprecated.h`

PMGetPrintSettingsExtendedData

Obtains extended print settings data previously stored by your application.

```
OSStatus PMGetPrintSettingsExtendedData (
   PMPrintSettings printSettings,
   OSType dataID,
   UInt32 *size,
   void *extendedData
);
```

Parameters

printSettings
The print settings object whose extended data you want to obtain.

dataID

The unique 4-character code of the data to retrieve. This is typically your application's creator code. However, if your creator code is outside the ASCII 7-bit character range 0x20–0x7F, you need to use a different 4-character code.

size

A pointer to a value that specifies the size of the buffer you have allocated for the extended print settings data. On return, this variable contains the number of bytes read into the buffer or the size of the extended data. You can pass the constant `kPMDontWantSize` if you do not need this information. (See "Data Not Wanted Constants" (page 2279) for more information.)

extendedData

A pointer to a buffer to receive the extended data. Pass the constant `kPMDontWantData` if you do not want to read the data. (See "Data Not Wanted Constants" (page 2279) for more information.)

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
Your application typically needs to call `PMGetPrintSettingsExtendedData` two times in order to retrieve the extended print settings data. The first time, pass the constant `kPMDontWantData` in the *extendedData* parameter to obtain the buffer size required for the extended data. Then allocate the buffer and call the function a second time to read the extended data into your buffer.

You may find it easier to use the functions `PMPrintSettingsSetValue` (page 2212) and `PMPrintSettingsGetValue` (page 2210) to store and retrieve user-defined data in a print settings object. If you use these functions, make sure that the custom keys you define for your private data do not conflict with other print settings keys.

Availability
Available in Mac OS X v10.0 and later.

See Also
`PMSetPrintSettingsExtendedData` (page 2261)

Declared In
`PMCore.h`

PMGetResolution

Obtains the current application's drawing resolution. (Deprecated in Mac OS X v10.5. Draw using Quartz 2D and call `CGContextScaleCTM` (page 105) instead.)

```
OSStatus PMGetResolution (
   PMPageFormat pageFormat,
   PMResolution *res
);
```

Parameters

pageFormat

The page format object whose drawing resolution you want to obtain.

res

A pointer to your `PMResolution` (page 2278) structure. On return, the structure contains the drawing resolution of the current application.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
This function obtains the drawing resolution specified in the page format, not the resolution of the current printer. You can use `PMPrinterGetPrinterResolutionCount` (page 2199) and `PMPrinterGetIndexedPrinterResolution` (page 2194) to examine the available printer resolutions.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`PMCoreDeprecated.h`

PMGetScale

Obtains the scaling factor currently applied to the page and paper rectangles.

```
OSStatus PMGetScale (
   PMPageFormat pageFormat,
   double *scale
);
```

Parameters

pageFormat
The page format object whose scaling factor you want to obtain.

scale
A pointer to your double-precision variable. On return, the variable contains the scaling factor expressed as a percentage. For example, a value of 100.0 means 100 percent (that is, no scaling); a value of 50.0 means 50 percent scaling.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Availability
Available in Mac OS X v10.0 and later.

See Also
`PMSetScale` (page 2263)

Declared In
`PMCore.h`

PMGetUnadjustedPageRect

Obtains the imageable area or page rectangle, unaffected by orientation, resolution, or scaling.

```
OSStatus PMGetUnadjustedPageRect (
   PMPageFormat pageFormat,
   PMRect *pageRect
);
```

Parameters

pageFormat

The page format object whose unadjusted page rectangle you want to obtain.

pageRect

A pointer to your `PMRect` (page 2277) data structure. On return, the structure contains the size of the page rectangle, in points. The page rectangle is the area of the page to which an application can draw. The coordinates for the upper-left corner of the page rectangle are (0,0). See *Supporting Printing in Your Carbon Application* for more information on page and paper rectangles.

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`PMCore.h`

PMGetUnadjustedPaperRect

Obtains the paper rectangle, unaffected by rotation, resolution, or scaling.

```
OSStatus PMGetUnadjustedPaperRect (
   PMPageFormat pageFormat,
   PMRect *paperRect
);
```

Parameters

pageFormat

The page format object whose unadjusted paper rectangle you want to obtain.

paperRect

A pointer to your `PMRect` (page 2277) data structure. On return, the structure contains the physical size of the paper, in points. The coordinates of the upper-left corner of the paper rectangle are specified relative to the page rectangle. The coordinates of the upper-left corner of the page rectangle are always (0,0), which means the coordinates of the upper-left corner of the paper rectangle are always negative or (0,0). See *Supporting Printing in Your Carbon Application* for more information on page and paper rectangles.

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`PMCore.h`

PMIsPostScriptDriver

Reports whether the current printer driver supports the PostScript language. (Deprecated in Mac OS X v10.4. Use `PMPrinterIsPostScriptCapable` (page 2201) or `PMPrinterIsPostScriptPrinter` (page 2202) instead.)

```
OSStatus PMIsPostScriptDriver (
    Boolean *isPostScript
);
```

Parameters

isPostScript
Returns `true` if the current printer driver supports PostScript.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
Valid after calling `PMBegin`. In Mac OS X, `PMIsPostScriptDriver` always returns `false`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`PMCoreDeprecated.h`

PMMakeOldPrintRecord

Creates an old-style print record from a `PMPageFormat` and a `PMPrintSettings` object. (Deprecated in Mac OS X v10.4. There is no replacement; old-style print records are obsolete and serve no useful purpose in Mac OS X.)

```
OSStatus PMMakeOldPrintRecord (
    PMPrintSettings printSettings,
    PMPageFormat pageFormat,
    Handle *printRecordHandle
);
```

Parameters

printSettings
A `PMPrintSettings` object.

pageFormat
A `PMPageFormat` object.

printRecordHandle
On return, a handle to a an old-style print record. Your application must dispose of this handle.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
Valid after calling `PMBegin` and creating a page format and print settings object. Use `PMMakeOldPrintRecord` to create a print record to store with your documents for compatibility with pre-Carbon versions of your application. Note that because the page format and print settings objects contain more information than the old-style print record, some settings may be lost in conversion.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`PMCoreDeprecated.h`

PMNewPageFormat

Creates a new `PMPageFormat` object. (Deprecated in Mac OS X v10.4. Use `PMCreatePageFormat` (page 2143) instead.)

```
OSStatus PMNewPageFormat (
    PMPageFormat *pageFormat
);
```

Parameters

pageFormat
On return, an initialized `PMPageFormat` object.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
Valid after calling `PMBegin`. The function `PMNewPageFormat` allocates memory for a new `PMPageFormat` object in your application's memory space. The new page format object is empty until you set its values, or until you call `PMDefaultPageFormat` or `PMValidatePageFormat`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`PMCoreDeprecated.h`

PMNewPrintSettings

Creates a new `PMPrintSettings` object. (Deprecated in Mac OS X v10.4. Use `PMCreatePrintSettings` (page 2144) instead.)

```
OSStatus PMNewPrintSettings (
    PMPrintSettings *printSettings
);
```

Parameters

printSettings
On return, an initialized `PMPrintSettings` object.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
Valid after calling `PMBegin`. The function `PMNewPrintSettings` allocates memory for a new `PMPrintSettings` object in your application's memory space. The new print settings object is empty until you set its values, or until you call `PMDefaultPrintSettings` or `PMValidatePrintSettings`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`PMCoreDeprecated.h`

PMPageFormatCreateDataRepresentation

Creates a data representation of a page format object.

```
OSStatus PMPageFormatCreateDataRepresentation (
    PMPageFormat pageFormat,
    CFDataRef *data,
    PMDataFormat format
);
```

Parameters

pageFormat

The page format object to convert.

data

A pointer to your `CFDataRef` variable. On return, the variable refers to a new Core Foundation data object that contains a representation of the specified page format object in the specified data format. You are responsible for releasing the data object.

format

A constant that specifies the format of the data representation. Supported values are:

- `kPMDataFormatXMLDefault` (compatible with all Mac OS X versions)
- `kPMDataFormatXMLMinimal` (approximately 3-5 times smaller; compatible with Mac OS X v10.5 and later)
- `kPMDataFormatXMLCompressed` (approximately 20 times smaller; compatible with Mac OS X v10.5 and later)

See "Data Representation Formats" (page 2280) for a full description of these formats.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
This function is typically used to convert a page format object into a data representation suitable for storage in a user document. For information about using a Core Foundation data object, see *CFData Reference*.

Before calling this function, you should call the function `PMSessionValidatePageFormat` (page 2248) to make sure the page format object contains valid values.

Availability
Available in Mac OS X v10.5 and later.

See Also
PMPageFormatCreateWithDataRepresentation (page 2175)

Declared In
PMCore.h

PMPageFormatCreateWithDataRepresentation

Creates a page format object from a data representation.

```
OSStatus PMPageFormatCreateWithDataRepresentation (
    CFDataRef data,
    PMPageFormat *pageFormat
);
```

Parameters

data

The data representation of a page format object. The data representation must have been previously created with the function PMPageFormatCreateDataRepresentation (page 2174).

pageFormat

A pointer to your PMPageFormat (page 2275) variable. On return, the variable refers to a new page format object that contains the information stored in the specified data object. You are responsible for releasing the page format object with the function PMRelease (page 2214).

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
This function is typically used to convert a data representation stored in a user document back into a page format object. For information about creating a Core Foundation data object from raw data, see *CFData Reference*.

After calling this function, you should call the function PMSessionValidatePageFormat (page 2248) to make sure the page format object contains valid values.

Availability
Available in Mac OS X v10.5 and later.

See Also
PMPageFormatCreateDataRepresentation (page 2174)

Declared In
PMCore.h

PMPageFormatGetPrinterID

Obtains the identifier of the formatting printer for a page format object.

```
OSStatus PMPageFormatGetPrinterID (
    PMPageFormat pageFormat,
    CFStringRef *printerID
);
```

Parameters

pageFormat

The page format object whose printer identifier you want to obtain.

printerID

A pointer to your `CFStringRef` variable. On return, the variable refers to a Core Foundation string that contains the identifier of the formatting printer for the specified page format object. If the page format object does not have that information, the variable is set to `NULL`. You should not release the string without first retaining it.

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Discussion

Page format objects can be created a number of different ways and some of them do not require a specific printer. If the printer ID is known, the printer is displayed in the Page Setup dialog's Format for pop-up menu. If the printer ID is not known, the default formatting printer is the generic Any Printer. The printing system provides default page and paper sizes for the generic printer.

Availability

Available in Mac OS X v10.5 and later.

Declared In

`PMCore.h`

PMPaperCreate

Creates a paper object. (Deprecated in Mac OS X v10.5. Use `PMPrinterGetPaperList` (page 2198) to find the built-in papers available for a given printer or use `PMPaperCreateCustom` (page 2177) to create a custom paper.)

```
OSStatus PMPaperCreate (
    PMPrinter printer,
    CFStringRef id,
    CFStringRef name,
    double width,
    double height,
    const PMPaperMargins *margins,
    PMPaper *paperP
);
```

Parameters

printer

A printer object for which the paper is appropriate.

id

A unique identifier for this paper.

name

The name to display to the user for this paper.

width
The width of the paper, in points.

height
The height of the paper, in points.

margins
A pointer to a `PMPaperMargins` (page 2276) structure that specifies the unprintable margins of the paper, in points. The four values in the structure specify the top, left, bottom, and right imageable area margins of the paper.

paperP
A pointer to your `PMPaper` (page 2275) variable. On return, the variable refers to a new paper object with the specified attributes. You are responsible for releasing the paper object with the function `PMRelease` (page 2214). The variable is set to `NULL` if the object could not be created.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
This function creates a paper object appropriate for the specified printer. To obtain one of the available built-in paper sizes for a given printer, you should use the function `PMPrinterGetPaperList` (page 2198).

Special Considerations

This function creates a paper object but does not mark it as a custom paper, so it appears to the printing system as if it were a built-in paper. This can be produce unpredictable results, so this function is deprecated.

Availability
Available in Mac OS X v10.3 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`PMCoreDeprecated.h`

PMPaperCreateCustom

Creates a custom paper object.

```
OSStatus PMPaperCreateCustom (
    PMPrinter printer,
    CFStringRef id,
    CFStringRef name,
    double width,
    double height,
    const PMPaperMargins *margins,
    PMPaper *paperP
);
```

Parameters

printer
A printer for which the specified paper size is appropriate.

id
A unique identifier for this custom paper. For example, you could create a UUID string and use it as the unique identifier.

name
The name to display to the user for this custom paper.

width
The width of the paper, in points.

height
The height of the paper, in points.

margins
A pointer to a `PMPaperMargins` (page 2276) structure that specifies the unprintable margins of the paper, in points. The four values in the structure specify the top, left, bottom, and right imageable area margins of the paper.

paperP
A pointer to your `PMPaper` (page 2275) variable. On return, the variable refers to a new custom paper object. You are responsible for releasing the paper object with the function `PMRelease` (page 2214).

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
This function creates a custom paper object appropriate for the specified printer. Custom papers are treated differently than built-in papers by the printing system. To obtain one of the available built-in papers for a given printer, you can use the function `PMPrinterGetPaperList` (page 2198).

Availability
Available in Mac OS X v10.5 and later.

Declared In
`PMCore.h`

PMPaperCreateLocalizedName

Obtains the localized name for a given paper.

```
OSStatus PMPaperCreateLocalizedName (
    PMPaper paper,
    PMPrinter printer,
    CFStringRef *paperName
);
```

Parameters

paper
The paper whose localized name you want to obtain.

printer
The printer for which the localization should be performed.

paperName
A pointer to your `CFStringRef` variable. On return, the variable refers to a Core Foundation string that contains the localized name of the paper. This name is appropriate to display in the user interface. If an error occurs, the variable is set to `NULL`. You are responsible for releasing the string.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
Not all printers have the same way of referring to a given paper. Generally, if you want to obtain the name of a paper, you want to localize the paper name for a particular printer. For example, if you were displaying a list of papers for a given printer, you would want the paper names to be localized for that printer.

Special Considerations

In Mac OS X v10.5 and later, Apple recommends using this function instead of `PMPaperGetName` (page 2180).

Availability
Available in Mac OS X v10.5 and later.

Declared In
`PMCore.h`

PMPaperGetHeight

Obtains the height of the sheet of paper represented by a paper object.

```
OSStatus PMPaperGetHeight (
   PMPaper paper,
   double *paperHeight
);
```

Parameters

paper

The paper whose height you want to obtain.

paperHeight

A pointer to your double-precision variable. On return, the variable contains the height of the specified paper, in points.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Availability
Available in Mac OS X v10.3 and later.

Declared In
`PMCore.h`

PMPaperGetID

Obtains the identifier of a paper object.

```
OSStatus PMPaperGetID (
   PMPaper paper,
   CFStringRef *paperID
);
```

Parameters

paper

The paper whose identifier you want to obtain.

paperID

A pointer to your `CFStringRef` variable. On return, the variable refers to a Core Foundation string containing the unique identifier for this paper. You should not release the string without first retaining it.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Availability
Available in Mac OS X v10.3 and later.

Declared In
`PMCore.h`

PMPaperGetMargins

Obtains the margins describing the unprintable area of the sheet represented by a paper object.

```
OSStatus PMPaperGetMargins (
   PMPaper paper,
   PMPaperMargins *paperMargins
);
```

Parameters

paper

The paper whose margins you want to obtain.

paperMargins

A pointer to your `PMPaperMargins` (page 2276) structure. On return, the structure contains the unprintable margins of the specified paper, in points. The four values in the structure specify the top, left, bottom, and right imageable area margins of the paper.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Availability
Available in Mac OS X v10.3 and later.

Declared In
`PMCore.h`

PMPaperGetName

Obtains the name for a given paper.

```
OSStatus PMPaperGetName (
   PMPaper paper,
   CFStringRef *paperName
);
```

Parameters

paper

The paper whose name you want to obtain.

paperName

A pointer to your `CFStringRef` variable. On return, the variable refers to a Core Foundation string containing the name for this paper. This name identifies the paper in the user interface. You should not release the string without first retaining it.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Special Considerations

This function does not necessarily return a paper name that's localized for a given printer. In Mac OS X v10.5 and later, instead of using this function, Apple recommends using the function `PMPaperCreateLocalizedName` (page 2178).

Availability
Available in Mac OS X v10.3 and later.

Declared In
`PMCore.h`

PMPaperGetPPDPaperName

Obtains the PPD paper name for a given paper.

```
OSStatus PMPaperGetPPDPaperName (
    PMPaper paper,
    CFStringRef *paperName
);
```

Parameters

paper

The paper whose PPD paper name you want to obtain.

paperName

A pointer to your `CFStringRef` variable. On return, the variable refers to a Core Foundation string that contains the PPD paper name for the specified paper. If an error occurs, the variable is set to `NULL`. You should not release the string without first retaining it.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
The Mac OS X printing system uses a PostScript Printer Description (PPD) file to describe a given printer and print queue for that printer. The PPD paper name is the name that uniquely identifies a given paper for the printer to which the paper corresponds. To obtain a list of papers for a given printer, use the function `PMPrinterGetPaperList` (page 2198).

Availability
Available in Mac OS X v10.5 and later.

Declared In
`PMCore.h`

PMPaperGetPrinterID

Obtains the printer ID of the printer to which a given paper corresponds.

```
OSStatus PMPaperGetPrinterID (
    PMPaper paper,
    CFStringRef *printerID
);
```

Parameters

paper

The paper whose printer ID you want to obtain.

printerID

A pointer to your `CFStringRef` variable. On return, the variable refers to a Core Foundation string that contains the printer ID for the specified paper. If an error occurs, the variable is set to `NULL`. You should not release the string without first retaining it.

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Discussion

Not all papers have a printer ID associated with them. If the printer ID is known, the printer is displayed in the Page Setup dialog's Format for pop-up menu. If the printer ID is not known, the default formatting printer is the generic Any Printer. The printing system provides default paper sizes for the generic printer.

Availability

Available in Mac OS X v10.5 and later.

Declared In

`PMCore.h`

PMPaperGetWidth

Obtains the width of the sheet of paper represented by a paper object.

```
OSStatus PMPaperGetWidth (
   PMPaper paper,
   double *paperWidth
);
```

Parameters

paper

The paper whose width you want to obtain.

paperWidth

A pointer to your double-precision variable. On return, the variable contains the width of the specified paper, in points.

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Availability

Available in Mac OS X v10.3 and later.

Declared In

`PMCore.h`

PMPaperIsCustom

Returns a Boolean value indicating whether a specified paper is a custom paper.

```
Boolean PMPaperIsCustom (
    PMPaper paper
);
```

Parameters

paper

The paper you're querying to determine whether it's a custom paper.

Return Value

If `true`, the specified paper is a custom paper; otherwise, `false`.

Discussion

You can create a custom paper with the function `PMPaperCreateCustom` (page 2177).

Availability

Available in Mac OS X v10.5 and later.

Declared In

`PMCore.h`

PMPostScriptBegin

Puts the current driver into PostScript mode, ready to accept PostScript data instead of QuickDraw data. (Deprecated in Mac OS X v10.4. Use `PMPrinterPrintWithFile` (page 2203), `PMPrinterPrintWithProvider` (page 2204), or `PMCGImageCreateWithEPSDataProvider` (page 2139) instead.)

```
OSStatus PMPostScriptBegin ();
```

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Discussion

Valid between calls to `PMBeginPage` and `PMEndPage`. Call `PMIsPostScriptDriver` before calling `PMPostScriptBegin` to ensure that the current driver supports PostScript data.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`PMCoreDeprecated.h`

PMPostScriptData

Passes PostScript data, referenced by a pointer, to the current printer driver. (Deprecated in Mac OS X v10.4. Use `PMPrinterPrintWithFile` (page 2203), `PMPrinterPrintWithProvider` (page 2204), or `PMCGImageCreateWithEPSDataProvider` (page 2139) instead.)

```
OSStatus PMPostScriptData (
    Ptr psPtr,
    Size len
);
```

Parameters

psPtr

A pointer to PostScript data.

len

The number of bytes of PostScript data to pass to the current driver.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
Valid between calls to `PMPostScriptBegin` and `PMPostScriptEnd`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`PMCoreDeprecated.h`

PMPostScriptEnd

Restores the current driver to QuickDraw mode, ready to accept QuickDraw data instead of PostScript data. (Deprecated in Mac OS X v10.4. Use `PMPrinterPrintWithFile` (page 2203), `PMPrinterPrintWithProvider` (page 2204), or `PMCGImageCreateWithEPSDataProvider` (page 2139) instead.)

```
OSStatus PMPostScriptEnd ();
```

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
Valid between calls to `PMBeginPage` and `PMEndPage`. Call `PMPostScriptEnd` to complete a PostScript session started with `PMPostScriptBegin`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`PMCoreDeprecated.h`

PMPostScriptFile

Passes PostScript data, contained in a file, to the current printer driver. (Deprecated in Mac OS X v10.4. Use `PMPrinterPrintWithFile` (page 2203), `PMPrinterPrintWithProvider` (page 2204), or `PMCGImageCreateWithEPSDataProvider` (page 2139) instead.)

```
OSStatus PMPostScriptFile (
    FSSpec *psFile
);
```

Parameters

psFile

A file specification.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
Valid between calls to `PMPostScriptBegin` and `PMPostScriptEnd`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`PMCoreDeprecated.h`

PMPostScriptHandle

Passes PostScript data, referenced by a handle, to the current printer driver. (Deprecated in Mac OS X v10.4. Use `PMPrinterPrintWithFile` (page 2203), `PMPrinterPrintWithProvider` (page 2204), or `PMCGImageCreateWithEPSDataProvider` (page 2139) instead.)

```
OSStatus PMPostScriptHandle (
    Handle psHandle
);
```

Parameters

psHandle

A reference to PostScript data.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
Valid between calls to `PMPostScriptBegin` and `PMPostScriptEnd`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`PMCoreDeprecated.h`

PMPresetCopyName

Obtains the localized name for a preset.

```
OSStatus PMPresetCopyName (
   PMPreset preset,
   CFStringRef *name
);
```

Parameters

preset

The preset object whose localized name you want to obtain. You can use the function `PMPrinterCopyPresets` (page 2189) to obtain the presets for a given printer.

paperID

A pointer to your `CFStringRef` variable. On return, the variable refers to a Core Foundation string containing the localized name of the specified preset. You are responsible for releasing the string.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Availability
Available in Mac OS X v10.3 and later.

Declared In
`PMCore.h`

PMPresetCreatePrintSettings

Creates a print settings object with settings that correspond to a preset.

```
OSStatus PMPresetCreatePrintSettings (
   PMPreset preset,
   PMPrintSession session,
   PMPrintSettings *printSettings
);
```

Parameters

preset

The preset whose settings you want to obtain. You can use the function `PMPrinterCopyPresets` (page 2189) to obtain the presets for a given printer.

session

The session you use to present the Print dialog.

printSettings

A pointer to your `PMPrintSettings` (page 2277) variable. On return, the variable refers to a print settings object with settings that correspond to the specified preset. You are responsible for releasing the print settings object with the function `PMRelease` (page 2214).

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Availability
Available in Mac OS X v10.3 and later.

Declared In
`PMCore.h`

PMPresetGetAttributes

Obtains the attributes of a preset.

```
OSStatus PMPresetGetAttributes (
   PMPreset preset,
   CFDictionaryRef *attributes
);
```

Parameters

preset

The preset whose attributes you want to obtain. You can use the function `PMPrinterCopyPresets` (page 2189) to obtain the presets for a given printer.

attributes

A pointer to your `CFDictionaryRef` variable. On return, the variable refers to a Core Foundation dictionary containing the attributes of the specified preset, or `NULL` if the attributes could not be obtained. For more information about these attributes, see the Discussion. You should not release this dictionary without first retaining it.

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Discussion

A preset has associated with it a dictionary containing the preset identifier, the localized name, and a description of the environment for which the preset is intended. In addition to these standard attributes, the preset you specify may contain additional attributes that reflect custom print settings.

Availability

Available in Mac OS X v10.3 and later.

Declared In

`PMCore.h`

PMPrinterCopyDescriptionURL

Obtains the URL of the description file for a given printer.

```
OSStatus PMPrinterCopyDescriptionURL (
   PMPrinter printer,
   CFStringRef descriptionType,
   CFURLRef *fileURL
);
```

Parameters

printer

The printer whose description file you want to obtain.

descriptionType

A constant that specifies the desired printer description file type. Currently, you must pass the constant `kPMPPDDescriptionType`.

fileURL

A pointer to your `CFURLRef` variable. On return, the variable refers to a Core Foundation URL that specifies the location of the file that contains a description of the specified printer. You are responsible for releasing the URL. If an error occurs, the variable is set to `NULL`.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
You can use this function to locate the PostScript printer description (PPD) file for a printer.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`PMCore.h`

PMPrinterCopyDeviceURI

Obtains the device URI of a given printer.

```
OSStatus PMPrinterCopyDeviceURI (
   PMPrinter printer,
   CFURLRef *deviceURI
);
```

Parameters

printer
The printer whose device URI you want to obtain.

deviceURI
A pointer to your `CFURLRef` variable. On return, the variable refers to a Core Foundation URL that specifies the printer's device URI. You are responsible for releasing the URL. If an error occurs, the variable is set to `NULL`.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
The device URI of a printer describes how to communicate with the device. For some devices, it also includes a unique identifier for the device.

Availability
Available in Mac OS X v10.4 and later.

Related Sample Code
PMPrinterTest

Declared In
`PMCore.h`

PMPrinterCopyHostName

Obtains the name of the server hosting the print queue for a given printer.

```
OSStatus PMPrinterCopyHostName (
    PMPrinter printer,
    CFStringRef *hostNameP
);
```

Parameters

printer

The printer whose print queue host name you want to obtain.

hostNameP

A pointer to your `CFStringRef` variable. On return, the variable refers to a Core Foundation string containing the name of the specified printer's server. You are responsible for releasing the string.

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Discussion

This function is typically used to obtain the name of the computer that hosts a shared printer, possibly for display in a user interface. In Mac OS X v10.5 and later, the typical way that users browse and communicate with a shared printer creates a local print queue and `PMPrinterCopyHostName` for such a print queue will return the name of the local host.

Availability

Available in Mac OS X v10.3 and later.

Declared In

`PMCore.h`

PMPrinterCopyPresets

Obtains a list of print settings presets for a printer.

```
OSStatus PMPrinterCopyPresets (
   PMPrinter printer,
   CFArrayRef *presetList
);
```

Parameters

printer

The printer whose presets you want to obtain.

presetList

A pointer to your `CFArrayRef` variable. On return, the variable refers to a Core Foundation array containing the presets for the specified printer. Each element in the array is an object of type `PMPreset` (page 2276). You are responsible for releasing the array.

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Discussion

A printer may have associated with it a list of preset settings. Each setting is optimized for a particular printing situation. This function returns all of the presets for a given printer. To obtain more information about a particular preset, you can use the function `PMPresetGetAttributes` (page 2187). To create a print settings object that contains the settings of a preset, call `PMPresetCreatePrintSettings` (page 2186).

Availability

Available in Mac OS X v10.3 and later.

Declared In
PMCore.h

PMPrinterCreateFromPrinterID

Creates a printer object from a print queue identifier.

```
PMPrinter PMPrinterCreateFromPrinterID (
   CFStringRef printerID
);
```

Parameters

printerID
The unique identifier of a print queue.

Return Value
A new printer object, or NULL if no print queue is available with the specified identifier. You are responsible for releasing the printer object with the function PMRelease (page 2214).

Discussion
This function is typically used to re-create a printer object using the print queue ID obtained by a call to PMPrinterGetID at an earlier time. If the print queue is deleted after obtaining the ID, this function returns NULL for that ID.

Availability
Available in Mac OS X v10.4 and later.

See Also
PMPrinterGetID (page 2193)

Declared In
PMCore.h

PMPrinterGetCommInfo

Obtains information about the communication channel for a printer.

```
OSStatus PMPrinterGetCommInfo (
   PMPrinter printer,
   Boolean *supportsTransparentP,
   Boolean *supportsEightBitP
);
```

Parameters

printer
The printer whose information you want to obtain.

supportsTransparentP
A pointer to your Boolean variable. On return, true indicates that the communication channel to the specified printer supports bytes in the range 0x0–0x1F; otherwise, false.

supportsEightBitP
A pointer to your Boolean variable. On return, true indicates that the communication channel to the specified printer supports bytes in the range 0x80–0xFF; otherwise, false.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
This function is typically relevant only to PostScript printers. All PostScript printers, regardless of what communications channel is used to send data to them, support data in the range 0x20–0x7F. Many communications channels can support data outside this range. You can use this function to determine whether the communications channel to the specified printer also supports bytes in the ranges 0x0–0x1F and 0x80–0xFF.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`PMCore.h`

PMPrinterGetDescriptionURL

Obtains a reference to the specified printer's description file. (Deprecated in Mac OS X v10.4. Use `PMPrinterCopyDescriptionURL` (page 2187) instead.)

```
OSStatus PMPrinterGetDescriptionURL (
   PMPrinter printer,
   CFStringRef descriptionType,
   CFURLRef *fileURL
);
```

Parameters

printer
The printer whose description file you want to obtain.

descriptionType
A Core Foundation string that specifies the type of description file for the selected printer. Currently, there is only one type defined—`kPMPPDDescriptionType`.

fileURL
A pointer to your `CFURLRef` variable. On return, the variable refers to a URL for the printer's description file. In spite of the name, the function `PMPrinterGetDescriptionURL` has Create/Copy semantics which means the caller must release the returned URL if it is not `NULL` and the result code `noErr` is returned.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
You can use this function to obtain a reference to the PostScript printer description (PPD) file for a PostScript printer.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`PMCoreDeprecated.h`

PMPrinterGetDeviceURI

Obtains a copy of a printer's device URI. (Deprecated in Mac OS X v10.4. Use `PMPrinterCopyDeviceURI` (page 2188) instead.)

```
OSStatus PMPrinterGetDeviceURI (
   PMPrinter printer,
   CFURLRef *deviceURI
);
```

Parameters

printer

The printer whose device URI you want to obtain.

deviceURI

A pointer to your `CFURLRef` variable. On return, the variable refers to a URI for the location of the printer device. In spite of the name, this function has Create/Copy semantics which means the caller must release the returned URL if it is not `NULL` and the result code `noErr` is returned.

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Availability

Available in Mac OS X v10.2 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`PMCoreDeprecated.h`

PMPrinterGetDriverCreator

Obtains the creator of the driver associated with the specified printer.

```
OSStatus PMPrinterGetDriverCreator (
   PMPrinter printer,
   OSType *creator
);
```

Parameters

printer

The printer whose driver creator you want to obtain.

creator

On return, the 4-byte creator code of the driver (for example, `'APPL'` for an Apple printer driver).

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Discussion

This function is not recommended because it makes your application driver-dependent.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`PMCore.h`

PMPrinterGetDriverReleaseInfo

Obtains version information for the driver associated with the specified printer.

```
OSStatus PMPrinterGetDriverReleaseInfo (
   PMPrinter printer,
   VersRec *release
);
```

Parameters

printer

The printer whose driver version you want to obtain.

release

A pointer to your `VersRec` data structure. On return, the structure contains the driver's short and long version strings and country code.

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Discussion

This function is not recommended because it makes your application driver-dependent. If you do use this function, you must call it between the creation and release of a printing session. See the function `PMCreateSession` (page 2145).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`PMCore.h`

PMPrinterGetID

Returns the unique identifier of a printer.

```
CFStringRef PMPrinterGetID (
   PMPrinter printer
);
```

Parameters

printer

The printer whose identifier you want to obtain.

Return Value

The identifier of the specified printer. You should not release the string without first retaining it. If the specified printer is not valid, this function returns `NULL`.

Discussion

You can use the function `PMPrinterGetID` to capture information about a printer for later use. To create a printer object from a printer ID returned by this function, use the function `PMPrinterCreateFromPrinterID` (page 2190).

Availability

Available in Mac OS X v10.2 and later.

Related Sample Code

PMPrinterTest

Declared In
PMCore.h

PMPrinterGetIndexedPrinterResolution

Obtains a resolution setting based on an index into the range of settings supported by the specified printer.

```
OSStatus PMPrinterGetIndexedPrinterResolution (
   PMPrinter printer,
   UInt32 index,
   PMResolution *resolutionP
);
```

Parameters

printer
The printer whose resolution you want to obtain.

index
An index into the range of resolution settings supported by the specified printer. Index values begin at 1.

res
A pointer to your PMResolution (page 2278) data structure. On return, the structure contains the printer resolution setting associated with the index value.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
You must call this function between the creation and release of a printing session. Before you call this function, you must call the function PMPrinterGetPrinterResolutionCount (page 2199) to obtain the number of resolution settings supported by the specified printer.

Availability
Available in Mac OS X v10.0 and later.

Declared In
PMCore.h

PMPrinterGetLanguageInfo

Obtains information about the imaging language for the specified printer.

```
OSStatus PMPrinterGetLanguageInfo (
   PMPrinter printer,
   PMLanguageInfo *info
);
```

Parameters

printer
The printer whose imaging language information you want to obtain.

info

A pointer to your `PMLanguageInfo` (page 2274) data structure. On return, the structure contains the printer's language level, version, and release information. The format of the returned data uses the syntax of the PostScript language.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
The function `PMPrinterGetLanguageInfo` is useful only for PostScript printers. You must call this function between the creation and release of a printing session.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`PMCore.h`

PMPrinterGetLocation

Returns the location of a printer.

```
CFStringRef PMPrinterGetLocation (
   PMPrinter printer
);
```

Parameters

printer

The printer whose location you want to obtain.

Return Value
The location of the specified printer. You should not release the string without first retaining it. If the printer is not valid, this function returns `NULL`.

Discussion
The location of a printer is specified when a user creates a print queue for the printer. In some cases, the printing system automatically determines the location. For example, the location may be set to "Local Zone". The user creating the print queue can also set the location.

Availability
Available in Mac OS X v10.2 and later.

Related Sample Code
PMPrinterTest

Declared In
`PMCore.h`

PMPrinterGetMakeAndModelName

Obtains the manufacturer and model name of the specified printer.

```
OSStatus PMPrinterGetMakeAndModelName (
   PMPrinter printer,
   CFStringRef *makeAndModel
);
```

Parameters

printer

The printer whose manufacturer and model name you want to obtain.

makeAndModel

A pointer to your `CFStringRef` variable. On return, the variable refers to a Core Foundation string containing the manufacturer and model name of the specified printer. You should not release the string without first retaining it. If an error occurs, the variable is set to `NULL`.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Availability
Available in Mac OS X v10.2 and later.

Related Sample Code
PMPrinterTest

Declared In
`PMCore.h`

PMPrinterGetMimeTypes

Obtains a list of MIME content types supported by a printer using the specified print settings.

```
OSStatus PMPrinterGetMimeTypes (
   PMPrinter printer,
   PMPrintSettings settings,
   CFArrayRef *mimeTypes
);
```

Parameters

printer

The printer whose supported MIME types you want to obtain.

settings

The print settings for the print job. The print settings object contains the job destination, which affects the available types. This parameter may be `NULL`.

mimeTypes

A pointer to your `CFArrayRef` variable. On return, the variable refers to a Core Foundation array containing the MIME types supported by the specified printer. Each element in the array is a Core Foundation string. You should not release the array without first retaining it.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
This function retrieves the types of data that can be submitted to a printer with the specified print settings; for example, `application/pdf`. This function is typically used in conjunction with the function `PMPrinterPrintWithFile` (page 2203).

Availability
Available in Mac OS X v10.3 and later.

Declared In
PMCore.h

PMPrinterGetName

Returns the human-readable name of a printer.

```
CFStringRef PMPrinterGetName (
   PMPrinter printer
);
```

Parameters

printer

The printer whose name you want to obtain.

Return Value
The name of the specified printer. This name identifies the printer in the user interface. You should not release the string without first retaining it.

Availability
Available in Mac OS X v10.2 and later.

Related Sample Code
PMPrinterTest

Declared In
PMCore.h

PMPrinterGetOutputResolution

Obtains the printer hardware output resolution for the specified print settings.

```
OSStatus PMPrinterGetOutputResolution (
    PMPrinter printer,
    PMPrintSettings printSettings,
    PMResolution *resolutionP
);
```

Parameters

printer

The printer whose output resolution you want to obtain.

printSettings

The print settings you want to use.

resolutionP

A pointer to your PMResolution (page 2278) structure. On return, the structure contains the output resolution of the specified printer in pixels per inch.

Return Value
A result code. If the resolution cannot be reliably determined, this function returns an error.

Discussion
Some printers allow programmatic control of their hardware output resolution on a print job basis. The hardware resolution is determined by the combination of printer and print settings used for the print job. This function returns the best guess as to what printer resolution setting will be used for the destination print job.

Most applications do not need to use this function because they draw the same content regardless of the destination device. For those few applications that do adjust their drawing based on the output device, they should only do so when the print job destination is `kPMDestinationPrinter` or `kPMDestinationFax`. You can use the function `PMSessionGetDestinationType` to determine the destination for a print job.

This function should be used after displaying the Print dialog to the user so that it correctly reflects changes in print settings performed prior to printing.

Availability
Available in Mac OS X v10.5 and later.

See Also
`PMPrinterSetOutputResolution` (page 2205)

Declared In
`PMCore.h`

PMPrinterGetPaperList

Obtains the list of papers available for a printer.

```
OSStatus PMPrinterGetPaperList (
   PMPrinter printer,
   CFArrayRef *paperList
);
```

Parameters

printer
The printer whose paper list you want to obtain.

paperList
A pointer to your `CFArrayRef` variable. On return, the variable refers to a Core Foundation array containing the paper list for the specified printer. Each element in the array is an object of type `PMPaper` (page 2275). You should not release the array without first retaining it.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
This function obtains a list of the papers that a given printer claims to support. The paper list does not include any custom paper sizes that may be available.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`PMCore.h`

PMPrinterGetPrinterResolution

Obtains a resolution setting for the specified printer. (Deprecated in Mac OS X v10.5. Use `PMPrinterGetPrinterResolutionCount` (page 2199) and `PMPrinterGetIndexedPrinterResolution` (page 2194) to examine the available printer resolutions.)

```
OSStatus PMPrinterGetPrinterResolution (
   PMPrinter printer,
   PMTag tag,
   PMResolution *res
);
```

Parameters

printer

The printer whose resolution you want to obtain.

tag

A tag that specifies the kind of resolution information you want to obtain (minimum, maximum, default, and so forth). See "Tag Constants" (page 2295) for a description of the constants you can pass in this parameter.

res

A pointer to your `PMResolution` (page 2278) data structure. On return, the structure contains the resolution setting associated with the tag value.

Return Value

A result code. The result code `kPMNotImplemented` indicates that the printer driver does not support multiple resolution settings.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`PMCoreDeprecated.h`

PMPrinterGetPrinterResolutionCount

Obtains the number of resolution settings supported by the specified printer.

```
OSStatus PMPrinterGetPrinterResolutionCount (
   PMPrinter printer,
   UInt32 *countP
);
```

Parameters

printer

The printer whose number of resolution settings you want to obtain.

count

A pointer to your `UInt32` variable. On return, the variable contains the number of resolutions that are supported for the specified printer.

Return Value

A result code. The result code `kPMNotImplemented` indicates that the printer driver does not support multiple resolution settings.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`PMCore.h`

PMPrinterGetState

Obtains the current state of the print queue for a printer.

```
OSStatus PMPrinterGetState (
   PMPrinter printer,
   PMPrinterState *state
);
```

Parameters

printer

The printer whose queue state you want to obtain.

state

A pointer to your `PMPrinterState` variable. On return, the variable contains a constant that indicates the current state of the print queue for the specified printer. Supported values are:

- `kPMPrinterIdle` (queue is idle)
- `kPMPrinterProcessing` (queue is processing a job)
- `kPMPrinterStopped` (queue is stopped)

See "Print Queue States" (page 2294) for a complete description of these constants.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Availability
Available in Mac OS X v10.2 and later.

Related Sample Code
PMPrinterTest

Declared In
`PMCore.h`

PMPrinterIsDefault

Returns a Boolean value indicating whether a printer is the default printer for the current user.

```
Boolean PMPrinterIsDefault (
   PMPrinter printer
);
```

Parameters

printer

The printer you're querying to determine whether it is the default printer.

Return Value
If `true`, the specified printer is the default printer for the current user; otherwise, `false`.

Discussion
The default printer is the printer selected by default in the Print dialog.

Availability
Available in Mac OS X v10.2 and later.

Related Sample Code
PMPrinterTest

Declared In
`PMCore.h`

PMPrinterIsFavorite

Returns a Boolean value indicating whether a printer is in the user's list of favorite printers.

```
Boolean PMPrinterIsFavorite (
   PMPrinter printer
);
```

Parameters

printer
The printer you're looking for in the favorite printer list.

Return Value
If `true`, the specified printer is in the user's list of favorite printers; otherwise, `false`.

Availability
Available in Mac OS X v10.2 and later.

Related Sample Code
PMPrinterTest

Declared In
`PMCore.h`

PMPrinterIsPostScriptCapable

Returns a Boolean value indicating whether a printer is PostScript capable.

```
Boolean PMPrinterIsPostScriptCapable (
   PMPrinter printer
);
```

Parameters

printer
The printer you're querying to determine whether it's PostScript capable.

Return Value
If `true`, the specified printer is a PostScript capable printer; otherwise, `false`.

Discussion
A printer that is PostScript capable is not necessarily a PostScript printer. The Mac OS X printing system can render PostScript content on non-PostScript printers.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`PMCore.h`

PMPrinterIsPostScriptPrinter

Determines whether a printer is a PostScript printer.

```
OSStatus PMPrinterIsPostScriptPrinter (
    PMPrinter printer,
    Boolean *isPSPrinter
);
```

Parameters

printer
The printer you're querying to determine whether it's a PostScript printer.

isPSPrinter
A pointer to your Boolean variable. On return, `true` indicates that the specified printer is a PostScript printer; otherwise, `false`.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
A printer is a PostScript printer if the printer driver takes PostScript directly.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`PMCore.h`

PMPrinterIsRemote

Indicates whether a printer is hosted by a remote print server.

```
OSStatus PMPrinterIsRemote (
    PMPrinter printer,
    Boolean *isRemoteP
);
```

Parameters

printer
The printer you're querying to determine whether it is hosted by a remote print server.

isRemoteP
A pointer to your Boolean variable. On return, `true` indicates that the printer is hosted by a remote print server; otherwise, `false`.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
If this function returns `true`, the printer is hosted by a remote print server and the printer can be considered a shared printer.

In Mac OS X, the typical way that users create a print queue for a shared printer is by browsing. Print queues for shared printers that are created by browsing are marked as remote queues, and `PMPrinterIsRemote` returns `true` for such printers. However, expert users can create a local queue for a remote printer manually, and such a printer does not appear to be remote printer.

Whether a printer is remote is derived from the CUPS printer-type attribute for the print queue.

Availability
Available in Mac OS X v10.3 and later.

Related Sample Code
PMPrinterTest

Declared In
`PMCore.h`

PMPrinterPrintWithFile

Submits a print job to a specified printer using a file that contains print data.

```
OSStatus PMPrinterPrintWithFile (
   PMPrinter printer,
   PMPrintSettings settings,
   PMPageFormat format,
   CFStringRef mimeType,
   CFURLRef fileURL
);
```

Parameters

printer
The destination printer.

settings
The print settings for the print job.

format
The physical page size and orientation with which the document should be printed. This parameter can be `NULL`.

mimeType
The MIME type of the data to be printed. If this parameter is `NULL`, the MIME type will be determined automatically. You can obtain a list of the MIME types supported by a given printer using the function `PMPrinterGetMimeTypes` (page 2196).

fileURL
The URL of the file that supplies the print data.

Return Value
A result code. See "Core Printing Result Codes" (page 2298). If the specified printer cannot handle the file's MIME type, a non-zero error code is returned.

Discussion
This function can fail if the specified printer cannot handle the file's MIME type. Use the function `PMPrinterGetMimeTypes` (page 2196) to check whether a MIME type is supported.

Availability
Available in Mac OS X v10.3 and later.

See Also
`PMPrinterPrintWithProvider` (page 2204)

Declared In
`PMCore.h`

PMPrinterPrintWithProvider

Submits a print job to a specified printer using a Quartz data provider to obtain the print data.

```
OSStatus PMPrinterPrintWithProvider (
   PMPrinter printer,
   PMPrintSettings settings,
   PMPageFormat format,
   CFStringRef mimeType,
   CGDataProviderRef provider
);
```

Parameters

printer
The destination printer.

settings
The print settings for the print job.

format
The physical page size and orientation with which the document should be printed. This parameter can be `NULL`.

mimeType
The MIME type of the data to be printed. This parameter cannot be `NULL`. If you want automatic typing, use the function `PMPrinterPrintWithFile` (page 2203) instead. You can obtain a list of the MIME types supported by a given printer using the function `PMPrinterGetMimeTypes` (page 2196).

provider
The data provider that supplies the print data.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
This function can fail if the specified printer cannot handle the data provider's MIME type. Use the function `PMPrinterGetMimeTypes` (page 2196) to check whether a MIME type is supported.

Special Considerations

In Mac OS X v10.4 and earlier, this function is not implemented and returns the error code –1 when called. You can write your print data to a file and use `PMPrinterPrintWithFile` instead.

Availability
Available in Mac OS X v10.3 and later.

See Also
PMPrinterPrintWithFile (page 2203)

Declared In
PMCore.h

PMPrinterSetDefault

Sets the default printer for the current user.

```
OSStatus PMPrinterSetDefault (
    PMPrinter printer
);
```

Parameters

printer
The printer to set as the default printer.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
The default printer is the printer selected by default in the Print dialog.

This function is rarely used. Most applications do not set the default printer directly, but instead let the user choose the default printer in the Print & Fax preference pane of System Preferences.

Availability
Available in Mac OS X v10.5 and later.

Declared In
PMCore.h

PMPrinterSetOutputResolution

Sets the print settings to reflect the specified printer hardware output resolution.

```
OSStatus PMPrinterSetOutputResolution (
    PMPrinter printer,
    PMPrintSettings printSettings,
    const PMResolution *resolutionP
);
```

Parameters

printer
The printer whose output resolution you want to change.

printSettings
The print settings object used for the print job.

resolutionP
A pointer to a PMResolution (page 2278) structure that specifies the desired resolution in pixels per inch.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
Some printers allow programmatic control of their hardware output resolution on a print job basis. The hardware resolution is determined by the combination of printer and print settings used for the print job. This function configures the print settings to the closest resolution setting that can be used for the destination print job. Note that not all printers allow control of their resolution setting.

This function is rarely used. Most applications do not set the output resolution but instead use the setting supplied by the user in the Print dialog.

Availability
Available in Mac OS X v10.5 and later.

See Also
`PMPrinterGetOutputResolution` (page 2197)

Declared In
`PMCore.h`

PMPrinterWritePostScriptToURL

Converts an input file of the specified MIME type to printer-ready PostScript for a destination printer.

```
OSStatus PMPrinterWritePostScriptToURL (
    PMPrinter printer,
    PMPrintSettings settings,
    PMPageFormat format,
    CFStringRef mimeType,
    CFURLRef sourceFileURL,
    CFURLRef destinationFileURL
);
```

Parameters

printer
The destination printer for which printer-ready PostScript will be generated.

settings
The print settings for the print job.

format
The page format specifying the physical page size and orientation on which the document should be printed.

mimeType
The MIME type of the file to be printed. If you pass `NULL`, the file is typed automatically. You can obtain a list of the MIME types supported by a given printer using the function `PMPrinterGetMimeTypes` (page 2196).

sourceFileURL
A URL specifying the input file to be converted to printer-ready PostScript data. Only file-based URLs are supported.

destinationFileURL
A URL specifying the destination file to be created. If the file already exists, it will be overwritten. Only file-based URLs are supported.

Return Value
A result code. If the printing system cannot convert the input MIME type to PostScript, this function fails and returns an error.

Discussion
This function is synchronous; the conversion of the input file to PostScript is performed before the function returns. This can take a significant amount of time for longer documents. You may want to perform this operation on a thread other than the main application thread or fork a separate process for this purpose.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`PMCore.h`

PMPrintSettingsCopyAsDictionary

Creates a dictionary that contains the settings in a print settings object.

```
OSStatus PMPrintSettingsCopyAsDictionary (
    PMPrintSettings printSettings,
    CFDictionaryRef *settingsDictionary
);
```

Parameters

printSettings
The print settings object with the desired settings.

settingsDictionary
A pointer to your `CFDictionaryRef` variable. On return, the variable refers to a Core Foundation dictionary that contains the settings in the specified print settings object. Some of the keys in this dictionary are currently defined in `PMTicket.h`; other keys are user-defined. You are responsible for releasing the dictionary. If an error occurs, the variable is set to `NULL`.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
Most developers have no need to use this function. However, one way this function might be useful would be to enumerate all the entries in a print settings object for inspection.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`PMCore.h`

PMPrintSettingsCopyKeys

Obtains the keys for items in a print settings object.

```
OSStatus PMPrintSettingsCopyKeys (
    PMPrintSettings printSettings,
    CFArrayRef *settingsKeys
);
```

Parameters

printSettings

The print settings object with the desired keys.

settingsKeys

A pointer to your `CFArrayRef` variable. On return, the variable refers to a Core Foundation array that contains the keys for items in the specified print settings object. Each of these keys may be passed to the function `PMPrintSettingsGetValue` to obtain a value. You are responsible for releasing the array. If an error occurs, the variable is set to `NULL`.

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Discussion

This function provides an array of the keys in a print settings object. You could get the values for the keys in the array with `PMPrintSettingsGetValue` (page 2210), or use the keys to look up the values in the dictionary returned by `PMPrintSettingsCopyAsDictionary` (page 2207).

Availability

Available in Mac OS X v10.5 and later.

Declared In

`PMCore.h`

PMPrintSettingsCreateDataRepresentation

Creates a data representation of a print settings object.

```
OSStatus PMPrintSettingsCreateDataRepresentation (
    PMPrintSettings printSettings,
    CFDataRef *data,
    PMDataFormat format
);
```

Parameters

printSettings

The print settings object to convert.

data

A pointer to your `CFDataRef` variable. On return, the variable refers to a new Core Foundation data object that contains a representation of the specified print settings object in the specified data format. You are responsible for releasing the data object.

format

A constant that specifies the format of the data representation. Supported values are:

- `kPMDataFormatXMLDefault` (compatible with all Mac OS X versions)
- `kPMDataFormatXMLMinimal` (approximately 3-5 times smaller; compatible with Mac OS X v10.5 and later)
- `kPMDataFormatXMLCompressed` (approximately 20 times smaller; compatible with Mac OS X v10.5 and later)

See "Data Representation Formats" (page 2280) for a full description of these formats.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
This function is typically used to convert a print settings object into a data representation suitable for storage in a user document. For information about using a Core Foundation data object, see *CFData Reference*.

Before calling this function, you should call the function `PMSessionValidatePrintSettings` (page 2249) to make sure the print settings object contains valid values.

Apple recommends that you do not reuse the print settings information if the user prints the document again. The information supplied by the user in the Print dialog should pertain to the document only while the document prints, so there is no need to save the print settings object.

Availability
Available in Mac OS X v10.5 and later.

See Also
`PMPrintSettingsCreateWithDataRepresentation` (page 2209)

Declared In
`PMCore.h`

PMPrintSettingsCreateWithDataRepresentation

Creates a print settings object from a data representation.

```
OSStatus PMPrintSettingsCreateWithDataRepresentation (
    CFDataRef data,
    PMPrintSettings *printSettings
);
```

Parameters

data

The data representation of a print settings object. The data representation must have been previously created with the function `PMPrintSettingsCreateDataRepresentation` (page 2208).

printSettings

A pointer to your `PMPrintSettings` (page 2277) variable. On return, the variable refers to a new print settings object that contains the printing information stored in the specified data object. You are responsible for releasing the print settings object with the function `PMRelease` (page 2214).

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
This function is typically used to convert a data representation stored in a user document back into a print settings object. For information about creating a Core Foundation data object from raw data, see *CFData Reference*.

After calling this function, you should call the function `PMSessionValidatePrintSettings` (page 2249) to make sure the print settings object contains valid values.

Availability
Available in Mac OS X v10.5 and later.

See Also
`PMPrintSettingsCreateDataRepresentation` (page 2208)

Declared In
`PMCore.h`

PMPrintSettingsGetJobName

Obtains the name of a print job.

```
OSStatus PMPrintSettingsGetJobName (
   PMPrintSettings printSettings,
   CFStringRef *name
);
```

Parameters

printSettings
The print settings for the current print job.

name
A pointer to your `CFStringRef` variable. On return, the variable refers to a Core Foundation string containing the name of the print job. This is the same job name you set using the function `PMPrintSettingsSetJobName` (page 2211). You should not release the string without first retaining it.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Availability
Available in Mac OS X v10.4 and later.

See Also
`PMPrintSettingsSetJobName` (page 2211)

Declared In
`PMCore.h`

PMPrintSettingsGetValue

Obtains the value of a setting in a print settings object.

```
OSStatus PMPrintSettingsGetValue (
    PMPrintSettings printSettings,
    CFStringRef key,
    CFTypeRef *value
);
```

Parameters

printSettings

The print settings object you want to access.

key

A string constant that specifies the key for the desired setting. Some keys are currently defined in `PMTicket.h`; other keys are user-defined.

value

A pointer to your Core Foundation variable. On return, the variable refers to a Core Foundation object that corresponds to the specified key. If no corresponding object exists, the variable is set to `NULL`.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
This function, together with the function `PMPrintSettingsSetValue`, makes it possible to access print settings directly.

Availability
Available in Mac OS X v10.4 and later.

See Also
`PMPrintSettingsSetValue` (page 2212)

Declared In
`PMCore.h`

PMPrintSettingsSetJobName

Specifies the name of a print job.

```
OSStatus PMPrintSettingsSetJobName (
   PMPrintSettings printSettings,
   CFStringRef name
);
```

Parameters

printSettings

The print settings object whose job name you want to set.

name

The new name for the print job.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
If you're using the Print dialog, you should call this function before presenting the dialog. You are strongly encouraged to create a print job name that's meaningful to the user and use this function to set the name; this produces the best user experience. If you do not specify the print job name, the printing system creates an appropriate job name for you.

If you call this function after initiating a print job, the change is ignored for the current job.

Availability
Available in Mac OS X v10.4 and later.

See Also
`PMPrintSettingsGetJobName` (page 2210)

Declared In
`PMCore.h`

PMPrintSettingsSetValue

Stores the value of a setting in a print settings object.

```
OSStatus PMPrintSettingsSetValue (
    PMPrintSettings printSettings,
    CFStringRef key,
    CFTypeRef value,
    Boolean locked
);
```

Parameters

printSettings
The print settings object you want to update.

key
A string constant that specifies the key for the desired setting. Some keys are currently defined in `PMTicket.h`; other keys are user-defined.

value
A Core Foundation object that corresponds to the specified key. If you pass `NULL`, any existing setting for the specified key is removed.

locked
If `true`, the item being set should be locked; otherwise, `false`. Currently, you should always pass `false`.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
This function makes it possible to add, change, or remove print settings directly. Print settings are stored as key-value pairs. The keys are Core Foundation strings and the corresponding values are Core Foundation objects.

You can use this function to store user-defined data in a print settings object. You should make sure that the custom keys you define for your private data do not conflict with any other keys in the object. Each data item you store needs to be a Core Foundation object. You can use the function `PMPrintSettingsGetValue` to retrieve your private data.

If you call this function after initiating a print job (for example, by calling `PMSessionBeginCGDocument`), the change is ignored for the current job.

Availability
Available in Mac OS X v10.4 and later.

See Also
`PMPrintSettingsGetValue` (page 2210)

Declared In
`PMCore.h`

PMPrintSettingsToOptions

Converts print settings into a CUPS options string.

```
OSStatus PMPrintSettingsToOptions (
    PMPrintSettings settings,
    char **options
);
```

Parameters

settings
The print settings to convert.

options
A pointer to a C string. On return, a CUPS options string describing the print settings, or `NULL` if the print settings could not be converted. The function allocates storage for the string. You are responsible for freeing the storage.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
This function creates a CUPS options string that captures the data in the specified print settings object. In Mac OS X v10.5 and later, Apple recommends that you use the `PMPrintSettingsToOptionsWithPrinterAndPageFormat` (page 2213) function instead.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`PMCore.h`

PMPrintSettingsToOptionsWithPrinterAndPageFormat

Converts print settings and page format data into a CUPS options string for a specified printer.

```
OSStatus PMPrintSettingsToOptionsWithPrinterAndPageFormat (
    PMPrintSettings settings,
    PMPrinter printer,
    PMPageFormat pageFormat,
    char **options
);
```

Parameters

settings

The print settings to convert.

printer

The printer to use for converting the print settings. This parameter must not be `NULL`.

pageFormat

The page format to convert, or `NULL` to specify default page format data.

options

A pointer to a C string. On return, a CUPS option string with the specified print settings and page format data, or `NULL` if the data could not be converted. The function allocates storage for the string. You are responsible for freeing the storage.

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Discussion

This function creates a CUPS options string for the destination printer that captures the data in the specified print settings and page format objects. For example, you could pass this string to the function `PMWorkflowSubmitPDFWithOptions` (page 2271) to submit a PDF file for workflow processing. You could also use the options string to run a CUPS filter directly.

Availability

Available in Mac OS X v10.5 and later.

Declared In

`PMCore.h`

PMRelease

Releases a printing object by decrementing its reference count.

```
OSStatus PMRelease (
   PMObject object
);
```

Parameters

object

The printing object you want to release.

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Discussion

Your application should use the `PMRelease` function to release any printing objects it creates or retains. When an object's reference count reaches 0, the object is deallocated.

For example, to terminate a printing session created with the function `PMCreateSession` (page 2145), pass the associated `PMPrintSession` (page 2277) object to `PMRelease`. To release printing objects created with the functions `PMCreatePageFormat` (page 2143) and `PMCreatePrintSettings` (page 2144), pass the associated `PMPageFormat` and `PMPrintSettings` objects to `PMRelease`.

Availability
Available in Mac OS X v10.0 and later.

See Also
`PMRetain` (page 2215)

Related Sample Code
CarbonSketch

Declared In
`PMCore.h`

PMRetain

Retains a printing object by incrementing its reference count.

```
OSStatus PMRetain (
   PMObject object
);
```

Parameters

object
The printing object you want to retain.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
You should retain a printing object when you receive it from elsewhere (that is, you did not create or copy it) and you want it to persist. If you retain a printing object, you are responsible for releasing it. (See `PMRelease`.) You can use the function `PMRetain` to increment a printing object's reference count so that multiple threads or routines can use the object without the risk of another thread or routine deallocating the object.

Availability
Available in Mac OS X v10.0 and later.

See Also
`PMRelease` (page 2214)

Declared In
`PMCore.h`

PMServerCreatePrinterList

Creates a list of printers available to a print server.

```
OSStatus PMServerCreatePrinterList (
   PMServer server,
   CFArrayRef *printerList
);
```

Parameters

server

The print server whose printers you want to obtain. To specify the local print server, pass the constant `kPMServerLocal`. Currently, you may specify only the local print server.

printerList

A pointer to your `CFArrayRef` variable. On return, the variable refers to a Core Foundation array containing the printers available to the specified print server. Each element in the array is a `PMPrinter` object. You are responsible for releasing the array.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Availability
Available in Mac OS X v10.2 and later.

Related Sample Code
PMPrinterTest

Declared In
`PMCore.h`

PMServerLaunchPrinterBrowser

Launches the printer browser to browse the printers available for a print server.

```
OSStatus PMServerLaunchPrinterBrowser (
    PMServer server,
    CFDictionaryRef options
);
```

Parameters

server

The print server to browse. Pass `kPMServerLocal` to specify the local print server. Currently, you may specify only the local print server.

options

This parameter is reserved for future use. At the present time, pass `NULL`. Passing `NULL` presents the printer browser in the default fashion.

Return Value
A result code. See "Core Printing Result Codes" (page 2298). If you specify a server whose printers cannot be browsed, this function returns the error code `kPMInvalidParameter`.

Discussion
This function displays the standard printer browser to allow the user to create a new print queue.

Availability
Available in Mac OS X v10.5 and later.

Declared In
PMCore.h

PMSessionBeginCGDocumentNoDialog

Begins a print job that draws into a Quartz graphics context and suppresses the printing status dialog.

```
OSStatus PMSessionBeginCGDocumentNoDialog (
   PMPrintSession printSession,
   PMPrintSettings printSettings,
   PMPageFormat pageFormat
);
```

Parameters

printSession
The printing session that provides a context for the new print job.

printSettings
The print settings to use for the new print job.

pageFormat
The page format to use for the new print job.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
This function starts a print job that draws directly into a Quartz graphics context and should be called within your application's print loop. This function is similar to the function PMSessionBeginCGDocument except that the printing status dialog is suppressed.

You must call PMSessionBeginCGDocumentNoDialog between the creation and release of a printing session. See the function PMCreateSession (page 2145). If you present a printing dialog before you call PMSessionBeginCGDocumentNoDialog, when calling this function you should use the same PMPrintSession (page 2277) object you used to present the dialog.

Before you call PMSessionBeginCGDocumentNoDialog, you should call PMSessionValidatePrintSettings (page 2249) and PMSessionValidatePageFormat (page 2248) to make sure the specified print settings and page format objects are updated and valid. After you call PMSessionBeginCGDocumentNoDialog, if you call a function that changes the specified print settings or page format object, the change is ignored for the current print job.

During the print job, the caller cannot obtain a Quickdraw graphics port for the printing session but can only obtain a Quartz graphics context. As a result, this function should be used in conjunction with PMSessionGetCGGraphicsContext (page 2230) instead of PMSessionGetGraphicsContext (page 2234).

This function must be called before its corresponding End function (PMSessionEndDocumentNoDialog (page 2227)). If the function PMSessionBeginCGDocumentNoDialog returns noErr, you must later call the End function, even if errors occur within the scope of the Begin and End functions.

The printing system automatically handles printing multiple copies. Your application does not need to perform any tasks other than specifying the number of copies in the printing session.

Availability
Available in Mac OS X v10.4 and later.

Declared In
PMCore.h

PMSessionBeginDocumentNoDialog

Begins a print job that, by default, draws into a QuickDraw graphics port, and suppresses the printing status dialog. (Deprecated in Mac OS X v10.5. Use PMSessionBeginCGDocumentNoDialog (page 2217) instead.)

```
OSStatus PMSessionBeginDocumentNoDialog (
   PMPrintSession printSession,
   PMPrintSettings printSettings,
   PMPageFormat pageFormat
);
```

Parameters

printSession
The printing session that provides a context for the new print job.

printSettings
The print settings to use for the new print job.

pageFormat
The page format to use for the new print job.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
The function PMSessionBeginDocumentNoDialog starts a print job and should be called within your application's print loop. This function is similar to the function PMSessionBeginDocument except that the printing status dialog is suppressed.

You must call this function between the creation and release of a printing session. See the function PMCreateSession (page 2145). If you present a printing dialog before you call PMSessionBeginDocumentNoDialog, when calling this function you should use the same PMPrintSession (page 2277) object you used to present the dialog.

Before you call PMSessionBeginDocumentNoDialog, you should call PMSessionValidatePrintSettings (page 2249) and PMSessionValidatePageFormat (page 2248) to make sure the specified print settings and page format objects are updated and valid. After you call PMSessionBeginDocumentNoDialog, if you call a function that changes the specified print settings or page format object, the change is ignored for the current print job.

This function must be called before its corresponding End function (PMSessionEndDocumentNoDialog (page 2227)). If the function PMSessionBeginDocumentNoDialog returns noErr, you must call the End function, even if errors occur within the scope of the Begin and End functions.

The printing system automatically handles printing multiple copies. Your application does not need to perform any tasks other than specifying the number of copies in the printing session.

Special Considerations

In Mac OS X v10.4 and later, Apple recommends using the function PMSessionBeginCGDocumentNoDialog (page 2217) instead of this function. QuickDraw is deprecated and your application should be using Quartz 2D for its rendering.

Availability
Available in Mac OS X v10.2 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`PMCoreDeprecated.h`

PMSessionBeginPageNoDialog

Starts a new page for printing in the specified printing session and suppresses the printing status dialog.

```
OSStatus PMSessionBeginPageNoDialog (
    PMPrintSession printSession,
    PMPageFormat pageFormat,
    const PMRect *pageFrame
);
```

Parameters

printSession
The printing session that provides a context for the print job.

pageFormat
The page format for the new page. If you pass `NULL`, the printing system uses the page format you passed to `PMSessionBeginCGDocumentNoDialog` (page 2217).

pageFrame
You should pass `NULL`, as this parameter is currently unsupported.

Return Value
A result code. If the user cancels the print job, this function returns `kPMCancel`.

Discussion
This function is similar to the function `PMSessionBeginPage` except that the function `PMSessionBeginPageNoDialog` suppresses the printing status dialog. You must call this function between the creation and release of a printing session. See the function `PMCreateSession` (page 2145). You must call the functions `PMSessionBeginPageNoDialog` and `PMSessionEndPageNoDialog` (page 2228) within the scope of calls to the `Begin` print job function (`PMSessionBeginCGDocumentNoDialog` (page 2217)) and the `End` print job function (`PMSessionEndDocumentNoDialog` (page 2227)).

You should call the function `PMSessionError` (page 2229) immediately before you call `PMSessionBeginPageNoDialog`. If `PMSessionError` returns an error, then you should not call the function `PMSessionBeginPageNoDialog`. Because `PMSessionBeginPage` also initializes the printing graphics context, your application should not make assumptions about the state of the context (for example, the current font) between successive pages. After each call to `PMSessionBeginPageNoDialog`, your application should call `PMSessionGetCGGraphicsContext` (page 2230) to obtain the current printing context.

If the function `PMSessionBeginPageNoDialog` returns `noErr`, you must later call the function `PMSessionEndPageNoDialog`, even if errors occur within the scope of `PMSessionBeginPageNoDialog` and `PMSessionEndPageNoDialog`.

The printing system automatically handles printing multiple copies. Your application does not need to perform any tasks other than specifying the number of copies in the printing session.

Special Considerations

Prior to Mac OS X v10.5, the *pageFormat* parameter is ignored. In Mac OS X v10.5 and later, the printing system supports multiple orientations within a print job. When you call this function and supply a page format, the orientation specified in the page format is used for the current page. Other settings in the page format, such as paper size or scaling, are ignored.

Availability

Available in Mac OS X v10.2 and later.

Declared In

PMCore.h

PMSessionConvertOldPrintRecord

Creates new page format and print settings objects from an old-style print record created for the classic Printing Manager. (Deprecated in Mac OS X v10.4. There is no replacement; during the transition from Mac OS 9 to Mac OS X, this function facilitated the migration of print records saved in documents created in Mac OS 9, but the function no longer serves any useful purpose in Mac OS X.)

```
OSStatus PMSessionConvertOldPrintRecord (
   PMPrintSession printSession,
   Handle printRecordHandle,
   PMPrintSettings *printSettings,
   PMPageFormat *pageFormat
);
```

Parameters

printSession

The current printing session.

printRecordHandle

A handle to an old-style print record created by the classic Printing Manager. You are responsible for disposing of the handle.

printSettings

On return, a print settings object that contains values converted from the print record. You are responsible for releasing the print settings object with the function PMRelease (page 2214).

pageFormat

On return, a page format object that contains values converted from the print record. You are responsible for releasing the page format object with the function PMRelease (page 2214).

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Discussion

You must call this function between the creation and release of a printing session. See the function PMCreateSession (page 2145).

You can use PMSessionConvertOldPrintRecord to create page format and print settings objects from old-style print records stored in documents created by pre-Carbon versions of your application. You should validate the page format and print settings objects returned to you by calling the functions PMSessionValidatePageFormat and PMSessionValidatePrintSettings. Note that perfect translation between the old and new style objects is not achievable.

In Mac OS X, the function assumes the print record to be converted is a LaserWriter 8 print record.

Special Considerations

If you need to convert a Mac OS 9 print record into data you can use in Mac OS X, you should extract the page size data from the print record and use the function `PMCreatePageFormatWithPMPaper` (page 2144) to create a `PMPageFormat` object that corresponds to that data.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`PMCoreDeprecated.h`

PMSessionCopyDestinationFormat

Obtains the destination format for a print job.

```
OSStatus PMSessionCopyDestinationFormat (
   PMPrintSession printSession,
   PMPrintSettings printSettings,
   CFStringRef *destFormatP
);
```

Parameters

printSession

The printing session that provides a context for the print job.

printSettings

The print settings object for the print job whose destination format you want to obtain.

destFormatP

A pointer to your `CFStringRef` variable. On return, the variable refers to a Core Foundation string that contains the destination format for the print job. You are responsible for releasing the string. Currently, there are two possible values: `kPMDocumentFormatPDF` or `kPMDocumentFormatPostScript`.

If an error occurs, the variable is set to `NULL`. If the function executes without error and the variable is set to `NULL`, the print job is set to use the default destination format.

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Discussion

You must call this function between the creation and release of a printing session. See the function `PMCreateSession` (page 2145).

Availability

Available in Mac OS X v10.1 and later.

Declared In

`PMCore.h`

PMSessionCopyDestinationLocation

Obtains a destination location for a print job.

```
OSStatus PMSessionCopyDestinationLocation (
   PMPrintSession printSession,
   PMPrintSettings printSettings,
   CFURLRef *destLocationP
);
```

Parameters

printSession

The printing session that provides a context for the print job.

printSettings

The print settings for the print job whose destination location you want to obtain.

destLocationP

A pointer to your `CFURLRef` variable. On return, the variable refers to a Core Foundation URL that specifies the destination location of the print job. You are responsible for releasing the URL. If `NULL` is returned and the function executes without error (result code is `noErr`), the print job uses the default destination location for the current destination type. If an error occurs, the variable is set to `NULL`.

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Discussion

You must call this function between the creation and release of a printing session. See the function `PMCreateSession` (page 2145).

Some destination types define a specific kind of destination location for a print job. For example, the destination type `kPMDestinationFile` uses a file system URL to specify where a new file should be created for the print job's output.

Availability

Available in Mac OS X v10.1 and later.

Declared In

`PMCore.h`

PMSessionCopyOutputFormatList

Obtains an array of destination formats supported by the current print destination.

```
OSStatus PMSessionCopyOutputFormatList (
   PMPrintSession printSession,
   PMDestinationType destType,
   CFArrayRef *documentFormatP
);
```

Parameters

printSession

The printing session that provides a context for the print job. The printer associated with this session is queried for the MIME types it supports.

destType

A destination type that specifies the destination for which you want to obtain valid destination formats. See "Destination Types" (page 2281) for a list of the possible destination types a print job can have.

documentFormatP

A pointer to your `CFArrayRef` variable. On return, the variable refers to a Core Foundation array that contains a list of destination formats that can be generated for the current print destination. See "Document Format Strings" (page 2282) for a list of some of the output formats that can be returned.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
You must call this function between the creation and release of a printing session. See the function `PMCreateSession` (page 2145).

Availability
Available in Mac OS X v10.1 and later.

Declared In
`PMCore.h`

PMSessionCreatePageFormatList

Obtains a list of page format objects, each of which describes a paper size available on the specified printer.

```
OSStatus PMSessionCreatePageFormatList (
    PMPrintSession printSession,
    PMPrinter printer,
    CFArrayRef *pageFormatList
);
```

Parameters

printSession

The current printing session.

printer

The printer whose list of page sizes you want to enumerate.

pageFormatList

A pointer to your `CFArrayRef` variable. On return, the variable refers to a Core Foundation array that contains the page format (`PMPageFormat`) objects associated with the specified printer. You are responsible for releasing the array. Each page format object describes a paper size available for the specified printer. If the function fails, then on return the array is `NULL`.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
You must call this function between the creation and release of a printing session. See the function `PMCreateSession` (page 2145).

You can use this function to find the available sheet sizes (and the imageable area for them) for a given printer. After you obtain the page format list, you can call the function `PMGetUnadjustedPaperRect` (page 2171) for each page format object in the list to obtain the sheet rectangle size. Once you find the paper size you want, call `PMGetUnadjustedPageRect` (page 2170) to obtain the imageable area for that paper size.

Availability
Available in Mac OS X v10.1 and later.

Declared In
PMCore.h

PMSessionCreatePrinterList

Creates a list of printers available in the specified printing session.

```
OSStatus PMSessionCreatePrinterList (
   PMPrintSession printSession,
   CFArrayRef *printerList,
   CFIndex *currentIndex,
   PMPrinter *currentPrinter
);
```

Parameters

printSession
The printing session whose printer list you want to obtain.

printerList
A pointer to your CFArrayRef variable. On return, the variable refers to a Core Foundation array containing a list of printers available in the specified printing session. Each element in the array is a Core Foundation string that contains a printer's name as shown in the user interface. You are responsible for releasing the array.

currentIndex
A pointer to your CFIndex variable. On return, the variable contains a value specifying where the current printer is in the printer list.

currentPrinter
A pointer to your PMPrinter (page 2276) variable. On return, the variable refers to a printer object that represents the current printer. You should not release the printer object without first retaining it. If the printer is the generic printer, the variable is set to NULL.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
You must call this function between the creation and release of a printing session. See the function PMCreateSession (page 2145).

You can call the function PMSessionCreatePrinterList to obtain a valid printer name to pass to the function PMSessionSetCurrentPrinter.

Special Considerations

In Mac OS X v10.2 and later, Apple recommends using the function PMServerCreatePrinterList (page 2215) instead. PMServerCreatePrinterList doesn't require a PMSession object; it can be called at any time. It also works directly with PMPrinter objects.

Availability
Available in Mac OS X v10.1 and later.

See Also
PMServerCreatePrinterList (page 2215)

Declared In
PMCore.h

PMSessionDefaultPageFormat

Assigns default parameter values to a page format object used in the specified printing session.

```
OSStatus PMSessionDefaultPageFormat (
   PMPrintSession printSession,
   PMPageFormat pageFormat
);
```

Parameters

printSession

The printing session for the specified page format object.

pageFormat

The page format object to which you want to assign default values.

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Discussion

You must call the function `PMSessionDefaultPageFormat` between the creation and release of the printing session. See the function `PMCreateSession` (page 2145).

Availability

Available in Mac OS X v10.0 and later.

Related Sample Code

CarbonSketch

Declared In

`PMCore.h`

PMSessionDefaultPrintSettings

Assigns default parameter values to a print settings object for the specified printing session.

```
OSStatus PMSessionDefaultPrintSettings (
   PMPrintSession printSession,
   PMPrintSettings printSettings
);
```

Parameters

printSession

The printing session for the specified print settings object.

printSettings

The print settings object to which you want to assign default values.

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Discussion

You must call the function `PMSessionDefaultPrintSettings` between the creation and release of a printing session. See the function `PMCreateSession` (page 2145).

Availability

Available in Mac OS X v10.0 and later.

Related Sample Code
CarbonSketch

Declared In
`PMCore.h`

PMSessionDisableColorSync

Disables use of a custom ColorSync profile previously enabled by the function `PMSessionEnableColorSync` (page 2226). (Deprecated in Mac OS X v10.5. There is no replacement; draw using Quartz 2D instead.)

```
OSStatus PMSessionDisableColorSync (
   PMPrintSession printSession
);
```

Parameters

printSession

The printing session whose page-specific ColorSync profile you want to disable.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
You must call the `PMSessionDisableColorSync` function between the creation and release of a printing session. See the function `PMCreateSession` (page 2145). You must call this function within the scope of calls to the functions `PMSessionBeginPage` and `PMSessionEndPage`.

The function `PMSessionDisableColorSync` applies only to the current page. The function is useful only if the graphics context is QuickDraw and the current port is the printing port.

Special Considerations

This function is deprecated because QuickDraw is deprecated. When drawing with Quartz, the current stroke and fill color space and the color space associated with an image are used to characterize color. Quartz provides ways to use ColorSync profiles to create color spaces, so you can characterize color using ColorSync simply by drawing with Quartz.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`PMCoreDeprecated.h`

PMSessionEnableColorSync

Enables use of a custom ColorSync profile previously set by the function `PMSetProfile` (page 2262). (Deprecated in Mac OS X v10.5. There is no replacement; draw using Quartz 2D instead.)

```
OSStatus PMSessionEnableColorSync (
   PMPrintSession printSession
);
```

Parameters

printSession

The printing session whose page-specific ColorSync profile you want to enable.

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Discussion

You must call this function between the creation and release of a printing session. See the function `PMCreateSession` (page 2145). You must call this function within the scope of calls to the functions `PMSessionBeginPage` and `PMSessionEndPage`.

The function `PMSessionEnableColorSync` applies only to the current page. The function is useful only if the graphics context is QuickDraw and the current port is the printing port.

Special Considerations

This function is deprecated because QuickDraw is deprecated. When drawing with Quartz, the current stroke and fill color space and the color space associated with an image are used to characterize color. Quartz provides ways to use ColorSync profiles to create color spaces, so you can characterize color using ColorSync simply by drawing with Quartz.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`PMCoreDeprecated.h`

PMSessionEndDocumentNoDialog

Ends a print job started by calling the function `PMSessionBeginCGDocumentNoDialog` (page 2217) or `PMSessionBeginDocumentNoDialog` (page 2218).

```
OSStatus PMSessionEndDocumentNoDialog (
   PMPrintSession printSession
);
```

Parameters

printSession

The current printing session. On return, the printing session is no longer valid; however, you must still call the function `PMRelease` (page 2214) to release the object.

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Discussion

This function is similar to the function `PMSessionEndDocument` except that the printing status dialog is suppressed.

This function is used to end a print job, and it should be called within your application's print loop after the call to the function `PMSessionEndPageNoDialog` and before releasing the printing session. The same printing session that is created by the function `PMCreateSession` for the Print dialog should be used for the print loop.

The function `PMSessionEndDocumentNoDialog` must be called after its corresponding `Begin` function (`PMSessionBeginCGDocumentNoDialog` (page 2217) or `PMSessionBeginDocumentNoDialog` (page 2218)). If the `Begin` function returns `noErr`, the function `PMSessionEndDocument` must be called, even if errors occur within the scope of the `Begin` and `End` functions. You should not call `PMSessionEndDocumentNoDialog` if the `Begin` function returns an error.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`PMCore.h`

PMSessionEndPageNoDialog

Indicates the end of drawing the current page for the specified printing session.

```
OSStatus PMSessionEndPageNoDialog (
   PMPrintSession printSession
);
```

Parameters

printSession
The printing session that provides a context for the print job.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
This function is similar to the function `PMSessionEndPage` except that the printing status dialog is suppressed.

You must call this function between the creation and release of a printing session. See the function `PMCreateSession` (page 2145). You must call the functions `PMSessionBeginPageNoDialog` and `PMSessionEndPageNoDialog` within the scope of calls to the `Begin` print job function (`PMSessionBeginCGDocumentNoDialog` (page 2217)) and the `End` print job function (`PMSessionEndDocumentNoDialog` (page 2227)).

If the function `PMSessionBeginPageNoDialog` returns `noErr`, you must later call the function `PMSessionEndPageNoDialog`, even if errors occur within the scope of `PMSessionBeginPageNoDialog` and `PMSessionEndPageNoDialog`. You should not call `PMSessionEndPageNoDialog` if `PMSessionBeginPageNoDialog` returns an error.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`PMCore.h`

PMSessionError

Obtains the result code for any error returned by the printing session.

```
OSStatus PMSessionError (
   PMPrintSession printSession
);
```

Parameters

printSession

The printing session whose last error you want to obtain.

Return Value

A result code. See "Core Printing Result Codes" (page 2298). The constant `kPMCancel` indicates the user canceled the current print job.

Discussion

You must call this function between the creation and release of a printing session. See the function `PMCreateSession` (page 2145).

The `PMSessionError` function returns the last printing session error, not the last error from a printing function (`PMxxx`). Because most printing functions return a result code, the `PMSessionError` function is not required for general error checking. However, you can use `PMSessionError` in your print loop to determine if the user cancels the current print job or if any other errors occur during printing that are not explicitly returned by one of the other calls. For example, if the user clicks the Cancel button in the status dialog or presses Command-period on the keyboard, this function returns the constant `kPMCancel`. If this or any other error is encountered during the print loop, your application should call the appropriate functions (for example, `PMSessionEndPage` and `PMSessionEndDocument`) to exit the print loop before your application reports the error.

Availability

Available in Mac OS X v10.0 and later.

Related Sample Code

CarbonSketch

Declared In

`PMCore.h`

PMSessionGeneral

Maintains compatibility with the `PrGeneral` function in the classic Printing Manager. (Deprecated in Mac OS X v10.4. Use `PMPrinterGetCommInfo` (page 2190) instead.)

```
OSStatus PMSessionGeneral (
   PMPrintSession printSession,
   Ptr pData
);
```

Parameters

printSession

The printing session whose data you want to obtain.

pData

A pointer to a `PrGeneral` data structure.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
The function `PMSessionGeneral` is valid for the printing session passed to the function. In Mac OS X, the function `PMSessionGeneral` makes an attempt to get the requested data if the opcode is `getPSInfoOp`. Otherwise the result code `kPMNotImplemented` is returned.

For more information about using the function `PMSessionGeneral`, see *Supporting Printing in Your Carbon Application*.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`PMCoreDeprecated.h`

PMSessionGetCGGraphicsContext

Obtains the Quartz graphics context for the current page in a printing session.

```
OSStatus PMSessionGetCGGraphicsContext (
   PMPrintSession printSession,
   CGContextRef *context
);
```

Parameters

printSession
The printing session whose Quartz graphics context you want to obtain.

context
A pointer to your `CGContextRef` (page 137) variable. On return, the variable refers to the Quartz graphics context for the current page in the specified printing session. The context's origin is at the lower-left corner of the sheet of paper, not the imageable area. You should not release the context without first retaining it. The context is valid only for the current page; you should not retain it beyond the end of the page.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
If you're using Quartz 2D to draw the content for a print job, after each call to `PMSessionBeginPage` you should call `PMSessionGetCGGraphicsContext` to obtain the Quartz graphics context for the current page. Note that before you can use the function `PMSessionGetCGGraphicsContext`, you must have called `PMSessionBeginCGDocument` or `PMSessionBeginCGDocumentNoDialog` (page 2217) instead of `PMSessionBeginDocument` or `PMSessionBeginDocumentNoDialog` (page 2218).

Availability
Available in Mac OS X v10.4 and later.

Declared In
`PMCore.h`

PMSessionGetCurrentPrinter

Obtains the current printer associated with a printing session.

```
OSStatus PMSessionGetCurrentPrinter (
   PMPrintSession printSession,
   PMPrinter *currentPrinter
);
```

Parameters

printSession

The printing session whose printer you want to obtain.

currentPrinter

A pointer to your PMPrinter (page 2276) variable. On return, the variable refers to the printer associated with the specified printing session. The printer object is valid as long as the printing session is valid or the current printer hasn't changed. You should not release this object without first retaining it.

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Discussion

You must call this function between the creation and release of a printing session. See the function PMCreateSession (page 2145).

Availability

Available in Mac OS X v10.0 and later.

See Also

PMSessionSetCurrentPMPrinter (page 2241)

Declared In

PMCore.h

PMSessionGetDataFromSession

Obtains application-specific data previously stored in a printing session object.

```
OSStatus PMSessionGetDataFromSession (
   PMPrintSession printSession,
   CFStringRef key,
   CFTypeRef *data
);
```

Parameters

printSession

The printing session whose data you want to obtain.

key

The key that uniquely identifies the data to be retrieved. You specify this key when you store the data using the function PMSessionSetDataInSession (page 2242).

data

A pointer to your CFTypeRef variable. On return, the variable refers to the data retrieved from the printing session.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
You must call this function between the creation and release of a printing session. See the function `PMCreateSession` (page 2145).

Availability
Available in Mac OS X v10.0 and later.

See Also
`PMSessionSetDataInSession` (page 2242)

Declared In
`PMCore.h`

PMSessionGetDestinationType

Obtains the output destination for a print job.

```
OSStatus PMSessionGetDestinationType (
   PMPrintSession printSession,
   PMPrintSettings printSettings,
   PMDestinationType *destTypeP
);
```

Parameters

printSession

The printing session that provides a context for the print job. This must be the same printing session used for the Print dialog. The printing session contains the preview setting, which can override the destination type in the print settings.

printSettings

The print settings for the print job whose destination you want to obtain.

destTypeP

A pointer to your `PMDestinationType` variable. On return, the variable contains the destination type for the specified print job. Possible values include:

- `kPMDestinationPrinter` (output to a printer)
- `kPMDestinationFile` (output to a file)
- `kPMDestinationFax` (output to a fax)
- `kPMDestinationPreview` (output to print preview)
- `kPMDestinationProcessPDF` (output to a PDF workflow option)

See "Destination Types" (page 2281) for a complete description of the destination type constants.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
You must call this function between the creation and release of a printing session. See the function `PMCreateSession` (page 2145).

All of the destination types are stored in the print settings object except for `kPMDestinationPreview`, which is stored in the printing session object. If the destination type is set as preview, the preview setting overrides the destination set in the print settings object.

Availability
Available in Mac OS X v10.1 and later.

Declared In
`PMCore.h`

PMSessionGetDocumentFormatGeneration

Obtains the spool file formats that can be generated for the specified printing session. (Deprecated in Mac OS X v10.4. If you're drawing using Quartz 2D instead of QuickDraw, use `PMSessionBeginCGDocument` or `PMSessionBeginCGDocumentNoDialog` (page 2217); for submitting PostScript data, use `PMPrinterPrintWithFile` (page 2203) or `PMPrinterPrintWithProvider` (page 2204); to draw EPS data, use `PMCGImageCreateWithEPSDataProvider` (page 2139).)

```
OSStatus PMSessionGetDocumentFormatGeneration (
   PMPrintSession printSession,
   CFArrayRef *docFormats
);
```

Parameters

`printSession`
The printing session whose spool file formats you want to obtain.

`docFormats`
A pointer to your `CFArrayRef` variable. On return, the variable refers to a Core Foundation array that contains the MIME types for the available spool file formats. Each element in the array is a Core Foundation string. Despite what its name implies, the function `PMSessionGetDocumentFormatGeneration` has Create/Copy semantics which means you are responsible for releasing the array.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
You must call the function `PMSessionGetDocumentFormatGeneration` between the creation and release of a printing session. See the function `PMCreateSession` (page 2145). You should call `PMSessionGetDocumentFormatGeneration` only after the Print dialog is dismissed.

The function `PMSessionGetDocumentFormatGeneration` determines the spool file formats that the specific print job supports. Spool file formats are represented by MIME types. The Mac OS X print spooler supports PDF and PICT + PS. The default spool file format is PDF. PICT + PS is supported only for printing to a PostScript printer.

Special Considerations

The PICT + PS spool file format is not available on Intel-based systems.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

See Also
PMSessionSetDocumentFormatGeneration (page 2244)

Declared In
PMCoreDeprecated.h

PMSessionGetDocumentFormatSupported

Obtains the spool file formats that are accepted by the current printer driver. (Deprecated in Mac OS X v10.4. Use PMPrinterPrintWithFile (page 2203), PMPrinterPrintWithProvider (page 2204), or PMCGImageCreateWithEPSDataProvider (page 2139) instead.)

```
OSStatus PMSessionGetDocumentFormatSupported (
   PMPrintSession printSession,
   CFArrayRef *docFormats,
   UInt32 limit
);
```

Parameters

printSession
The current printing session.

docFormats
On return, an array of CFString values containing MIME types specifying the spool file formats supported by the current printer driver. See "Document Format Strings" for a description of possible return values.

limit
The maximum number of supported document formats to be returned.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
Valid within the context of a printing session.

Spool file formats are represented by MIME types. In Mac OS X, printer modules may support a wide range of spool file formats. The first item in the list of supported spool file formats is the default for the current printer driver.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
PMCoreDeprecated.h

PMSessionGetGraphicsContext

Obtains the graphics context for the current page in a printing session. (Deprecated in Mac OS X v10.5. Use PMSessionGetCGGraphicsContext (page 2230) instead.)

```
OSStatus PMSessionGetGraphicsContext (
   PMPrintSession printSession,
   CFStringRef graphicsContextType,
   void **graphicsContext
);
```

Parameters

printSession

The printing session whose current graphics context you want to obtain.

graphicsType

The desired graphics context type. This parameter is currently ignored.

graphicsContext

On return, a reference to the current graphics context. The graphics context returned is the one last set by a call to the function `PMSessionSetDocumentFormatGeneration` or the default (QuickDraw) if there was no call to the function. You must typecast the context to an appropriate graphics type, either `grafPtr` or `CGContextRef` (page 137).

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Discussion

You must call this function between the creation and release of a printing session. See the function `PMCreateSession` (page 2145). You must also call the function `PMSessionGetGraphicsContext` within the scope of the functions `PMSessionBeginPage` and `PMSessionEndPage`.

In Mac OS X v10.3 and earlier, you should call this function for each page you draw for a print job. After each call to the function `PMSessionBeginPage` your application should call `PMSessionGetGraphicsContext` to obtain the current graphics context. If that context is a QuickDraw context, then set the drawing port to this port by calling the QuickDraw `SetPort` function. See the discussion of the function `PMSessionBeginPage` for more information.

Special Considerations

In Mac OS X v10.4 and later, Apple recommends using the function `PMSessionGetCGGraphicsContext` (page 2230) instead of this function. QuickDraw is deprecated and your application should be using Quartz 2D for its rendering.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Related Sample Code

CarbonSketch

Declared In

`PMCoreDeprecated.h`

PMSessionIsDocumentFormatSupported

Reports whether the current printer driver supports a specified spool file format. (Deprecated in Mac OS X v10.4. Use `PMPrinterPrintWithFile` (page 2203), `PMPrinterPrintWithProvider` (page 2204), or `PMCGImageCreateWithEPSDataProvider` (page 2139) instead.)

```
OSStatus PMSessionIsDocumentFormatSupported (
   PMPrintSession printSession,
   CFStringRef docFormat,
   Boolean *supported
);
```

Parameters

printSession

The current printing session.

docFormat

A spool file format represented by a MIME type.

supported

Returns `true` if the spool file format is supported by the current printer driver.

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Discussion

Valid within the context of a printing session.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`PMCoreDeprecated.h`

PMSessionMakeOldPrintRecord

Creates an old-style print record from page format and print settings objects. (Deprecated in Mac OS X v10.4. There is no replacement; old-style print records are obsolete and serve no useful purpose in Mac OS X.)

```
OSStatus PMSessionMakeOldPrintRecord (
   PMPrintSession printSession,
   PMPrintSettings printSettings,
   PMPageFormat pageFormat,
   Handle *printRecordHandle
);
```

Parameters

printSession

The current printing session.

printSettings

A print settings object. To create a print settings object you can call the function `PMCreatePrintSettings` (page 2144) and then call the function `PMSessionDefaultPrintSettings` (page 2225) to initialize the print settings object to default values.

pageFormat

A page format object. To create a page format object you can call the function `PMCreatePageFormat` (page 2143) and then call the function `PMSessionDefaultPageFormat` (page 2225) to initialize the page format object to default values.

printRecordHandle
On return, a handle to an old-style print record. You are responsible for disposing of the handle.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
You must call this function between the creation and release of a printing session. See the function `PMCreateSession` (page 2145).

You can use `PMSessionMakeOldPrintRecord` to create an old-style print record to store with your documents for compatibility with pre-Carbon versions of your application. Note that because the page format and print settings objects contain more information than the old print record, some settings may be lost in the conversion. That is, perfect translation between the old and new style objects is not achievable.

In Mac OS X, the function always creates a LaserWriter 8 compatible print record.

Special Considerations

The proper way to keep page format information for use in Mac OS X is with a flattened `PMPageFormat` object. Typically applications don't keep print settings with a document but if that is appropriate for a given application, the proper way to do so is to use a flattened `PMPrintSettings` object.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`PMCoreDeprecated.h`

PMSessionPostScriptBegin

Puts the current printer driver into PostScript mode, ready to accept PostScript data instead of QuickDraw data. (Deprecated in Mac OS X v10.4. Use `PMPrinterPrintWithFile` (page 2203), `PMPrinterPrintWithProvider` (page 2204), or `PMCGImageCreateWithEPSDataProvider` (page 2139) instead.)

```
OSStatus PMSessionPostScriptBegin (
   PMPrintSession printSession
);
```

Parameters

printSession
The current printing session.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
You must call the function `PMSessionPostScriptBegin` between the creation and release of a printing session. See the function `PMCreateSession` (page 2145). You must also call the function within the scope of the functions `PMSessionBeginPage` and `PMSessionEndPage`.

To ensure that the current printer driver supports PostScript data, call `PMSessionGetDocumentFormatGeneration` before you call the function `PMSessionPostScriptBegin`. Check the list of supported spool file formats. If PICT + PS is one of them, select that format by calling the function `PMSessionSetDocumentFormatGeneration`. The function `PMSessionSetDocumentFormatGeneration` must be called before you call `PMSessionBeginDocument`.

The function `PMSessionPostScriptBegin` is not useful unless the current port is the printing port. The function returns `true` if the document format is not PICT + PS.

Special Considerations

The PICT + PS spool file format is not available on Intel-based systems.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`PMCoreDeprecated.h`

PMSessionPostScriptData

Passes PostScript data, referenced by a pointer, to the current printer driver. (Deprecated in Mac OS X v10.4. Use `PMPrinterPrintWithFile` (page 2203), `PMPrinterPrintWithProvider` (page 2204), or `PMCGImageCreateWithEPSDataProvider` (page 2139) instead.)

```
OSStatus PMSessionPostScriptData (
   PMPrintSession printSession,
   Ptr psPtr,
   Size len
);
```

Parameters

printSession

The current printing session.

psPtr

A pointer to the PostScript data you want to pass to the current printer driver.

len

The number of bytes of PostScript data.

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Discussion

You must call this function between the creation and release of a printing session. See the function `PMCreateSession` (page 2145). Typically you call this function with the scope of calls to the functions `PMSessionPostScriptBegin` and `PMSessionPostScriptEnd`.

The function `PMSessionPostScriptData` is not useful unless the current port is the printing port and the document format is PICT + PS.

Special Considerations

The PICT + PS spool file format is not available on Intel-based systems.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`PMCoreDeprecated.h`

PMSessionPostScriptEnd

Restores the current driver to QuickDraw mode, ready to accept QuickDraw data instead of PostScript data. (Deprecated in Mac OS X v10.4. Use `PMPrinterPrintWithFile` (page 2203), `PMPrinterPrintWithProvider` (page 2204), or `PMCGImageCreateWithEPSDataProvider` (page 2139) instead.)

```
OSStatus PMSessionPostScriptEnd (
   PMPrintSession printSession
);
```

Parameters

printSession
The current printing session.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
You must call this function between the creation and release of a printing session. See the function `PMCreateSession` (page 2145). You must also call this function with the scope of calls to the functions `PMSessionBeginPage` and `PMSessionEndPage`.

You call the function `PMSessionPostScriptEnd` to complete a PostScript block started with `PMSessionPostScriptBegin`. The function `PMSessionPostScriptEnd` is not useful unless the current port is the printing port and the document format is PICT + PS.

Special Considerations

The PICT + PS spool file format is not available on Intel-based systems.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`PMCoreDeprecated.h`

PMSessionPostScriptFile

Passes the PostScript data, contained in a file, to the current printer driver. (Deprecated in Mac OS X v10.4. Use `PMPrinterPrintWithFile` (page 2203), `PMPrinterPrintWithProvider` (page 2204), or `PMCGImageCreateWithEPSDataProvider` (page 2139) instead.)

```
OSStatus PMSessionPostScriptFile (
   PMPrintSession printSession,
   FSSpec *psFile
);
```

Parameters

printSession

The current printing session.

psFile

A pointer to a variable that specifies a file location. The file should contain the PostScript data you want to pass to the current printer driver.

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Discussion

You must call this function between the creation and release of a printing session. See the function `PMCreateSession` (page 2145). You typically call this function within the scope of calls to the function `PMSessionPostScriptBegin` and `PMSessionPostScriptEnd`.

The function `PMSessionPostScriptFile` is not useful unless the current port is the printing port and the document format is PICT + PS.

Special Considerations

The PICT + PS spool file format is not available on Intel-based systems.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`PMCoreDeprecated.h`

PMSessionPostScriptHandle

Passes the PostScript data, referenced by a Memory Manager handle, to the current printer driver. (Deprecated in Mac OS X v10.4. Use `PMPrinterPrintWithFile` (page 2203), `PMPrinterPrintWithProvider` (page 2204), or `PMCGImageCreateWithEPSDataProvider` (page 2139) instead.)

```
OSStatus PMSessionPostScriptHandle (
   PMPrintSession printSession,
   Handle psHandle
);
```

Parameters

printSession

The current printing session.

psHandle

A handle to the PostScript data you want to pass to the current printer driver. You must make sure the handle is of the appropriate size for the data, otherwise you risk corrupting the spool file.

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Discussion
You must call this function between the creation and release of a printing session. See the function `PMCreateSession` (page 2145). You must also call this function within the scope of calls to the function `PMSessionPostScriptBegin` and `PMSessionPostScriptEnd`.

The function `PMSessionPostScriptEnd` is not useful unless the current port is the printing port and the document format is PICT + PS.

Special Considerations

The PICT + PS spool file format is not available on Intel-based systems.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`PMCoreDeprecated.h`

PMSessionSetCurrentPMPrinter

Changes the current printer for a printing session.

```
OSStatus PMSessionSetCurrentPMPrinter (
   PMPrintSession session,
   PMPrinter printer
);
```

Parameters

session
The printing session whose printer you want to change.

printer
The new printer for the printing session.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
You must call this function between the creation and release of a printing session. See the function `PMCreateSession` (page 2145).

Availability
Available in Mac OS X v10.3 and later.

See Also
`PMSessionGetCurrentPrinter` (page 2231)

Declared In
`PMCore.h`

PMSessionSetCurrentPrinter

Changes the current printer for a printing session to a printer specified by name. (Deprecated in Mac OS X v10.4. Use `PMSessionSetCurrentPMPrinter` (page 2241) instead.)

```
OSStatus PMSessionSetCurrentPrinter (
   PMPrintSession session,
   CFStringRef printerName
);
```

Parameters

session

The printing session whose printer you want to change.

printerName

The name of the printer you want to set as the current printer.

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Discussion

You must call this function between the creation and release of a printing session. See the function `PMCreateSession` (page 2145).

Availability

Available in Mac OS X v10.1 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`PMCoreDeprecated.h`

PMSessionSetDataInSession

Stores your application-specific data in a printing session object.

```
OSStatus PMSessionSetDataInSession (
   PMPrintSession printSession,
   CFStringRef key,
   CFTypeRef data
);
```

Parameters

printSession

The printing session in which you want to store application-specific data.

key

A key that uniquely identifies the data being added. This key is required to retrieve the data using the function `PMSessionGetDataFromSession` (page 2231).

data

The data to be stored in the printing session.

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Discussion
You must call this function between the creation and release of a printing session. See the function `PMCreateSession` (page 2145).

Availability
Available in Mac OS X v10.0 and later.

See Also
`PMSessionGetDataFromSession` (page 2231)

Declared In
`PMCore.h`

PMSessionSetDestination

Sets the destination location, format, and type for a print job.

```
OSStatus PMSessionSetDestination (
   PMPrintSession printSession,
   PMPrintSettings printSettings,
   PMDestinationType destType,
   CFStringRef destFormat,
   CFURLRef destLocation
);
```

Parameters

printSession
The printing session that provides a context for the print job.

printSettings
The print settings for the print job whose destination you want to set.

destType
The destination type for the print job associated with the specified printing session and print settings. Possible values include:

- `kPMDestinationPrinter` (output to a printer)
- `kPMDestinationFile` (output to a file)
- `kPMDestinationFax` (output to a fax)
- `kPMDestinationPreview` (output to print preview)
- `kPMDestinationProcessPDF` (output to a PDF workflow option)

See "Destination Types" (page 2281) for a complete description of destination types you can specify.

destFormat
The MIME type to be generated for the specified destination type. Pass `NULL` if you want to use the default format for the specified destination type. To obtain a list of valid formats for a given destination type, use the function `PMSessionCopyOutputFormatList` (page 2222).

destLocation
A reference to a Core Foundation URL that specifies a destination location. You can provide this if the destination type supports a destination location. Otherwise, pass `NULL`. For example, if the destination type is a file (`kPMDestinationFile`) you can supply a file system URL to specify where the file resides.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
You can use the function `PMSessionSetDestination` when you want to send print output to a file without requiring user interaction. You must call this function between the creation and release of a printing session. See the function `PMCreateSession` (page 2145).

Availability
Available in Mac OS X v10.1 and later.

Declared In
`PMCore.h`

PMSessionSetDocumentFormatGeneration

Requests a specified spool file format and supplies the graphics context type to use for drawing pages within the print loop. (Deprecated in Mac OS X v10.4. If you're drawing using Quartz 2D instead of QuickDraw, use `PMSessionBeginCGDocument` or `PMSessionBeginCGDocumentNoDialog` (page 2217); for submitting PostScript data, use `PMPrinterPrintWithFile` (page 2203) or `PMPrinterPrintWithProvider` (page 2204); to draw EPS data, use `PMCGImageCreateWithEPSDataProvider` (page 2139).)

```
OSStatus PMSessionSetDocumentFormatGeneration (
   PMPrintSession printSession,
   CFStringRef docFormat,
   CFArrayRef graphicsContextTypes,
   CFTypeRef options
);
```

Parameters

printSession
The printing session whose spool file format and graphics context type you want to specify.

docFormat
A Core Foundation string that specifies the desired spool file format as a MIME type. See "Document Format Strings" (page 2282) for a description of the constants you can use to specify the document format.

graphicsContexts
A reference to a Core Foundation array of graphics contexts to use for drawing pages within the print loop. You can supply a QuickDraw graphics context (`kPMGraphicsContextQuickDraw`) or a Quartz 2D graphics context (`kPMGraphicsContextCoreGraphics`). An array of length 1 is the only length that is supported, regardless of graphics context type. See "Graphics Context Types" (page 2283) for a description of the constants you can use to specify a graphics context.

options
Reserved for future use.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
You only need to call the function `PMSessionSetDocumentFormatGeneration` if you want to specify a format other than the default format (PDF) or a graphics context other than the default context (QuickDraw). If you want to use the default format for the operating system and to draw with QuickDraw, then you do not

need to call this function. If you want to generate PICT + PS to use as one of the supported formats, then call `PMSessionSetDocumentFormatGeneration` to set the graphics context to QuickDraw and the format to PICT + PS. Note that the PICT + PS format is not available on Intel-based systems.

If you want to use a Quartz 2D graphics context to draw each page, you can call the following code to inform the printing system in all versions of Mac OS X.

```
static OSStatus MyPMSessionBeginCGDocument (
    PMPrintSession printSession,
    PMPrintSettings printSettings,
    PMPageFormat pageFormat)
{
    OSStatus err = noErr;

    // Use the simpler call if it is present.
    if(&PMSessionBeginCGDocument != NULL) {
       err = PMSessionBeginCGDocument (printSession, printSettings, pageFormat);
    }
    else {
        CFStringRef s[1] = { kPMGraphicsContextCoreGraphics };
        CFArrayRef graphicsContextsArray = CFArrayCreate (
            kCFAllocatorDefault, (const void**)s, 1, &kCFTypeArrayCallBacks);
        err = PMSessionSetDocumentFormatGeneration (
            printSession, kPMDocumentFormatPDF, graphicsContextsArray, NULL);
        CFRelease (graphicsContextsArray);
        if(!err)
            err = PMSessionBeginDocument (
                printSession, printSettings, pageFormat);
    }
    return err;
}
```

The previous code informs the printing system that you want a Quartz graphics context, but you get the actual context for your printing port only after you call the function `PMSessionBeginPage` and then call the following code.

```
static OSStatus MyPMSessionGetCGGraphicsContext (
    PMPrintSession printSession,
    CGContextRef *printingContextP)
{
    OSStatus err = noErr;

    // Use the simpler call if it is present.
    if(&PMSessionGetCGGraphicsContext != NULL) {
        err = PMSessionGetCGGraphicsContext (printSession, printingContextP);
    }
    else {
        err = PMSessionGetGraphicsContext (
            printSession, kPMGraphicsContextCoreGraphics,
            (void**)printingContextP);
    }
    return err;
}
```

The printing context you get is a Quartz context into which you can draw. Note that the default coordinate system for Quartz 2D is not the same as that used for QuickDraw. Quartz 2D defines the coordinates of the lower-left corner of the sheet as (0,0) whereas the origin for the QuickDraw port is the upper-left corner of the imageable area.

You must call this function between the creation and release of a printing session. See the function `PMCreateSession` (page 2145). You must call the function `PMSessionSetDocumentFormatGeneration` before you call `PMSessionBeginDocument` or `PMSessionBeginDocumentNoDialog` (page 2218). Before requesting a spool file format using this function, you should call the function `PMSessionGetDocumentFormatGeneration` to get the list of supported formats.

Special Considerations

The PICT + PS spool file format is not available on Intel-based systems.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

`PMSessionGetDocumentFormatGeneration` (page 2233)

Related Sample Code

CarbonSketch

Declared In

`PMCoreDeprecated.h`

PMSessionSetError

Sets the value of the current result code for the specified printing session.

```
OSStatus PMSessionSetError (
   PMPrintSession printSession,
   OSStatus printError
);
```

Parameters

printSession

The printing session whose result code you want to set.

printError

The result code you want to set. This result code is returned by the `PMSessionError` function.

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Discussion

You must call this function between the creation and release of a printing session. See the function `PMCreateSession` (page 2145).

You can use this function to terminate a printing session if your application encounters any errors inside the print loop. Typically, this function is used by an application's idle function. The idle function isn't called in Mac OS X, so this usage is not available.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`PMCore.h`

PMSessionSetIdleProc

Installs an idle callback function in your print loop. (Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Mac OS X, but it serves no useful purpose.)

```
OSStatus PMSessionSetIdleProc (
   PMPrintSession printSession,
   PMIdleUPP idleProc
);
```

Parameters

printSession

The printing session that provides a context for the print job.

idleProc

A universal procedure pointer to your idle function. Your idle function is defined by the callback `PMIdleProcPtr` (page 2273).

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
You do not need this function in Mac OS X. Instead, use the standard idle proc.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`PMCoreDeprecated.h`

PMSessionSetPSInjectionData

Specifies a set of PostScript code injection points and the PostScript data to be injected. (Deprecated in Mac OS X v10.4. Use `PMPrinterPrintWithFile` (page 2203) or `PMPrinterPrintWithProvider` (page 2204) instead.)

```
OSStatus PMSessionSetPSInjectionData (
   PMPrintSession printSession,
   PMPrintSettings printSettings,
   CFArrayRef injectionDictArray
);
```

Parameters

printSession

The current printing session.

printSettings

The print settings object in which to place the specified injection points.

injectionDictArray

A reference to a Core Foundation array that contains one or more Core Foundation dictionary (`CFDictionary`) entries. Each dictionary entry specifies PostScript injection data you want inserted at a specific point in the print stream. See "PostScript Injection Dictionary Keys" (page 2285) for a description of the constants you can use as keys for these dictionary entries.

Return Value

A result code. See "Core Printing Result Codes" (page 2298). The result code `kPMInvalidParameter` is returned if the `injectionDictArray` object contains any invalid entries. The result code `kPMInvalidPrintSession` is returned if the document format has not been set to `kPMDocumentFormatPICTPS` for the specified printing session.

Discussion

You must call this function between the creation and release of a printing session. See the function `PMCreateSession` (page 2145). Before calling `PMSessionSetPSInjectionData`, your application must set the document format of the printing session to `kPMDocumentFormatPICTPS` using the function `PMSessionSetDocumentFormatGeneration` (page 2244).

For applications that require extensive control over PostScript code generation, the function `PMSessionSetPSInjectionData` provides the ability to insert PostScript code into specified places in the print stream. It is intended for use by desktop publishing applications for which functions such as `PMSessionPostScriptData` do not provide sufficient control.

You specify the injection points by creating an array of `CFDictionary` entries. Each dictionary consists of key-value pairs in which the key specifies where to inject the PostScript and the value specifies the PostScript data you want to inject. The function verifies that the `injectionDictArray` parameter is properly formed, and returns the `kPMInvalidParameter` result code if the array does not contain valid entries.

If you call the function `PMSessionSetPSInjectionData` a second time for a given print settings object, the injection points you specified previously are replaced with the new injection points.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`PMCoreDeprecated.h`

PMSessionValidatePageFormat

Updates the values in a page format object and validates them against the current formatting printer.

```
OSStatus PMSessionValidatePageFormat (
   PMPrintSession printSession,
   PMPageFormat pageFormat,
   Boolean *result
);
```

Parameters

printSession

The printing session for the specified page format object.

pageFormat
The page format object to validate.

result
A pointer to your Boolean variable. On return, `true` if the function set the page format object to default values; otherwise, `false`.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
You must call this function between the creation and release of the printing session. See the function `PMCreateSession` (page 2145).

The function `PMSessionValidatePageFormat` validates the page format object against the current formatting printer. The formatting printer is displayed in the Format for pop-up menu in the Page Setup dialog. The default formatting printer is the generic Any Printer. If the page format object contains values that are not valid for the formatting printer, the page format object is set to default values and the *result* parameter is set to `true`.

Validating a page format object also causes calculated fields (such as the adjusted paper and page rectangles) to be updated based on the changed settings (such as resolution, scaling, and page orientation). If the page format object contains values that are valid for the formatting printer but need to be updated, the *result* parameter is set to `false`.

After you call any function that makes changes to a page format object (such as `PMSetOrientation`), you should call the function `PMSessionValidatePageFormat` to validate the page format object before using that object.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
CarbonSketch

Declared In
`PMCore.h`

PMSessionValidatePrintSettings

Validates a print settings object within the context of the specified printing session.

```
OSStatus PMSessionValidatePrintSettings (
   PMPrintSession printSession,
   PMPrintSettings printSettings,
   Boolean *result
);
```

Parameters
printSession
The printing session for the specified print settings object.

printSettings
The print settings object to validate.

result
A pointer to your Boolean variable. On return, `true` if any parameters changed, or `false` if no parameters changed.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
You must call this function between the creation and release of a printing session. See the function `PMCreateSession` (page 2145).

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
CarbonSketch

Declared In
`PMCore.h`

PMSetAdjustedPageRect

Requests a particular page size, adjusted for the current rotation, resolution, or scaling settings. (Deprecated in Mac OS X v10.5. To set a particular paper size and margins, obtain or create a `PMPaper` (page 2275) object and call `PMCreatePageFormatWithPMPaper` (page 2144).)

```
OSStatus PMSetAdjustedPageRect (
   PMPageFormat pageFormat,
   const PMRect *pageRect
);
```

Parameters

pageFormat
The page format object whose page rectangle you want to set.

pageRect
A pointer to your `PMRect` (page 2277) data structure that specifies the desired size of the page rectangle, in points. The top-left coordinates should be (0,0). See *Supporting Printing in Your Carbon Application* for more information on page and paper rectangles.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
This function is not recommended. You should call this function only if your application provides desktop publishing and the Page Setup dialog does not provide sufficient control. Typically, such applications display their own specialized document format dialog.

If you decide to use this function, you must call the function between the creation and release of a printing session. See the function `PMCreateSession` (page 2145). You can use `PMSetAdjustedPageRect` to set a drawing rectangle without going through the Page Setup dialog or calling other page format accessor functions. This function allows an application to specify the dimensions of the imageable area into which it draws.

If you call this function after initiating a print job, the change is ignored for the current job.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`PMCoreDeprecated.h`

PMSetCollate

Specifies whether the job collate option is selected.

```
OSStatus PMSetCollate (
   PMPrintSettings printSettings,
   Boolean collate
);
```

Parameters

`printSettings`
The print settings object whose job collate option you want to set.

`collate`
If `true`, the job collate option is selected; if `false` the option is not selected.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
The Collated checkbox is displayed in the Copies & Pages pane of the Print dialog. This option determines how printed material is organized. For example, if you have a document that is three pages long and you are printing multiple copies with the Collated option selected, the job prints pages 1, 2, and 3 in that order and then repeats. However, if the Collated option is not selected and you're printing multiple copies of those same three pages, the job prints copies of page 1, then copies of page 2, and finally copies of page 3.

If you call this function after initiating a print job, the change is ignored for the current job.

Availability
Available in Mac OS X v10.2 and later.

See Also
`PMGetCollate` (page 2154)

Declared In
`PMCore.h`

PMSetColorMode

Sets the desired color mode for the print job. (Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Mac OS X, but it serves no useful purpose.)

```
OSStatus PMSetColorMode (
   PMPrintSettings printSettings,
   PMColorMode colorMode
);
```

Parameters

printSettings

The print settings object whose color mode you want to set.

colorMode

The desired color mode. See "Color Modes" (page 2298) for a list of possible values.

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Special Considerations

This function does nothing in Mac OS X.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`PMCoreDeprecated.h`

PMSetCopies

Sets the initial value for the number of copies to be printed.

```
OSStatus PMSetCopies (
   PMPrintSettings printSettings,
   UInt32 copies,
   Boolean lock
);
```

Parameters

printSettings

The print settings object you want to initialize.

copies

The initial value of the number of copies to print.

lock

The lock state of the setting. Locking is not supported at this time.

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Discussion

If you call this function after initiating a print job, the change is ignored for the current job.

Availability

Available in Mac OS X v10.0 and later.

PMCore.h

PMSetDuplex

Sets the duplex mode.

```
OSStatus PMSetDuplex (
   PMPrintSettings printSettings,
   PMDuplexMode duplexSetting
);
```

Parameters

printSettings

The print settings object whose duplex mode you want to set.

duplexSetting

The new duplex mode setting. Possible values include:

- kPMDuplexNone (one-sided printing)
- kPMDuplexNoTumble (two-sided printing)
- kPMDuplexTumble (two-sided printing with tumbling)

See "Duplex Modes" (page 2282) for a full description of the constants you can use to specify the new setting.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
Duplex printing is a print job that prints on both sides of the paper. Two-Sided printing controls are displayed in the Layout pane of the Print dialog. Note that not all printers support duplex printing. This function specifies a setting that might not be available on a given destination.

If you call this function after initiating a print job, the change is ignored for the current job.

Availability
Available in Mac OS X v10.4 and later.

See Also
PMGetDuplex (page 2158)

Declared In
PMCore.h

PMSetError

Sets the value of the current result code. (Deprecated in Mac OS X v10.4. Use PMSessionSetError (page 2246) instead.)

```
OSStatus PMSetError (
    OSStatus printError
);
```

Parameters

printError

The result code you wish to set. This result code will be returned by the `PMError` function.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
Valid after calling `PMBegin`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`PMCoreDeprecated.h`

PMSetFirstPage

Sets the default page number of the first page to be printed.

```
OSStatus PMSetFirstPage (
   PMPrintSettings printSettings,
   UInt32 first,
   Boolean lock
);
```

Parameters

printSettings

The print settings object whose first page number you want to set.

first

The page number of the first page to print. This value appears in the From field of the Print dialog.

lock

The lock state of the setting. Locking is not supported at this time.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
Typically, this function isn't used. In Mac OS X, if you call the function `PMSetPageRange` (page 2259) and then call `PMSetFirstPage` or `PMSetLastPage` using the same page range you specified for `PMSetPageRange`, then the Print dialog shows the From button selected. If you use the constant `kPMPrintAllPages` to set the page range with the function `PMSetPageRange`, then the Print dialog opens with the All button selected regardless of whether you also call `PMSetFirstPage` or `PMSetLastPage`.

If you call this function after initiating a print job, the change is ignored for the current job.

Availability
Available in Mac OS X v10.0 and later.

See Also
PMGetFirstPage (page 2159)

Related Sample Code
CarbonSketch

Declared In
PMCore.h

PMSetIdleProc

Installs an idle callback function in your print loop. (Deprecated in Mac OS X v10.4. There is no replacement; this function was included to facilitate porting legacy applications to Mac OS X, but it serves no useful purpose.)

```
OSStatus PMSetIdleProc (
    PMIdleUPP idleProc
);
```

Parameters

idleProc

A universal procedure pointer to your idle function. Your idle function is defined by the callback PMIdleProcPtr.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
Valid after calling PMBegin. The printing system calls your idle function periodically during your print loop.

Special Considerations

Your idle function is not called in Mac OS X. It's only called in Mac OS 8 and 9.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
PMCoreDeprecated.h

PMSetJobName

Specifies the name of the print job. (Deprecated in Mac OS X v10.4. Use PMPrintSettingsSetJobName (page 2211) instead.)

```
OSStatus PMSetJobName (
   PMPrintSettings printSettings,
   StringPtr name
);
```

Parameters

printSettings

A PMPrintSettings object.

name

The name to assign to the print job. This string will be used to name the spool file.

Return Value
A result code. The result code `kPMInvalidParameter` is returned if you attempt to set the job name to an invalid file name or a null string.

Discussion
Valid after calling `PMBegin` and creating a print settings object.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`PMCoreDeprecated.h`

PMSetJobNameCFString

Specifies the name of a print job. (Deprecated in Mac OS X v10.5. Use `PMPrintSettingsSetJobName` (page 2211) instead.)

```
OSStatus PMSetJobNameCFString (
   PMPrintSettings printSettings,
   CFStringRef name
);
```

Parameters

printSettings

The print settings object whose job name you want to set.

name

The new name for the print job.

Return Value
A result code. See "Core Printing Result Codes" (page 2298). The result code `kPMInvalidParameter` is returned if you pass `NULL` or an empty string in the `name` parameter.

Discussion
You should call this function before you open the Print dialog.

If you call this function after initiating a print job, the change is ignored for the current job.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

See Also
`PMGetJobNameCFString` (page 2161)

Related Sample Code
CarbonSketch

Declared In
PMCoreDeprecated.h

PMSetLastPage

Sets the page number of the last page to be printed.

```
OSStatus PMSetLastPage (
   PMPrintSettings printSettings,
   UInt32 last,
   Boolean lock
);
```

Parameters

printSettings

The print settings object whose last page number you want to set.

last

The page number of the last page to print. This value appears in the To field of the Print dialog. Pass the constant kPMPrintAllPages to print the entire document.

lock

The lock state of the setting. Locking is not supported at this time.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
Typically, you call this function after the Print dialog is displayed to indicate the number of the last page number to be printed. In Mac OS X, setting the last page provides information used by the progress dialog that is shown during printing.

If you call the function PMSetPageRange (page 2259) and then call PMSetFirstPage or PMSetLastPage using the same page range you specified for PMSetPageRange, then the Print dialog shows the From button selected. If you use the constant kPMPrintAllPages to set the page range with the function PMSetPageRange, then the Print dialog opens with the All button selected regardless of whether you also call PMSetFirstPage or PMSetLastPage.

If you call this function after initiating a print job, the change is ignored for the current job.

Availability
Available in Mac OS X v10.0 and later.

See Also
PMGetLastPage (page 2162)

Related Sample Code
CarbonSketch

Declared In
PMCore.h

PMSetOrientation

Sets the page orientation for printing.

```
OSStatus PMSetOrientation (
   PMPageFormat pageFormat,
   PMOrientation orientation,
   Boolean lock
);
```

Parameters

pageFormat

The page format object whose page orientation you want to set.

orientation

A constant specifying the desired page orientation. Supported values are:

- `kPMPortrait`
- `kPMLandscape`
- `kPMReversePortrait` (Mac OS X v10.5 and later)
- `kPMReverseLandscape`

See "Page Orientation Constants" (page 2283) for a full description of the values you can use to specify page orientation.

lock

The lock state of the setting. You should pass `kPMUnlocked`. Locking is not supported at this time.

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Special Considerations

In Mac OS X 10.4 and earlier, if you want to set the page orientation you need to call this function before initiating the print job (for example, by calling `PMSessionBeginCGDocument`). The page orientation you set applies to the entire print job. In Mac OS X 10.5 and later, you can use this function to change the orientation of an individual page in a print job by passing the updated page format to `PMSessionBeginPage` or `PMSessionBeginPageNoDialog`.

Availability

Available in Mac OS X v10.0 and later.

See Also

`PMGetOrientation` (page 2163)

Declared In

`PMCore.h`

PMSetPageFormatExtendedData

Stores your application-specific data in a page format object.

```
OSStatus PMSetPageFormatExtendedData (
   PMPageFormat pageFormat,
   OSType dataID,
   UInt32 size,
   void *extendedData
);
```

Parameters

pageFormat

The page format object in which to store your extended data.

dataID

A 4-character code that identifies your data. This is typically your application's creator code. If your creator code is outside the ASCII 7-bit character range 0x20–0x7F, you need to use a different 4-character code.

size

The size, in bytes, of the data to be stored in the page format object.

extendedData

A pointer to the application-specific data you want to store in the page format object.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
You can retrieve the data you store with the function `PMSetPageFormatExtendedData` by calling the function `PMGetPageFormatExtendedData`.

Availability
Available in Mac OS X v10.0 and later.

See Also
`PMGetPageFormatExtendedData` (page 2164)

Declared In
`PMCore.h`

PMSetPageRange

Sets the valid range of pages that can be printed.

```
OSStatus PMSetPageRange (
   PMPrintSettings printSettings,
   UInt32 minPage,
   UInt32 maxPage
);
```

Parameters

printSettings

The print settings object whose page range you want to set.

minPage

The minimum page number allowed. This value appears as the default in the From field of the Print dialog.

maxPage

The maximum page number allowed. This value appears as the default in the To field of the Print dialog. Pass the constant `kPMPrintAllPages` to allow the user to print the entire document. If the first page is set to 1, then passing `kPMPrintAllPages` as the maximum page number causes the All button to be selected.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
The function `PMSetPageRange` allows applications to set the minimum and maximum page numbers that can be printed for a document. If the user enters a value outside of this range in the Print dialog, the value is set to the closest allowed value. You can use the `PMGetFirstPage` (page 2159) and `PMGetLastPage` (page 2162) functions to obtain the values entered by the user in the Print dialog.)

If you call the function `PMSetPageRange` to set the maximum page to a value other than the constant `kPMPrintAllPages`, the function `PMSetPageRange` causes the page range in the Print dialog to be properly restricted to the specified range. If you call the function `PMSetPageRange` without also calling the functions `PMSetFirstPage` or `PMSetLastPage`, then the Print dialog shows the specified page range in the From and To fields but with the All button selected. If you call the function `PMSetPageRange` and then call `PMSetFirstPage` or `PMSetLastPage` using the same page range you specified for `PMSetPageRange`, then the Print dialog shows the From button selected.

In all cases, if your application sets a range with `PMSetPageRange` and subsequently calls `PMSetFirstPage` (page 2254) or `PMSetLastPage` (page 2257) with values outside of the specified range, Core Printing returns a result code of `kPMValueOutOfRange`. Conversely, if your application calls `PMSetPageRange` after calling `PMSetFirstPage` or `PMSetLastPage` (or after displaying the Print dialog), the page range specified by `PMSetPageRange` takes precedence, and the first and last page values are adjusted accordingly.

If you call this function after initiating a print job, the change is ignored for the current job.

Availability
Available in Mac OS X v10.0 and later.

See Also
`PMGetPageRange` (page 2165)

Related Sample Code
CarbonSketch

Declared In
`PMCore.h`

PMSetPhysicalPaperSize

Requests a particular paper size, unaffected by rotation, resolution, or scaling. (Deprecated in Mac OS X v10.4. Use `PMCreatePageFormatWithPMPaper` (page 2144) instead.)

```
OSStatus PMSetPhysicalPaperSize (
   PMPageFormat pageFormat,
   const PMRect *paperSize
);
```

Parameters

pageFormat

The `PMPageFormat` which will hold the new physical paper size.

paperSize

The desired paper size expressed as a `PMRect`. The units are 1/72 inch. A `PMRect` is a rectangle whose individual components are doubles.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`PMCoreDeprecated.h`

PMSetPrintSettingsExtendedData

Stores your application-specific data in a print settings object.

```
OSStatus PMSetPrintSettingsExtendedData (
   PMPrintSettings printSettings,
   OSType dataID,
   UInt32 size,
   void *extendedData
);
```

Parameters

printSettings

The print settings object in which to store your application-specific data.

dataID

A 4-character code that will be used to identify your data. The 4-character code must not contain any characters outside the standard ASCII 7-bit character range 0x20–0x7F. This is typically your application's creator code.

size

The size, in bytes, of the data to be stored in the print settings object.

extendedData

A pointer to a buffer that contains the extended data you want to store.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
You can retrieve the data you store with the function `PMSetPrintSettingsExtendedData` by calling the function `PMGetPrintSettingsExtendedData`.

You may find it easier to use the functions `PMPrintSettingsSetValue` (page 2212) and `PMPrintSettingsGetValue` (page 2210) to store and retrieve user-defined data in a print settings object. If you use these functions, make sure that the custom keys you define for your private data do not conflict with other print settings keys.

Availability
Available in Mac OS X v10.0 and later.

See Also
`PMGetPrintSettingsExtendedData` (page 2168)

Declared In
`PMCore.h`

PMSetProfile

Embeds a color profile during printing. (Deprecated in Mac OS X v10.5. There is no replacement; draw using Quartz 2D instead.)

```
OSStatus PMSetProfile (
   PMPrintSettings printSettings,
   PMTag tag,
   const CMProfileLocation *profile
);
```

Parameters

printSettings

The print settings object in which to embed the color profile.

tag

A tag that describes the usage of the profile. Currently, the only tag value you can pass is the constant `kPMSourceProfile`. See "Tag Constants" (page 2295) for more information on this constant.

profile

A pointer to a structure of type `CMProfileLocation` that specifies the location of a ColorSync profile. The profile must be version 2 or later. If you pass a profile that is an earlier version, the function returns the result code `kPMNotImplemented`.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
You can use the function `PMSetProfile` to tag QuickDraw drawing with a custom ColorSync profile. The function `PMSetProfile` is useful only if the graphics context is QuickDraw and the current port is the printing port.

You should call this function each time you want to change the profile used to draw page elements. The printing system resets the profile to the default at the beginning of each page. If you call the function `PMSetProfile` a second time, the old profile is ignored.

Special Considerations

This function is deprecated because QuickDraw is deprecated. When drawing with Quartz, the current stroke and fill color space and the color space associated with an image are used to characterize color. Quartz provides ways to use ColorSync profiles to create color spaces, so you can characterize color using ColorSync simply by drawing with Quartz.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`PMCoreDeprecated.h`

PMSetResolution

Sets the application drawing resolution. (Deprecated in Mac OS X v10.5. Draw using Quartz 2D and call `CGContextScaleCTM` (page 105) instead.)

```
OSStatus PMSetResolution (
   PMPageFormat pageFormat,
   const PMResolution *res
);
```

Parameters

pageFormat
The page format object whose drawing resolution you want to set.

res
A pointer to a structure of type `PMResolution` (page 2278) that specifies the desired drawing resolution for your application. You should specify the best resolution for your data. The printing system handles the mapping between the resolution you specify and the printer resolution.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
If you call this function after initiating a print job, the change is ignored for the current job.

Special Considerations

This function was needed in the past because QuickDraw uses integer coordinates and has no notion of scaling coordinate systems. For Quartz drawing, this function is obsolete. To change the resolution, draw with fractional coordinates or scale the coordinate system and draw with integer coordinates.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`PMCoreDeprecated.h`

PMSetScale

Sets the scaling factor for the page and paper rectangles.

```
OSStatus PMSetScale (
   PMPageFormat pageFormat,
   double scale
);
```

Parameters

pageFormat

The page format object whose scaling factor you want to set.

scale

The desired scaling factor expressed as a percentage. For example, for 50 percent scaling, pass a value of 50.0; for no scaling, pass 100.0.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
You can call the function `PMSetScale` to change the scaling factor that appears when your application invokes the Page Setup dialog.

If you call `PMSetScale` after calling `PMSessionPageSetupDialog`, make sure you call `PMSessionValidatePageFormat` (page 2248) before you call `PMSessionBeginCGDocument` or `PMSessionBeginDocument`.

If you call this function after initiating a print job, the change is ignored for the current job.

Availability
Available in Mac OS X v10.0 and later.

See Also
`PMGetScale` (page 2170)

Declared In
`PMCore.h`

PMSetUnadjustedPaperRect

Requests a particular paper size, unaffected by rotation, resolution, or scaling. (Deprecated in Mac OS X v10.5. To set a particular paper size, obtain or create a `PMPaper` (page 2275) object and call `PMCreatePageFormatWithPMPaper` (page 2144).)

```
OSStatus PMSetUnadjustedPaperRect (
   PMPageFormat pageFormat,
   const PMRect *paperRect
);
```

Parameters

pageFormat

The page format object whose unadjusted paper rectangle you want to set.

paperRect

A pointer to a structure of type `PMRect` that specifies the desired paper size, in points. The coordinates of the upper-left corner of the paper rectangle are specified relative to the page rectangle. See *Supporting Printing in Your Carbon Application* for more information on page and paper rectangles.

Return Value
A result code. See "Core Printing Result Codes" (page 2298). The result code `kPMValueOutOfRange` indicates that the printer driver does not support the requested page size.

Discussion
This function is not recommended. You should call this function only if your application provides desktop publishing and the Page Setup dialog does not provide sufficient control. Typically, such applications display their own specialized document format dialog.

If you decide to use this function, you must call it between the creation and release of a printing session. After using the function `PMSetUnadjustedPaperRect` you should always call `PMSessionValidatePageFormat` (page 2248) then call `PMGetUnadjustedPaperRect` (page 2171) to verify that the paper size you set is recorded by the printer driver.

If you call this function after initiating a print job, the change is ignored for the current job.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`PMCoreDeprecated.h`

PMUnflattenPageFormat

Rebuilds a page format object from a Memory Manager handle that contains flattened page format data. (Deprecated in Mac OS X v10.5. Use `PMPageFormatCreateWithDataRepresentation` (page 2175) instead.)

```
OSStatus PMUnflattenPageFormat (
   Handle flatFormat,
   PMPageFormat *pageFormat
);
```

Parameters

flatFormat
A handle to a previously flattened page format object. You are responsible for disposing of the handle.

pageFormat
A pointer to your `PMPageFormat` (page 2275) variable. On return, the variable refers to a page format object that contains the data retrieved from the flattened page format data. You are responsible for releasing the page format object with the function `PMRelease` (page 2214).

Return Value
A result code. See "Core Printing Result Codes" (page 2298). The result code `kPMInvalidParameter` is returned if the flattened `PMPageFormat` object was created by an incompatible version of Core Printing.

Discussion
The `PMUnflattenPageFormat` function creates a new `PMPageFormat` object that contains the data from the flattened page format data. You should call the function `PMSessionValidatePageFormat` (page 2248) to make sure the page format object contains valid values.

If the function returns the result code `kPMInvalidParameter` you need to create a new, default page format object. You should also notify the user that the flattened page format is not valid.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`PMCoreDeprecated.h`

PMUnflattenPageFormatWithCFData

Rebuilds a page format object from a Core Foundation data object that contains flattened page format data. (Deprecated in Mac OS X v10.5. Use `PMPageFormatCreateWithDataRepresentation` (page 2175) instead.)

```
OSStatus PMUnflattenPageFormatWithCFData (
   CFDataRef flattenCFData,
   PMPageFormat *pageFormat
);
```

Parameters

`flattenCFData`
A Core Foundation data object that contains a flattened representation of a page format object.

`pageFormat`
A pointer to your `PMPageFormat` (page 2275) variable. On return, the variable refers to a page format object that is rebuilt from the specified Core Foundation data object. You are responsible for releasing the page format object with the function `PMRelease` (page 2214).

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Availability
Available in Mac OS X v10.4 and later.
Deprecated in Mac OS X v10.5.

See Also
`PMFlattenPageFormatToCFData` (page 2149)

Declared In
`PMCoreDeprecated.h`

PMUnflattenPageFormatWithURL

Rebuilds a page format object from a file system URL that contains flattened page format data. (Deprecated in Mac OS X v10.5. Instead read the data into a CFData object and use `PMPageFormatCreateWithDataRepresentation` (page 2175).)

```
OSStatus PMUnflattenPageFormatWithURL (
   CFURLRef flattenFileURL,
   PMPageFormat *pageFormat
);
```

Parameters

flattenFileURL

A Core Foundation URL that specifies a file containing a flattened representation of a page format object.

pageFormat

A pointer to your PMPageFormat (page 2275) variable. On return, the variable refers to a page format object that is rebuilt from the specified file. You are responsible for releasing the page format object with the function PMRelease (page 2214).

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Availability

Available in Mac OS X v10.4 and later.

Deprecated in Mac OS X v10.5.

See Also

PMFlattenPageFormatToURL (page 2150)

Declared In

PMCoreDeprecated.h

PMUnflattenPrintSettings

Rebuilds a print settings object from a Memory Manager handle that contains flattened print settings data. (Deprecated in Mac OS X v10.5. Use PMPrintSettingsCreateWithDataRepresentation (page 2209) instead.)

```
OSStatus PMUnflattenPrintSettings (
   Handle flatSettings,
   PMPrintSettings *printSettings
);
```

Parameters

flatSettings

A handle to a flattened representation of a print settings object.

printSettings

A pointer to your PMPrintSettings (page 2277) variable. On return, the variable refers to a print settings object that contains the data retrieved from the flattened print settings. You are responsible for releasing the print settings object with the function PMRelease (page 2214).

Return Value

A result code. See "Core Printing Result Codes" (page 2298). The result code kPMInvalidParameter is returned if the flattened PMPrintSettings object was created by an incompatible version of Core Printing.

Discussion

The PMUnflattenPrintSettings function creates a new PMPrintSettings object containing the data from the flattened print settings. You should call the function PMSessionValidatePrintSettings (page 2249), as some values in the print settings object may no longer be valid.

If the function returns the result code `kPMInvalidParameter` you need to create a new, default print settings object. You should also notify the user that the print settings are not valid.

There are no scoping requirements as to when you may use this function.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`PMCoreDeprecated.h`

PMUnflattenPrintSettingsWithCFData

Rebuilds a print settings object from a Core Foundation data object that contains flattened print settings data. (Deprecated in Mac OS X v10.5. Use `PMPrintSettingsCreateWithDataRepresentation` (page 2209) instead.)

```
OSStatus PMUnflattenPrintSettingsWithCFData (
   CFDataRef flattenCFData,
   PMPrintSettings *printSettings
);
```

Parameters

`flattenCFData`
A flattened representation of a print settings object.

`printSettings`
A pointer to your `PMPrintSettings` (page 2277) variable. On return, the variable refers to a print settings object rebuilt from the specified Core Foundation data object. You are responsible for releasing the print settings object with the function `PMRelease` (page 2214).

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Availability
Available in Mac OS X v10.4 and later.
Deprecated in Mac OS X v10.5.

See Also
`PMFlattenPrintSettingsToCFData` (page 2151)

Declared In
`PMCoreDeprecated.h`

PMUnflattenPrintSettingsWithURL

Rebuilds a print settings object from a file that contains flattened print settings data. (Deprecated in Mac OS X v10.5. Instead read the data into a CFData object and use `PMPrintSettingsCreateWithDataRepresentation` (page 2209).)

```
OSStatus PMUnflattenPrintSettingsWithURL (
   CFURLRef flattenFileURL,
   PMPrintSettings *printSettings
);
```

Parameters

flattenFileURL

A file containing a flattened representation of a print settings object.

printSettings

A pointer to your PMPrintSettings (page 2277) variable. On return, the variable refers to a print settings object rebuilt from the specified file. You are responsible for releasing the print settings object with the function PMRelease (page 2214).

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Availability
Available in Mac OS X v10.4 and later.
Deprecated in Mac OS X v10.5.

See Also
PMFlattenPrintSettingsToURL (page 2152)

Declared In
PMCoreDeprecated.h

PMValidatePageFormat

Obtains a valid PMPageFormat object. (Deprecated in Mac OS X v10.4. Use PMSessionValidatePageFormat (page 2248) instead.)

```
OSStatus PMValidatePageFormat (
    PMPageFormat pageFormat,
    Boolean *result
);
```

Parameters

pageFormat

A PMPageFormat object to be validated.

result

Returns true if any parameters were changed, false if no changes were required.

Return Value
A result code. See "Core Printing Result Codes" (page 2298).

Discussion
Valid after calling PMBegin and creating a page format object.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
PMCoreDeprecated.h

PMValidatePrintSettings

Obtains a valid `PMPrintSettings` object. (Deprecated in Mac OS X v10.4. Use `PMSessionValidatePrintSettings` (page 2249) instead.)

```
OSStatus PMValidatePrintSettings (
    PMPrintSettings printSettings,
    Boolean *result
);
```

Parameters

printSettings

The `PMPrintSettings` object to be validated.

result

On return, a value of `true` if any parameters were changed, or `false` if no changes were required.

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Discussion

Valid after calling `PMBegin` and creating a print settings object.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`PMCoreDeprecated.h`

PMWorkflowCopyItems

Obtains an array of the available PDF workflow items.

```
OSStatus PMWorkflowCopyItems (
   CFArrayRef *workflowItems
);
```

Parameters

workflowItems

A pointer to your `CFArrayRef` variable. On return, the variable refers to an Core Foundation array. Each element in the array is a dictionary that describes either a PDF workflow item or a folder containing a set of PDF workflow items. For a list of possible keys, see "`PDF Workflow Dictionary Keys`" (page 2284). You are responsible for releasing the array.

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Availability

Available in Mac OS X v10.3 and later.

Declared In

`PMCore.h`

PMWorkflowSubmitPDFWithOptions

Submits a PDF file for workflow processing using the specified CUPS options string.

```
OSStatus PMWorkflowSubmitPDFWithOptions (
   CFURLRef workflowItem,
   CFStringRef title,
   const char *options,
   CFURLRef pdfFile
);
```

Parameters

workflowItem

A file system URL pointing to the workflow item that will handle the PDF file. See `PMWorkflowCopyItems` (page 2270). The following table describes the different types of workflow items for this function.

Workflow item	Description
Automator action	The action is executed for the PDF file. Available in Mac OS X v10.4 and later.
Folder alias	The PDF file is moved to the resolved folder.
Application or application alias	The application is sent an open event along with a reference to the PDF file.
Compiled AppleScript	The script is run with an open event along with a reference to the PDF file.
Executable tool	The tool is run with the following parameters: *title*, *options*, and *pdfFile*.

title

The user-displayable name of the PDF document.

options

A string of CUPS-style key-value pairs that may be passed to the PDF workflow item. This parameter can be `NULL` in which case an empty string of options is used.

pdfFile

A file system URL pointing to the PDF file to be processed by the workflow item.

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Discussion

The printing system uses this function in conjunction with the function `PMWorkflowCopyItems` (page 2270) to implement the PDF workflow button in the Print dialog.

Availability

Available in Mac OS X v10.3 and later.

Declared In

`PMCore.h`

PMWorkflowSubmitPDFWithSettings

Submits a PDF file for workflow processing using the specified print settings.

```
OSStatus PMWorkflowSubmitPDFWithSettings (
   CFURLRef workflowItem,
   PMPrintSettings settings,
   CFURLRef pdfFile
);
```

Parameters

workflowItem

A file system URL pointing to the workflow item that will handle the PDF file. See `PMWorkflowCopyItems` (page 2270). The following table describes the different types of workflow items for this function.

Workflow item	Description
Automator action	The action is executed for the PDF file. Available in Mac OS X v10.4 and later.
Folder alias	The PDF file is moved to the resolved folder.
Application or application alias	The application is sent an open event along with a reference to the PDF file.
Compiled AppleScript	The script is run with an open event along with a reference to the PDF file.
Executable tool	The tool is run with the specified settings and PDF file. This function converts these parameters into a CUPS options string and passes the options string to the tool.

settings

The print settings to apply to the PDF document. These settings are passed to the workflow item as a CUPS options string.

pdfFile

A file system URL pointing to the PDF file to be processed by the workflow item.

Return Value

A result code. See "Core Printing Result Codes" (page 2298).

Discussion

The printing system uses this function in conjunction with the function `PMWorkflowCopyItems` (page 2270) to implement the PDF workflow button in the Print dialog.

Special Considerations

In Mac OS X v10.4 and earlier, this function is not implemented and returns an error. You can use the function `PMWorkflowSubmitPDFWithOptions` (page 2271) together with the function `PMPrintSettingsToOptions` (page 2213) instead.

Availability

Available in Mac OS X v10.3 and later.

Declared In
`PMCore.h`

Callbacks

PMIdleProcPtr

Defines a pointer to an idle function. (**Deprecated.** There is no replacement; this callback function was included to facilitate porting legacy applications to Mac OS X, but it serves no useful purpose.)

```
typedef void (*PMIdleProcPtr) (void);
```

You would declare your idle function like this if you were to name it `MyPrintIdleCallback`:

```
void MyPrintIdleCallback (void);
```

Discussion
If you install an idle function using the function `PMSessionSetIdleProc`, the printing system calls your idle function periodically during your print loop. Your idle function can display application status while printing, but it should not duplicate information displayed by the printing system or the printer driver. If you don't install an idle function, you get the standard dialog for the current driver in Mac OS 8 and 9.

Your idle function must check whether the user has pressed Command-period, in which case your application should stop its printing operation. If your status dialog contains a button to cancel the printing operation, your idle function should also check for clicks in the button and respond accordingly.

To provide a pointer to your idle function, you create a universal procedure pointer (UPP) of type `PMIdleUPP`, using the function `NewPMIdleUPP`. You can do so with code similar to the following:

```
PMIdleUPP MyPrintIdleUPP;
MyPrintIdleUPP = NewPMIdleUPP (&MyPrintIdleCallback);
```

When your print job is completed, you should use the function `DisposePMIdleUPP` to dispose of the universal procedure pointer associated with your idle function. However, if you will use the same idle function in subsequent print jobs, you can reuse the same UPP, rather than dispose of it and later create a new UPP.

Special Considerations

Your idle function is not called in Mac OS X. It's only called in Mac OS 8 and 9.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`PMCoreDeprecated.h`

Data Types

PMDialog

An opaque type that represents a custom printing dialog.

```
typedef struct OpaquePMDialog* PMDialog;
```

Discussion
This data type is used by functions that are not recommended or deprecated.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`PMDefinitionsDeprecated.h`

PMIdleUPP

A type that defines a universal procedure pointer to an idle callback.

```
typedef PMIdleProcPtr PMIdleUPP;
```

Discussion
This data type is used by functions that are not recommended or deprecated.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`PMCoreDeprecated.h`

PMLanguageInfo

A data structure that contains level, version, and release information for the imaging language used by a printer driver.

```
struct PMLanguageInfo {
    Str32 level;
    Str32 version;
    Str32 release;
};
```

Fields
`level`
Specifies the level of the imaging language used by the printer driver.
`version`
Specifies the version of the imaging language.

`release`
: Specifies the release of the imaging language.

PMObject

The base type for all the opaque types used in Core Printing.

```
typedef const void* PMObject;
```

Discussion
`PMObject` is the base type for opaque types such as `PMPrintSession`, `PMPageFormat`, `PMPrintSettings`, `PMPrinter`, `PMPaper`, `PMPreset`, and `PMServer`. `PMObject` is used in functions such as `PMRetain` (page 2215) and `PMRelease` (page 2214) that operate on any opaque type.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`PMDefinitions.h`

PMPageFormat

An opaque type that stores the settings in the Page Setup dialog.

```
typedef struct OpaquePMPageFormat* PMPageFormat;
```

Discussion
Your application uses page format objects to store information such as the paper size, orientation, and scale of pages in a printing session. To create a page format object, you use the function `PMCreatePageFormat` (page 2143). A new page format object is empty and unusable until you call `PMSessionDefaultPageFormat` (page 2225) or `PMCopyPageFormat` (page 2141) to initialize the settings. You can also use the functions `PMSetPageFormatExtendedData` (page 2258) and `PMGetPageFormatExtendedData` (page 2164) to store and retrieve application-specific data in a page format object.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`PMDefinitions.h`

PMPaper

An opaque type that stores information about the paper used in a print job.

```
typedef struct OpaquePMPaper* PMPaper;
```

Discussion
Your application uses paper objects to identify standard and custom types of printing paper.

Availability
Available in Mac OS X v10.3 and later.

Declared In
PMDefinitions.h

PMPaperMargins

A data structure that specifies the unprintable area of a paper object.

```
typedef PMRect PMPaperMargins;
```

Discussion
Your application specifies paper margins when calling the function PMPaperCreateCustom (page 2177) to create a custom paper type. You can obtain a paper's margins with the function PMPaperGetMargins (page 2180).

Availability
Available in Mac OS X v10.3 and later.

Declared In
PMDefinitions.h

PMPreset

An opaque type that stores information about a named preset available for a print job.

```
typedef struct OpaquePMPreset* PMPreset;
```

Discussion
Your application uses a preset object to identify a named preset in the Print dialog. You typically obtain an instance of this type using the function PMPrinterCopyPresets (page 2189).

Availability
Available in Mac OS X v10.3 and later.

Declared In
PMDefinitions.h

PMPrinter

An opaque type that represents a printer.

```
typedef struct OpaquePMPrinter* PMPrinter;
```

Discussion
You typically obtain a printer object using the function PMSessionGetCurrentPrinter (page 2231) or PMServerCreatePrinterList (page 2215).

Availability
Available in Mac OS X v10.0 and later.

Declared In
PMDefinitions.h

PMPrintSession

An opaque type that stores information about a print job.

```
typedef struct OpaquePMPrintSession* PMPrintSession;
```

Discussion
A printing session object contains information that's needed by the page format and print settings objects, such as default page format and print settings values. For this reason, some printing functions can be called only after you have created a printing session object. For example, setting defaults for or validating page format and print settings objects can only be done after you have created a printing session object. Your application creates a printing session object using the function `PMCreateSession` (page 2145).

You can use a printing session to implement multithreaded printing, and you can create multiple sessions within a single-threaded application. If your application does not use sheets, then your application can open only one dialog at a time. Each printing session can have its own dialog, and settings changed in one dialog are independent of settings in any other dialog.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`PMDefinitions.h`

PMPrintSettings

An opaque type that stores the settings in the Print dialog.

```
typedef struct OpaquePMPrintSettings* PMPrintSettings;
```

Discussion
Your application uses print settings objects to store information such as the number of copies and the range of pages to print in a printing session. To create a print settings object, you use the function `PMCreatePrintSettings` (page 2144). A new print settings object is empty and unusable until you call `PMSessionDefaultPrintSettings` (page 2225) or `PMCopyPrintSettings` (page 2142) to initialize the settings. You can also use the functions `PMSetPrintSettingsExtendedData` (page 2261) and `PMGetPrintSettingsExtendedData` (page 2168) to store and retrieve application-specific data in a print settings object.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`PMDefinitions.h`

PMRect

A data structure that describes a rectangle using four double-precision coordinates.

```
struct PMRect {
    double top;
    double left;
    double bottom;
    double right;
};
```

Fields

`top`
The vertical coordinate for the upper-left point of the rectangle.

`left`
The horizontal coordinate for the upper-left point of the rectangle.

`bottom`
The vertical coordinate for the lower-right point of the rectangle.

`right`
The horizontal coordinate for the lower-right point of the rectangle.

PMResolution

A data structure that contains printing resolution information.

```
struct PMResolution {
    double hRes;
    double vRes;
};
```

Fields

`hRes`
The horizontal resolution in dots per inch (dpi).

`vRes`
The vertical resolution in dots per inch (dpi).

Discussion
The functions `PMGetResolution` (page 2169) and `PMPrinterGetPrinterResolution` (page 2199) use this structure to return printing resolution information. Your application can pass this information to the function `PMSetResolution` (page 2263).

PMServer

An opaque type that identifies a local or remote print server.

```
typedef struct OpaquePMServer* PMServer;
```

Availability
Available in Mac OS X v10.2 and later.

Declared In
`PMDefinitions.h`

PMPrintContext

An opaque type that describes the graphics environment for printing a document.

```
typedef struct OpaquePMPrintContext* PMPrintContext;
```

Discussion
This data type is used by functions that are not recommended or deprecated.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`PMDefinitionsDeprecated.h`

PMColorMode

A type that specifies color modes to use for printing.

```
typedef UInt16 PMColorMode;
```

Discussion
This data type is used by functions that are not recommended or deprecated.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`PMDefinitionsDeprecated.h`

Constants

Data Not Wanted Constants

Constants your application can use to indicate it does not need certain types of data returned by various printing functions.

```
#define kPMNoData  NULL
#define kPMDontWantSize  NULL
#define kPMDontWantData  NULL
#define kPMDontWantBoolean  NULL
#define kPMNoPrintSettings  NULL
#define kPMNoPageFormat  NULL
#define kPMNoReference  NULL
```

Constants
`kPMNoData`
Specifies that your application does not need data returned for a particular parameter. For future compatibility, you are encouraged to use one of the following constants in cases where a specific type of data is not required.

`kPMDontWantSize`
Specifies that your application does not need the size information returned by the printing function.

`kPMDontWantData`
Specifies that your application does not need the data returned by the printing function.

`kPMDontWantBoolean`
Specifies that your application does not need a Boolean value returned by the printing function.

`kPMNoPrintSettings`
Specifies that your application does not need a `PMPrintSettings` object returned by the printing function.

`kPMNoPageFormat`
Specifies that your application does not need a `PMPageFormat` object returned by the printing function.

`kPMNoReference`
Specifies that your application does not need a reference returned by the printing function.

Data Representation Formats

Constants that specify the format of the data representation created with the functions `PMPageFormatCreateDataRepresentation` (page 2174) and `PMPrintSettingsCreateDataRepresentation` (page 2208).

```
enum PMDataFormat {
  kPMDataFormatXMLDefault = 0,
  kPMDataFormatXMLMinimal = 1,
  kPMDataFormatXMLCompressed = 2
};
typedef enum PMDataFormat PMDataFormat;
```

Constants

`kPMDataFormatXMLDefault`
Specifies a data format that is compatible with all Mac OS X versions. Data in this format can be used with the `PMUnflattenXXX` functions present in versions of Mac OS X prior to 10.5. This format is a pure XML representation of the data. However, this format is much larger than the more modern data formats described below.

Available in Mac OS X v10.5 and later.

Declared in `PMDefinitions.h`.

`kPMDataFormatXMLMinimal`
Specifies an uncompressed data format that is approximately 3-5 times smaller than `kPMDataFormatXMLDefault`. This data format is only compatible with Mac OS X v10.5 and later. This format is a good choice when you do not need to use the data in versions of Mac OS X prior to 10.5 and you need a pure XML representation of the data.

Available in Mac OS X v10.5 and later.

Declared in `PMDefinitions.h`.

`kPMDataFormatXMLCompressed`
: Specifies a compressed data format that is approximately 20 times smaller than `kPMDataFormatXMLDefault`. This data format is only compatible with Mac OS X v10.5 and later. This format is a good choice when you do not need to use the data in versions of Mac OS X prior to 10.5 and the minimum data size is important. Note that this format is not a pure XML representation of the data.

Available in Mac OS X v10.5 and later.

Declared in `PMDefinitions.h`.

Destination Types

Constants that specify a destination for a print job.

```
typedef UInt16 PMDestinationType;
enum {
    kPMDestinationInvalid = 0,
    kPMDestinationPrinter = 1,
    kPMDestinationFile = 2,
    kPMDestinationFax = 3,
    kPMDestinationPreview = 4,
    kPMDestinationProcessPDF = 5
};
```

Constants

`kPMDestinationInvalid`
: Specifies the destination is invalid.

Available in Mac OS X v10.1 and later.

Declared in `PMDefinitions.h`.

`kPMDestinationPrinter`
: Specifies output to a printer.

Available in Mac OS X v10.0 and later.

Declared in `PMDefinitions.h`.

`kPMDestinationFile`
: Specifies output to a file.

Available in Mac OS X v10.0 and later.

Declared in `PMDefinitions.h`.

`kPMDestinationFax`
: Specifies output to a fax. This destination is currently not supported.

Available in Mac OS X v10.0 and later.

Declared in `PMDefinitions.h`.

`kPMDestinationPreview`
: Specifies output to print preview.

Available in Mac OS X v10.1 and later.

Declared in `PMDefinitions.h`.

`kPMDestinationProcessPDF`
Specifies output to a PDF workflow option.

Available in Mac OS X v10.4 and later.

Declared in `PMDefinitions.h`.

Document Format Strings

Constants that specify the document format for a print job.

```
#define kPMDocumentFormatDefault
            CFSTR("com.apple.documentformat.default")
#define kPMDocumentFormatPDF
            CFSTR("application/pdf")
#define kPMDocumentFormatPICT
            CFSTR("application/vnd.apple.printing-pict")
#define kPMDocumentFormatPICTPS
            CFSTR("application/vnd.apple.printing-pict-ps")
#define kPMDocumentFormatPostScript
            CFSTR("application/postscript")
```

Constants

`kPMDocumentFormatDefault`
Specifies the default format for the printing system. In Mac OS X, the default format is PDF.

`kPMDocumentFormatPDF`
Specifies PDF.

`kPMDocumentFormatPICT`
Specifies PICT format.

`kPMDocumentFormatPICTPS`
Specifies PICT format with embedded PostScript.

`kPMDocumentFormatPostScript`
Specifies PostScript format.

Duplex Modes

Constants that specify duplex mode settings.

```
typedef UInt32 PMDuplexMode;
enum {
    kPMDuplexNone = 0x0001,
    kPMDuplexNoTumble = 0x0002,
    kPMDuplexTumble = 0x0003,
    kPMSimplexTumble = 0x0004
};
```

Constants

`kPMDuplexNone`
Print on only one side of the paper.

Available in Mac OS X v10.0 and later.

Declared in `PMDefinitions.h`.

`kPMDuplexNoTumble`
Print on both sides of the paper, with both sides oriented in the same direction (no tumbling.)

Available in Mac OS X v10.0 and later.

Declared in `PMDefinitions.h`.

`kPMDuplexTumble`
Print on both sides of the paper, with the output on the second side flipped relative to the first side (tumbling on.)

Available in Mac OS X v10.0 and later.

Declared in `PMDefinitions.h`.

`kPMSimplexTumble`
Print on only one side of the paper, but tumble the images while printing. This mode is not supported at this time.

Available in Mac OS X v10.0 and later.

Declared in `PMDefinitions.h`.

Graphics Context Types

Constants that specify the graphics context for a print job.

```
#define kPMGraphicsContextDefault
        CFSTR("com.apple.graphicscontext.default")
#define kPMGraphicsContextQuickdraw
        CFSTR("com.apple.graphicscontext.quickdraw")
#define kPMGraphicsContextCoreGraphics
        CFSTR("com.apple.graphicscontext.coregraphics")
```

Constants

`kPMGraphicsContextDefault`
Specifies the default graphics context for the application's runtime environment.

`kPMGraphicsContextQuickdraw`
Specifies a QuickDraw graphics context.

`kPMGraphicsContextCoreGraphics`
Specifies a Quartz graphics context. The default coordinate system for a Quartz printing context is not the same as that used for a QuickDraw printing context. A Quartz printing context defines the coordinates of the lower-left corner of the paper as (0,0) whereas the origin for a QuickDraw is at the upper-right corner of the paper's imageable area.

Page Orientation Constants

Constants that specify page orientation.

```
typedef UInt16 PMOrientation;
enum {
    kPMPortrait = 1,
    kPMLandscape = 2,
    kPMReversePortrait = 3,
    kPMReverseLandscape = 4
};
```

Constants

`kPMPortrait`

Specifies portrait (vertical) page orientation. Portrait orientation performs no alteration of the logical page.

Available in Mac OS X v10.0 and later.

Declared in `PMDefinitions.h`.

`kPMLandscape`

Specifies landscape (horizontal) orientation. Landscape orientation performs a 90° counterclockwise rotation on the logical page image and sets the Quartz origin to the upper-left corner of the unrotated logical page with positive y-values increasing across and to the right of the unrotated page. This has the effect of rotating the logical page image 90° clockwise. In other words, the image appears on the unrotated page as if it were rotated 90° clockwise.

Available in Mac OS X v10.0 and later.

Declared in `PMDefinitions.h`.

`kPMReversePortrait`

Specifies reverse portrait orientation. Reverse portrait orientation performs a 180° rotation on the logical page rectangle and sets the Quartz origin to the upper-right corner of the unrotated logical page with positive y-values increasing downwards. This has the effect of rotating the logical page image 180°. Reverse portrait orientation is supported in Mac OS X v10.5 and later.

Available in Mac OS X v10.0 and later.

Declared in `PMDefinitions.h`.

`kPMReverseLandscape`

Specifies reverse landscape page orientation. Landscape orientation performs a 90° clockwise rotation on the logical page rectangle and sets the Quartz origin to the lower-right corner of the unrotated logical page, with the positive y-values increasing to across and to the left of the unrotated page. This has the effect of rotating the logical page image 90° counterclockwise. In other words, the image appears on the unrotated page as if it were rotated 90° counterclockwise.

Available in Mac OS X v10.0 and later.

Declared in `PMDefinitions.h`.

PDF Workflow Dictionary Keys

Constants that specify the keys in a PDF workflow dictionary.

```
#define kPDFWorkFlowItemURLKey CFSTR("itemURL")
#define kPDFWorkflowDisplayNameKey CFSTR("displayName")
#define kPDFWorkflowFolderURLKey CFSTR("folderURL")
#define kPDFWorkflowItemsKey CFSTR("items")
```

Constants

`kPDFWorkFlowItemURLKey`
The URL to the PDF workflow item.

Available in Mac OS X v10.3 and later.

Declared in `PMDefinitions.h`.

`kPDFWorkflowDisplayNameKey`
The user-displayable name for the PDF workflow item.

Available in Mac OS X v10.3 and later.

Declared in `PMDefinitions.h`.

`kPDFWorkflowFolderURLKey`
The URL to the folder containing PDF workflow items.

Available in Mac OS X v10.5 and later.

Declared in `PMDefinitions.h`.

`kPDFWorkflowItemsKey`
A Core Foundation array describing the PDF workflow items in the folder.

Available in Mac OS X v10.3 and later.

Declared in `PMDefinitions.h`.

PostScript Injection Dictionary Keys

Constants that specify keys for PostScript injection dictionary entries.

```
#define kPSInjectionSectionKey     CFSTR("section")
#define kPSInjectionSubSectionKey  CFSTR("subsection")
#define kPSInjectionPageKey        CFSTR("page")
#define kPSInjectionPlacementKey   CFSTR("place")
#define kPSInjectionPostScriptKey  CFSTR("psdata")
```

Constants

`kPSInjectionSectionKey`
Specifies a section.

`kPSInjectionSubSectionKey`
Specifies a subsection.

`kPSInjectionPageKey`
Specifies a page.

`kPSInjectionPlacementKey`
Specifies placement.

`kPSInjectionPostScriptKey`
Specifies PostScript data.

PostScript Page Injection Options

Constants that specify PostScript injection options.

```
enum {
    kPSPageInjectAllPages = -1,
    kPSInjectionMaxDictSize = 5
};
```

Constants

`kPSPageInjectAllPages`

Specifies to inject all pages in the print job with PostScript code.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `PMDefinitionsDeprecated.h`.

`kPSInjectionMaxDictSize`

Specifies the maximum size needed for a dictionary used for PostScript injection.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `PMDefinitionsDeprecated.h`.

PostScript Injection Placement Options

Constants that specify where in the print job to inject PostScript code.

```
typedef UInt16 PSInjectionPlacement;
enum {
    kPSInjectionBeforeSubsection = 1,
    kPSInjectionAfterSubsection = 2,
    kPSInjectionReplaceSubsection = 3
};
```

Constants

`kPSInjectionBeforeSubsection`

Specifies that your PostScript code be inserted before the standard PostScript code that is normally emitted for the subsection.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `PMDefinitionsDeprecated.h`.

`kPSInjectionAfterSubsection`

Specifies that your PostScript code be inserted after the standard PostScript code that is normally emitted for the subsection.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `PMDefinitionsDeprecated.h`.

`kPSInjectionReplaceSubsection`

Specifies that your PostScript code replace the standard PostScript code that is normally emitted for the subsection.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `PMDefinitionsDeprecated.h`.

PostScript Injection Sections

Constants that specify keys for PostScript injection section values.

```
typedef SInt32 PSInjectionSection;
enum {
    kInjectionSectJob = 1,
    kInjectionSectCoverPage = 2
};
```

Constants

`kInjectionSectJob`

Specifies the job section. This is the default section if you do not specify a section key explicitly.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `PMDefinitionsDeprecated.h`.

`kInjectionSectCoverPage`

Specifies the cover page section. Currently unsupported.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `PMDefinitionsDeprecated.h`.

PostScript Injection Subsections

Constants that specify PostScript injection values for the subsection key.

```
typedef SInt32 PSInjectionSubsection;
enum {
    kInjectionSubPSAdobe = 1,
    kInjectionSubPSAdobeEPS = 2,
    kInjectionSubBoundingBox = 3,
    kInjectionSubEndComments = 4,
    kInjectionSubOrientation = 5,
    kInjectionSubPages = 6,
    kInjectionSubPageOrder = 7,
    kInjectionSubBeginProlog = 8,
    kInjectionSubEndProlog = 9,
    kInjectionSubBeginSetup = 10,
    kInjectionSubEndSetup = 11,
    kInjectionSubBeginDefaults = 12,
    kInjectionSubEndDefaults = 13,
    kInjectionSubDocFonts = 14,
    kInjectionSubDocNeededFonts = 15,
    kInjectionSubDocSuppliedFonts = 16,
    kInjectionSubDocNeededRes = 17,
    kInjectionSubDocSuppliedRes = 18,
    kInjectionSubDocCustomColors = 19,
    kInjectionSubDocProcessColors = 20,
    kInjectionSubPlateColor = 21,
    kInjectionSubPageTrailer = 22,
    kInjectionSubTrailer = 23,
    kInjectionSubEOF = 24,
    kInjectionSubBeginFont = 25,
    kInjectionSubEndFont = 26,
    kInjectionSubBeginResource = 27,
    kInjectionSubEndResource = 28,
    kInjectionSubPage = 29,
    kInjectionSubBeginPageSetup = 30,
    kInjectionSubEndPageSetup = 31
};
```

Constants

`kInjectionSubPSAdobe`

Specifies the "%!PS-Adobe" subsection.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `PMDefinitionsDeprecated.h`.

`kInjectionSubPSAdobeEPS`

Specifies the "%!PS-Adobe-3.0 EPSF-3.0" subsection.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `PMDefinitionsDeprecated.h`.

`kInjectionSubBoundingBox`

Specifies the "%BoundingBox" subsection.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `PMDefinitionsDeprecated.h`.

`kInjectionSubEndComments`
Specifies the "%EndComments" subsection.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `PMDefinitionsDeprecated.h`.

`kInjectionSubOrientation`
Specifies the "%Orientation" subsection.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `PMDefinitionsDeprecated.h`.

`kInjectionSubPages`
Specifies the "%Pages" subsection.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `PMDefinitionsDeprecated.h`.

`kInjectionSubPageOrder`
Specifies the "%PageOrder" subsection.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `PMDefinitionsDeprecated.h`.

`kInjectionSubBeginProlog`
Specifies the "%BeginProlog" subsection.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `PMDefinitionsDeprecated.h`.

`kInjectionSubEndProlog`
Specifies the "%EndProlog" subsection.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `PMDefinitionsDeprecated.h`.

`kInjectionSubBeginSetup`
Specifies the "%BeginSetup" subsection.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `PMDefinitionsDeprecated.h`.

`kInjectionSubEndSetup`
Specifies the "%EndSetup" subsection.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `PMDefinitionsDeprecated.h`.

`kInjectionSubBeginDefaults`
Specifies the "%BeginDefaults" subsection.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `PMDefinitionsDeprecated.h`.

`kInjectionSubEndDefaults`
Specifies the "%EndDefaults" subsection.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `PMDefinitionsDeprecated.h`.

`kInjectionSubDocFonts`
Specifies the "%DocumentFonts" subsection.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `PMDefinitionsDeprecated.h`.

`kInjectionSubDocNeededFonts`
Specifies the "%DocumentNeededFonts" subsection.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `PMDefinitionsDeprecated.h`.

`kInjectionSubDocSuppliedFonts`
Specifies the "%DocumentSuppliedFonts" subsection.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `PMDefinitionsDeprecated.h`.

`kInjectionSubDocNeededRes`
Specifies the "%DocumentNeededResources" subsection.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `PMDefinitionsDeprecated.h`.

`kInjectionSubDocSuppliedRes`
Specifies the "%DocumentSuppliedResources" subsection.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `PMDefinitionsDeprecated.h`.

`kInjectionSubDocCustomColors`
Specifies the "%DocumentCustomColors" subsection.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `PMDefinitionsDeprecated.h`.

`kInjectionSubDocProcessColors`
Specifies the "%DocumentProcessColors" subsection.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `PMDefinitionsDeprecated.h`.

`kInjectionSubPlateColor`
Specifies the "%PlateColor" subsection.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `PMDefinitionsDeprecated.h`.

`kInjectionSubPageTrailer`
Specifies the "%PageTrailer" subsection.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `PMDefinitionsDeprecated.h`.

`kInjectionSubTrailer`
Specifies the "%Trailer" subsection.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `PMDefinitionsDeprecated.h`.

`kInjectionSubEOF`
Specifies the "%EOF" (end of file) subsection.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `PMDefinitionsDeprecated.h`.

`kInjectionSubBeginFont`
Specifies the "%BeginFont" subsection.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `PMDefinitionsDeprecated.h`.

`kInjectionSubEndFont`
Specifies the "%EndFont" subsection.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `PMDefinitionsDeprecated.h`.

`kInjectionSubBeginResource`
Specifies the "%BeginResource" subsection.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `PMDefinitionsDeprecated.h`.

`kInjectionSubEndResource`
Specifies the "%EndResource" subsection.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `PMDefinitionsDeprecated.h`.

`kInjectionSubPage`
Specifies the "%Page" subsection.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `PMDefinitionsDeprecated.h`.

`kInjectionSubBeginPageSetup`
Specifies the "%BeginPageSetup" subsection.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `PMDefinitionsDeprecated.h`.

`kInjectionSubEndPageSetup`
Specifies the "%EndPageSetup" subsection.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `PMDefinitionsDeprecated.h`.

PostScript Printer Description File Domains

Constants that specify the domains for PostScript printer description (PPD) files.

```
typedef UInt16 PMPPDDomain;
enum {
    kAllPPDDomains = 1,
    kSystemPPDDomain = 2,
    kLocalPPDDomain = 3,
    kNetworkPPDDomain = 4,
    kUserPPDDomain = 5,
    kCUPSPPDDomain = 6
};
```

Constants

`kAllPPDDomains`
Specifies all available domains.

Available in Mac OS X v10.3 and later.

Declared in `PMDefinitions.h`.

`kSystemPPDDomain`
Specifies the system domain.

Available in Mac OS X v10.3 and later.

Declared in `PMDefinitions.h`.

`kLocalPPDDomain`
Specifies the local domain.

Available in Mac OS X v10.3 and later.

Declared in `PMDefinitions.h`.

`kNetworkPPDDomain`
Specifies the network domain.

Available in Mac OS X v10.3 and later.

Declared in `PMDefinitions.h`.

`kUserPPDDomain`
Specifies the user domain.

Available in Mac OS X v10.3 and later.

Declared in `PMDefinitions.h`.

`kCUPSPPDDomain`
Specifies the CUPS domain.

Available in Mac OS X v10.3 and later.

Declared in `PMDefinitions.h`.

Print All Pages Constant

A constant that specifies that all pages of a document should be printed.

```
enum {
    kPMPrintAllPages = -1
};
```

Constants

`kPMPrintAllPages`
Specifies that all pages of a document should be printed.

Available in Mac OS X v10.0 and later.

Declared in `PMDefinitions.h`.

Print Quality Modes

Constants that specify standard options for print quality.

```
typedef UInt32 PMQualityMode;
enum {
    kPMQualityLowest = 0,
    kPMQualityInkSaver = 1,
    kPMQualityDraft = 4,
    kPMQualityNormal = 8,
    kPMQualityPhoto = 11,
    kPMQualityBest = 13,
    kPMQualityHighest = 15
};
```

Constants

`kPMQualityLowest`
Specifies to use the lowest print quality available to the printer.
Available in Mac OS X v10.0 and later.
Declared in `PMDefinitions.h`.

`kPMQualityInkSaver`
Specifies to use a mode that saves ink, even if it slows printing.
Available in Mac OS X v10.0 and later.
Declared in `PMDefinitions.h`.

`kPMQualityDraft`
Specifies to print at the highest speed, with the amount of ink used as a secondary consideration.
Available in Mac OS X v10.0 and later.
Declared in `PMDefinitions.h`.

`kPMQualityNormal`
Specifies a general usage mode that balances quality and speed.
Available in Mac OS X v10.0 and later.
Declared in `PMDefinitions.h`.

`kPMQualityPhoto`
Specifies to optimize the quality of photos on the page, with speed not a concern.
Available in Mac OS X v10.0 and later.
Declared in `PMDefinitions.h`.

`kPMQualityBest`
Specifies to get the best print quality for all objects and photos on a page.
Available in Mac OS X v10.0 and later.
Declared in `PMDefinitions.h`.

`kPMQualityHighest`
Specifies to use the highest print quality available to the printer.
Available in Mac OS X v10.0 and later.
Declared in `PMDefinitions.h`.

Print Queue States

Constants that specify the current state of a print queue.

```
typedef UInt16 PMPrinterState;
enum {
    kPMPrinterIdle = 3,
    kPMPrinterProcessing = 4,
    kPMPrinterStopped = 5
};
```

Constants

`kPMPrinterIdle`

Specifies the idle state.

Available in Mac OS X v10.2 and later.

Declared in `PMDefinitions.h`.

`kPMPrinterProcessing`

Specifies the processing state.

Available in Mac OS X v10.2 and later.

Declared in `PMDefinitions.h`.

`kPMPrinterStopped`

Specifies the stopped state.

Available in Mac OS X v10.2 and later.

Declared in `PMDefinitions.h`.

Printer Description Types

Constants that specify printer description types.

```
#define kPMPPDDescriptionType CFSTR("PMPPDDescriptionType")
```

Constants

`kPMPPDDescriptionType`

Specifies a PostScript printer description (PPD).

Available in Mac OS X v10.0 and later.

Declared in `PMDefinitions.h`.

Tag Constants

Constants that specify values, such as minimum and maximum values, that your application can pass to or obtain from printing functions.

```
typedef UInt32 PMTag;
enum {
    kPMCurrentValue = 'curr',
    kPMDefaultValue = 'dflt',
    kPMMinimumValue = 'minv',
    kPMMaximumValue = 'maxv',
    kPMSourceProfile = 'srcp',
    kPMMinRange = 'mnrg',
    kPMMaxRange = 'mxrg',
    kPMMinSquareResolution = 'mins',
    kPMMaxSquareResolution = 'maxs',
    kPMDefaultResolution = 'dftr'
};
```

Constants

`kPMCurrentValue`
Specifies the current setting or value.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `PMDefinitionsDeprecated.h`.

`kPMDefaultValue`
Specifies the default setting or value.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `PMDefinitionsDeprecated.h`.

`kPMMinimumValue`
Specifies the minimum setting or value.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `PMDefinitionsDeprecated.h`.

`kPMMaximumValue`
Specifies the maximum setting or value.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `PMDefinitionsDeprecated.h`.

`kPMSourceProfile`
Specifies a ColorSync source profile.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `PMDefinitionsDeprecated.h`.

`kPMMinRange`
Specifies the minimum resolution supported by the printer.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `PMDefinitionsDeprecated.h`.

`kPMMaxRange`
Specifies the maximum resolution supported by the printer.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `PMDefinitionsDeprecated.h`.

`kPMMinSquareResolution`
Specifies the minimum resolution setting for which the horizontal and vertical resolutions are equal.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `PMDefinitionsDeprecated.h`.

`kPMMaxSquareResolution`
Specifies the maximum resolution setting for which the horizontal and vertical resolutions are equal.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `PMDefinitionsDeprecated.h`.

`kPMDefaultResolution`
Specifies the default resolution setting for the printer (typically 72 dots per inch).

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `PMDefinitionsDeprecated.h`.

User Cancellation Constant

A constant that specifies an error value that indicates the user canceled a printing operation.

```
enum {
    kPMCancel = 128
};
```

Constants

`kPMCancel`
Specifies that the user clicked the Cancel button in a Print or Page Setup dialog.

Available in Mac OS X v10.0 and later.

Declared in `PMDefinitions.h`.

Discussion

This constant is provided for compatibility with old applications and printer drivers that expect the `iPrAbort` error code to be returned when the user cancels a printing operation.

The default idle function checks for Command-period keyboard events during printing, and sets the error condition equal to `kPMCancel` if one occurs. Your application can check for this condition using the `PMSessionError` function, and should cancel the print job if `kPMCancel` is returned.

If you supply your own idle function (not needed in Mac OS 8, 9, or X), your function must check for Command-period keyboard events, and set the error condition using the function `PMSessionSetError`.

Color Modes

Constants that specify a color mode to use for printing.

```
typedef UInt16 PMColorMode;
enum {
    kPMBlackAndWhite = 1,
    kPMGray = 2,
    kPMColor = 3,
    kPMColorModeDuotone = 4,
    kPMColorModeSpecialColor = 5
};
```

Constants

`kPMBlackAndWhite`
Specifies black-and-white mode.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `PMDefinitionsDeprecated.h`.

`kPMGray`
Specifies grayscale mode.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `PMDefinitionsDeprecated.h`.

`kPMColor`
Specifies color mode.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `PMDefinitionsDeprecated.h`.

`kPMColorModeDuotone`
Specifies two-channel color mode.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `PMDefinitionsDeprecated.h`.

`kPMColorModeSpecialColor`
Specifies to allow special colors such as metallic and light cyan.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `PMDefinitionsDeprecated.h`.

Discussion
These constants are used by functions that are deprecated.

Result Codes

This table lists the result codes defined for Core Printing.

Result Code	Value	Description
kPMGeneralError	-30870	An unspecified error occurred. Available in Mac OS X v10.0 and later.
kPMOutOfScope	-30871	Your application called this function out of sequence with other printing functions. Available in Mac OS X v10.0 and later.
kPMNoDefaultPrinter	-30872	The user has not specified a default printer. Available in Mac OS X v10.0 and later.
kPMNotImplemented	-30873	The function is not implemented. Available in Mac OS X v10.0 and later.
kPMNoSuchEntry	-30874	There is no entry to match your application's request. Available in Mac OS X v10.0 and later.
kPMInvalidPrintSettings	-30875	Your application passed an invalid print settings object. Available in Mac OS X v10.0 and later.
kPMInvalidPageFormat	-30876	Your application passed an invalid page format object. Available in Mac OS X v10.0 and later.
kPMValueOutOfRange	-30877	Your application passed an out-of-range value. Available in Mac OS X v10.0 and later.
kPMLockIgnored	-30878	The lock value was ignored. Available in Mac OS X v10.0 and later.
kPMInvalidPrintSession	-30879	Your application passed an invalid printing session object. Available in Mac OS X v10.0 and later.
kPMInvalidPrinter	-30880	Your application passed an invalid printer object. Available in Mac OS X v10.0 and later.
kPMObjectInUse	-30881	The specified object is in use. Available in Mac OS X v10.0 and later.
kPMInvalidIndex	-30882	An array index is invalid. Available in Mac OS X v10.0 and later.
kPMStringConversionFailure	-30883	An internal error occurred while converting a string. Available in Mac OS X v10.0 and later.
kPMXMLParseError	-30884	An error occurred while parsing XML data. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
kPMInvalidJobTemplate	-30885	An internal error occurred while creating a job template. Available in Mac OS X v10.0 and later.
kPMInvalidPrinterInfo	-30886	The printer information is invalid. Available in Mac OS X v10.0 and later.
kPMInvalidConnection	-30887	The printer connection type is invalid. Available in Mac OS X v10.0 and later.
kPMInvalidKey	-30888	The key in a ticket, job template, or dictionary is invalid. Available in Mac OS X v10.0 and later.
kPMInvalidValue	-30889	The value in a ticket, job template, or dictionary is missing. Available in Mac OS X v10.0 and later.
kPMInvalidAllocator	-30890	The specified memory allocator is invalid. Available in Mac OS X v10.0 and later.
kPMInvalidTicket	-30891	The job ticket is invalid. Available in Mac OS X v10.0 and later.
kPMInvalidItem	-30892	The item being added to a ticket is invalid. Available in Mac OS X v10.0 and later.
kPMInvalidType	-30893	The data type in a ticket, job template, or dictionary is not the expected type. Available in Mac OS X v10.0 and later.
kPMInvalidReply	-30894	A remote server or client sent an invalid reply. Available in Mac OS X v10.0 and later.
kPMInvalidFileType	-30895	The file type is invalid. Available in Mac OS X v10.0 and later.
kPMInvalidObject	-30896	The object is invalid. Available in Mac OS X v10.0 and later.
kPMInvalidPaper	-30897	Your application passed an invalid paper object. Available in Mac OS X v10.2 and later.
kPMInvalidCalibrationTarget	-30898	The dictionary specifying a printer calibration target is invalid. Available in Mac OS X v10.3 and later.
kPMInvalidPreset	-30899	Your application passed an invalid preset object. Available in Mac OS X v10.3 and later.

CGImageProperties Reference

Framework: ApplicationServices/ImageIO

Declared in CGImageProperties.h

Overview

CGImageProperties Reference defines constants that represent characteristics of images used by the Image I/O framework.

Constants

Format-Specific Dictionaries

Properties that have an associated dictionary of file-format or metadata-format specific key-value pairs.

```
CFStringRef kCGImagePropertyTIFFDictionary;
CFStringRef kCGImagePropertyGIFDictionary;
CFStringRef kCGImagePropertyJFIFDictionary;
CFStringRef kCGImagePropertyExifDictionary;
CFStringRef kCGImagePropertyPNGDictionary;
CFStringRef kCGImagePropertyIPTCDictionary;
CFStringRef kCGImagePropertyGPSDictionary;
CFStringRef kCGImagePropertyRawDictionary;
CFStringRef kCGImagePropertyCIFFDictionary;
CFStringRef kCGImageProperty8BIMDictionary;
CFStringRef kCGImagePropertyDNGDictionary;
CFStringRef kCGImagePropertyExifAuxDictionary;
```

Constants

`kCGImagePropertyTIFFDictionary`

A dictionary of key-value pairs for an image that uses Tagged Image File Format (TIFF). See "TIFF Dictionary Keys" (page 2328).

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyGIFDictionary`

A dictionary of key-value pairs for an image that uses Graphics Interchange Format (GIF). See "GIF Dictionary Keys" (page 2316).

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyJFIFDictionary`
A dictionary of key-value pairs for an image that uses JPEG File Interchange Format (JFIF). See "JFIF Dictionary Keys" (page 2326).

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyExifDictionary`
A dictionary of key-value pairs for an image that uses Exchangeable Image File Format (EXIF). See "EXIF Dictionary Keys" (page 2307).

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyPNGDictionary`
A dictionary of key-value pairs for an image that uses Portable Network Graphics (PNG) format. See "PNG Dictionary Keys" (page 2327).

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCDictionary`
A dictionary of key-value pairs for an image that uses International Press Telecommunications Council (IPTC) metadata. See "IPTC Dictionary Keys" (page 2320).

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyGPSDictionary`
A dictionary of key-value pairs for an image that has Global Positioning System (GPS) information. See "GPS Dictionary Keys" (page 2316).

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyRawDictionary`
A dictionary of key-value pairs for an image that contains minimally processed, or raw, data.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyCIFFDictionary`
A dictionary of key-value pairs for an image that uses Camera Image File Format (CIFF). See "CIFF Dictionary Keys" (page 2332).

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImageProperty8BIMDictionary`
A dictionary of key-value pairs for an Adobe Photoshop image. See "8BIM Dictionary Keys" (page 2332).

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyDNGDictionary`
A dictionary of key-value pairs for an image that uses the Digital Negative (DNG) archival format. See "DNG Dictionary Keys" (page 2331).

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyExifAuxDictionary`
An auxiliary dictionary of key-value pairs for an image that uses Exchangeable Image File Format (EXIF).

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

Discussion
If any of these constants are returned by the functions`CGImageSourceCopyProperties` (page 240) or `CGImageSourceCopyPropertiesAtIndex` (page 241) the associated value is a dictionary of file-format or metadata-format specific key-value pairs.

Declared In
`CGImageProperties.h`

Camera Maker Dictionaries

Properties that have an associated dictionary of key-value pairs for a specific camera manufacturer.

```
CFStringRef kCGImagePropertyMakerCanonDictionary;
CFStringRef kCGImagePropertyMakerNikonDictionary;
CFStringRef kCGImagePropertyMakerMinoltaDictionary;
CFStringRef kCGImagePropertyMakerFujiDictionary;
CFStringRef kCGImagePropertyMakerOlympusDictionary;
CFStringRef kCGImagePropertyMakerPentaxDictionary;
```

Constants
`kCGImagePropertyMakerCanonDictionary`
A dictionary of key-value pairs for an image from a Canon camera. See "Canon Camera Dictionary Keys" (page 2337).

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyMakerNikonDictionary`
A dictionary of key-value pairs for an image from a Nikon camera. See "Nikon Camera Dictionary Keys" (page 2334).

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyMakerMinoltaDictionary`
A dictionary of key-value pairs for an image from a Minolta camera.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyMakerFujiDictionary`
A dictionary of key-value pairs for an image from a Fuji camera.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyMakerOlympusDictionary`
A dictionary of key-value pairs for an image from a Olympus camera.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyMakerPentaxDictionary`
A dictionary of key-value pairs for an image from a Pentax camera.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

Declared In
`CGImageProperties.h`

Image Source Container Properties

Properties that apply to the container in general but not necessarily to any individual image in the container.

```
CFStringRef kCGImagePropertyFileSize;
```

Constants
`kCGImagePropertyFileSize`
The size of the image file in bytes, if known. If present, this key is a `CFNumber` value.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

Discussion
These properties can be returned by the function `CGImageSourceCopyProperties` (page 240).

Declared In
`CGImageProperties.h`

Individual Image Properties

Properties that apply to an individual image in an image source.

```
CFStringRef kCGImagePropertyDPIHeight;
CFStringRef kCGImagePropertyDPIWidth;
CFStringRef kCGImagePropertyPixelWidth;
CFStringRef kCGImagePropertyPixelHeight;
CFStringRef kCGImagePropertyDepth;
CFStringRef kCGImagePropertyOrientation;
CFStringRef kCGImagePropertyIsFloat;
CFStringRef kCGImagePropertyIsIndexed;
CFStringRef kCGImagePropertyHasAlpha;
CFStringRef kCGImagePropertyColorModel;
CFStringRef kCGImagePropertyProfileName;
```

Constants
`kCGImagePropertyDPIHeight`
The resolution, in dots per inch, in the x dimension. If present, this key is a `CFNumber` value.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyDPIWidth`
The resolution, in dots per inch, in the y dimension. If present, this key is a `CFNumber` value.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyPixelWidth`
The number of pixels in the x dimension. If present, this key is a `CFNumber` value.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyPixelHeight`
The number of pixels in the y dimension. If present, this key is a `CFNumber` value.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyDepth`
The number of bits in each color sample of each pixel. If present, this key is a `CFNumber` value.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyOrientation`
The intended display orientation of the image. If present, this key is a `CFNumber` value with the same value as defined by the TIFF and EXIF specifications. The value specifies where the origin `(0,0)` of the image is locates, as shown in Table 49-1. If not present, a value of 1 is assumed.

Table 49-1

Value	Location of the origin of the image
1	Top, left
2	Top, right
3	Bottom, right
4	Bottom, left
5	Left, top
6	Right, top
7	Right, bottom
8	Left, bottom

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyIsFloat`
Whether or not the image contains floating-point pixel samples. The value of this key is `kCFBooleanTrue` if the image contains them.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyIsIndexed`
Whether or not the image contains indexed pixel samples (sometimes called paletted samples). The value of this key is `kCFBooleanTrue` if the image contains them.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyHasAlpha`
Whether or not the image has an alpha channel. The value of this key is `kCFBooleanTrue` if the image contains an alpha channel.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyColorModel`
The color model of the image such as, "RGB", "CMYK", "Gray", or "Lab". The value of this key is CFStringRef.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyProfileName`
The name of the optional ICC profile embedded in the image, if known. If present, the value of this key is a CFStringRef.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

Discussion
These properties can be returned by the function `CGImageSourceCopyPropertiesAtIndex` (page 241).

Declared In
`CGImageProperties.h`

Color Model Values

Values for the color model property.

```
const CFStringRef kCGImagePropertyColorModelRGB;
const CFStringRef kCGImagePropertyColorModelGray;
const CFStringRef kCGImagePropertyColorModelCMYK;
const CFStringRef kCGImagePropertyColorModelLab;
```

Constants
`kCGImagePropertyColorModelRGB`
An RGB color model.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyColorModelGray`
A Gray color model.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyColorModelCMYK`
A CMYK color model.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyColorModelLab`

A Lab color model.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

Discussion
A color model describes how color values are represented mathematically. A color space is a color model combined with a definition of how to interpret values within the model.

Declared In
`CGImageProperties.h`

EXIF Dictionary Keys

Keys for for an image that uses Exchangeable Image File Format (EXIF).

```
const CFStringRef kCGImagePropertyExifExposureTime;
const CFStringRef kCGImagePropertyExifFNumber;
const CFStringRef kCGImagePropertyExifExposureProgram;
const CFStringRef kCGImagePropertyExifSpectralSensitivity;
const CFStringRef kCGImagePropertyExifISOSpeedRatings;
const CFStringRef kCGImagePropertyExifOECF;
const CFStringRef kCGImagePropertyExifVersion;
const CFStringRef kCGImagePropertyExifDateTimeOriginal;
const CFStringRef kCGImagePropertyExifDateTimeDigitized;
const CFStringRef kCGImagePropertyExifComponentsConfiguration;
const CFStringRef kCGImagePropertyExifCompressedBitsPerPixel;
const CFStringRef kCGImagePropertyExifShutterSpeedValue;
const CFStringRef kCGImagePropertyExifApertureValue;
const CFStringRef kCGImagePropertyExifBrightnessValue;
const CFStringRef kCGImagePropertyExifExposureBiasValue;
const CFStringRef kCGImagePropertyExifMaxApertureValue;
const CFStringRef kCGImagePropertyExifSubjectDistance;
const CFStringRef kCGImagePropertyExifMeteringMode;
const CFStringRef kCGImagePropertyExifLightSource;
const CFStringRef kCGImagePropertyExifFlash;
const CFStringRef kCGImagePropertyExifFocalLength;
const CFStringRef kCGImagePropertyExifSubjectArea;
const CFStringRef kCGImagePropertyExifMakerNote;
const CFStringRef kCGImagePropertyExifUserComment;
const CFStringRef kCGImagePropertyExifSubsecTime;
const CFStringRef kCGImagePropertyExifSubsecTimeOrginal;
const CFStringRef kCGImagePropertyExifSubsecTimeDigitized;
const CFStringRef kCGImagePropertyExifFlashPixVersion;
const CFStringRef kCGImagePropertyExifColorSpace;
const CFStringRef kCGImagePropertyExifPixelXDimension;
const CFStringRef kCGImagePropertyExifPixelYDimension;
const CFStringRef kCGImagePropertyExifRelatedSoundFile;
const CFStringRef kCGImagePropertyExifFlashEnergy;
const CFStringRef kCGImagePropertyExifSpatialFrequencyResponse;
const CFStringRef kCGImagePropertyExifFocalPlaneXResolution;
const CFStringRef kCGImagePropertyExifFocalPlaneYResolution;
const CFStringRef kCGImagePropertyExifFocalPlaneResolutionUnit;
const CFStringRef kCGImagePropertyExifSubjectLocation;
const CFStringRef kCGImagePropertyExifExposureIndex;
const CFStringRef kCGImagePropertyExifSensingMethod;
const CFStringRef kCGImagePropertyExifFileSource;
const CFStringRef kCGImagePropertyExifSceneType;
const CFStringRef kCGImagePropertyExifCFAPattern;
const CFStringRef kCGImagePropertyExifCustomRendered;
const CFStringRef kCGImagePropertyExifExposureMode;
const CFStringRef kCGImagePropertyExifWhiteBalance;
const CFStringRef kCGImagePropertyExifDigitalZoomRatio;
const CFStringRef kCGImagePropertyExifFocalLenIn35mmFilm;
const CFStringRef kCGImagePropertyExifSceneCaptureType;
const CFStringRef kCGImagePropertyExifGainControl;
const CFStringRef kCGImagePropertyExifContrast;
const CFStringRef kCGImagePropertyExifSaturation;
const CFStringRef kCGImagePropertyExifSharpness;
const CFStringRef kCGImagePropertyExifDeviceSettingDescription;
const CFStringRef kCGImagePropertyExifSubjectDistRange;
const CFStringRef kCGImagePropertyExifImageUniqueID;
const CFStringRef kCGImagePropertyExifGamma;
```

Constants

`kCGImagePropertyExifExposureTime`
The exposure time.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyExifFNumber`
The F number.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyExifExposureProgram`
The exposure program.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyExifSpectralSensitivity`
The spectral sensitivity of each channel.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyExifISOSpeedRatings`
ISO speed ratings.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyExifOECF`
The opto-electrical conversion function (OECF), which defines the relationship between the optical input of the camera and the image values.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyExifVersion`
The version.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyExifDateTimeOriginal`
The original date and time.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyExifDateTimeDigitized`
The digitized date and time.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyExifComponentsConfiguration`
The components configuration. For compressed data, specifies that the channels of each component are arranged in increasing numeric order (from first component to the fourth).

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyExifCompressedBitsPerPixel`
The compressed bits per pixel.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyExifShutterSpeedValue`
The shutter speed value.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyExifApertureValue`
The aperture value.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyExifBrightnessValue`
The brightness value.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyExifExposureBiasValue`
The exposure bias value.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyExifMaxApertureValue`
The maximum aperture value.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyExifSubjectDistance`
The distance to the subject, in meters.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyExifMeteringMode`
The metering mode.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyExifLightSource`
The light source.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyExifFlash`
The flash status when the image was shot.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyExifFocalLength`
The focal length.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyExifSubjectArea`
The subject area.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyExifMakerNote`
A maker note.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyExifUserComment`
A user comment.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyExifSubsecTime`
The fraction of seconds for the date and time tag.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyExifSubsecTimeOrginal`
The fraction of seconds for the original date and time tag.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyExifSubsecTimeDigitized`
The fraction of seconds for the digitized time tag.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyExifFlashPixVersion`
The FlashPix version supported by an FPXR file. FlashPix is a format for multi-resolution, tiled images, that facilitates fast onscreen viewing.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyExifColorSpace`
The color space.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyExifPixelXDimension`
The pixel x dimension.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyExifPixelYDimension`
The pixel y dimension.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyExifRelatedSoundFile`
A related sound file.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyExifFlashEnergy`
The strobe energy when the image was captures, in beam candle power seconds.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyExifSpatialFrequencyResponse`
The spatial frequency table and spatial frequency response values in the direction of image width, image height, and diagonal directions. See ISO 12233..

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyExifFocalPlaneXResolution`
The number of image-width pixels (x) per focal plane resolution unit.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyExifFocalPlaneYResolution`
The number of image-height pixels (y)per focal plane resolution unit.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyExifFocalPlaneResolutionUnit`
The unit of measurement for the focal plane x and y tags.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyExifSubjectLocation`
The location of the scene's primary subject.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyExifExposureIndex`
The selected exposure index.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyExifSensingMethod`
The sensor type of the camera or input device.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyExifFileSource`
The image source.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyExifSceneType`
The scene type.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyExifCFAPattern`
The color filter array (CFA) pattern, which is the geometric patter of the image sensor for a 1-chip color sensor area.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyExifCustomRendered`
Special rendering performed on the image data.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyExifExposureMode`
The exposure mode setting.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyExifWhiteBalance`
The white balance mode.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyExifDigitalZoomRatio`
The digital zoom ratio.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyExifFocalLenIn35mmFilm`
The equivalent focal length in 35 mm film.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyExifSceneCaptureType`
The scene capture type (standard, landscape, portrait, night).

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyExifGainControl`
The gain adjustment applied to the image.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyExifContrast`
The contrast applied to the image.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyExifSaturation`
The saturation applied to the image.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyExifSharpness`
The sharpness applied to the image.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyExifDeviceSettingDescription`
For a particular camera mode, indicates the conditions for taking the picture.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyExifSubjectDistRange`
The subject distance range.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyExifImageUniqueID`
The unique ID of the image.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyExifGamma`
The gamma setting.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

Declared In
`CGImageProperties.h`

EXIF Auxiliary Dictionary Keys

Auxiliary keys for for an image that uses Exchangeable Image File Format (EXIF).

```
const CFStringRef kCGImagePropertyExifAuxLensInfo;
const CFStringRef kCGImagePropertyExifAuxLensModel;
const CFStringRef kCGImagePropertyExifAuxSerialNumber;
const CFStringRef kCGImagePropertyExifAuxLensID;
const CFStringRef kCGImagePropertyExifAuxLensSerialNumber;
const CFStringRef kCGImagePropertyExifAuxImageNumber;
const CFStringRef kCGImagePropertyExifAuxFlashCompensation;
const CFStringRef kCGImagePropertyExifAuxOwnerName;
const CFStringRef kCGImagePropertyExifAuxFirmware;
```

Constants

`kCGImagePropertyExifAuxLensInfo`
Lens information.
Available in Mac OS X v10.5 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyExifAuxLensModel`
The lens model.
Available in Mac OS X v10.5 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyExifAuxSerialNumber`
The serial number.
Available in Mac OS X v10.5 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyExifAuxLensID`
The lens ID.
Available in Mac OS X v10.5 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyExifAuxLensSerialNumber`
The lens serial number.
Available in Mac OS X v10.5 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyExifAuxImageNumber`
The image number.
Available in Mac OS X v10.5 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyExifAuxFlashCompensation`
Flash compensation.
Available in Mac OS X v10.5 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyExifAuxOwnerName`
The owner name.
Available in Mac OS X v10.5 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyExifAuxFirmware`
Firmware information.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

Declared In
`CGImageProperties.h`

GIF Dictionary Keys

Keys for an image that uses Graphics Interchange Format (GIF).

```
const CFStringRef kCGImagePropertyGIFLoopCount;
const CFStringRef kCGImagePropertyGIFDelayTime;
const CFStringRef kCGImagePropertyGIFImageColorMap;
const CFStringRef kCGImagePropertyGIFHasGlobalColorMap;
```

Constants
`kCGImagePropertyGIFLoopCount`
The loop count.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyGIFDelayTime`
The delay time.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyGIFImageColorMap`
The image color map.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyGIFHasGlobalColorMap`
Whether or not the GIF has a global color map.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

Declared In
`CGImageProperties.h`

GPS Dictionary Keys

Keys for an image that has Global Positioning System (GPS) information.

```
const CFStringRef kCGImagePropertyGPSVersion;
const CFStringRef kCGImagePropertyGPSLatitudeRef;
const CFStringRef kCGImagePropertyGPSLatitude;
const CFStringRef kCGImagePropertyGPSLongitudeRef;
const CFStringRef kCGImagePropertyGPSLongitude;
const CFStringRef kCGImagePropertyGPSAltitudeRef;
const CFStringRef kCGImagePropertyGPSAltitude;
const CFStringRef kCGImagePropertyGPSTimeStamp;
const CFStringRef kCGImagePropertyGPSSatellites;
const CFStringRef kCGImagePropertyGPSStatus;
const CFStringRef kCGImagePropertyGPSMeasureMode;
const CFStringRef kCGImagePropertyGPSDOP;
const CFStringRef kCGImagePropertyGPSSpeedRef;
const CFStringRef kCGImagePropertyGPSSpeed;
const CFStringRef kCGImagePropertyGPSTrackRef;
const CFStringRef kCGImagePropertyGPSTrack;
const CFStringRef kCGImagePropertyGPSImgDirectionRef;
const CFStringRef kCGImagePropertyGPSImgDirection;
const CFStringRef kCGImagePropertyGPSMapDatum;
const CFStringRef kCGImagePropertyGPSDestLatitudeRef;
const CFStringRef kCGImagePropertyGPSDestLatitude;
const CFStringRef kCGImagePropertyGPSDestLongitudeRef;
const CFStringRef kCGImagePropertyGPSDestLongitude;
const CFStringRef kCGImagePropertyGPSDestBearingRef;
const CFStringRef kCGImagePropertyGPSDestBearing;
const CFStringRef kCGImagePropertyGPSDestDistanceRef;
const CFStringRef kCGImagePropertyGPSDestDistance;
const CFStringRef kCGImagePropertyGPSProcessingMethod;
const CFStringRef kCGImagePropertyGPSAreaInformation;
const CFStringRef kCGImagePropertyGPSDateStamp;
const CFStringRef kCGImagePropertyGPSDifferental;
```

Constants

`kCGImagePropertyGPSVersion`

The version.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyGPSLatitudeRef`

Whether the latitude is northern or southern.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyGPSLatitude`

The latitude.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyGPSLongitudeRef`

Whether the longitude is east or west.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyGPSLongitude`
The longitude.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyGPSAltitudeRef`
The reference altitude.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyGPSAltitude`
The altitude.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyGPSTimeStamp`
The time as UTC (Coordinated Universal Time).

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyGPSSatellites`
The satellites used for GPS measurements.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyGPSStatus`
The status of the GPS receiver.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyGPSMeasureMode`
The measurement mode.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyGPSDOP`
The data degree of precision (DOP).

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyGPSSpeedRef`
The unit for expressing the GPS receiver speed of movement.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyGPSSpeed`
The GPS receiver speed of movement.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyGPSTrackRef`
The reference for the direction of GPS receiver movement.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyGPSTrack`
The direction of GPS receiver movement.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyGPSImgDirectionRef`
The reference for the direction of the image.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyGPSImgDirection`
The direction of the image.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyGPSMapDatum`
The geodetic survey data used by the GPS receiver.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyGPSDestLatitudeRef`
Whether the latitude of the destination point is northern or southern.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyGPSDestLatitude`
The latitude of the destination point.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyGPSDestLongitudeRef`
Whether the longitude of the destination point is east or west.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyGPSDestLongitude`
The longitude of the destination point.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyGPSDestBearingRef`
The reference for giving the bearing to the destination point.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyGPSDestBearing`
The bearing to the destination point.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyGPSDestDistanceRef`
The units for expressing the distance to the destination point.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyGPSDestDistance`
The distance to the destination point.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyGPSProcessingMethod`
The name of the method used for finding a location.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyGPSAreaInformation`
The name of the GPS area.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyGPSDateStamp`
The data and time information relative to Coordinated Universal Time (UTC).

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyGPSDifferental`
Whether differential correction is applied to the GPS receiver.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

Declared In
`CGImageProperties.h`

IPTC Dictionary Keys

Keys for an image that uses International Press Telecommunications Council (IPTC) metadata.

```
const CFStringRef kCGImagePropertyIPTCObjectTypeReference;
const CFStringRef kCGImagePropertyIPTCObjectAttributeReference;
const CFStringRef kCGImagePropertyIPTCObjectName;
const CFStringRef kCGImagePropertyIPTCEditStatus;
const CFStringRef kCGImagePropertyIPTCEditorialUpdate;
const CFStringRef kCGImagePropertyIPTCUrgency;
const CFStringRef kCGImagePropertyIPTCSubjectReference;
const CFStringRef kCGImagePropertyIPTCCategory;
const CFStringRef kCGImagePropertyIPTCSupplementalCategory;
const CFStringRef kCGImagePropertyIPTCFixtureIdentifier;
const CFStringRef kCGImagePropertyIPTCKeywords;
const CFStringRef kCGImagePropertyIPTCContentLocationCode;
const CFStringRef kCGImagePropertyIPTCContentLocationName;

const CFStringRef kCGImagePropertyIPTCWriterEditor;
const CFStringRef kCGImagePropertyIPTCImageType;
const CFStringRef kCGImagePropertyIPTCImageOrientation;
const CFStringRef kCGImagePropertyIPTCLanguageIdentifier;
const CFStringRef kCGImagePropertyIPTCStarRating;
```

Constants

`kCGImagePropertyIPTCObjectTypeReference`

The object type.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCObjectAttributeReference`
The object attribute.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCObjectName`
The object name.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCEditStatus`
The edit status.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCEditorialUpdate`
An editorial update.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCUrgency`
The urgency level.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCSubjectReference`
The subject.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCCategory`
The category.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCSupplementalCategory`
A supplemental category.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCFixtureIdentifier`
A fixture identifier.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCKeywords`
Keywords.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCContentLocationCode`
The content location code.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCContentLocationName`
The content location name.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCReleaseDate`
The release date.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCReleaseTime`
The release time.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCExpirationDate`
The expiration date.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCExpirationTime`
The expiration time.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCSpecialInstructions`
Special instructions.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCActionAdvised`
The advised action.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCReferenceService`
The reference service.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCReferenceDate`
The reference date.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCReferenceNumber`
The reference number.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCDateCreated`
The date created.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCTimeCreated`
The time created.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCDigitalCreationDate`
The digital creation date.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCDigitalCreationTime`
The digital creation time.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCOriginatingProgram`
The originating program.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCProgramVersion`
The program version.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCObjectCycle`
The object cycle.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCByline`
The byline.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCBylineTitle`
The byline title.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCCity`
The city.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCSubLocation`
The sublocation.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCProvinceState`
The province or state.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCCountryPrimaryLocationCode`
The country primary location code.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCCountryPrimaryLocationName`
The country primary location name.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCOriginalTransmissionReference`
The original transmission reference.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCHeadline`
The headline.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCCredit`
Credit information.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCSource`
The source.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCCopyrightNotice`
The copyright notice.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCContact`
Contact information.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCCaptionAbstract`
The caption abstract.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCWriterEditor`
The writer or editor.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCImageType`
The image type.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCImageOrientation`
The image orientation.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCLanguageIdentifier`
The language identifier.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyIPTCStarRating`
The star rating.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

Discussion
IPTC constants are metadata elements of the Information Interchange Model (IIM) used to provide information about images. The IIM was developer by the Newspaper Association of America (NAA) and the International Press Telecommunications Council (IPTC).

`CGImageProperties.h`

JFIF Dictionary Keys

Keys for an image that uses JPEG File Interchange Format (JFIF).

```
const CFStringRef kCGImagePropertyJFIFVersion;
const CFStringRef kCGImagePropertyJFIFXDensity;
const CFStringRef kCGImagePropertyJFIFYDensity;
const CFStringRef kCGImagePropertyJFIFDensityUnit;
const CFStringRef kCGImagePropertyJFIFIsProgressive;
```

Constants

`kCGImagePropertyJFIFVersion`
The version.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyJFIFXDensity`
The x density.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyJFIFYDensity`
The y density.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyJFIFDensityUnit`
The density unit.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyJFIFIsProgressive`
Whether or not the image is progressive.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

Declared In
`CGImageProperties.h`

PNG Dictionary Keys

Keys for an image that uses Portable Network Graphics (PNG) format.

```
const CFStringRef kCGImagePropertyPNGGamma;
const CFStringRef kCGImagePropertyPNGInterlaceType;
const CFStringRef kCGImagePropertyPNGXPixelsPerMeter;
const CFStringRef kCGImagePropertyPNGYPixelsPerMeter;
const CFStringRef kCGImagePropertyPNGsRGBIntent;
const CFStringRef kCGImagePropertyPNGChromaticities;
```

Constants

`kCGImagePropertyPNGGamma`
The gamma value.
Available in Mac OS X v10.4 and later.
Declared in `CGImageProperties.h`.

`kCGImagePropertyPNGInterlaceType`
The interlace type.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyPNGXPixelsPerMeter`
The number of x pixels per meter.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyPNGYPixelsPerMeter`
The number of y pixels per meter.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyPNGsRGBIntent`
The sRGB intent.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyPNGChromaticities`
The chromaticities.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

Declared In
`CGImageProperties.h`

TIFF Dictionary Keys

Keys for an image that uses Tagged Image File Format (TIFF).

```
const CFStringRef kCGImagePropertyTIFFCompression;
const CFStringRef kCGImagePropertyTIFFPhotometricInterpretation;
const CFStringRef kCGImagePropertyTIFFDocumentName;
const CFStringRef kCGImagePropertyTIFFImageDescription;
const CFStringRef kCGImagePropertyTIFFMake;
const CFStringRef kCGImagePropertyTIFFModel;
const CFStringRef kCGImagePropertyTIFFOrientation;
const CFStringRef kCGImagePropertyTIFFXResolution;
const CFStringRef kCGImagePropertyTIFFYResolution;
const CFStringRef kCGImagePropertyTIFFResolutionUnit;
const CFStringRef kCGImagePropertyTIFFSoftware;
const CFStringRef kCGImagePropertyTIFFTransferFunction;
const CFStringRef kCGImagePropertyTIFFDateTime;
const CFStringRef kCGImagePropertyTIFFArtist;
const CFStringRef kCGImagePropertyTIFFHostComputer;
const CFStringRef kCGImagePropertyTIFFCopyright;
const CFStringRef kCGImagePropertyTIFFWhitePoint;
const CFStringRef kCGImagePropertyTIFFPrimaryChromaticities;
```

Constants

`kCGImagePropertyTIFFCompression`

The compression scheme used on the image data.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyTIFFPhotometricInterpretation`

The color space of the image data.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyTIFFDocumentName`

The document name.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyTIFFImageDescription`

The image description.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyTIFFMake`

The camera or input device make.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyTIFFModel`

A camera or input device model.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyTIFFOrientation`

The image orientation.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyTIFFXResolution`
The number of pixels per resolution unit in the image width direction.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyTIFFYResolution`
The number of pixels per resolution unit in the image height direction.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyTIFFResolutionUnit`
The units of resolution.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyTIFFSoftware`
The name and version of the software used for image creation.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyTIFFTransferFunction`
The transfer function, in tabular format, used to map pixel components from a nonlinear form into a linear form.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyTIFFDateTime`
The date and time.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyTIFFArtist`
The artist.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyTIFFHostComputer`
The computer or operation system used when the image was created.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyTIFFCopyright`
Copyright information.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyTIFFWhitePoint`
The white point.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyTIFFPrimaryChromaticities`
The chromaticities of the primaries of the image.

Available in Mac OS X v10.4 and later.

Declared in `CGImageProperties.h`.

Declared In
`CGImageProperties.h`

DNG Dictionary Keys

Keys for an image that uses the Digital Negative (DNG) archival format.

```
CFStringRef  kCGImagePropertyDNGVersion;
CFStringRef  kCGImagePropertyDNGBackwardVersion;
CFStringRef  kCGImagePropertyDNGUniqueCameraModel;
CFStringRef kCGImagePropertyDNGLocalizedCameraModel;
CFStringRef  kCGImagePropertyDNGCameraSerialNumber;
CFStringRef  kCGImagePropertyDNGLensInfo;
```

Constants
`kCGImagePropertyDNGVersion`
An encoding of the four-tier version number.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyDNGBackwardVersion`
The oldest version for which a file is compatible.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyDNGUniqueCameraModel`
A unique, nonlocalized name for the camera mode.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyDNGLocalizedCameraModel`
The localized camera model name.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyDNGCameraSerialNumber`
The camera serial number.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyDNGLensInfo`
Information about the lens used for the image.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

Declared In
`CGImageProperties.h`

8BIM Dictionary Keys

A key for an Adobe Photoshop image.

```
CFStringRef  kCGImageProperty8BIMLayerNames;
```

Constants

`kCGImageProperty8BIMLayerNames`

The layer names for an Adobe Photoshop file.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

Declared In

`CGImageProperties.h`

CIFF Dictionary Keys

Keys for an image that uses Camera Image File Format (CIFF).

```
CFStringRef  kCGImagePropertyCIFFDescription;
CFStringRef  kCGImagePropertyCIFFFirmware;
CFStringRef  kCGImagePropertyCIFFOwnerName;
CFStringRef  kCGImagePropertyCIFFImageName;
CFStringRef  kCGImagePropertyCIFFImageFileName;
CFStringRef  kCGImagePropertyCIFFReleaseMethod;
CFStringRef  kCGImagePropertyCIFFReleaseTiming;
CFStringRef  kCGImagePropertyCIFFRecordID;
CFStringRef  kCGImagePropertyCIFFSelfTimingTime;
CFStringRef  kCGImagePropertyCIFFCameraSerialNumber;
CFStringRef  kCGImagePropertyCIFFImageSerialNumber;
CFStringRef  kCGImagePropertyCIFFContinuousDrive;
CFStringRef  kCGImagePropertyCIFFFocusMode;
CFStringRef  kCGImagePropertyCIFFMeteringMode;
CFStringRef  kCGImagePropertyCIFFShootingMode;
CFStringRef  kCGImagePropertyCIFFLensMaxMM;
CFStringRef  kCGImagePropertyCIFFLensMinMM;
CFStringRef  kCGImagePropertyCIFFLensModel;
CFStringRef  kCGImagePropertyCIFFWhiteBalanceIndex;
CFStringRef  kCGImagePropertyCIFFFlashExposureComp;
CFStringRef  kCGImagePropertyCIFFMeasuredEV;
```

Constants

`kCGImagePropertyCIFFDescription`

The camera description..

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyCIFFFirmware`

The firmware version.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyCIFFOwnerName`
The owner name.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyCIFFImageName`
The image name.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyCIFFImageFileName`
The image file name.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyCIFFReleaseMethod`
The release method.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyCIFFReleaseTiming`
The release timing.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyCIFFRecordID`
The record ID>

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyCIFFSelfTimingTime`
The self timing time.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyCIFFCameraSerialNumber`
The camera serial number.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyCIFFImageSerialNumber`
The image serial number.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyCIFFContinuousDrive`
The continuous drive mode.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyCIFFFocusMode`
The focus mode.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyCIFFMeteringMode`
The metering mode.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyCIFFShootingMode`
The shooting mode.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyCIFFLensMaxMM`
The maximum lens length.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyCIFFLensMinMM`
The minimum lens length.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyCIFFLensModel`
The lens model.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyCIFFWhiteBalanceIndex`
The white balance index.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyCIFFFlashExposureComp`
The flash exposure compensation.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyCIFFMeasuredEV`
The measured EV.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

Declared In
`CGImageProperties.h`

Nikon Camera Dictionary Keys

Keys for an image from a Nikon camera.

```
CFStringRef  kCGImagePropertyMakerNikonISOSetting;
CFStringRef  kCGImagePropertyMakerNikonColorMode;
CFStringRef  kCGImagePropertyMakerNikonQuality;
CFStringRef  kCGImagePropertyMakerNikonWhiteBalanceMode;
CFStringRef  kCGImagePropertyMakerNikonSharpenMode;
CFStringRef  kCGImagePropertyMakerNikonFocusMode;
CFStringRef  kCGImagePropertyMakerNikonFlashSetting;
CFStringRef  kCGImagePropertyMakerNikonISOSelection;
CFStringRef  kCGImagePropertyMakerNikonFlashExposureComp;
CFStringRef  kCGImagePropertyMakerNikonImageAdjustment;
CFStringRef  kCGImagePropertyMakerNikonLensAdapter;
CFStringRef  kCGImagePropertyMakerNikonLensType;
CFStringRef  kCGImagePropertyMakerNikonLensInfo;
CFStringRef  kCGImagePropertyMakerNikonFocusDistance;
CFStringRef  kCGImagePropertyMakerNikonDigitalZoom;
CFStringRef  kCGImagePropertyMakerNikonShootingMode;
CFStringRef  kCGImagePropertyMakerNikonShutterCount;
CFStringRef  kCGImagePropertyMakerNikonCameraSerialNumber;
```

Constants

`kCGImagePropertyMakerNikonISOSetting`

The ISO setting.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyMakerNikonColorMode`

The color mode.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyMakerNikonQuality`

The quality setting.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyMakerNikonWhiteBalanceMode`

The white balance mode.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyMakerNikonSharpenMode`

The sharpening mode.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyMakerNikonFocusMode`

The focus mode.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyMakerNikonFlashSetting`

The flash setting.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyMakerNikonISOSelection`
The ISO selection.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyMakerNikonFlashExposureComp`
The flash exposure compensation.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyMakerNikonImageAdjustment`
Image adjustment setting.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyMakerNikonLensAdapter`
The lens adapter.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyMakerNikonLensType`
The lens type.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyMakerNikonLensInfo`
Lens information.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyMakerNikonFocusDistance`
The focus distance.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyMakerNikonDigitalZoom`
The digital zoom setting.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyMakerNikonShootingMode`
The shooting mode.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyMakerNikonShutterCount`
The shutter count.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyMakerNikonCameraSerialNumber`
The camera serial number.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

Declared In
`CGImageProperties.h`

Canon Camera Dictionary Keys

Keys for an image from a Canon camera.

```
CFStringRef  kCGImagePropertyMakerCanonOwnerName;
CFStringRef  kCGImagePropertyMakerCanonCameraSerialNumber;
CFStringRef  kCGImagePropertyMakerCanonImageSerialNumber;
CFStringRef  kCGImagePropertyMakerCanonFlashExposureComp;
CFStringRef  kCGImagePropertyMakerCanonContinuousDrive;
CFStringRef  kCGImagePropertyMakerCanonLensModel;
CFStringRef  kCGImagePropertyMakerCanonFirmware;
CFStringRef  kCGImagePropertyMakerCanonAspectRatioInfo;
```

Constants
`kCGImagePropertyMakerCanonOwnerName`
The owner name.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyMakerCanonCameraSerialNumber`
The camera serial number.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyMakerCanonImageSerialNumber`
The image serial number.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyMakerCanonFlashExposureComp`
The flash exposure compensation.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyMakerCanonContinuousDrive`
The presence of a continuous drive.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyMakerCanonLensModel`
The lens model.

Available in Mac OS X v10.5 and later.

Declared in `CGImageProperties.h`.

`kCGImagePropertyMakerCanonFirmware`
: The firmware version.

  Available in Mac OS X v10.5 and later.

  Declared in `CGImageProperties.h`.

`kCGImagePropertyMakerCanonAspectRatioInfo`
: The image aspect ratio.

  Available in Mac OS X v10.5 and later.

  Declared in `CGImageProperties.h`.

`CGImageProperties.h`

CGAffineTransform Reference

Framework:	ApplicationServices/ApplicationServices.h
Declared in	CGAffineTransform.h
Companion guide	Quartz 2D Programming Guide

Overview

The `CGAffineTransform` data structure represents a matrix used for affine transformations. A transformation specifies how points in one coordinate system map to points in another coordinate system. An affine transformation is a special type of mapping that preserves parallel lines in a path but does not necessarily preserve lengths or angles. Scaling, rotation, and translation are the most commonly used manipulations supported by affine transforms, but skewing is also possible.

Quartz provides functions that create, concatenate, and apply affine transformations using the `CGAffineTransform` data structure. For information on how to use affine transformation functions, see *Quartz 2D Programming Guide*.

You typically do not need to create an affine transform directly—*CGContext Reference* describes functions that modify the current affine transform. If you don't plan to reuse an affine transform, you may want to use `CGContextScaleCTM` (page 105), `CGContextRotateCTM` (page 104), `CGContextTranslateCTM` (page 136), or `CGContextConcatCTM` (page 82).

Functions by Task

Creating an Affine Transformation Matrix

`CGAffineTransformMake` (page 2342)
Returns an affine transformation matrix constructed from values you provide.

`CGAffineTransformMakeRotation` (page 2344)
Returns an affine transformation matrix constructed from a rotation value you provide.

`CGAffineTransformMakeScale` (page 2344)
Returns an affine transformation matrix constructed from scaling values you provide.

`CGAffineTransformMakeTranslation` (page 2345)
Returns an affine transformation matrix constructed from translation values you provide.

Modifying Affine Transformations

`CGAffineTransformTranslate` (page 2348)
Returns an affine transformation matrix constructed by translating an existing affine transform.

`CGAffineTransformScale` (page 2347)
Returns an affine transformation matrix constructed by scaling an existing affine transform.

`CGAffineTransformRotate` (page 2346)
Returns an affine transformation matrix constructed by rotating an existing affine transform.

`CGAffineTransformInvert` (page 2341)
Returns an affine transformation matrix constructed by inverting an existing affine transform.

`CGAffineTransformConcat` (page 2340)
Returns an affine transformation matrix constructed by combining two existing affine transforms.

Applying Affine Transformations

`CGPointApplyAffineTransform` (page 2348)
Returns the point resulting from an affine transformation of an existing point.

`CGSizeApplyAffineTransform` (page 2349)
Returns the height and width resulting from a transformation of an existing height and width.

`CGRectApplyAffineTransform` (page 2349)
Applies an affine transform to a rectangle.

Evaluating Affine Transforms

`CGAffineTransformIsIdentity` (page 2342)
Checks whether an affine transform is the identity transform.

`CGAffineTransformEqualToTransform` (page 2341)
Checks whether two affine transforms are equal.

Functions

CGAffineTransformConcat

Returns an affine transformation matrix constructed by combining two existing affine transforms.

```
CGAffineTransform CGAffineTransformConcat (
   CGAffineTransform t1,
   CGAffineTransform t2
);
```

Parameters

t1
The first affine transform.

t2

The second affine transform. This affine transform is concatenated to the first affine transform.

Return Value
A new affine transformation matrix. That is, t' = t1*t2.

Discussion
Concatenation combines two affine transformation matrices by multiplying them together. You might perform several concatenations in order to create a single affine transform that contains the cumulative effects of several transformations.

Note that matrix operations are not commutative—the order in which you concatenate matrices is important. That is, the result of multiplying matrix `t1` by matrix `t2` does not necessarily equal the result of multiplying matrix `t2` by matrix `t1`.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`CGAffineTransform.h`

CGAffineTransformEqualToTransform

Checks whether two affine transforms are equal.

```
bool CGAffineTransformEqualToTransform (
   CGAffineTransform t1,
   CGAffineTransform t2
);
```

Parameters

t1

An affine transform.

t2

An affine transform.

Return Value
Returns `true` if `t1` and `t2` are equal, `false` otherwise.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGAffineTransform.h`

CGAffineTransformInvert

Returns an affine transformation matrix constructed by inverting an existing affine transform.

```
CGAffineTransform CGAffineTransformInvert (
   CGAffineTransform t
);
```

Parameters

t

An existing affine transform.

Return Value
A new affine transformation matrix. If the affine transform passed in parameter `t` cannot be inverted, Quartz returns the affine transform unchanged.

Discussion
Inversion is generally used to provide reverse transformation of points within transformed objects. Given the coordinates (x,y), which have been transformed by a given matrix to new coordinates (x′,y′), transforming the coordinates (x′,y′) by the inverse matrix produces the original coordinates (x,y).

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`CGAffineTransform.h`

CGAffineTransformIsIdentity

Checks whether an affine transform is the identity transform.

```
bool CGAffineTransformIsIdentity (
   CGAffineTransform t
);
```

Parameters

t

The affine transform to check.

Return Value
Returns `true` if `t` is the identity transform, `false` otherwise.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGAffineTransform.h`

CGAffineTransformMake

Returns an affine transformation matrix constructed from values you provide.

```
CGAffineTransform CGAffineTransformMake (
   CGFloat a,
   CGFloat b,
   CGFloat c,
   CGFloat d,
   CGFloat tx,
   CGFloat ty
);
```

Parameters

a
The value at position [1,1] in the matrix.

b
The value at position [1,2] in the matrix.

c
The value at position [2,1] in the matrix.

d
The value at position [2,2] in the matrix.

tx
The value at position [3,1] in the matrix.

ty
The value at position [3,2] in the matrix.

Return Value
A new affine transform matrix constructed from the values you specify.

Discussion
This function creates a `CGAffineTransform` structure that represents a new affine transformation matrix, which you can use (and reuse, if you want) to transform a coordinate system. The matrix takes the following form:

$$\begin{bmatrix} a & b & 0 \\ c & d & 0 \\ t_x & t_y & 1 \end{bmatrix}$$

Because the third column is always `(0,0,1)`, the `CGAffineTransform` data structure returned by this function contains values for only the first two columns.

If you want only to transform an object to be drawn, it is not necessary to construct an affine transform to do so. The most direct way to transform your drawing is by calling the appropriate `CGContext` function to adjust the current transformation matrix.

Availability
Available in Mac OS X version 10.0 and later.

Related Sample Code
CarbonSketch

Declared In
`CGAffineTransform.h`

CGAffineTransformMakeRotation

Returns an affine transformation matrix constructed from a rotation value you provide.

```
CGAffineTransform CGAffineTransformMakeRotation (
   CGFloat angle
);
```

Parameters

angle

The angle, in radians, by which this matrix rotates the coordinate system axes. A positive value specifies clockwise rotation, a negative value specifies counterclockwise.

Return Value

A new affine transformation matrix.

Discussion

This function creates a `CGAffineTransform` structure, which you can use (and reuse, if you want) to rotate a coordinate system. The matrix takes the following form:

$$\begin{bmatrix} \cos a & \sin a & 0 \\ -\sin a & \cos a & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

Because the third column is always `(0,0,1)`, the `CGAffineTransform` data structure returned by this function contains values for only the first two columns.

These are the resulting equations that Quartz uses to apply the rotation to a point (x, y):

$$x' = x\cos a - y\sin a$$
$$y' = x\sin a + y\cos a$$

If you want only to rotate an object to be drawn, it is not necessary to construct an affine transform to do so. The most direct way to rotate your drawing is by calling the function `CGContextRotateCTM` (page 104).

Availability

Available in Mac OS X version 10.0 and later.

Declared In

`CGAffineTransform.h`

CGAffineTransformMakeScale

Returns an affine transformation matrix constructed from scaling values you provide.

```
CGAffineTransform CGAffineTransformMakeScale (
   CGFloat sx,
   CGFloat sy
);
```

Parameters

sx

The factor by which to scale the x-axis of the coordinate system.

sy

The factor by which to scale the y-axis of the coordinate system.

Return Value
A new affine transformation matrix.

Discussion
This function creates a `CGAffineTransform` structure, which you can use (and reuse, if you want) to scale a coordinate system. The matrix takes the following form:

$$\begin{bmatrix} s_x & 0 & 0 \\ 0 & s_y & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

Because the third column is always `(0,0,1)`, the `CGAffineTransform` data structure returned by this function contains values for only the first two columns.

These are the resulting equations that Quartz uses to scale the coordinates of a point (x,y):

$$x' = x \cdot s_x$$
$$y' = y \cdot s_y$$

If you want only to scale an object to be drawn, it is not necessary to construct an affine transform to do so. The most direct way to scale your drawing is by calling the function `CGContextScaleCTM` (page 105).

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`CGAffineTransform.h`

CGAffineTransformMakeTranslation

Returns an affine transformation matrix constructed from translation values you provide.

```
CGAffineTransform CGAffineTransformMake Translation (
   CGFloat tx,
   CGFloat ty
);
```

Parameters

tx

The value by which to move the x-axis of the coordinate system.

ty

The value by which to move the y-axis of the coordinate system.

Return Value
A new affine transform matrix.

Discussion
This function creates a `CGAffineTransform` structure. which you can use (and reuse, if you want) to move a coordinate system. The matrix takes the following form:

$$\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ t_x & t_y & 1 \end{bmatrix}$$

Because the third column is always `(0,0,1)`, the `CGAffineTransform` data structure returned by this function contains values for only the first two columns.

These are the resulting equations Quartz uses to apply the translation to a point (x,y):

$$x' = x + t_x$$
$$y' = y + t_y$$

If you want only to move the location where an object is drawn, it is not necessary to construct an affine transform to do so. The most direct way to move your drawing is by calling the function `CGContextTranslateCTM` (page 136).

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`CGAffineTransform.h`

CGAffineTransformRotate

Returns an affine transformation matrix constructed by rotating an existing affine transform.

```
CGAffineTransform CGAffineTransformRotate (
   CGAffineTransform t,
   CGFloat angle
);
```

Parameters

t

An existing affine transform.

angle

The angle, in radians, by which to rotate the affine transform.

Return Value
A new affine transformation matrix.

Discussion
You use this function to create a new affine transformation matrix by adding a rotation value to an existing affine transform. The resulting structure represents a new affine transform, which you can use (and reuse, if you want) to rotate a coordinate system.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`CGAffineTransform.h`

CGAffineTransformScale

Returns an affine transformation matrix constructed by scaling an existing affine transform.

```
CGAffineTransform CGAffineTransformScale (
   CGAffineTransform t,
   CGFloat sx,
   CGFloat sy
);
```

Parameters

t

An existing affine transform.

sx

The value by which to scale x values of the affine transform.

sy

The value by which to scale y values of the affine transform.

Return Value
A new affine transformation matrix.

Discussion
You use this function to create a new affine transformation matrix by adding scaling values to an existing affine transform. The resulting structure represents a new affine transform, which you can use (and reuse, if you want) to scale a coordinate system.

Availability
Available in Mac OS X version 10.0 and later.

Related Sample Code
HID Calibrator

Declared In
`CGAffineTransform.h`

CGAffineTransformTranslate

Returns an affine transformation matrix constructed by translating an existing affine transform.

```
CGAffineTransform CGAffineTransformTranslate (
   CGAffineTransform t,
   CGFloat tx,
   CGFloat ty
);
```

Parameters

t
: An existing affine transform.

tx
: The value by which to move x values with the affine transform.

ty
: The value by which to move y values with the affine transform.

Return Value
A new affine transformation matrix.

Discussion
You use this function to create a new affine transform by adding translation values to an existing affine transform. The resulting structure represents a new affine transform, which you can use (and reuse, if you want) to move a coordinate system.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`CGAffineTransform.h`

CGPointApplyAffineTransform

Returns the point resulting from an affine transformation of an existing point.

```
CGPoint CGPointApplyAffineTransform (
   CGPoint point,
   CGAffineTransform t
);
```

Parameters

point
: A point that specifies the x- and y-coordinates to transform.

t
: The affine transform to apply.

Return Value
A new point resulting from applying the specified affine transform to the existing point.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`CGAffineTransform.h`

CGRectApplyAffineTransform

Applies an affine transform to a rectangle.

```
CGRect CGRectApplyAffineTransform (
   CGRect rect,
   CGAffineTransform t
);
```

Parameters

rect

The rectangle whose corner points you want to transform.

t

The affine transform to apply to the `rect` parameter.

Return Value
The transformed rectangle.

Discussion
Because affine transforms do not preserve rectangles in general, the function `CGRectApplyAffineTransform` returns the smallest rectangle that contains the transformed corner points of the `rect` parameter. If the affine transform `t` consists solely of scaling and translation operations, then the returned rectangle coincides with the rectangle constructed from the four transformed corners.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGAffineTransform.h`

CGSizeApplyAffineTransform

Returns the height and width resulting from a transformation of an existing height and width.

```
CGSize CGSizeApplyAffineTransform (
   CGSize size,
   CGAffineTransform t
);
```

Parameters

size

A size that specifies the height and width to transform.

t

The affine transform to apply.

Return Value
A new size resulting from applying the specified affine transform to the existing size.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`CGAffineTransform.h`

Data Types

CGAffineTransform

A structure for holding an affine transformation matrix.

```
struct CGAffineTransform {
    CGFloat a;
    CGFloat b;
    CGFloat c;
    CGFloat d;
    CGFloat tx;
    CGFloat ty;
};
typedef struct CGAffineTransform CGAffineTransform;
```

Fields

`a`
The entry at position [1,1] in the matrix.

`b`
The entry at position [1,2] in the matrix.

`c`
The entry at position [2,1] in the matrix.

`d`
The entry at position [2,2] in the matrix.

`tx`
The entry at position [3,1] in the matrix.

`ty`
The entry at position [3,2] in the matrix.

Discussion
In Quartz 2D, an affine transformation matrix is used to rotate, scale, translate, or skew the objects you draw in a graphics context. The `CGAffineTransform` type provides functions for creating, concatenating, and applying affine transformations.

In Quartz, affine transforms are represented by a 3 by 3 matrix:

$$\begin{bmatrix} a & b & 0 \\ c & d & 0 \\ t_x & t_y & 1 \end{bmatrix}$$

Because the third column is always `(0,0,1)`, the `CGAffineTransform` data structure contains values for only the first two columns.

Conceptually, a Quartz affine transform multiplies a row vector representing each point (x,y) in your drawing by this matrix, producing a vector that represents the corresponding point (x′,y′):

$$\begin{bmatrix} x' & y' & 1 \end{bmatrix} = \begin{bmatrix} x & y & 1 \end{bmatrix} \times \begin{bmatrix} a & b & 0 \\ c & d & 0 \\ t_x & t_y & 1 \end{bmatrix}$$

Given the 3 by 3 matrix, Quartz uses the following equations to transform a point (x, y) in one coordinate system into a resultant point (x′,y′) in another coordinate system.

$$x' = ax + cy + t_x$$
$$y' = bx + dy + t_y$$

The matrix thereby "links" two coordinate systems—it specifies how points in one coordinate system map to points in another.

Note that you do not typically need to create affine transforms directly. If you want only to draw an object that is scaled or rotated, for example, it is not necessary to construct an affine transform to do so. The most direct way to manipulate your drawing—whether by movement, scaling, or rotation—is to call the functions `CGContextTranslateCTM` (page 136), `CGContextScaleCTM` (page 105), or `CGContextRotateCTM` (page 104), respectively. You should generally only create an affine transform if you want to reuse it later.

Availability
Available in Mac OS X v10.0 and later.

CGGeometry Reference

Framework:	ApplicationServices/ApplicationServices.h
Declared in	CGGeometry.h
Companion guide	Quartz 2D Programming Guide

Overview

CGGeometry Reference defines structures for geometric primitives and functions that operate on them. The data structure `CGPoint` represents a point in a two-dimensional coordinate system. The data structure `CGRect` represents the location and dimensions of a rectangle. The data structure `CGSize` represents the dimensions of width and height.

Functions by Task

Creating a Geometric Primitive From a Dictionary Representation

`CGPointCreateDictionaryRepresentation` (page 2355)
Returns a dictionary representation of the provided point.

`CGSizeCreateDictionaryRepresentation` (page 2371)
Returns a dictionary representation of the provided size.

`CGRectCreateDictionaryRepresentation` (page 2358)
Returns a dictionary representation of the provided rectangle.

Creating a Dictionary Representation From a Geometric Primitive

`CGPointMakeWithDictionaryRepresentation` (page 2357)
Fills in a `CGPoint` structure using the contents of the provided dictionary.

`CGSizeMakeWithDictionaryRepresentation` (page 2372)
Fills in a `CGSize` structure using the contents of the provided dictionary.

`CGRectMakeWithDictionaryRepresentation` (page 2369)
Fills in a `CGRect` structure using the contents of the provided dictionary.

Creating a Geometric Primitive From Values

`CGPointMake` (page 2356)
Returns a `CGPoint` structure filled in with the coordinate values you provide.

`CGRectMake` (page 2368)
Returns a `CGRect` structure filled in with the coordinate and dimension values you provide.

`CGSizeMake` (page 2372)
Returns a `CGSize` structure filled in with dimension values you provide.

Modifying Rectangles

`CGRectDivide` (page 2359)
Divides a source rectangle into two component rectangles.

`CGRectInset` (page 2364)
Returns a rectangle that is smaller or larger than the source rectangle, with the same center point.

`CGRectIntegral` (page 2365)
Returns the smallest rectangle that results from converting the source rectangle values to integers.

`CGRectIntersection` (page 2365)
Returns the intersection of two rectangles.

`CGRectOffset` (page 2369)
Returns a rectangle with an origin that is offset from that of the source rectangle.

`CGRectStandardize` (page 2370)
Returns a rectangle with a positive width and height.

`CGRectUnion` (page 2371)
Returns the smallest rectangle that contains the two provided rectangles.

Comparing Values

`CGPointEqualToPoint` (page 2356)
Returns whether two points are equal.

`CGSizeEqualToSize` (page 2371)
Returns whether two sizes are equal.

`CGRectEqualToRect` (page 2359)
Returns whether two rectangles are equal in size and position.

`CGRectIntersectsRect` (page 2366)
Returns whether two rectangles intersect.

Checking for Membership

`CGRectContainsPoint` (page 2357)
Returns whether a rectangle contains a specified point.

`CGRectContainsRect` (page 2358)
Returns whether the first rectangle contains the second rectangle.

Getting Min, Mid, and Max Values

`CGRectGetMinX` (page 2362)
Returns the x-coordinate that establishes the left edge of a rectangle.

`CGRectGetMinY` (page 2363)
Returns the y-coordinate that establishes the bottom edge of a rectangle.

`CGRectGetMidX` (page 2361)
Returns the x- coordinate that establishes the center of a rectangle.

`CGRectGetMidY` (page 2362)
Returns the y-coordinate that establishes the center of a rectangle.

`CGRectGetMaxX` (page 2360)
Returns the x-coordinate that establishes the right edge of a rectangle.

`CGRectGetMaxY` (page 2361)
Returns the y-coordinate that establishes the top edge of a rectangle.

Getting Height and Width

`CGRectGetHeight` (page 2360)
Returns the height of a rectangle.

`CGRectGetWidth` (page 2363)
Returns the width of a rectangle.

Checking Rectangle Characteristics

`CGRectIsEmpty` (page 2366)
Returns whether a rectangle has zero width or height, or is a null rectangle.

`CGRectIsNull` (page 2368)
Returns whether a rectangle is invalid.

`CGRectIsInfinite` (page 2367)
Returns whether a rectangle is infinite.

`CGRectIsIntegral` (page 2367)
Returns whether the origin and size of the rectangle can be represented exactly as integers.

Functions

CGPointCreateDictionaryRepresentation

Returns a dictionary representation of the provided point.

```
CFDictionaryRef CGPointCreateDictionaryRepresentation(
    CGPoint point
);
```

Parameters

point

A point.

Return Value
The dictionary representation of the point.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`CGGeometry.h`

CGPointEqualToPoint

Returns whether two points are equal.

```
bool CGPointEqualToPoint (
   CGPoint point1,
   CGPoint point2
);
```

Parameters

point1

The first point to examine.

point2

The second point to examine.

Return Value
Returns `1` if the two specified points are the same; otherwise, `0`.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`CGGeometry.h`

CGPointMake

Returns a `CGPoint` structure filled in with the coordinate values you provide.

```
CGPoint CGPointMake (
   CGFloat x,
   CGFloat y
);
```

Parameters

x

The x-coordinate of the point to construct.

y
The y-coordinate of the point to construct.

Return Value
Returns a `CGPoint` structure, representing a single (x,y) coordinate pair.

Availability
Available in Mac OS X version 10.0 and later.

Related Sample Code

CarbonSketch

Declared In
`CGGeometry.h`

CGPointMakeWithDictionaryRepresentation

Fills in a `CGPoint` structure using the contents of the provided dictionary.

```
bool CGPointMakeWithDictionaryRepresentation(
    CFDictionaryRef dict,
    CGPoint *point
);
```

Parameters
dict
A dictionary that was previously returned from the function `CGPointCreateDictionaryRepresentation` (page 2355).

point
On return, the point created from the provided dictionary.

Return Value
`true` if successful; `false` otherwise.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`CGGeometry.h`

CGRectContainsPoint

Returns whether a rectangle contains a specified point.

```
bool CGRectContainsPoint (
   CGRect rect,
   CGPoint point
);
```

Parameters
rect
The rectangle to examine.

point
The point to examine.

Return Value
Returns `1` if the specified point is located within the specified rectangle; otherwise, `0`.

Availability
Available in Mac OS X version 10.0 and later.

Related Sample Code
CarbonSketch

Declared In
`CGGeometry.h`

CGRectContainsRect

Returns whether the first rectangle contains the second rectangle.

```
bool CGRectContainsRect (
   CGRect rect1,
   CGRect rect2
);
```

Parameters
rect1
The rectangle to examine for containment of the rectangle passed in `rect2`.

rect2
The rectangle to examine for being contained in the rectangle passed in `rect1`.

Return Value
Returns `1` if the rectangle specified by `rect2` is contained in the rectangle passed in `rect1`; otherwise, `0`. The first rectangle contains the second if the union of the two rectangles is equal to the first rectangle.

Availability
Available in Mac OS X version 10.0 and later.

Related Sample Code
CarbonSketch

Declared In
`CGGeometry.h`

CGRectCreateDictionaryRepresentation

Returns a dictionary representation of the provided rectangle.

```
CFDictionaryRef CGRectCreateDictionaryRepresentation(
    CGRect rect
);
```

Parameters
rect
A rectangle.

Return Value
The dictionary representation of the rectangle.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`CGGeometry.h`

CGRectDivide

Divides a source rectangle into two component rectangles.

```
void CGRectDivide (
   CGRect rect,
   CGRect *slice,
   CGRect *remainder,
   CGFloat amount,
   CGRectEdge edge
);
```

Parameters

rect
The source `CGRect` structure.

slice
On input, a pointer to an uninitialized `CGRect` structure. On return, a `CGRect` structure filled in with the specified edge and values that extends the distance beyond the edge specified by the *amount* parameter.

remainder
On input, a pointer to an uninitialized rectangle `CGRect` structure. On return, the `CGRect` structure contains the portion of the source `CGRect` structure that remains after `CGRectEdge` produces the "slice" rectangle.

amount
A distance from the rectangle side that is specified in the *edge* parameter. This distance defines the line, parallel to the specified side, that Quartz uses to divide the source `CGRect` structure.

edge
A `CGRectEdge` value (`CGRectMinXEdge` (page 2376), `CGRectMinYEdge` (page 2376), `CGRectMaxXEdge` (page 2376), or `CGRectMaxYEdge` (page 2376)) that specifies the side of the rectangle from which the distance passed in the `amount` parameter is measured. `CGRectDivide` produces a "slice" rectangle that contains the specified edge and extends `amount` distance beyond it.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`CGGeometry.h`

CGRectEqualToRect

Returns whether two rectangles are equal in size and position.

```
bool CGRectEqualToRect (
   CGRect rect1,
   CGRect rect2
);
```

Parameters

rect1

The first rectangle to examine.

rect2

The second rectangle to examine.

Return Value

Returns `1` if the two specified rectangles have equal size and origin values, or are both `null`. Otherwise, returns `0`.

Availability

Available in Mac OS X version 10.0 and later.

Declared In

`CGGeometry.h`

CGRectGetHeight

Returns the height of a rectangle.

```
CGFloat CGRectGetHeight (
   CGRect rect
);
```

Parameters

rect

The rectangle to examine.

Return Value

The height of the specified rectangle.

Availability

Available in Mac OS X version 10.0 and later.

CGRectInset

Returns a rectangle that is smaller or larger than the source rectangle, with the same center point.

```
CGRect CGRectInset (
   CGRect rect,
   CGFloat dx,
   CGFloat dy
);
```

Parameters

rect

The source `CGRect` structure.

dx

The x-coordinate value to use for adjusting the source rectangle. To create an inset rectangle, specify a positive value. To create a larger, encompassing rectangle, specify a negative value.

dy

The y-coordinate value to use for adjusting the source rectangle. To create an inset rectangle, specify a positive value. To create a larger, encompassing rectangle, specify a negative value.

Return Value
A filled-in `CGRect` structure. The origin value is offset in the x-axis by the distance specified by the `dx` parameter and in the y-axis by the distance specified by the `dy` parameter, and its size adjusted by `(2*dx,2*dy)`, relative to the source rectangle. If `dx` and `dy` are positive values, then the rectangle's size is decreased. If `dx` and `dy` are negative values, the rectangle's size is increased.

Availability
Available in Mac OS X version 10.0 and later.

Related Sample Code
CarbonSketch

Declared In
`CGGeometry.h`

CGRectIntegral

Returns the smallest rectangle that results from converting the source rectangle values to integers.

```
CGRect CGRectIntegral (
   CGRect rect
);
```

Parameters

rect
The source rectangle.

Return Value
A filled-in `CGRect` structure whose values represent the rectangle with the smallest integer values for its origin and size that contains the source rectangle. That is, given a rectangle with fractional origin or size values, `CGRectIntegral` rounds the rectangle's origin downward and its size upward to the nearest whole integers, such that the result contains the original rectangle.

Availability
Available in Mac OS X version 10.0 and later.

See Also
`CGRectIsIntegral` (page 2367)

Related Sample Code
WhackedTV

Declared In
`CGGeometry.h`

CGRectIntersection

Returns the intersection of two rectangles.

```
CGRect CGRectIntersection (
   CGRect r1,
   CGRect r2
);
```

Parameters

rect1
The first source rectangle.

rect2
The second source rectangle.

Return Value
A filled-in `CGRect` structure that represents the intersection of the two specified rectangles. If the two rectangles do not intersect, returns the null rectangle. To check for this condition, use `CGRectIsNull` (page 2368).

Availability
Available in Mac OS X version 10.0 and later.

Related Sample Code
WhackedTV

Declared In
`CGGeometry.h`

CGRectIntersectsRect

Returns whether two rectangles intersect.

```
bool CGRectIntersectsRect (
   CGRect rect1,
   CGRect rect2
);
```

Parameters

rect1
The first rectangle to examine.

rect2
The second rectangle to examine.

Return Value
Returns `1` if the two specified rectangles intersect; otherwise, `0`. The first rectangle intersects the second if the intersection of the rectangles is not equal to the null rectangle.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`CGGeometry.h`

CGRectIsEmpty

Returns whether a rectangle has zero width or height, or is a null rectangle.

```
bool CGRectIsEmpty (
   CGRect rect
);
```

Parameters

rect
The rectangle to examine.

Return Value
Returns `1` if the specified rectangle is empty; otherwise, `0`.

Discussion
An empty rectangle is either a null rectangle or a valid rectangle with zero height or width. See also `CGRectIsNull` (page 2368).

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`CGGeometry.h`

CGRectIsInfinite

Returns whether a rectangle is infinite.

```
bool CGRectIsInfinite (
    CGRect rect
);
```

Parameters

rect
The rectangle to examine.

Return Value
Returns `true` if the specified rectangle is infinite, `false` otherwise.

Discussion
An infinite rectangle is one that has no defined bounds. Infinite rectangles can be created as output from a tiling filter. For example, the Core Image framework perspective tile filter creates an image whose extent is described by an infinite rectangle.

Availability
Available in Mac OS X v10.4 and later.

Related Sample Code
WhackedTV

Declared In
`CGGeometry.h`

CGRectIsIntegral

Returns whether the origin and size of the rectangle can be represented exactly as integers.

```
bool CGRectIsIntegral (
   CGRect rect
);
```

Parameters

rect
The rectangle to examine.

Return Value
Returns `true` if the origin and size of the rectangle can be represented exactly as integers; `false` otherwise.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`CGGeometry.h`

CGRectIsNull

Returns whether a rectangle is invalid.

```
bool CGRectIsNull (
   CGRect rect
);
```

Parameters

rect
The rectangle to examine.

Return Value
Returns `1` if the specified rectangle is null; otherwise, `0`.

Discussion
A null rectangle is one that is not valid (you cannot draw a null rectangle). For example, the result of intersecting two disjoint rectangles is a null rectangle. See also `CGRectIsEmpty` (page 2366).

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`CGGeometry.h`

CGRectMake

Returns a `CGRect` structure filled in with the coordinate and dimension values you provide.

```
CGRect CGRectMake (
   CGFloat x,
   CGFloat y,
   CGFloat width,
   CGFloat height
);
```

Parameters

x
The x-coordinate of the rectangle's origin point.

y
The y-coordinate of the rectangle's origin point.

width
The width of the rectangle.

height
The height of the rectangle.

Return Value
Returns a rectangle with the specified location and dimensions.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`CGGeometry.h`

CGRectMakeWithDictionaryRepresentation

Fills in a `CGRect` structure using the contents of the provided dictionary.

```
bool CGRectMakeWithDictionaryRepresentation(
    CFDictionaryRef dict,
    CGRect *rect
);
```

Parameters

dict
A dictionary that was previously returned from the function `CGRectCreateDictionaryRepresentation` (page 2358).

rect
On return, the rectangle created from the provided dictionary.

Return Value
`true` if successful; `false` otherwise.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`CGGeometry.h`

CGRectOffset

Returns a rectangle with an origin that is offset from that of the source rectangle.

```
CGRect CGRectOffset (
   CGRect rect,
   CGFloat dx,
   CGFloat dy
);
```

Parameters

rect

The source rectangle.

dx

The offset value for the x-coordinate.

dy

The offset value for the y-coordinate.

Return Value
A filled-in `CGRect` structure that is the same size as the source, but with its origin offset by `dx` units along the x-axis and `dy` units along the y-axis with respect to the source.

Availability
Available in Mac OS X version 10.0 and later.

Related Sample Code
CarbonSketch

Declared In
`CGGeometry.h`

CGRectStandardize

Returns a rectangle with a positive width and height.

```
CGRect CGRectStandardize (
   CGRect rect
);
```

Parameters

rect

The source rectangle.

Return Value
A filled-in `CGRect` structure that represents the source rectangle, but with positive width and height values.

Availability
Available in Mac OS X version 10.0 and later.

Related Sample Code
CarbonSketch

Declared In
`CGGeometry.h`

CGRectUnion

Returns the smallest rectangle that contains the two provided rectangles.

```
CGRect CGRectUnion (
   CGRect r1,
   CGRect r2
);
```

Parameters

r1

The first source rectangle.

r2

The second source rectangle.

Return Value

A filled-in `CGRect` structure that represents the smallest rectangle that completely contains both of the source rectangles.

Discussion

If one of the rectangles has 0 (or negative) width or height, a copy of the other rectangle is returned; but if both have 0 (or negative) width or height, the returned rectangle has its origin at (0.0, 0.0) and has 0 width and height.

Availability

Available in Mac OS X version 10.0 and later.

Declared In

`CGGeometry.h`

CGSizeCreateDictionaryRepresentation

Returns a dictionary representation of the provided size.

```
CFDictionaryRef CGSizeCreateDictionaryRepresentation(
    CGSize size
);
```

Parameters

size

A size.

Return Value

The dictionary representation of the size.

Availability

Available in Mac OS X v10.5 and later.

Declared In

`CGGeometry.h`

CGSizeEqualToSize

Returns whether two sizes are equal.

```
bool CGSizeEqualToSize (
   CGSize size1,
   CGSize size2
);
```

Parameters

size1

The first size to examine.

size2

The second size to examine.

Return Value
Returns `1` if the two specified sizes are equal; otherwise, `0`.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`CGGeometry.h`

CGSizeMake

Returns a `CGSize` structure filled in with dimension values you provide.

```
CGSize CGSizeMake (
   CGFloat width,
   CGFloat height
);
```

Parameters

width

A width value.

height

A height value.

Return Value
Returns a `CGSize` structure with the specified width and height.

Availability
Available in Mac OS X version 10.0 and later.

Related Sample Code
CarbonSketch

Declared In
`CGGeometry.h`

CGSizeMakeWithDictionaryRepresentation

Fills in a `CGSize` structure using the contents of the provided dictionary.

```
bool CGSizeMakeWithDictionaryRepresentation(
    CFDictionaryRef dict,
    CGSize *size
);
```

Parameters

dict

A dictionary that was previously returned from the function `CGSizeCreateDictionaryRepresentation` (page 2371).

size

On return, the size created from the provided dictionary.

Return Value

`true` if successful; `false` otherwise.

Availability

Available in Mac OS X v10.5 and later.

Declared In

`CGGeometry.h`

Data Types

CGPoint

A structure that contains a point in a two-dimensional coordinate system.

```
struct CGPoint {
     CGFloat x;
    CGFloat y;
};
typedef struct CGPoint CGPoint;
```

Fields

`x`

The x-coordinate of the point.

`y`

The y-coordinate of the point.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CGGeometry.h`

CGRect

A structure that contains the location and dimensions of a rectangle.

```
struct CGRect {
    CGPoint origin;
    CGSize size;
};
typedef struct CGRect CGRect;
```

Fields

`origin`
A `CGPoint` (page 2373) structure that specifies the coordinates of the rectangle's origin. The origin is located in the lower-left of the rectangle.

`size`
A `CGSize` (page 2374) structure that specifies the height and width of the rectangle.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGGeometry.h`

CGSize

A structure that contains width and height values.

```
struct CGSize {
    CGFloat width;
    CGFloat height;
};
typedef struct CGSize CGSize;
```

Fields

`width`
A width value.

`height`
A height value.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGGeometry.h`

Constants

CGRectInfinite

A rectangle that has infinite extent.

```
const CGRect CGRectInfinite;
```

Constants

`CGRectInfinite`

A rectangle that has infinite extent.

Available in Mac OS X v10.4 and later.

Declared in `CGGeometry.h`.

Availability

Available in Mac OS X v10.4 and later.

Declared In

`CGGeometry.h`

Geometric Zeroes

A zero point, zero rectangle, or zero size.

```
const CGPoint CGPointZero;
const CGRect CGRectZero;
const CGSize CGSizeZero;
```

Constants

`CGPointZero`

A point constant with location `(0, 0)`. The zero point is equivalent to `CGPointMake(0,0)`.

Available in Mac OS X v10.0 and later.

Declared in `CGGeometry.h`.

`CGRectZero`

A rectangle constant with location `(0,0)`, and width and height of 0. The zero rectangle is equivalent to `CGRectMake(0,0,0,0)`.

Available in Mac OS X v10.0 and later.

Declared in `CGGeometry.h`.

`CGSizeZero`

A size constant with width and height of *0*. The zero size is equivalent to `CGSizeMake(0,0)`.

Available in Mac OS X v10.0 and later.

Declared in `CGGeometry.h`.

Declared In

`CGGeometry.h`

Geometrical Null

The null or empty rectangle.

```
const CGRect CGRectNull;
```

Constants

`CGRectNull`

The null rectangle. This is the rectangle returned when, for example, you intersect two disjoint rectangles. Note that the null rectangle is not the same as the zero rectangle.

Available in Mac OS X v10.0 and later.

Declared in `CGGeometry.h`.

Declared In

`CGGeometry.h`

CGRectEdge

Coordinates that establish the edges of a rectangle.

```
enum CGRectEdge {
    CGRectMinXEdge,
    CGRectMinYEdge,
    CGRectMaxXEdge,
    CGRectMaxYEdge
};
typedef enum CGRectEdge CGRectEdge;
```

Constants

`CGRectMinXEdge`

The x-coordinate that establishes the left edge of a rectangle.

Available in Mac OS X v10.0 and later.

Declared in `CGGeometry.h`.

`CGRectMinYEdge`

The y-coordinate that establishes the minimum edge of a rectangle. In Mac OS X, this is typically the bottom edge of the rectangle. If the coordinate system is flipped (or if you are using the default coordinate system in iPhone OS), this constant refers to the top edge of the rectangle.

Available in Mac OS X v10.0 and later.

Declared in `CGGeometry.h`.

`CGRectMaxXEdge`

The x-coordinate that establishes the right edge of a rectangle.

Available in Mac OS X v10.0 and later.

Declared in `CGGeometry.h`.

`CGRectMaxYEdge`

The y-coordinate that establishes the maximum edge of a rectangle. In Mac OS X, this is typically the top edge of the rectangle. If the coordinate system is flipped (or if you are using the default coordinate system in iPhone OS), this constant refers to the bottom edge of the rectangle.

Available in Mac OS X v10.0 and later.

Declared in `CGGeometry.h`.

Declared In

`CGGeometry.h`

CGFloat Informational Macros

Informational macros for the `CGFloat` type.

```
#define CGFLOAT_MIN FLT_MIN                                     // 32-bit
#define CGFLOAT_MAX FLT_MAX
#define CGFLOAT_IS_DOUBLE 0

#define CGFLOAT_MIN DBL_MIN                                     // 64-bit
#define CGFLOAT_MAX DBL_MAX
#define CGFLOAT_IS_DOUBLE 1
```

Constants

`CGFLOAT_MIN`

The minimum allowable value for a `CGFloat` type. For 32-bit code, this value is `1.17549435e-38F`. For 64-bit code, it is `2.2250738585072014e-308`.

Available in Mac OS X v10.5 and later.

Declared in `CABase.h`.

`CGFLOAT_MAX`

The maximum allowable value for a `CGFloat` type. For 32-bit code, this value is `3.40282347e+38F`. For 64-bit code, it is `1.7976931348623157e+308`.

Available in Mac OS X v10.5 and later.

Declared in `CABase.h`.

`CGFLOAT_IS_DOUBLE`

Indicates whether `CGFloat` is defined as a `float` or `double` type.

Available in Mac OS X v10.5 and later.

Declared in `CABase.h`.

Find By Content Reference (Not Recommended)

Framework: ApplicationServices/ApplicationServices.h

Declared in FindByContent.h

Overview

Important: The Find by Content API is deprecated as of Mac OS X v10.4. A much more complete solution for finding and displaying information is provided by the Search Kit. See *Search Kit Programming Guide* for guidelines on using the Search Kit.

Whereas the Find by Content API searches specified volumes or folders for words typed in by a user, Search Kit uses a much faster fully indexed search to return relevant content of all sorts. Because the Search Kit takes a different approach to searching for and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Seach Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Previous to Mac OS X version 10.2, the main client for Find by Content was Sherlock; in versions 10.2 and 10.3 it was the Finder. In version 10.4 and later, Search Kit is used instead by the Finder, Mail, and Spotlight.

Carbon supports Find By Content, but note that it is not contained within the Carbon framework.

Functions by Task

Working With Indexes

`FBCDeleteIndexFileForFolder` (page 2389) Deprecated in Mac OS X v10.4

Deletes the index file associated with a folder. (Deprecated. Use Search Kit instead; see *Search Kit Programming Guide*.)

`FBCIndexItemsInLanguages` (page 2403) Deprecated in Mac OS X v10.4

Indexes one or more directories. (Deprecated. Use Search Kit instead; see *Search Kit Programming Guide*.)

Setting Up a Search Session Object

`FBCCreateSearchSession` (page 2388) Deprecated in Mac OS X v10.4
Creates a search session. (Deprecated. Use Search Kit instead; see *Search Kit Programming Guide*.)

`FBCSetSessionCallback` (page 2406) Deprecated in Mac OS X v10.4
Sets a callback function that allows your application to cancel a search operation. (Deprecated. Use Search Kit instead; see *Search Kit Programming Guide*.)

`FBCSetSessionHitTest` (page 2407) Deprecated in Mac OS X v10.4
Sets a callback function that allows your application to perform search-hit testing. (Deprecated. Use Search Kit instead; see *Search Kit Programming Guide*.)

Executing a Search

`FBCBlindExampleSearchWithCallback` (page 2386) Deprecated in Mac OS X v10.4
Performs a similarity search that uses example files instead of a query string, and installs callbacks for progress reporting and search hit testing. (Deprecated. Use Search Kit instead; see *Search Kit Programming Guide*.)

`FBCDoCFStringSearch` (page 2391) Deprecated in Mac OS X v10.4
Initiates a search using a `CFString` as the query string. (Deprecated. Use Search Kit instead; see *Search Kit Programming Guide*.)

`FBCDoExampleSearch` (page 2393) Deprecated in Mac OS X v10.4
Performs a similarity search that uses example files instead of a query string. (Deprecated. Use Search Kit instead; see *Search Kit Programming Guide*.)

`FBCDoQuerySearch` (page 2394) Deprecated in Mac OS X v10.4
Initiates a search using a C string as the query string. (Deprecated. Use Search Kit instead; see *Search Kit Programming Guide*.)

Getting Information About Search Session Hits

`FBCGetHitCount` (page 2395) Deprecated in Mac OS X v10.4
Obtains the number of hits returned for a search session. (Deprecated. Use Search Kit instead; see *Search Kit Programming Guide*.)

`FBCGetHitDocument` (page 2396) Deprecated in Mac OS X v10.4
Retrieves the `FSSpec` associated with a specific hit and search. (Deprecated. Use Search Kit instead; see *Search Kit Programming Guide*.)

`FBCGetHitDocumentRef` (page 2397) Deprecated in Mac OS X v10.4
Retrieves the `FSRef` associated with a specific hit and search. (Deprecated. Use Search Kit instead; see *Search Kit Programming Guide*.)

`FBCGetHitScore` (page 2397) Deprecated in Mac OS X v10.4
Obtains the hit score associated with a specific hit. (Deprecated. Use Search Kit instead; see *Search Kit Programming Guide*.)

Deallocating Hit Lists and Search Sessions

`FBCDestroySearchSession` (page 2390) Deprecated in Mac OS X v10.4
Disposes of a search session object. (Deprecated. Use Search Kit instead; see *Search Kit Programming Guide*.)

`FBCReleaseSessionHits` (page 2404) Deprecated in Mac OS X v10.4
Releases the hits associated with a search session object. (Deprecated. Use Search Kit instead; see *Search Kit Programming Guide*.)

Summarizing Text

`FBCDisposeSummary` (page 2391) Deprecated in Mac OS X v10.4
Disposes of a summary reference object. (Deprecated. Use Search Kit instead; see *Search Kit Programming Guide*.)

`FBCGetSummaryOfCFString` (page 2400) Deprecated in Mac OS X v10.4
Creates a summary reference object for `CFString`. (Deprecated. Use Search Kit instead; see *Search Kit Programming Guide*.)

`FBCGetSummarySentenceCount` (page 2400) Deprecated in Mac OS X v10.4
Obtains the number of sentences in a summary reference object. (Deprecated. Use Search Kit instead; see *Search Kit Programming Guide*.)

`FBCGetSummarySentences` (page 2401) Deprecated in Mac OS X v10.4
Obtains a summary that contains a specified number of sentences. (Deprecated. Use Search Kit instead; see *Search Kit Programming Guide*.)

`FBCSummarize` (page 2408) Deprecated in Mac OS X v10.4
Summarizes text that is specified as an ASCII buffer. (Deprecated. Use Search Kit instead; see *Search Kit Programming Guide*.)

`FBCSummarizeCFString` (page 2409) Deprecated in Mac OS X v10.4
Summarizes text that is specified as a `CFString`. (Deprecated. Use Search Kit instead; see *Search Kit Programming Guide*.)

Working with Universal Procedure Pointers

`DisposeFBCCallbackUPP` (page 2383) Deprecated in Mac OS X v10.4
Disposes of universal procedure pointer (UPP) to a search cancellation callback. (Deprecated. Use Search Kit instead; see *Search Kit Programming Guide*.)

`DisposeFBCHitTestUPP` (page 2384) Deprecated in Mac OS X v10.4
Disposes of universal procedure pointer (UPP) to a search-hit testing callback. (Deprecated. Use Search Kit instead; see *Search Kit Programming Guide*.)

`InvokeFBCCallbackUPP` (page 2412) Deprecated in Mac OS X v10.4
Invokes a universal procedure pointer (UPP) to a search cancellation callback. (Deprecated. Use Search Kit instead; see *Search Kit Programming Guide*.)

`InvokeFBCHitTestUPP` (page 2413) Deprecated in Mac OS X v10.4
Invokes a universal procedure pointer (UPP) to a search-hit testing callback. (Deprecated. Use Search Kit instead; see *Search Kit Programming Guide*.)

NewFBCCallbackUPP (page 2413) Deprecated in Mac OS X v10.4
Creates a new universal procedure pointer (UPP) to a search cancellation callback. (Deprecated. Use Search Kit instead; see *Search Kit Programming Guide*.)

NewFBCHitTestUPP (page 2414) Deprecated in Mac OS X v10.4
Creates a new universal procedure pointer (UPP) to a search-hit testing callback. (Deprecated. Use Search Kit instead; see *Search Kit Programming Guide*.)

Deprecated Functions

FBCAddAllVolumesToSession (page 2384) Deprecated in Mac OS X v10.4
Adds all volumes to a search session. (Deprecated. Use Search Kit instead; see *Search Kit Programming Guide*.)

FBCAddVolumeToSession (page 2385) Deprecated in Mac OS X v10.4
Adds one volume to a session. (Deprecated. Use Search Kit instead; see *Search Kit Programming Guide*.)

FBCBlindExampleSearch (page 2385) Deprecated in Mac OS X v10.4
Executes a similarity search. (Deprecated. Use Search Kit instead; see *Search Kit Programming Guide*.)

FBCCloneSearchSession (page 2388) Deprecated in Mac OS X v10.4
Clones a search session. (Deprecated. Use Search Kit instead; see *Search Kit Programming Guide*.)

FBCDestroyWordList (page 2390) Deprecated in Mac OS X v10.4
Destroys a word list. (Deprecated. Use Search Kit instead; see *Search Kit Programming Guide*.)

FBCFindIndexFileFolderForFolder (page 2395) Deprecated in Mac OS X v10.4
Gets the location of the index file associated with a directory. (Deprecated. Use Search Kit instead; see *Search Kit Programming Guide*.)

FBCGetMatchedWords (page 2398) Deprecated in Mac OS X v10.4
Gets a list of matched words for a search session. (Deprecated. Use Search Kit instead; see *Search Kit Programming Guide*.)

FBCGetSessionVolumeCount (page 2399) Deprecated in Mac OS X v10.4
Gets a volume count for a search session. (Deprecated. Use Search Kit instead; see *Search Kit Programming Guide*.)

FBCGetSessionVolumes (page 2399) Deprecated in Mac OS X v10.4
Gets the volumes associated with a search session. (Deprecated. Use Search Kit instead; see *Search Kit Programming Guide*.)

FBCGetTopicWords (page 2402) Deprecated in Mac OS X v10.4
Gets a list of topic words for a search session. (Deprecated. Use Search Kit instead; see *Search Kit Programming Guide*.)

FBCIndexItems (page 2403) Deprecated in Mac OS X v10.4
Indexes one or more files or folders. (Deprecated. Use Search Kit instead; see *Search Kit Programming Guide*.)

FBCRemoveVolumeFromSession (page 2405) Deprecated in Mac OS X v10.4
Removes a volume from a search session. (Deprecated. Use Search Kit instead; see *Search Kit Programming Guide*.)

FBCSetCallback (page 2405) Deprecated in Mac OS X v10.4
Sets a callback. (Deprecated. Use Search Kit instead; see *Search Kit Programming Guide*.)

FBCSetHeapReservation (page 2406) Deprecated in Mac OS X v10.4
Sets the amount of heap space to reserve for application use when Find by Content allocates memory. (Deprecated. Use Search Kit instead; see *Search Kit Programming Guide*.)

`FBCSetSessionVolumes` (page 2408) Deprecated in Mac OS X v10.4
: Sets the volumes for a search session. (Deprecated. Use Search Kit instead; see *Search Kit Programming Guide*.)

`FBCVolumeIndexPhysicalSize` (page 2410) Deprecated in Mac OS X v10.4
: Obtains the physical size of an index. (Deprecated. Use Search Kit instead; see *Search Kit Programming Guide*.)

`FBCVolumeIndexTimeStamp` (page 2410) Deprecated in Mac OS X v10.4
: Obtains the date and time when an index was last updated. (Deprecated. Use Search Kit instead; see *Search Kit Programming Guide*.)

`FBCVolumeIsIndexed` (page 2411) Deprecated in Mac OS X v10.4
: Determines whether a volume is indexed. (Deprecated. Use Search Kit instead; see *Search Kit Programming Guide*.)

`FBCVolumeIsRemote` (page 2411) Deprecated in Mac OS X v10.4
: Determines whether a volume is remote. (Deprecated. Use Search Kit instead; see *Search Kit Programming Guide*.)

Functions

DisposeFBCCallbackUPP

Disposes of universal procedure pointer (UPP) to a search cancellation callback. (Deprecated in Mac OS X v10.4. Use Search Kit instead; see *Search Kit Programming Guide*.)

```
void DisposeFBCCallbackUPP (
    FBCCallbackUPP userUPP
);
```

Parameters

userUPP
: The universal procedure pointer.

Discussion

See the callback `FBCCallbackProcPtr` (page 2414) for more information.

Special Considerations

Because the Search Kit takes a different approach to finding and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Search Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Availability

Available in Mac OS X v10.0 through Mac OS X v10.4.

Deprecated in Mac OS X v10.4.

Declared In

`FindByContent.h`

DisposeFBCHitTestUPP

Disposes of universal procedure pointer (UPP) to a search-hit testing callback. (Deprecated in Mac OS X v10.4. Use Search Kit instead; see *Search Kit Programming Guide*.)

```
void DisposeFBCHitTestUPP (
    FBCHitTestUPP userUPP
);
```

Parameters

userUPP

The universal procedure pointer.

Discussion

See the callback `FBCHitTestProcPtr` (page 2415) for more information.

Special Considerations

Because the Search Kit takes a different approach to finding and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Search Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Availability

Available in Mac OS X v10.2 through Mac OS X v10.4.

Deprecated in Mac OS X v10.4.

Declared In

`FindByContent.h`

FBCAddAllVolumesToSession

Adds all volumes to a search session. (Deprecated in Mac OS X v10.4. Use Search Kit instead; see *Search Kit Programming Guide*.)

Not recommended

```
OSErr FBCAddAllVolumesToSession (
    FBCSearchSession theSession,
    Boolean includeRemote
);
```

Special Considerations

Because the Search Kit takes a different approach to finding and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Search Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Carbon Porting Notes

This function does nothing in Mac OS X.

Availability

Available in Mac OS X v10.0 through Mac OS X v10.4.

Deprecated in Mac OS X v10.4.

Declared In
`FindByContent.h`

FBCAddVolumeToSession

Adds one volume to a session. (Deprecated in Mac OS X v10.4. Use Search Kit instead; see *Search Kit Programming Guide*.)

Not recommended

```
OSErr FBCAddVolumeToSession (
    FBCSearchSession theSession,
    SInt16 vRefNum
);
```

Special Considerations

Because the Search Kit takes a different approach to finding and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Search Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Carbon Porting Notes

This function does nothing in Mac OS X.

Availability

Available in Mac OS X v10.0 through Mac OS X v10.4.

Deprecated in Mac OS X v10.4.

Declared In

`FindByContent.h`

FBCBlindExampleSearch

Executes a similarity search. (Deprecated in Mac OS X v10.4. Use Search Kit instead; see *Search Kit Programming Guide*.)

Not recommended

```
OSErr FBCBlindExampleSearch (
    const FSSpec examples[],
    UInt32 numExamples,
    const FSSpec targetDirs[],
    UInt32 numTargets,
    UInt32 maxHits,
    UInt32 maxHitWords,
    Boolean allIndexes,
    Boolean includeRemote,
    FBCSearchSession * theSession
);
```

Special Considerations

Because the Search Kit takes a different approach to finding and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Search Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Carbon Porting Notes

Use the function `FBCBlindExampleSearchWithCallback` (page 2386) instead.

Availability

Available in Mac OS X v10.0 through Mac OS X v10.4.
Deprecated in Mac OS X v10.4.

Declared In

`FindByContent.h`

FBCBlindExampleSearchWithCallback

Performs a similarity search that uses example files instead of a query string, and installs callbacks for progress reporting and search hit testing. (Deprecated in Mac OS X v10.4. Use Search Kit instead; see *Search Kit Programming Guide*.)

```
OSErr FBCBlindExampleSearchWithCallback (
    const FSSpec examples[],
    UInt32 numExamples,
    const FSSpec targetDirs[],
    UInt32 numTargets,
    UInt32 maxHits,
    UInt32 maxHitWords,
    Boolean allIndexes,
    Boolean includeRemote,
    FBCSearchSession * theSession,
    FBCCallbackUPP callback,
    void * callbackData,
    FBCHitTestUPP userHitTest,
    void * userHitTestData
);
```

Parameters

examples

An array of `FSSpec` data types that specify the location of one or more examples files. The hits are the files that most resemble the examples in terms of weighted word frequencies.

numExamples
The number of examples in the `examples` array.

targetDirs
An array of `FSSpec` data types that specify the directories you want to search. Any directories that are not indexed are skipped.

numTargets
A value that specifies number of directories specified by the `targetDirs` parameter.

maxHits
A value that specifies the maximum number of hits you want. If you pass N for this parameter, you get the N most relevant hits found in an exhaustive search of the indexes (or all the hits if there are less than N).

maxHitWords
This parameter is ignored in Mac OS X version 10.2 and later.

allIndexes
This parameter is ignored in Mac OS X version 10.2 and later.

includeRemote
This parameter is ignored in Mac OS X version 10.2 and later.

theSession
A valid search session object. You obtain a search session object by calling the function `FBCCreateSearchSession`.

callback
A universal procedure pointer to your callback for cancelling a search. See `FBCCallbackProcPtr` (page 2414) for more information.

callbackData
A pointer to data needed by the callback specified by the `callback` parameter. Pass `NULL` if your callback does not require any data.

userHitTest
A universal procedure pointer a your callback for testing search hits. See `FBCHitTestProcPtr` (page 2415) for more information.

callbackData
A pointer to data needed by the callback specified by the `userHitTest` parameter. Pass `NULL` if your callback does not require any data.

Return Value
A result code. See "Find By Content Result Codes" (page 2421).

Discussion
You should use the function `FBCBlindExampleSearchWithCallback` for cases where your example files have not been indexed. If the files have been indexed, it is simpler and more efficient for you to use the function `FBCDoExampleSearch`.

Special Considerations

Because the Search Kit takes a different approach to finding and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Search Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Availability
Available in Mac OS X v10.2 through Mac OS X v10.4.

Deprecated in Mac OS X v10.4.

Declared In
`FindByContent.h`

FBCCloneSearchSession

Clones a search session. (Deprecated in Mac OS X v10.4. Use Search Kit instead; see *Search Kit Programming Guide*.)

Not recommended

```
OSErr FBCCloneSearchSession (
    FBCSearchSession original,
    FBCSearchSession * clone
);
```

Parameters

original

A valid search session object. You obtain a search session object by calling the function `FBCCreateSearchSession`.

clone

On return, points to a newly-created search session object that is a copy of the one specified by the `original` parameter.

Return Value
A result code. See "Find By Content Result Codes" (page 2421).

Special Considerations

Because the Search Kit takes a different approach to finding and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Search Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Availability
Available in Mac OS X v10.0 through Mac OS X v10.4.
Deprecated in Mac OS X v10.4.

Declared In
`FindByContent.h`

FBCCreateSearchSession

Creates a search session. (Deprecated in Mac OS X v10.4. Use Search Kit instead; see *Search Kit Programming Guide*.)

```
OSErr FBCCreateSearchSession (
    FBCSearchSession * searchSession
);
```

Parameters

searchSession

On return, points to a newly-created search session object. You provide a search session object as a parameter when you call other other search functions.

Return Value
A result code. See "Find By Content Result Codes" (page 2421).

Discussion
You must create a search session using the function `FBCCreateSearchSession` before you can use any other search function.

Special Considerations

Because the Search Kit takes a different approach to finding and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Search Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Availability
Available in Mac OS X v10.0 through Mac OS X v10.4.
Deprecated in Mac OS X v10.4.

Declared In
`FindByContent.h`

FBCDeleteIndexFileForFolder

Deletes the index file associated with a folder. (Deprecated in Mac OS X v10.4. Use Search Kit instead; see *Search Kit Programming Guide*.)

```
OSErr FBCDeleteIndexFileForFolder (
    const FSRef * folder
);
```

Parameters

folder

An `FSRef` that specifies the folder whose index file you want to delete.

Return Value
A result code. See "Find By Content Result Codes" (page 2421).

Special Considerations

Because the Search Kit takes a different approach to finding and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Search Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Availability
Available in Mac OS X v10.0 through Mac OS X v10.4.
Deprecated in Mac OS X v10.4.

Declared In
`FindByContent.h`

FBCDestroySearchSession

Disposes of a search session object. (Deprecated in Mac OS X v10.4. Use Search Kit instead; see *Search Kit Programming Guide*.)

```
OSErr FBCDestroySearchSession (
    FBCSearchSession theSession
);
```

Parameters

`theSession`

The search session object you want to dispose of. You obtain a search session object by calling the function `FBCCreateSearchSession`.

Return Value
A result code. See "Find By Content Result Codes" (page 2421).

Special Considerations

Because the Search Kit takes a different approach to finding and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Search Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Availability
Available in Mac OS X v10.0 through Mac OS X v10.4.
Deprecated in Mac OS X v10.4.

Declared In
`FindByContent.h`

FBCDestroyWordList

Destroys a word list. (Deprecated in Mac OS X v10.4. Use Search Kit instead; see *Search Kit Programming Guide*.)

Not recommended

```
OSErr FBCDestroyWordList (
    FBCWordList theList,
    UInt32 wordCount
);
```

Special Considerations

Because the Search Kit takes a different approach to finding and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Search Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Availability
Available in Mac OS X v10.0 through Mac OS X v10.4.

Deprecated in Mac OS X v10.4.

Declared In
`FindByContent.h`

FBCDisposeSummary

Disposes of a summary reference object. (Deprecated in Mac OS X v10.4. Use Search Kit instead; see *Search Kit Programming Guide*.)

```
OSStatus FBCDisposeSummary (
    FBCSummaryRef summary
);
```

Parameters

summary

The summary reference object you want to dispose of. You obtain a summary reference object when you call the function `FBCGetSummaryOfCFString` (page 2400).

Return Value
A result code. See "Find By Content Result Codes" (page 2421).

Discussion
You must dispose of a summary reference object when you no longer need it.

Special Considerations

Because the Search Kit takes a different approach to finding and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Search Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Availability
Available in Mac OS X v10.2 through Mac OS X v10.4.
Deprecated in Mac OS X v10.4.

Declared In
`FindByContent.h`

FBCDoCFStringSearch

Initiates a search using a `CFString` as the query string. (Deprecated in Mac OS X v10.4. Use Search Kit instead; see *Search Kit Programming Guide*.)

```
OSErr FBCDoCFStringSearch (
    FBCSearchSession theSession,
    CFStringRef queryString,
    const FSSpec targetDirs[],
    UInt32 numTargets,
    UInt32 maxHits,
    UInt32 maxHitWords
);
```

Parameters

theSession

A valid search session object. You obtain a search session object by calling the function `FBCCreateSearchSession`.

queryString

The query string specified as a `CFString`.

targetDirs

An array of `FSSpec` data types that specify the directories you want to search. Any directories that are not indexed are skipped.

numTargets

A value that specifies number of directories specified by the `targetDirs` parameter.

maxHits

A value that specifies the maximum number of hits you want. If you pass N for this parameter, you get the N most relevant hits found in an exhaustive search of the indexes (or all the hits if there are less than N).

maxHitWords

This parameter is ignored in Mac OS X version 10.2 and later.

Return Value

A result code. See "Find By Content Result Codes" (page 2421).

Discussion

When the function `FBCDoCFStringSearch` returns, you must retrieve hit information by calling the functions `FBCGetHitCount` (page 2395), `FBCGetHitDocumentRef` (page 2397), and `FBCGetHitScore` (page 2397). You call `FBCGetHitCount` (page 2395) to obtain the number of hits found. Then you can iterate through each hit to get the associated `FSRef` and score by calling `FBCGetHitDocumentRef` (page 2397) and `FBCGetHitScore` (page 2397).

Special Considerations

Because the Search Kit takes a different approach to finding and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Search Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Availability

Available in Mac OS X v10.0 through Mac OS X v10.4.

Deprecated in Mac OS X v10.4.

Declared In

`FindByContent.h`

FBCDoExampleSearch

Performs a similarity search that uses example files instead of a query string. (Deprecated in Mac OS X v10.4. Use Search Kit instead; see *Search Kit Programming Guide*.)

```
OSErr FBCDoExampleSearch (
    FBCSearchSession theSession,
    const UInt32 * exampleHitNums,
    UInt32 numExamples,
    const FSSpec targetDirs[],
    UInt32 numTargets,
    UInt32 maxHits,
    UInt32 maxHitWords
);
```

Parameters

theSession

A valid search session object. You must provide the search session object you provided to the search function `FBCDoCFStringSearch`.

exampleHitNums

A pointer to the hits obtained from a previous search using `theSession` search session object.

numExamples

The number of examples pointed to by the `exampleHitNums` parameter.

targetDirs

An array of `FSSpec` data types that specify the directories you want to search. Any directories that are not indexed are skipped.

numTargets

A value that specifies number of directories specified by the `targetDirs` parameter.

maxHits

A value that specifies the maximum number of hits you want. If you pass N for this parameter, you get the N most relevant hits found in an exhaustive search of the indexes (or all the hits if there are less than N).

maxHitWords

This parameter is ignored in Mac OS X version 10.2 and later.

Return Value

A result code. See "Find By Content Result Codes" (page 2421).

Discussion

You should use the function `FBCDoExampleSearch` for cases where you example files have been indexed. If you example files have not been indexed, us the function `FBCBlindExampleSearchWithCallback`.

Special Considerations

Because the Search Kit takes a different approach to finding and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Search Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Availability

Available in Mac OS X v10.0 through Mac OS X v10.4.

Deprecated in Mac OS X v10.4.

Declared In
`FindByContent.h`

FBCDoQuerySearch

Initiates a search using a C string as the query string. (Deprecated in Mac OS X v10.4. Use Search Kit instead; see *Search Kit Programming Guide*.)

```
OSErr FBCDoQuerySearch (
    FBCSearchSession theSession,
    char * queryText,
    const FSSpec targetDirs[],
    UInt32 numTargets,
    UInt32 maxHits,
    UInt32 maxHitWords
);
```

Parameters

theSession
A valid search session object. You obtain a search session object by calling the function `FBCCreateSearchSession`.

queryText
The query string specified as a C string.

numTargets
A value that specifies number of directories specified by the `targetDirs` parameter.

maxHits
A value that specifies the maximum number of hits you want. If you pass N for this parameter, you get the N most relevant hits found in an exhaustive search of the indexes (or all the hits if there are less than N).

maxHitWords
This parameter is ignored in Mac OS X version 10.2 and later.

Return Value
A result code. See "Find By Content Result Codes" (page 2421).

Discussion
You should use the function `FBCDoCFStringSearch` (page 2391) instead of this one.

Special Considerations

Because the Search Kit takes a different approach to finding and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Search Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Availability
Available in Mac OS X v10.0 through Mac OS X v10.4.
Deprecated in Mac OS X v10.4.

Declared In
`FindByContent.h`

FBCFindIndexFileFolderForFolder

Gets the location of the index file associated with a directory. (Deprecated in Mac OS X v10.4. Use Search Kit instead; see *Search Kit Programming Guide*.)

Not recommended

```
OSErr FBCFindIndexFileFolderForFolder (
    const FSRef * inFolder,
    FSRef * outFolder
);
```

Parameters

inFolder

A pointer to an `FSRef` that specifies the location of the folder that contains the index file for a directory.

outFolder

On output, points to the `FSRef` that specifies the directory that contains he index file.

Return Value

A result code. See "Find By Content Result Codes" (page 2421).

Special Considerations

Because the Search Kit takes a different approach to finding and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Search Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Availability

Available in Mac OS X v10.0 through Mac OS X v10.4.

Deprecated in Mac OS X v10.4.

Declared In

`FindByContent.h`

FBCGetHitCount

Obtains the number of hits returned for a search session. (Deprecated in Mac OS X v10.4. Use Search Kit instead; see *Search Kit Programming Guide*.)

```
OSErr FBCGetHitCount (
    FBCSearchSession theSession,
    UInt32 * count
);
```

Parameters

theSession

A valid search session object. You must provide the search session object you provided to the search function `FBCDoCFStringSearch`.

count

On return, points to the number of hits returned for the search on the object specified by `theSession`.

Return Value

A result code. See "Find By Content Result Codes" (page 2421).

Discussion
You can iterate through each hit to get the associated `FSRef` and score by calling the functions `FBCGetHitDocumentRef` (page 2397) and `FBCGetHitScore` (page 2397).

Special Considerations

Because the Search Kit takes a different approach to finding and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Search Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Availability
Available in Mac OS X v10.0 through Mac OS X v10.4.
Deprecated in Mac OS X v10.4.

Declared In
`FindByContent.h`

FBCGetHitDocument

Retrieves the `FSSpec` associated with a specific hit and search. (Deprecated in Mac OS X v10.4. Use Search Kit instead; see *Search Kit Programming Guide*.)

```
OSErr FBCGetHitDocument (
    FBCSearchSession theSession,
    UInt32 hitNumber,
    FSSpec * theDocument
);
```

Parameters

`theSession`
A valid search session object. You must provide the search session object you provided to the search function `FBCDoCFStringSearch`.

`hitNumber`
A value that specifies the hit whose document you want to retrieve.

`theDocument`
A pointer to an `FSSpec` that specifies the location of the document associated with `hitNumber` for the search previously carried out on `theSession`.

Return Value
A result code. See "Find By Content Result Codes" (page 2421).

Special Considerations

Because the Search Kit takes a different approach to finding and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Search Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Availability
Available in Mac OS X v10.0 through Mac OS X v10.4.
Deprecated in Mac OS X v10.4.

Declared In
`FindByContent.h`

FBCGetHitDocumentRef

Retrieves the `FSRef` associated with a specific hit and search. (Deprecated in Mac OS X v10.4. Use Search Kit instead; see *Search Kit Programming Guide*.)

```
OSErr FBCGetHitDocumentRef (
    FBCSearchSession theSession,
    UInt32 hitNumber,
    FSRef * theDocument
);
```

Parameters

theSession

A valid search session object. You must provide the search session object you provided to the search function `FBCDoCFStringSearch`.

hitNumber

A value that specifies the hit whose document you want to retrieve.

theDocument

A pointer to an `FSRef` that specifies the location of the document associated with `hitNumber` for the search previously carried out on `theSession`.

Return Value

A result code. See "Find By Content Result Codes" (page 2421).

Special Considerations

Because the Search Kit takes a different approach to finding and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Search Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Availability

Available in Mac OS X v10.0 through Mac OS X v10.4.

Deprecated in Mac OS X v10.4.

Declared In

`FindByContent.h`

FBCGetHitScore

Obtains the hit score associated with a specific hit. (Deprecated in Mac OS X v10.4. Use Search Kit instead; see *Search Kit Programming Guide*.)

```
OSErr FBCGetHitScore (
    FBCSearchSession theSession,
    UInt32 hitNumber,
    float * score
);
```

Parameters

theSession

A valid search session object. You must provide the search session object you provided to the search function `FBCDoCFStringSearch`.

hitNumber

A value that specifies the hit whose document you want to retrieve.

float

A pointer to a value that specifies the hit score. Scores are normalized to range from 1.0 (most significant) to 0 (least significant).

Return Value
A result code. See "Find By Content Result Codes" (page 2421).

Special Considerations

Because the Search Kit takes a different approach to finding and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Search Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Availability
Available in Mac OS X v10.0 through Mac OS X v10.4.
Deprecated in Mac OS X v10.4.

Declared In
`FindByContent.h`

FBCGetMatchedWords

Gets a list of matched words for a search session. (Deprecated in Mac OS X v10.4. Use Search Kit instead; see *Search Kit Programming Guide*.)

Not recommended

```
OSErr FBCGetMatchedWords (
    FBCSearchSession theSession,
    UInt32 hitNumber,
    UInt32 * wordCount,
    FBCWordList * list
);
```

Special Considerations

Because the Search Kit takes a different approach to finding and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Search Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Carbon Porting Notes

This function does nothing in Mac OS X.

Availability
Available in Mac OS X v10.0 through Mac OS X v10.4.
Deprecated in Mac OS X v10.4.

Declared In
`FindByContent.h`

FBCGetSessionVolumeCount

Gets a volume count for a search session. (Deprecated in Mac OS X v10.4. Use Search Kit instead; see *Search Kit Programming Guide*.)

Not recommended

```
OSErr FBCGetSessionVolumeCount (
    FBCSearchSession theSession,
    UInt16 * count
);
```

Special Considerations

Because the Search Kit takes a different approach to finding and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Search Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Carbon Porting Notes

This function does nothing in Mac OS X.

Availability

Available in Mac OS X v10.0 through Mac OS X v10.4.

Deprecated in Mac OS X v10.4.

Declared In

`FindByContent.h`

FBCGetSessionVolumes

Gets the volumes associated with a search session. (Deprecated in Mac OS X v10.4. Use Search Kit instead; see *Search Kit Programming Guide*.)

Not recommended

```
OSErr FBCGetSessionVolumes (
    FBCSearchSession theSession,
    SInt16 vRefNums[],
    UInt16 * numVolumes
);
```

Special Considerations

Because the Search Kit takes a different approach to finding and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Search Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Carbon Porting Notes

This function does nothing in Mac OS X.

Availability

Available in Mac OS X v10.0 through Mac OS X v10.4.

Deprecated in Mac OS X v10.4.

Declared In
`FindByContent.h`

FBCGetSummaryOfCFString

Creates a summary reference object for `CFString`. (Deprecated in Mac OS X v10.4. Use Search Kit instead; see *Search Kit Programming Guide*.)

```
OSStatus FBCGetSummaryOfCFString (
    CFStringRef inString,
    FBCSummaryRef * summary
);
```

Parameters

`inString`

A `CFStringRef` representing the text you want summarized. Summarization works with all languages that use white space to separate words, plus Japanese. It works best with text that is not broken into lines using CR and/or LF characters.

`summary`

On output, a newly-created summary reference object that contains summary information for the string specified by the `inString` parameter. A summary reference object is an opaque object. To access the information in this object, you can use the functions `FBCGetSummarySentenceCount` (page 2400) and `FBCGetSummarySentences` (page 2401). You should call the function `FBCDisposeSummary` (page 2391) when you no longer need the summary reference object.

Return Value
A result code. See "Find By Content Result Codes" (page 2421).

Discussion
A summary reference object is an opaque object that can very quickly give you a summary containing any desired number of sentences from 1 up to the total number of sentences found in the original text.

Special Considerations

Because the Search Kit takes a different approach to finding and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Search Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Availability
Available in Mac OS X v10.2 through Mac OS X v10.4.
Deprecated in Mac OS X v10.4.

Declared In
`FindByContent.h`

FBCGetSummarySentenceCount

Obtains the number of sentences in a summary reference object. (Deprecated in Mac OS X v10.4. Use Search Kit instead; see *Search Kit Programming Guide*.)

```
OSStatus FBCGetSummarySentenceCount (
    FBCSummaryRef summary,
    UInt32 * numSentences
);
```

Parameters

summary

A valid summary reference object. You obtain a summary reference object when you call the function `FBCGetSummaryOfCFString` (page 2400).

numSentences

On output, a pointer to the number of sentences contained in the summary.

Return Value

A result code. See "Find By Content Result Codes" (page 2421).

Special Considerations

Because the Search Kit takes a different approach to finding and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Search Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Availability

Available in Mac OS X v10.2 through Mac OS X v10.4.

Deprecated in Mac OS X v10.4.

Declared In

`FindByContent.h`

FBCGetSummarySentences

Obtains a summary that contains a specified number of sentences. (Deprecated in Mac OS X v10.4. Use Search Kit instead; see *Search Kit Programming Guide*.)

```
OSStatus FBCGetSummarySentences (
    FBCSummaryRef summary,
    CFStringRef * outString,
    UInt32 * numSentences,
    Boolean paragraphs
);
```

Parameters

summary

A valid summary reference object. You obtain a summary reference object when you call the function `FBCGetSummaryOfCFString` (page 2400).

outString

On output, a pointer to a `CFStringRef` that contains the summary. You are responsible for releasing the `CFStringRef` when you no longer need it.

numSentences

On input, the number of sentences you want in the summary. On output, the number of sentences actually written into the summary. If you pass `0`, Find by Content uses a logarithmic function to determine the number of sentences.

paragraphs

A Boolean value that specifies the content of the summary. If you pass `true` the summary is made up of whole paragraphs that contain the relevant sentences. If it is `false`, only the relevant sentences are included.

Return Value
A result code. See "Find By Content Result Codes" (page 2421).

Special Considerations

Because the Search Kit takes a different approach to finding and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Search Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Availability
Available in Mac OS X v10.2 through Mac OS X v10.4.
Deprecated in Mac OS X v10.4.

Declared In
`FindByContent.h`

FBCGetTopicWords

Gets a list of topic words for a search session. (Deprecated in Mac OS X v10.4. Use Search Kit instead; see *Search Kit Programming Guide*.)

Not recommended

```
OSErr FBCGetTopicWords (
    FBCSearchSession theSession,
    UInt32 hitNumber,
    UInt32 * wordCount,
    FBCWordList * list
);
```

Special Considerations

Because the Search Kit takes a different approach to finding and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Search Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Carbon Porting Notes

This function does nothing in Mac OS X.

Availability
Available in Mac OS X v10.0 through Mac OS X v10.4.
Deprecated in Mac OS X v10.4.

Declared In
`FindByContent.h`

FBCIndexItems

Indexes one or more files or folders. (Deprecated in Mac OS X v10.4. Use Search Kit instead; see *Search Kit Programming Guide*.)

Not recommended

```
OSErr FBCIndexItems (
    FSSpecArrayPtr theItems,
    UInt32 itemCount
);
```

Special Considerations

Because the Search Kit takes a different approach to finding and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Search Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Availability

Available in Mac OS X v10.0 through Mac OS X v10.4.

Deprecated in Mac OS X v10.4.

Declared In

`FindByContent.h`

FBCIndexItemsInLanguages

Indexes one or more directories. (Deprecated in Mac OS X v10.4. Use Search Kit instead; see *Search Kit Programming Guide*.)

```
OSErr FBCIndexItemsInLanguages (
    FSSpecArrayPtr theItems,
    UInt32 itemCount,
    UInt32 languageHighBits,
    UInt32 languageLowBits
);
```

Parameters

`theItems`

An `FSPecArrayPtr` that specifies the directory or directories to be indexed; subdirectories are included automatically.

`itemCount`

The number of items pointed to by `theItems` parameter.

`languageHighBits`

A value that specifies the languages to be used. The high bits are obtained by summing the desired constants defined in Language Constants (page 2418).

`languageLowBits`

A value that specifies the languages to be used. The low bits should always be 0.

Return Value

A result code. See "Find By Content Result Codes" (page 2421).

Discussion
Your application must first call the function `FBCIndexItemsInLanguages` to make an index of the files to be searched. Find by Content looks at the contents of each file (including the file's name) to make the index. For PDF and HTML files, the textual content is separated out from formatting information; for all other file types, the entire data of the file is used. The index is an invisible file.

Some file types do not contain words that are useful for searching, such as graphics files and application software. Find by Content has lists of Mac OS file types and filename extensions for such files, and any file that has one of the listed types or one of the listed extensions is treated specially when it is indexed. That is, the name of the file is indexed, but the contents are not. In addition, folder names are indexed. The lists of types and extensions are text files named StopTypes and StopExts. You can edit these lists using an editor (such as BBEdit or TextEdit). The files are located in the `/System/Library/Find/` directory.

Special Considerations

Because the Search Kit takes a different approach to finding and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Search Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Availability
Available in Mac OS X v10.0 through Mac OS X v10.4.
Deprecated in Mac OS X v10.4.

Declared In
`FindByContent.h`

FBCReleaseSessionHits

Releases the hits associated with a search session object. (Deprecated in Mac OS X v10.4. Use Search Kit instead; see *Search Kit Programming Guide*.)

```
OSErr FBCReleaseSessionHits (
    FBCSearchSession theSession
);
```

Parameters

theSession
A valid search session object. You obtain a search session object by calling the function `FBCCreateSearchSession`.

Return Value
A result code. See "Find By Content Result Codes" (page 2421).

Discussion
The function `FBCReleaseSessionHits` releases the hits associated with a specific search session object, resetting the object so it can be used in another search. You are responsible for releasing a search session object when you no longer need it by calling the function `FBCDestroySearchSession` (page 2390).

Special Considerations

Because the Search Kit takes a different approach to finding and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Search Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Availability
Available in Mac OS X v10.0 through Mac OS X v10.4.
Deprecated in Mac OS X v10.4.

Declared In
`FindByContent.h`

FBCRemoveVolumeFromSession

Removes a volume from a search session. (Deprecated in Mac OS X v10.4. Use Search Kit instead; see *Search Kit Programming Guide*.)

Not recommended

```
OSErr FBCRemoveVolumeFromSession (
    FBCSearchSession theSession,
    SInt16 vRefNum
);
```

Special Considerations

Because the Search Kit takes a different approach to finding and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Search Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Carbon Porting Notes

This function does nothing in Mac OS X.

Availability
Available in Mac OS X v10.0 through Mac OS X v10.4.
Deprecated in Mac OS X v10.4.

Declared In
`FindByContent.h`

FBCSetCallback

Sets a callback. (Deprecated in Mac OS X v10.4. Use Search Kit instead; see *Search Kit Programming Guide*.)

Not Recommended.

```
void FBCSetCallback (
    FBCCallbackUPP fn,
    void * data
);
```

Special Considerations

Because the Search Kit takes a different approach to finding and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Search Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Carbon Porting Notes

Use the function `FBCSetSessionCallback` (page 2406) instead.

Availability

Available in Mac OS X v10.0 through Mac OS X v10.4.
Deprecated in Mac OS X v10.4.

Declared In

`FindByContent.h`

FBCSetHeapReservation

Sets the amount of heap space to reserve for application use when Find by Content allocates memory. (Deprecated in Mac OS X v10.4. Use Search Kit instead; see *Search Kit Programming Guide*.)

Not recommended

```
void FBCSetHeapReservation (
    UInt32 bytes
);
```

Special Considerations

Because the Search Kit takes a different approach to finding and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Search Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Carbon Porting Notes

This function does nothing in Mac OS X.

Availability

Available in Mac OS X v10.0 through Mac OS X v10.4.
Deprecated in Mac OS X v10.4.

Declared In

`FindByContent.h`

FBCSetSessionCallback

Sets a callback function that allows your application to cancel a search operation. (Deprecated in Mac OS X v10.4. Use Search Kit instead; see *Search Kit Programming Guide*.)

```
void FBCSetSessionCallback (
    FBCSearchSession searchSession,
    FBCCallbackUPP fn,
    void * data
);
```

Parameters

searchSession

A valid search session object. You obtain a search session object by calling the function `FBCCreateSearchSession`.

fn

A universal procedure pointer to your callback for cancelling a search. See `FBCCallbackProcPtr` (page 2414) for more information.

data

A pointer to data needed by your callback. Pass `NULL` if your callback does not require any data.

Special Considerations

Because the Search Kit takes a different approach to finding and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Search Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Availability

Available in Mac OS X v10.2 through Mac OS X v10.4.

Deprecated in Mac OS X v10.4.

Declared In

`FindByContent.h`

FBCSetSessionHitTest

Sets a callback function that allows your application to perform search-hit testing. (Deprecated in Mac OS X v10.4. Use Search Kit instead; see *Search Kit Programming Guide*.)

```
void FBCSetSessionHitTest (
    FBCSearchSession theSession,
    FBCHitTestUPP fn,
    void * data
);
```

Parameters

theSession

A valid search session object. You obtain a search session object by calling the function `FBCCreateSearchSession`.

fn

A universal procedure pointer a your callback for testing search-hits. See `FBCHitTestProcPtr` (page 2415) for more information.

data

A pointer to data needed by your callback. Pass `NULL` if your callback does not require any data.

Special Considerations

Because the Search Kit takes a different approach to finding and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Search Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Availability

Available in Mac OS X v10.2 through Mac OS X v10.4.

Deprecated in Mac OS X v10.4.

Declared In

`FindByContent.h`

FBCSetSessionVolumes

Sets the volumes for a search session. (Deprecated in Mac OS X v10.4. Use Search Kit instead; see *Search Kit Programming Guide*.)

Not recommended

```
OSErr FBCSetSessionVolumes (
    FBCSearchSession theSession,
    const SInt16 vRefNums[],
    UInt16 numVolumes
);
```

Special Considerations

Because the Search Kit takes a different approach to finding and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Search Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Carbon Porting Notes

This function does nothing in Mac OS X.

Availability

Available in Mac OS X v10.0 through Mac OS X v10.4.

Deprecated in Mac OS X v10.4.

Declared In

`FindByContent.h`

FBCSummarize

Summarizes text that is specified as an ASCII buffer. (Deprecated in Mac OS X v10.4. Use Search Kit instead; see *Search Kit Programming Guide*.)

```
OSErr FBCSummarize (
    const void * inBuf,
    UInt32 inLength,
    void * outBuf,
    UInt32 * outLength,
    UInt32 * numSentences
);
```

Parameters

inBuf

A pointer to the ASCII text you want summarized.

inLength

The length of the text buffer pointed to by `inBuf`.

outBuf

On output, points to the summarized text.

outLength

On output, points to a value that specifies the length of the summarized text.

numSentences

On input, points to a value that specifies the number of sentences desired in the summary. On output, points to the number of sentences actually written into the summary. If you pass `0`, Find by Content uses a logarithmic function to determine the number of sentences.

Return Value
A result code. See "Find By Content Result Codes" (page 2421).

Discussion
You should use the function `FBCSummarizeCFString` instead of `FBCSummarize` because the `CFString` version is more reliable and accurate.

Special Considerations

Because the Search Kit takes a different approach to finding and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Search Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Availability
Available in Mac OS X v10.0 through Mac OS X v10.4.
Deprecated in Mac OS X v10.4.

Declared In
`FindByContent.h`

FBCSummarizeCFString

Summarizes text that is specified as a `CFString`. (Deprecated in Mac OS X v10.4. Use Search Kit instead; see *Search Kit Programming Guide*.)

```
OSStatus FBCSummarizeCFString (
    CFStringRef inString,
    CFStringRef * outString,
    UInt32 * numSentences
);
```

Parameters

inString

A `CFStringRef` representing the text you want summarized. Summarization works with all languages that use white space to separate words, plus Japanese. It works best with text that is not broken into lines using CR and/or LF characters.

outString

On output, points to the summarization. You are responsible for releasing this string.

numSentences

On input, points to a value that specifies the number of sentences you want in the summary. On output, points to the number of sentences actually written into the summary. If you pass `0`, Find by Content uses a logarithmic function to determine the number of sentences.

Return Value
A result code. See "Find By Content Result Codes" (page 2421).

Special Considerations

Because the Search Kit takes a different approach to finding and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Search Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Availability

Available in Mac OS X v10.2 through Mac OS X v10.4.
Deprecated in Mac OS X v10.4.

Declared In

`FindByContent.h`

FBCVolumeIndexPhysicalSize

Obtains the physical size of an index. (Deprecated in Mac OS X v10.4. Use Search Kit instead; see *Search Kit Programming Guide*.)

Not recommended

```
OSErr FBCVolumeIndexPhysicalSize (
    SInt16 theVRefNum,
    UInt32 * size
);
```

Special Considerations

Because the Search Kit takes a different approach to finding and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Search Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Carbon Porting Notes

This function does nothing in Mac OS X.

Availability

Available in Mac OS X v10.0 through Mac OS X v10.4.
Deprecated in Mac OS X v10.4.

Declared In

`FindByContent.h`

FBCVolumeIndexTimeStamp

Obtains the date and time when an index was last updated. (Deprecated in Mac OS X v10.4. Use Search Kit instead; see *Search Kit Programming Guide*.)

Not recommended

```
OSErr FBCVolumeIndexTimeStamp (
    SInt16 theVRefNum,
    UInt32 * timeStamp
);
```

Special Considerations

Because the Search Kit takes a different approach to finding and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Search Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Carbon Porting Notes

This function does nothing in Mac OS X.

Availability

Available in Mac OS X v10.0 through Mac OS X v10.4.

Deprecated in Mac OS X v10.4.

Declared In

`FindByContent.h`

FBCVolumeIsIndexed

Determines whether a volume is indexed. (Deprecated in Mac OS X v10.4. Use Search Kit instead; see *Search Kit Programming Guide*.)

Not recommended

```
Boolean FBCVolumeIsIndexed (
    SInt16 theVRefNum
);
```

Special Considerations

Because the Search Kit takes a different approach to finding and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Search Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Carbon Porting Notes

This function does nothing in Mac OS X.

Availability

Available in Mac OS X v10.0 through Mac OS X v10.4.

Deprecated in Mac OS X v10.4.

Declared In

`FindByContent.h`

FBCVolumeIsRemote

Determines whether a volume is remote. (Deprecated in Mac OS X v10.4. Use Search Kit instead; see *Search Kit Programming Guide*.)

Not recommended

```
Boolean FBCVolumeIsRemote (
    SInt16 theVRefNum
);
```

Special Considerations

Because the Search Kit takes a different approach to finding and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Search Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Carbon Porting Notes

This function does nothing in Mac OS X.

Availability

Available in Mac OS X v10.0 through Mac OS X v10.4.

Deprecated in Mac OS X v10.4.

Declared In

`FindByContent.h`

InvokeFBCCallbackUPP

Invokes a universal procedure pointer (UPP) to a search cancellation callback. (Deprecated in Mac OS X v10.4. Use Search Kit instead; see *Search Kit Programming Guide*.)

```
Boolean InvokeFBCCallbackUPP (
    UInt16 phase,
    float percentDone,
    void * data,
    FBCCallbackUPP userUPP
);
```

Discussion

You should not need to call this function as Find by Content invokes your callback for you.

Special Considerations

Because the Search Kit takes a different approach to finding and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Search Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Availability

Available in Mac OS X v10.0 through Mac OS X v10.4.

Deprecated in Mac OS X v10.4.

Declared In

`FindByContent.h`

InvokeFBCHitTestUPP

Invokes a universal procedure pointer (UPP) to a search-hit testing callback. (Deprecated in Mac OS X v10.4. Use Search Kit instead; see *Search Kit Programming Guide*.)

```
Boolean InvokeFBCHitTestUPP (
    const FSRef * theFile,
    void * data,
    FBCHitTestUPP userUPP
);
```

Discussion

You should not need to call this function as Find by Content invokes your callback for you.

Special Considerations

Because the Search Kit takes a different approach to finding and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Search Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Availability

Available in Mac OS X v10.2 through Mac OS X v10.4.

Deprecated in Mac OS X v10.4.

Declared In

`FindByContent.h`

NewFBCCallbackUPP

Creates a new universal procedure pointer (UPP) to a search cancellation callback. (Deprecated in Mac OS X v10.4. Use Search Kit instead; see *Search Kit Programming Guide*.)

```
FBCCallbackUPP NewFBCCallbackUPP (
    FBCCallbackProcPtr userRoutine
);
```

Parameters

`userRoutine`

A pointer to your progress callback.

Return Value

See the description of the `FBCCallbackUPP` data type.

Discussion

See the callback `FBCCallbackProcPtr` (page 2414) for more information.

Special Considerations

Because the Search Kit takes a different approach to finding and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Search Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Availability

Available in Mac OS X v10.0 through Mac OS X v10.4.

Deprecated in Mac OS X v10.4.

Declared In
`FindByContent.h`

NewFBCHitTestUPP

Creates a new universal procedure pointer (UPP) to a search-hit testing callback. (Deprecated in Mac OS X v10.4. Use Search Kit instead; see *Search Kit Programming Guide*.)

```
FBCHitTestUPP NewFBCHitTestUPP (
    FBCHitTestProcPtr userRoutine
);
```

Parameters

`userRoutine`

A pointer to your search-hit-testing callback.

Return Value
See the description of the `FBCHitTestUPP` data type.

Discussion
See the callback `FBCHitTestProcPtr` (page 2415) for more information.

Special Considerations

Because the Search Kit takes a different approach to finding and displaying information from that used by the Find by Content API, you cannot make a one-to-one substitution of Search Kit functions for Find by Content functions. However, the basic features of the Search Kit can be implemented very quickly, and Search Kit offers much greater capability than the Find by Content API.

Availability
Available in Mac OS X v10.2 through Mac OS X v10.4.
Deprecated in Mac OS X v10.4.

Declared In
`FindByContent.h`

Callbacks

FBCCallbackProcPtr

Defines a pointer to a function that can cancel a search operation.

```
typedef Boolean (*FBCCallbackProcPtr)
(
    UInt16 phase,
    float percentDone,
    void * data
);
```

If you name your function `MyFBCCallbackProc`, you would declare it like this:

```
Boolean MyFBCCallbackProcPtr (
    UInt16 phase,
```

```
    float percentDone,
    void * data
);
```

Parameters

phase

percentDone

data

A pointer to data needed by your callback. This is the same data you provided to the function `FBCSetSessionCallback` (page 2406) in the `data` parameter.

Return Value

Return `true` if you wants to cancel the current operation. Otherwise return `false`.

Discussion

Find by Content invoke your callback periodically (approximately every 5 ticks) while searching. Your callback can cancel a search operation by returning a value of `true`.

Availability

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared In

`FindByContent.h`

FBCHitTestProcPtr

Defines a pointer to a function that performs search-hit testing.

```
typedef Boolean (*FBCHitTestProcPtr)
(
    const FSRef * theFile,
    void * data
);
```

If you name your function `MyFBCHitTestProc`, you would declare it like this:

```
Boolean MyFBCHitTestProcPtr (
    const FSRef * theFile,
    void * data
);
```

Parameters

theFile

A pointer to an `FSRef` that specifies the location of file that matches the search query.

data

A pointer to data needed by your callback. This is the same data you provided to the function `FBCSetSessionHitTest` (page 2407) in the `data` parameter.

Return Value

Return `true` if your callback wants to accept the file as a valid match or `false` to reject it.

Discussion
You can use this callback to impose additional matching criteria in addition to that provided to Find by Content. For example, you could accept a hit only if the file has a creation date later than a specified date.

Availability
Available in Mac OS X v10.2 through Mac OS X v10.4.

Declared In
`FindByContent.h`

Data Types

FBCCallbackUPP

Defines a universal procedure pointer to a search cancellation callback.

```
typedef FBCCallbackProcPtr FBCCallbackUPP;
```

Discussion
For more information, see the description of the `FBCCallbackProcPtr` (page 2414) callback function.

Availability
Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared In
`FindByContent.h`

FBCHitTestUPP

Defines a universal procedure pointer to a search-hit testing callback.

```
typedef FBCHitTestProcPtr FBCHitTestUPP;
```

Discussion
For more information, see the description of the `FBCHitTestProcPtr` (page 2415) callback function.

Availability
Available in Mac OS X v10.2 through Mac OS X v10.4.

Declared In
`FindByContent.h`

FBCSearchSession

Defines pointer to an opaque data type (referred to as a search session object) that contains a collection of state information used in a search session.

```
typedef struct OpaqueFBCSearchSession * FBCSearchSession;
```

Discussion
You call the function `FBCCreateSearchSession` (page 2388)to create a new search session object. When no longer need the search session object, you must dispose of it by calling the function `FBCDestroySearchSession` (page 2390).

Availability
Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared In
`FindByContent.h`

FBCSummaryRef

A pointer to an opaque data type (referred to as a summary reference object) that contains summary information, from which summary text can be obtained.

```
typedef struct OpaqueFBCSummaryRef * FBCSummaryRef;
```

Discussion
You call the function `FBCGetSummaryOfCFString` (page 2400)to create a new summary reference object. When no longer need the summary reference object, you must dispose of it by calling the function `FBCDisposeSummary` (page 2391).

Availability
Available in Mac OS X v10.2 through Mac OS X v10.4.

Declared In
`FindByContent.h`

FBCWordItem

Defines a data type for an ordinary C string used for searching.

```
typedef char* FBCWordItem;
```

Availability
Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared In
`FindByContent.h`

FBCWordList

Defines an array of word items.

```
typedef FBCWordItem * FBCWordList;
```

Availability
Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared In
`FindByContent.h`

Constants

Language Constants

Define values for language constants.

```
enum {
    kFBCenglishHighWord = 0x80000000,
    kFBCdutchHighWord = 0x40000000,
    kFBCgermanHighWord = 0x20000000,
    kFBCswedishHighWord = 0x10000000,
    kFBCdanishHighWord = 0x08000000,
    kFBCspanishHighWord = 0x04000000,
    kFBCportugueseHighWord = 0x02000000,
    kFBCitalianHighWord = 0x01000000,
    kFBCfrenchHighWord = 0x00800000,

    kFBCgreekHighWord = 0x00004000,
    kFBCcyrillicHighWord = 0x00002000,
    kFBCdevanagariHighWord = 0x00001000,
    kFBCgujuratiHighWord = 0x00000800,
    kFBCgurmukhiHighWord = 0x00000400,
    kFBCjapaneseHighWord = 0x00000200,
    kFBCkoreanHighWord = 0x00000100,
    kFBCdefaultLanguagesHighWord = 0xFF800000
};
```

Discussion
Language constants are passed as parameters to the function `FBCIndexItemsInLanguages` (page 2403). The purpose of these constants is to tell Find by Content what languages the user expects the files to contain. From this, Find by Content infer the character encodings to look for, and for some languages, what lists of words to exclude from the index and what rules to use in reducing words to their stems.

These constants are bits in a 64-bit array that consists of two `UInt32` words. In the current implementation the low word is always `0`, so values for the high word are given. If both `UInt32` words are `0`, the default value of `kDefaultLanguagesHighWord` is used.

Phase Values

Define values that are passed to a progress callback function to indicate what phase of an operation Find By Content is currently performing; most of these values are not used in Mac OS X.

```
enum {
    kFBCphIndexing = 0,
    kFBCphFlushing = 1,
    kFBCphMerging = 2,
    kFBCphMakingIndexAccessor = 3,
    kFBCphCompacting = 4,
    kFBCphIndexWaiting = 5,
    kFBCphSearching = 6,
    kFBCphMakingAccessAccessor = 7,
    kFBCphAccessWaiting = 8,
    kFBCphSummarizing = 9,
    kFBCphIdle = 10,
    kFBCphCanceling = 11
};
```

Constants

`kFBCphIndexing`
Indicates an indexing phase. This is no longer used in Mac OS X.
Available in Mac OS X v10.0 through Mac OS X v10.4.
Declared in `FindByContent.h`.

`kFBCphFlushing`
Indicates an indexing phase. This is no longer used in Mac OS X.
Available in Mac OS X v10.0 through Mac OS X v10.4.
Declared in `FindByContent.h`.

`kFBCphMerging`
Indicates an indexing phase. This is no longer used in Mac OS X.
Available in Mac OS X v10.0 through Mac OS X v10.4.
Declared in `FindByContent.h`.

`kFBCphMakingIndexAccessor`
Indicates an indexing phase. This is no longer used in Mac OS X.
Available in Mac OS X v10.0 through Mac OS X v10.4.
Declared in `FindByContent.h`.

`kFBCphCompacting`
Indicates an indexing phase. This is no longer used in Mac OS X.
Available in Mac OS X v10.0 through Mac OS X v10.4.
Declared in `FindByContent.h`.

`kFBCphIndexWaiting`
Indicates an access phase. This is no longer used in Mac OS X.
Available in Mac OS X v10.0 through Mac OS X v10.4.
Declared in `FindByContent.h`.

`kFBCphSearching`
Indicates searching phase. In Mac OS X, this is the only phase value returned to your `FBCCallbackProcPtr` callback.
Available in Mac OS X v10.0 through Mac OS X v10.4.
Declared in `FindByContent.h`.

`kFBCphMakingAccessAccessor`
Indicates an access phase. This is no longer used in Mac OS X.
Available in Mac OS X v10.0 through Mac OS X v10.4.
Declared in `FindByContent.h`.

`kFBCphAccessWaiting`
Indicates an access phase. This is no longer used in Mac OS X.
Available in Mac OS X v10.0 through Mac OS X v10.4.
Declared in `FindByContent.h`.

`kFBCphSummarizing`
Indicates summarization. This is no longer used in Mac OS X.
Available in Mac OS X v10.0 through Mac OS X v10.4.
Declared in `FindByContent.h`.

`kFBCphIdle`
Indicates indexing or accessing. This is no longer used in Mac OS X.
Available in Mac OS X v10.0 through Mac OS X v10.4.
Declared in `FindByContent.h`.

`kFBCphCanceling`
Indicates cancellation. This is no longer used in Mac OS X.
Available in Mac OS X v10.0 through Mac OS X v10.4.
Declared in `FindByContent.h`.

Discussion
The values are meaningless in Mac OS X.

Deprecated Language Constants

Redefine old language constants as new ones; you should use the new value.

```
enum {
    englishHighWord = kFBCenglishHighWord,
    dutchHighWord = kFBCdutchHighWord,
    germanHighWord = kFBCgermanHighWord,
    swedishHighWord = kFBCswedishHighWord,
    danishHighWord = kFBCdanishHighWord,
    spanishHighWord = kFBCspanishHighWord,
    portugueseHighWord = kFBCportugueseHighWord,
    italianHighWord = kFBCitalianHighWord,
    frenchHighWord = kFBCfrenchHighWord,
    romanHighWord = kFBCromanHighWord,
    icelandicHighWord = kFBCicelandicHighWord,
    hebrewHighWord = kFBChebrewHighWord,
    arabicHighWord = kFBCarabicHighWord,
    centeuroHighWord = kFBCcenteuroHighWord,
    croatianHighWord = kFBCcroatianHighWord,
    turkishHighWord = kFBCturkishHighWord,
    romanianHighWord = kFBCromanianHighWord,
    greekHighWord = kFBCgreekHighWord,
    cyrillicHighWord = kFBCcyrillicHighWord,
    devanagariHighWord = kFBCdevanagariHighWord,
    gujuratiHighWord = kFBCgujuratiHighWord,
    gurmukhiHighWord = kFBCgurmukhiHighWord,
    japaneseHighWord = kFBCjapaneseHighWord,
    koreanHighWord = kFBCkoreanHighWord,
    kDefaultLanguagesHighWord = kFBCdefaultLanguagesHighWord
};
```

Result Codes

The result codes returned by Find By Content are listed below.

Result Code	Value	Description
errIANoErr	0	Available in Mac OS X v10.0 and later.
kFBCvTwinExceptionErr	-30500	No telling what it was Available in Mac OS X v10.0 and later.
kFBCnoIndexesFound	-30501	Indexes not found Available in Mac OS X v10.0 and later.
kFBCallocFailed	-30502	Possibly due to low memory Available in Mac OS X v10.0 and later.
kFBCbadParam	-30503	Bad parameter passed to a function Available in Mac OS X v10.0 and later.
kFBCfileNotIndexed	-30504	File not indexed Available in Mac OS X v10.0 and later.

Result Code	Value	Description
kFBCbadIndexFile	-30505	Bad FSSpec, or bad data in file Available in Mac OS X v10.0 and later.
kFBCcompactionFailed	-30506	V-Twin exception caught Available in Mac OS X v10.0 and later.
kFBCvalidationFailed	-30507	V-Twin exception caught Available in Mac OS X v10.0 and later.
kFBCindexingFailed	-30508	V-Twin exception caught Available in Mac OS X v10.0 and later.
kFBCcommitFailed	-30509	V-Twin exception caught Available in Mac OS X v10.0 and later.
kFBCdeletionFailed	-30510	V-Twin exception caught Available in Mac OS X v10.0 and later.
kFBCmoveFailed	-30511	V-Twin exception caught Available in Mac OS X v10.0 and later.
kFBCtokenizationFailed	-30512	Couldn't read from document or query Available in Mac OS X v10.0 and later.
kFBCmergingFailed	-30513	Couldn't merge index files Available in Mac OS X v10.0 and later.
kFBCindexCreationFailed	-30514	Couldn't create index Available in Mac OS X v10.0 and later.
kFBCaccessorStoreFailed	-30515	Available in Mac OS X v10.0 and later.
kFBCaddDocFailed	-30516	Available in Mac OS X v10.0 and later.
kFBCflushFailed	-30517	Available in Mac OS X v10.0 and later.
kFBCindexNotFound	-30518	Index not found Available in Mac OS X v10.0 and later.
kFBCnoSearchSession	-30519	Search session object not created Available in Mac OS X v10.0 and later.
kFBCindexingCanceled	-30520	Indexing cancelled Available in Mac OS X v10.0 and later.
kFBCaccessCanceled	-30521	Available in Mac OS X v10.0 and later.

Result Code	Value	Description
kFBCindexFileDestroyed	-30522	Index file destroyed Available in Mac OS X v10.0 and later.
kFBCindexNotAvailable	-30523	Index not available Available in Mac OS X v10.0 and later.
kFBCsearchFailed	-30524	Search failed Available in Mac OS X v10.0 and later.
kFBCsomeFilesNotIndexed	-30525	Some files are not indexed Available in Mac OS X v10.0 and later.
kFBCillegalSessionChange	-30526	Tried to add/remove volumes to a session. Available in Mac OS X v10.0 and later.
kFBCanalysisNotAvailable	-30527	Available in Mac OS X v10.0 and later.
kFBCbadIndexFileVersion	-30528	Available in Mac OS X v10.0 and later.
kFBCsummarizationCanceled	-30529	Summarization operation cancelled Available in Mac OS X v10.0 and later.
kFBCindexDiskIOFailed	-30530	Available in Mac OS X v10.0 and later.
kFBCbadSearchSession	-30531	Available in Mac OS X v10.0 and later.
kFBCnoSuchHit	-30532	Hit doesn't exist Available in Mac OS X v10.0 and later.
kFBCsummarizationFailed	-30533	Summarization operation failed Available in Mac OS X v10.2 through Mac OS X v10.4.
kFBCnotAllFoldersSearchable	-30533	Not all folders are searchable Available in Mac OS X v10.2 through Mac OS X v10.4.

FontSync Reference

Framework: ApplicationServices/ApplicationServices.h
Declared in FontSync.h

Overview

FontSync is an API that provides a way for your application to identify fonts based upon the content of the font, rather than just the font name. Your application can use FontSync to compare fonts that are available on different computers. This document is relevant for anyone who is writing a text-intensive application that must minimize font mismatch errors when a file is moved from one computer to another. To use this document, you should understand the basics of fonts and be familiar with FontSync references and profiles.

Carbon supports FontSync. However, in Mac OS X, Apple recommends that you use FontSync only in OS X version 10.1 and later.

Functions by Task

Determining Availability, Version, and Feature Information

`FNSEnabled` (page 2427)
Indicates whether FontSync is enabled.

`FNSMatchDefaultsGet` (page 2427)
Determines the default match options used by FontSync functions performing font matching.

`FNSSysInfoGet` (page 2455)
Determines version and feature information for the version of FontSync installed on the user's system.

Providing User Interface Support

`FNSReferenceCountNames` (page 2441)
Determines the number of internal font names in a reference.

`FNSReferenceFindName` (page 2444)
Finds the first name that matches the given font name parameters, if any.

`FNSReferenceGetFamilyInfo` (page 2447)
Obtains information about a font family represented by a font reference.

`FNSReferenceGetIndName` (page 2448)
Finds the font name string and other font name parameters for an indexed font name.

Searching by Font Reference

`FNSProfileMatchReference` (page 2435)
Obtains a list of the references in a profile that match a given reference.

`FNSReferenceMatchFamilies` (page 2452)
Obtains a list of font families that match a reference.

`FNSReferenceMatchFonts` (page 2453)
Obtains a list of font objects that match a reference.

Working With FontSync Profiles

`FNSProfileAddReference` (page 2428)
Adds a font reference to a profile.

`FNSProfileClear` (page 2429)
Removes all font references from a profile.

`FNSProfileClose` (page 2430)
Closes the file associated with a font profile and disposes of run-time data.

`FNSProfileCompact` (page 2430)
Compacts a font profile.

`FNSProfileCountReferences` (page 2431)
Determines the number of font references in a font profile.

`FNSProfileCreate` (page 2432)
Creates an empty FontSync profile using an `FSSpec`.

`FNSProfileCreateWithFSRef` (page 2433)
Creates an empty FontSync profile using an `FSRef`.

`FNSProfileGetIndReference` (page 2434)
Retrieves an indexed font reference from a profile.

`FNSProfileGetVersion` (page 2435)
Retrieves the format version of an open font profile.

`FNSProfileOpen` (page 2437)
Opens an existing font profile using an `FSSpec`.

`FNSProfileOpenWithFSRef` (page 2438)
Opens an existing font profile using an `FSRef`.

`FNSProfileRemoveIndReference` (page 2439)
Deletes an indexed font reference from a profile.

`FNSProfileRemoveReference` (page 2440)
Deletes a font reference from a profile.

Working With FontSync References

`FNSReferenceCreate` (page 2441)
Creates a font reference based on a font object.

Functions

FNSEnabled

Indicates whether FontSync is enabled.

```
Boolean FNSEnabled (
   void
);
```

Return Value
A `Boolean` value indicating whether FontSync is enabled. If `true`, your application can perform FontSync operations. See the Mac Types documentation for a description of the `Boolean` data type.

Discussion
You should check the flag returned by the `FNSEnabled` function before starting a sequence of FontSync calls, although it has no effect on the operation of the rest of the FontSync API.

Version Notes
Available beginning with FontSync 1.0. In FontSync 1.0, `FNSEnabled` always returns `true`.

Availability
Available in CarbonLib 1.0 and later when Font Sync 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`FontSync.h`

FNSMatchDefaultsGet

Determines the default match options used by FontSync functions performing font matching.

```
FNSMatchOptions FNSMatchDefaultsGet (
   void
);
```

Return Value
A bit mask indicating the default match options. This is the value used when the mask constant `kFNSMatchDefaults` is passed to FontSync functions that perform matching. See the description of the `FNSMatchOptions` data type.

Discussion
The `FNSMatchDefaultsGet` function retrieves the bit mask used when the mask constant `kFNSMatchDefaults` is passed to the functions `FNSReferenceMatch` (page 2451), `FNSProfileMatchReference` (page 2435), `FNSReferenceMatchFonts` (page 2453), and `FNSReferenceMatchFamilies` (page 2452). The bit mask value is read from a preferences file which is created when the user sets match criteria via the control panel. The preference file is maintained by the FontSync library. If there is no preferences file, or it is unreadable, the implementation-defined fallback value `kFNSMatchAll` is returned.

There is no API for setting the default match criteria. Your application can specify options that are different from the user's preferences via the bitmask in the FontSync matching calls.

Version Notes
Available beginning with FontSync 1.0. In FontSync 1.0, the implementation-defined fallback value is `kFNSMatchAll`, that is, all defined options turned on. In other words, if the user does not set the match criteria via the control panel, FontSync uses the implementation-defined fallback value of all match criteria selected.

Availability
Available in CarbonLib 1.0 and later when Font Sync 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`FontSync.h`

FNSProfileAddReference

Adds a font reference to a profile.

```
OSStatus FNSProfileAddReference (
   FNSFontProfile iProfile,
   FNSFontReference iReference
);
```

Parameters

`iProfile`
A reference to the font profile to which you want to add a font reference. The profile must be writable.

`iReference`
A reference to the font reference you wish to add.

Return Value
A result code. See "FontSync Result Codes" (page 2462). The result code `kFNSBadProfileVersionErr` indicates that a font profile has an unsupported format version. This may indicate that the profile is valid, but created by a later version of FontSync, or that the profile is truly invalid. The result code `kFNSInvalidProfileErr`

indicates that a profile does not have a valid structure. The result code `kFNSBadReferenceVersionErr` indicates that a font reference has an unsupported format version. This may indicate that the reference is valid, but created by a later version of FontSync, or that the reference is truly invalid. The result code `kFNSInvalidReferenceErr` indicates that a font reference is invalid. The result code `kFNSDuplicateReferenceErr` indicates that an identical reference already exists in the profile. In this case, the new one is not added. The File Manager error `permErr` indicates that the file is either locked and not editable or opened for read-only access. `FNSProfileAddReference` may return other File Manager errors. Memory Manager errors indicate that you did not have enough memory available in your heap.

Discussion
The `FNSProfileAddReference` function adds a font reference to a profile that has read/write access. If an identical reference already exists in the profile, the reference is not added and the result code `kFNSDuplicateReferenceErr` is returned. A matching reference is not necessarily identical, since not all the data in a font reference is examined when a matching operation is performed.

Version Notes
Available beginning with FontSync 1.0.

Availability
Available in CarbonLib 1.0 and later when Font Sync 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`FontSync.h`

FNSProfileClear

Removes all font references from a profile.

```
OSStatus FNSProfileClear (
   FNSFontProfile iProfile
);
```

Parameters

iProfile

A font profile reference. Pass a reference to the font profile whose references you wish to remove. The profile must be editable (that is, opened with read/write access).

Return Value
A result code. See "FontSync Result Codes" (page 2462). The result code `kFNSBadProfileVersionErr` indicates that the font profile has an unsupported format version. This may indicate that the profile is valid, but created by a later version of FontSync, or that the profile is truly invalid. The result code `kFNSInvalidProfileErr` indicates that the profile does not have a valid structure. The File Manager error `permErr` indicates that the file is either locked and not editable or opened for read-only access. `FNSProfileClear` may return other File Manager errors.

Discussion
The `FNSProfileClear` function clears all font references from a specified profile. Note that this is only true for editable profiles (that is, those opened with read/write access). The file of the font profile remains the same size after this operation.

Version Notes
Available beginning with FontSync 1.0.

Availability
Available in CarbonLib 1.0 and later when Font Sync 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`FontSync.h`

FNSProfileClose

Closes the file associated with a font profile and disposes of run-time data.

```
OSStatus FNSProfileClose (
   FNSFontProfile iProfile
);
```

Parameters

`iProfile`
A pointer to a font profile reference. Pass a reference to the font profile you wish to close.

Return Value
A result code. See "FontSync Result Codes" (page 2462). The result code `kFNSBadProfileVersionErr` indicates that a font profile has an unsupported format version. This may indicate that the profile is valid, but created by a later version of FontSync, or that the profile is truly invalid. The result code `kFNSInvalidProfileErr` indicates that a profile does not have a valid structure. `FNSProfileClose` may return File Manager errors.

Discussion
The `FNSProfileClose` function closes the file associated with a font profile. Any memory associated with the reference is released. You should call the function `FNSProfileCompact` (page 2430) before closing a profile that has been edited, since closing a profile does not automatically compact it.

Version Notes
Available beginning with FontSync 1.0.

Availability
Available in CarbonLib 1.0 and later when Font Sync 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`FontSync.h`

FNSProfileCompact

Compacts a font profile.

```
OSStatus FNSProfileCompact (
   FNSFontProfile iProfile
);
```

Parameters

iProfile

A font profile reference. Pass a reference to the font profile you wish to compact. The profile must be editable (that is, opened with read/write access).

Return Value

A result code. See "FontSync Result Codes" (page 2462). The result code `kFNSBadProfileVersionErr` indicates that a font profile has an unsupported format version. This may indicate that the profile is valid, but created by a later version of FontSync, or that the profile is truly invalid. The result code `kFNSInvalidProfileErr` indicates that a profile does not have a valid structure. `FNSProfileCompact` may return File Manager errors.

Discussion

The `FNSProfileCompact` function eliminates excess space created when creating a font profile (that is, the space you designate for not-yet-existent font references). This space is necessary to minimize growing the file and shuffling data. If a profile has not been opened for read/write access, `FNSProfileCompact` simply returns without doing anything.

You should call `FNSProfileCompact` before closing a profile that has been edited.

Version Notes

Available beginning with FontSync 1.0.

Availability

Available in CarbonLib 1.0 and later when Font Sync 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Not available to 64-bit applications.

Declared In

`FontSync.h`

FNSProfileCountReferences

Determines the number of font references in a font profile.

```
OSStatus FNSProfileCountReferences (
   FNSFontProfile iProfile,
   ItemCount *oCount
);
```

Parameters

iProfile

A reference to the font profile whose font references you wish to count.

oCount

On return, a pointer to the number of font references in the profile.

Return Value

A result code. See "FontSync Result Codes" (page 2462). The result code `kFNSBadProfileVersionErr` indicates that a font profile has an unsupported format version. This may indicate that a profile is valid, but created by a later version of FontSync, or that a profile is truly invalid. The result code `kFNSInvalidProfileErr` indicates that a profile does not have a valid structure.

Version Notes
Available beginning with FontSync 1.0.

Availability
Available in CarbonLib 1.0 and later when Font Sync 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`FontSync.h`

FNSProfileCreate

Creates an empty FontSync profile using an `FSSpec`.

```
OSStatus FNSProfileCreate (
   const FSSpec *iFile,
   FourCharCode iCreator,
   ItemCount iEstNumRefs,
   FNSObjectVersion iDesiredVersion,
   FNSFontProfile *oProfile
);
```

Parameters

iFile
A pointer to the file that you want to initialize as an empty font profile.

iCreator
The creator code to set for the file. To specify the file creator code assigned by FontSync, pass the `kFNSCreatorDefault` constant, described in "Font Profile Constants" (page 2461).

iEstNumRefs
The estimated number of font references that the font profile will contain. Estimating this value minimizes the number of times the file needs to be grown, since the new profile will usually immediately have font references added to it. Pass 0 if you don't know how many font references your profile will contain.

iDesiredVersion
The desired format version of the font profile. Pass a value in the range returned by the function `FNSSysInfoGet` (page 2455) in the `oCurProfileVersion` and `oMinProfileVersion` fields of the system information structure. To specify the most recent version supported by the FontSync library regardless of format version, pass the constant `kFNSVersionDontCare`, described in "Version Constants" (page 2462).

oProfile
On return, a pointer to a reference to the newly-created font profile.

Return Value
A result code. See "FontSync Result Codes" (page 2462). The result code `kFNSBadProfileVersionErr` indicates that you requested an unsupported profile format version. Memory Manager errors indicate that the font profile could not be created because you did not have enough memory available in your heap. `FNSProfileCreate` may return File Manager errors.

Discussion
The `FNSProfileCreate` function creates an empty file containing a FontSync font profile. The newly-created font profile is ready for use. You can add font references to the profile by calling the function `FNSProfileAddReference` (page 2428).

`FNSProfileCreate` requires that you specify the desired profile version format because there will likely be changes to the profile file format in future versions. This allows earlier versions of FontSync to use the font profiles you create.

Version Notes
Available beginning with FontSync 1.0. In FontSync 1.0, if you specify the constant `kFNSCreatorDefault` in the `iCreator` parameter of the function `FNSProfileCreate`, FontSync assigns the creator code `'fns'`

Availability
Available in CarbonLib 1.0 and later when Font Sync 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`FontSync.h`

FNSProfileCreateWithFSRef

Creates an empty FontSync profile using an `FSRef`.

```
OSStatus FNSProfileCreateWithFSRef (
   const FSRef *iParentDirectory,
   UniCharCount iNameLength,
   const UniChar *iName,
   FourCharCode iCreator,
   ItemCount iEstNumRefs,
   FNSObjectVersion iDesiredVersion,
   FNSFontProfile *oProfile
);
```

Parameters

iParentDirectory
A pointer to the parent directory of the file that you want to initialize as an empty font profile.

iNameLength
The number of `UniChar` characters in the `iName` parameter.

iName
The name of the file in which you are storing the profile.

iCreator
The creator code to set for the file. To specify the file creator code assigned by FontSync, pass the `kFNSCreatorDefault` constant, described in "Font Profile Constants" (page 2461).

iEstNumRefs
The estimated number of font references that the font profile will contain. Estimating this value minimizes the number of times the file needs to be grown, since the new profile will usually immediately have font references added to it. Pass 0 if you don't know how many font references your profile will contain.

iDesiredVersion

The desired format version of the font profile. Pass a value in the range returned by the function `FNSSysInfoGet` (page 2455) in the `oCurProfileVersion` and `oMinProfileVersion` fields of the system information structure. To specify the most recent version supported by the FontSync library regardless of format version, pass the constant `kFNSVersionDontCare`, described in "Version Constants" (page 2462).

oProfile

On return, a pointer to the newly-created font profile.

Return Value
A result code. See "FontSync Result Codes" (page 2462).

Discussion
The function `FNSProfileCreateWithFSRef` works similarly to the function `FNSProfileCreate`, except that `FNSProfileCreateWithFSRef` uses an `FSRef` instead of an `FSSpec`. An `FSSpec` cannot handle Unicode names that are too long, as long names are truncated. In addition, an `FSSpec` cannot be shared between processes since an `FSSpec` references volume IDs which are different between different processes.

Availability
Not available in CarbonLib 1.0.
Available in Mac OS X 10.1 and later.
Not available to 64-bit applications.

Declared In
`FontSync.h`

FNSProfileGetIndReference

Retrieves an indexed font reference from a profile.

```
OSStatus FNSProfileGetIndReference (
   FNSFontProfile iProfile,
   UInt32 iWhichReference,
   FNSFontReference *oReference
);
```

Parameters

iProfile

A reference to the font profile whose indexed font reference you want to determine.

iWhichReference

An index into the list of font references in the profile. Pass a value between 0 and one less than the number of references in the profile returned by the function `FNSProfileCountReferences` (page 2431).

oReference

On return, a pointer to a reference to the indexed font reference.

Return Value
A result code. See "FontSync Result Codes" (page 2462). The result code `kFNSBadProfileVersionErr` indicates that the font profile has an unsupported format version. This may indicate that the profile is valid, but created by a later version of FontSync, or that the profile is truly invalid. The result code `inputOutOfBounds` indicates that the specified index was out of range. The result code `kFNSInvalidProfileErr` indicates that the profile does not have a valid structure. `FNSProfileGetIndReference` may return File Manager errors. Memory Manager errors indicate that you did not have enough memory available in your heap.

Version Notes
Available beginning with FontSync 1.0.

Availability
Available in CarbonLib 1.0 and later when Font Sync 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`FontSync.h`

FNSProfileGetVersion

Retrieves the format version of an open font profile.

```
OSStatus FNSProfileGetVersion (
   FNSFontProfile iProfile,
   FNSObjectVersion *oVersion
);
```

Parameters

iProfile
A reference to the font profile whose format version number you wish to obtain.

oVersion
On return, a pointer to the format version number of the font profile.

Return Value
A result code. See "FontSync Result Codes" (page 2462). The result code `kFNSInvalidProfileErr` indicates that the profile does not have a valid structure.

Availability
Available in CarbonLib 1.0 and later when Font Sync 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`FontSync.h`

FNSProfileMatchReference

Obtains a list of the references in a profile that match a given reference.

```
OSStatus FNSProfileMatchReference (
   FNSFontProfile iProfile,
   FNSFontReference iReference,
   FNSMatchOptions iMatchOptions,
   ItemCount iOutputSize,
   UInt32 oIndices[],
   ItemCount *oNumMatches
);
```

Parameters

iProfile

A reference to the font profile containing the font references you wish to compare.

iReference

A reference to a font reference against which you are performing the comparison.

iMatchOptions

A bit mask you can use to set the matching option bits to be used in the comparison. To specify the global default match criteria, pass the bit mask returned by the function `FNSMatchDefaultsGet` (page 2427). Your application can specify options that are different from the user's preferences via this mask.

iOutputSize

The number of font references you want passed back in the `oIndices` array. This may be less than the actual number of matches passed back in the `oNumMatches` parameter. To determine this value, see the discussion below.

oIndices

On return, a pointer to an array of indices identifying the font references that matched. The number of indices returned is limited by the value you specify in the `iOutputSize` parameter. The total number of matching references is passed back in the `oNumMatches` parameter.

oNumMatches

On return, a pointer to the total number of matching font references. This value may be greater than the number of indices passed back in the `oIndices` array.

Return Value

A result code. See "FontSync Result Codes" (page 2462). The result code `kFNSBadProfileVersionErr` indicates that a font profile has an unsupported version number. This may indicate that the profile is valid, but created by a later version of FontSync, or that the profile is truly invalid. The result code `kFNSInvalidProfileErr` indicates that a profile does not have a valid structure. The result code `kFNSBadReferenceVersionErr` indicates that a font reference has an unsupported version number. This may indicate that the reference is valid, but created by a later version of FontSync, or that the reference is truly invalid. The result code `kFNSInvalidReferenceErr` indicates that a font reference is invalid. The result code `kFNSMismatchErr` indicates that no matches were found. The File Manager error `permErr` indicates that the file is either locked and not editable or opened for read-only access. `FNSProfileMatchReference` may return other File Manager errors. Memory Manager errors indicate that you did not have enough memory available in your heap.

Discussion

The `FNSProfileMatchReference` function obtains a list of the font references that match a specified reference. Since there may be more than one matching reference, a list is returned.

The number of font references passed back in the `oIndices` array is limited by the value you specify in the `iOutputSize` parameter. The actual number of matches is passed back in the `oNumMatches` parameter. You can check this value to determine whether the `oIndices` array was large enough to contain the matches.

If you want to determine whether the profile has a matching font, but don't care which one, pass 0 for the `iOutputSize` parameter and `NULL` for the `oNumMatches` parameter. The result code `noErr` indicates that matches were found, while the result code `kFNSMismatchErr` indicates that no matches were found.

To determine the number of matches, call `FNSProfileMatchReference` and pass 0 for the `iOutputSize` parameter. The pointer passed back in the `oNumMatches` parameter will point to the actual number of matches. You can then call `FNSProfileMatchReference` again, passing the returned number of matches in the `iOutputSize` parameter.

Version Notes
Available beginning with FontSync 1.0.

Availability
Available in CarbonLib 1.0 and later when Font Sync 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`FontSync.h`

FNSProfileOpen

Opens an existing font profile using an `FSSpec`.

```
OSStatus FNSProfileOpen (
   const FSSpec *iFile,
   Boolean iOpenForWrite,
   FNSFontProfile *oProfile
);
```

Parameters

iFile
A pointer to the font profile file that you wish to open.

iOpenForWrite
A flag indicating whether the profile file is read/write or read-only. Pass `true` to allow read/write access. This is necessary if the profile is going to be editable.

oProfile
On return, a pointer to a reference to the open font profile.

Return Value
A result code. See "FontSync Result Codes" (page 2462). The result code `kFNSBadProfileVersionErr` indicates that a font profile has an unsupported format version. This may indicate that the profile is valid, but created by a later version of FontSync, or that the profile is truly invalid. The result code `kFNSInvalidProfileErr` indicates that a profile does not have a valid structure. Memory Manager errors indicate that you did not have enough memory available in your heap. `FNSProfileOpen` may return File Manager errors.

Discussion
The `FNSProfileOpen` function opens an already-existing font profile (that is, one that contains font references). If you want to make the font profile editable, pass true in the `iOpenForWrite` parameter. `FNSProfileOpen` will not open an empty profile created by the function `FNSProfileCreate` (page 2432).

Font profiles are housed in a file. FontSync attempts to moderate access to this file. Ideally, it tries to either allow many readers or exactly one writer but not both. The Mac OS File Manager does not allow this kind of exclusion on local volumes, so it may still be possible for someone to get write access to a profile when there are active readers. Rather than complicating the implementation to work around this limitation, FontSync profile files are treated like most document files. That is, the caller is responsible for making sure this does not occur. If the user wishes to modify a profile, your application should make a copy of the file, modify the copy, and swap file names when done. This has the added benefit of preserving the original profile if an error leaves the new profile invalid.

Version Notes
Available beginning with FontSync 1.0.

Availability
Available in CarbonLib 1.0 and later when Font Sync 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`FontSync.h`

FNSProfileOpenWithFSRef

Opens an existing font profile using an `FSRef`.

```
OSStatus FNSProfileOpenWithFSRef (
   const FSRef *iFile,
   Boolean iOpenForWrite,
   FNSFontProfile *oProfile
);
```

Parameters

`iFile`
A pointer to the `FSRef` that specifies the file that you wish to open.

`iOpenForWrite`
A flag indicating whether the profile file is read/write or read-only. Pass `true` to allow read/write access. This is necessary if the profile is going to be editable.

`oProfile`
On return, a pointer to a reference to the open font profile.

Return Value
A result code. See "FontSync Result Codes" (page 2462). The result code `kFNSBadProfileVersionErr` indicates that a font profile has an unsupported format version. This may indicate that the profile is valid, but created by a later version of FontSync, or that the profile is truly invalid. The result code `kFNSInvalidProfileErr` indicates that a profile does not have a valid structure. Memory Manager errors indicate that you did not have enough memory available in your heap. `FNSProfileOpen` may return File Manager errors.

Discussion
The function `FNSProfileOpenWithFSRef` works similarly to the function `FNSProfileOpen`, `FNSProfileOpenWithFSRef` uses an `FSRef` instead of an `FSSpec`. An `FSSpec` cannot handle Unicode names that are too long, as long names are truncated. In addition, an `FSSpec` cannot be shared between processes since an `FSSpec` references volume IDs which are different between different processes.

Availability
Not available in CarbonLib 1.0.
Available in Mac OS X 10.1 and later
Not available to 64-bit applications.

Declared In
`FontSync.h`

FNSProfileRemoveIndReference

Deletes an indexed font reference from a profile.

```
OSStatus FNSProfileRemoveIndReference (
   FNSFontProfile iProfile,
   UInt32 iIndex
);
```

Parameters

iProfile

A reference to the font profile whose indexed font reference you want to delete. The profile must be writable.

iIndex

An index into the list of font references in the profile. Pass a value between 0 and one less than the number of references in the profile, returned by the function `FNSProfileCountReferences` (page 2431). Note that this will change the indices of all succeeding references.

Return Value
A result code. See "FontSync Result Codes" (page 2462). The result code `kFNSBadProfileVersionErr` indicates that a font profile has an unsupported format version. This may indicate that the profile is valid, but created by a later version of FontSync, or that the profile is truly invalid. The result code `kFNSInvalidProfileErr` indicates that a profile does not have a valid structure. The result code `permErr` indicates that a specified file is locked and not writable. The result code `kFNSBadReferenceVersionErr` indicates that a font reference has an unsupported format version. This may indicate that the reference is valid, but created by a later version of FontSync, or that the reference is truly invalid. The result code `kFNSInvalidReferenceErr` indicates that a font reference is invalid. The result code `inputOutOfBounds` indicates that the specified index was out of range. The File Manager error `permErr` indicates that the file is either locked and not editable or opened for read-only access. `FNSProfileRemoveIndReference` may return other File Manager errors. Memory Manager errors indicate that you did not have enough memory available in your heap.

Discussion
The `FNSProfileRemoveIndReference` function deletes an indexed font reference from an editable profile. The reference must be identical to the reference specified in the `iReference` parameter. A matching reference is not enough, since not all the data in a font reference is examined when a matching operation is performed.

You can use either `FNSProfileRemoveIndReference` or the function `FNSProfileRemoveReference` (page 2440) to remove a font reference, depending upon what you know about the reference. If you know its value, call `FNSProfileRemoveReference` (page 2440). If you know its index in the list of font references, call `FNSProfileRemoveIndReference`.

Version Notes
Available beginning with FontSync 1.0.

Availability
Available in CarbonLib 1.0 and later when Font Sync 1.0 or later is present.

Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`FontSync.h`

FNSProfileRemoveReference

Deletes a font reference from a profile.

```
OSStatus FNSProfileRemoveReference (
   FNSFontProfile iProfile,
   FNSFontReference iReference
);
```

Parameters

iProfile

A reference to the font profile whose font reference you want to delete. The profile must be writable.

iReference

A reference to the font reference you wish to remove.

Return Value
A result code. See "FontSync Result Codes" (page 2462). The result code `kFNSBadProfileVersionErr` indicates that a font profile has an unsupported format version. This may indicate that the profile is valid, but created by a later version of FontSync, or that the profile is truly invalid. The result code `kFNSInvalidProfileErr` indicates that a profile does not have a valid structure. The result code `kFNSBadReferenceVersionErr` indicates that a font reference has an unsupported format version. This may indicate that the reference is valid, but created by a later version of FontSync, or that the reference is truly invalid. The result code `kFNSInvalidReferenceErr` indicates that a font reference is invalid. The result code `kFNSMismatchErr` indicates that the reference you wish to remove is not in the profile. The File Manager error `permErr` indicates that the file is either locked and not editable or opened for read-only access. `FNSProfileRemoveReference` may return other File Manager errors. Memory Manager errors indicate that you did not have enough memory available in your heap.

Discussion
The `FNSProfileRemoveReference` function deletes a font reference from an editable profile. The reference must be identical to the reference specified in the `iReference` parameter. A matching reference is not necessarily identical, since not all the data in a font reference is examined when a matching operation is performed.

You can use either `FNSProfileRemoveReference` or the function `FNSProfileRemoveIndReference` (page 2439) to remove a font reference, depending upon what you know about the reference. If you know the value of the reference, call `FNSProfileRemoveReference`. If you know its index in the list of font references, call `FNSProfileRemoveIndReference` (page 2439).

Version Notes
Available beginning with FontSync 1.0.

Availability
Available in CarbonLib 1.0 and later when Font Sync 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`FontSync.h`

FNSReferenceCountNames

Determines the number of internal font names in a reference.

```
OSStatus FNSReferenceCountNames (
   FNSFontReference iReference,
   ItemCount *oNameCount
);
```

Parameters

`iReference`

A reference to the font reference whose font names you wish to count.

`oNameCount`

On return, a pointer to the number of internal font names, other than the font family name passed to the `GetFNum` function, recorded in the reference. The font family passed to the function `GetFNum` is available by calling the function `GetFamilyInfo`. This includes the PostScript and unique names, if available.

Return Value
A result code. See "FontSync Result Codes" (page 2462). The result code `kFNSBadReferenceVersionErr` indicates that a font reference has an unsupported version number. This may indicate that the reference is valid, but created by a later version of FontSync, or that the reference is truly invalid. The result code `kFNSInvalidReferenceErr` indicates that a font reference is invalid. The result code `kFNSInsufficientDataErr` indicates that the mask constant `kFNSMissingDataNoMatch` was set and both references being compared are missing the same data. The result code `kFNSMismatchErr` indicates that no font names were recorded in the reference.

Version Notes
Available beginning with FontSync 1.0.

Availability
Available in CarbonLib 1.0 and later when Font Sync 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`FontSync.h`

FNSReferenceCreate

Creates a font reference based on a font object.

```
OSStatus FNSReferenceCreate (
   FMFont iFont,
   FNSObjectVersion iDesiredVersion,
   FNSFontReference *oReference
);
```

Parameters

iFont

The font object ID representing the font whose reference you wish to create.

iDesiredVersion

The desired font reference format version number. Pass a value between the oldest and current format version numbers supported by the FontSync library. You can determine this range by examining the `oCurRefVersion` and `oMinRefVersion` fields of the `FNSSysInfo` (page 2458) structure. This structure is passed back in the `ioInfo` parameter of the function `FNSSysInfoGet` (page 2455). To specify the most recent version supported by the FontSync library regardless of format version, pass the constant `kFNSVersionDontCare`, described in "Version Constants" (page 2462).

oReference

On return, a pointer to a reference to the newly-created FontSync reference.

Return Value

A result code. See "FontSync Result Codes" (page 2462). The result code `kFNSBadReferenceVersionErr` indicates that you requested an unsupported reference format version. The Font Manager result code `kFMInvalidFontErr` indicates that a font is invalid. Memory Manager errors indicate that a font reference could not be created because you did not have enough memory available in your heap.

Discussion

You should call the `FNSReferenceCreate` function to create a font reference if your application uses ATSUI to render text. If the specified font object is associated with a font family, the newly-created font reference will contain the QuickDraw Text-specific information from that associated family.

The `FNSReferenceCreate` function requires that you specify the desired font reference format version because there will likely be changes to the nature of the "fingerprints" in a font reference in future versions. This allows earlier versions of FontSync to use the font references you create.

Version Notes

Available beginning with FontSync 1.0. In FontSync 1.0, a font object can only belong to one family. FontSync uses the family returned by the Font Manager function `FMGetFontFamilyInstanceFromFont`.

Availability

Available in CarbonLib 1.0 and later when Font Sync 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Not available to 64-bit applications.

Declared In

`FontSync.h`

FNSReferenceCreateFromFamily

Creates a font reference based on a font family and style.

```
OSStatus FNSReferenceCreateFromFamily (
   FMFontFamily iFamily,
   FMFontStyle iStyle,
   FNSObjectVersion iDesiredVersion,
   FNSFontReference *oReference,
   FMFontStyle *oActualStyle
);
```

Parameters

iFamily

The font family of the font whose reference you wish to create.

iStyle

The style of the font family. This value is often not the actual style of the font reference being created, since there are often left-over style bits. The actual style of the newly-created font reference is passed back in the `oActualStyle` parameter. For more information, see the discussion.

iDesiredVersion

The desired format version of the font reference. Pass a value in the range returned by the function `FNSSysInfoGet` (page 2455) in the `oCurRefVersion` and `oMinRefVersion` fields of the system information structure. To specify the most recent version supported by the FontSync library regardless of format version, pass the constant `kFNSVersionDontCare`, described in "Version Constants" (page 2462).

oReference

On return, a pointer to a reference to the newly-created FontSync reference.

oActualStyle

On return, a pointer to the actual style of the newly-created font reference. This value may differ from the value you passed in the `iStyle` parameter. For more information, see the discussion. This value may be `NULL`.

Return Value

A result code. See "FontSync Result Codes" (page 2462). The result code `kFNSBadReferenceVersionErr` indicates that you requested an unsupported reference format version. The Font Manager result code `kFMInvalidFontFamilyErr` indicates that a font family is invalid. Memory Manager errors indicate that a font reference could not be created because you did not have enough memory available in your heap.

Discussion

You should call the `FNSReferenceCreateFromFamily` function to create a font reference if your application uses QuickDraw Text to render text.

The style you specify in the `iStyle` parameter is often not the actual style of the font reference being created, since there may not be a real face corresponding to that style. For example, a family may not have a real italic face, so any italicization is handled by skewing the glyphs. The actual style of the newly-created font reference is passed back in the `oActualStyle` parameter.

The `FNSReferenceCreateFromFamily` function requires that you specify the desired font reference format version because there will likely be changes to the nature of the "fingerprints" in a font reference in future versions. This allows earlier versions of FontSync to use the font references you create.

Version Notes

Available beginning with FontSync 1.0.

Availability

Available in CarbonLib 1.0 and later when Font Sync 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Not available to 64-bit applications.

Declared In
`FontSync.h`

FNSReferenceDispose

Disposes of the storage associated with a font reference.

```
OSStatus FNSReferenceDispose (
   FNSFontReference iReference
);
```

Parameters

iReference

A pointer to the font reference whose associated memory you wish to dispose of.

Return Value
A result code. See "FontSync Result Codes" (page 2462). The result code `kFNSBadReferenceVersionErr` indicates that a font reference has an unsupported format version. This may indicate that the font reference is valid, but created by a later version of FontSync, or that the reference is truly invalid. The result code `kFNSInvalidReferenceErr` indicates that a font reference is invalid. Memory Manager errors indicate that you did not have enough memory available in your heap.

Special Considerations

You should not use a font reference after calling the `FNSReferenceDispose` function to dispose of its storage.

Version Notes
Available beginning with FontSync 1.0.

Availability
Available in CarbonLib 1.0 and later when Font Sync 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`FontSync.h`

FNSReferenceFindName

Finds the first name that matches the given font name parameters, if any.

```
OSStatus FNSReferenceFindName (
   FNSFontReference iReference,
   FontNameCode iFontNameCode,
   FontPlatformCode iFontNamePlatform,
   FontScriptCode iFontNameScript,
   FontLanguageCode iFontNameLanguage,
   ByteCount iMaximumNameLength,
   Ptr oName,
   ByteCount *oActualNameLength,
   ItemCount *oFontNameIndex
);
```

Parameters

iReference

A reference to the font reference whose font name you are searching for.

iFontNameCode

The type of the font name string you are searching for.

iFontNamePlatform

The encoding of the font name string you are searching for. You can pass the `kFontNoPlatform` constant if you do not care about the encoding of a font name. In this case, `FNSReferenceFindName` will pass back the first name matching the other font name parameters.

iFontNameScript

The script code of the font name string you are searching for. You can pass the `kFontNoScript` constant if you do not care about the script ID. In this case, `FNSReferenceFindName` will pass back the first name matching the other font name parameters.

iFontNameLanguage

The language code of the font name string you are searching for. You can pass the `kFontNoLanguage` constant if you do not care about the language of the font name. In this case, `FNSReferenceFindName` will pass back the first name matching the other font name parameters.

iMaximumNameLength

The maximum length of the font name. Typically, this is equivalent to the size of the buffer allocated to contain the font name pointed to by the `oName` parameter. To determine this length, see the discussion below.

oName

A pointer to a buffer. Before calling `FNSReferenceFindName`, pass a pointer to memory that you have allocated for this buffer. On return, the buffer contains the font name string. If the buffer you allocate is not large enough, `FNSReferenceFindName` passes back a partial string.

oActualNameLength

On return, a pointer to the actual length of the font name string. This may be greater than the value passed in the `iMaximumNameLength` parameter. You should check this value to make sure that you allocated enough memory for the buffer.

oFontNameIndex

On return, a pointer to a 0-based index of the font name in the font name table. This can be used with the function `FNSReferenceGetIndName` (page 2448) to determine the actual values of unknown font name parameters.

Return Value

A result code. See "FontSync Result Codes" (page 2462). The result code `kFNSBadReferenceVersionErr` indicates that a font reference has an unsupported version number. This may indicate that the reference is valid, but created by a later version of FontSync, or that the reference is truly invalid. The result code `kFNSInvalidReferenceErr` indicates that a font reference is invalid. The result code

kFNSInsufficientDataErr indicates that the mask constant kFNSMissingDataNoMatch was set and both references being compared are missing the same data. The result code kFNSNameNotFoundErr indicates that there was no name in the font reference that matched the given parameters.

Version Notes
Available beginning with FontSync 1.0.

Availability
Available in CarbonLib 1.0 and later when Font Sync 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
FontSync.h

FNSReferenceFlatten

Flattens a font reference.

```
OSStatus FNSReferenceFlatten (
   FNSFontReference iReference,
   void *oFlatReference,
   ByteCount *oFlattenedSize
);
```

Parameters

iReference
The font reference that you want to flatten.

oFlatReference
A pointer to the storage for the font reference to be flattened. Pass a NULL pointer if you wish to determine the size of the flattened reference without actually creating it.

oFlattenedSize
On return, a pointer to the flattened size (in bytes) of the font reference.

Return Value
A result code. See "FontSync Result Codes" (page 2462). The result code kFNSBadReferenceVersionErr indicates that a font reference has an unsupported format version. This may indicate that the reference is valid, but created by a later version of FontSync, or that the reference is truly invalid. The result code kFNSInvalidReferenceErr indicates that a font reference is invalid.

Discussion
The FNSReferenceFlatten function flattens a font reference into a form which can be stored externally (for example, in a document or embedded in an Apple event), and returns the size of the flattened reference in the oFlattenedSize parameter. FNSReferenceFlatten assumes that the storage pointed to by iFlatReference is large enough to hold the data and will always contain a full flattened reference.

If you simply want to calculate the size of a flattened reference, you can pass a NULL pointer in the iFlatReference parameter or call the function FNSReferenceFlattenedSize (page 2447).

Version Notes
Available beginning with FontSync 1.0.

Availability
Available in CarbonLib 1.0 and later when Font Sync 1.0 or later is present.

Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`FontSync.h`

FNSReferenceFlattenedSize

Calculates the space required for the flattened form of a font reference.

```
OSStatus FNSReferenceFlattenedSize (
   FNSFontReference iReference,
   ByteCount *oFlattenedSize
);
```

Parameters

`iReference`
The font reference whose flattened form you wish to compute.

`oFlattenedSize`
On return, a pointer to the flattened size (in bytes) of the font reference.

Return Value
A result code. See "FontSync Result Codes" (page 2462). The result code `kFNSBadReferenceVersionErr` indicates that the font reference has an unsupported format version. This may indicate that the reference is valid, but created by a later version of FontSync, or that the reference is truly invalid. The result code `kFNSInvalidReferenceErr` indicates that the font reference is invalid.

Discussion
You can call the `FNSReferenceFlattenedSize` function to calculate the size of a flattened reference. You can also accomplish this by passing a `NULL` pointer in the `iFlatReference` parameter of the function `FNSReferenceFlatten` (page 2446).

Version Notes
Available beginning with FontSync 1.0.

Availability
Available in CarbonLib 1.0 and later when Font Sync 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`FontSync.h`

FNSReferenceGetFamilyInfo

Obtains information about a font family represented by a font reference.

```
OSStatus FNSReferenceGetFamilyInfo (
   FNSFontReference iReference,
   Str255 oFamilyName,
   ScriptCode *oFamilyNameScript,
   FMFontStyle *oActualStyle
);
```

Parameters

iReference

A reference to the font reference representing a font family.

oFamilyName

On return, the name by which the font is known to the classic Font Manager (that is, the string you pass to the Font Manager function `GetFNum`). If you do not want to obtain this information, pass `NULL`.

oFamilyNameScript

On return, a pointer to the script code of the family name string. If you do not want to obtain this information, pass `NULL`.

oActualStyle

On return, a pointer to the actual QuickDraw style associated with the font reference. This is the value passed back in the `oActualStyle` parameter of the function `FNSReferenceCreateFromFamily` (page 2442). If you do not want to obtain this information, pass `NULL`. For more information, see the discussion of `FNSReferenceCreateFromFamily` (page 2442).

Return Value

A result code. See "FontSync Result Codes" (page 2462). The result code `kFNSBadReferenceVersionErr` indicates that a font reference has an unsupported version number. This may indicate that the reference is valid, but created by a later version of FontSync, or that the reference is truly invalid. The result code `kFNSInvalidReferenceErr` indicates that a font reference is invalid. The result code `kFNSInsufficientDataErr` indicates that the mask constant `kFNSMissingDataNoMatch` was set and both references being compared are missing the same data. The result code `kFNSMismatchErr` indicates that no font names were recorded in the reference.

Version Notes

Available beginning with FontSync 1.0.

Availability

Available in CarbonLib 1.0 and later when Font Sync 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Not available to 64-bit applications.

Declared In

`FontSync.h`

FNSReferenceGetIndName

Finds the font name string and other font name parameters for an indexed font name.

```
OSStatus FNSReferenceGetIndName (
   FNSFontReference iReference,
   ItemCount iFontNameIndex,
   ByteCount iMaximumNameLength,
   Ptr oName,
   ByteCount *oActualNameLength,
   FontNameCode *oFontNameCode,
   FontPlatformCode *oFontNamePlatform,
   FontScriptCode *oFontNameScript,
   FontLanguageCode *oFontNameLanguage
);
```

Parameters

iReference

A reference to the font reference whose indexed font name you want information about.

iFontNameIndex

An index of the font name you want information about. Pass a value between 0 and one less than the count passed back by the function `FNSProfileCountReferences` (page 2431).

iMaximumNameLength

The maximum length of the font name. Typically, this is equivalent to the size of the buffer allocated to contain the font name pointed to by the `oName` parameter. To determine this length, see the discussion below.

oName

A pointer to a buffer. Before calling `FNSReferenceGetIndName`, pass a pointer to memory that you have allocated for this buffer. If you are uncertain of how much memory to allocate, see the discussion below. On return, the buffer contains the font name string. If the buffer you allocate is not large enough, `FNSReferenceGetIndName` passes back a partial string.

oActualNameLength

On return, a pointer to the actual length of the font name string. This may be greater than the value passed in the `iMaximumNameLength` parameter. You should check this value to make sure that you allocated enough memory for the buffer.

oFontNameCode

On return, a pointer to the type of the font name string.

oFontNamePlatform

On return, a pointer to the encoding of the font name string.

oFontNameScript

On return, a pointer to the script ID of the font name string.

oFontNameLanguage

On return, a pointer to the language of the font name string.

Return Value

A result code. See "FontSync Result Codes" (page 2462). The result code `kFNSBadReferenceVersionErr` indicates that a font reference has an unsupported version number. This may indicate that the reference is valid, but created by a later version of FontSync, or that the reference is truly invalid. The result code `kFNSInvalidReferenceErr` indicates that a font reference is invalid. The result code `kFNSInsufficientDataErr` indicates that the mask constant `kFNSMissingDataNoMatch` was set and both references being compared are missing the same data. The result code `inputOutOfBounds` indicates that the specified index was out of range.

Discussion
You should call the `FNSReferenceGetIndName` function to iterate through the entries of a font name table to find the font name string, name code, language code, script code, and platform code of an indexed font name.

The best way to use `FNSReferenceGetIndName` is to call it twice:

- Pass the reference of the font whose name table you want to iterate in the `iReference` parameter, `NULL` for the `oName` parameter, and 0 for the other parameters. `FNSReferenceGetIndName` returns the length of the font name string in the `oActualNameLength` parameter.
- Allocate enough space for a font name buffer of the returned size, then call the function again, passing a pointer in the `oName` parameter; on return, the pointer references the font name string.

To find the index and font name of the first font in a name table matching given font name parameters, call the function `FNSReferenceFindName` (page 2444).

Version Notes
Available beginning with FontSync 1.0.

Availability
Available in CarbonLib 1.0 and later when Font Sync 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`FontSync.h`

FNSReferenceGetVersion

Indicates the format version number of a font reference.

```
OSStatus FNSReferenceGetVersion (
   FNSFontReference iReference,
   FNSObjectVersion *oVersion
);
```

Parameters

iReference
The font reference whose format version number you wish to determine.

oVersion
On return, a pointer to the format version number of the specified font reference.

Return Value
A result code. See "FontSync Result Codes" (page 2462). The result code `kFNSInvalidReferenceErr` indicates that the font reference is invalid.

Version Notes
Available beginning with FontSync 1.0.

Availability
Available in CarbonLib 1.0 and later when Font Sync 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`FontSync.h`

FNSReferenceMatch

Compares font references using specified matching options.

```
OSStatus FNSReferenceMatch (
   FNSFontReference iReference1,
   FNSFontReference iReference2,
   FNSMatchOptions iOptions,
   FNSMatchOptions *oFailedMatchOptions
);
```

Parameters

iReference1

A font reference whose contents you wish to compare to the font reference in the `iReference2` parameter.

iReference2

A font reference whose contents you wish to compare to the font reference in the `iReference1`parameter.

iOptions

A bit mask you can use to set the match option bits to be used in the font comparison. To specify the global default match criteria, pass the bit mask returned by the function `FNSMatchDefaultsGet` (page 2427). Your application can specify options that are different from the user's preferences via this mask.

oFailedMatchOptions

Before calling `FNSReferenceMatch`, pass `NULL` if you do not desire to know which match options failed. On return, a pointer to a bit mask that you can test to determine the match options that failed to match in the event of a mismatch.

Return Value
A result code. See "FontSync Result Codes" (page 2462). The result code `kFNSBadReferenceVersionErr` indicates that a font reference has an unsupported format version. This may indicate that the reference is valid, but created by a later version of FontSync, or that the reference is truly invalid. The result code `kFNSInvalidReferenceErr` indicates that a font reference is invalid. The result code `kFNSMismatchErr` indicates that a font reference did not match. The result code `kFNSInsufficientDataErr` indicates that the mask constant `kFNSMissingDataNoMatch` was set and both references being compared are missing the same data.

Discussion
The `FNSReferenceMatch` function returns a bit mask indicating the matching options that did not match when comparing two font references. You should specify which match options you wish to compare in the `iOptions` parameter. To specify the default match criteria, pass the bit mask returned by the function `FNSMatchDefaultsGet` (page 2427). If the match fails, on return, the `oFailedMatchOptions` parameter contains a bit mask of the elements that failed to match. You can use the bit mask to determine the criteria under which the fonts failed to match.

Availability
Available in CarbonLib 1.0 and later when Font Sync 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
FontSync.h

FNSReferenceMatchFamilies

Obtains a list of font families that match a reference.

```
OSStatus FNSReferenceMatchFamilies (
   FNSFontReference iReference,
   FNSMatchOptions iMatchOptions,
   ItemCount iOutputSize,
   FMFontFamilyInstance oFonts[],
   ItemCount *oNumMatches
);
```

Parameters

iReference

A reference to the font reference whose matching font(s) you wish to determine.

iMatchOptions

A bit mask you can use to set the matching option bits to be used in the comparison. To specify the global default match criteria, pass the bit mask returned by the function FNSMatchDefaultsGet (page 2427). The total number of matching references is passed back in the oNumMatches parameter. Your application can specify options that are different from the user's preferences via this mask.

iOutputSize

The capacity of the oFonts array. This may be less than the actual number of matches passed back in the oNumMatches parameter.

oFonts

On return, a pointer to an array of indices identifying the fonts matching the specified reference. The number of indices returned is limited by the value you specify in the iOutputSize parameter.

oNumMatches

On return, a pointer to the total number of font families that match the specified reference. This value may be greater than the number of fonts passed back in the oFonts array.

Return Value

A result code. See "FontSync Result Codes" (page 2462). The result code kFNSBadReferenceVersionErr indicates that a font reference has an unsupported version number. This may indicate that the reference is valid, but created by a later version of FontSync, or that the reference is truly invalid. The result code kFNSInvalidReferenceErr indicates that a font reference is invalid. The result code kFNSMismatchErr indicates that no matches were found. Memory Manager errors indicate that you did not have enough memory available in your heap.

Discussion

The FNSReferenceMatchFamilies function maps a font reference to an active font that can be used with QuickDraw Text. Since there may be more than one such font, a list is returned.

The number of fonts passed back in the oFonts array is limited by the value you specify in the iOutputSize parameter. The actual number of matches is passed back in the oNumMatches parameter. You can check this value to determine whether the oFonts array was large enough to contain the matches.

If FNSReferenceMatchFamilies cannot find a font family that matches a font reference and someone has registered interest in this process, FontSync sends an Apple Event with the details of the request to the third party font-management utility in question. For more information, see the discussion for the function FNSReferenceMatchFonts (page 2453).

If you want to determine whether the profile has a matching font, but don't care which one, pass 0 for the iOutputSize parameter and NULL for the oNumMatches parameter. The result code noErr indicates that matches were found, while the result code kFNSMismatchErr indicates that no matches were found.

To determine the number of matches, call FNSReferenceMatchFamilies and pass 0 for the iOutputSize parameter. The pointer passed back in the oNumMatches parameter will point to the actual number of matches. You can then call FNSReferenceMatchFamilies again, passing the returned number of matches in the iOutputSize parameter.

Version Notes
Available beginning with FontSync 1.0.

Availability
Available in CarbonLib 1.0 and later when Font Sync 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

FontSync.h

FNSReferenceMatchFonts

Obtains a list of font objects that match a reference.

```
OSStatus FNSReferenceMatchFonts (
   FNSFontReference iReference,
   FNSMatchOptions iMatchOptions,
   ItemCount iOutputSize,
   FMFont oFonts[],
   ItemCount *oNumMatches
);
```

Parameters

iReference
A reference to the font reference whose matching font(s) you wish to determine.

iMatchOptions
A bit mask you can use to set the matching option bits to be used in the comparison. To specify the global default match criteria, pass the bit mask returned by the function FNSMatchDefaultsGet (page 2427). The total number of matching references is passed back in the oNumMatches parameter. Your application can specify options that are different from the user's preferences via this mask.

iOutputSize
The capacity of the oFonts array. This may be less than the actual number of matches passed back in the oNumMatches parameter.

oFonts
On return, a pointer to an array of indices identifying the fonts matching the specified reference. The number of indices returned is limited by the value you specify in the iOutputSize parameter.

oNumMatches

On return, a pointer to the total number of font objects that match the specified reference. This value may be greater than the number of fonts passed back in the `oFonts` array.

Return Value
A result code. See "FontSync Result Codes" (page 2462). The result code `kFNSBadReferenceVersionErr` indicates that a font reference has an unsupported format version number. This may indicate that the reference is valid, but created by a later version of FontSync, or that the reference is truly invalid. The result code `kFNSInvalidReferenceErr` indicates that a font reference is invalid. The result code `kFNSMismatchErr` indicates that no matches were found. Memory Manager errors indicate that you did not have enough memory available in your heap.

Discussion
The `FNSReferenceMatchFonts` function passes back a list of active fonts which match the specified reference. `FNSReferenceMatchFonts` maps a font reference to an actual font that can be used with ATSUI. Since there may be more than one such font, a list is returned.

The number of fonts passed back in the `oFonts` array is limited by the value you specify in the `iOutputSize` parameter. The actual number of matches is passed back in the `oNumMatches` parameter. You can check this value to determine whether the `oFonts` array was large enough to contain the matches.

If you want to determine whether the profile has a matching font, but don't care which one, pass 0 for the `iOutputSize` parameter and `NULL` for the `oNumMatches` parameter. The result code `noErr` indicates that matches were found, while the result code `kFNSMismatchErr` indicates that no matches were found.

To determine the number of matches, call `FNSReferenceMatchFonts` and pass 0 for the `iOutputSize` parameter. The pointer passed back in the `oNumMatches` parameter will point to the actual number of matches. You can then call `FNSReferenceMatchFonts` again, passing the returned number of matches in the `iOutputSize` parameter.

If `FNSReferenceMatchFonts` cannot find an active font that matches a font reference and your application has registered interest in this process, FontSync sends an Apple Event with the details of the request to the third party font-management utility in question. The receiver should respond with a list of matching fonts, taking whatever steps are necessary to identify and activate them before replying to the event. Registration is handled by the simple expedient of installing a handler for the appropriate Apple Event. This handler will typically be installed in the system table, though FontSync will check for handlers both in the system and in the context's local handler table. The Apple Event will be a send-to-self.

Version Notes
Available beginning with FontSync 1.0.

Availability
Available in CarbonLib 1.0 and later when Font Sync 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`FontSync.h`

FNSReferenceUnflatten

Reconstitutes a flattened font reference.

```
OSStatus FNSReferenceUnflatten (
   const void *iFlatReference,
   ByteCount iFlattenedSize,
   FNSFontReference *oReference
);
```

Parameters

iFlatReference

A pointer to the flattened font reference.

iFlattenedSize

The size (in bytes) of the flattened font reference.

oReference

On return, a pointer to a reference to the reconstituted font reference.

Return Value

A result code. See "FontSync Result Codes" (page 2462). The result code `kFNSBadReferenceVersionErr` indicates that a font reference has an unsupported format version. This may indicate that the reference is valid, but created by a later version of FontSync, or that the reference is truly invalid. The result code `kFNSBadFlattenedSizeErr` indicates that either the specified size doesn't match the size recorded in the flattened reference or the size was not large enough to hold a flattened reference. The result code `kFNSInvalidReferenceErr` indicates that a reconstructed reference is bad. Memory Manager errors indicate that you did not have enough memory available in your heap.

Discussion

The `FNSReferenceUnflatten` function reconstitutes a flattened font reference from its external form. For example, you could use `FNSReferenceUnflatten` to read a font reference out of a document. The `iFlattenedSize` parameter is not really necessary since a flattened reference contains its own size. However, you can use this value to check that you have passed the right amount of data for the flattened reference.

Version Notes

Available beginning with FontSync 1.0.

Availability

Available in CarbonLib 1.0 and later when Font Sync 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Not available to 64-bit applications.

Declared In

`FontSync.h`

FNSSysInfoGet

Determines version and feature information for the version of FontSync installed on the user's system.

```
void FNSSysInfoGet (
   FNSSysInfo *ioInfo
);
```

Parameters

ioInfo

Before calling the `FNSSysInfoGet` function, pass a pointer to a `FNSSysInfo` (page 2458) structure. Fill in the `iSysInfoVersion` field of the structure with the version of this structure. Pass the constant `kFNSCurSysInfoVersion`, described in "Version Constants" (page 2462), to represent the current version. On return, `FNSSysInfoGet` fills in the remaining fields and passes back a pointer to the structure.

Discussion

Before calling the `FNSSysInfoGet` function, you should fill in the `iSysInfoVersion` field of the `FNSSysInfo` (page 2458) structure with the version of this structure. Pass the constant `kFNSCurSysInfoVersion`, described in "Version Constants" (page 2462) , to represent the current version. `FNSSysInfoGet` fills in the remaining fields and passes back the structure in the `ioInfo` parameter. The information it provides includes the version of FontSync running in the current context and available features, as well as the current and oldest font reference and profile format versions supported by the FontSync library.

New fields may be added to the end of the structure in future versions of FontSync. FontSync uses the `iSysInfoVersion` field to determine which version of the structure you are using. The value of the current version constant `kFNSCurSysInfoVersion` will change accordingly.

Version Notes

Available beginning with FontSync 1.0. In FontSync 1.0, the current structure version is defined by the constant `kFNSCurSysInfoVersion`, described in "Version Constants" (page 2462).

Availability

Available in CarbonLib 1.0 and later when Font Sync 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Not available to 64-bit applications.

Declared In

`FontSync.h`

Data Types

FNSFeatureFlags

Represents a mask that you can use to determine available FontSync features.

```
typedef UInt32 FNSFeatureFlags;
```

Discussion

The `FNSFeatureFlags` type defines a bit mask your application can use to determine available FontSync features. The function `FNSSysInfoGet` (page 2455) passes back a mask of this type in the `oFeatures` field of the `FNSSysInfo` (page 2458) structure in the `ioInfo` parameter. You can use this mask to determine available FontSync features.

Version Notes

Available beginning with FontSync 1.0. In FontSync 1.0, the value is 0, since no feature flags are defined.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`FontSync.h`

FNSFontProfile

Represents a reference to a font profile.

```
typedef struct OpaqueFNSFontProfile * FNSFontProfile;
```

Discussion
The `FNSFontProfile` type is a reference to an opaque structure containing a collection of font references. It defines a set of fonts on the user's system. Although you do not need to use font profiles to iterate, identify, and match fonts on the user's system, they are necessary in building font menus and other font selection human interface elements.

You pass a font profile to FontSync functions that manipulate font profiles. A font reference is passed back by functions that create font profiles. For a description of these functions, see "Working With FontSync Profiles" (page 2426).

Version Notes
Available beginning with FontSync 1.0.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`FontSync.h`

FNSFontReference

Represents a reference to a font reference.

```
typedef struct OpaqueFNSFontReference * FNSFontReference;
```

Discussion
The `FNSFontReference` type is a reference to an opaque structure containing information about a font. Some of the data contained in a font reference includes the QuickDraw font family name, ATSUI-visible font name, type of font, font version, checksums of the data, and information from the font name table.

You pass a font reference to FontSync functions that manipulate font references. A font reference is passed back by functions that create font references. For a description of these functions, see "Working With FontSync References" (page 2426).

Version Notes
Available beginning with FontSync 1.0.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`FontSync.h`

FNSSysInfo

Contains FontSync version and feature information.

```
struct FNSSysInfo {
    FNSObjectVersion iSysInfoVersion;
    FNSFeatureFlags oFeatures;
    FNSObjectVersion oCurRefVersion;
    FNSObjectVersion oMinRefVersion;
    FNSObjectVersion oCurProfileVersion;
    FNSObjectVersion oMinProfileVersion;
    UInt16 oFontSyncVersion;
};
typedef struct FNSSysInfo FNSSysInfo;
```

Fields

`iSysInfoVersion`
: On input, the version of this parameter block structure. In FontSync 1.0, the version number of this structure is 1. Pass the constant `kFNSCurSysInfoVersion`, described in "Version Constants" (page 2462). For more information, see the discussion.

`oFeatures`
: On output, the FontSync features that are available. In FontSync 1.0, no feature flags are defined.

`oCurRefVersion`
: On output, the current font reference format version supported by the FontSync library.

`oMinRefVersion`
: On output, the oldest font reference format version supported by the FontSync library.

`oCurProfileVersion`
: On output, the current font profile format version supported by the FontSync library.

`oMinProfileVersion`
: On output, the oldest font profile format version supported by the FontSync library.

`oFontSyncVersion`
: On output, a binary-coded decimal value indicating the version of FontSync currently running. The high-order 8 bits give the major version, the next four give the minor version, and the last four give the revision. For example, version 1.0 would be encoded as 0x0100.

Discussion

Before calling the function `FNSSysInfoGet` (page 2455), you should fill in the `iSysInfoVersion` field of this structure with the version of this structure. Pass the constant `kFNSCurSysInfoVersion`, described in "Version Constants" (page 2462), to represent the current version. `FNSSysInfoGet` (page 2455) fills in the remaining fields and passes back the structure in the `ioInfo` parameter. The information it provides includes the version of FontSync running in the current context and available features, as well as the current and oldest font reference and profile format versions supported by the FontSync library.

New fields may be added to the end of the structure in future versions of FontSync. FontSync uses the `iSysInfoVersion` field to determine which version of the structure you are using. The value of the current version constant `kFNSCurSysInfoVersion` will change accordingly.

Version Notes

Available beginning with FontSync 1.0. In FontSync 1.0, the value of the `iSysInfoVersion` field is 1. The value of the `oFeatures` field is 0, since no feature flags are defined.

Availability

Available in Mac OS X v10.0 and later.

Declared In
`FontSync.h`

Constants

Matching Options

Represent a mask that you can use to set and determine default match options.

```
typedef UInt32 FNSMatchOptions;
enum {
    kFNSMatchNames = 0x00000001,
    kFNSMatchTechnology = 0x00000002,
    kFNSMatchGlyphs = 0x00000004,
    kFNSMatchEncodings = 0x00000008,
    kFNSMatchQDMetrics = 0x00000010,
    kFNSMatchATSUMetrics = 0x00000020,
    kFNSMatchKerning = 0x00000040,
    kFNSMatchWSLayout = 0x00000080,
    kFNSMatchAATLayout = 0x00000100,
    kFNSMatchPrintEncoding = 0x00000200,
    kFNSMissingDataNoMatch = 0x80000000,
    kFNSMatchAll = 0xFFFFFFFF,
    kFNSMatchDefaults = 0
};
```

Constants

`kFNSMatchNames`

If the bit specified by this mask is set, all significant font names must match. This includes the QuickDraw Text family, ATSUI, unique, full, manufacturer, and version names. Note that the PostScript names are also examined as part of the `kFNSMatchPrintEncoding` option.

Available in Mac OS X v10.0 and later.

Declared in `FontSync.h`.

`kFNSMatchTechnology`

If the bit specified by this mask is set, scaler technologies must match. It is possible to match other parts of the font across different technologies, but this is not supported by FontSync 1.0. As a result, even if this bit is not set, fonts of different technologies will probably not match under any other criteria.

Available in Mac OS X v10.0 and later.

Declared in `FontSync.h`.

`kFNSMatchGlyphs`

If the bit specified by this mask is set, glyph repertoires and outline/bitmap data must match.

Available in Mac OS X v10.0 and later.

Declared in `FontSync.h`.

`kFNSMatchEncodings`
If the bit specified by this mask is set, the `'cmap'` tables must match. If the order of the `'cmap'` tables is different, although the tables are the same, this may be considered a mismatch, since it can cause QuickDraw Text to use a different `'cmap'table`.

Available in Mac OS X v10.0 and later.

Declared in `FontSync.h`.

`kFNSMatchQDMetrics`
If the bit specified by this mask is set, metrics used by QuickDraw Text must match. This includes the effect of `fractEnable` and any metric information in the `'FOND'` resource.

Available in Mac OS X v10.0 and later.

Declared in `FontSync.h`.

`kFNSMatchATSUMetrics`
If the bit specified by this mask is set, metrics used by ATSUI must match. This includes both horizontal and vertical metrics.

Available in Mac OS X v10.0 and later.

Declared in `FontSync.h`.

`kFNSMatchKerning`
If the bit specified by this mask is set, kerning data must match.

Available in Mac OS X v10.0 and later.

Declared in `FontSync.h`.

`kFNSMatchWSLayout`
If the bit specified by this mask is set, layout information given by an `'itl5'` table, whether attached directly to the font or the one provided in the script bundle, must match.

Available in Mac OS X v10.0 and later.

Declared in `FontSync.h`.

`kFNSMatchAATLayout`
If the bit specified by this mask is set, advanced layout information such as that used by ATSUI, must match. This includes such things as ligature and morphing tables. OpenType-style layout information is included in this option.

Available in Mac OS X v10.0 and later.

Declared in `FontSync.h`.

`kFNSMatchPrintEncoding`
If the bit specified by this mask is set, PostScript names and `'FOND'` re-encoding vectors must match. Note that it is an error for a font's internal PostScript name to be different from the one in the `'FOND'`, but FontSync will record both and consider them separately.

Available in Mac OS X v10.0 and later.

Declared in `FontSync.h`.

`kFNSMissingDataNoMatch`
If the bit specified by this mask is set, FontSync will report font reference mismatches when both fonts are missing data needed by a selected option. This is useful, since some older fonts may not have all the data needed for matching newer fonts. This makes the mask constant `kFNSMatchAll` specify the most stringent possible match criteria.

Available in Mac OS X v10.0 and later.

Declared in `FontSync.h`.

`kFNSMatchAll`
: If the bit specified by this mask is set, all of the match options must match. In this case, the bit specified by the mask constant `kFNSMissingDataNoMatch` is also set, asserting the most stringent possible match criteria.

  Available in Mac OS X v10.0 and later.

  Declared in `FontSync.h`.

`kFNSMatchDefaults`
: If this constant is specified, the global default match criteria established by the API are used (that is, use all of the options described above in the match). If the user changes the FontSync Control Panel settings, that becomes the new default. This constant basically says to use whatever the user has set.

  Available in Mac OS X v10.0 and later.

  Declared in `FontSync.h`.

Discussion
The `FNSMatchOptions` enumeration defines masks your application can use to set or test match option bits. You can use this mask with the functions `FNSReferenceMatch` (page 2451), `FNSProfileMatchReference` (page 2435), `FNSReferenceMatchFonts` (page 2453), and `FNSReferenceMatchFamilies` (page 2452) to set the match options used during font comparison. If you wish, your application can specify options that are different from the user's preferences via this mask. You can use this mask to test the match option bits produced by the function `FNSMatchDefaultsGet` (page 2427), thereby obtaining the default match options to use in a font comparison. You can also use this mask to test the match option bits produced by the function `FNSReferenceMatch`, thereby determining the match options under consideration that did not match.

At least one of the match options must be set. Having all of these bits clear is equivalent to saying "don't look at anything," which would allow any font to match. Since having all flags clear is nonsensical, the value of the mask constant `kFNSMatchDefaults` is 0. Setting undefined bits does not generate an error and provides backward compatibility.

Version Notes
Available beginning with FontSync 1.0.

Font Profile Constants

Represent the file type and default creator code of a font profile.

```
enum {
    kFNSCreatorDefault = 0,
    kFNSProfileFileType = 'fnsp'
};
```

Constants
`kFNSCreatorDefault`
: Assigns a file creator code instead of using one of your own. Pass this constant in the `iCreator` parameter of the function `FNSProfileCreate` (page 2432).

  Available in Mac OS X v10.0 and later.

  Declared in `FontSync.h`.

`kFNSProfileFileType`
The file type of a profile. It is not used in the API, but is provided for convenience. For example, you can use it to put up a Navigation Services dialog box to select a profile.

Available in Mac OS X v10.0 and later.

Declared in `FontSync.h`.

Version Notes
Available beginning with FontSync 1.0. In FontSync 1.0, if you specify the constant `kFNSCreatorDefault` in the `iCreator` parameter of the function `FNSProfileCreate` (page 2432), FontSync assigns the creator code `'fns'`.

Version Constants

Represents version information.

```
typedef UInt32 FNSObjectVersion;
enum {
    kFNSVersionDontCare = 0,
    kFNSCurSysInfoVersion = 1
};
```

Constants
`kFNSVersionDontCare`
Specifies the most recent font reference or font profile version supported by the FontSync library, regardless of version number. In FontSync 1.0, the most recent version for both font references and profiles is version 1. You pass this constant in the `iDesiredVersion` parameter of the functions `FNSSysInfo` (page 2458), `FNSSysInfoGet` (page 2455), and `FNSProfileCreate` (page 2432).

Available in Mac OS X v10.0 and later.

Declared in `FontSync.h`.

`kFNSCurSysInfoVersion`
Identifies the current version of the parameter block structure `FNSSysInfo` (page 2458) returned by the function `FNSSysInfoGet` (page 2455). You pass this constant in the `iSysInfoVersion` field of the system information structure. The version of the structure used by FontSync 1.0 is version 1.

Available in Mac OS X v10.0 and later.

Declared in `FontSync.h`.

Discussion
You can pass the `kFNSVersionDontCare` constant in the `iDesiredVersion` parameter of the functions `FNSReferenceCreate` (page 2441), `FNSReferenceCreateFromFamily` (page 2442), and `FNSProfileCreate` (page 2432), to specify the most recent font reference or font profile version supported by the FontSync library. You can use the `kFNSCurSysInfoVersion` constant in the `iSysInfoVersion` field of the structure `FNSSysInfo` (page 2458) to indicate the current version of the structure.

Result Codes

The most common result codes returned by FontSync are listed below.

Result Code	Value	Description
kFNSInvalidReferenceErr	-29580	Returned by FontSync functions that operate on font references to indicate that the specified font reference is invalid. This can also be returned by the function FNSReferenceUnflatten if the reconstructed reference is bad. Available in Mac OS X v10.0 and later.
kFNSBadReferenceVersionErr	-29581	Returned by FontSync functions that operate on font references to indicate that the reference has an unsupported version number. This may indicate that the reference is valid, but created by a later version of FontSync, or that the reference is truly invalid This is also be returned by font reference creation functions if an unsupported reference version was requested. Available in Mac OS X v10.0 and later.
kFNSInvalidProfileErr	-29582	Returned by FontSync functions that operate on font profiles to indicate that the profile does not have a valid structure. Available in Mac OS X v10.0 and later.
kFNSBadProfileVersionErr	-29583	Returned by FontSync functions that operate on font profiles to indicate that the profile has an unsupported version number. This may indicate that the profile is valid, but created by a later version of FontSync, or that the profile is truly invalid. This is also be returned by font profile creation functions if an unsupported profile version was requested. Available in Mac OS X v10.0 and later.
kFNSDuplicateReferenceErr	-29584	Returned by the function FNSProfileAddReference to indicate that the font reference being added already exists in the profile. Available in Mac OS X v10.0 and later.
kFNSMismatchErr	-29585	Indicates that either a reference did not match, the reference you wish to remove is not in the profile, or that no font names were recorded in the reference. Available in Mac OS X v10.0 and later.
kFNSInsufficientDataErr	-29586	Returned by the functions FNSReferenceMatch, FNSReferenceGetFamilyInfo, FNSReferenceFindName, and FNSReferenceGetIndName to indicate that the mask constant kFNSMissingDataNoMatch has been set and both references being compared are missing the same data. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
kFNSBadFlattenedSizeErr	-29587	Returned by the function FNSReferenceUnflatten to indicate that the specified size doesn't match the size recorded in the flattened reference or that the size was not large enough for a flattened reference. Available in Mac OS X v10.0 and later.
kFNSNameNotFoundErr	-29589	Returned by the function FNSReferenceFindName to indicate that there was no name in the font reference that matched the given parameters. Available in Mac OS X v10.0 and later.

Internet Config Reference

Framework: Carbon/Carbon.h

Declared in InternetConfig.h

Overview

Internet Config, a Mac OS 8 and 9 API, supports centralized entry and management of Internet preferences for all of a user's Internet applications. For example, email programs and Web browsers can obtain a user's name, email address, home page, incoming mail server, and similar preferences from one common place that is easily edited by the user via the Internet Config application.

Mac OS X applications should employ Launch Services and System Configuration for managing Internet preferences. In Mac OS X, Internet Config calls through to these newer APIs. Using them directly increases your application's efficiency.

If you use Internet Config in Mac OS X, perhaps to maintain backward compatibility for your application with Mac OS 8 and 9, here are some ways to optimize performance.

- Getting multiple preferences at once.

  Your program may access several Internet Config preferences within a single operation. For example, an FTP program on startup might always get the kICFTPHost, kICFTPProxyHost, kICFTPProxyAccount, kICFTPProxyPassword, and kICFTPProxyUser preferences. Bracket such a sequence of ICGetPref calls with an ICBegin and ICEnd function pair for significantly faster performance.

- Calling Internet Config less often.

  Your application can cache Internet Config preference data and then watch for changes using one of the preference coherency strategies described in the developer's online documentation:

  http://www.quinn.echidna.id.au/Quinn/Config/Prog_Docs.html#PreferenceCoherency

- Using preferences from underlying frameworks.

  Starting with Mac OS X, Internet Config is no longer the final authority on Internet preferences. For example, Launch Services stores URL helper application settings, and System Configuration stores the various proxy settings. When called by an application, Internet Config must call through to the appropriate underlying framework. Call Launch Services and System Configuration directly to improve performance.

The Mac OS 8 and 9 implementation of Internet Config is in the public domain, and Carbon supports all of its commonly-used functions. Functions that are not compatible with preemptive threads are not supported, and Internet Config no longer supports multiple configuration files. This document contains information on replacement functions.

For more information on Internet Config see its developer's web site:

http://www.quinn.echidna.id.au/Quinn/Config

Functions by Task

Starting and Stopping Internet Config

These functions let you create, configure, and destroy connections to Internet Config, denoted by the `ICInstance` type. Although it is usual to create one connection when your program starts and destroy it when it terminates, you can create an arbitrary number of connections at any time.

`ICStart` (page 2509)
: Call this routine to start using Internet Config—typically at application initialization time—passing it your program's creator code.

`ICGetVersion` (page 2502)
: Returns the version of Internet Config installed on the system.

`ICStop` (page 2509)
: Call this when your application is done using Internet Config, passing it the instance you got from `ICStart`.

Getting Information About an Instance

`ICGetConfigName` (page 2496)
: Returns a displayable string that represents the instance's current configuration.

`ICGetSeed` (page 2501)
: Returns the seed for the current preferences set.

`ICGetPerm` (page 2500)
: Returns the current permissions for this instance, i.e. the permission value you used when you called `ICBegin`, or returns `ioNoPerm` if you haven't call `ICBegin`.

Preparing to Read and Write Preferences

These routines are not always required because the commonly used reading and writing calls perform this operation automatically. However, even in that case, these routines are useful if you are making repeated calls because they allow those calls to work faster.

`ICBegin` (page 2473)
: Prepares Internet Config to read (and, optionally, to write) preferences.

`ICEnd` (page 2494)
: Tells Internet Config that you have finished accessing preference information.

Reading and Writing Preferences

`ICGetPref` (page 2500)
: Given a preference's key, gets the preference's data and places it into a buffer that you supply.

`ICSetPref` (page 2507)
Sets a preference given its key, attributes, and a buffer containing the preference data.

`ICFindPrefHandle` (page 2495)
Gets a preference's data, like `ICGetPref`, but returns the data in a handle.

`ICSetPrefHandle` (page 2508)
Sets a preference, like `ICSetPref`, but takes its input as a handle.

`ICGetDefaultPref` (page 2498)
Gets the default value for the preference associated with the specified key.

`ICDeletePref` (page 2493)
Deletes the preference for the specified key.

Enumerating All Preferences

You must call `ICBegin` before calling any of these routines.

`ICCountPref` (page 2487)
Returns the total number of preferences available.

`ICGetIndPref` (page 2498)
Returns the key associated with the preference at the specified index.

Accessing the User Interface

We recommend that you do not provide a user interface for editing Internet Config preferences from within your application. In Mac OS X, simply provide a way for the user to open the Internet pane of System Preferences. The `ICEditPreferences` function provides support for this.

`ICEditPreferences` (page 2494)
Opens the Internet pane of System Preferences.

URL Functions

`ICParseURL` (page 2505)
Parses a URL out of the specified text and returns it to the calling program.

`ICLaunchURL` (page 2502)
Parses a URL out of the specified text and feeds it to the appropriate helper application.

`ICCreateGURLEvent` (page 2489)
Creates a GURL Apple event, targetted at the application with the specified creator code

`ICSendGURLEvent` (page 2506)
Sends a specified Apple Event to the target application.

Mapping-Database High-Level Functions

Internet Config's high-level functions are suitable for applications that want to easily look up a file type and creator based on an extension, or vice versa. These functions are significantly slower than their lower level counterparts, especially if you call them repeatedly.

`ICMapFilename` (page 2504)
Given a filename, returns the most appropriate `ICMapEntry` based on the filename extension.

`ICMapTypeCreator` (page 2504)
Given a file type and creator (and optionally a filename), returns the most appropriate `ICMapEntry`.

Mapping-Database Mid-Level Functions

These functions are useful if you are doing multiple searches because they avoid the overhead of accessing the mappings database each time.

`ICMapEntriesFilename` (page 2503)
Given a filename, returns the most appropriate `ICMapEntry` based on the filename extension—without the overhead of a mappings database access.

`ICMapEntriesTypeCreator` (page 2503)
Given a file type and creator (and optionally a filename), returns the most appropriate `ICMapEntry`—without the overhead of a mappings database access.

Mapping-Database Low-Level Functions

Internet Config's low-level functions give you access to the primitive operations used to implement the other mapping functions.

`ICCountMapEntries` (page 2487)
Counts the number of entries in the mappings database preference provided.

`ICGetIndMapEntry` (page 2498)
Returns the mappings database entry for a specified index .

`ICGetMapEntry` (page 2499)
Returns a mappings database entry based on its position in the Mapping preference.

`ICSetMapEntry` (page 2507)
Sets an entry in a specified Mapping preference.

`ICDeleteMapEntry` (page 2493)
Deletes an entry in the specified Mapping preference.

`ICAddMapEntry` (page 2472)
Adds an entry to the mappings database.

Profile Functions

`ICGetCurrentProfile` (page 2497)
Returns the profile ID of the current profile.

`ICSetCurrentProfile` (page 2506)
Sets the current profile to a specified profile ID.

`ICCountProfiles` (page 2488)
Returns the number of available profiles.

`ICGetIndProfile` (page 2499)
Returns the ID of the profile at the specified index.

`ICGetProfileName` (page 2501)
Returns the name of the profile that has the specified ID.

`ICSetProfileName` (page 2508)
Sets the name of the profile that has the specified ID.

`ICAddProfile` (page 2473)
Creates a new profile and returns its ID.

`ICDeleteProfile` (page 2494)
Deletes the profile that has the specified ID.

Deprecated functions

`ICGetPrefHandle` (page 2501)
Deprecated. While this function works in Mac OS X, you should use ICFindPrefHandle instead.

Unsupported Functions

`ICCSetPref` (page 2491)

`ICCAddMapEntry` (page 2473)

`ICCAddProfile` (page 2474)

`ICCBegin` (page 2474)

`ICCChooseConfig` (page 2474)

`ICCChooseNewConfig` (page 2474)

`ICCCountMapEntries` (page 2475)

`ICCCountPref` (page 2475)

`ICCCountProfiles` (page 2475)

`ICCCreateGURLEvent` (page 2476)

`ICCDefaultFileName` (page 2476)

`ICCDeleteMapEntry` (page 2476)

`ICCDeletePref` (page 2477)

Functions

ICAddMapEntry

Adds an entry to the mappings database.

```
OSStatus ICAddMapEntry (
   ICInstance inst,
   Handle entries,
   const ICMapEntry *entry
);
```

Return Value
A result code. See "Result Codes" (page 2538).

Availability
Available in CarbonLib 1.0.2 and later when Internet Config 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`InternetConfig.h`

ICAddProfile

Creates a new profile and returns its ID.

```
OSStatus ICAddProfile (
   ICInstance inst,
   ICProfileID prototypeID,
   ICProfileID *newID
);
```

Return Value
A result code. See "Result Codes" (page 2538).

Availability
Available in CarbonLib 1.0.2 and later when Internet Config 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`InternetConfig.h`

ICBegin

Prepares Internet Config to read (and, optionally, to write) preferences.

```
OSStatus ICBegin (
   ICInstance inst,
   ICPerm perm
);
```

Return Value
A result code. See "Result Codes" (page 2538).

Availability
Available in CarbonLib 1.0.2 and later when Internet Config 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`InternetConfig.h`

ICCAddMapEntry

Unsupported

```
OSStatus ICCAddMapEntry (
    ComponentInstance inst,
    Handle entries,
    ICMapEntry *entry
);
```

Carbon Porting Notes

Use `ICAddMapEntry` (page 2472) instead.

Declared In
`InternetConfig.h`

ICCAddProfile

Unsupported

```
OSStatus ICCAddProfile (
    ComponentInstance inst,
    ICProfileID prototypeID,
    ICProfileID *newID
);
```

Carbon Porting Notes

Use `ICAddProfile` (page 2473) instead.

Declared In

`InternetConfig.h`

ICCBegin

Unsupported

```
OSStatus ICCBegin (
    ComponentInstance inst,
    ICPerm perm
);
```

Carbon Porting Notes

Use `ICBegin` (page 2473) instead.

Declared In

`InternetConfig.h`

ICCChooseConfig

Unsupported

```
OSStatus ICCChooseConfig (
    ComponentInstance inst
);
```

Carbon Porting Notes

Because Internet Config no longer supports multiple configuration files, this function is obsolete, and there is no replacement function.

Declared In

`InternetConfig.h`

ICCChooseNewConfig

Unsupported

```
OSStatus ICCChooseNewConfig (
    ComponentInstance inst
);
```

Carbon Porting Notes

Because Internet Config no longer supports multiple configuration files, this function is obsolete, and there is no replacement function.

Declared In

`InternetConfig.h`

ICCCountMapEntries

Unsupported

```
OSStatus ICCCountMapEntries (
    ComponentInstance inst,
    Handle entries,
    SInt32 *count
);
```

Carbon Porting Notes

Use `ICCountMapEntries` (page 2487) instead.

Declared In

`InternetConfig.h`

ICCCountPref

Unsupported

```
OSStatus ICCCountPref (
    ComponentInstance inst,
    SInt32 *count
);
```

Carbon Porting Notes

Use `ICCountPref` (page 2487) instead.

Declared In

`InternetConfig.h`

ICCCountProfiles

Unsupported

```
OSStatus ICCCountProfiles (
    ComponentInstance inst,
    SInt32 *count
);
```

Carbon Porting Notes

Use `ICCountProfiles` (page 2488) instead.

Declared In
InternetConfig.h

ICCCreateGURLEvent
Unsupported

```
OSStatus ICCCreateGURLEvent (
    ComponentInstance inst,
    OSType helperCreator,
    Handle urlH,
    AppleEvent *theEvent
);
```

Carbon Porting Notes

Use ICCreateGURLEvent (page 2489) instead.

Declared In
InternetConfig.h

ICCDefaultFileName
Unsupported

```
OSStatus ICCDefaultFileName (
    ComponentInstance inst,
    Str63 name
);
```

Carbon Porting Notes

Functions related to finding different IC database files are obsolete. You can simply remove these calls from your code—there are no replacement functions.

Declared In
InternetConfig.h

ICCDeleteMapEntry
Unsupported

```
OSStatus ICCDeleteMapEntry (
    ComponentInstance inst,
    Handle entries,
    SInt32 pos
);
```

Carbon Porting Notes

Use ICDeleteMapEntry (page 2493) instead.

Declared In
InternetConfig.h

ICCDeletePref

Unsupported

```
OSStatus ICCDeletePref (
    ComponentInstance inst,
    ConstStr255Param key
);
```

Carbon Porting Notes

Use `ICDeletePref` (page 2493) instead.

Declared In

`InternetConfig.h`

ICCDeleteProfile

Unsupported

```
OSStatus ICCDeleteProfile (
    ComponentInstance inst,
    ICProfileID thisID
);
```

Carbon Porting Notes

Use `ICDeleteProfile` (page 2494) instead.

Declared In

`InternetConfig.h`

ICCEditPreferences

Unsupported

```
OSStatus ICCEditPreferences (
    ComponentInstance inst,
    ConstStr255Param key
);
```

Carbon Porting Notes

Use `ICEditPreferences` (page 2494) instead.

Declared In

`InternetConfig.h`

ICCEnd

Unsupported

```
OSStatus ICCEnd (
    ComponentInstance inst
);
```

Carbon Porting Notes

Use `ICEnd` (page 2494) instead.

Declared In

`InternetConfig.h`

ICCFindConfigFile

Unsupported

```
OSStatus ICCFindConfigFile (
    ComponentInstance inst,
    SInt16 count,
    ICDirSpecArrayPtr folders
);
```

Carbon Porting Notes

Functions related to finding different IC database files are obsolete. You can simply remove these calls from your code—there are no replacement functions.

Declared In

`InternetConfig.h`

ICCFindPrefHandle

Unsupported

```
OSStatus ICCFindPrefHandle (
    ComponentInstance inst,
    ConstStr255Param key,
    ICAttr *attr,
    Handle prefh
);
```

Carbon Porting Notes

Use `ICFindPrefHandle` (page 2495) instead.

Declared In

`InternetConfig.h`

ICCFindUserConfigFile

Unsupported

```
OSStatus ICCFindUserConfigFile (
    ComponentInstance inst,
    ICDirSpec *where
);
```

Carbon Porting Notes

Functions related to finding different IC database files are obsolete. You can simply remove these calls from your code—there are no replacement functions.

Declared In

`InternetConfig.h`

ICCGeneralFindConfigFile

Unsupported

```
OSStatus ICCGeneralFindConfigFile (
    ComponentInstance inst,
    Boolean searchPrefs,
    Boolean canCreate,
    SInt16 count,
    ICDirSpecArrayPtr folders
);
```

Carbon Porting Notes

Functions related to finding different IC database files are obsolete. You can simply remove these calls from your code—there are no replacement functions.

Declared In

`InternetConfig.h`

ICCGetComponentInstance

Unsupported

```
OSStatus ICCGetComponentInstance (
    ComponentInstance inst,
    ComponentInstance *componentInst
);
```

Carbon Porting Notes

Because Internet Config is not component-based under Mac OS X, use `ICGetVersion` (page 2502) instead.

Declared In

`InternetConfig.h`

ICCGetConfigName

Unsupported

```
OSStatus ICCGetConfigName (
    ComponentInstance inst,
    Boolean longname,
    Str255 name
);
```

Carbon Porting Notes

Use `ICGetConfigName` (page 2496) instead.

Declared In

`InternetConfig.h`

ICCGetConfigReference

Unsupported

```
OSStatus ICCGetConfigReference (
    ComponentInstance inst,
    ICConfigRefHandle ref
);
```

Carbon Porting Notes

Because Internet Config no longer supports multiple configuration files, this function is obsolete, and there is no replacement function.

Declared In

`InternetConfig.h`

ICCGetCurrentProfile

Unsupported

```
OSStatus ICCGetCurrentProfile (
    ComponentInstance inst,
    ICProfileID *currentID
);
```

Carbon Porting Notes

Use `ICGetCurrentProfile` (page 2497) instead.

Declared In

`InternetConfig.h`

ICCGetDefaultPref

Unsupported

```
OSStatus ICCGetDefaultPref (
    ComponentInstance inst,
    ConstStr255Param key,
    Handle prefH
);
```

Carbon Porting Notes

Use `ICGetDefaultPref` (page 2498) instead.

Declared In

`InternetConfig.h`

ICCGetIndMapEntry

Unsupported

```
OSStatus ICCGetIndMapEntry (
    ComponentInstance inst,
    Handle entries,
    SInt32 index,
    SInt32 *pos,
    ICMapEntry *entry
);
```

Carbon Porting Notes

Use `ICGetIndMapEntry` (page 2498) instead.

Declared In

`InternetConfig.h`

ICCGetIndPref

Unsupported

```
OSStatus ICCGetIndPref (
    ComponentInstance inst,
    SInt32 index,
    Str255 key
);
```

Carbon Porting Notes

Use `ICGetIndPref` (page 2498) instead.

Declared In

`InternetConfig.h`

ICCGetIndProfile

Unsupported

```
OSStatus ICCGetIndProfile (
    ComponentInstance inst,
    SInt32 index,
    ICProfileID *thisID
);
```

Carbon Porting Notes

Use `ICGetIndProfile` (page 2499) instead.

Declared In

`InternetConfig.h`

ICCGetMapEntry

Unsupported

```
OSStatus ICCGetMapEntry (
    ComponentInstance inst,
    Handle entries,
    SInt32 pos,
    ICMapEntry *entry
);
```

Carbon Porting Notes

Use `ICGetMapEntry` (page 2499) instead.

Declared In

`InternetConfig.h`

ICCGetMappingInterruptSafe

Unsupported

```
OSStatus ICCGetMappingInterruptSafe (
    ComponentInstance inst,
    Ptr *mappingPref,
    SInt32 *mappingPrefSize
);
```

Carbon Porting Notes

`ICCGetMappingInterruptSafe` is not compatible with preemptive threads. If your application relies on this API, contact Apple Developer Technical Support.

Declared In

`InternetConfig.h`

ICCGetPerm

Unsupported

```
OSStatus ICCGetPerm (
    ComponentInstance inst,
    ICPerm *perm
);
```

Carbon Porting Notes

Use `ICGetPerm` (page 2500) instead.

Declared In

`InternetConfig.h`

ICCGetPref

Unsupported

```
OSStatus ICCGetPref (
    ComponentInstance inst,
    ConstStr255Param key,
    ICAttr *attr,
    Ptr buf,
    SInt32 *size
);
```

Carbon Porting Notes

Use `ICGetPref` (page 2500) instead.

Declared In

`InternetConfig.h`

ICCGetPrefHandle

Unsupported

```
OSStatus ICCGetPrefHandle (
    ComponentInstance inst,
    ConstStr255Param key,
    ICAttr *attr,
    Handle *prefh
);
```

Carbon Porting Notes

Use `ICFindPrefHandle` (page 2495) instead.

Declared In

`InternetConfig.h`

ICCGetProfileName

Unsupported

```
OSStatus ICCGetProfileName (
    ComponentInstance inst,
    ICProfileID thisID,
    Str255 name
);
```

Carbon Porting Notes

Use `ICGetProfileName` (page 2501) instead.

Declared In

`InternetConfig.h`

ICCGetSeed

Unsupported

```
OSStatus ICCGetSeed (
    ComponentInstance inst,
    SInt32 *seed
);
```

Carbon Porting Notes

Use `ICGetSeed` (page 2501) instead.

Declared In

`InternetConfig.h`

ICCGetSeedInterruptSafe

Unsupported

```
OSStatus ICCGetSeedInterruptSafe (
    ComponentInstance inst,
    SInt32 *seed
);
```

Carbon Porting Notes

`ICCGetSeedInterruptSafe` is not compatible with preemptive threads. If your application relies on this API, contact Apple Developer Technical Support.

Declared In

`InternetConfig.h`

ICCGetVersion

Unsupported

```
OSStatus ICCGetVersion (
    ComponentInstance inst,
    SInt32 whichVersion,
    UInt32 *version
);
```

Carbon Porting Notes

Use `ICGetVersion` (page 2502) instead.

Declared In

`InternetConfig.h`

ICChooseConfig

Unsupported

```
OSStatus ICChooseConfig (
    ICInstance inst
);
```

Carbon Porting Notes

Because Internet Config no longer supports multiple configuration files, this function is obsolete, and there is no replacement function.

Declared In

`InternetConfig.h`

ICChooseNewConfig

Unsupported

```
OSStatus ICChooseNewConfig (
    ICInstance inst
);
```

Carbon Porting Notes

Because Internet Config no longer supports multiple configuration files, this function is obsolete, and there is no replacement function.

Declared In

`InternetConfig.h`

ICCLaunchURL

Unsupported

```
OSStatus ICCLaunchURL (
    ComponentInstance inst,
    ConstStr255Param hint,
    Ptr data,
    SInt32 len,
    SInt32 *selStart,
    SInt32 *selEnd
);
```

Carbon Porting Notes

Use `ICLaunchURL` (page 2502) instead.

Declared In

`InternetConfig.h`

ICCMapEntriesFilename

Unsupported

```
OSStatus ICCMapEntriesFilename (
    ComponentInstance inst,
    Handle entries,
    ConstStr255Param filename,
    ICMapEntry *entry
);
```

Carbon Porting Notes

Use `ICMapEntriesFilename` (page 2503) instead.

Declared In

`InternetConfig.h`

ICCMapEntriesTypeCreator

Unsupported

```
OSStatus ICCMapEntriesTypeCreator (
    ComponentInstance inst,
    Handle entries,
    OSType fType,
    OSType fCreator,
    ConstStr255Param filename,
    ICMapEntry *entry
);
```

Carbon Porting Notes

Use `ICMapEntriesTypeCreator` (page 2503) instead.

Declared In

`InternetConfig.h`

ICCMapFilename

Unsupported

```
OSStatus ICCMapFilename (
    ComponentInstance inst,
    ConstStr255Param filename,
    ICMapEntry *entry
);
```

Carbon Porting Notes

Use `ICMapFilename` (page 2504) instead.

Declared In

`InternetConfig.h`

ICCMapTypeCreator

Unsupported

```
OSStatus ICCMapTypeCreator (
    ComponentInstance inst,
    OSType fType,
    OSType fCreator,
    ConstStr255Param filename,
    ICMapEntry *entry
);
```

Carbon Porting Notes

Use `ICMapTypeCreator` (page 2504) instead.

Declared In

`InternetConfig.h`

ICCountMapEntries

Counts the number of entries in the mappings database preference provided.

```
OSStatus ICCountMapEntries (
   ICInstance inst,
   Handle entries,
   long *count
);
```

Return Value

A result code. See "Result Codes" (page 2538).

Availability

Available in CarbonLib 1.0.2 and later when Internet Config 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In

`InternetConfig.h`

ICCountPref

Returns the total number of preferences available.

```
OSStatus ICCountPref (
   ICInstance inst,
   long *count
);
```

Return Value
A result code. See "Result Codes" (page 2538).

Availability
Available in CarbonLib 1.0.2 and later when Internet Config 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`InternetConfig.h`

ICCountProfiles

Returns the number of available profiles.

```
OSStatus ICCountProfiles (
   ICInstance inst,
   long *count
);
```

Return Value
A result code. See "Result Codes" (page 2538).

Availability
Available in CarbonLib 1.0.2 and later when Internet Config 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`InternetConfig.h`

ICCParseURL

Unsupported

```
OSStatus ICCParseURL (
    ComponentInstance inst,
    ConstStr255Param hint,
    Ptr data,
    SInt32 len,
    SInt32 *selStart,
    SInt32 *selEnd,
    Handle url
);
```

Carbon Porting Notes

Use `ICParseURL` (page 2505) instead.

Declared In
`InternetConfig.h`

ICCreateGURLEvent

Creates a GURL Apple event, targetted at the application with the specified creator code

```
OSStatus ICCreateGURLEvent (
   ICInstance inst,
   OSType helperCreator,
   Handle urlH,
   AppleEvent *theEvent
);
```

Return Value
A result code. See "Result Codes" (page 2538).

Availability
Available in CarbonLib 1.0.2 and later when Internet Config 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`InternetConfig.h`

ICCRefreshCaches

Unsupported

```
OSStatus ICCRefreshCaches (
    ComponentInstance inst
);
```

Carbon Porting Notes

This function is obsolete, because there is no supported way to modify the Internet Config database without going through the Internet Config API. There is no replacement function.

Declared In
`InternetConfig.h`

ICCRequiresInterruptSafe

Unsupported

```
OSStatus ICCRequiresInterruptSafe (
    ComponentInstance inst
);
```

Carbon Porting Notes

This function is not compatible with preemptive threads. There is no replacement.

Declared In
`InternetConfig.h`

ICCSendGURLEvent

Unsupported

```
OSStatus ICCSendGURLEvent (
    ComponentInstance inst,
    AppleEvent *theEvent
);
```

Carbon Porting Notes

Use `ICSendGURLEvent` (page 2506) instead.

Declared In

`InternetConfig.h`

ICCSetConfigReference

Unsupported

```
OSStatus ICCSetConfigReference (
    ComponentInstance inst,
    ICConfigRefHandle ref,
    SInt32 flags
);
```

Carbon Porting Notes

Because Internet Config no longer supports multiple configuration files, this function is obsolete, and there is no replacement function.

Declared In

`InternetConfig.h`

ICCSetCurrentProfile

Unsupported

```
OSStatus ICCSetCurrentProfile (
    ComponentInstance inst,
    ICProfileID newID
);
```

Carbon Porting Notes

Use `ICSetCurrentProfile` (page 2506) instead.

Declared In

`InternetConfig.h`

ICCSetMapEntry

Unsupported

```
OSStatus ICCSetMapEntry (
    ComponentInstance inst,
    Handle entries,
    SInt32 pos,
    ICMapEntry *entry
);
```

Carbon Porting Notes

Use `ICSetMapEntry` (page 2507)`ICSetMapEntry` instead.

Declared In

`InternetConfig.h`

ICCSetPref

Unsupported

```
OSStatus ICCSetPref (
    ComponentInstance inst,
    ConstStr255Param key,
    ICAttr attr,
    Ptr buf,
    SInt32 size
);
```

Carbon Porting Notes

Use `ICSetPref` (page 2507) instead.

Declared In

`InternetConfig.h`

ICCSetPrefHandle

Unsupported

```
OSStatus ICCSetPrefHandle (
    ComponentInstance inst,
    ConstStr255Param key,
    ICAttr attr,
    Handle prefh
);
```

Carbon Porting Notes

Use `ICSetPrefHandle` (page 2508) instead.

Declared In

`InternetConfig.h`

ICCSetProfileName

Unsupported

```
OSStatus ICCSetProfileName (
    ComponentInstance inst,
    ICProfileID thisID,
    ConstStr255Param name
);
```

Carbon Porting Notes

Use `ICSetProfileName` (page 2508) instead.

Declared In

`InternetConfig.h`

ICCSpecifyConfigFile

Unsupported

```
OSStatus ICCSpecifyConfigFile (
    ComponentInstance inst,
    FSSpec *config
);
```

Carbon Porting Notes

Functions related to finding different IC database files are obsolete. You can simply remove these calls from your code—there are no replacement functions.

Declared In

`InternetConfig.h`

ICCStart

Unsupported

```
OSStatus ICCStart (
    ComponentInstance *inst,
    OSType creator
);
```

Carbon Porting Notes

Use `ICStart` (page 2509) instead.

Declared In

`InternetConfig.h`

ICCStop

Unsupported

```
OSStatus ICCStop (
    ComponentInstance inst
);
```

Carbon Porting Notes

Use `ICStop` (page 2509) instead.

Declared In
InternetConfig.h

ICDefaultFileName

Unsupported

```
OSStatus ICDefaultFileName (
    ICInstance inst,
    Str63 name
);
```

Carbon Porting Notes

Functions related to finding different IC database files are obsolete. You can simply remove these calls from your code—there are no replacement functions.

Declared In
InternetConfig.h

ICDeleteMapEntry

Deletes an entry in the specified Mapping preference.

```
OSStatus ICDeleteMapEntry (
   ICInstance inst,
   Handle entries,
   long pos
);
```

Return Value
A result code. See "Result Codes" (page 2538).

Availability
Available in CarbonLib 1.0.2 and later when Internet Config 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
InternetConfig.h

ICDeletePref

Deletes the preference for the specified key.

```
OSStatus ICDeletePref (
   ICInstance inst,
   ConstStr255Param key
);
```

Return Value
A result code. See "Result Codes" (page 2538).

Availability
Available in CarbonLib 1.0.2 and later when Internet Config 2.0 or later is present.

Available in Mac OS X 10.0 and later.

Declared In
`InternetConfig.h`

ICDeleteProfile

Deletes the profile that has the specified ID.

```
OSStatus ICDeleteProfile (
   ICInstance inst,
   ICProfileID thisID
);
```

Return Value
A result code. See "Result Codes" (page 2538).

Availability
Available in CarbonLib 1.0.2 and later when Internet Config 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`InternetConfig.h`

ICEditPreferences

Opens the Internet pane of System Preferences.

```
OSStatus ICEditPreferences (
   ICInstance inst,
   ConstStr255Param key
);
```

Return Value
A result code. See "Result Codes" (page 2538).

Discussion
This function launches the Internet preference control appropriate to the operating system version. In Mac OS X, it opens the Internet pane of System Preferences. In Mac OS 8 and 9 wiith Carbon, it launches the Internet control panel. On earlier systems, it launches Internet Config.

Availability
Available in CarbonLib 1.0.2 and later when Internet Config 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`InternetConfig.h`

ICEnd

Tells Internet Config that you have finished accessing preference information.

```
OSStatus ICEnd (
   ICInstance inst
);
```

Return Value
A result code. See "Result Codes" (page 2538).

Availability
Available in CarbonLib 1.0.2 and later when Internet Config 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`InternetConfig.h`

ICFindConfigFile

Unsupported

```
OSStatus ICFindConfigFile (
    ICInstance inst,
    SInt16 count,
    ICDirSpecArrayPtr folders
);
```

Carbon Porting Notes

Functions related to finding different IC database files are obsolete. You can simply remove these calls from your code—there are no replacement functions.

Declared In
`InternetConfig.h`

ICFindPrefHandle

Gets a preference's data, like `ICGetPref`, but returns the data in a handle.

```
OSStatus ICFindPrefHandle (
   ICInstance inst,
   ConstStr255Param key,
   ICAttr *attr,
   Handle prefh
);
```

Return Value
A result code. See "Result Codes" (page 2538).

Availability
Available in CarbonLib 1.0.2 and later when Internet Config 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`InternetConfig.h`

ICFindUserConfigFile

Unsupported

```
OSStatus ICFindUserConfigFile (
    ICInstance inst,
    ICDirSpec *where
);
```

Carbon Porting Notes

Functions related to finding different IC database files are obsolete. You can simply remove these calls from your code—there are no replacement functions.

Declared In

`InternetConfig.h`

ICGeneralFindConfigFile

Unsupported

```
OSStatus ICGeneralFindConfigFile (
    ICInstance inst,
    Boolean searchPrefs,
    Boolean canCreate,
    SInt16 count,
    ICDirSpecArrayPtr folders
);
```

Carbon Porting Notes

Functions related to finding different IC database files are obsolete. You can simply remove these calls from your code—there are no replacement functions.

Declared In

`InternetConfig.h`

ICGetComponentInstance

Unsupported

```
OSStatus ICGetComponentInstance (
    ICInstance inst,
    ComponentInstance *componentInst
);
```

Carbon Porting Notes

Because Internet Config is not component-based under X, use `ICGetVersion` instead of `ICGetComponentInstance`.

Declared In

`InternetConfig.h`

ICGetConfigName

Returns a displayable string that represents the instance's current configuration.

```
OSStatus ICGetConfigName (
   ICInstance inst,
   Boolean longname,
   Str255 name
);
```

Return Value
A result code. See "Result Codes" (page 2538).

Availability
Available in CarbonLib 1.0.2 and later when Internet Config 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`InternetConfig.h`

ICGetConfigReference

Unsupported

```
OSStatus ICGetConfigReference (
    ICInstance inst,
    ICConfigRefHandle ref
);
```

Carbon Porting Notes

Because Internet Config no longer supports multiple configuration files, this function is obsolete, and there is no replacement function.

Declared In
`InternetConfig.h`

ICGetCurrentProfile

Returns the profile ID of the current profile.

```
OSStatus ICGetCurrentProfile (
   ICInstance inst,
   ICProfileID *currentID
);
```

Return Value
A result code. See "Result Codes" (page 2538).

Availability
Available in CarbonLib 1.0.2 and later when Internet Config 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`InternetConfig.h`

ICGetDefaultPref

Gets the default value for the preference associated with the specified key.

```
OSStatus ICGetDefaultPref (
   ICInstance inst,
   ConstStr255Param key,
   Handle prefH
);
```

Return Value
A result code. See "Result Codes" (page 2538).

Availability
Available in CarbonLib 1.0.2 and later when Internet Config 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`InternetConfig.h`

ICGetIndMapEntry

Returns the mappings database entry for a specified index .

```
OSStatus ICGetIndMapEntry (
   ICInstance inst,
   Handle entries,
   long index,
   long *pos,
   ICMapEntry *entry
);
```

Return Value
A result code. See "Result Codes" (page 2538).

Availability
Available in CarbonLib 1.0.2 and later when Internet Config 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`InternetConfig.h`

ICGetIndPref

Returns the key associated with the preference at the specified index.

```
OSStatus ICGetIndPref (
   ICInstance inst,
   long index,
   Str255 key
);
```

Return Value
A result code. See "Result Codes" (page 2538).

Availability
Available in CarbonLib 1.0.2 and later when Internet Config 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`InternetConfig.h`

ICGetIndProfile

Returns the ID of the profile at the specified index.

```
OSStatus ICGetIndProfile (
   ICInstance inst,
   long index,
   ICProfileID *thisID
);
```

Return Value
A result code. See "Result Codes" (page 2538).

Availability
Available in CarbonLib 1.0.2 and later when Internet Config 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`InternetConfig.h`

ICGetMapEntry

Returns a mappings database entry based on its position in the Mapping preference.

```
OSStatus ICGetMapEntry (
   ICInstance inst,
   Handle entries,
   long pos,
   ICMapEntry *entry
);
```

Return Value
A result code. See "Result Codes" (page 2538).

Availability
Available in CarbonLib 1.0.2 and later when Internet Config 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`InternetConfig.h`

ICGetMappingInterruptSafe

Unsupported

```
OSStatus ICGetMappingInterruptSafe (
    ICInstance inst,
    Ptr *mappingPref,
    SInt32 *mappingPrefSize
);
```

Carbon Porting Notes

Because `ICGetMappingInterruptSafe` is not compatible with preemptive threads, it has been removed from Carbon.

Declared In
`InternetConfig.h`

ICGetPerm

Returns the current permissions for this instance, i.e. the permission value you used when you called `ICBegin`, or returns `ioNoPerm` if you haven't call `ICBegin`.

```
OSStatus ICGetPerm (
   ICInstance inst,
   ICPerm *perm
);
```

Return Value
A result code. See "Result Codes" (page 2538).

Availability
Available in CarbonLib 1.0.2 and later when Internet Config 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`InternetConfig.h`

ICGetPref

Given a preference's key, gets the preference's data and places it into a buffer that you supply.

```
OSStatus ICGetPref (
   ICInstance inst,
   ConstStr255Param key,
   ICAttr *attr,
   void *buf,
   long *size
);
```

Return Value
A result code. See "Result Codes" (page 2538).

Availability
Available in CarbonLib 1.0.2 and later when Internet Config 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`InternetConfig.h`

ICGetPrefHandle

Deprecated. While this function works in Mac OS X, you should use ICFindPrefHandle instead.

```
OSStatus ICGetPrefHandle (
   ICInstance inst,
   ConstStr255Param key,
   ICAttr *attr,
   Handle *prefh
);
```

Return Value
A result code. See "Result Codes" (page 2538).

Availability
Available in CarbonLib 1.0.2 and later when Internet Config 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`InternetConfig.h`

ICGetProfileName

Returns the name of the profile that has the specified ID.

```
OSStatus ICGetProfileName (
   ICInstance inst,
   ICProfileID thisID,
   Str255 name
);
```

Return Value
A result code. See "Result Codes" (page 2538).

Availability
Available in CarbonLib 1.0.2 and later when Internet Config 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`InternetConfig.h`

ICGetSeed

Returns the seed for the current preferences set.

```
OSStatus ICGetSeed (
   ICInstance inst,
   long *seed
);
```

Return Value
A result code. See "Result Codes" (page 2538).

Availability
Available in CarbonLib 1.0.2 and later when Internet Config 2.0 or later is present.

Available in Mac OS X 10.0 and later.

Declared In
`InternetConfig.h`

ICGetSeedInterruptSafe

Unsupported

```
OSStatus ICGetSeedInterruptSafe (
    ICInstance inst,
    SInt32 *seed
);
```

Carbon Porting Notes

Because `ICGetSeedInterruptSafe` is not compatible with preemptive threads, it has been removed from Carbon.

Declared In
`InternetConfig.h`

ICGetVersion

Returns the version of Internet Config installed on the system.

```
OSStatus ICGetVersion (
   ICInstance inst,
   long whichVersion,
   UInt32 *version
);
```

Return Value
A result code. See "Result Codes" (page 2538).

Discussion
For the range of versions, refer to "Version Constants" (page 2538).

Availability
Available in CarbonLib 1.0.2 and later when Internet Config 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`InternetConfig.h`

ICLaunchURL

Parses a URL out of the specified text and feeds it to the appropriate helper application.

```
OSStatus ICLaunchURL (
   ICInstance inst,
   ConstStr255Param hint,
   const void *data,
   long len,
   long *selStart,
   long *selEnd
);
```

Return Value
A result code. See "Result Codes" (page 2538).

Availability
Available in CarbonLib 1.0.2 and later when Internet Config 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`InternetConfig.h`

ICMapEntriesFilename

Given a filename, returns the most appropriate `ICMapEntry` based on the filename extension—without the overhead of a mappings database access.

```
OSStatus ICMapEntriesFilename (
   ICInstance inst,
   Handle entries,
   ConstStr255Param filename,
   ICMapEntry *entry
);
```

Return Value
A result code. See "Result Codes" (page 2538).

Availability
Available in CarbonLib 1.0.2 and later when Internet Config 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`InternetConfig.h`

ICMapEntriesTypeCreator

Given a file type and creator (and optionally a filename), returns the most appropriate `ICMapEntry`—without the overhead of a mappings database access.

```
OSStatus ICMapEntriesTypeCreator (
   ICInstance inst,
   Handle entries,
   OSType fType,
   OSType fCreator,
   ConstStr255Param filename,
   ICMapEntry *entry
);
```

Return Value
A result code. See "Result Codes" (page 2538).

Availability
Available in CarbonLib 1.0.2 and later when Internet Config 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`InternetConfig.h`

ICMapFilename

Given a filename, returns the most appropriate `ICMapEntry` based on the filename extension.

```
OSStatus ICMapFilename (
   ICInstance inst,
   ConstStr255Param filename,
   ICMapEntry *entry
);
```

Return Value
A result code. See "Result Codes" (page 2538).

Availability
Available in CarbonLib 1.0.2 and later when Internet Config 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`InternetConfig.h`

ICMapTypeCreator

Given a file type and creator (and optionally a filename), returns the most appropriate `ICMapEntry`.

```
OSStatus ICMapTypeCreator (
   ICInstance inst,
   OSType fType,
   OSType fCreator,
   ConstStr255Param filename,
   ICMapEntry *entry
);
```

Return Value
A result code. See "Result Codes" (page 2538).

Availability
Available in CarbonLib 1.0.2 and later when Internet Config 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`InternetConfig.h`

ICParseURL

Parses a URL out of the specified text and returns it to the calling program.

```
OSStatus ICParseURL (
   ICInstance inst,
   ConstStr255Param hint,
   const void *data,
   long len,
   long *selStart,
   long *selEnd,
   Handle url
);
```

Return Value
A result code. See "Result Codes" (page 2538).

Availability
Available in CarbonLib 1.0.2 and later when Internet Config 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`InternetConfig.h`

ICRefreshCaches

Unsupported

```
OSStatus ICRefreshCaches (
    ICInstance inst
);
```

Carbon Porting Notes

This function `ICRefreshCaches` is obsolete. There is no supported way to modify the Internet Config database without going through the Internet Config API. There is no replacement function.

Declared In
`InternetConfig.h`

ICRequiresInterruptSafe

Unsupported

```
OSStatus ICRequiresInterruptSafe (
    ICInstance inst
);
```

Carbon Porting Notes

Because `ICRequiresInterruptSafe` is not compatible with preemptive threads, it has been removed from Carbon.

Declared In
`InternetConfig.h`

ICSendGURLEvent

Sends a specified Apple Event to the target application.

```
OSStatus ICSendGURLEvent (
   ICInstance inst,
   AppleEvent *theEvent
);
```

Return Value
A result code. See "Result Codes" (page 2538).

Availability
Available in CarbonLib 1.0.2 and later when Internet Config 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`InternetConfig.h`

ICSetConfigReference

Unsupported

```
OSStatus ICSetConfigReference (
    ICInstance inst,
    ICConfigRefHandle ref,
    SInt32 flags
);
```

Carbon Porting Notes

Because Internet Config no longer supports multiple configuration files, this function is obsolete, and there is no replacement function.

Declared In
`InternetConfig.h`

ICSetCurrentProfile

Sets the current profile to a specified profile ID.

```
OSStatus ICSetCurrentProfile (
   ICInstance inst,
   ICProfileID newID
);
```

Return Value
A result code. See "Result Codes" (page 2538).

Availability
Available in CarbonLib 1.0.2 and later when Internet Config 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`InternetConfig.h`

ICSetMapEntry

Sets an entry in a specified Mapping preference.

```
OSStatus ICSetMapEntry (
   ICInstance inst,
   Handle entries,
   long pos,
   const ICMapEntry *entry
);
```

Return Value
A result code. See "Result Codes" (page 2538).

Availability
Available in CarbonLib 1.0.2 and later when Internet Config 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`InternetConfig.h`

ICSetPref

Sets a preference given its key, attributes, and a buffer containing the preference data.

```
OSStatus ICSetPref (
   ICInstance inst,
   ConstStr255Param key,
   ICAttr attr,
   const void *buf,
   long size
);
```

Return Value
A result code. See "Result Codes" (page 2538).

Availability
Available in CarbonLib 1.0.2 and later when Internet Config 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`InternetConfig.h`

ICSetPrefHandle

Sets a preference, like `ICSetPref`, but takes its input as a handle.

```
OSStatus ICSetPrefHandle (
   ICInstance inst,
   ConstStr255Param key,
   ICAttr attr,
   Handle prefh
);
```

Return Value
A result code. See "Result Codes" (page 2538).

Availability
Available in CarbonLib 1.0.2 and later when Internet Config 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`InternetConfig.h`

ICSetProfileName

Sets the name of the profile that has the specified ID.

```
OSStatus ICSetProfileName (
   ICInstance inst,
   ICProfileID thisID,
   ConstStr255Param name
);
```

Return Value
A result code. See "Result Codes" (page 2538).

Availability
Available in CarbonLib 1.0.2 and later when Internet Config 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`InternetConfig.h`

ICSpecifyConfigFile

Unsupported

```
OSStatus ICSpecifyConfigFile (
    ICInstance inst,
    FSSpec *config
);
```

Carbon Porting Notes

Functions related to finding different IC database files are obsolete. You can simply remove these calls from your code—there are no replacement functions.

Declared In
`InternetConfig.h`

ICStart

Call this routine to start using Internet Config—typically at application initialization time—passing it your program's creator code.

```
OSStatus ICStart (
   ICInstance *inst,
   OSType signature
);
```

Return Value
A result code. See "Result Codes" (page 2538).

Availability
Available in CarbonLib 1.0.2 and later when Internet Config 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`InternetConfig.h`

ICStop

Call this when your application is done using Internet Config, passing it the instance you got from `ICStart`.

```
OSStatus ICStop (
   ICInstance inst
);
```

Return Value
A result code. See "Result Codes" (page 2538).

Availability
Available in CarbonLib 1.0.2 and later when Internet Config 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`InternetConfig.h`

Data Types

ICAppSpec

A fixed length record used to specify an application.

```
struct ICAppSpec {
    OSType fCreator;
    Str63 name;
};
typedef struct ICAppSpec ICAppSpec;
typedef ICAppSpec * ICAppSpecPtr;
typedef ICAppSpecPtr * ICAppSpecHandle;
```

Discussion
The program using this specification is expected to look up the location of the application in the desktop database. The name is provided to display to the user, and should not affect the search.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`InternetConfig.h`

ICAppSpecList

Represents a list of application specifications.

```
struct ICAppSpecList {
    short numberOfItems;
    ICAppSpec appSpecs[1];
};
typedef struct ICAppSpecList ICAppSpecList;
typedef ICAppSpecList * ICAppSpecListPtr;
typedef ICAppSpecListPtr * ICAppSpecListHandle;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`InternetConfig.h`

ICCharTable

Specifies a mapping from MacRoman encoding (kTextEncodingMacRoman) to Mac Net ASCII (kTextEncodingMacRomanLatin1) and vice versa.

```
struct ICCharTable {
    unsigned char netToMac[256];
    unsigned char macToNet[256];
};
typedef struct ICCharTable ICCharTable;
typedef ICCharTable * ICCharTablePtr;
typedef ICCharTablePtr * ICCharTableHandle;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`InternetConfig.h`

ICConfigRef

Stores a permanent reference to an Internet Config configuration.

```
struct ICConfigRef {
    OSType manufacturer;
};
typedef struct ICConfigRef ICConfigRef;
typedef ICConfigRef * ICConfigRefPtr;
typedef ICConfigRefPtr * ICConfigRefHandle;
```

Discussion
The `ICConfigRef` type varies in length and only the first four bytes, representing the manufacturer field, has a public meaning. For more information see the IC Internals Documentation.

Availability
Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared In
`InternetConfig.h`

ICDirSpec

Holds the `vRefNum` and `dirID` of a directory.

```
struct ICDirSpec {
    short vRefNum;
    long dirID;
};
typedef struct ICDirSpec ICDirSpec;
typedef ICDirSpec ICDirSpecArray[4];
typedef ICDirSpecArray * ICDirSpecArrayPtr;
```

Discussion
An array of `ICDirSpec` records is supplied to the pre-Carbon-only function `ICFindConfigFile` to specify the search path. This array is defined to contain just 4 elements, but is in fact arbitrarily extensible.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`InternetConfig.h`

ICError

Used for all error results from Internet Config.

```
typedef long ICError;
```

Discussion
ICError uses a long integer because Internet Config makes calls to Component Manager, which uses long integers for error codes.

Special Considerations

This data type is available only if you define `OLDROUTINENAMES`.

Availability
Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared In
`InternetConfig.h`

ICFileInfo

Defines the format of a key.

```
struct ICFileInfo {
    OSType fType;
    OSType fCreator;
    Str63 name;
};
typedef struct ICFileInfo ICFileInfo;
typedef ICFileInfo * ICFileInfoPtr;
typedef ICFileInfoPtr * ICFileInfoHandle;
```

Special Considerations

This data type defines the format of a key. That key data type has previouisly been removed from the header file. `ICFileInfo` is deprecated and will also be removed, but for the moment, it is available if you define `OLDROUTINENAMES`.

Availability
Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared In
`InternetConfig.h`

ICFileSpec

A variable length data structure used to specify a file or folder.

```
struct ICFileSpec {
    Str31 volName;
    long volCreationDate;
    FSSpec fss;
    AliasRecord alias;
};
typedef struct ICFileSpec ICFileSpec;
typedef ICFileSpec * ICFileSpecPtr;
typedef ICFileSpecPtr * ICFileSpecHandle;
```

Discussion
`ICFileSpec` contains both an alias and a 'poor man's alias.' All modern applications can use the real alias and ignore the poor man's alias. The latter was included so that programs running under System 6 could specify file positions using `vol_name` and `vol_creation_date` for the volume, `fss.parID` for the directory on the volume, and `fss.name` for the file in the directory.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`InternetConfig.h`

ICFontRecord

A fixed length record used to specify a font, size and face.

```
struct ICFontRecord {
    short size;
    Style face;
    char pad;
    Str255 font;
};
typedef struct ICFontRecord ICFontRecord;
typedef ICFontRecord * ICFontRecordPtr;
typedef ICFontRecordPtr * ICFontRecordHandle;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`InternetConfig.h`

ICInstance

An opaque type used to hold a reference to a session with Internet Config.

```
typedef struct OpaqueICInstance * ICInstance;
```

Discussion
Applications can create IC instances by calling `ICStart`, use them with any of the API routines, and destroy them by calling `ICStop`.

An `ICInstance` is a pointer, so you can use the system `nil` value to denote an invalid instance. Do not pass an `ICInstance` between processes. Also, do not pass an `ICInstance` between instruction set architectures, i.e. from PowerPC to 68K or vice versa.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`InternetConfig.h`

ICMapEntry

Specifies an Internet Config map entry.

```
struct ICMapEntry {
    short totalLength;
    ICFixedLength fixedLength;
    short version;
    OSType fileType;
    OSType fileCreator;
    OSType postCreator;
    ICMapEntryFlags flags;
    Str255 extension;
    Str255 creatorAppName;
    Str255 postAppName;
    Str255 MIMEType;
    Str255 entryName;
};
typedef struct ICMapEntry ICMapEntry;
typedef ICMapEntry * ICMapEntryPtr;
typedef ICMapEntryPtr * ICMapEntryHandle;
```

Fields

`totalLength`
The length of the map entry, in bytes, from beginning of the record. This includes the fixed length, the length of the packed Pascal strings at the end of the entry, and the length of the user data that follow those strings.

`fixedLength`
The length of the fixed part of the map entry, in bytes, from beginning of the record.

`version`
The version number of the map entry. The only version currently defined is 0.

`fileType`
The four-character file type for the map entry.

`fileCreator`
The four-character creator code for the map entry.

`postCreator`
The creator code for the post-processing application for the map entry. Applications should consult this field only if the `ICmap_post_bit` is set in the `flags` field, but even if that bit is not set, applications can determine the post-processing application by looking at this field. If no post processing application has even been set, this field's value will be 0.

`flags`
: Flags associated with this map entry. For flag definitions, see "Map Constants" (page 2532), "Map Entry Flags" (page 2533), and "Map Entry Masks" (page 2534).

`extension`
: The filename extension for this map entry.

`creatorAppName`
: The name of the creator application identified by the `fileCreator` field. You can use this field to display the application name even if the application is not installed.

`postAppName`
: The name of the post-processing application identified by the `postCreator` field. You can use this field to display the post-processing application's name even if the that application is not installed. See the `post_creator` field description for details as to when this field is valid.

`MIMEType`
: The MIME type for the map entry, for example, "application/zip".

`entryName`
: The user-visible name for the map entry.

Discussion
The value of the Mappings preference is not an array, so you cannot index it directly. It is instead a packed array of `ICMapEntry` types, with each entry packed to remove the empty space at the end of the strings. Entries can start on an odd address and entries can contain user data . We strongly recommend that you access this data structure using the routines described in this section. These routines return an unpacked `ICMapEntry`, which is a lot easier to deal with.

Each `ICMapEntry` data type provides a filename extension, a MIME type, and a file type and creator. The database of `ICMapEntry` types is not normalised; that is, there can be multiple entries with the same creator, file type, MIME type, filename extension, and so on. In general, each application determines how these entries are used in a particular circumstance, although IC does define some policies by way of its high level mapping routines.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`InternetConfig.h`

ICServiceEntry

Specifies an Internet Config TCP service entry.

```
struct ICServiceEntry {
    Str255 name;
    short port;
    ICServiceEntryFlags flags;
};
typedef struct ICServiceEntry ICServiceEntry;
typedef ICServiceEntry * ICServiceEntryPtr;
typedef ICServiceEntryPtr * ICServiceEntryHandle;
```

Fields
`name`
: The name for the TCP service entry.

`port`
The port for the TCP service entry.

`flags`
For descriptions of the flags, see "Services Constants" (page 2535), "Services Bits" (page 2537), and "Services Masks" (page 2537).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`InternetConfig.h`

ICServices

Specifies the mapping between TCP service names and their ports.

```
struct ICServices {
    short count;
    ICServiceEntry services[1];
};
typedef struct ICServices ICServices;
typedef ICServices * ICServicesPtr;
typedef ICServicesPtr * ICServicesHandle;
```

Fields
`count`
`services`
An unbounded array of `ICServiceEntry` (page 2515)records.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`InternetConfig.h`

internetConfigurationComponent

```
typedef ComponentInstance internetConfigurationComponent;
```

Special Considerations

This data type is obsolete. Use the data type `ICInstance` (page 2513) instead.

Availability
Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared In
`InternetConfig.h`

Constants

Apple Event Constants

```
enum {
    kInternetEventClass = 'GURL',
    kAEGetURL = 'GURL',
    kAEFetchURL = 'FURL',
    keyAEAttaching = 'Atch'
};
```

Attribute Constants

These are old names, mapped to newer names for backward compatibility, available only if you define `OLDROUTINENAMES`.

```
enum {
    ICattr_no_change = (unsigned long) (kICAttrNoChange),
    ICattr_locked_bit = kICAttrLockedBit,
    ICattr_locked_mask = kICAttrLockedMask,
    ICattr_volatile_bit = kICAttrVolatileBit,
    ICattr_volatile_mask = kICAttrVolatileMask,
    icNoUserInteraction_bit = kICNoUserInteractionBit,
    icNoUserInteraction_mask = kICNoUserInteractionMask,
    ICfiletype = kICFileType,
    ICcreator = kICCreator
};
```

Component Identifiers

Define the component type, subtype, and manufacturer of the Internet Config component.

```
enum {
    kICComponentType = 'PREF',
    kICComponentSubType = 'ICAp',
    kICComponentManufacturer = 'JPQE'
};
```

Component Identifiers (Deprecated)

```
enum {
    internetConfigurationComponentType = 'PREF',
    internetConfigurationComponentSubType = 'ICAp',
    internetConfigurationComponentInterfaceVersion0 = 0x00000000,
    internetConfigurationComponentInterfaceVersion1 = 0x00010000,
    internetConfigurationComponentInterfaceVersion2 = 0x00020000,
    internetConfigurationComponentInterfaceVersion3 = 0x00030000,
    internetConfigurationComponentInterfaceVersion =
internetConfigurationComponentInterfaceVersion3
};
```

Discussion
These constants are deprecated. Please use `Component Interface Version` (page 2518) and `Component Identifiers` (page 2517) instead.

Component Interface Version

Define the possible version numbers returned by the Internet Config component.

```
enum {
    kICComponentInterfaceVersion0 = 0x00000000,
    kICComponentInterfaceVersion1 = 0x00010000,
    kICComponentInterfaceVersion2 = 0x00020000,
    kICComponentInterfaceVersion3 = 0x00030000,
    kICComponentInterfaceVersion4 = 0x00040000,
    kICComponentInterfaceVersion = kICComponentInterfaceVersion4
};
```

Constants

`kICComponentInterfaceVersion0`
Internet Config versions greater than or equal to 1.0.
Available in Mac OS X v10.0 and later.
Declared in `InternetConfig.h`.

`kICComponentInterfaceVersion1`
Internet Config versions greater than or equal to 1.1.
Available in Mac OS X v10.0 and later.
Declared in `InternetConfig.h`.

`kICComponentInterfaceVersion2`
Internet Config versions greater than or equal to 1.2.
Available in Mac OS X v10.0 and later.
Declared in `InternetConfig.h`.

`kICComponentInterfaceVersion3`
Internet Config versions greater than or equal to 2.0.
Available in Mac OS X v10.0 and later.
Declared in `InternetConfig.h`.

`kICComponentInterfaceVersion4`
Internet Config versions greater than or equal to 2.5.
Available in Mac OS X v10.0 and later.
Declared in `InternetConfig.h`.

`kICComponentInterfaceVersion`
The current version number is 4.
Available in Mac OS X v10.0 and later.
Declared in `InternetConfig.h`.

Discussion
These constants define the possible version numbers returned by the Internet Config component in response to a `ICGetVersion` (page 2502) call. The constants define only the high word of the version number, which is the version of the programming interface. The low word of the version number is the implementation version, which changes with each bug fix release of Internet Config.

Component Selectors

Represent component selectors for each Internet Config function.

```
enum {
    kICCStart = 0,
    kICCStop = 1,
    kICCGetVersion = 50,
    kICCFindConfigFile = 2,
    kICCFindUserConfigFile = 14,
    kICCGeneralFindConfigFile = 30,
    kICCChooseConfig = 33,
    kICCChooseNewConfig = 34,
    kICCGetConfigName = 35,
    kICCGetConfigReference = 31,
    kICCSetConfigReference = 32,
    kICCSpecifyConfigFile = 3,
    kICCRefreshCaches = 47,
    kICCGetSeed = 4,
    kICCGetPerm = 13,
    kICCDefaultFileName = 11,
    kICCBegin = 5,
    kICCGetPref = 6,
    kICCSetPref = 7,
    kICCFindPrefHandle = 36,
    kICCGetPrefHandle = 26,
    kICCSetPrefHandle = 27,
    kICCCountPref = 8,
    kICCGetIndPref = 9,
    kICCDeletePref = 12,
    kICCEnd = 10,
    kICCGetDefaultPref = 49,
    kICCEditPreferences = 15,
    kICCLaunchURL = 17,
    kICCParseURL = 16,
    kICCCreateGURLEvent = 51,
    kICCSendGURLEvent = 52,
    kICCMapFilename = 24,
    kICCMapTypeCreator = 25,
    kICCMapEntriesFilename = 28,
    kICCMapEntriesTypeCreator = 29,
    kICCCountMapEntries = 18,
    kICCGetIndMapEntry = 19,
    kICCGetMapEntry = 20,
    kICCSetMapEntry = 21,
    kICCDeleteMapEntry = 22,
    kICCAddMapEntry = 23,
    kICCGetCurrentProfile = 37,
    kICCSetCurrentProfile = 38,
    kICCCountProfiles = 39,
    kICCGetIndProfile = 40,
    kICCGetProfileName = 41,
    kICCSetProfileName = 42,
    kICCAddProfile = 43,
    kICCDeleteProfile = 44,
    kICCRequiresInterruptSafe = 45,
    kICCGetMappingInterruptSafe = 46,
    kICCGetSeedInterruptSafe = 48,
    kICCFirstSelector = kICCStart,
    kICCLastSelector = 52
};
```

Discussion
These constants are component selectors for each Internet Config fuction. You can use these values as parameters to the Component Manager's `ComponentFunctionImplemented` function. These are also useful for authors of override components.

Component Selector Proc Information

```
enum {
    kICCStartProcInfo = 1008,
    kICCStopProcInfo = 240,
    kICCGetVersionProcInfo = 4080,
    kICCFindConfigFileProcInfo = 3824,
    kICCFindUserConfigFileProcInfo = 1008,
    kICCGeneralFindConfigFileProcInfo = 58864,
    kICCChooseConfigProcInfo = 240,
    kICCChooseNewConfigProcInfo = 240,
    kICCGetConfigNameProcInfo = 3568,
    kICCGetConfigReferenceProcInfo = 1008,
    kICCSetConfigReferenceProcInfo = 4080,
    kICCSpecifyConfigFileProcInfo = 1008,
    kICCRefreshCachesProcInfo = 240,
    kICCGetSeedProcInfo = 1008,
    kICCGetPermProcInfo = 1008,
    kICCDefaultFileNameProcInfo = 1008,
    kICCGetComponentInstanceProcInfo = 1008,
    kICCBeginProcInfo = 496,
    kICCGetPrefProcInfo = 65520,
    kICCSetPrefProcInfo = 65520,
    kICCFindPrefHandleProcInfo = 16368,
    kICCGetPrefHandleProcInfo = 16368,
    kICCSetPrefHandleProcInfo = 16368,
    kICCCountPrefProcInfo = 1008,
    kICCGetIndPrefProcInfo = 4080,
    kICCDeletePrefProcInfo = 1008,
    kICCEndProcInfo = 240,
    kICCGetDefaultPrefProcInfo = 4080,
    kICCEditPreferencesProcInfo = 1008,
    kICCLaunchURLProcInfo = 262128,
    kICCParseURLProcInfo = 1048560,
    kICCCreateGURLEventProcInfo = 16368,
    kICCSendGURLEventProcInfo = 1008,
    kICCMapFilenameProcInfo = 4080,
    kICCMapTypeCreatorProcInfo = 65520,
    kICCMapEntriesFilenameProcInfo = 16368,
    kICCMapEntriesTypeCreatorProcInfo = 262128,
    kICCCountMapEntriesProcInfo = 4080,
    kICCGetIndMapEntryProcInfo = 65520,
    kICCGetMapEntryProcInfo = 16368,
    kICCSetMapEntryProcInfo = 16368,
    kICCDeleteMapEntryProcInfo = 4080,
    kICCAddMapEntryProcInfo = 4080,
    kICCGetCurrentProfileProcInfo = 1008,
    kICCSetCurrentProfileProcInfo = 1008,
    kICCCountProfilesProcInfo = 1008,
    kICCGetIndProfileProcInfo = 4080,
    kICCGetProfileNameProcInfo = 4080,
    kICCSetProfileNameProcInfo = 4080,
    kICCAddProfileProcInfo = 4080,
    kICCDeleteProfileProcInfo = 1008,
    kICCRequiresInterruptSafeProcInfo = 240,
    kICCGetMappingInterruptSafeProcInfo = 4080,
    kICCGetSeedInterruptSafeProcInfo = 1008
};
```

Edit Preference Constants

Specify AppleEvent details for Internet Config preference requests.

```
enum {
    kICEditPreferenceEventClass = 'ICAp',
    kICEditPreferenceEvent = 'ICAp',
    keyICEditPreferenceDestination = 'dest'
};
```

Discussion
These constants specify details of the AppleEvent that the `ICEditPreferences` (page 2494) function sends to the Internet Config application to request it to open the edit window for a specific preference. Consult the Internet Config terminology resource (`'aete'`) for the meaning of these constants.

File Specification Header Size

```
enum {
    kICFileSpecHeaderSize = sizeof(ICFileSpec) - sizeof(AliasRecord)
};
```

File Specification Header Size (Deprecated)

```
enum {
    ICfile_spec_header_size = kICFileSpecHeaderSize
};
```

Discussion
This constant is available only if you define `OLDROUTINENAMES`.

File Type Constants

Define the file type and creator code for the Internet preferences file.

```
enum {
    kICFileType = 'ICAp',
    kICCreator = 'ICAp'
};
```

Constants

`kICFileType`
The Finder file type for the Internet preferences file.
Available in Mac OS X v10.0 and later.
Declared in `InternetConfig.h`.

`kICCreator`
The Finder creator code for the Internet preferences file.
Available in Mac OS X v10.0 and later.
Declared in `InternetConfig.h`.

Keys

```
#define kICReservedKey                  "\pkICReservedKey"
#define kICArchieAll                    "\pArchieAll"
#define kICArchiePreferred              "\pArchiePreferred"
#define kICCharacterSet                 "\pCharacterSet"
#define kICDocumentFont                 "\pDocumentFont"
#define kICDownloadFolder               "\pDownloadFolder"
#define kICEmail                        "\pEmail"
#define kICFTPHost                      "\pFTPHost"
#define kICFTPProxyAccount              "\pFTPProxyAccount"
#define kICFTPProxyHost                 "\pFTPProxyHost"
#define kICFTPProxyPassword             "\pFTPProxyPassword"
#define kICFTPProxyUser                 "\pFTPProxyUser"
#define kICFingerHost                   "\pFingerHost"
#define kICGopherHost                   "\pGopherHost"
#define kICGopherProxy                  "\pGopherProxy"
#define kICHTTPProxyHost                "\pHTTPProxyHost"
#define kICHelper                       "\pHelper•"
#define kICHelperDesc                   "\pHelperDesc•"
#define kICHelperList                   "\pHelperList•"
#define kICIRCHost                      "\pIRCHost"
#define kICInfoMacAll                   "\pInfoMacAll"
#define kICInfoMacPreferred             "\pInfoMacPreferred"
#define kICLDAPSearchbase               "\pLDAPSearchbase"
#define kICLDAPServer                   "\pLDAPServer"
#define kICListFont                     "\pListFont"
#define kICMacSearchHost                "\pMacSearchHost"
#define kICMailAccount                  "\pMailAccount"

#define kICMailPassword                 "\pMailPassword"
#define kICMapping                      "\pMapping"
#define kICNNTPHost                     "\pNNTPHost"
#define kICNTPHost                      "\pNTPHost"
#define kICNewMailDialog                "\pNewMailDialog"
#define kICNewMailFlashIcon             "\pNewMailFlashIcon"
#define kICNewMailPlaySound             "\pNewMailPlaySound"
#define kICNewMailSoundName             "\pNewMailSoundName"
#define kICNewsAuthPassword             "\pNewsAuthPassword"
#define kICNewsAuthUsername             "\pNewsAuthUsername"
#define kICNewsHeaders                  "\pNewsHeaders"
#define kICNoProxyDomains               "\pNoProxyDomains"
#define kICOrganization                 "\pOrganization"
#define kICPhHost                       "\pPhHost"
#define kICPlan                         "\pPlan"
#define kICPrinterFont                  "\pPrinterFont"
#define kICQuotingString                "\pQuotingString"
#define kICRealName                     "\pRealName"
#define kICRTSPProxyHost                "\pRTSPProxyHost"
#define kICSMTPHost                     "\pSMTPHost"
#define kICScreenFont                   "\pScreenFont"
#define kICServices                     "\pServices"
#define kICSignature                    "\pSignature"
#define kICSnailMailAddress             "\pSnailMailAddress"
#define kICSocksHost                    "\pSocksHost"
#define kICTelnetHost                   "\pTelnetHost"
#define kICUMichAll                     "\pUMichAll"
#define kICUMichPreferred               "\pUMichPreferred"
```

```
#define kICUseFTPProxy                  "\pUseFTPProxy"
#define kICUseGopherProxy               "\pUseGopherProxy"
#define kICUseHTTPProxy                 "\pUseHTTPProxy"
#define kICUsePassiveFTP                "\pUsePassiveFTP"
#define kICUseRTSPProxy                 "\pUseRTSPProxy"
#define kICUseSocks                     "\pUseSocks"
#define kICWAISGateway                  "\pWAISGateway"
#define kICWWWHomePage                  "\pWWWHomePage"
#define kICWebBackgroundColour          "\pWebBackgroundColour"
#define kICWebReadColor                 "\p646F6777•WebReadColor"
#define kICWebSearchPagePrefs           "\pWebSearchPagePrefs"
#define kICWebTextColor                 "\pWebTextColor"
#define kICWebUnderlineLinks            "\p646F6777•WebUnderlineLinks"
#define kICWebUnreadColor               "\p646F6777•WebUnreadColor"
#define kICWhoisHost                    "\pWhoisHost"
```

Constants

`kICReservedKey`

Reserved for use by Internet Config.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICArchieAll`

Formatted string list of Archie servers.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICArchiePreferred`

Formatted string naming the preferred Archie server.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICCharacterSet`

For conversion between kTextEncodingMacRoman (“Mac”) and kTextEncodingMacRomanLatin1 (“Net”). Deprecated. Use the Text Encoding Conversion manager and Unicode instead.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICDocumentFont`

Font to use for proportional text.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICDownloadFolder`

Location in the file system for newly downloaded files.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICEmail`

Return address for the user.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICFTPHost`
Default FTP server.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICFTPProxyAccount`
Second-level FTP proxy authorization. Read-only in Mac OS X; use System Configuration to set this value.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICFTPProxyHost`
Default FTP proxy server. Read-only in Mac OS X; use System Configuration to set this value.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICFTPProxyPassword`
Password (scrambled) for FTP proxy user. Read-only in Mac OS X; use System Configuration to set this value.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICFTPProxyUser`
First-level FTP proxy authorization. Read-only in Mac OS X; use System Configuration to set this value.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICFingerHost`
Default finger-protocol server.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICGopherHost`
Default gopher-protocol server.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICGopherProxy`
Read-only in Mac OS X; use System Configuration to set this value.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICHTTPProxyHost`
Default HTTP proxy server. Read-only in Mac OS X; use System Configuration to set this value.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICHelper`
Helpers for URL schemes.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICHelperDesc`
Descriptions for URL schemes.
Available in Mac OS X v10.0 and later.
Declared in `InternetConfig.h`.

`kICHelperList`
Common helpers for URL schemes.
Available in Mac OS X v10.0 and later.
Declared in `InternetConfig.h`.

`kICIRCHost`
Internet Relay Chat server.
Available in Mac OS X v10.0 and later.
Declared in `InternetConfig.h`.

`kICInfoMacAll`
Formatted list of Info-Mac servers.
Available in Mac OS X v10.0 and later.
Declared in `InternetConfig.h`.

`kICInfoMacPreferred`
Formatted string containing preferred Info-Mac server.
Available in Mac OS X v10.0 and later.
Declared in `InternetConfig.h`.

`kICLDAPSearchbase`
Default LDAP search base.
Available in Mac OS X v10.0 and later.
Declared in `InternetConfig.h`.

`kICLDAPServer`
Default LDAP server.
Available in Mac OS X v10.0 and later.
Declared in `InternetConfig.h`.

`kICListFont`
Font used for lists, such as news article lists.
Available in Mac OS X v10.0 and later.
Declared in `InternetConfig.h`.

`kICMacSearchHost`
Host for MacSearch queries.
Available in Mac OS X v10.0 and later.
Declared in `InternetConfig.h`.

`kICMailAccount`
Account from which to fetch email.
Available in Mac OS X v10.0 and later.
Declared in `InternetConfig.h`.

`kICMailHeaders`
: Additional headers for email messages.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICMailPassword`
: Password (scrambled) for the default mail account.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICMapping`
: File-type mapping.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICNNTPHost`
: Default NNTP server.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICNTPHost`
: Default NTP (Network Time Protocol) server.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICNewMailDialog`
: Boolean value indicating whether to display a new email dialog.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICNewMailFlashIcon`
: Boolean value indicating whether to flash a new email icon.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICNewMailPlaySound`
: Boolean value indicating whether to play a new email sound.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICNewMailSoundName`
: The name of the preferred new email sound.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICNewsAuthPassword`
: Password (scrambled) for authorized news account.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICNewsAuthUsername`
User name for authorized news account.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICNewsHeaders`
Additional headers for news messages.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICNoProxyDomains`
List of domains not to be proxied.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICOrganization`
String for the X-Organization MIME header.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICPhHost`
Default Ph protocol server.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICPlan`
Default response for finger servers.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICPrinterFont`
Font used to print the monospaced text displayed on screen (see kICScreenFont).

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICQuotingString`
A short string used to indicate quoting in email and news replies.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICRealName`
Real name of user.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICRTSPProxyHost`
Default RTSP proxy server. Read-only in Mac OS X; use System Configuration to set this value.

Available in Mac OS X v10.1 and later.

Declared in `InternetConfig.h`.

`kICSMTPHost`
Default SMTP host.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICScreenFont`
Font for monospaced text.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICServices`
TCP and IP port-to-name mapping.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICSignature`
Block of text to append to outgoing news and email messages.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICSnailMailAddress`
Preferred postal mail address.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICSocksHost`
Default SOCKS host. (The host.domain format allows ":port" and " port")

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICTelnetHost`
Default Telnet host.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICUMichAll`
Formatted list of UMich servers.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICUMichPreferred`
Formatted string containing preferred UMich server.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICUseFTPProxy`
Boolean value indicating whether to use an FTP proxy. Read-only in Mac OS X; use System Configuration to set this value.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICUseGopherProxy`
: Boolean value indicating whether to use a Gopher proxy. Read-only in Mac OS X; use System Configuration to set this value.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICUseHTTPProxy`
: Boolean value indicating whether to use an HTTP proxy. Read-only in Mac OS X; use System Configuration to set this value.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICUsePassiveFTP`
: Boolean value indicating whether to use the PASV command for FTP transfers.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICUseRTSPProxy`
: Boolean value indicating whether to use an RTSP proxy. Read-only in Mac OS X; use System Configuration to set this value.

Available in Mac OS X v10.1 and later.

Declared in `InternetConfig.h`.

`kICUseSocks`
: Boolean value indicating whether to use SOCKS.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICWAISGateway`
: Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICWWWHomePage`
: User's default Web home page.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICWebBackgroundColour`
: Background color for Web pages.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICWebReadColor`
: Color for Web links that have been visited.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICWebSearchPagePrefs`
: URL for the default search engine page.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICWebTextColor`
Color for normal text on Web pages.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICWebUnderlineLinks`
Boolean value indicating whether to underline Web links.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICWebUnreadColor`
Color for Web links that have not been visited.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

`kICWhoisHost`
Default whois server.

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

Map Constants

```
enum {
    ICmap_binary_bit = kICMapBinaryBit,
    ICmap_binary_mask = kICMapBinaryMask,
    ICmap_resource_fork_bit = kICMapResourceForkBit,
    ICmap_resource_fork_mask = kICMapResourceForkMask,
    ICmap_data_fork_bit = kICMapDataForkBit,
    ICmap_data_fork_mask = kICMapDataForkMask,
    ICmap_post_bit = kICMapPostBit,
    ICmap_post_mask = kICMapPostMask,
    ICmap_not_incoming_bit = kICMapNotIncomingBit,
    ICmap_not_incoming_mask = kICMapNotIncomingMask,
    ICmap_not_outgoing_bit = kICMapNotOutgoingBit,
    ICmap_not_outgoing_mask = kICMapNotOutgoingMask,
    ICmap_fixed_length = kICMapFixedLength
};
```

Discussion
For descriptions of these constants, see "Map Entry Flags" (page 2533) and "Map Entry Masks" (page 2534). These constants are available only if you define `OLDROUTINENAMES`.

Map Entry Flags

```
typedef long ICMapEntryFlags;
enum {
    kICMapBinaryBit = 0,
    kICMapResourceForkBit = 1,
    kICMapDataForkBit = 2,
    kICMapPostBit = 3,
    kICMapNotIncomingBit = 4,
    kICMapNotOutgoingBit = 5
};
```

Constants

`kICMapBinaryBit`
When this bit is set, indicates the file should be transferred in binary as opposed to text mode.
Available in Mac OS X v10.0 and later.
Declared in `InternetConfig.h`.

`kICMapResourceForkBit`
When this bit is set, indicates the resource fork of the file is significant.
Available in Mac OS X v10.0 and later.
Declared in `InternetConfig.h`.

`kICMapDataForkBit`
When this bit is set, indicates the data fork of the file is significant.
Available in Mac OS X v10.0 and later.
Declared in `InternetConfig.h`.

`kICMapPostBit`
When this bit is set, indicates post process using post fields.
Available in Mac OS X v10.0 and later.
Declared in `InternetConfig.h`.

`kICMapNotIncomingBit`
When this bit is set, indicates to ignore this mapping for incoming files.
Available in Mac OS X v10.0 and later.
Declared in `InternetConfig.h`.

`kICMapNotOutgoingBit`
When this bit is set, indicates to ignore this mapping for outgoing files.
Available in Mac OS X v10.0 and later.
Declared in `InternetConfig.h`.

Map Entry Masks

```
enum {
    kICMapBinaryMask = 0x00000001,
    kICMapResourceForkMask = 0x00000002,
    kICMapDataForkMask = 0x00000004,
    kICMapPostMask = 0x00000008,
    kICMapNotIncomingMask = 0x00000010,
    kICMapNotOutgoingMask = 0x00000020
};
```

Constants

`kICMapBinaryMask`
Indicates the file should be transferred in binary as opposed to text mode.
Available in Mac OS X v10.0 and later.
Declared in `InternetConfig.h`.

`kICMapResourceForkMask`
Indicates the resource fork of the file is significant.
Available in Mac OS X v10.0 and later.
Declared in `InternetConfig.h`.

`kICMapDataForkMask`
Indicates the data fork of the file is significant.
Available in Mac OS X v10.0 and later.
Declared in `InternetConfig.h`.

`kICMapPostMask`
Indicates to post process using post fields.
Available in Mac OS X v10.0 and later.
Declared in `InternetConfig.h`.

`kICMapNotIncomingMask`
Indicates to ignore this mapping for incoming files.
Available in Mac OS X v10.0 and later.
Declared in `InternetConfig.h`.

`kICMapNotOutgoingMask`
Indicates to ignore this mapping for outgoing files.
Available in Mac OS X v10.0 and later.
Declared in `InternetConfig.h`.

Map Fixed Length Constants

```
typedef short     ICFixedLength;
enum {
    kICMapFixedLength = 22
};
```

Constants

`kICMapFixedLength`

Use in the `fixedLength` field of a structure `ICMapEntry` (page 2514).

Available in Mac OS X v10.0 and later.

Declared in `InternetConfig.h`.

Services Constants

```
enum {
    ICservices_tcp_bit = kICServicesTCPBit,
    ICservices_tcp_mask = kICServicesTCPMask,
    ICservices_udp_bit = kICServicesUDPBit,
    ICservices_udp_mask = kICServicesUDPMask
};
```

Special Considerations

These constants are available only if you define `OLDROUTINENAMES`.

Permissions

The ICPerm type is used to specify whether you wish to access the preferences as read-only or read/write.

```
typedef UInt8 ICPerm;
enum {
    icNoPerm = 0,
    icReadOnlyPerm = 1,
    icReadWritePerm = 2
};
```

Preference Attribute Bits and Masks

```
typedef UInt32 ICAttr;
enum {
    kICAttrLockedBit = 0,
    kICAttrVolatileBit = 1
};
```

```
enum {
    kICAttrNoChange = 0xFFFFFFFF,
    kICAttrLockedMask = 0x00000001,
    kICAttrVolatileMask = 0x00000002
};
```

Constants

`kICAttrLockedBit`
If the locked bit is set, any attempt to set the preference will result in an error.
Available in Mac OS X v10.0 and later.
Declared in `InternetConfig.h`.

`kICAttrVolatileBit`
If the volatile bit is set, you should not cache the value of this preference because it is subject to non-seed changing changes.
Available in Mac OS X v10.0 and later.
Declared in `InternetConfig.h`.

`kICAttrNoChange`
Used when you call ICSetPref and do not want to mess around with attributes. You can supply this value and IC will not change the attribute of the preference.
Available in Mac OS X v10.0 and later.
Declared in `InternetConfig.h`.

`kICAttrLockedMask`
Available in Mac OS X v10.0 and later.
Declared in `InternetConfig.h`.

`kICAttrVolatileMask`
Available in Mac OS X v10.0 and later.
Declared in `InternetConfig.h`.

Discussion
The ICAttr type is simply a longint containing flags that describe the attributes of a key and its data.

Preference Attribute Masks

```
enum {
    kICAttrNoChange = 0xFFFFFFFF,
    kICAttrLockedMask = 0x00000001,
    kICAttrVolatileMask = 0x00000002
};
```

Profile IDs

The `ICProfileID` type is an opaque reference to a particular profile.

```
typedef long ICProfileID;
typedef ICProfileID * ICProfileIDPtr;
enum {
    kICNilProfileID = 0
};
```

Constants

`kICNilProfileID`
Use to denote no profile.
Available in Mac OS X v10.0 and later.
Declared in `InternetConfig.h`.

Services Bits

```
typedef short ICServiceEntryFlags;
enum {
    kICServicesTCPBit = 0,
    kICServicesUDPBit = 1
};
```

Constants

`kICServicesTCPBit`
When this bit is set, indicates the service is TCP.
Available in Mac OS X v10.0 and later.
Declared in `InternetConfig.h`.

`kICServicesUDPBit`
When this bit is set, indicates the service is UDP.
Available in Mac OS X v10.0 and later.
Declared in `InternetConfig.h`.

Discussion
Both these bits may be set to indicate the service is both TCP and UDP.

Services Masks

```
enum {
    kICServicesTCPMask = 0x00000001,
    kICServicesUDPMask = 0x00000002
};
```

Constants

`kICServicesTCPMask`
Indicates the service is TCP.
Available in Mac OS X v10.0 and later.
Declared in `InternetConfig.h`.

`kICServicesUDPMask`
Indicates the service is UDP.
Available in Mac OS X v10.0 and later.
Declared in `InternetConfig.h`.

Discussion
Both these bits may be set to indicate the service is both TCP and UDP.

User Interaction Constants

```
enum {
    kICNoUserInteractionBit = 0
};
```

User Interaction Masks

```
enum {
    kICNoUserInteractionMask = 0x00000001
};
```

Version Constants

```
enum {
    kICComponentVersion = 0,
    kICNumVersion = 1
};
```

Result Codes

The most common result codes returned by Internet Config are listed in the table below.

Result Code	Value	Description
`icPrefNotFoundErr`	-666	The preference was not found. Available in Mac OS X v10.0 and later.
`icPermErr`	-667	The preference cannot be set because of premissions restrictions. Available in Mac OS X v10.0 and later.
`icPrefDataErr`	-668	There was a problem with the preference data. Available in Mac OS X v10.0 and later.
`icInternalErr`	-669	An internal error occurred. Available in Mac OS X v10.0 and later.
`icTruncatedErr`	-670	More data was present than was returned. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
icNoMoreWritersErr	-671	You can't begin a write session because there is already one in progress. Available in Mac OS X v10.0 and later.
icNothingToOverrideErr	-672	There is no component for the override component to capture. Available in Mac OS X v10.0 and later.
icNoURLErr	-673	No URL was found. Available in Mac OS X v10.0 and later.
icConfigNotFoundErr	-674	No configuration was found. Available in Mac OS X v10.0 and later.
icConfigInappropriateErr	-675	The manufacturer code is incorrect. Available in Mac OS X v10.0 and later.
icProfileNotFoundErr	-676	The profile was not found. Available in Mac OS X v10.0 and later.
icTooManyProfilesErr	-677	There are too many profiles in the database. Available in Mac OS X v10.0 and later.

QuickDraw Reference

Framework:	ApplicationServices/ApplicationServices.h
Declared in	QuickdrawAPI.h QuickdrawTypes.h QDOffscreen.h QDPictToCGContext.h
Companion guide	Quartz Programming Guide for QuickDraw Developers

Overview

QuickDraw is the legacy 2D drawing engine for Macintosh computers. QuickDraw provides routines for drawing, manipulating, and displaying graphic objects such as lines, arcs, rectangles, ovals, regions, and bitmap images. Carbon supports most of the classic QuickDraw programming interface.

Note: QuickDraw has been deprecated for deployment targets Mac OS X version 10.4 and later. The replacement API is Quartz 2D. Because of the fundamental differences in the imaging models and design goals between QuickDraw and Quartz, there is no direct correspondence between QuickDraw and Quartz concepts and interfaces. For certain purposes, some QuickDraw functions may still be needed during a transition period; nevertheless, most of them have been deprecated to express the overriding goal of eliminating the use of QuickDraw in the future.

Functions by Task

Drawing QuickDraw Pictures in a Quartz Context

`QDPictCreateWithProvider` (page 2766)
Creates a QDPict picture, using QuickDraw picture data supplied with a Quartz data provider.

`QDPictCreateWithURL` (page 2767)
Creates a QDPict picture, using QuickDraw picture data specified with a Core Foundation URL.

`QDPictDrawToCGContext` (page 2767)
Draws a QuickDraw picture in a Quartz context.

`QDPictGetBounds` (page 2768)
Returns the intended location and size of a QDPict picture.

`QDPictGetResolution` (page 2769)
Returns the horizontal and vertical resolution of a QDPict picture.

`QDPictRelease` (page 2769)
Releases a QDPict picture.

`QDPictRetain` (page 2770) Deprecated in Mac OS X v10.3
Retains a QDPict picture.

Using Quartz 2D to Draw in a Graphics Port

`QDBeginCGContext` (page 2756)
Returns a Quartz 2D drawing environment associated with a graphics port.

`QDEndCGContext` (page 2758)
Terminates a Quartz 2D drawing environment associated with a graphics port.

`ClipCGContextToRegion` (page 2579) Deprecated in Mac OS X v10.4
Sets the clipping path in a Quartz 2D graphics context, using a clipping region. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`CreateCGContextForPort` (page 2591) Deprecated in Mac OS X v10.4
Creates a Quartz 2D drawing environment associated with a graphics port. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`SyncCGContextOriginWithPort` (page 2826) Deprecated in Mac OS X v10.4
Synchronizes the origin in a Quartz context with the lower-left corner of the associated graphics port. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Other Quartz-Related Functions in QuickDraw

`QDGetCGDirectDisplayID` (page 2761)
Returns the Quartz display ID that corresponds to a QuickDraw graphics device.

`CreateNewPortForCGDisplayID` (page 2592) Deprecated in Mac OS X v10.4
Creates a graphics port associated with a display. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`LockPortBits` (page 2705) Deprecated in Mac OS X v10.4
Acquires an exclusive lock on the back buffer for a Carbon window. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`QDFlushPortBuffer` (page 2760) Deprecated in Mac OS X v10.4
Calls the Quartz compositor to flush all new drawing in a Carbon window to the display. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`UnlockPortBits` (page 2829) Deprecated in Mac OS X v10.4
Releases a previously acquired lock on the back buffer for a Carbon window. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Calculating Black-and-White Fills

`CalcMask` (page 2578) Deprecated in Mac OS X v10.4
Determines where filling will not occur when filling from the outside of a rectangle. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`SeedFill` (page 2788) Deprecated in Mac OS X v10.4
Determines how far filling will extend from a seeding point. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Calculating Color Fills

`CalcCMask` (page 2577) Deprecated in Mac OS X v10.4
Determines where filling will not occur when filling from the outside of a rectangle. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`SeedCFill` (page 2787) Deprecated in Mac OS X v10.4
Determines how far filling will extend to pixels matching the color of a particular pixel. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Changing Black-and-White Cursors

`GetCursor` (page 2638) Deprecated in Mac OS X v10.4
Loads a cursor resource into memory. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`SetCursor` (page 2792) Deprecated in Mac OS X v10.4
Sets the current cursor. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Changing Color Cursors

`AllocCursor` (page 2572) Deprecated in Mac OS X v10.4
Reallocates cursor memory. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`DisposeCCursor` (page 2598) Deprecated in Mac OS X v10.4
Disposes of all structures allocated by the `GetCCursor` function. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`GetCCursor` (page 2635) Deprecated in Mac OS X v10.4
Loads a color cursor resource into memory. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`SetCCursor` (page 2790) Deprecated in Mac OS X v10.4
Specifies a color cursor for display on the screen. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Changing the Background Bit Pattern

`BackPat` (page 2575) Deprecated in Mac OS X v10.4
Changes the bit pattern used as the background pattern by the current graphics port. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Changing the Background Pixel Pattern

`BackPixPat` (page 2576) Deprecated in Mac OS X v10.4
Assigns a pixel pattern as the background pattern. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Compressing and Decompressing Data

`PackBits` (page 2739) Deprecated in Mac OS X v10.4
Compresses a data buffer stored in RAM. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`UnpackBits` (page 2830) Deprecated in Mac OS X v10.4
Decompresses a data buffer containing data compressed by `PackBits`. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Converting Between Angle and Slope Values

`AngleFromSlope` (page 2574)
Converts a slope value to an angle value.

`SlopeFromAngle` (page 2814)
Converts an angle value to a slope value.

Copying Images

`CopyBits` (page 2584) Deprecated in Mac OS X v10.4
Copies a portion of a bitmap or a pixel map from one graphics port or offscreen graphics world into another graphics port. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`CopyDeepMask` (page 2586) Deprecated in Mac OS X v10.4
Uses a mask when copying bitmaps or pixel maps between graphics ports (or from an offscreen graphics world into a graphics port). (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`CopyMask` (page 2588) Deprecated in Mac OS X v10.4
Copies a bit or pixel image from one graphics port or offscreen graphics world into another graphics port only where the bits in a mask are set to 1. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Creating, Altering, and Disposing of Offscreen Graphics Worlds

`NewGWorld` (page 2715)
Creates an offscreen graphics world. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`DisposeGWorld` (page 2601) Deprecated in Mac OS X v10.4
Disposes of all the memory allocated for an offscreen graphics world. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`DisposeScreenBuffer` (page 2609) Deprecated in Mac OS X v10.4
Disposes an offscreen graphics world. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`NewScreenBuffer` (page 2727) Deprecated in Mac OS X v10.4
Creates an offscreen `PixMap` structure and allocates memory for the base address of its pixel image. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`NewTempScreenBuffer` (page 2728) Deprecated in Mac OS X v10.4
Creates an offscreen `PixMap` structure and allocate temporary memory for the base address of its pixel image applications generally don't need to use `NewTempScreenBuffer`. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`UpdateGWorld` (page 2831) Deprecated in Mac OS X v10.4
Changes the pixel depth, boundary rectangle, or color table for an existing offscreen graphics world. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Creating and Disposing of Color Tables

`DisposeCTable` (page 2599) Deprecated in Mac OS X v10.4
Disposes a `ColorTable` structure. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`GetCTable` (page 2636) Deprecated in Mac OS X v10.4
Obtains a color table stored in a `'clut'` resource. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Creating and Disposing of Pictures

`ClosePicture` (page 2581) Deprecated in Mac OS X v10.4
Completes the collection of drawing commands and picture comments that define your picture. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`KillPicture` (page 2691) Deprecated in Mac OS X v10.4
Releases the memory occupied by a picture not stored in a `'PICT'` resource. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`OpenCPicture` (page 2734) Deprecated in Mac OS X v10.4
Begins defining a picture in extended version 2 format. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`OpenPicture` (page 2736) Deprecated in Mac OS X v10.4
Creates a picture which allows you to specify resolutions for your pictures. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`PicComment` (page 2748) Deprecated in Mac OS X v10.4
Inserts a picture comment into a picture that you are defining or into your printing code. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Creating and Disposing of Pixel Patterns

`CopyPixPat` (page 2590) Deprecated in Mac OS X v10.4
Copies the contents of one pixel pattern to another. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`DisposePixPat` (page 2602) Deprecated in Mac OS X v10.4
Releases the storage allocated to a pixel pattern. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`GetPixPat` (page 2651) Deprecated in Mac OS X v10.4
Obtains a pixel pattern (`'ppat'`) resource stored in a resource file. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`MakeRGBPat` (page 2706) Deprecated in Mac OS X v10.4
Creates the appearance of otherwise unavailable colors on indexed devices. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`NewPixPat` (page 2720) Deprecated in Mac OS X v10.4
Creates a new pixel pattern. Generally, however, your application should create a pixel pattern in a `'ppat'` resource. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Creating and Managing Polygons

`ClosePoly` (page 2581) Deprecated in Mac OS X v10.4
Completes the collection of lines that defines a polygon. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`KillPoly` (page 2691) Deprecated in Mac OS X v10.4
Releases the memory occupied by a polygon. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`OffsetPoly` (page 2731) Deprecated in Mac OS X v10.4
Moves a polygon. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`OpenPoly` (page 2737) Deprecated in Mac OS X v10.4
Begins defining a polygon. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Creating and Managing Rectangles

`EmptyRect` (page 2611)
Determines whether a rectangle is an empty rectangle.

`EqualRect` (page 2613)
Determines whether two rectangles are equal.

`InsetRect` (page 2672)
Shrinks or expands a rectangle.

`OffsetRect` (page 2732)
Moves a rectangle.

`Pt2Rect` (page 2753)
Determines the smallest rectangle that encloses two given points.

`PtInRect` (page 2753)
Determines whether a pixel below is enclosed in a rectangle.

`PtToAngle` (page 2754)
Calculates an angle between a vertical line pointing straight up from the center of a rectangle and a line from the center to a given point.

`SectRect` (page 2785)
Determines whether two rectangles intersect.

`SetRect` (page 2809)
Assigns coordinates to a rectangle.

`UnionRect` (page 2827)
Calculates the smallest rectangle that encloses two rectangles.

Creating and Managing Regions

`CopyRgn` (page 2590)
Makes a copy of a region.

`DiffRgn` (page 2598)
Subtracts one region from another.

`DisposeRgn` (page 2609)
Releases the memory occupied by a region.

`EmptyRgn` (page 2612)
Determines whether a region is empty.

`EqualRgn` (page 2614)
Determines whether two regions have identical sizes, shapes, and locations.

`InsetRgn` (page 2673)
Shrinks or expands a region.

`NewRgn` (page 2726)
Begins creating a new region.

`OffsetRgn` (page 2732)
Moves a region.

`PtInRgn` (page 2754)
Determines whether a pixel is within a region.

`RectInRgn` (page 2776)
Determines whether a rectangle intersects a region.

`RectRgn` (page 2776)
Changes the structure of an existing region to that of a rectangle.

`SectRgn` (page 2786)
Calculates the intersection of two regions.

`SetEmptyRgn` (page 2794)
Sets an existing region to be empty.

`SetRectRgn` (page 2810)
Changes the structure of an existing region to that of a rectangle.

`UnionRgn` (page 2828)
Calculates the union of two regions.

`XorRgn` (page 2833)
Calculates the difference between the union and the intersection of two regions.

`CloseRgn` (page 2582) Deprecated in Mac OS X v10.4
Organizes a collection of lines and shapes into a region definition. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`OpenRgn` (page 2737) Deprecated in Mac OS X v10.4
Begins defining a region. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Creating, Setting, and Disposing of GDevice Records

`DisposeGDevice` (page 2601) Deprecated in Mac OS X v10.4
Disposes of a `GDevice` structure, releases the space allocated for it, and disposes of all the data structures allocated for it. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`InitGDevice` (page 2671) Deprecated in Mac OS X v10.4
Initializes a `GDevice` structure. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`NewGDevice` (page 2714) Deprecated in Mac OS X v10.4
Creates a new `GDevice` structure. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`SetDeviceAttribute` (page 2793) Deprecated in Mac OS X v10.4
Sets the attribute bits of a `GDevice` structure. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`SetGDevice` (page 2796) Deprecated in Mac OS X v10.4
Sets a `GDevice` structure as the current device. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Creating, Setting, and Disposing of Pixel Maps

`CopyPixMap` (page 2589) Deprecated in Mac OS X v10.4
Duplicates a `PixMap` structure. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`DisposePixMap` (page 2602) Deprecated in Mac OS X v10.4
Disposes a `PixMap` structure and its color table. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`NewPixMap` (page 2719) Deprecated in Mac OS X v10.4
Creates a new, initialized `PixMap` structure. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`SetPortPix` (page 2805) Deprecated in Mac OS X v10.4
Sets the pixel map for the current color graphics port. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Customizing Color QuickDraw Operations

`SetStdCProcs` (page 2811) Deprecated in Mac OS X v10.4
Obtains a `CQDProcs` structure with fields that point to QuickDraw's standard low-level functions, which you can modify to change QuickDraw's standard low-level behavior. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Customizing QuickDraw Operations

`SetStdProcs` (page 2812) Deprecated in Mac OS X v10.4
Obtains a `QDProcs` structure with fields that point to basic QuickDraw's standard low-level functions, which you can modify to point to your own functions. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`StdArc` (page 2815) Deprecated in Mac OS X v10.4
QuickDraw's standard low-level function for drawing an arc or a wedge. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`StdBits` (page 2816) Deprecated in Mac OS X v10.4
QuickDraw's standard low-level function for transferring bits and pixels. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`StdComment` (page 2817) Deprecated in Mac OS X v10.4
QuickDraw's standard low-level function for processing a picture comment. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`StdGetPic` (page 2817) Deprecated in Mac OS X v10.4
QuickDraw's standard low-level function for retrieving information from the definition of a picture. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`StdLine` (page 2818) Deprecated in Mac OS X v10.4
QuickDraw's standard low-level function for drawing a line. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`StdOval` (page 2819) Deprecated in Mac OS X v10.4
QuickDraw's standard low-level function for drawing an oval. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`StdPoly` (page 2820) Deprecated in Mac OS X v10.4
QuickDraw's standard low-level function for drawing a polygon. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`StdPutPic` (page 2820) Deprecated in Mac OS X v10.4
QuickDraw's standard low-level function for saving information as the definition of a picture. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`StdRect` (page 2821) Deprecated in Mac OS X v10.4
QuickDraw's standard low-level function for drawing a rectangle. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`StdRgn` (page 2822) Deprecated in Mac OS X v10.4
QuickDraw's standard low-level function for drawing a region. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`StdRRect` (page 2822) Deprecated in Mac OS X v10.4
QuickDraw's standard low-level function for drawing a rounded rectangle. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Determining Current Colors and Best Intermediate Colors

`GetBackColor` (page 2634) Deprecated in Mac OS X v10.4
Obtains the background color of the current graphics port. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`GetCPixel` (page 2636) Deprecated in Mac OS X v10.4
Determines the color of an individual pixel specified in the `h` and `v` parameters. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`GetForeColor` (page 2639) Deprecated in Mac OS X v10.4
Obtains the color of the foreground color for the current graphics port. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Determining the Characteristics of a Video Device

`DeviceLoop` (page 2597) Deprecated in Mac OS X v10.4
Draws images that are optimized for every screen they cross. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`ScreenRes` (page 2783) Deprecated in Mac OS X v10.4
Determines the resolution of the main device. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`TestDeviceAttribute` (page 2826) Deprecated in Mac OS X v10.4
Determines whether the flag bit for an attribute has been set in the `gdFlags` field of a `GDevice` structure. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Determining Whether QuickDraw Has Finished Drawing

`QDDone` (page 2758) Deprecated in Mac OS X v10.4
Determines whether QuickDraw has completed drawing in a given graphics port. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Drawing Arcs and Wedges

`EraseArc` (page 2615) Deprecated in Mac OS X v10.4
Erases a wedge. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`FillArc` (page 2619) Deprecated in Mac OS X v10.4
Fills a wedge with any available bit pattern. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`FrameArc` (page 2629) Deprecated in Mac OS X v10.4
Draws an arc of the oval that fits inside a rectangle. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`InvertArc` (page 2674) Deprecated in Mac OS X v10.4
Inverts the pixels of a wedge. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`PaintArc` (page 2740) Deprecated in Mac OS X v10.4
Paints a wedge of the oval that fits inside a rectangle. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Drawing Lines

`Line` (page 2692) Deprecated in Mac OS X v10.4
Draws a line a specified distance from the graphics pen's current location in the current graphics port. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`LineTo` (page 2693) Deprecated in Mac OS X v10.4
Draws a line from the graphics pen's current location to a new location. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`Move` (page 2711) Deprecated in Mac OS X v10.4
Moves the graphics pen a particular distance. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`MoveTo` (page 2712) Deprecated in Mac OS X v10.4
Moves the graphics pen to a particular location in the current graphics port. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Drawing Ovals

`EraseOval` (page 2615) Deprecated in Mac OS X v10.4
Erases an oval. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`FillOval` (page 2624) Deprecated in Mac OS X v10.4
Fills an oval with any available bit pattern. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`FrameOval` (page 2630) Deprecated in Mac OS X v10.4
Draws an outline inside an oval. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`InvertOval` (page 2675) Deprecated in Mac OS X v10.4
Inverts the pixels enclosed by an oval. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`PaintOval` (page 2741) Deprecated in Mac OS X v10.4
Paints an oval with the graphics pen's pattern and pattern mode. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Drawing Pictures

`DrawPicture` (page 2610) Deprecated in Mac OS X v10.4
Draws a picture on any type of output device. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`GetPicture` (page 2648) Deprecated in Mac OS X v10.4
Obtains a handle to a picture stored in a `'PICT'` resource. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Drawing Polygons

`ErasePoly` (page 2616) Deprecated in Mac OS X v10.4
Erases a polygon. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`FillPoly` (page 2625) Deprecated in Mac OS X v10.4
Fills a polygon with any available bit pattern. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`FramePoly` (page 2630) Deprecated in Mac OS X v10.4
Draws the outline of a polygon. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`InvertPoly` (page 2676) Deprecated in Mac OS X v10.4
Inverts the pixels enclosed by a polygon. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`PaintPoly` (page 2741) Deprecated in Mac OS X v10.4
Paints a polygon with the graphics pen's pattern and pattern mode. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Drawing Rectangles

`EraseRect` (page 2617) Deprecated in Mac OS X v10.4
Erases a rectangle. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`FillRect` (page 2626) Deprecated in Mac OS X v10.4
Fills a rectangle with any available bit pattern. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`FrameRect` (page 2631) Deprecated in Mac OS X v10.4
Draws an outline inside a rectangle. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`InvertRect` (page 2677) Deprecated in Mac OS X v10.4
Inverts the pixels enclosed by a rectangle. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`PaintRect` (page 2742) Deprecated in Mac OS X v10.4
Paints a rectangle with the graphics pen's pattern and pattern mode. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Drawing Regions

`EraseRgn` (page 2618) Deprecated in Mac OS X v10.4
Erases a region. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`FillRgn` (page 2626) Deprecated in Mac OS X v10.4
Fills a region with any available bit pattern. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`FrameRgn` (page 2632) Deprecated in Mac OS X v10.4
Draws an outline inside a region. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`InvertRgn` (page 2678) Deprecated in Mac OS X v10.4
Inverts the pixels enclosed by a region. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`PaintRgn` (page 2743) Deprecated in Mac OS X v10.4
Paints a region with the graphics pen's pattern and pattern mode. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Drawing Rounded Rectangles

`EraseRoundRect` (page 2618) Deprecated in Mac OS X v10.4
Erases a rounded rectangle. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`FillRoundRect` (page 2627) Deprecated in Mac OS X v10.4
Fills a rounded rectangle with any available bit pattern. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`FrameRoundRect` (page 2633) Deprecated in Mac OS X v10.4
Draws an outline inside a rounded rectangle. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`InvertRoundRect` (page 2679) Deprecated in Mac OS X v10.4
Inverts the pixels enclosed by a rounded rectangle. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`PaintRoundRect` (page 2743) Deprecated in Mac OS X v10.4
Paints a rounded rectangle with the graphics pen's pattern and pattern mode. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Drawing With Color QuickDraw Colors

`FillCArc` (page 2620) Deprecated in Mac OS X v10.4
Fills a wedge with the given pixel pattern, using the `patCopy` pattern mode. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`FillCOval` (page 2621) Deprecated in Mac OS X v10.4
Fills an oval with the given pixel pattern, using the `patCopy` pattern mode. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`FillCPoly` (page 2621) Deprecated in Mac OS X v10.4
Fills a polygon with the given pixel pattern, using the `patCopy` pattern mode. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`FillCRect` (page 2622) Deprecated in Mac OS X v10.4
Fills a rectangle with the given pixel pattern, using the `patCopy` pattern mode. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`FillCRgn` (page 2622) Deprecated in Mac OS X v10.4
Fills a region with the given pixel pattern, using the `patCopy` pattern mode. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`FillCRoundRect` (page 2623) Deprecated in Mac OS X v10.4
Fills a rounded rectangle with the given pixel pattern, using the `patCopy` pattern mode. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`HiliteColor` (page 2670) Deprecated in Mac OS X v10.4
Changes the highlight color for the current color graphics port. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`OpColor` (page 2733) Deprecated in Mac OS X v10.4
Sets the maximum color values for the `addPin` and `subPin` arithmetic transfer modes and the weight color for the `blend` arithmetic transfer mode. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`RGBBackColor` (page 2779) Deprecated in Mac OS X v10.4
Changes the background color. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`RGBForeColor` (page 2780) Deprecated in Mac OS X v10.4
Changes the color of the "ink" used for framing and painting. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`SetCPixel` (page 2791) Deprecated in Mac OS X v10.4
Sets the color of an individual pixel to the color that most closely matches the RGB color that you specify in the `cPix` parameter. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Drawing With the Eight-Color System

`BackColor` (page 2574) Deprecated in Mac OS X v10.4
Changes a basic graphics port's background color. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`ColorBit` (page 2584) Deprecated in Mac OS X v10.4
Sets the foreground color for all printing in the current graphics port. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`ForeColor` (page 2628) Deprecated in Mac OS X v10.4
Changes the color of the "ink" used for framing, painting, and filling on computers that support only basic QuickDraw. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Getting Pattern Resources

`GetIndPattern` (page 2643) Deprecated in Mac OS X v10.4
Obtains a pattern stored in a pattern list (`'PAT#'`) resource. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`GetPattern` (page 2646) Deprecated in Mac OS X v10.4
Obtains a pattern (`'PAT'`) resource stored in a resource file. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Getting the Available Graphics Devices

`GetDeviceList` (page 2639) Deprecated in Mac OS X v10.4
: Obtains a handle to the first `GDevice` structure in the device list. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`GetGDevice` (page 2640) Deprecated in Mac OS X v10.4
: Obtains a handle to the `GDevice` structure for the current device. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`GetMainDevice` (page 2644) Deprecated in Mac OS X v10.4
: Obtains a handle to the `GDevice` structure for the main screen. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`GetMaxDevice` (page 2644) Deprecated in Mac OS X v10.4
: Obtains a handle to the `GDevice` structure for the video device with the greatest pixel depth. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`GetNextDevice` (page 2645) Deprecated in Mac OS X v10.4
: Returns a handle to the next `GDevice` structure in the device list. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Hiding and Showing Cursors

`InitCursor` (page 2671)
: Sets the cursor to the standard arrow and makes the cursor visible.

`HideCursor` (page 2668)
: Hides the cursor if it is visible on the screen.

`ObscureCursor` (page 2730)
: Hides the cursor until the next time the user moves the mouse.

`ShieldCursor` (page 2813)
: Hides the cursor in a rectangle.

`ShowCursor` (page 2813)
: Displays a cursor hidden by the `HideCursor` or `ShieldCursor` functions.

Managing a Color Graphics Pen

`PenPixPat` (page 2747) Deprecated in Mac OS X v10.4
: Sets the pixel pattern used by the graphics pen in the current color graphics port. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Managing an Offscreen Graphics World's Pixel Image

`GetPixBaseAddr` (page 2648)
: Obtains a pointer to an offscreen pixel map.

`AllowPurgePixels` (page 2573) Deprecated in Mac OS X v10.4
: Makes the base address for an offscreen pixel image purgeable. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`GetGWorldPixMap` (page 2642) Deprecated in Mac OS X v10.4
Obtains the pixel map created for an offscreen graphics world. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`GetPixelsState` (page 2651) Deprecated in Mac OS X v10.4
Saves the current information about the memory allocated for an offscreen pixel image. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`LockPixels` (page 2704) Deprecated in Mac OS X v10.4
Prevents the base address for an offscreen pixel image from being moved while you draw into or copy from its pixel map. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`NoPurgePixels` (page 2729) Deprecated in Mac OS X v10.4
Prevents the Memory Manager from purging the base address for an offscreen pixel image. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`PixMap32Bit` (page 2749) Deprecated in Mac OS X v10.4
Determines whether a pixel map requires 32-bit addressing mode for access to its pixel image. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`SetPixelsState` (page 2799) Deprecated in Mac OS X v10.4
Restores an offscreen pixel image to the state that you saved with the `GetPixelsState` function. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`UnlockPixels` (page 2829) Deprecated in Mac OS X v10.4
Allows the Memory Manager to move the base address for the offscreen pixel map that you specify in the `pm` parameter. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Managing Bitmaps, Port Rectangles, and Clipping Regions

`GetClip` (page 2635)
Saves the clipping region of the current graphics port (basic or color). (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`SetClip` (page 2791)
Changes the clipping region of the current graphics port (basic or color) to a region you specify. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`BitMapToRegion` (page 2576) Deprecated in Mac OS X v10.4
Converts a bitmap or pixel map to a region. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`ClipRect` (page 2580) Deprecated in Mac OS X v10.4
Changes the clipping region of the current graphics port (basic or color). (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`MovePortTo` (page 2711) Deprecated in Mac OS X v10.4
Changes the position of the port rectangle of the current graphics port (basic or color). (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`PortSize` (page 2751) Deprecated in Mac OS X v10.4
Changes the size of the port rectangle of the current graphics port (basic or color). (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`ScrollRect` (page 2784) Deprecated in Mac OS X v10.4
Scroll the pixels of a specified portion of a basic graphics port's bitmap (or a color graphics port's pixel map). (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`SetOrigin` (page 2797) Deprecated in Mac OS X v10.4
Changes the coordinates of the window origin of the port rectangle of the current graphics port (basic or color). (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`SetPortBits` (page 2801) Deprecated in Mac OS X v10.4
Sets the bitmap for the current basic graphics port. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Managing Color Tables

`GetCTSeed` (page 2638) Deprecated in Mac OS X v10.4
Obtains a unique seed value for a color table created by your application. This function is used by system software and your application should not need to call it. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`ProtectEntry` (page 2752) Deprecated in Mac OS X v10.4
Adds protection to or removes protection from an entry in the current `GDevice` data structure's color table. This function is used by system software and your application should not need to call it. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`ReserveEntry` (page 2777) Deprecated in Mac OS X v10.4
Reserves or removes reservation from an entry in the current `GDevice` data structure's color table. This function is used by system software and your application should not need to call it. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`RestoreEntries` (page 2778) Deprecated in Mac OS X v10.4
Restores a selection of color table entries. This function is used by system software and your application should not need to call it. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`SaveEntries` (page 2781) Deprecated in Mac OS X v10.4
Saves a selection of color table entries. This function is used by system software and your application should not need to call it. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`SetEntries` (page 2794) Deprecated in Mac OS X v10.4
Sets a group of color table entries for the current `GDevice` data structure. This function is used by system software and your application should not need to call it. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Managing Colors

`Color2Index` (page 2583) Deprecated in Mac OS X v10.4
Obtains the index of the best available approximation for a given color in the color table of the current `GDevice` data structure. This function is used only by system software. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`GetSubTable` (page 2667) Deprecated in Mac OS X v10.4

Searches one color table for the best matches to colors in another color table. Your application should not need to call this function; it is used by system software only. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`Index2Color` (page 2670) Deprecated in Mac OS X v10.4

Obtains the `RGBColor` data structure corresponding to an index value in the color table of the current `GDevice` data structure. Your application should not need to call this function; it is used by system software only. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`InvertColor` (page 2675) Deprecated in Mac OS X v10.4

Finds the complement of an `RGBColor` data structure. This function is used only by system software. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`MakeITable` (page 2706) Deprecated in Mac OS X v10.4

Generates an inverse table for a color table. Your application should not need to call this function; it is used by system software only. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`RealColor` (page 2775) Deprecated in Mac OS X v10.4

Determines whether a given `RGBColor` data structure exists in the current device's color table. This function is used by system software and your application should not need to call it. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Managing the Graphics Pen

`GetPen` (page 2646) Deprecated in Mac OS X v10.4

Determines the location of the graphics pen. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`GetPenState` (page 2647) Deprecated in Mac OS X v10.4

Determines the graphics pen's location, size, pattern, and pattern mode. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`HidePen` (page 2669) Deprecated in Mac OS X v10.4

Makes the graphics pen invisible, so that pen drawing doesn't show on the screen. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`PenMode` (page 2744) Deprecated in Mac OS X v10.4

Sets the pattern mode of the graphics pen in the current graphics port. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`PenNormal` (page 2745) Deprecated in Mac OS X v10.4

Sets the size, pattern, and pattern mode of the graphics pen in the current graphics port to their initial values. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`PenPat` (page 2746) Deprecated in Mac OS X v10.4

Sets the bit pattern to be used by the graphics pen in the current graphics port. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`PenSize` (page 2747) Deprecated in Mac OS X v10.4

Sets the dimensions of the graphics pen in the current graphics port. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`SetPenState` (page 2798) Deprecated in Mac OS X v10.4

Restores the state of the graphics pen that was saved with the `GetPenState` function. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`ShowPen` (page 2814) Deprecated in Mac OS X v10.4
Changes the ink of a graphics pen from invisible to visible, making pen drawing appear on the screen. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Manipulating Points in Graphics Ports

`AddPt` (page 2571)
Adds the coordinates of two points.

`EqualPt` (page 2613)
Determines whether the coordinates of two given points are equal.

`SetPt` (page 2807)
Assigns two coordinates to a point.

`SubPt` (page 2824)
Subtracts the coordinates of one point from another.

`DeltaPoint` (page 2596) Deprecated in Mac OS X v10.4
Subtracts the coordinates of one point from another. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`GetPixel` (page 2650) Deprecated in Mac OS X v10.4
Determines whether the pixel associated with a point is black or white. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`GlobalToLocal` (page 2667) Deprecated in Mac OS X v10.4
Converts the coordinates of a point from global coordinates to the local coordinates of the current graphics port (basic or color). (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`LocalToGlobal` (page 2703) Deprecated in Mac OS X v10.4
Converts a point's coordinates from the local coordinates of the current graphics port (basic or color) to global coordinates. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Obtaining a Pseudorandom Number

`Random` (page 2775) Deprecated in Mac OS X v10.4
Obtains a pseudorandom integer. (Deprecated. Use the Standard C Library `random(3)` function instead.)

Operations on Search and Complement Functions

`AddComp` (page 2571) Deprecated in Mac OS X v10.4
Adds a function to the head of the current device data structure's list of complement functions. This function is used by system software and your application should not need to call it. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`AddSearch` (page 2572) Deprecated in Mac OS X v10.4
Adds a function to the head of the current `GDevice` data structure's list of search functions. This function is used by system software and your application should not need to call it. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`DelComp` (page 2595) Deprecated in Mac OS X v10.4
Removes a custom complement function from the current `GDevice` data structure's list of complement functions. This function is used by system software and your application should not need to call it. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`DelSearch` (page 2595) Deprecated in Mac OS X v10.4
Removes a custom search function from the current `GDevice` data structure's list of search functions. This function is used by system software and your application should not need to call it. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`SetClientID` (page 2790) Deprecated in Mac OS X v10.4
Sets the `gdID` field in the current `GDevice` data structure to identify this client program to its search and complement functions. This function is used by system software and your application should not need to call it. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Reporting Data Structure Changes to QuickDraw

`CTabChanged` (page 2593) Deprecated in Mac OS X v10.4
Signals QuickDraw that the content of a `ColorTable` structure has been modified. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`GDeviceChanged` (page 2633) Deprecated in Mac OS X v10.4
Notifies QuickDraw that the content of a `GDevice` structure has been modified. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`PixPatChanged` (page 2750) Deprecated in Mac OS X v10.4
Notifies QuickDraw that the content of a `PixPat` structure, including its `PixMap` structure or the image in its `patData` field, has been modified. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`PortChanged` (page 2751) Deprecated in Mac OS X v10.4
Notifies QuickDraw that the content of a `GrafPort` structure or `CGrafPort` structure, including any of the data structures specified by handles within the structure, has been modified. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Retrieving Color QuickDraw Result Codes

`QDError` (page 2759) Deprecated in Mac OS X v10.4
Obtains a result code from the last applicable QuickDraw function that you called. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Saving and Restoring Graphics Ports

`GetPort` (page 2652) Deprecated in Mac OS X v10.4
Saves the current graphics port (basic or color). (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`SetPort` (page 2799) Deprecated in Mac OS X v10.4
Changes the current graphics port (basic or color). (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Saving and Restoring Graphics Ports and Offscreen Graphics Worlds

`GetGWorld` (page 2640)
Saves the current graphics port (basic, color, or offscreen) and the current `GDevice` structure. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`SetGWorld` (page 2796)
Changes the current graphics port (basic, color, or offscreen). (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`GetGWorldDevice` (page 2641) Deprecated in Mac OS X v10.4
Obtains a handle to the `GDevice` structure associated with an offscreen graphics world. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Scaling and Mapping Points, Rectangles, Polygons, and Regions

`MapPt` (page 2708)
Maps a point in one rectangle to an equivalent position in another rectangle.

`MapRect` (page 2709)
Maps and scales a rectangle within one rectangle to another rectangle.

`MapRgn` (page 2710)
Maps and scales a region within one rectangle to another rectangle.

`ScalePt` (page 2782)
Scales a height and width according to the proportions of two rectangles.

`MapPoly` (page 2707) Deprecated in Mac OS X v10.4
Maps and scales a polygon within one rectangle to another rectangle. (Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Miscellaneous

`GetRegionBounds` (page 2666)

`HandleToRgn` (page 2668)

`IsRegionRectangular` (page 2690)

`IsValidRgnHandle` (page 2690)

`QDGetPatternOrigin` (page 2762)
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

`QDRegionToRects` (page 2770)

`RgnToHandle` (page 2781)

`CloseCursorComponent` (page 2581) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

CreateNewPort (page 2592) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

CursorComponentChanged (page 2594) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

CursorComponentSetData (page 2594) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

deltapoint (page 2596) Deprecated in Mac OS X v10.4
(Deprecated. Use DeltaPoint (page 2596) instead.)

DisposeColorComplementUPP (page 2599) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

DisposeColorSearchUPP (page 2599) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

DisposeDeviceLoopDrawingUPP (page 2600) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

DisposeDragGrayRgnUPP (page 2600) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

DisposePort (page 2603) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

DisposeQDArcUPP (page 2603) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

DisposeQDBitsUPP (page 2603) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

DisposeQDCommentUPP (page 2604) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

DisposeQDGetPicUPP (page 2604) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

DisposeQDJShieldCursorUPP (page 2604) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

DisposeQDLineUPP (page 2605) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

DisposeQDOpcodeUPP (page 2605) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

DisposeQDOvalUPP (page 2605) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

DisposeQDPolyUPP (page 2606) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

DisposeQDPutPicUPP (page 2606) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

GetPortChExtra (page 2655) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

GetPortClipRegion (page 2655) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

GetPortCustomXFerProc (page 2655) Deprecated in Mac OS X v10.4

GetPortFillPixPat (page 2656) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

GetPortForeColor (page 2656) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

GetPortFracHPenLocation (page 2657) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

GetPortGrafProcs (page 2657) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

GetPortHiliteColor (page 2658) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

GetPortOpColor (page 2658) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

GetPortPenLocation (page 2658) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

GetPortPenMode (page 2659) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

GetPortPenPixPat (page 2659) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

GetPortPenSize (page 2660) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

GetPortPenVisibility (page 2660) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

GetPortPixMap (page 2660) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

GetPortSpExtra (page 2661) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

GetPortTextFace (page 2661) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

GetPortTextFont (page 2662) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

GetPortTextMode (page 2662) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

GetPortTextSize (page 2662) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

GetPortVisibleRegion (page 2663) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

GetQDGlobalsArrow (page 2663) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

GetQDGlobalsBlack (page 2663) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

GetQDGlobalsDarkGray (page 2664) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

GetQDGlobalsGray (page 2664) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

GetQDGlobalsLightGray (page 2665) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

GetQDGlobalsRandomSeed (page 2665) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

GetQDGlobalsScreenBits (page 2665) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

GetQDGlobalsThePort (page 2666) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

GetQDGlobalsWhite (page 2666) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

GrafDevice (page 2668) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Functions

AddComp

Adds a function to the head of the current device data structure's list of complement functions. This function is used by system software and your application should not need to call it. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void AddComp (
   ColorComplementUPP compProc
);
```

Parameters

compProc
A pointer to your complement function, `ColorComplementProcPtr` (page 2834).

Discussion

`AddComp` creates and allocates a `CProcRec` (page 2852) data structure.

Availability

Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

AddPt

Adds the coordinates of two points.

```
void AddPt (
   Point src,
   Point *dst
);
```

Parameters

src
A point, the coordinates of which are to be added to the point in the `dstPt` parameter.

dst

A pointer to a point, the coordinates of which are to be added to the point in the `srcPt` parameter. On return, this value contains the result of adding the coordinates of the points you supplied in the `srcPt` and `dstPt` parameters.

Discussion
The `AddPt` function adds the coordinates of the point specified in the `srcPt` parameter to the coordinates of the point specified in the `dstPt` parameter, and returns the result in the `dstPt` parameter.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
CarbonSketch

Declared In
`QuickdrawAPI.h`

AddSearch

Adds a function to the head of the current `GDevice` data structure's list of search functions. This function is used by system software and your application should not need to call it. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void AddSearch (
   ColorSearchUPP searchProc
);
```

Parameters

searchProc

A pointer to your custom search function, `ColorSearchProcPtr` (page 2834).

Discussion
`AddSearch` creates and allocates an `SProcRec` (page 2883) data structure.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

AllocCursor

Reallocates cursor memory. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void AllocCursor (
   void
);
```

Discussion
Under normal circumstances, you should never need to use this function, since Color QuickDraw handles reallocation of cursor memory.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

AllowPurgePixels

Makes the base address for an offscreen pixel image purgeable. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void AllowPurgePixels (
   PixMapHandle pm
);
```

Parameters

pm
A handle to an offscreen pixel map.

Discussion
The `AllowPurgePixels` function allows the Memory Manager to free the memory it occupies if available memory space becomes low. By default, `NewGWorld` creates an unpurgeable base address for an offscreen pixel image.

To get a handle to an offscreen pixel map, first use the `GetGWorldPixMap` (page 2642) function. Then supply this handle for the `pm` parameter of `AllowPurgePixels`.

Your application should call the `LockPixels` (page 2704) function before drawing into or copying from an offscreen pixel map. If the Memory Manager has purged the base address for its pixel image, `LockPixels` returns `FALSE`. In that case either your application should use the `UpdateGWorld` (page 2831) function to begin reconstructing the offscreen pixel image, or it should draw directly to an onscreen graphics port.

Only unlocked memory blocks can be made purgeable. If you use `LockPixels`, you must use the `UnlockPixels` function before calling `AllowPurgePixels`.

Special Considerations

The `AllowPurgePixels` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QDOffscreen.h`

AngleFromSlope

Converts a slope value to an angle value.

```
short AngleFromSlope (
   Fixed slope
);
```

Parameters

slope

The slope, defined as Dx/Dy, which is the horizontal change divided by the vertical change between any two points on a line with the slope.

Return Value
The angle corresponding to the slope specified in the `slope` parameter treated `MOD` 180. Angles are defined in clockwise degrees from 12 o'clock. The negative y-axis is defined as being at 12 o'clock, and the positive y-axis at 6 o'clock. The x-axis is defined as usual, with the positive side defined as being at 3 o'clock.

Special Considerations

The `AngleFromSlope` function is most useful when you require speed more than accuracy in performing the calculation. The integer result is within 1 degree of the correct answer, but not necessarily within half a degree.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

BackColor

Changes a basic graphics port's background color. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void BackColor (
   long color
);
```

Parameters

color

One of eight color values. See "Color Constants" (page 2885).

Discussion
The background color is the color of the pixels in the bitmap wherever no drawing has taken place. By default the background color of a `GrafPort` is white.

The `BackColor` function sets the background color for the current graphics port to the color that you specify in the `color` parameter. When you draw with the `patCopy` and `srcCopy` transfer modes, for example, white pixels are drawn in the color you specify with `BackColor`.

All nonwhite colors appear as black on black-and-white screens. Before you use `BackColor`, use the `DeviceLoop` function to determine the color characteristics of the current screen.

Special Considerations

The `BackColor` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Version Notes
In System 7, use the Color QuickDraw function `RGBBackColor`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

BackPat

Changes the bit pattern used as the background pattern by the current graphics port. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void BackPat (
   const Pattern *pat
);
```

Parameters

pat

A bit pattern, as defined by a `Pattern` (page 2866) structure.

Discussion
The `BackPat` function sets the bit pattern defined in the `Pattern` structure, which you specify in the `pat` parameter, to be the background pattern. (The standard bit patterns `white`, `black`, `gray`, `ltGray`, and `dkGray` are predefined; the initial background pattern for the graphics port is `white`.) This pattern is stored in the `bkPat` field of a `GrafPort` structure.

The `BackPat` function also sets a bit pattern for the background color in a color graphics port. The `BackPat` function creates a handle, of type `PixPatHandle`, for the bit pattern and stores this handle in the `bkPixPat` field of the `CGrafPort` structure. As in basic graphics ports, Color QuickDraw draws patterns in color graphics ports at the time of drawing, not at the time you use `PenPat` to set the pattern.

To define your own patterns, you typically create pattern, 'PAT', or pattern list, 'PAT#', resources.

Special Considerations

The `BackPat` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
QuickdrawAPI.h

BackPixPat

Assigns a pixel pattern as the background pattern. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void BackPixPat (
   PixPatHandle pp
);
```

Parameters

pp
A handle to the pixel pattern to use as the background pattern.

Discussion
Setting the background pattern allows the ScrollRect function and the shape-erasing functions (for example, EraseRect) to fill the background with a colored patterned "ink."

The BackPixPat function is similar to the basic QuickDraw function BackPat, except that you pass BackPixPat a handle to a multicolored pixel pattern instead of a bit pattern.

The handle to the pixel pattern is stored in the bkPixPat field of the CGrafPort structure, therefore, you should not dispose of this handle since QuickDraw removes all references to your pattern from an existing graphics port when you dispose of it.

If you use BackPixPat to set a background pixel pattern in a basic graphics port, the data in the pat1Data field of the PixPat (page 2871) structure is placed into the bkPat field of the GrafPort structure.

To define your own pixel pattern, create a pixel pattern resource, x is described on 'ppat', or use the NewPixPat (page 2720) function. To set the background pattern to a bit pattern, you can also use the QuickDraw function, BackPat.

Special Considerations

The BackPixPat function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

QuickdrawAPI.h

BitMapToRegion

Converts a bitmap or pixel map to a region. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
OSErr BitMapToRegion (
   RgnHandle region,
   const BitMap *bMap
);
```

Parameters

region

A handle to a region to hold the converted `BitMap` or `PixMap` structure. This must be a valid region handle created with the `NewRgn` function. The old region contents are lost.

bMap

A pointer to a `BitMap` or `PixMap` structure to be converted. If you supply a `PixMap` structure, its pixel depth must be 1.

Return Value
A result code.

Discussion
The `BitMapToRegion` function converts a given `BitMap` or `PixMap` structure to a region. Pixels are added to the region where the corresponding entries in the bitmap have a value of 1. You would generally use this region later for drawing operations.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

CalcCMask

Determines where filling will not occur when filling from the outside of a rectangle. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void CalcCMask (
   const BitMap *srcBits,
   const BitMap *dstBits,
   const Rect *srcRect,
   const Rect *dstRect,
   const RGBColor *seedRGB,
   ColorSearchUPP matchProc,
   long matchData
);
```

Parameters

srcBits

The source image. If the image is in a pixel map, you must coerce its `PixMap` structure to a `BitMap` structure.

dstBits

The destination image. The `CalcCMask` function returns the generated bitmap mask in this parameter. You can then use this mask with the `CopyBits`, `CopyMask`, and `CopyDeepMask` functions.

srcRect

The rectangle of the source image.

dstRect
The rectangle of the destination image.

seedRGB
An `RGBColor` structure specifying the color for pixels that should not be filled.

matchProc
An optional matching function.

matchData
Data for the optional matching function.

Discussion
Specify a source image in the `srcBits` parameter and in the `srcRect` parameter, specify a rectangle within that source image. Starting from the edges of this rectangle, `CalcCMask` calculates which pixels cannot be filled. By default, `CalcCMask` returns 1's in the mask to indicate which pixels have the exact color that you specify in the `seedRGB` parameter and which pixels are enclosed by shapes whose outlines consist entirely of pixels with this color.

For instance, if the source image in `srcBits` contains a dark blue rectangle on a red background, and your application sets `seedRGB` equal to dark blue, then `CalcCMask` returns a mask with 1's in the positions corresponding to the edges and interior of the rectangle, and the 0's outside of the rectangle.

If you set the `matchProc` and `matchData` parameters to 0, `CalcCMask` uses the exact color specified in the `RGBColor` structure that you supply in the `seedRGB` parameter. You can customize `CalcCMask` by writing your own color search function and pointing to it in the `matchProc` parameter. As with `SeedCFill`, you can then use the `matchData` parameter in any manner useful for your application.

The `CalcCMask` function does not scale so the source and destination rectangles must be the same size. Calls to `CalcCMask` are not clipped to the current port and are not stored into QuickDraw pictures.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

CalcMask

Determines where filling will not occur when filling from the outside of a rectangle. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void CalcMask (
   const void *srcPtr,
   void *dstPtr,
   short srcRow,
   short dstRow,
   short height,
   short words
);
```

Parameters

srcPtr
A pointer to the source bit image.

dstPtr
A pointer to the destination bit image.

srcRow
Row width of the source bitmap.

dstRow
Row width of the destination bitmap.

height
Height (in pixels) of the fill rectangle.

words
Width (in words) of the fill rectangle.

Discussion
The `CalcMask` function produces a bit image with 1's in all pixels to which paint could not flow from any of the outer edges of the rectangle. Use this bit image as a mask with the `CopyBits` or `CopyMask` function. A hollow object produces a solid mask, but an open object produces a mask of itself.

As with the `SeedFill` function, point to the bit image you want to fill with the `srcPtr` parameter, which can point to the image's base address or a word boundary within the image. Specify a pixel height and word width with the `height` and `words` parameters to define a fill rectangle that delimits the area you want to fill. The fill rectangle can be the entire bit image or a subset of it. Point to a destination image with the `dstPtr` parameter. Specify the row widths of the source and destination bitmaps (their `rowBytes` values) with the `srcRow` and `dstRow` parameters. (The bitmaps can be different sizes, but they must be large enough to contain the fill rectangle at the origins specified by `srcPtr` and `dstPtr`.)

Calls to `CalcMask` are not clipped to the current port and are not stored into QuickDraw pictures.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

ClipCGContextToRegion

Sets the clipping path in a Quartz 2D graphics context, using a clipping region. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
OSStatus ClipCGContextToRegion (
   CGContextRef gc,
   const Rect *portRect,
   RgnHandle region
);
```

Parameters
context
A Quartz context associated with a graphics port. You can obtain such a context by calling `QDBeginCGContext` (page 2756).

portRect
The `portRect` for the graphics port associated with the context.

region
A region that represents the desired clipping path.

Return Value
A result code. If `noErr`, the clipping path is now the region-based path.

Discussion
This function sets the clipping path in the specified context to closely approximate the geometry of the specified region.

Unlike clipping in Quartz 2D, this function does not intersect the new region-based path with the current clipping path—the new path simply replaces the current clipping path.

You should use this function only when absolutely necessary—it's relatively inefficient when compared to Quartz 2D clipping functions such as `CGContextClipToRect`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

ClipRect

Changes the clipping region of the current graphics port (basic or color). (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void ClipRect (
   const Rect *r
);
```

Parameters
r
A pointer to a rectangle for the boundary of the new clipping region. The `ClipRect` function changes the clipping region of the current graphics port to a region that's equivalent to this rectangle. `ClipRect` doesn't change the region handle, but it affects the clipping region itself.

Discussion
Since `ClipRect` makes a copy of the given rectangle, any subsequent changes you make to that rectangle do not affect the clipping region of the port.

The `ClipRect` function may move or purge memory blocks in the application heap. Your application should not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

CloseCursorComponent

(Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
OSErr CloseCursorComponent (
   ComponentInstance ci
);
```

Return Value
A result code.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

ClosePicture

Completes the collection of drawing commands and picture comments that define your picture. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void ClosePicture (
   void
);
```

Discussion
The `ClosePicture` function stops collecting drawing commands and picture comments for the currently open picture. You should perform one and only one call to `ClosePicture` for every call to the `OpenCPicture` (or `OpenPicture`) function.

The `ClosePicture` function calls the `ShowPen` function, balancing the call made by `OpenCPicture` (or `OpenPicture`) to the `HidePen` function.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

ClosePoly

Completes the collection of lines that defines a polygon. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void ClosePoly (
   void
);
```

Discussion
The `ClosePoly` function stops collecting line-drawing commands for the currently open polygon and computes the `polyBBox` field of the `Polygon` (page 2873) structure. You should call `ClosePoly` only once for every call to the `OpenPoly` function.

The `ClosePoly` function uses the `ShowPen` function, balancing the call to the `HidePen` function made by the `OpenPoly` function.

Special Considerations

The `ClosePoly` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

CloseRgn

Organizes a collection of lines and shapes into a region definition. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void CloseRgn (
   RgnHandle dstRgn
);
```

Parameters

`dstRgn`

The handle to the region to close. This handle should be a region handle returned by the `NewRgn` (page 2726) function.

Discussion
The `CloseRgn` function stops the collection of lines and framed shapes, organizes them into a region definition, and saves the result in the region whose handle you pass in the `dstRgn` parameter.

The `CloseRgn` function does not create the destination region; you must have already allocated space for it by using the `OpenRgn` function. The `CloseRgn` function calls the `ShowPen` function, balancing the call to the `HidePen` function made by `OpenRgn`.

When you no longer need the memory occupied by the region, use the `DisposeRgn` (page 2609) function.

If the points or rectangles supplied to this function are defined in a graphics port other than your current graphics port, you must convert them to the local coordinate system of your current graphics port. You can accomplish this by using the `SetPort` function to change to the graphics port containing the points or rectangles, using the `LocalGlobal` function to convert their locations to global coordinates, using `SetPort` to return to your starting graphics port, and then using the `GlobalToLocal` function to convert the locations of points or rectangles to the local coordinates of your current graphics port.

Special Considerations

Regions are limited to 32 KB in size in basic QuickDraw and 64 KB in Color QuickDraw. When you structure drawing operations in an open region, the resulting region description may overflow this limit. Should this happen in Color QuickDraw, the `QDError` function returns the result code `regionTooBigError`. Since the resulting region is potentially corrupt, the `CloseRgn` function returns an empty region if it detects `QDError` has returned `regionTooBigError`.

The `CloseRgn` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

Color2Index

Obtains the index of the best available approximation for a given color in the color table of the current `GDevice` data structure. This function is used only by system software. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
long Color2Index (
   const RGBColor *myColor
);
```

Parameters

myColor

A pointer to the RGB color value to be approximated.

Return Value

The index of the best approximation for the given color that is available in the color table of the current `GDevice` data structure. Note that `Color2Index` returns a long integer, in which the low-order word is the index value; the high-order word contains zeros.

Discussion

You should not call `Color2Index` from within a custom search function (described in `ColorSearchProcPtr` (page 2834)).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

ColorBit

Sets the foreground color for all printing in the current graphics port. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void ColorBit (
   short whichBit
);
```

Parameters

whichBit

An integer specifying the plane to draw into.

Discussion

The `ColorBit` function is called by printing software for a color printer (or other color-imaging software) to set the `GrafPort` structure's `colorBit` field to the value in the `whichBit` parameter. This value tells QuickDraw which plane of the color picture to draw into. QuickDraw draws into the plane corresponding to the bit number specified by the `whichBit` parameter. Since QuickDraw can support output devices that have up to 32 bits of color information per pixel, the possible range of values for `whichBit` is 0 through 31. The initial value of the `colorBit` field is 0.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

CopyBits

Copies a portion of a bitmap or a pixel map from one graphics port or offscreen graphics world into another graphics port. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void CopyBits (
   const BitMap *srcBits,
   const BitMap *dstBits,
   const Rect *srcRect,
   const Rect *dstRect,
   short mode,
   RgnHandle maskRgn
);
```

Parameters

srcBits

The source `BitMap` structure.

dstBits

The destination `BitMap` structure.

srcRect

The source rectangle.

dstRect

The destination rectangle.

mode

One of the eight source modes in which the copy is to be performed. See "Source, Pattern, and Arithmetic Transfer Mode Constants" (page 2898). The `CopyBits` function always dithers images when shrinking them between pixel maps on direct devices.

When transferring pixels from a source pixel map to a destination pixel map, color QuickDraw interprets the source mode constants differently than basic QuickDraw does.

When you use `CopyBits` on a computer running color QuickDraw, you can also specify one of the transfer modes in the `mode` parameter.

maskRgn

A region to use as a clipping mask. You can pass a region handle to specify a mask region the resulting image is always clipped to this mask region and to the boundary rectangle of the destination bitmap. If the destination bitmap is the current graphics port's bitmap, it is also clipped to the intersection of the graphics port's clipping region and visible region. If you do not want to clip to a masking region, just pass `NULL` for this parameter.

Discussion

The `CopyBits` function transfers any portion of a bitmap between two basic graphics ports, or any portion of a pixel map between two color graphics ports. Use `CopyBits` to move offscreen graphic images into an onscreen window, to blend colors for the image in a pixel map, and to shrink and expand images.

Specify a source bitmap in the `srcBits` parameter and a destination bitmap in the `dstBits` parameter. When copying images between color graphics ports, you must coerce each `CGrafPort` structure to a `GrafPort` structure, dereference the `portBits` fields of each, and then pass these "bitmaps" in the `srcBits` and `dstBits` parameters. If your application copies a pixel image from a color graphics port called `MyColorPort`, for example, you could specify `(* GrafPtr(MyColorPort)).portBits` in the `srcBits` parameter. In a `CGrafPort` structure, the high 2 bits of the `portVersion` field are set. This field, which shares the same position in a `CGrafPort` structure as the `portBits.rowBytes` field in a `GrafPort` structure, indicates to `CopyBits` that you have passed it a handle to a pixel map rather than a bitmap.

Using the `srcRect` and `dstRect` parameters, you can specify identically or differently sized source and destination rectangles; for differently sized rectangles, `CopyBits` scales the source image to fit the destination. If the bit image is a circle in a square source rectangle, and the destination rectangle is not square, the bit image appears as an oval in the destination. When you specify rectangles in the `srcRect` and `dstRect` parameters, use the local coordinate systems of, respectively, the source and destination graphics ports.

The `CopyDeepMask` (page 2586) function combines the functions of the `CopyBits` and `CopyMask` functions.

Special Considerations

When you use the `CopyBits` function to transfer an image between pixel maps, the source and destination images may be of different pixel depths, of different sizes, and they may have different color tables. However, `CopyBits` assumes that the destination pixel map uses the same color table as the color table for the current `GDevice` structure. (This is because the Color Manager requires an inverse table for translating the color table from the source pixel map to the destination pixel map.)

The `CopyBits` function applies the foreground and background colors of the current graphics port to the image in the destination pixel map (or bitmap), even if the source image is a bitmap. This causes the foreground color to replace all black pixels in the destination and the background color to replace all white pixels. To avoid unwanted coloring of the image, use the `RGBForeColor` function to set the foreground to black and use the `RGBBackColor` function to set the background to white before calling `CopyBits`.

The source bitmap or pixel map must not occupy more memory than half the available stack space. The stack space required by `CopyBits` is roughly five times the value of the `rowBytes` field of the source pixel map: one `rowBytes` value for the pixel map (or bitmap), an additional `rowBytes` value for dithering, another

rowBytes value when stretching or shrinking the source pixel map into the destination, another rowBytes value for any color map changing, and a fifth additional rowBytes value for any color aliasing. If there is insufficient memory to complete a CopyBits operation in Color QuickDraw, the QDError function returns the result code –143.

If you use CopyBits to copy between two graphics ports that overlap, you must first use the LocalToGlobal function to convert to global coordinates, and then specify the global variable screenBits for both the srcBits and dstBits parameters.

The CopyBits function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

If you are reading directly from a NuBus video card with a base address of Fs00000 and there is not a card in the slot (s–1) below it, CopyBits reads addresses less than the base address of the pixel map. This causes a bus error. To work around the problem, remap the baseAddr field of the pixel map in your video card to at least 20 bytes above the NuBus boundary; an address link of Fs000020 precludes the problem.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
QuickdrawAPI.h

CopyDeepMask

Uses a mask when copying bitmaps or pixel maps between graphics ports (or from an offscreen graphics world into a graphics port). (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void CopyDeepMask (
   const BitMap *srcBits,
   const BitMap *maskBits,
   const BitMap *dstBits,
   const Rect *srcRect,
   const Rect *maskRect,
   const Rect *dstRect,
   short mode,
   RgnHandle maskRgn
);
```

Parameters

srcBits
The source BitMap structure.

maskBits
The masking BitMap structure.

dstBits
The destination BitMap structure. The result is clipped to the mask region that you specify in the maskRgn parameter, and to the boundary rectangle that you specify in the dstRect parameter.

srcRect
The source rectangle.

maskRect

The mask rectangle. This must be the same size as the rectangle passed in the `srcRect` parameter. The rectangle you pass here selects the portion of the bitmap or pixel map that you specify in the `maskBits` parameter to use as the mask.

dstRect

The destination rectangle.

mode

The source mode.

maskRgn

The mask clipping region. If you do not want to clip to the mask region, specify `NULL`.

Discussion

`CopyDeepMask` combines the effects of the `CopyBits` and `CopyMask` functions. You specify a mask to `CopyDeepMask` so that it transfers the source image to the destination image only where the bits of the mask are set to 1. Use `CopyDeepMask` to move offscreen graphic images into an onscreen window, to blend colors for the image in a pixel map, and to shrink and expand images.

When copying images between color graphics ports, you must coerce each port's `CGrafPort` structure to a `GrafPort` structure, dereference the `portBits` fields of each, and then pass these "bitmaps" in the `srcBits` and `dstBits` parameters. If your application copies a pixel image from a color graphics port called `MyColorPort`, for example, you could specify (* `GrafPtr(MyColorPort)).portBits` in the `srcBits` parameter. The transfer can be performed in any of the transfer modes—with or without adding the `ditherCopy` constant—that are available to `CopyBits` (page 2584).

Using the `srcRect` and `dstRect` parameters, you can specify identically or differently sized source and destination rectangles; for differently sized rectangles, `CopyDeepMask` scales the source image to fit the destination. When you specify rectangles in the `srcRect` and `dstRect` parameters, use the local coordinate systems of, respectively, the source and destination graphics ports.

If you specify pixel maps to `CopyDeepMask`, they may range from 1 to 32 pixels in depth. The pixel depth of the mask that you specify in the `maskBits` parameter is applied as a filter between the source and destination pixel maps that you specify in the `srcBits` and `dstBits` parameters. A black mask pixel value means that the copy operation is to take the source pixel a white value means that the copy operation is to take the destination pixel. Intermediate values specify a weighted average, which is calculated on a color component basis. For each pixel's color component value, the calculation is

(1 – mask) x source + (mask) x destination

Thus high mask values for a pixel's color component reduce that component's contribution from the source `PixMap` structure.

Special Considerations

As with the `CopyMask` function, calls to `CopyDeepMask` are not recorded in pictures and do not print.

See the list of special considerations for `CopyBits` (page 2584); these considerations also apply to `CopyDeepMask`.

The `CopyDeepMask` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

CopyMask

Copies a bit or pixel image from one graphics port or offscreen graphics world into another graphics port only where the bits in a mask are set to 1. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void CopyMask (
   const BitMap *srcBits,
   const BitMap *maskBits,
   const BitMap *dstBits,
   const Rect *srcRect,
   const Rect *maskRect,
   const Rect *dstRect
);
```

Parameters

srcBits
The source `BitMap` structure.

maskBits
The mask `BitMap` structure.

dstBits
The destination `BitMap` structure.

srcRect
The source rectangle.

maskRect
The mask rectangle. This must be the same size as the rectangle passed in the `srcRect` parameter. The rectangle you pass in this parameter selects the portion of the bitmap or pixel map that you specify in the `maskBits` parameter to use as the mask.

dstRect
The destination rectangle.

Discussion
The `CopyMask` function copies the source bitmap or pixel map that you specify in the `srcBits` parameter to a destination bitmap or pixel map that you specify in the `dstBits` parameter—but only where the bits of the mask bitmap or pixel map that you specify in the `maskBits` parameter are set to 1. When copying images between color graphics ports, you must coerce each `CGrafPort` structure to a `GrafPort` structure, dereference the `portBits` fields of each, and then pass these "bitmaps" in the `srcBits` and `dstBits` parameters. If your application copies a pixel image from a color graphics port called `MyColorPort`, for example, you could specify (* `GrafPtr(MyColorPort)).portBits` in the `srcBits` parameter.

Using the `srcRect` and `dstRect` parameters, you can specify identically or differently sized source and destination rectangles; for differently sized rectangles, `CopyMask` scales the source image to fit the destination. When you specify rectangles in the `srcRect` and `dstRect` parameters, use the local coordinate systems of, respectively, the source and destination graphics ports.

If you specify pixel maps to `CopyMask`, they may range from 1 to 32 pixels in depth. The pixel depth of the mask that you specify in the `maskBits` parameter is applied as a filter between the source and destination pixel maps that you specify in the `srcBits` and `dstBits` parameters. A black mask pixel value means that the copy operation is to take the source pixel a white value means that the copy operation is to take the destination pixel. Intermediate values specify a weighted average, which is calculated on a color component basis. For each pixel's color component value, the calculation is

(1 – mask) x source + (mask) x destination

Thus high mask values for a pixel's color component reduce that component's contribution from the source `PixMap` structure.

Use the bitmap returned by `CalcMask` (page 2578) as the mask in order to implement a mask copy similar to that performed by the MacPaint lasso tool. In the same way, you can use the pixel map returned by the `CalcCMask` function.

The `CopyDeepMask` (page 2586) function combines the functions of the `CopyMask` and `CopyBits` functions.

Special Considerations

Calls to `CopyMask` are not recorded in pictures and do not print.

See the list of special considerations for `CopyBits` (page 2584); these considerations also apply to `CopyMask`.

The `CopyMask` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

CopyPixMap

Duplicates a `PixMap` structure. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void CopyPixMap (
   PixMapHandle srcPM,
   PixMapHandle dstPM
);
```

Parameters

srcPM
A handle to the `PixMap` structure to be copied.

dstPM
On return, a handle to the duplicated `PixMap` structure.

Discussion
Typically, you do not need to call this function in your application code, because the `CopyPixMap` function copies the contents of the source `PixMap` structure to the destination `PixMap` structure. The contents of the color table are copied, so the destination `PixMap` has its own copy of the color table. Because the `baseAddr` field of the `PixMap` structure is a pointer, the pointer, but not the image itself, is copied.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

CopyPixPat

Copies the contents of one pixel pattern to another. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void CopyPixPat (
   PixPatHandle srcPP,
   PixPatHandle dstPP
);
```

Parameters

srcPP
A handle to a source pixel pattern, the contents of which you want to copy.

dstPP
A handle to a destination pixel pattern, into which you want to copy the contents of the pixel pattern in the `srcPP` parameter.

Discussion
The `CopyPixPat` function copies all of the fields in the source `PixPat` (page 2871) structure, including the contents of the data handle, expanded data handle, expanded map, pixel map handle, and color table.

Generally, your application should create a pixel pattern in a `'ppat'` resource, instead of using this function.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

CopyRgn

Makes a copy of a region.

```
void CopyRgn (
    RgnHandle srcRgn,
    RgnHandle dstRgn
);
```

Parameters

srcRgn

A handle to the region to copy.

dstRgn

A handle to the region to receive the copy.

Discussion

The `CopyRgn` function copies the mathematical structure of the region whose handle you pass in the `srcRgn` parameter into the region whose handle you pass in the `dstRgn` parameter; that is, `CopyRgn` makes a duplicate copy of `srcRgn`. When calling `CopyRgn`, pass handles that have been returned by the `NewRgn` function in the `srcRgn` and `dstRgn` parameters.

Once this is done, the region indicated by `srcRgn` may be altered (or even disposed of) without affecting the region indicated by `dstRgn`. The `CopyRgn` function does not create the destination region; space must already have been allocated for it by using the `NewRgn` function.

Special Considerations

The `CopyRgn` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

CreateCGContextForPort

Creates a Quartz 2D drawing environment associated with a graphics port. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

Not Recommended

```
OSStatus CreateCGContextForPort (
   CGrafPtr inPort,
   CGContextRef *outContext
);
```

Parameters

port

A color graphics port in which to draw. Offscreen graphics worlds with pixel depths of 1, 2, 4, and 8 are not supported. When using Quartz 2D to draw in a offscreen graphics world, alpha information is always ignored. Printing ports are not supported—if you specify a printing port, this function does nothing and returns a non-zero result code.

contextPtr

A pointer to your storage for a Quartz context. Upon completion, `contextPtr` points to a context associated with the port. The context matches the port's pixel depth, width, and height. Otherwise the context is in a default state and does not necessarily match other port attributes such as foreground color, background color, or clip region.

You should release this context when you no longer need it.

Return Value
A result code. If `noErr`, the context was successfully created.

Discussion
This function is not recommended in Mac OS X version 10.1 and later. For information about its replacement, see `QDBeginCGContext` (page 2756).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

CreateNewPort

(Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
CGrafPtr CreateNewPort (
   void
);
```

Return Value

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

CreateNewPortForCGDisplayID

Creates a graphics port associated with a display. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
CGrafPtr CreateNewPortForCGDisplayID (
   UInt32 inCGDisplayID
);
```

Parameters

displayID

A display identifier. If the identifier is not valid, the main display is used instead. For information about finding displays, see *Quartz Display Services Reference*.

Return Value

A new display port. The `portBounds` rectangle is the same size as the display. When you are finished using the port, you should call `DisposePort` (page 2603) to release it.

Discussion

This function returns a graphics port used to draw directly to a display. The pixel map for the new port is taken from the `GDevice` record corresponding to the display. There is no back buffer associated with the port.

Before calling this function, you should capture the display. For information about capturing displays, see *Quartz Display Services Reference*.

You should not call this function and then attempt to create a Quartz drawing environment inside the port. Instead, applications using Quartz 2D can call `CGDisplayGetDrawingContext` (page 1497) to obtain a context suitable for drawing directly to a captured display.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

CTabChanged

Signals QuickDraw that the content of a `ColorTable` structure has been modified. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void CTabChanged (
   CTabHandle ctab
);
```

Parameters

ctab

A handle to the `ColorTable` structure changed by your application.

Discussion

The `CTabChanged` function calls the function `GetCTSeed` and gets a new, unique identifier in the `ctSeed` field of the `ColorTable` structure, and notifies QuickDraw of the change.

Your application should never need to directly modify a `ColorTable` structure and use the `CTabChanged` function; instead, your application should use the QuickDraw functions provided for manipulating the values in a `ColorTable` structure.

Special Considerations

The `CTabChanged` function may move or purge memory in the application heap; do not call the `CTabChanged` function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In

`QDOffscreen.h`

CursorComponentChanged

(Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
OSErr CursorComponentChanged (
   ComponentInstance ci
);
```

Return Value

A result code.

Carbon Porting Notes

This function is not implemented on Mac OS X.

Availability

Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

CursorComponentSetData

(Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
OSErr CursorComponentSetData (
   ComponentInstance ci,
   long data
);
```

Return Value

A result code.

Carbon Porting Notes

This function is not implemented on Mac OS X.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

DelComp

Removes a custom complement function from the current `GDevice` data structure's list of complement functions. This function is used by system software and your application should not need to call it. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void DelComp (
   ColorComplementUPP compProc
);
```

Parameters

compProc
A pointer to the complement function, `ColorComplementProcPtr` (page 2834), to be deleted. `DelComp` disposes of the chain element, but does nothing to the `ProcPtr` data structure.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

DelSearch

Removes a custom search function from the current `GDevice` data structure's list of search functions. This function is used by system software and your application should not need to call it. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void DelSearch (
   ColorSearchUPP searchProc
);
```

Parameters

searchProc
A pointer to the custom search function, `ColorSearchProcPtr` (page 2834) to be deleted. `DelSearch` disposes of the chain element, but does nothing to the `ProcPtr` data structure.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

DeltaPoint

Subtracts the coordinates of one point from another. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
long DeltaPoint (
   Point ptA,
   Point ptB
);
```

Parameters

p1

The first point.

p2

The second point, the coordinates of which are to be subtracted from the coordinates of the first point.

Return Value

A 32-bit value that contains the differences between the coordinates of the points `p1` and `p2`. The vertical difference is returned in the high 16 bits and the horizontal difference is returned in the low 16 bits.

Discussion

You should not cast the result to a `Point` data structure. Instead, use `HiWord` and `LoWord` to obtain the horizontal and vertical differences.

For example:

```
Point pointDiff;
SInt32 difference = DeltaPoint(p1, p2);
pointDiff.h = LoWord(difference);
pointDiff.v = HiWord(difference);
```

While `DeltaPoint` is supported in Carbon, you can achieve the same result in a more direct manner using the function `SubPt` (page 2824).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

deltapoint

(Deprecated in Mac OS X v10.4. Use `DeltaPoint` (page 2596) instead.)

```
long deltapoint (
   Point *ptA,
   Point *ptB
);
```

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
QuickdrawAPI.h

DeviceLoop

Draws images that are optimized for every screen they cross. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void DeviceLoop (
   RgnHandle drawingRgn,
   DeviceLoopDrawingUPP drawingProc,
   long userData,
   DeviceLoopFlags flags
);
```

Parameters

drawingRgn
A handle to the region in which you will draw; this drawing region uses coordinates that are local to its graphics port.

drawingProc
A pointer to your own drawing function.

userData
Any additional data that you wish to supply to your drawing function.

flags
One or more members of the set of flags defined by the " Device Loop Flags" (page 2889) data type. if you want to use the default behavior of DeviceLoop, specify an empty set ([]) in this parameter.

Discussion
The DeviceLoop function searches for graphics devices that intersect your window's drawing region, and it calls your drawing function for each dissimilar video device it finds.

Because DeviceLoop provides your drawing function with the pixel depth and other attributes of each video device, your drawing function can optimize its drawing for each video device.

See DeviceLoopDrawingProcPtr (page 2836) for a description of the drawing function you must provide for the drawingProc parameter.

Special Considerations

The DeviceLoop function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
QuickdrawAPI.h

DiffRgn

Subtracts one region from another.

```
void DiffRgn (
   RgnHandle srcRgnA,
   RgnHandle srcRgnB,
   RgnHandle dstRgn
);
```

Parameters

srcRgnA

A handle to the region to subtract from.

srcRgnB

A handle to the region to subtract.

dstRgn

On return, a handle to the region holding the resulting area. If the first source region is empty, `DiffRgn` sets the destination to the empty region defined by the rectangle (0,0,0,0).

The `DiffRgn` function does not create the destination region; you must have already allocated memory for it by using the `NewRgn` (page 2726) function.

The destination region may be one of the source regions, if desired.

Discussion

The DiffRgn procedure subtracts the region whose handle you pass in the srcRgnB parameter from the region whose handle you pass in the srcRgnA parameter and places the difference in the region whose handle you pass in the dstRgn parameter. If the first source region is empty, DiffRgn sets the destination to the empty region defined by the rectangle (0,0,0,0).

The DiffRgn procedure does not create the destination region; you must have already allocated memory for it by using the NewRgn function. The destination region may be one of the source regions, if desired.

Special Considerations

The `DiffRgn` function may temporarily use heap space that's twice the size of the two input regions.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

DisposeCCursor

Disposes of all structures allocated by the `GetCCursor` function. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void DisposeCCursor (
   CCrsrHandle cCrsr
);
```

Parameters

cCrsr

A handle to the color cursor to be disposed of.

Discussion
Use `DisposeCCursor` for each call to the `GetCCursor` (page 2635) function.

The `DisposeCCursor` function is also available as the `DisposCCursor` function.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

DisposeColorComplementUPP

(Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void DisposeColorComplementUPP (
   ColorComplementUPP userUPP
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`QuickdrawTypes.h`

DisposeColorSearchUPP

(Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void DisposeColorSearchUPP (
   ColorSearchUPP userUPP
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`QuickdrawTypes.h`

DisposeCTable

Disposes a `ColorTable` structure. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void DisposeCTable (
   CTabHandle cTable
);
```

Parameters

cTable

A handle to a `ColorTable` structure to dispose of.

Discussion

The DisposeCTable procedure disposes of the ColorTable record whose handle you pass in the cTable parameter.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

DisposeDeviceLoopDrawingUPP

(Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void DisposeDeviceLoopDrawingUPP (
   DeviceLoopDrawingUPP userUPP
);
```

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`QuickdrawTypes.h`

DisposeDragGrayRgnUPP

(Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void DisposeDragGrayRgnUPP (
   DragGrayRgnUPP userUPP
);
```

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`QuickdrawTypes.h`

DisposeGDevice

Disposes of a `GDevice` structure, releases the space allocated for it, and disposes of all the data structures allocated for it. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void DisposeGDevice (
   GDHandle gdh
);
```

Parameters

gdh

A handle to the `GDevice` structure.

Discussion

Generally, you should never need to use this function. Color QuickDraw calls this function when appropriate. The `DisposeGDevice` function is also available as the `DisposGDevice` function.

When your application uses the `DisposeGWorld` function to dispose of an offscreen graphics world, `DisposeGDevice` disposes of its `GDevice` structure.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

DisposeGWorld

Disposes of all the memory allocated for an offscreen graphics world. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void DisposeGWorld (
   GWorldPtr offscreenGWorld
);
```

Parameters

offscreenGWorld

A pointer to an offscreen graphics world. In this parameter, pass the pointer returned to your application by the `NewGWorld` function when you created the offscreen graphics world.

Discussion

The `DisposeGWorld` function disposes of all the memory allocated for the specified offscreen graphics world, including the pixel map, color table, pixel image, and `GDevice` structure (if one was created).

Call `DisposeGWorld` only when your application no longer needs the pixel image associated with this offscreen graphics world. If this offscreen graphics world was the current device, the current device is reset to the device stored in the global variable `MainDevice`.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Related Sample Code
QTCarbonShell
WhackedTV

Declared In
`QDOffscreen.h`

DisposePixMap

Disposes a `PixMap` structure and its color table. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void DisposePixMap (
   PixMapHandle pm
);
```

Parameters

pm

A handle to the `PixMap` structure to be disposed of.

Discussion
The `CloseCPort` function calls `DisposePixMap`.

Your application typically does not need to call this function. This function is also available as `DisposPixMap`.

If your application uses `DisposePixMap`, take care that it does not dispose of a `PixMap` structure whose color table is the same as the current device's CLUT.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Related Sample Code
LiveVideoMixer2

Declared In
`QuickdrawAPI.h`

DisposePixPat

Releases the storage allocated to a pixel pattern. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void DisposePixPat (
   PixPatHandle pp
);
```

Parameters

pp

A handle to the pixel pattern to be disposed of.

Discussion
The `DisposePixPat` function disposes of the data handle, expanded data handle, and pixel map handle allocated to the pixel pattern that you specify in the `ppat` parameter.

The `DisposePixPat` function is also available as the `DisposPixPat` function.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

DisposePort

(Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`QuickdrawAPI.h`

DisposeRgn

Releases the memory occupied by a region.

```
void DisposeRgn (
   RgnHandle rgn
);
```

Parameters

rgn

A handle to the region to dispose. This handle should be a region handle returned by the `NewRgn` (page 2726) function.

Discussion
Use `DisposeRgn` only after you are completely through with a region.

Special Considerations

The `DisposeRgn` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

`QuickdrawAPI.h`

DisposeScreenBuffer

Disposes an offscreen graphics world. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void DisposeScreenBuffer (
   PixMapHandle offscreenPixMap
);
```

Parameters

offscreenPixMap

A handle to an existing offscreen `PixMap` structure.

Discussion
Generally, applications do not need to use `DisposeScreenBuffer`. The `DisposeGWorld` (page 2601) function uses the `DisposeScreenBuffer` function when disposing of an offscreen graphics world.

The `DisposeScreenBuffer` function disposes of the memory allocated for the base address of an offscreen pixel image.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QDOffscreen.h`

DrawPicture

Draws a picture on any type of output device. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void DrawPicture (
   PicHandle myPicture,
   const Rect *dstRect
);
```

Parameters

myPicture

A handle to the picture to be drawn. You must access a picture through its handle.

When creating pictures, the `OpenCPicture` (page 2734) and `OpenPicture` (page 2736) functions return their handles. You can use the `GetPicture` (page 2648) function to get a handle to a QuickDraw picture stored in a `'PICT'` resource. To get a handle to a QuickDraw picture stored in a `'PICT'` file, you must use File Manager functions. To get a picture stored in the scrap, use the Scrap Manager function `GetScrap` to get a handle to its data and then coerce this handle to one of type `PicHandle`.

dstRect

A destination rectangle, specified in coordinates local to the current graphics port, in which to draw the picture. The `DrawPicture` function shrinks or expands the picture as necessary to align the borders of its bounding rectangle with the rectangle you specify in this parameter. To display a picture at a resolution other than that at which it was created, your application should compute an appropriate destination rectangle by scaling its width and height by the following factor:

```
scale factor = destination resolution / source resolution
```

For example, if a picture was created at 300 dpi and you want to display it at 75 dpi, then your application should compute the destination rectangle width and height as 1/4 of those of the picture's bounding rectangle. Use the `GetPictInfo` function to gather information about a picture. The `PictInfo` structure returned by `GetPictInfo` returns the picture's resolution in its `hRes` and `vRes` fields. The `sourceRect` field contains the bounding rectangle for displaying the image at its optimal resolution.

Discussion
Within the rectangle that you specify in the `dstRect` parameter, the `DrawPicture` function draws the picture that you specify in the `myPicture` parameter.

The DrawPicture function passes any picture comments to the StdComment function pointed to by the commentProc field of the CQDProcs or QDProcs structure, which in turn is pointed to by the grafProcs field of a CGrafPort or GrafPort structure. The default StdComment function provided by QuickDraw does no comment processing whatsoever. If you want to process picture comments when drawing a picture, use the SetStdCProcs function to assist you in changing the CQDProcs structure and use the SetStdProcs function to assist you in changing the QDProcs structure.

Special Considerations

Always use the ClipRect function to specify a clipping region appropriate for your picture before defining it with the OpenCPicture (or OpenPicture) function. If you do not use ClipRect to specify a clipping region, OpenCPicture uses the clipping region specified in the current graphics port. If the clipping region is very large (as it is when a graphics port is initialized) and you want to scale the picture, the clipping region can become invalid when DrawPicture scales the clipping region—in which case, your picture will not be drawn. On the other hand, if the graphics port specifies a small clipping region, part of your drawing may be clipped when DrawPicture draws it. Setting a clipping region equal to the port rectangle of the current graphics port always sets a valid clipping region.

When it scales, DrawPicture changes the size of the font instead of scaling the bits. However, the widths used by bitmap fonts are not always linear. For example, the 12-point width isn't exactly 1/2 of the 24-point width. This can cause lines of text to become slightly longer or shorter as the picture is scaled. The difference is often insignificant, but if you are trying to draw a line of text that fits exactly into a box (a spreadsheet cell, for example), the difference can become noticeable to the user—most typically, at print time. The easiest way to avoid such problems is to specify a destination rectangle that is the same size as the bounding rectangle for the picture. Otherwise, your application may need to directly process the opcodes in the picture instead of using DrawPicture.

You may also have disappointing results if the fonts contained in an image are not available on the user's system. Before displaying a picture, your application may want to use the Picture Utilities to determine what fonts are contained in the picture, and then use Font Manager functions to determine whether the fonts are available on the user's system. If they are not, you can use Dialog Manager functions to display an alert box warning the user of display problems.

If there is insufficient memory to draw a picture in Color QuickDraw, the QDError function returns the result code noMemForPictPlaybackErr.

The DrawPicture function may move or purge memory.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

QuickdrawAPI.h

EmptyRect

Determines whether a rectangle is an empty rectangle.

```
Boolean EmptyRect (
   const Rect *r
);
```

Parameters

r

The rectangle to examine.

Return Value

`TRUE` if the rectangle that you specify in the `r` parameter is an empty rectangle, `FALSE` if it is not. A rectangle is considered empty if the bottom coordinate is less than or equal to the top coordinate or if the right coordinate is less than or equal to the left.

Discussion

If the points or rectangles supplied to this function are defined in a graphics port other than your current graphics port, you must convert them to the local coordinate system of your current graphics port. You can accomplish this by using the `SetPort` function to change to the graphics port containing the points or rectangles, using the `LocalGlobal` function to convert their locations to global coordinates, using `SetPort` to return to your starting graphics port, and then using the `GlobalToLocal` function to convert the locations of points or rectangles to the local coordinates of your current graphics port.

Availability

Available in Mac OS X v10.0 and later.

Related Sample Code

Declared In

`QuickdrawAPI.h`

EmptyRgn

Determines whether a region is empty.

```
Boolean EmptyRgn (
   RgnHandle rgn
);
```

Parameters

rgn

A handle to the region to test for emptiness.

Return Value

`TRUE` if the region whose handle you pass in the `rgn` parameter is an empty region or `FALSE` if it is not.

Discussion

The `EmptyRgn` function does not create an empty region. To create an empty region, you can perform any of the following operations:

- Use `NewRgn` (page 2726).
- Pass the handle to an empty region to `CopyRgn` (page 2590).
- Pass an empty rectangle to either `SetRectRgn` (page 2810) or `RectRgn` (page 2776).

- Call `CloseRgn` (page 2582) without a previous call to `OpenRgn` (page 2737).
- Call `CloseRgn` (page 2582) without performing any drawing after calling `OpenRgn` (page 2737).
- Pass an empty region to `OffsetRgn` (page 2732).
- Pass an empty region or too large an inset to `InsetRgn` (page 2673)
- Pass two nonintersecting regions to `SectRgn` (page 2786).
- Pass two empty regions to `UnionRgn` (page 2828).
- Pass two identical or nonintersecting regions to `DiffRgn` (page 2598) or `XorRgn` (page 2833).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

`QuickdrawAPI.h`

EqualPt

Determines whether the coordinates of two given points are equal.

```
Boolean EqualPt (
   Point pt1,
   Point pt2
);
```

Parameters

pt1
The first of two points to be compared.

pt2
The second of two points to be compared.

Return Value
`TRUE` if the coordinates of the two points are equal, or `FALSE` if they are not.

Discussion
The EqualPt function compares the points specified in the pt1 and pt2 parameters and returns TRUE if their coordinates are equal or FALSE if they are not.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`QuickdrawAPI.h`

EqualRect

Determines whether two rectangles are equal.

```
Boolean EqualRect (
    const Rect * rect1,
    const Rect * rect2
);
```

Parameters

rect1

The first of two rectangles to compare.

rect2

The second of two rectangles to compare.

Return Value

`TRUE` if the rectangles are equal, `FALSE` if they are not.

Discussion

If the points or rectangles supplied to this function are defined in a graphics port other than your current graphics port, you must convert them to the local coordinate system of your current graphics port. You can accomplish this by using the `SetPort` function to change to the graphics port containing the points or rectangles, using the `LocalGlobal` function to convert their locations to global coordinates, using `SetPort` to return to your starting graphics port, and then using the `GlobalToLocal` function to convert the locations of points or rectangles to the local coordinates of your current graphics port.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`QuickdrawAPI.h`

EqualRgn

Determines whether two regions have identical sizes, shapes, and locations.

```
Boolean EqualRgn (
    RgnHandle rgnA,
    RgnHandle rgnB
);
```

Parameters

rgnA

A handle to the first of two regions to compare.

rgnB

A handle to the second of two regions to compare.

Return Value

`TRUE` if the two regions are equal; `FALSE` if they are not. The two regions must have identical sizes, shapes, and locations to be considered equal. Any two empty regions are always equal.

Discussion

The EqualRgn function compares the two regions whose handles you pass in the rgnA and rgnB parameters and returns TRUE if they're equal or FALSE if they're not.

The two regions must have identical sizes, shapes, and locations to be considered equal. Any two empty regions are always equal.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
QuickdrawAPI.h

EraseArc

Erases a wedge. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void EraseArc (
   const Rect *r,
   short startAngle,
   short arcAngle
);
```

Parameters

r
The rectangle that defines an oval's boundaries.

startAngle
The angle indicating the start of the arc.

arcAngle
The angle indicating the arc's extent.

Discussion
Using the patCopy pattern mode, the EraseArc function draws a wedge of the oval bounded by the rectangle that you specify in the r parameter with the background pattern for the current graphics port. As in FrameArc (page 2629) , use the startAngle and arcAngle parameters to define the arc of the wedge.

This function leaves the location of the graphics pen unchanged.

Special Considerations

The EraseArc function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
QuickdrawAPI.h

EraseOval

Erases an oval. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void EraseOval (
   const Rect *r
);
```

Parameters

r

The rectangle that defines the oval's boundary.

Discussion

Using the background pattern for the current graphics port and the `patCopy` pattern mode, the `EraseOval` function draws the interior of an oval just inside the bounding rectangle that you specify in the `r` parameter. This effectively erases the oval bounded by the specified rectangle.

This function leaves the location of the graphics pen unchanged.

Special Considerations

The `EraseOval` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

ErasePoly

Erases a polygon. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void ErasePoly (
   PolyHandle poly
);
```

Parameters

poly

A handle to the polygon to erase. The `OpenPoly` (page 2737) function returns this handle when you first create the polygon.

Discussion

Using the `patCopy` pattern mode, the `ErasePoly` function draws the interior of the polygon whose handle you pass in the `poly` parameter with the background pattern for the current graphics port.

This function leaves the location of the graphics pen unchanged.

This function temporarily converts the polygon into a region to perform their operations. The amount of memory required for this temporary region may be far greater than the amount required by the polygon alone.

You can estimate the size of this region by scaling down the polygon with the `MapPoly` (page 2707) , converting the polygon into a region, checking the region's size with the Memory Manager function `GetHandleSize`, and multiplying that value by the factor by which you scaled the polygon.

The result of this graphics operation is undefined whenever any horizontal or vertical line drawn through the polygon would intersect the polygon's outline more than 50 times.

Special Considerations

The `ErasePoly` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

EraseRect

Erases a rectangle. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void EraseRect (
   const Rect *r
);
```

Parameters

r

The rectangle to erase.

Discussion
Using the `patCopy` pattern mode, the `EraseRect` function draws the interior of the rectangle that you specify in the `r` parameter with the background pattern for the current graphics port. This effectively erases the rectangle, making the shape blend into the background pattern of the graphics port. For example, use `EraseRect` to erase the port rectangle for a window before redrawing into the window.

This function leaves the location of the graphics pen unchanged.

Special Considerations

The `EraseRect` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

HID Explorer

Declared In
`QuickdrawAPI.h`

EraseRgn

Erases a region. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void EraseRgn (
   RgnHandle rgn
);
```

Parameters

rgn

The region to erase.

Discussion

Using the `patCopy` pattern mode, the `EraseRgn` function draws the interior of the region whose handle you pass in the `rgn` parameter with the background pattern for the current graphics port.

This function leaves the location of the graphics pen unchanged.

This function depends on the local coordinate system of the current graphics port. If you draw a region in a graphics port different from the one in which you defined the region, it may not appear in the proper position in the graphics port.

If any horizontal or vertical line drawn through the region would intersect the region's outline more than 50 times, the results of this graphics operation are undefined.

Special Considerations

The `EraseRgn` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

EraseRoundRect

Erases a rounded rectangle. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void EraseRoundRect (
   const Rect *r,
   short ovalWidth,
   short ovalHeight
);
```

Parameters

r

The rectangle that defines the rounded rectangle's boundaries.

ovalWidth

The width of the oval defining the rounded corner.

ovalHeight
The height of the oval defining the rounded corner.

Discussion
Using the `patCopy` pattern mode, the `EraseRoundRect` function draws the interior of the rounded rectangle bounded by the rectangle that you specify in the `r` parameter with the background pattern of the current graphics port. This effectively erases the rounded rectangle. Use the `ovalWidth` and `ovalHeight` parameters to specify the diameters of curvature for the corners of the rounded rectangle.

This function leaves the location of the graphics pen unchanged.

Special Considerations

The `EraseRoundRect` function may move or purge memory blocks in the application; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

FillArc

Fills a wedge with any available bit pattern. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void FillArc (
   const Rect *r,
   short startAngle,
   short arcAngle,
   const Pattern *pat
);
```

Parameters

r
The rectangle that defines an oval's boundaries.

startAngle
The angle indicating the start of the arc.

arcAngle
The bit pattern to use for the fill.

pat
The angle indicating the arc's extent.

Discussion
Using the `patCopy` pattern mode and the pattern defined in the `Pattern` (page 2866) structure that you specify in the `pat` parameter, the `FillArc` function draws a wedge of the oval bounded by the rectangle that you specify in the `r` parameter. As in `FrameArc` (page 2629) use the `startAngle` and `arcAngle` parameters to define the arc of the wedge.

This function leaves the location of the graphics pen unchanged.

Use `GetPattern` (page 2646) and `GetIndPattern` (page 2643) to get a pattern stored in a resource.

Use `PaintArc` (page 2740) to draw a wedge with the pen pattern for the current graphics port.

To fill a wedge with a pixel pattern, use the `FillCArc` function.

Special Considerations

The `FillArc` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

FillCArc

Fills a wedge with the given pixel pattern, using the `patCopy` pattern mode. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void FillCArc (
   const Rect *r,
   short startAngle,
   short arcAngle,
   PixPatHandle pp
);
```

Parameters

r
The rectangle that defines the oval's boundaries.

startAngle
The angle indicating the start of the arc.

arcAngle
The angle indicating the arc's extent.

pp
A handle to the `PixPat` structure for the pixel pattern to be used for the fill.

Discussion
Use the `startAngle` and `arcAngle` parameters to define the arc of the wedge. This function ignores the `pnPat`, `pnMode`, and `bkPat` fields of the current graphics port and leaves the pen location unchanged.

Special Considerations

The `FillCArc` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

FillCOval

Fills an oval with the given pixel pattern, using the `patCopy` pattern mode. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void FillCOval (
   const Rect *r,
   PixPatHandle pp
);
```

Parameters

r

The rectangle containing the oval to be filled.

pp

A handle to the `PixPat` structure for the pixel pattern to be used for the fill.

Discussion
This function ignores the `pnPat`, `pnMode`, and `bkPat` fields of the current graphics port and leaves the pen location unchanged.

Special Considerations

The `FillCOval` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

FillCPoly

Fills a polygon with the given pixel pattern, using the `patCopy` pattern mode. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void FillCPoly (
   PolyHandle poly,
   PixPatHandle pp
);
```

Parameters

poly

A handle to the polygon to be filled.

pp

A handle to the `PixPat` structure for the pixel pattern to be used for the fill.

Discussion
This function ignores the `pnPat`, `pnMode`, and `bkPat` fields of the current graphics port and leaves the pen location unchanged.

Special Considerations

The `FillCPoly` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

FillCRect

Fills a rectangle with the given pixel pattern, using the `patCopy` pattern mode. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void FillCRect (
   const Rect *r,
   PixPatHandle pp
);
```

Parameters

r
The rectangle to be filled.

pp
A handle to the `PixPat` structure for the pixel pattern to be used for the fill.

Discussion
This function ignores the `pnPat`, `pnMode`, and `bkPat` fields of the current graphics port and leaves the pen location unchanged.

Special Considerations

The `FillCRect` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

FillCRgn

Fills a region with the given pixel pattern, using the `patCopy` pattern mode. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void FillCRgn (
   RgnHandle rgn,
   PixPatHandle pp
);
```

Parameters

rgn

A handle to the region to be filled.

pp

A handle to the `PixPat` structure for the pixel pattern to be used for the fill.

Discussion

This function ignores the `pnPat`, `pnMode`, and `bkPat` fields of the current graphics port and leaves the pen location unchanged.

Special Considerations

The `FillCRgn` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

`QuickdrawAPI.h`

FillCRoundRect

Fills a rounded rectangle with the given pixel pattern, using the `patCopy` pattern mode. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void FillCRoundRect (
   const Rect *r,
   short ovalWidth,
   short ovalHeight,
   PixPatHandle pp
);
```

Parameters

r

The rectangle that defines the rounded rectangle's boundaries.

ovalWidth

The width of the oval defining the rounded corner.

ovalHeight

The height of the oval defining the rounded corner.

pp

A handle to the `PixPat` structure for the pixel pattern to be used for the fill.

Discussion

Use the `ovalWidth` and `ovalHeight` parameters to specify the diameters of curvature for the corners. This function ignores the `pnPat`, `pnMode`, and `bkPat` fields of the current graphics port and leaves the pen location unchanged.

Special Considerations

The `FillCRoundRect` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

`QuickdrawAPI.h`

FillOval

Fills an oval with any available bit pattern. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void FillOval (
   const Rect *r,
   const Pattern *pat
);
```

Parameters

r

The rectangle that defines the oval's boundaries.

pat

The bit pattern to use for the fill.

Discussion

Using the `patCopy` pattern mode and the bit pattern defined in the `Pattern` (page 2866) structure that you specify in the `pat` parameter, the `FillOval` function draws the interior of an oval just inside the bounding rectangle that you specify in the `r` parameter. The pen location does not change.

Use `GetPattern` (page 2646) and `GetIndPattern` (page 2643) , to get a pattern stored in a resource. Use the `PaintOval` (page 2741) function to draw the interior of an oval with the pen pattern for the current graphics port.

To fill an oval with a pixel pattern, use the `FillCOval` function.

Special Considerations

The `FillOval` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

FillPoly

Fills a polygon with any available bit pattern. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void FillPoly (
   PolyHandle poly,
   const Pattern *pat
);
```

Parameters

poly

A handle to the polygon to fill. The `OpenPoly` (page 2737) function returns this handle when you first create the polygon.

pat

The bit pattern to use for the fill.

Discussion

Using the `patCopy` pattern mode, the `FillPoly` function draws the interior of the polygon whose handle you pass in the `poly` parameter with the pattern defined in the `Pattern` (page 2866) structure that you specify in the `pat` parameter.

This function leaves the location of the graphics pen unchanged.

This function temporarily converts the polygon into a region to perform their operations. The amount of memory required for this temporary region may be far greater than the amount required by the polygon alone.

You can estimate the size of this region by scaling down the polygon with the `MapPoly` (page 2707) , converting the polygon into a region, checking the region's size with the Memory Manager function `GetHandleSize`, and multiplying that value by the factor by which you scaled the polygon.

The result of this graphics operation is undefined whenever any horizontal or vertical line drawn through the polygon would intersect the polygon's outline more than 50 times.

Use `GetPattern` (page 2646) and `GetIndPattern` (page 2643) to get a pattern stored in a resource.

Use `PaintPoly` (page 2741) to draw the interior of a polygon with the pen pattern for the current graphics port. To fill a polygon with a pixel pattern, use the `FillCPoly` function.

Special Considerations

The `FillPoly` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

FillRect

Fills a rectangle with any available bit pattern. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void FillRect (
    const Rect * r,
    const Pattern * pat
);
```

Parameters

r

The rectangle to fill.

pat

The bit pattern to use for the fill.

Discussion

Using the `patCopy` pattern mode, the `FillRect` function draws the interior of the rectangle that you specify in the `r` parameter with the pattern defined in the `Pattern` (page 2866) structure that you specify in the `pat` parameter. This function leaves the pen location unchanged.

Use `GetPattern` (page 2646) and `GetIndPattern` (page 2643) , to get a pattern stored in a resource.

Use the `PaintRect` (page 2742) to draw the interior of a rectangle with the pen pattern for the current graphics port. To fill a rectangle with a pixel pattern, use the `FillCRect` function.

Special Considerations

The `FillRect` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

FillRgn

Fills a region with any available bit pattern. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void FillRgn (
    RgnHandle rgn,
    const Pattern * pat
);
```

Parameters

rgn

A handle to the region to fill.

pat

The bit pattern to use for the fill.

Discussion
Using the `patCopy` pattern mode, the `FillRgn` function draws the interior of the region with the pattern defined in the `Pattern` (page 2866) structure that you specify in the `pat` parameter.

This function leaves the location of the graphics pen unchanged.

This function depends on the local coordinate system of the current graphics port. If you draw a region in a graphics port different from the one in which you defined the region, it may not appear in the proper position in the graphics port.

If any horizontal or vertical line drawn through the region would intersect the region's outline more than 50 times, the results of this graphics operation are undefined.

Use `GetPattern` (page 2646) and `GetIndPattern` (page 2643) to get a pattern stored in a resource.

Use `PaintRgn` (page 2743) to draw the interior of a region with the pen pattern for the current graphics port. To fill a region with a pixel pattern, use the `FillCRegion` function.

Special Considerations

The `FillRgn` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

FillRoundRect

Fills a rounded rectangle with any available bit pattern. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void FillRoundRect (
   const Rect *r,
   short ovalWidth,
   short ovalHeight,
   const Pattern *pat
);
```

Parameters

r
The rectangle that defines the rounded rectangle's boundaries.

ovalWidth
The width of the oval defining the rounded corner.

ovalHeight
The height of the oval defining the rounded corner.

pat
The bit pattern to use for the fill.

Discussion
Using the `patCopy` pattern mode, the `FillRoundRect` function draws the interior of the rounded rectangle bounded by the rectangle that you specify in the `r` parameter with the bit pattern defined in the `Pattern` structure that you specify in the `pat` parameter. Use the `ovalWidth` and `ovalHeight` parameters to specify the diameters of curvature for the corners. The pen location does not change.

To fill a rounded rectangle with a pixel pattern, use the `FillCRoundRect` function.

Use `GetPattern` (page 2646) and `GetIndPattern` (page 2643) to get a pattern stored in a resource. Use `PaintRoundRect` (page 2743) to draw the interior of a rounded rectangle with the pen pattern for the current graphics port.

Special Considerations

The `FillRoundRect` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

ForeColor

Changes the color of the "ink" used for framing, painting, and filling on computers that support only basic QuickDraw. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void ForeColor (
   long color
);
```

Parameters

color

One of eight color values. See "Color Constants" (page 2885).

Discussion
By default, the foreground color of a `GrafPort` is black.

The `ForeColor` function sets the foreground color for the current graphics port to the color that you specify in the `color` parameter. When you draw with the `patCopy` and `srcCopy` transfer modes, for example, black pixels are drawn in the color you specify with `ForeColor`.

When printing, use the `ColorBit` (page 2584) function to set the foreground color.

All nonwhite colors appear as black on black-and-white screens. Before you use `ForeColor`, use the `DeviceLoop` function to determine the color characteristics of the current screen.

Special Considerations

The `ForeColor` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Version Notes
In System 7, you may instead use the color QuickDraw function `RGBForeColor`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Related Sample Code

Declared In
`QuickdrawAPI.h`

FrameArc

Draws an arc of the oval that fits inside a rectangle. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void FrameArc (
   const Rect *r,
   short startAngle,
   short arcAngle
);
```

Parameters

r
The rectangle that defines an oval's boundaries.

startAngle
The angle indicating the start of the arc.

arcAngle
The angle indicating the arc's extent.

Discussion
Using the pattern, pattern mode, and size of the graphics pen for the current graphics port, the `FrameArc` function draws an arc of the oval bounded by the rectangle that you specify in the `r` parameter. Use the `startAngle` parameter to specify where the arc begins as modulo 360. Use the `arcAngle` parameter to specify how many degrees the arc covers. Specify whether the angles are in positive or negative degrees a positive angle goes clockwise, while a negative angle goes counterclockwise. Zero degrees is at 12 o'clock high, 90 (or –270) is at 3 o'clock, 180 (or –180) is at 6 o'clock, and 270 (or –90) is at 9 o'clock. Measure other angles relative to the bounding rectangle.

A line from the center of the rectangle through its upper-right corner is at 45, even if the rectangle is not square a line through the lower-right corner is at 135, and so on.

The arc is as wide as the pen width and as tall as the pen height. The pen location does not change.

Special Considerations

The `FrameArc` function differs from other QuickDraw functions that frame shapes in that the arc is not mathematically added to the boundary of a region that's open and being formed.

The `FrameArc` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

FrameOval

Draws an outline inside an oval. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void FrameOval (
   const Rect *r
);
```

Parameters

r

The rectangle that defines the oval's boundary.

Discussion
Using the pattern, pattern mode, and size of the graphics pen for the current graphics port, the `FrameOval` function draws an outline just inside the oval with the bounding rectangle that you specify in the `r` parameter. The outline is as wide as the pen width and as tall as the pen height. The pen location does not change.

If a region is open and being formed, the outside outline of the new oval is mathematically added to the region's boundary.

Special Considerations

The `FrameOval` function may move or purge memory blocks in the application; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

FramePoly

Draws the outline of a polygon. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void FramePoly (
   PolyHandle poly
);
```

Parameters

poly

A handle to the polygon to draw. The `OpenPoly` (page 2737) function returns this handle when you first create the polygon.

Discussion

Using the current graphics port's pen pattern, pattern mode, and size, the `FramePoly` function plays back the line-drawing commands that define the polygon whose handle you pass in the `poly` parameter.

The graphics pen hangs below and to the right of each point on the boundary of the polygon. Thus, the drawn polygon extends beyond the right and bottom edges of the polygon's bounding rectangle (which is stored in the `polyBBox` field of the `Polygon` structure) by the pen width and pen height, respectively. All other graphics operations, such as painting a polygon with the `PaintPoly` function, occur strictly within the boundary of the polygon.

If a polygon is open and being formed, `FramePoly` affects the outline of the polygon just as if the line-drawing functions themselves had been called. If a region is open and being formed, the outside outline of the polygon being framed is mathematically added to the region's boundary.

The result of this function is undefined whenever any horizontal or vertical line through the polygon would intersect the polygon's outline more than 50 times.

Special Considerations

The `FramePoly` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

FrameRect

Draws an outline inside a rectangle. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void FrameRect (
    const Rect * r
);
```

Parameters

r

The rectangle to frame.

Discussion

Using the pattern, pattern mode, and size of the graphics pen for the current graphics port, the `FrameRect` function draws an outline just inside the rectangle that you specify in the `r` parameter. The outline is as wide as the pen width and as tall as the pen height. The pen location does not change.

If a region is open and being formed, the outside outline of the new rectangle is mathematically added to the region's boundary.

Special Considerations

The `FrameRect` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

FrameRgn

Draws an outline inside a region. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void FrameRgn (
    RgnHandle rgn
);
```

Parameters

rgn
A handle to the region to frame.

Discussion
Using the current graphics port's pen pattern, pattern mode, and pen size, the `FrameRgn` function draws an outline just inside the region whose handle you pass in the rgn parameter. The outline never goes outside the region boundary. The pen location does not change.

If a region is open and being formed, the outside outline of the region being framed is mathematically added to that region's boundary.

This function depends on the local coordinate system of the current graphics port. If you draw a region in a graphics port different from the one in which you defined the region, it may not appear in the proper position in the graphics port.

If any horizontal or vertical line drawn through the region would intersect the region's outline more than 50 times, the results of this graphics operation are undefined. The `FrameRgn` function in particular requires that there would be no more than 25 such intersections.

Special Considerations

The `FrameRgn` function calls the functions `CopyRgn`, `InsetRgn`, and `DiffRgn`, so `FrameRgn` may temporarily use heap space that's three times the size of the original region.

The `FrameRgn` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

FrameRoundRect

Draws an outline inside a rounded rectangle. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void FrameRoundRect (
   const Rect *r,
   short ovalWidth,
   short ovalHeight
);
```

Parameters

r
The rectangle that defines the rounded rectangle's boundaries.

ovalWidth
The width of the oval defining the rounded corner.

ovalHeight
The height of the oval defining the rounded corner.

Discussion
Using the pattern, pattern mode, and size of the graphics pen for the current graphics port, the `FrameRoundRect` function draws an outline just inside the rounded rectangle bounded by the rectangle that you specify in the `r` parameter. The outline is as wide as the pen width and as tall as the pen height. The pen location does not change.

Use the `ovalWidth` and `ovalHeight` parameters to specify the diameters of curvature for the corners of the rounded rectangle.

If a region is open and being formed, the outside outline of the new rounded rectangle is mathematically added to the region's boundary.

Special Considerations

The `FrameRoundRect` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

GDeviceChanged

Notifies QuickDraw that the content of a `GDevice` structure has been modified. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void GDeviceChanged (
   GDHandle gdh
);
```

Discussion
If your application changes the `pmTable` field of the `PixMap` structure specified in a `GDevice` structure, call `GDeviceChanged`. If your application changes the content of the `ColorTable` structure referenced by the `PixMap` structure, call both `GDeviceChanged` and `CTabChanged`.

Your application should never need to directly modify a `GDevice` structure and use the `GDeviceChanged` function; instead, your application should use the QuickDraw functions described in this book for manipulating the values in a `GDevice` structure.

Special Considerations

The `GDeviceChanged` function may move or purge memory in the application heap; do not call the `GDeviceChanged` function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QDOffscreen.h`

GetBackColor

Obtains the background color of the current graphics port. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void GetBackColor (
   RGBColor *color
);
```

Parameters

color

On return, the `RGBColor` structure for the current background color.

Discussion
This function operates for graphics ports defined by both the `GrafPort` and `CGrafPort` structures. If the current graphics port is defined by a `CGrafPort` structure, the returned value is taken directly from the `rgbBkColor` field.

If the current graphics port is defined by a `GrafPort` structure, then only eight possible colors can be returned. These eight colors are determined by the values in a global variable named `QDColors`, which is a handle to a color table containing the current QuickDraw colors.

Use the `RGBBackColor` (page 2779) function to change the background color.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

GetCCursor

Loads a color cursor resource into memory. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
CCrsrHandle GetCCursor (
   short crsrID
);
```

Parameters

crsrID

The resource ID of the cursor that you want to display.

Return Value
A handle to the new `CCrsr` structure. To display this cursor on the screen, call `SetCCursor`. If a resource with the specified ID isn't found, then this function returns a `NULL` handle.

Discussion
The `GetCCursor` function creates a new `CCrsr` (page 2847) structure and initializes it using the information in the 'crsr' resource with the specified ID.

Since the `GetCCursor` function creates a new `CCrsr` structure each time it is called, do not call the `GetCCursor` function before each call to the `SetCCursor` function. Unlike the way `GetCursor` and `SetCursor` are normally used, `GetCCursor` does not dispose of or detach the resource, so resources of type `'crsr'` should typically be purgeable. Call the `DisposeCCursor` (page 2598) function when you are finished using the color cursor created with `GetCCursor`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

GetClip

Saves the clipping region of the current graphics port (basic or color). (**Deprecated.** Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void GetClip (
   RgnHandle rgn
);
```

Parameters

rgn

A handle to the region to be clipped. The `GetClip` function changes this region to one that's equivalent to the clipping region of the current graphics port. The `GetClip` function doesn't change the region handle.

Discussion
You can use the `GetClip` and `SetClip` functions to preserve the current clipping region: use `GetClip` to save the current port's clipping region, and use `SetClip` to restore it. If, for example, you want to draw a half-circle on the screen, you can set the clipping region to half of the square that would enclose the whole circle, and then draw the whole circle. Only the half within the clipping region is actually drawn in the graphics port.

The `GetClip` function may move or purge memory blocks in the application heap. Your application should not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ImageCompression.k.h`

GetCPixel

Determines the color of an individual pixel specified in the `h` and `v` parameters. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void GetCPixel (
   short h,
   short v,
   RGBColor *cPix
);
```

Parameters

h
The horizontal coordinate of the point at the upper-left corner of the pixel.

v
The vertical coordinate of the point at the upper-left corner of the pixel.

cPix
On return, the `RGBColor` structure for the pixel color.

Discussion
Use the `SetCPixel` (page 2791) function to change the color of this pixel.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

GetCTable

Obtains a color table stored in a `'clut'` resource. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
CTabHandle GetCTable (
   short ctID
);
```

Parameters

ctID

The resource ID of a `'clut'` resource.

Return Value

A handle to the color table. If the `'clut'` resource with that ID is not found, `GetCTable` returns `NULL`. Before you place this handle in the `pmTable` field of a `PixMap` structure, first use the `DisposeCTable` function to dispose of the handle already there.

Discussion

Before you modify a `ColorTable` structure, change its `ctSeed` field to invalidate it. To do this, use the `CTabChanged` (page 2593) function.

The `GetCTable` function recognizes a number of standard `'clut'` resource IDs. You can obtain the default grayscale color table for a given pixel depth by calling `GetCTable`, adding 32 (decimal) to the pixel depth, and passing these values in the `ctID` parameter:

- A pixel depth of 1. Pass a resource ID of 33. Color table composition: black, white.
- A pixel depth of 2. Pass a resource ID of 34. Color table composition: black, 33% gray, 66% gray, white.
- A pixel depth of 4. Pass a resource ID of 36. Color table composition: black, 14 shades of gray, white.
- A pixel depth of 8. Pass a resource ID of 40. Color table composition: black, 254 shades of gray, white.

For full color, obtain the default color tables by adding 64 to the pixel depth and passing these values in the `ctID` parameter:

- A pixel depth of 2. Pass a resource ID of 66. Color table composition: black, 50% gray, highlight color, white.
- A pixel depth of 4. Pass a resource ID of 68. Color table composition: black, 14 colors including the highlight color, white.
- A pixel depth of 8. Pass a resource ID of 72. Color table composition: black, 254 colors including the highlight color, white.

Special Considerations

The `GetCTable` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

GetCTSeed

Obtains a unique seed value for a color table created by your application. This function is used by system software and your application should not need to call it. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
long GetCTSeed (
   void
);
```

Return Value

A unique seed value that you can use in the `ctSeed` field of a color table created by your application. It is greater than the value stored in the constant `minSeed`.

Discussion

The seed value guarantees that the color table is recognized as distinct from the destination, and that color table translation is performed properly.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

GetCursor

Loads a cursor resource into memory. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
CursHandle GetCursor (
    short cursorID
);
```

Parameters

cursorID

The resource ID for the cursor you want to display. You can supply one of the "Cursor ID Constants" (page 2886) to get a handle to one of the standard cursors.

Return Value

A handle to a `Cursor` structure for the cursor with the resource ID that you specify in the `cursorID` parameter. If the resource cannot be read into memory, `GetCursor` returns `NULL`.

Discussion

To get a handle to a color cursor, use the `GetCCursor` (page 2635) function.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

GetDeviceList

Obtains a handle to the first `GDevice` structure in the device list. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
GDHandle GetDeviceList (
   void
);
```

Return Value
A handle to the first `GDevice` structure in the global variable `DeviceList`.

Discussion
All existing `GDevice` structures are linked together in the device list. After using this function to obtain a handle to the current `GDevice` structure, your application can use the `GetNextDevice` function to obtain a handle to the next `GDevice` structure in the list.

Special Considerations

The `GetDeviceList` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

GetForeColor

Obtains the color of the foreground color for the current graphics port. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void GetForeColor (
   RGBColor *color
);
```

Parameters

color

On return, the `RGBColor` structure for the current foreground color.

Discussion
This function operates for graphics ports defined by both the `GrafPort` and `CGrafPort` structures. If the current graphics port is defined by a `CGrafPort` structure, the returned value is taken directly from the `rgbFgColor` field.

If the current graphics port is defined by a `GrafPort` structure, then only eight possible RGB values can be returned. These eight values are determined by the values in a global variable named `QDColors`, which is a handle to a color table containing the current QuickDraw colors.

Use the `RGBForeColor` (page 2780) function to change the foreground color.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Simple DrawSprocket

Declared In
`QuickdrawAPI.h`

GetGDevice

Obtains a handle to the `GDevice` structure for the current device. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
GDHandle GetGDevice (
   void
);
```

Return Value
A handle to the current device.

Discussion
At any given time, exactly one video device is the current device—that is, the one on which drawing is actually taking place.

Color QuickDraw stores a handle to the current device in the global variable `TheGDevice`.

All existing `GDevice` structures are linked together in the device list. After using this function to obtain a handle to the current `GDevice` structure, your application can use the `GetNextDevice` function to obtain a handle to the next `GDevice` structure in the list.

You can also use the `GetGWorld` function to get a handle to the `GDevice` structure for the current device.

Special Considerations

The `GetGDevice` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

GetGWorld

Saves the current graphics port (basic, color, or offscreen) and the current `GDevice` structure. (**Deprecated.** Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void GetGWorld (
   CGrafPtr *port,
   GDHandle *gdh
);
```

Parameters

port

On return, a pointer to the current graphics port in the `port` parameter. This parameter can return values of type `GrafPtr`, `CGrafPtr`, or `GWorldPtr`, depending on whether the current graphics port is a basic graphics port, color graphics port, or offscreen graphics world.

gdh

On return, a pointer to a handle to the `GDevice` structure for the current device.

Discussion

After using `GetGWorld` to save a graphics port and a `GDevice` structure, use the `SetGWorld` (page 2796) function to restore them.

Special Considerations

The `GetGWorld` function may move or purge memory blocks in the application heap. Your application should not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Related Sample Code

QTCarbonShell

Simple DrawSprocket

`ImageCompression.k.h`

GetGWorldDevice

Obtains a handle to the `GDevice` structure associated with an offscreen graphics world. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
GDHandle GetGWorldDevice (
   GWorldPtr offscreenGWorld
);
```

Parameters

offscreenGWorld

A pointer to an offscreen graphics world. The pointer returned to your application by the `NewGWorld` function.

Return Value

A handle to the `GDevice` structure associated with the offscreen graphics world specified by the `offscreenGWorld` parameter.

If you created the offscreen world by specifying the `noNewDevice` flag, the `GDevice` structure is for one of the screen devices or is the `GDevice` structure that you specified to `NewGWorld` or `UpdateGWorld`.

If you point to a `GrafPort` or `CGrafPort` structure in the `offscreenGWorld` parameter, `GetGWorldDevice` returns the current device.

Special Considerations

The `GetGWorldDevice` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

WhackedTV

Declared In

`QDOffscreen.h`

GetGWorldPixMap

Obtains the pixel map created for an offscreen graphics world. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
PixMapHandle GetGWorldPixMap (
   GWorldPtr offscreenGWorld
);
```

Parameters

`offscreenGWorld`

A pointer to an offscreen graphics world. Pass the pointer returned to your application by the `NewGWorld` (page 2715) function when you created the offscreen graphics world.

Return Value

A handle to the pixel map created for an offscreen graphics world. Your application can, in turn, pass the handle returned by `GetGWorldPixMap` as a parameter to other QuickDraw functions that accept a handle to a pixel map.

On a system running only basic QuickDraw, the `GetGWorldPixMap` function returns the handle to a 1-bit pixel map that your application can supply as a parameter to the other functions related to offscreen graphics worlds. However, your application should not supply this handle to color QuickDraw functions.

Special Considerations

To ensure compatibility on systems running basic QuickDraw instead of Color QuickDraw, use `GetGWorldPixMap` whenever you need to gain access to the bitmap created for a graphics world—that is, do not dereference the `GWorldPtr` structure for that graphics world.

Version Notes

The `GetGWorldPixMap` function is not available in systems preceding System 7. You can make sure that the `GetGWorldPixMap` function is available by using the `Gestalt` function with the `gestaltSystemVersion` selector. Test the low-order word in the `response` parameter; if the value is $0700 or greater, then `GetGWorldPixMap` is available.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
QDOffscreen.h

GetIndPattern

Obtains a pattern stored in a pattern list (`'PAT#'`) resource. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void GetIndPattern (
   Pattern *thePat,
   short patternListID,
   short index
);
```

Parameters

thePat
On return, a pointer to a `Pattern` (page 2866) structure for the pattern stored in the specified pattern list resource.

patternListID
The resource ID for a resource of type `'PAT#'`.

index
The index number for the desired pattern within the pattern list (`'PAT#'`) resource. The index number can range from 1 to the number of patterns in the pattern list resource.

Discussion
The `GetIndPattern` function calls the following Resource Manager function with these parameters:

```
GetResource('PAT#', patternListID);
```

There is a pattern list resource in the System file that contains the standard Macintosh patterns used by MacPaint. The resource ID is represented by the constant `sysPatListID`.

Special Considerations

The `GetIndPattern` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
QuickdrawAPI.h

GetMainDevice

Obtains a handle to the `GDevice` structure for the main screen. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
GDHandle GetMainDevice (
   void
);
```

Return Value
A handle to the device for the main screen, which is the device containing the menu bar.

Discussion
A handle to the main device is kept in the global variable `MainDevice`.

All existing `GDevice` structures are linked together in the device list. After using this function to obtain a handle to the current `GDevice` structure, your application can use the `GetNextDevice` function to obtain a handle to the next `GDevice` structure in the list.

Special Considerations

The `GetMainDevice` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

GetMaskTable

(Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
Ptr GetMaskTable (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

GetMaxDevice

Obtains a handle to the `GDevice` structure for the video device with the greatest pixel depth. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
GDHandle GetMaxDevice (
   const Rect *globalRect
);
```

Parameters

globalRect

A rectangle, in global coordinates, that intersects the graphics devices that you are searching to find the one with the greatest pixel depth.

Return Value
A handle to the device with the greatest pixel depth.

Discussion
All existing `GDevice` structures are linked together in the device list. After using this function to obtain a handle to the current `GDevice` structure, your application can use the `GetNextDevice` function to obtain a handle to the next `GDevice` structure in the list.

Special Considerations

The `GetMaxDevice` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

GetNextDevice

Returns a handle to the next `GDevice` structure in the device list. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
GDHandle GetNextDevice (
   GDHandle curDevice
);
```

Parameters

curDevice

A handle to the `GDevice` structure at which you want the search to begin.

Return Value
A handle to the next device. If there are no more `GDevice` structures in the list, `NULL`.

Discussion
After using any of the functions `GetDeviceList` (page 2639) , `GetGDevice` (page 2640) , `GetMainDevice` (page 2644) , or `GetMaxDevice` (page 2644) to obtain a handle to a `GDevice` structure, use the `GetNextDevice` function to obtain a handle to the next `GDevice` structure in the list.

Special Considerations

The `GetNextDevice` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

GetPattern

Obtains a pattern (`'PAT'`) resource stored in a resource file. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
PatHandle GetPattern (
   short patternID
);
```

Parameters

`patternID`
The resource ID for a resource of type 'PAT'.

Return Value
a handle to the pattern having the resource ID that you specify in the `patID` parameter. If a pattern resource with the ID that you request does not exist, the `GetPattern` function returns `NULL`.

Discussion
The `GetPattern` function calls the following Resource Manager function with these parameters:

GetResource('PAT', patID);

When you are finished using the pattern, dispose of its handle with the Memory Manager function `DisposeHandle`.

Special Considerations

The `GetPattern` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

GetPen

Determines the location of the graphics pen. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void GetPen (
   Point *pt
);
```

Parameters

pt

On return, a pointer to the graphics pen's current position in the current graphics port. The point returned is in the local coordinates of the current graphics port.

Discussion
In the pt parameter, the GetPen procedure returns the current pen position. The point returned is in the local coordinates of the current graphics port.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

GetPenState

Determines the graphics pen's location, size, pattern, and pattern mode. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void GetPenState (
   PenState *pnState
);
```

Parameters

pnState

On return, a pointer to a `PenState` structure holding information about the graphics pen. The `GetPenState` function saves the location, size, pattern, and pattern mode of the graphics pen for the current graphics port in this structure.

Discussion
After changing the graphics pen as necessary, restore these pen states with the `SetPenState` (page 2798) function.

This pen-manipulation function uses the local coordinate system of the current graphics port. Remember that each graphics port has its own pen, the state of which is stored in several fields of its `GrafPort` or `CGrafPort` structure. If you draw in one graphics port, change to another, and return to the first, the pen for the first graphics port has the same state as when you left it.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

GetPicture

Obtains a handle to a picture stored in a `'PICT'` resource. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
PicHandle GetPicture (
   short pictureID
);
```

Parameters

pictureID

The resource ID for a `'PICT'` resource.

Return Value

A handle to the picture in the specified 'PICT' resource. To draw the picture stored in the resource, pass this handle to the `DrawPicture` (page 2610) function. If the resource cannot be read, `GetPicture` returns `NULL`.

Discussion

The `GetPicture` function calls the Resource Manager function `GetResource` as follows:

```
GetResource('PICT', picID)
```

Special Considerations

To release the memory occupied by a picture stored in a `'PICT'` resource, use the Resource Manager function `ReleaseResource`.

The `GetPicture` function may move or purge memory.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

GetPixBaseAddr

Obtains a pointer to an offscreen pixel map.

```
Ptr GetPixBaseAddr (
   PixMapHandle pm
);
```

Parameters

pm

A handle to an offscreen pixel map. To get a handle to an offscreen pixel map, use the `GetGWorldPixMap` (page 2642) function.

Return Value

A 32-bit pointer to the beginning of a pixel image. If the offscreen buffer has been purged, `GetPixBaseAddr` returns `NULL`.

Discussion
The `baseAddr` field of the `PixMap` structure for an offscreen graphics world contains a handle instead of a pointer, which is what the `baseAddr` field for an onscreen pixel map contains. You must use the `GetPixBaseAddr` function to obtain a pointer to the `PixMap` structure for an offscreen graphics world.

Your application should never directly access the `baseAddr` field of the `PixMap` structure for an offscreen graphics world; instead, always use `GetPixBaseAddr`. If your application is using 24-bit mode, use the `PixMap32Bit` (page 2749) function to determine whether a pixel map requires 32-bit addressing mode for access to its pixel image.

Special Considerations

Any QuickDraw functions that your application uses after calling `GetPixBaseAddr` may change the base address for the offscreen pixel image.

The `GetPixBaseAddr` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

`QDOffscreen.h`

GetPixBounds

(Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
Rect * GetPixBounds (
   PixMapHandle pixMap,
   Rect *bounds
);
```

Carbon Porting Notes

Use this new accessor function in place of direct access to structures.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

GetPixDepth

(Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
short GetPixDepth (
   PixMapHandle pixMap
);
```

Carbon Porting Notes

Use this new accessor function in place of direct access to structures.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

GetPixel

Determines whether the pixel associated with a point is black or white. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
Boolean GetPixel (
    short h,
    short v
);
```

Parameters

h

The horizontal coordinate of the point for the pixel to be tested.

v

The vertical coordinate of the point for the pixel to be tested.

Return Value

Returns `TRUE` if the pixel is black or `FALSE` if it is white.

Discussion

The selected pixel is immediately below and to the right of the point whose coordinates you supply in the `h` and `v` parameters, in the local coordinates of the current graphics port. There's no guarantee that the specified pixel actually belongs to the current graphics port, however it may have been drawn in a graphics port overlapping the current one. To see if the point indeed belongs to the current graphics port, you could use the `PtInRgn` function to test whether the point is in the current graphics port's visible region.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

GetPixelsState

Saves the current information about the memory allocated for an offscreen pixel image. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
GWorldFlags GetPixelsState (
   PixMapHandle pm
);
```

Parameters

pm

A handle to an offscreen pixel map. To get a handle to an offscreen pixel map, use the `GetGWorldPixMap` (page 2642) function.

Return Value

Information about the memory allocated for the base address for an offscreen pixel image. This result can be either of the constants, `pixelsPurgeable` or `pixelsLocked`. If the `pixelsPurgeable` flag is not returned, then the base address for the offscreen pixel image is unpurgeable. If the `pixelsLocked` flag is not returned, then the base address for the offscreen pixel image is unlocked.

Discussion

After using `GetPixelsState` to save this state information, use the `SetPixelsState` (page 2799) function to restore this state to the offscreen graphics world.

After using `GetPixelsState` and before using `SetPixelsState`, temporarily use the `AllowPurgePixels` (page 2573) function to make the base address for an offscreen pixel image purgeable, the `NoPurgePixels` (page 2729) function to make it unpurgeable, the `LockPixels` (page 2704) function to prevent it from being moved, and the `UnlockPixels` (page 2829) function to allow it to be moved.

Special Considerations

The `GetPixelsState` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QDOffscreen.h`

GetPixPat

Obtains a pixel pattern (`'ppat'`) resource stored in a resource file. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
PixPatHandle GetPixPat (
   short patID
);
```

Parameters

patID

The resource ID for a resource of type `'ppat'`.

Return Value
A handle to the pixel pattern having the resource ID you specify in the `patID` parameter. The `GetPixPat` function calls the following Resource Manager function with these parameters:

```
GetResource('ppat', patID);
```

If a `'ppat'` resource with the ID that you request does not exist, the `GetPixPat` function returns `NULL`.

Discussion
When you are finished with the pixel pattern, use the `DisposePixPat` (page 2602) function. For more information on the pixel pattern resource, see `'ppat'`.

Pixel patterns can use colors at any pixel depth and can be of any width and height that's a power of 2. To create a pixel pattern, you typically define it in a `'ppat'` resource, which you store in a resource file. To retrieve the pixel pattern stored in a `'ppat'` resource, you can use the `GetPixPat` function.

Special Considerations

The `GetPixPat` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

GetPixRowBytes

(Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
SInt32 GetPixRowBytes (
   PixMapHandle pm
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QDOffscreen.h`

GetPort

Saves the current graphics port (basic or color). (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void GetPort (
   GrafPtr *port
);
```

Parameters

port

On return, a pointer to a `GrafPort` structure for the current graphics port. If the current graphics port is a color graphics port, `GetPort` coerces its `CGrafPort` structure into a `GrafPort` structure.

Discussion

When your application runs in Color QuickDraw or uses offscreen graphics worlds, it should use the `GetGWorld` function instead of `GetPort`. The `GetGWorld` function saves the current graphics port for basic and color graphics ports as well as offscreen graphics worlds.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

GetSubTable

Searches one color table for the best matches to colors in another color table. Your application should not need to call this function; it is used by system software only. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void GetSubTable (
   CTabHandle myColors,
   short iTabRes,
   CTabHandle targetTbl
);
```

Parameters

myColors

A handle to a color table containing the colors for which you want matches.

iTabRes

The resolution of the inverse table to be used.

targetTbl

A handle to a color table whose colors are to be matched. If you supply `NULL` for `targetTbl`, then the Color Manager searches the current `GDevice` data structure's CLUT, and uses its inverse table. Otherwise a temporary inverse table is built, with a resolution of the value in the `iTabRes` parameter.

Discussion

The Color Manager uses the `Color2Index` (page 2583) function for each `RGBColor` data structure in the color table of the `myColors` parameter. It determines the best match in the target table and stores that index value in the `value` field of the color table of the `myColors` parameter.

Depending on the requested resolution, building the inverse table can require large amounts of temporary space in the application heap: twice the size of the table itself, plus a fixed overhead of 3–15 KB for each inverse table resolution.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

GlobalToLocal

Converts the coordinates of a point from global coordinates to the local coordinates of the current graphics port (basic or color). (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void GlobalToLocal (
   Point *pt
);
```

Parameters

pt

A pointer to a point expressed in global coordinates (where the upper-left corner of the main screen has coordinates [0,0]). On return, this point is converted to local coordinates.

Discussion
The GlobalToLocal procedure takes a point expressed in global coordinates (where the upper-left corner of the main screen has coordinates [0,0]) and converts it into the local coordinates of the current graphics port.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

HandleToRgn

```
void HandleToRgn (
   Handle oldRegion,
   RgnHandle region
);
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

HideCursor

Hides the cursor if it is visible on the screen.

```
void HideCursor (
   void
);
```

Discussion
The `HideCursor` function removes the cursor from the screen, restores the bits under the cursor image, and decrements the cursor level (which `InitCursor` initialized to 0). You might want to use HideCursor when the user is using the keyboard to create content in one of your application's windows. Every call to `HideCursor` should be balanced by a subsequent call to the `ShowCursor` (page 2813) function.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
Simple DrawSprocket

Declared In
`QuickdrawAPI.h`

HidePen

Makes the graphics pen invisible, so that pen drawing doesn't show on the screen. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void HidePen (
   void
);
```

Discussion
The `HidePen` function is called by the `OpenRgn` (page 2737) , `OpenPicture`, and `OpenPoly` (page 2737) functions so that you can create regions, pictures, and polygons without drawing on the screen.

The `HidePen` function decrements the `pnVis` field of the current graphics port. The `pnVis` field is initialized to 0 by the `OpenPort` function. Whenever `pnVis` is negative, the pen does not draw on the screen. The `pnVis` field keeps track of the number of times the pen has been hidden to compensate for nested calls to the `HidePen` and `ShowPen` functions.

Every call to `HidePen` should be balanced by a subsequent call to `ShowPen` (page 2814).

This pen-manipulation function uses the local coordinate system of the current graphics port. Remember that each graphics port has its own pen, the state of which is stored in several fields of its `GrafPort` or `CGrafPort` structure. If you draw in one graphics port, change to another, and return to the first, the pen for the first graphics port has the same state as when you left it.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

HiliteColor

Changes the highlight color for the current color graphics port. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void HiliteColor (
   const RGBColor *color
);
```

Parameters

color

An `RGBColor` structure that defines the highlight color.

Discussion

All drawing operations that use the `hilite` transfer mode use the highlight color. When a color graphics port is created, its highlight color is initialized from the global variable `HiliteRGB`.

If the current graphics port is a basic graphics port, `HiliteColor` has no effect.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

Index2Color

Obtains the `RGBColor` data structure corresponding to an index value in the color table of the current `GDevice` data structure. Your application should not need to call this function; it is used by system software only. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void Index2Color (
   long index,
   RGBColor *aColor
);
```

Parameters

index

The index value whose color entry is sought; you should supply a long integer in which the high-order word is padded with zeros.

aColor

A pointer to the returned `RGBColor` data structure.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

InitCursor

Sets the cursor to the standard arrow and makes the cursor visible.

```
void InitCursor (
   void
);
```

Discussion
This function initializes the standard arrow cursor, sets the current cursor to the standard arrow, and makes the cursor visible. Classic Mac OS applications need to call this function when launching because the system sets the cursor to the watch cursor. Carbon applications running in Mac OS 9 or Mac OS X do not need to call this function.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

`QuickdrawAPI.h`

InitGDevice

Initializes a `GDevice` structure. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void InitGDevice (
   short qdRefNum,
   long mode,
   GDHandle gdh
);
```

Parameters

qdRefNum
Reference number of the graphics device. System software sets this number at system startup time for most graphics devices.

mode
The device configuration mode. Used by the screen driver, this value sets the pixel depth and specifies color or black and white.

gdh
The handle, returned by the `NewGDevice` function, to the `GDevice` (page 2859) structure to be initialized.

Discussion
The `InitGDevice` function sets the graphics device whose driver has the reference number specified in the `gdRefNum` parameter to the mode specified in the `mode` parameter. The `InitGDevice` function then fills out the `GDevice` structure, previously created with the `NewGDevice` function, to contain all information describing that mode.

The `mode` parameter determines the configuration of the device. Possible modes for a device are determined by interrogating the video device's ROM through Slot Manager functions. The information describing the device's mode is primarily contained in the video device's ROM. If the video device has a fixed color table, then that table is read directly from the ROM. If the video device has a variable color table, then `InitGDevice` uses the default color table defined in a `'clut'` resource, contained in the System file, that has a resource ID equal to the video device's pixel depth.

In general, your application should never need to call `InitGDevice`. All video devices are initialized at start time, and users change modes through the Monitors control panel.

If your program uses `NewGDevice` to create a graphics device without a driver, `InitGDevice` does nothing; instead, your application must initialize all fields of the `GDevice` structure. After your application initializes the color table for the `GDevice` structure, call the Color Manager function `MakeITable` to build the inverse table for the graphics device.

Special Considerations

The `InitGDevice` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

InsetRect

Shrinks or expands a rectangle.

```
void InsetRect (
    Rect * r,
    short dh,
    short dv
);
```

Parameters

r

A pointer to the rectangle to alter.

dh

The horizontal distance to move the left and right sides in toward or outward from the center of the rectangle.

dv

The vertical distance to move the top and bottom sides in toward or outward from the center of the rectangle.

Discussion

The `InsetRect` function shrinks or expands the rectangle that you specify in the `r` parameter: the left and right sides are moved in by the amount you specify in the `dh` parameter; the top and bottom are moved toward the center by the amount you specify in the `dv` parameter. If the value you pass in `dh` or `dv` is negative,

the appropriate pair of sides is moved outward instead of inward. The effect is to alter the size by `2*dh` horizontally and `2*dv` vertically, with the rectangle remaining centered in the same place on the coordinate plane.

If the resulting width or height becomes less than 1, the rectangle is set to the empty rectangle (0,0,0,0).

If the points or rectangles supplied to this function are defined in a graphics port other than your current graphics port, you must convert them to the local coordinate system of your current graphics port. You can accomplish this by using the `SetPort` function to change to the graphics port containing the points or rectangles, using the `LocalGlobal` function to convert their locations to global coordinates, using `SetPort` to return to your starting graphics port, and then using the `GlobalToLocal` function to convert the locations of points or rectangles to the local coordinates of your current graphics port.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`QuickdrawAPI.h`

InsetRgn

Shrinks or expands a region.

```
void InsetRgn (
   RgnHandle rgn,
   short dh,
   short dv
);
```

Parameters

rgn

A handle to the region to alter.

dh

The horizontal distance to move points on the left and right boundaries in toward or outward from the center.

dv

The vertical distance to move points on the top and bottom boundaries in toward or outward from the center.

Discussion
The `InsetRgn` function moves all points on the region boundary of the region whose handle you pass in the `rgn` parameter inward by the vertical distance that you specify in the `dv` parameter and by the horizontal distance that you specify in the `dh` parameter. If you specify negative values for `dh` or `dv`, the `InsetRgn` function moves the points outward in that direction.

The `InsetRgn` function leaves the region's center at the same position, but moves the outline in (for positive values of `dh` and `dv`) or out (for negative values of `dh` and `dv`). Using `InsetRgn` on a rectangular region has the same effect as using the `InsetRect` function.

Special Considerations

The `InsetRgn` function temporarily uses heap space that's twice the size of the original region.

The `InsetRgn` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

InvertArc

Inverts the pixels of a wedge. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void InvertArc (
   const Rect *r,
   short startAngle,
   short arcAngle
);
```

Parameters

r
The rectangle that defines an oval's boundaries.

startAngle
The angle indicating the start of the arc.

arcAngle
The angle indicating the arc's extent.

Discussion
The `InvertArc` function inverts the pixels enclosed by a wedge of the oval bounded by the rectangle that you specify in the `r` parameter. Every white pixel becomes black and every black pixel becomes white. As in `FrameArc` (page 2629) , use the `startAngle` and `arcAngle` parameters to define the arc of the wedge.

This function leaves the location of the graphics pen unchanged.

Special Considerations

The `InvertArc` function was designed for 1-bit images in basic graphics ports. This function operates on color pixels in color graphics ports, but the results are predictable only with direct devices or 1-bit pixel maps. For indexed pixels, Color QuickDraw performs the inversion on the pixel indexes, which means the results depend entirely on the contents of the CLUT. The eight colors used in basic QuickDraw are stored in a color table represented by the global variable `QDColors`. To display those eight basic QuickDraw colors on an indexed device, Color QuickDraw uses the Color Manager to obtain indexes to the colors in the CLUT that best map to the colors in the `QDColors` color table. Because the index, not the color value, is inverted, the results are unpredictable.

Inversion works better for direct pixels. Inverting a pure green, for example, that has red, green, and blue component values of $0000, $FFFF, and $0000 results in magenta, which has component values of $FFFF, $0000, and $FFFF.

The `InvertArc` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

InvertColor

Finds the complement of an `RGBColor` data structure. This function is used only by system software. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void InvertColor (
   RGBColor *myColor
);
```

Parameters

myColor

A pointer to the `RGBColor` data structure for which the complement is to be found. The `InvertColor` function returns the complement of an absolute color, using the list of complement functions in the current device data structure. The default complement function uses the one's complement of each component of the given color.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

InvertOval

Inverts the pixels enclosed by an oval. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void InvertOval (
   const Rect *r
);
```

Parameters

r

The rectangle that defines the oval's boundary.

Discussion
The `InvertOval` function inverts the pixels enclosed by an oval just inside the bounding rectangle that you specify in the `r` parameter. Every white pixel becomes black and every black pixel becomes white. The pen location does not change.

Special Considerations

The `InvertOval` function was designed for 1-bit images in basic graphics ports. This function operates on color pixels in color graphics ports, but the results are predictable only with direct devices or 1-bit pixel maps. For indexed pixels, Color QuickDraw performs the inversion on the pixel indexes, which means the results depend entirely on the contents of the CLUT. The eight colors used in basic QuickDraw are stored in a color table represented by the global variable `QDColors`. To display those eight basic QuickDraw colors on an indexed device, Color QuickDraw uses the Color Manager to obtain indexes to the colors in the CLUT that best map to the colors in the `QDColors` color table. Because the index, not the color value, is inverted, the results are unpredictable.

Inversion works better for direct pixels. Inverting a pure green, for example, that has red, green, and blue component values of $0000, $FFFF, and $0000 results in magenta, which has component values of $FFFF, $0000, and $FFFF.

The `InvertOval` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

InvertPoly

Inverts the pixels enclosed by a polygon. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void InvertPoly (
   PolyHandle poly
);
```

Parameters

poly

A handle to a polygon, the pixels of which you want to invert. The `OpenPoly` (page 2737) function returns this handle when you first create the polygon.

Discussion

The `InvertPoly` function inverts the pixels enclosed by the polygon whose handle you pass in the `poly` parameter. Every white pixel becomes black and every black pixel becomes white.

This function leaves the location of the graphics pen unchanged.

`InvertPoly` temporarily converts the polygon into a region to perform their operations. The amount of memory required for this temporary region may be far greater than the amount required by the polygon alone.

You can estimate the size of this region by scaling down the polygon with the `MapPoly` (page 2707) , converting the polygon into a region, checking the region's size with the Memory Manager function `GetHandleSize`, and multiplying that value by the factor by which you scaled the polygon.

The result of this graphics operation is undefined whenever any horizontal or vertical line drawn through the polygon would intersect the polygon's outline more than 50 times.

Special Considerations

The `InvertPoly` function was designed for 1-bit images in basic graphics ports. This function operates on color pixels in color graphics ports, but the results are predictable only with 1-bit or direct pixels. For indexed pixels, Color QuickDraw performs the inversion on the pixel indexes, which means the results depend entirely on the contents of the CLUT. The eight colors used in basic QuickDraw are stored in a color table represented by the global variable `QDColors`. To display those eight basic QuickDraw colors on an indexed device, Color QuickDraw uses the Color Manager to obtain indexes to the colors in the CLUT that best map to the colors in the `QDColors` color table. Because the index, not the color value, is inverted, the results are unpredictable.

Inversion works better for direct pixels. Inverting a pure green, for example, that has red, green, and blue component values of $0000, $FFFF, and $0000 results in magenta, which has component values of $FFFF, $0000, and $FFFF.

The `InvertPoly` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

InvertRect

Inverts the pixels enclosed by a rectangle. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void InvertRect (
    const Rect * r
);
```

Parameters

r

The rectangle whose enclosed pixels are to be inverted.

Discussion
The `InvertRect` function inverts the pixels enclosed by the rectangle that you specify in the `r` parameter. Every white pixel becomes black and every black pixel becomes white. The pen location does not change.

Special Considerations

The `InvertRect` function was designed for 1-bit images in basic graphics ports. This function operates on color pixels in color graphics ports, but the results are predictable only with direct pixels or 1-bit pixel maps. For indexed pixels, Color QuickDraw performs the inversion on the pixel indexes, which means the results depend entirely on the contents of the CLUT. The eight colors used in basic QuickDraw are stored in a color table represented by the global variable `QDColors`. To display those eight basic QuickDraw colors on an indexed device, Color QuickDraw uses the Color Manager to obtain indexes to the colors in the CLUT that best map to the colors in the `QDColors` color table. Because the index, not the color value, is inverted, the results are unpredictable.

Inversion works better for direct pixels. Inverting a pure green, for example, that has red, green, and blue component values of $0000, $FFFF, and $0000 results in magenta, which has component values of $FFFF, $0000, and $FFFF.

Declared In
`QuickdrawAPI.h`

InvertRgn

Inverts the pixels enclosed by a region. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void InvertRgn (
    RgnHandle rgn
);
```

Parameters

rgn
A handle to the region whose pixels are to invert.

Discussion
The `InvertRgn` function inverts the pixels enclosed by the region whose handle you pass in the `rgn` parameter. Every white pixel becomes black and every black pixel becomes white.

This function leaves the location of the graphics pen unchanged.

This function depends on the local coordinate system of the current graphics port. If you draw a region in a graphics port different from the one in which you defined the region, it may not appear in the proper position in the graphics port.

If any horizontal or vertical line drawn through the region would intersect the region's outline more than 50 times, the results of this graphics operation are undefined.

Special Considerations

The `InvertRgn` function was designed for 1-bit images in basic graphics ports. This function operates on color pixels in color graphics ports, but the results are predictable only with 1-bit or direct pixels. For indexed pixels, Color QuickDraw performs the inversion on the pixel indexes, which means the results depend entirely on the contents of the CLUT. The eight colors used in basic QuickDraw are stored in a color table represented by the global variable `QDColors`. To display those eight basic QuickDraw colors on an indexed device, Color QuickDraw uses the Color Manager to obtain indexes to the colors in the CLUT that best map to the colors in the `QDColors` color table. Because the index, not the color value, is inverted, the results are unpredictable.

Inversion works better for direct pixels. Inverting a pure green, for example, that has red, green, and blue component values of $0000, $FFFF, and $0000 results in magenta, which has component values of $FFFF, $0000, and $FFFF.

InvertRoundRect

Inverts the pixels enclosed by a rounded rectangle. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void InvertRoundRect (
   const Rect *r,
   short ovalWidth,
   short ovalHeight
);
```

Parameters

r
The rectangle that defines the rounded rectangle's boundaries.

ovalWidth
The width of the oval defining the rounded corner.

ovalHeight
The height of the oval defining the rounded corner.

Discussion
The `InvertRoundRect` function inverts the pixels enclosed by the rounded rectangle bounded by the rectangle that you specify in the `r` parameter. Every white pixel becomes black and every black pixel becomes white. The `ovalWidth` and `ovalHeight` parameters specify the diameters of curvature for the corners. The pen location does not change.

Special Considerations

The `InvertRoundRect` function was designed for 1-bit images in basic graphics ports. This function operates on color pixels in color graphics ports, but the results are predictable only with direct devices or 1-bit pixel maps. For indexed pixels, Color QuickDraw performs the inversion on the pixel indexes, which means the results depend entirely on the contents of the CLUT. The eight colors used in basic QuickDraw are stored in a color table represented by the global variable `QDColors`. To display those eight basic QuickDraw colors on an indexed device, Color QuickDraw uses the Color Manager to obtain indexes to the colors in the CLUT that best map to the colors in the `QDColors` color table. Because the index, not the color value, is inverted, the results are unpredictable.

Inversion works better for direct pixels. Inverting a pure green, for example, that has red, green, and blue component values of $0000, $FFFF, and $0000 results in magenta, which has component values of $FFFF, $0000, and $FFFF.

The `InvertRoundRect` function may move or purge memory blocks in the application; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

InvokeColorComplementUPP

(Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

IsValidRgnHandle

```
Boolean IsValidRgnHandle (
   RgnHandle rgn
);
```

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

KillPicture

Releases the memory occupied by a picture not stored in a `'PICT'` resource. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void KillPicture (
   PicHandle myPicture
);
```

Parameters

myPicture
A handle to the picture whose memory can be released.

Discussion
Use this function only when you are completely finished with a picture.

Special Considerations

If you use the Window Manager function `SetWindowPic` to store a picture handle in the window structure, use the Window Manager function `DisposeWindow` or `CloseWindow` to release the memory allocated to the picture. These functions automatically call `KillPicture` for the picture.

If the picture is stored in a `'PICT'` resource, use the Resource Manager function `ReleaseResource` instead of `KillPicture`. The Window Manager functions `DisposeWindow` and `CloseWindow` will not delete it. Instead, call `ReleaseResource` before calling `DisposeWindow` or `CloseWindow`.

The `KillPicture` function may move or purge memory.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

KillPoly

Releases the memory occupied by a polygon. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void KillPoly (
   PolyHandle poly
);
```

Parameters

poly
A handle to the polygon to dispose of.

Discussion
Use `KillPoly` only when you are completely through with a polygon.

Special Considerations

The `KillPoly` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

Line

Draws a line a specified distance from the graphics pen's current location in the current graphics port. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void Line (
   short dh,
   short dv
);
```

Parameters

dh

The horizontal distance of the graphics pen's movement.

dv

The vertical distance of the graphics pen's movement.

Discussion

Starting at the current location of the graphics pen, the `Line` function draws a line the horizontal distance that you specify in the `dh` parameter and the vertical distance that you specify in the `dv` parameter. The `Line` function calls

LineTo(h+dh,v+dv)

where `(h,v)` is the current location in local coordinates. The pen location becomes the coordinates of the end of the line after the line is drawn. If you are using `Line` to draw a region or polygon, its outline is infinitely thin and is not affected by the values of the `pnSize`, `pnMode`, and `pnPat` fields of the graphics port.

Special Considerations

The `Line` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

LineTo

Draws a line from the graphics pen's current location to a new location. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void LineTo (
    short h,
    short v
);
```

Parameters

h

The horizontal coordinate of the graphics pen's new location.

v

The vertical coordinate of the graphics pen's new location.

Discussion

The `LineTo` function draws a line from the graphics pen's current location in the current graphics port to the new location `(h,v)`, which you specify in the local coordinates of the current graphics port. If you are using `LineTo` to draw a region or polygon, its outline is infinitely thin and is not affected by the values of the `pnSize`, `pnMode`, or `pnPat` field of the graphics port.

Special Considerations

The `LineTo` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

LocalToGlobal

Converts a point's coordinates from the local coordinates of the current graphics port (basic or color) to global coordinates. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void LocalToGlobal (
   Point *pt
);
```

Parameters

pt
A pointer to a point in local coordinates. On return, this point is converted to global coordinates.

Discussion
The `LocalToGlobal` function converts the given point from the current graphics port's local coordinate system into the global coordinate system (where the upper-left corner of the main screen has coordinates [0,0]). This global point can then be compared to other global points, or it can be changed into the local coordinates of another graphics port.

Because a rectangle is defined by two points, you can convert a rectangle into global coordinates with two calls to `LocalToGlobal`. In conjunction with `LocalToGlobal`, you can use the `OffsetRect`, `OffsetRgn`, or `OffsetPoly` functions to convert a rectangle, region, or polygon into global coordinates.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

LockPixels

Prevents the base address for an offscreen pixel image from being moved while you draw into or copy from its pixel map. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
Boolean LockPixels (
   PixMapHandle pm
);
```

Parameters

pm

A handle to an offscreen pixel map. To get a handle to an offscreen pixel map, use the `GetGWorldPixMap` (page 2642) function .

Return Value
If the base address for an offscreen pixel image hasn't been purged by the Memory Manager or is not purgeable, `LockPixels` returns `TRUE` as its function result, and your application can draw into or copy from the offscreen pixel map. However, if the base address for an offscreen pixel image has been purged, `LockPixels` returns `FALSE` to indicate that you can perform no drawing to or copying from the pixel map. At that point, your application should either call the `UpdateGWorld` (page 2831) function to reallocate the offscreen pixel image and then reconstruct it, or draw directly in a window instead of preparing the image in an offscreen graphics world.

Discussion
You must call `LockPixels` before drawing to or copying from an offscreen graphics world.

The `baseAddr` field of the `PixMap` structure for an offscreen graphics world contains a handle instead of a pointer (which is what the `baseAddr` field for an onscreen pixel map contains). The `LockPixels` function dereferences the `PixMap` handle into a pointer. When you use the `UnlockPixels` function the handle is recovered.

As soon as you are finished drawing into and copying from the offscreen pixel image, call the `UnlockPixels` (page 2829) function.

Special Considerations

The `LockPixels` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

LockPortBits

Acquires an exclusive lock on the back buffer for a Carbon window. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
OSErr LockPortBits (
   GrafPtr port
);
```

Parameters

port
A window port.

Return Value
A result code. If `noErr`, the window's back buffer is locked and available for direct access.

Discussion
In Mac OS X, a Carbon window's port bits are in a back buffer shared by the application and the Quartz compositor (sometimes called the window server). When an application needs to update this buffer, the Quartz compositor must be locked out temporarily. You can use this function together with `UnlockPortBits` (page 2829) to acquire and release an exclusive lock.

If you're using QuickDraw or Quartz 2D to draw in a window, you do not need to call this function—buffer locks are handled for you automatically. If you're writing code that reads or modifies the port bits directly, you should bracket your code with calls to this function and `UnlockPortBits` (page 2829).

Nested calls to this function for the same port are permitted. For a given port, if you call `LockPortBits` *n* times, the lock is actually released after the *n*th balancing call to `UnlockPortBits` (page 2829).

You should not call any QuickTime functions while holding the lock. To avoid degrading the user experience, you should release the lock as quickly as possible.

In Mac OS 9, this function does nothing and returns `noErr`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

MakeITable

Generates an inverse table for a color table. Your application should not need to call this function; it is used by system software only. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void MakeITable (
   CTabHandle cTabH,
   ITabHandle iTabH,
   short res
);
```

Parameters

cTabH

The color table for which an inverse table is to be generated. Passing `NULL` substitutes an appropriate handle from the current `GDevice` data structure.

iTabH

The generated inverse table. Passing `NULL` substitutes an appropriate handle from the current `GDevice` data structure.

res

The resolution needed for the inverse table. Passing 0 substitutes the current `GDevice` data structure's inverse table resolution.

Discussion

The `MakeITable` function generates an inverse table based on the current contents of the color table pointed to by the `cTabH` parameter, with a resolution specified by the value in the `res` parameter. Reserved color table pixel values are not included in the resulting color table. `MakeITable` tests its input parameters and returns an error in `QDError` if the resolution is less than three or greater than five.

This function allows maximum precision in mapping colors, even if colors in the color table differ by less than the resolution of the inverse table. Five-bit inverse tables are not needed when drawing in normal Color QuickDraw modes. However, Color QuickDraw transfer modes such as add, subtract, and blend may require a 5-bit inverse table for best results with certain color tables. The `'mitq'` resource governs how much memory is allocated for temporary internal structures; this resource type is for internal use only.

Depending on the requested resolution, building the inverse table can require large amounts of temporary space in the application heap: twice the size of the table itself, plus a fixed overhead of 3–15 KB for each inverse table resolution.

`QuickdrawAPI.h`

MakeRGBPat

Creates the appearance of otherwise unavailable colors on indexed devices. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void MakeRGBPat (
   PixPatHandle pp,
   const RGBColor *myColor
);
```

Parameters

pp

On return, a handle to the generated pixel pattern.

myColor

An `RGBColor` structure that defines the color you want to approximate.

Discussion

The `MakeRGBPat` function generates a `PixPat` (page 2871) structure that approximates the color you specify in the `myColor` parameter. For example, if your application draws to an indexed device that supports 4 bits per pixel, you only have 16 colors available if you simply set the foreground color and draw. If you use `MakeRGBPat` to create a pattern, and then draw using that pattern, you effectively get 125 different colors. If the graphics device has 8 bits per pixel, you effectively get 2197 colors. (More color are theoretically possible; this implementation opted for a fast pattern selection rather than the best possible pattern selection.)

For a pixel pattern, the (** `patMap).bounds` field of the `PixPat` structure always contains the values (0,0,8,8), and the (** `patMap).rowbytes` field equals 2.

Because patterns produced with `MakeRGBPat` aren't usually solid—they provide a selection of colors by alternating between colors, with up to four colors in a pattern— lines that are only one pixel wide may not look good.

When `MakeRGBPat` creates a `ColorTable` structure, it fills in only the `rgb` fields of its `ColorSpec` structures; the `value` fields are computed at the time the drawing actually takes place, using the current pixel depth for the system.

`QuickdrawAPI.h`

MapPoly

Maps and scales a polygon within one rectangle to another rectangle. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void MapPoly (
   PolyHandle poly,
   const Rect *srcRect,
   const Rect *dstRect
);
```

Parameters

poly

A handle to a polygon. Upon input, this is the polygon to map. Upon completion, this polygon is the one mapped to a new location.

srcRect
The rectangle containing the polygon.

dstRect
The rectangle in which the new region will be mapped.

Discussion
The `MapPoly` function takes a polygon within one rectangle and maps and scales it to another rectangle. In the `poly` parameter, you specify a handle to a polygon that lies within the rectangle that you specify in the `srcRect` parameter. By calling the `MapPt` function to map all the points that define the polygon specified in the `poly` parameter, `MapPoly` maps and scales it to the rectangle that you specify in the `dstRect` parameter. The `MapPoly` function returns the result in the polygon whose handle you initially passed in the `poly` parameter.

Similar to the `MapRgn` function described in the previous section, the `MapPoly` function is useful for determining whether a polygon operation will exceed available memory.

Special Considerations

If the points or rectangles supplied to this function are defined in a graphics port other than your current graphics port, you must convert them to the local coordinate system of your current graphics port. You can accomplish this by using the `SetPort` function to change to the graphics port containing the points or rectangles, using the `LocalGlobal` function to convert their locations to global coordinates, using `SetPort` to return to your starting graphics port, and then using the `GlobalToLocal` function to convert the locations of points or rectangles to the local coordinates of your current graphics port.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

MapPt

Maps a point in one rectangle to an equivalent position in another rectangle.

```
void MapPt (
   Point *pt,
   const Rect *srcRect,
   const Rect *dstRect
);
```

Parameters

pt
Upon input, a pointer to the point in the source rectangle to map; upon completion, a pointer to its mapped position in the destination rectangle.

srcRect
The source rectangle containing the original point.

dstRect
The destination rectangle in which the point will be mapped.

Discussion
The `MapPt` function maps a point in one rectangle to an equivalent position in another rectangle.

In the `pt` parameter, you specify a point that lies within the rectangle that you specify in the `srcRect` parameter. The `MapPt` function maps this point to a similarly located point within the rectangle that you specify in the `dstRect` parameter—that is, to where it would fall if it were part of a drawing being expanded or shrunk to fit the destination rectangle. The `MapPt` function returns the location of the mapped point in the `pt` parameter. For example, a corner point of the source rectangle would be mapped to the corresponding corner point of the destination rectangle in `dstRect`, and the center of the source rectangle would be mapped to the center of destination rectangle.

The source and destination rectangles may overlap, and the point you specify need not actually lie within the source rectangle.

If you are going to draw inside the destination rectangle, you'll probably also want to scale the graphics pen size accordingly with `ScalePt` (page 2782).

Special Considerations

If the points or rectangles supplied to this function are defined in a graphics port other than your current graphics port, you must convert them to the local coordinate system of your current graphics port. You can accomplish this by using the `SetPort` function to change to the graphics port containing the points or rectangles, using the `LocalGlobal` function to convert their locations to global coordinates, using `SetPort` to return to your starting graphics port, and then using the `GlobalToLocal` function to convert the locations of points or rectangles to the local coordinates of your current graphics port.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`QuickdrawAPI.h`

MapRect

Maps and scales a rectangle within one rectangle to another rectangle.

```
void MapRect (
   Rect *r,
   const Rect *srcRect,
   const Rect *dstRect
);
```

Parameters

r
Upon input, a pointer to the rectangle to map; upon completion, the mapped rectangle.

srcRect
The rectangle containing the rectangle to map.

dstRect
The rectangle in which the new rectangle will be mapped.

Discussion
The `MapRect` function takes a rectangle within one rectangle and maps and scales it to another rectangle. In the `r` parameter, you specify a rectangle that lies within the rectangle that you specify in the `srcRect` parameter. By calling the `MapPt` function to map the upper-left and lower-right corners of the rectangle in the `r` parameter, `MapRect` maps and scales it to the rectangle that you specify in the `dstRect` parameter. The `MapRect` function returns the newly mapped rectangle in the `r` parameter.

Special Considerations

If the points or rectangles supplied to this function are defined in a graphics port other than your current graphics port, you must convert them to the local coordinate system of your current graphics port. You can accomplish this by using the `SetPort` function to change to the graphics port containing the points or rectangles, using the `LocalGlobal` function to convert their locations to global coordinates, using `SetPort` to return to your starting graphics port, and then using the `GlobalToLocal` function to convert the locations of points or rectangles to the local coordinates of your current graphics port.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`QuickdrawAPI.h`

MapRgn

Maps and scales a region within one rectangle to another rectangle.

```
void MapRgn (
   RgnHandle rgn,
   const Rect *srcRect,
   const Rect *dstRect
);
```

Parameters

rgn

A handle to a region. Upon input, this is the region to map. Upon completion, this region is the one mapped to a new location.

srcRect

The rectangle containing the region to map.

dstRect

The rectangle in which the new region will be mapped.

Discussion

The `MapRgn` function takes a region within one rectangle and maps and scales it to another rectangle. In the `rgn` parameter, you specify a handle to a region that lies within the rectangle that you specify in the `srcRect` parameter. By calling the `MapPt` function to map all the points of the region in the `rgn` parameter, `MapRgn` maps and scales it to the rectangle that you specify in the `dstRect` parameter. The `MapRgn` function returns the result in the region whose handle you initially passed in the `rgn` parameter.

The `MapRgn` function is useful for determining whether a region operation will exceed available memory. By mapping a large region into a smaller one and performing the operation (without actually drawing), you can estimate how much memory will be required by the anticipated operation.

Special Considerations

If the points or rectangles supplied to this function are defined in a graphics port other than your current graphics port, you must convert them to the local coordinate system of your current graphics port. You can accomplish this by using the `SetPort` function to change to the graphics port containing the points or rectangles, using the `LocalGlobal` function to convert their locations to global coordinates, using `SetPort` to return to your starting graphics port, and then using the `GlobalToLocal` function to convert the locations of points or rectangles to the local coordinates of your current graphics port.

The `MapRgn` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

Move

Moves the graphics pen a particular distance. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void Move (
   short dh,
   short dv
);
```

Parameters

dh

The horizontal distance of the graphics pen's movement.

dv

The vertical distance of the graphics pen's movement.

Discussion
The `Move` function moves the graphics pen from its current location in the current graphics port a horizontal distance that you specify in the `dh` parameter and a vertical distance that you specify in the `dv` parameter. The `Move` function calls

MoveTo(h+dh,v+dv)

where `(h,v)` is the graphics pen's current location in local coordinates. The `Move` function performs no drawing.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

MovePortTo

Changes the position of the port rectangle of the current graphics port (basic or color). (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void MovePortTo (
   short leftGlobal,
   short topGlobal
);
```

Parameters

leftGlobal

The horizontal distance to move the port rectangle.

topGlobal

The vertical distance to move the port rectangle.

Discussion

The `MovePortTo` function is normally called only by the Window Manager. The `MovePortTo` function changes the position of the current graphics port's port rectangle: the `leftGlobal` and `topGlobal` parameters set the distance between the upper-left corner of the boundary rectangle and the upper-left corner of the new port rectangle.

This does not affect the screen; it merely changes the location at which subsequent drawing inside the graphics port appears. Like the `PortSize` function, `MovePortTo` doesn't change the clipping or visible region, nor does it affect the local coordinate system of the graphics port.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

MoveTo

Moves the graphics pen to a particular location in the current graphics port. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void MoveTo (
   short h,
   short v
);
```

Parameters

h

The horizontal coordinate of the graphics pen's new position.

v

The vertical coordinate of the graphics pen's new position.

Discussion

The `MoveTo` function changes the graphics pen's current location to the new horizontal coordinate you specify in the `h` parameter and the new vertical coordinate you specify in the `v` parameter. Specify the new location in the local coordinates of the current graphics port. The `MoveTo` function performs no drawing.

Availability

Available in Mac OS X v10.0 and later.

NewGDevice

Creates a new `GDevice` structure. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
GDHandle NewGDevice (
   short refNum,
   long mode
);
```

Parameters

refNum

Reference number of the graphics device for which you are creating a `GDevice` structure. For most video devices, this information is set at system startup.

mode

The device configuration mode. Used by the screen driver, this value sets the pixel depth and specifies color or black and white.

Return Value
A handle to the new `GDevice` (page 2859) structure. If the request is unsuccessful, `NewGDevice` returns `NULL`.

Discussion
Generally, you do not need to use `NewGDevice`, because Color QuickDraw uses this function to create `GDevice` structures for your application automatically. When the system starts up, it allocates and initializes one handle to a `GDevice` structure for each video device it finds. When you use the `NewGWorld` function, QuickDraw automatically creates a `GDevice` structure for the new offscreen graphics world.

For the graphics device whose driver is specified in the `refNum` parameter and whose mode is specified in the `mode` parameter, the `NewGDevice` function allocates a new `GDevice` structure and all of its handles, and then calls the `InitGDevice` function to initialize the structure.

`NewGDevice` allocates the new `GDevice` structure and all of its handles in the system heap, and the `NewGDevice` function sets all attributes in the `gdFlags` field of the `GDevice` structure to `FALSE`. If your application creates a `GDevice` structure, use the `SetDeviceAttribute` (page 2793) function to change the flag bits in the `gdFlags` field of the `GDevice` structure to `TRUE`. Your application should never directly change the `gdFlags` field of the `GDevice` structure. Instead, use only the `SetDeviceAttribute` function.

If your application creates a `GDevice` structure without a driver, set the `mode` parameter to –1. In this case, `InitGDevice` cannot initialize the `GDevice` structure, so your application must perform all initialization of the structure. A `GDevice` structure's default mode is defined as 128. This is assumed to be a black-and-white mode. If you specify a value other than 128 in the `mode` parameter, the structure's `gdDevType` bit in the `gdFlags` field of the `GDevice` structure is set to `TRUE` to indicate that the graphics device is capable of displaying color.

The `NewGDevice` function does not automatically insert the `GDevice` structure into the device list. In general, your application should not create `GDevice` structures, and if it ever does, it should never add them to the device list.

If your program uses `NewGDevice` to create a graphics device without a driver, `InitGDevice` does nothing; instead, your application must initialize all fields of the `GDevice` structure. After your application initializes the color table for the `GDevice` structure, call the Color Manager function `MakeITable` to build the inverse table for the graphics device.

Special Considerations

The `NewGDevice` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

NewGWorld

Creates an offscreen graphics world. (**Deprecated.** Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
QDErr NewGWorld (
   GWorldPtr *offscreenGWorld,
   short PixelDepth,
   const Rect *boundsRect,
   CTabHandle cTable,
   GDHandle aGDevice,
   GWorldFlags flags
);
```

Parameters

offscreenGWorld

On return, a pointer to the offscreen graphics world created by this function. You use this pointer when referring to this new offscreen world in other QuickDraw functions.

PixelDepth

The pixel depth of the offscreen world; possible depths are 1, 2, 4, 8, 16, and 32 bits per pixel. The default parameter (0) uses the pixel depth of the screen with the greatest pixel depth from among all screens whose boundary rectangles intersect the rectangle that you specify in the `boundsRect` parameter. If you specify 0 in this parameter, `NewGWorld` also uses the `GDevice` structure from this device instead of creating a new `GDevice` structure for the offscreen world. If you use `NewGWorld` on a computer that supports only basic QuickDraw, you may specify only 0 or 1 in this parameter.

boundsRect

The boundary rectangle and port rectangle for the offscreen pixel map. This becomes the boundary rectangle for the `GDevice` structure, if `NewGWorld` creates one. If you specify 0 in the `pixelDepth` parameter, `NewGWorld` interprets the boundaries in global coordinates that it uses to determine which screens intersect the rectangle. `NewGWorld` then uses the pixel depth, color table, and `GDevice` structure from the screen with the greatest pixel depth from among all screens whose boundary rectangles intersect this rectangle. Typically, your application supplies this parameter with the port rectangle for the onscreen window into which your application will copy the pixel image from this offscreen world.

cTable

A handle to a `ColorTable` structure. If you pass `NULL` in this parameter, `NewGWorld` uses the default color table for the pixel depth that you specify in the `pixelDepth` parameter. If you set the `pixelDepth` parameter to 0, `NewGWorld` ignores the `cTable` parameter and instead copies and uses the color table of the graphics device with the greatest pixel depth among all graphics devices whose boundary rectangles intersect the rectangle that you specify in the `boundsRect` parameter. If you use `NewGWorld` on a computer that supports only basic QuickDraw, you may specify only `NULL` in this parameter.

aGDevice

A handle to a `GDevice` structure that is used only when you specify the `noNewDevice` flag in the `flags` parameter, in which case `NewGWorld` attaches this `GDevice` structure to the new offscreen graphics world. If you set the `pixelDepth` parameter to 0, or if you do not set the `noNewDevice` flag, `NewGWorld` ignores the `aGDevice` parameter, so set it to `NULL`. If you set the `pixelDepth` parameter to 0, `NewGWorld` uses the `GDevice` structure for the graphics device with the greatest pixel depth among all graphics devices whose boundary rectangles intersect the rectangle that you specify in the `boundsRect` parameter. You should pass `NULL` in this parameter if the computer supports only basic QuickDraw. Generally, your application should never create `GDevice` structures for offscreen graphics worlds.

flags

Options available to your application. You can set a combination of the flags `pixPurge`, `noNewDevice`, `useTempMem`, and `keepLocal`. If you don't wish to use any of these flags, specify 0 in this parameter to accept the default behavior for `NewGWorld`. The default behavior creates an offscreen graphics world where the base address for the offscreen pixel image is unpurgeable, it uses an existing `GDevice` structure (if you pass 0 in the `depth` parameter) or creates a new `GDevice` structure, it uses memory in your application heap, and it allows graphics accelerators to cache the offscreen pixel image. See "Graphics World Flags" (page 2891) for a description of the values you can use here.

Return Value
A result code.

Discussion
Typically, you pass 0 in the `pixelDepth` parameter, a window's port rectangle in the `boundsRect` parameter, `NULL` in the `cTable` and `aGDevice` parameters, and in the `flags` parameter a 0. This provides your application with the default behavior of `NewGWorld`, and it supports computers running basic QuickDraw. This also allows QuickDraw to optimize the `CopyBits`, `CopyMask`, and `CopyDeepMask` functions when your application copies the image in an offscreen graphics world into an onscreen graphics port.

The `NewGWorld` function allocates memory for an offscreen graphics port and its pixel map. On computers that support only basic QuickDraw, `NewGWorld` creates a 1-bit pixel map that your application can manipulate using other relevant functions described in this chapter. Your application can copy this 1-bit pixel map into basic graphics ports.

Unless you specify 0 in the `pixelDepth` parameter–or pass the `noNewDevice` flag in the `flags` parameter and supply a `GDevice` structure in the `aGDevice` parameter– `NewGWorld` also allocates a new offscreen `GDevice` structure.

When creating an image, use the `NewGWorld` function to create an offscreen graphics world that is optimized for an image's characteristics—for example, its best pixel depth. After creating the image, use the `CopyBits`, `CopyMask`, or `CopyDeepMask` function to copy that image to an onscreen graphics port. Color QuickDraw automatically renders the image at the best available pixel depth for the screen. Creating an image in an offscreen graphics port and then copying it to the screen in this way prevents the visual choppiness that would otherwise occur if your application were to build a complex image directly onscreen.

The `NewGWorld` function initializes the offscreen graphics port by calling the `OpenCPort` function. The `NewGWorld` function sets the offscreen graphics port's visible region to a rectangular region coincident with its boundary rectangle. The `NewGWorld` function generates an inverse table with the Color Manager function `MakeITable`, unless one of the `GDevice` structures for the screens has the same color table as the `GDevice` structure for the offscreen world, in which case `NewGWorld` uses the inverse table from that `GDevice` structure.

The address of the offscreen pixel image is not directly accessible from the `PixMap` structure for the offscreen graphics world. However, you can use the `GetPixBaseAddr` (page 2648) function to get a pointer to the beginning of the offscreen pixel image.

For purposes of estimating memory use, you can compute the size of the offscreen pixel image by using this formula:

rowBytes * (boundsRect.bottom – boundsRect.top)

In the `flags` parameter, you can specify several options. If you don't want to use any of these options, pass 0 in the `flags` parameter:

- If you specify the `pixPurge` flag, `NewGWorld` stores the offscreen pixel image in a purgeable block of memory. In this case, before drawing to or from the offscreen pixel image, your application should call the `LockPixels` (page 2704) function and ensure that it returns `TRUE`. If `LockPixels` returns `FALSE`, the memory for the pixel image has been purged, and your application should either call `UpdateGWorld` (page 2831) to reallocate it and then reconstruct the pixel image, or draw directly in a window instead of preparing the image in an offscreen graphics world. Never draw to or copy from an offscreen pixel image that has been purged without reallocating its memory and then reconstructing it.
- If you specify the `noNewDevice` flag, `NewGWorld` does not create a new offscreen `GDevice` structure. Instead, it uses the `GDevice` structure that you specify in the `aGDevice` parameter–and its associated pixel depth and color table–to create the offscreen graphics world. (If you set the `pixelDepth` parameter to 0, `NewGWorld` uses the `GDevice` structure for the screen with the greatest pixel depth among all the screens whose boundary rectangles intersect the rectangle that you specify in the `boundsRect` parameter–even if you specify the `noNewDevice` flag.) The `NewGWorld` function keeps a reference to the `GDevice` structure for the offscreen graphics world, and the `SetGWorld` (page 2796) function uses that structure to set the current graphics device.
- If you set the `useTempMem` flag, `NewGWorld` creates the base address for an offscreen pixel image in temporary memory. You generally would not use this flag, because you should use temporary memory only for fleeting purposes and only with the `AllowPurgePixels` (page 2573) function.
- If you specify the `keepLocal` flag, your offscreen pixel image is kept in Macintosh main memory and is not cached to a graphics accelerator card. use this flag carefully, as it negates the advantages provided by any graphics acceleration card that might be present.

If your application needs to change the pixel depth, boundary rectangle, or color table for an offscreen graphics world, use the `UpdateGWorld` (page 2831) function.

Special Considerations

If you supply a handle to a `ColorTable` structure in the `cTable` parameter, `NewGWorld` makes a copy of the structure and stores its handle in the offscreen `PixMap` structure. It is your application's responsibility to make sure that the `ColorTable` structure you specify in the `cTable` parameter is valid for the offscreen graphics port's pixel depth.

If when using `NewGWorld` you specify a pixel depth, color table, or `GDevice` structure that differs from those used by the window into which you copy your offscreen image, the `CopyBits`, `CopyMask`, and `CopyDeepMask` functions require extra time to complete.

To use a custom color table in an offscreen graphics world, you need to create the associated offscreen `GDevice` structure, because Color QuickDraw needs its inverse table.

The `NewGWorld` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

NewGWorldFromPtr

(Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
QDErr NewGWorldFromPtr (
   GWorldPtr *offscreenGWorld,
   UInt32 PixelFormat,
   const Rect *boundsRect,
   CTabHandle cTable,
   GDHandle aGDevice,
   GWorldFlags flags,
   Ptr newBuffer,
   SInt32 rowBytes
);
```

Return Value

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QDOffscreen.h`

NewPixMap

Creates a new, initialized `PixMap` structure. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
PixMapHandle NewPixMap (
   void
);
```

Return Value
A handle to the new `PixMap` structure.

Discussion
All fields of the `PixMap` structure are copied from the current device's `PixMap` structure except the color table. In System 7, the `hRes` and `vRes` fields are set to 72 dpi, no matter what values the current device's `PixMap` structure contains. A handle to the color table is allocated but not initialized.

Typically, you do not need to call this function because `PixMap` structures are created for you when you create a window using the Window Manager functions `NewCWindow` and `GetNewCWindow` and when you create an offscreen graphics world with the `NewGWorld` function.

If your application creates a pixel map, your application must initialize the `PixMap` structure's color table to describe the pixels. Use the `GetCTable` (page 2636) function to read such a table from a resource file. Use the `DisposeCTable` (page 2599) function to dispose of the `PixMap` structure's color table and replace it with the one returned by `GetCTable`.

Special Considerations

The `NewPixMap` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

NewPixPat

Creates a new pixel pattern. Generally, however, your application should create a pixel pattern in a `'ppat'` resource. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
PixPatHandle NewPixPat (
   void
);
```

Return Value
A handle to the new `PixPat` (page 2871) structure created by the `NewPixPat` function.

Discussion
This function calls the `NewPixMap` (page 2719) function to allocate the pattern's `PixMap` structure and initializes it to the same settings as the pixel map of the current `GDevice` structure. `NewPixPat` also sets the `pat1Data` field of the new `PixPat` structure to a 50 percent gray pattern. `NewPixPat` allocates new handles for the `PixPat` structure's data, expanded data, expanded map, and color table but does not initialize them instead, your application must initialize them.

Set the `rowBytes`, `bounds`, and `pixelSize` fields of the pattern's `PixMap` structure to the dimensions of the desired pattern. The `rowBytes` value should be equal to

```
(width of bounds) x pixelSize/8
```

The `rowBytes` value need not be even. The width and height of the bounds must be a power of 2. Each scan line of the pattern must be at least 1 byte in length—that is, ([width of bounds] x `pixelSize`) must be at least 8.

Your application can explicitly specify the color corresponding to each pixel value with a color table. The color table for the pattern must be placed in the `pmTable` field in the pattern's `PixMap` structure.

Including the `PixPat` structure itself, `NewPixPat` allocates a total of five handles. The sizes of the handles to the `PixPat` and `PixMap` structures are the sizes of their respective data structures. The other three handles are initially small in size. Once the pattern is drawn, the size of the expanded data is proportional to the size of the pattern data, but adjusted to the depth of the screen. The color table size is the size of the structure plus 8 bytes times the number of colors in the table.

When you are finished using the pixel pattern, use the `DisposePixPat` (page 2602) function to make the memory used by the pixel pattern available again.

Special Considerations

The `NewPixPat` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

NewRgn

Begins creating a new region.

```
RgnHandle NewRgn (
   void
);
```

Return Value
A handle to the new region.

Discussion
The `NewRgn` function allocates space for a new, variable-size region and initializes it to the empty region defined by the rectangle (0,0,0,0). This is the only function that creates a new region; other functions merely alter the size or shape of existing regions.

To begin defining a region, use the `OpenRgn` (page 2737) function.

If the points or rectangles supplied to this function are defined in a graphics port other than your current graphics port, you must convert them to the local coordinate system of your current graphics port. You can accomplish this by using the `SetPort` function to change to the graphics port containing the points or rectangles, using the `LocalGlobal` function to convert their locations to global coordinates, using `SetPort` to return to your starting graphics port, and then using the `GlobalToLocal` function to convert the locations of points or rectangles to the local coordinates of your current graphics port.

Special Considerations

The `NewRgn` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Use the Memory Manager function `MaxMem` to determine whether the memory for the region is valid before using `NewRgn`.

Ensure that the memory for a region is valid before calling this function to manipulate that region if there isn't sufficient memory, the system may crash. Regions are limited to 32 KB in size in basic QuickDraw and 64 KB in color QuickDraw. Before defining a region, you can use the Memory Manager function `MaxMem` to determine whether the memory for the region is valid. You can determine the current size of an existing region by calling the Memory Manager function `GetHandleSize`. When you record drawing operations in an open region, the resulting region description may overflow the 32 KB or 64 KB limit. Should this happen in color QuickDraw, the `QDError` function returns the result code `regionTooBigError`.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

`QuickdrawAPI.h`

NewScreenBuffer

Creates an offscreen `PixMap` structure and allocates memory for the base address of its pixel image. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
QDErr NewScreenBuffer (
   const Rect *globalRect,
   Boolean purgeable,
   GDHandle *gdh,
   PixMapHandle *offscreenPixMap
);
```

Parameters

globalRect

The boundary rectangle, in global coordinates, for the offscreen pixel map.

purgeable

A value of `TRUE` to make the memory block for the offscreen pixel map purgeable, or a value of `FALSE` to make it unpurgeable.

gdh

On return, a pointer to the handle to the `GDevice` structure for the graphics device with the greatest pixel depth among all graphics devices whose boundary rectangles intersect the rectangle specified in the `globalRect` parameter.

offscreenPixMap

On return, a pointer to a handle to the new offscreen `PixMap` structure.

Return Value
A result code.

Discussion
Applications generally do not need to use `NewScreenBuffer`. The `NewGWorld` (page 2715) function uses the `NewScreenBuffer` function to create and allocate memory for an offscreen pixel image.

Special Considerations

The `NewScreenBuffer` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`QDOffscreen.h`

NewTempScreenBuffer

Creates an offscreen `PixMap` structure and allocate temporary memory for the base address of its pixel image applications generally don't need to use `NewTempScreenBuffer`. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
QDErr NewTempScreenBuffer (
   const Rect *globalRect,
   Boolean purgeable,
   GDHandle *gdh,
   PixMapHandle *offscreenPixMap
);
```

Parameters

globalRect

The boundary rectangle, in global coordinates, for the offscreen pixel map.

purgeable

A value of `TRUE` to make the memory block for the offscreen pixel map purgeable, or a value of `FALSE` to make it unpurgeable.

gdh

On return, a pointer to the handle to the `GDevice` structure for the graphics device with the greatest pixel depth among all graphics devices whose boundary rectangles intersect the rectangle specified in the `globalRect` parameter.

offscreenPixMap

On return, a pointer to the handle to the new offscreen `PixMap` structure.

Return Value
A result code.

Discussion
The `NewTempScreenBuffer` function performs the same functions as `NewScreenBuffer` except that it creates the base address for the offscreen pixel image in temporary memory. When an application passes it the `useTempMem` flag, the `NewGWorld` function uses `NewTempScreenBuffer` instead of `NewScreenBuffer`.

Your application should not need to use this function.

Special Considerations

The `NewTempScreenBuffer` function may move or purge memory blocks in the application heap. Your application should not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QDOffscreen.h`

NoPurgePixels

Prevents the Memory Manager from purging the base address for an offscreen pixel image. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void NoPurgePixels (
   PixMapHandle pm
);
```

Parameters

pm

A handle to an offscreen pixel map.

Discussion

The `NoPurgePixels` function marks the base address for an offscreen pixel image as unpurgeable.

To get a handle to an offscreen pixel map, use the `GetGWorldPixMap` (page 2642) function. Then supply this handle for the `pm` parameter of `NoPurgePixels`.

Special Considerations

The `NoPurgePixels` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

```
SInt32 OffscreenVersion (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QDOffscreen.h`

OffsetPoly

Moves a polygon. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void OffsetPoly (
   PolyHandle poly,
   short dh,
   short dv
);
```

Parameters

poly
A handle to a polygon to move.

dh
The horizontal distance to move the polygon.

dv
The vertical distance to move the polygon.

Discussion
The `OffsetPoly` function moves the polygon whose handle you pass in the `poly` parameter by adding the value you specify in the `dh` parameter to the horizontal coordinates of its points, and by adding the value you specify in the `dv` parameter to the vertical coordinates of all points of its region boundary. If the values of `dh` and `dv` are positive, the movement is to the right and down; if either is negative, the corresponding movement is in the opposite direction. The region retains its size and shape. This does not affect the screen unless you subsequently call a function to draw the region.

`OffsetPoly` is an especially efficient operation, because the data defining a polygon is stored relative to the first point of the polygon and so is not actually changed by `OffsetPoly`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

OffsetRect

Moves a rectangle.

```
void OffsetRect (
    Rect * r,
    short dh,
    short dv
);
```

Parameters

r

A pointer to the rectangle to move.

dh

The horizontal distance to move the rectangle.

dv

The vertical distance to move the rectangle.

Discussion

The `OffsetRect` function moves the rectangle that you specify in the `r` parameter by adding the value you specify in the `dh` parameter to each of its horizontal coordinates and the value you specify in the `dv` parameter to each of its vertical coordinates. If the `dh` and `dv` parameters are positive, the movement is to the right and down; if either is negative, the corresponding movement is in the opposite direction. The rectangle retains its shape and size; it is merely moved on the coordinate plane. The movement does not affect the screen unless you subsequently call a function to draw within the rectangle.

If the points or rectangles supplied to this function are defined in a graphics port other than your current graphics port, you must convert them to the local coordinate system of your current graphics port. You can accomplish this by using the `SetPort` function to change to the graphics port containing the points or rectangles, using the `LocalGlobal` function to convert their locations to global coordinates, using `SetPort` to return to your starting graphics port, and then using the `GlobalToLocal` function to convert the locations of points or rectangles to the local coordinates of your current graphics port.

Availability

Available in Mac OS X v10.0 and later.

Related Sample Code

CarbonSketch

HID Calibrator

OffsetRgn

Moves a region.

```
void OffsetRgn (
    RgnHandle rgn,
    short dh,
    short dv
);
```

Parameters

rgn

A handle to the region to move.

dh

The horizontal distance to move the region.

dv

The vertical distance to move the region.

Discussion

The `OffsetRgn` function moves the region whose handle you pass in the `rgn` parameter by adding the value you specify in the `dh` parameter to the horizontal coordinates of all points of its region boundary, and by adding the value you specify in the `dv` parameter to the vertical coordinates of all points of its region boundary. If the values of `dh` and `dv` are positive, the movement is to the right and down; if either is negative, the corresponding movement is in the opposite direction. The region retains its size and shape. This does not affect the screen unless you subsequently call a function to draw the region.

The `OffsetRgn` function is an especially efficient operation, because most of the data defining a region is stored relative to the `rgnBBox` field in its `Region` structure and so is not actually changed by `OffsetRgn`.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

`QuickdrawAPI.h`

OpColor

Sets the maximum color values for the `addPin` and `subPin` arithmetic transfer modes and the weight color for the `blend` arithmetic transfer mode. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void OpColor (
   const RGBColor *color
);
```

Parameters

color

An `RGBColor` structure that defines a color.

Discussion

Specify the red, green, and blue values in the `RGBColor` structure and specify this structure in the `color` parameter.

If the current graphics port is defined by a `GrafPort` structure, `OpColor` has no effect.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

OpenCPicture

Begins defining a picture in extended version 2 format. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
PicHandle OpenCPicture (
   const OpenCPicParams *newHeader
);
```

Parameters

newHeader

An `OpenCPicParams` structure.

Return Value
A handle to a new `Picture` structure. `OpenCPicture` collects your subsequent drawing commands in this structure. Use this handle when referring to the picture in subsequent functions, such as the `DrawPicture` function.

Discussion
When defining a picture, you can use all other QuickDraw drawing functions, with the exception of `CopyMask`, `CopyDeepMask`, `SeedFill`, `SeedCFill`, `CalcMask`, and `CalcCMask`. You can also use the `PicComment` (page 2748) function to include picture comments in your picture definition.

The `OpenCPicture` function creates a pictures in the extended version 2 format. This format permits your application to specify resolutions when creating images.

Use the `OpenCPicParams` (page 2865) structure you pass in the `newHeader` parameter to specify the horizontal and vertical resolution for the picture, and specify an optimal bounding rectangle for displaying the picture at this resolution. When you later call the `DrawPicture` (page 2610) function to play back the saved picture, supply a destination rectangle, and `DrawPicture` scales the picture so that it is completely aligned with the destination rectangle. To display a picture at a resolution other than that at which it was created, compute an appropriate destination rectangle by scaling its width and height by the following factor:

```
scale factor = destination resolution / source resolution
```

For example, if a picture was created at 300 dpi and you want to display it at 75 dpi, then your application should compute the destination rectangle width and height as 1/4 of those of the picture's bounding rectangle.

The `OpenCPicture` function calls the `HidePen` function, so no drawing occurs on the screen while the picture is open (unless you call the `ShowPen` function just after `OpenCPicture`, or you called `ShowPen` previously without balancing it by a call to `HidePen`).

After defining the picture, close it by using the `ClosePicture` (page 2581) function.

After creating the picture, use the `GetPictInfo` function to gather information about it. The `PictInfo` structure returned by `GetPictInfo` returns the picture's resolution and optimal bounding rectangle.

Special Considerations

When creating a picture, use the `ClosePicture` function to finish it before you open the Printing Manager with the `PrOpen` function. There are two main reasons for this. First, you should allow the printing driver to use as much memory as possible. Second, the Printing Manager creates its own type of graphics port, one that replaces the standard QuickDraw drawing operations stored in the `grafProcs` field of a `CGrafPort` or `GrafPort` structure. To avoid unexpected results when creating a picture, draw into a graphics port created with QuickDraw instead of drawing into a printing port created by the Printing Manager.

After calling `OpenCPicture`, be sure to finish your picture definition by calling `ClosePicture` before you call `OpenCPicture` again. You cannot nest calls to `OpenCPicture`.

Always use the `ClipRect` procedure to specify a clipping region appropriate for your picture before you call `OpenCPicture`. If you do not use `ClipRect` to specify a clipping region, `OpenCPicture` uses the clipping region specified in the current graphics port. If the clipping region is very large (as it is when a graphics port is initialized) and you scale the picture when drawing it, the clipping region can become invalid when `DrawPicture` scales the clipping region—in which case, your picture will not be drawn.

The `OpenCPicture` function may move or purge memory; do not call at interrupt time.

`QuickdrawAPI.h`

OpenPicture

Creates a picture which allows you to specify resolutions for your pictures. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
PicHandle OpenPicture (
   const Rect *picFrame
);
```

Parameters

picFrame

The bounding rectangle for the picture. The `DrawPicture` function uses this rectangle to scale the picture if you draw it into a destination rectangle of a different size.

Return Value

A handle to a new `Picture` structure. `OpenPicture` collects your subsequent drawing commands in this structure. Use this handle when referring to the picture in subsequent functions, such as the `DrawPicture` function.

Discussion

The `OpenPicture` function, which was created for earlier versions of system software, is described here for completeness. Use the `OpenPicture` function to begin defining a picture.

The `OpenPicture` function calls the `HidePen` function, so no drawing occurs on the screen while the picture is open (unless you call the `ShowPen` function just after `OpenPicture` or you called `ShowPen` previously without balancing it by a call to `HidePen`).

The `OpenPicture` function creates pictures in the version 2 format on computers with Color QuickDraw when the current graphics port is a color graphics port. Pictures created in this format support color drawing operations at 72 dpi. On computers supporting only basic QuickDraw, or when the current graphics port is a basic graphics port, this function creates pictures in version 1 format. Pictures created in version 1 format support only black-and-white drawing operations at 72 dpi.

When defining a picture, you can use all other QuickDraw drawing functions, with the exception of `CopyMask`, `CopyDeepMask`, `SeedFill`, `SeedCFill`, `CalcMask`, and `CalcCMask`. You can also use the `PicComment` (page 2748) function to include picture comments in your picture definition.

After defining the picture, close it by using the `ClosePicture` (page 2581) function. To draw the picture, use the `DrawPicture` (page 2610) function.

Special Considerations

The version 2 and version 1 picture formats support only 72-dpi resolution. The `OpenCPicture` function creates pictures in the extended version 2 format. The extended version 2 format, which is created by the `OpenCPicture` function on all Macintosh computers running System 7, permits your application to specify additional resolutions when creating images.

Version 1 pictures are limited to 32 KB. You can determine the picture size while it is being formed by calling the Memory Manager function `GetHandleSize`.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

OpenPoly

Begins defining a polygon. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
PolyHandle OpenPoly (
   void
);
```

Return Value
A handle to a new polygon.

Discussion
The `OpenPoly` function starts saving lines for processing as a polygon definition. While a polygon is open, all calls to the `Line` and `LineTo` functions affect the outline of the polygon. Only the line endpoints affect the polygon definition; the pattern mode, pattern, and size do not affect it. The `OpenPoly` function calls the `HidePen` function, so no drawing occurs on the screen while the polygon is open (unless you call the `ShowPen` function just after calling `OpenPoly`, or you called `ShowPen` previously without balancing it by a call to `HidePen`).

A polygon should consist of a sequence of connected lines. The `OpenPoly` function stores the definition for a polygon in a `Polygon` structure.

When a polygon is open, the current graphics port's `polySave` field contains a handle to information related to the polygon definition. If you want to temporarily disable the polygon definition, you can save the current value of this field, set the field to `NULL`, and later restore the saved value to resume the polygon definition.

Even though the onscreen presentation of a polygon is clipped, the definition of a polygon is not; you can define a polygon anywhere on the coordinate plane.

When you are finished calling the line-drawing functions that define your polygon, use the `ClosePoly` (page 2581) function.

Special Considerations

Do not call `OpenPoly` while a region or another polygon is already open.

Polygons are limited to 64 KB. You can determine the polygon size while it is being formed by calling the Memory Manager function `GetHandleSize`.

The `OpenPoly` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

`QuickdrawAPI.h`

OpenRgn

Begins defining a region. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void OpenRgn (
   void
);
```

Discussion

The `OpenRgn` function allocates temporary memory to start saving lines and framed shapes for processing as a region definition. Call `OpenRgn` only after initializing a region with the `NewRgn` function.

The `NewRgn` function stores the definition for a region in a `Region` structure.

While a region is open, all calls to `Line`, `LineTo`, and the functions that draw framed shapes (except arcs) affect the outline of the region. Only the line endpoints and shape boundaries affect the region definition—the pattern mode, pattern, and size do not affect it.

When you are finished defining the region, call the `CloseRgn` (page 2582) function.

The `OpenRgn` function calls `HidePen`, so no drawing occurs on the screen while the region is open (unless you call `ShowPen` just after `OpenRgn`, or you called `ShowPen` previously without balancing it by a call to `HidePen`). Since the pen hangs below and to the right of the pen location, drawing lines with even the smallest pen changes pixels that lie outside the region you define.

The outline of a region is mathematically defined and infinitely thin, and it separates the bit or pixel image into two groups of pixels: those within the region and those outside it.

A region should consist of one or more closed loops. Each framed shape itself constitutes a loop. Any lines drawn with the `Line` or `LineTo` function should connect with each other or with a framed shape. Even if the onscreen presentation of a region is clipped, the definition of a region is not; you can define a region anywhere on the coordinate plane with complete disregard for the location of various graphics port entities on that plane.

When a region is open, the current graphics port's `rgnSave` field contains a handle to information related to the region definition. If you want to temporarily disable the collection of lines and shapes, you can save the current value of this field, set the field to `NULL`, and later restore the saved value to resume the region definition. Also, calling `SetPort` while a region is being formed discontinues formation of the region until another call to `SetPort` resets the region's original graphics port.

If the points or rectangles supplied to this function are defined in a graphics port other than your current graphics port, you must convert them to the local coordinate system of your current graphics port. You can accomplish this by using the `SetPort` function to change to the graphics port containing the points or rectangles, using the `LocalGlobal` function to convert their locations to global coordinates, using `SetPort` to return to your starting graphics port, and then using the `GlobalToLocal` function to convert the locations of points or rectangles to the local coordinates of your current graphics port.

Special Considerations

Regions are limited to 32 KB in size in basic QuickDraw and 64 KB in Color QuickDraw. You can determine the current size of an existing region by calling the Memory Manager function `GetHandleSize`. When you structure drawing operations in an open region, the resulting region description may overflow the 32 KB or 64 KB limit. Should this happen in Color QuickDraw, the `QDError` function returns the result code `regionTooBigError`.

Do not call `OpenRgn` while another region or a polygon is already open. When you are finished constructing the region, use the `CloseRgn` function, which is described next.

The `OpenRgn` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

PackBits

Compresses a data buffer stored in RAM. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void PackBits (
   Ptr *srcPtr,
   Ptr *dstPtr,
   short srcBytes
);
```

Parameters

srcPtr
On entry, a pointer to the first byte of a buffer of data to be compressed. On exit, a pointer to the first byte following the bytes compressed.

dstPtr
On entry, a pointer to the first byte in which to store compressed data. On exit, a pointer to the first byte following the compressed data.

srcBytes
The number of bytes of uncompressed data to be compressed. In versions of software prior to version 6.0.2, this number must be 127 or less.

Discussion
You must allocate memory for the destination buffer itself. Allocate enough memory for a worst-case scenario where the destination buffer is 128 bytes long for each block of source data up to 127 bytes. Use the following formula to determine how much space to allocate for the destination buffer:

maxDstBytes := srcBytes + (srcBytes+126) DIV 127;

where `maxDstBytes` stands for the maximum number of destination bytes.

The `PackBits` algorithm is most effective on data buffers in which there are likely to be series of bytes containing the same value. For example, resources of many formats often contain many consecutive zeros. If you have a data buffer in which there are only likely to be a series of words or long words containing the same values, `PackBits` is unlikely to be effective.

Special Considerations

Because your application must allocate memory for the source and destination buffers, `PackBits` does not move relocatable blocks. Thus, you can call it at interrupt time.

Because `PackBits` changes the values of the `srcPtr` and `dstPtr` parameters, you should pass to `PackBits` only copies of the pointers to the source and destination buffers. This allows you to access the beginning of the source and destination buffers after `PackBits` returns. Also, if the source or destination buffer is stored in an unlocked, relocatable block, this technique prevents `PackBits` from changing the value of a master pointer, which would make the original handle invalid.

`QuickdrawAPI.h`

PaintArc

Paints a wedge of the oval that fits inside a rectangle. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void PaintArc (
   const Rect *r,
   short startAngle,
   short arcAngle
);
```

Parameters

r
The rectangle that defines an oval's boundaries.

startAngle
The angle indicating the start of the arc.

arcAngle
The angle indicating the arc's extent.

Discussion
Using the pen pattern and pattern mode of the current graphics port, the `PaintArc` function draws a wedge of the oval bounded by the rectangle that you specify in the `r` parameter. As in the `FrameArc` function, use the `startAngle` and `arcAngle` parameters to define the arc of the wedge.

The pen location does not change.

Use `FillArc` (page 2619) , to draw a wedge with a pattern different from that specified in the `pnPat` field of the current graphics port.

Special Considerations

The `PaintArc` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

PaintOval

Paints an oval with the graphics pen's pattern and pattern mode. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void PaintOval (
   const Rect *r
);
```

Parameters

r

The rectangle that defines the oval's boundary.

Discussion

Using the pen pattern and pattern mode for the current graphics port, the `PaintOval` function draws the interior of an oval just inside the bounding rectangle that you specify in the `r` parameter. The pen location does not change.

Use `FillOval` (page 2624) to draw the interior of an oval with a pen pattern different from that for the current graphics port.

Special Considerations

The `PaintOval` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

PaintPoly

Paints a polygon with the graphics pen's pattern and pattern mode. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void PaintPoly (
   PolyHandle poly
);
```

Parameters

poly

A handle to the polygon to paint. The `OpenPoly` (page 2737) function returns this handle when you first create the polygon.

Discussion

Using the pen pattern and pattern mode for the current graphics port, the `PaintPoly` function draws the interior of a polygon whose handle you pass in the `poly` parameter. The pen location does not change.

This function temporarily converts the polygon into a region to perform their operations. The amount of memory required for this temporary region may be far greater than the amount required by the polygon alone.

You can estimate the size of this region by scaling down the polygon with the `MapPoly` (page 2707) , converting the polygon into a region, checking the region's size with the Memory Manager function `GetHandleSize`, and multiplying that value by the factor by which you scaled the polygon.

The result of this graphics operation is undefined whenever any horizontal or vertical line drawn through the polygon would intersect the polygon's outline more than 50 times.

Use the `FillPoly` (page 2625) function to draw the interior of a polygon with a pattern different from that specified in the `pnPat` field of the current graphics port.

Special Considerations

Do not create a height or width for the polygon greater than 32,767 pixels, or `PaintPoly` will crash.

The `PaintPoly` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

PaintRect

Paints a rectangle with the graphics pen's pattern and pattern mode. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void PaintRect (
   const Rect *r
);
```

Parameters

r

The rectangle to paint.

Discussion

The `PaintRect` function draws the interior of the rectangle that you specify in the `r` parameter with the pen pattern for the current graphics port, according to the pattern mode for the current graphics port. The pen location does not change.

Use the `FillRect` (page 2626) to draw the interior of a rectangle with a pen pattern different from that for the current graphics port.

Special Considerations

The `PaintRect` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

PaintRgn

Paints a region with the graphics pen's pattern and pattern mode. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void PaintRgn (
    RgnHandle rgn
);
```

Parameters

rgn

A handle to the region to paint.

Discussion
Using the pen pattern and pattern mode for the current graphics port, the `PaintRgn` function draws the interior of the region whose handle you pass in the `rgn` parameter. The pen location does not change.

This function depends on the local coordinate system of the current graphics port. If you draw a region in a graphics port different from the one in which you defined the region, it may not appear in the proper position in the graphics port.

If any horizontal or vertical line drawn through the region would intersect the region's outline more than 50 times, the results of this graphics operation are undefined.

Use `FillRgn` (page 2626) to draw the interior of a region with a pen pattern different from that for the current graphics port.

Special Considerations

The `PaintRgn` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

PaintRoundRect

Paints a rounded rectangle with the graphics pen's pattern and pattern mode. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void PaintRoundRect (
   const Rect *r,
   short ovalWidth,
   short ovalHeight
);
```

Parameters

r

The rectangle that defines the rounded rectangle's boundaries.

ovalWidth

The width of the oval defining the rounded corner.

ovalHeight

The height of the oval defining the rounded corner.

Discussion

Using the pattern and pattern mode of the graphics pen for the current graphics port, the `PaintRoundRect` function draws the interior of the rounded rectangle bounded by the rectangle that you specify in the `r` parameter. Use the `ovalWidth` and `ovalHeight` parameters to specify the diameters of curvature for the corners of the rounded rectangle.

The pen location does not change.

Use `FillRoundRect` (page 2627) to draw the interior of a rounded rectangle with a pen pattern different from that for the current graphics port.

Special Considerations

The `PaintRoundRect` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

PenMode

Sets the pattern mode of the graphics pen in the current graphics port. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void PenMode (
   short mode
);
```

Parameters

mode

The pattern mode. See "Source, Pattern, and Arithmetic Transfer Mode Constants" (page 2898).

Discussion

Using the pattern mode you specify in the `mode` parameter, the `PenMode` function sets the manner in which the pattern of the graphics pen is transferred onto the bitmap (or pixel map) when you draw lines or shapes in the current graphics port.

If you specify a source mode (such as one used with the `CopyBits` function) instead of a pattern mode, no drawing is performed.

The current pattern mode is stored in the `pnMode` field of the current graphics port. The initial pattern mode value is `patCopy`, in which the pen pattern is copied directly to the bitmap.

To use highlighting, add the `hilite` constant or its value to the source or pattern mode:

With highlighting, QuickDraw replaces the background color with the highlight color when your application draws or copies images between graphics ports. This has the visual effect of using a highlighting pen to select the object. (The global variable `HiliteRGB` is read from parameter RAM when the machine starts. Basic graphics ports use the color stored in the `HiliteRGB` global variable as the highlight color. Color graphics ports default to the `HiliteRGB` global variable, but can be overridden by the `HiliteColor` function.

This pen-manipulation function uses the local coordinate system of the current graphics port. Remember that each graphics port has its own pen, the state of which is stored in several fields of its `GrafPort` or `CGrafPort` structure. If you draw in one graphics port, change to another, and return to the first, the pen for the first graphics port has the same state as when you left it.

Special Considerations

When your application draws with a pixel pattern, Color QuickDraw ignores the pattern mode and simply transfers the pattern directly to the pixel map without regard to the foreground and background colors.

The results of inverting a pixel are predictable only with direct pixels or 1-bit pixel maps. For indexed pixels, Color QuickDraw performs the inversion on the pixel indexes, which means the results depend entirely on the contents of the color table. The eight colors used in basic QuickDraw are stored in a color table represented by the global variable `QDColors`. To display those eight basic QuickDraw colors on an indexed device, Color QuickDraw uses the Color Manager to obtain indexes to the colors in the CLUT that best map to the colors in the `QDColors` color table. Because the index, not the color value, is inverted, the results are unpredictable.

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

PenNormal

Sets the size, pattern, and pattern mode of the graphics pen in the current graphics port to their initial values. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void PenNormal (
   void
);
```

Discussion

The `PenNormal` function restores the size, pattern, and pattern mode of the graphics pen in the current graphics port to their initial values: a size of 1 pixel by 1 pixel, a pattern mode of `patCopy`, and a pattern of `black`. The pen location does not change.

Special Considerations

The `PenNormal` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

PenPat

Sets the bit pattern to be used by the graphics pen in the current graphics port. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void PenPat (
   const Pattern *pat
);
```

Parameters

pat

A bit pattern, as defined by a `Pattern` structure.

Discussion

The `PenPat` function sets the graphics pen to use the bit pattern defined in the `Pattern` (page 2866) structure that you specify in the `pat` parameter. (The standard patterns `white`, `black`, `gray`, `ltGray`, and `dkGray` are predefined; the initial bit pattern for the pen is `black`.) This pattern is stored in the `pnPat` field of a `GrafPort` structure. The QuickDraw painting functions (such as `PaintRect`) also use the pen's pattern when drawing a shape.

The `PenPat` function also sets a bit pattern for the graphics pen in a color graphics port. The `PenPat` function creates a handle, of type `PixPatHandle`, for the bit pattern and stores this handle in the `pnPixPat` field of the `CGrafPort` structure. This pattern always uses the graphics port's current foreground and background colors.

To define your own patterns, you typically create pattern, 'PAT', or pattern list, 'PAT#', resources.

Special Considerations

The `PenPat` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

PenPixPat

Sets the pixel pattern used by the graphics pen in the current color graphics port. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void PenPixPat (
   PixPatHandle pp
);
```

Parameters

pp

A handle to the pixel pattern to use as the pen pattern.

Discussion

The `PenPixPat` function is similar to the basic QuickDraw function `PenPat`, except that you pass `PenPixPat` a handle to a multicolored pixel pattern rather than a bit pattern.

The `PenPixPat` function stores the handle to the pixel pattern in the `pnPixPat` field of the `CGrafPort` structure, therefore, you should not dispose of this handle since QuickDraw removes all references to your pattern from an existing graphics port when you dispose of it.

If you use `PenPixPat` to set a pixel pattern in a basic graphics port, the data in the `pat1Data` field of the `PixPat` (page 2871) structure is placed into the `pnPat` field of the `GrafPort` structure.

To define your own pixel pattern, you can create a pixel pattern resource, which is described in `'ppat'`, or you can use the `NewPixPat` (page 2720) function. To set the pen to use a bit pattern, you can also use the QuickDraw function `PenPat`.

Special Considerations

The `PenPixPat` function may move or purge memory blocks in the application heap. Your application should not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

`QuickdrawAPI.h`

PenSize

Sets the dimensions of the graphics pen in the current graphics port. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void PenSize (
   short width,
   short height
);
```

Parameters

width

The pen width, as an integer from 0 to 32,767. If you set the value to 0, the pen does not draw. Values less than 0 are undefined.

height

The pen height, as an integer from 0 to 32,767. If you set the value to 0, the pen does not draw. Values less than 0 are undefined.

Discussion

The `PenSize` function sets the width that you specify in the `width` parameter and the height that you specify in the `height` parameter for the graphics pen in the current graphics port. All subsequent calls to the `Line` and `LineTo` functions and to the functions that draw framed shapes in the current graphics port use the new pen dimensions.

You can get the current pen dimensions from the `pnSize` field of the current graphics port, where the width and height are stored as a `Point` structure.

This pen-manipulation function uses the local coordinate system of the current graphics port. Remember that each graphics port has its own pen, the state of which is stored in several fields of its `GrafPort` or `CGrafPort` structure. If you draw in one graphics port, change to another, and return to the first, the pen for the first graphics port has the same state as when you left it.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

PicComment

Inserts a picture comment into a picture that you are defining or into your printing code. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void PicComment (
   short kind,
   short dataSize,
   Handle dataHandle
);
```

Parameters

kind

The type of comment.

dataSize

Size of any additional data passed in the `dataHandle` parameter. If no additional data is used, specify 0 in this parameter.

dataHandle

A handle to additional data, if used. If no additional data is used, specify `NULL` in this parameter.

Discussion

When used after your application begins creating a picture with the `OpenCPicture` (or `OpenPicture`) function, the `PicComment` function inserts the specified comment into the `Picture` structure. When sent to a printer driver after your application uses the `PrOpenPage` function, `PicComment` passes the data or commands in the specified comment directly to the printer.

Picture comments contain data or commands for special processing by output devices, such as printers.

Usually printer drivers process picture comments, but applications can also do so. For your application to process picture comments, it must replace the `StdComment` function pointed to by the `commentProc` field of the `CQDProcs` or `QDProcs` structure, which in turn is pointed to by the `grafProcs` field of a `CGrafPort` or `GrafPort` structure. The default `StdComment` function provided by QuickDraw does no comment processing whatsoever. You can use the `SetStdCProcs` function to assist you in changing the `CQDProcs` structure, and you can use the `SetStdProcs` function to assist you in changing the `QDProcs` structure.

If you create and process your own picture comments, you should define comments so that they contain information that identifies your application (to avoid using the same comments as those used by Apple or by other third-party products). You should define a comment as an `ApplicationComment` comment type with a `kind` value of 100. The first 4 bytes of the data for the comment should specify your application's signature. You can use the next 2 bytes to identify the type of comment—that is, to specify a `kind` value to your own application.

Suppose your application signature were `'WAVE'`, and you wanted to use the value 128 to identify a `kind` value to your own application. You would supply values to the `kind` and `data` parameters to `PicComment` as follows:

`kind` = 100; `data` = `'WAVE'` [4 bytes] + 128 [2 bytes] + additional data [n bytes]

Your application can then parse the first 6 bytes of the comment to determine whether and how to process the rest of the data in the comment. It is up to you to publish information about your comments if you wish them to be understood and used by other applications.

Special Considerations

These former picture comments are now obsolete: `SetGrayLevel`, `ResourcePS`, `PostScriptFile`, and `TextIsPostScript`.

The `PicComment` function may move or purge memory.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

PixMap32Bit

Determines whether a pixel map requires 32-bit addressing mode for access to its pixel image. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
Boolean PixMap32Bit (
   PixMapHandle pmHandle
);
```

Parameters

pmHandle

A handle to an offscreen pixel map.

Return Value

`TRUE` if a pixel map requires 32-bit addressing mode for access to its pixel image. If your application is in 24-bit mode, you must change to 32-bit mode.

Discussion
To get a handle to an offscreen pixel map, first use the `GetGWorldPixMap` (page 2642) function. Then supply this handle for the `pm` parameter of `PixMap32Bit`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QDOffscreen.h`

PixPatChanged

Notifies QuickDraw that the content of a `PixPat` structure, including its `PixMap` structure or the image in its `patData` field, has been modified. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void PixPatChanged (
   PixPatHandle ppat
);
```

Parameters

ppat
A handle to the changed pixel pattern.

Discussion
The `PixPatChanged` function sets the `patXValid` field of the `PixPat` structure specified in the `ppat` parameter to –1 and notifies QuickDraw of the change.

If your application changes the `pmTable` field of a pixel pattern's `PixMap` structure, it should call `PixPatChanged`. However, if your application changes the content of the color table referenced by the `PixMap` structure's `pmTable` field, it should call both the `PixPatChanged` and the `CTabChanged` functions.

Your application should never need to directly modify a `PixPat` structure and use the `PixPatChanged` function; instead, your application should use the QuickDraw functions for manipulating the values in a `PixPat` structure.

Special Considerations

The `PixPatChanged` function may move or purge memory in the application heap; do not call the `PixPatChanged` function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QDOffscreen.h`

PortChanged

Notifies QuickDraw that the content of a `GrafPort` structure or `CGrafPort` structure, including any of the data structures specified by handles within the structure, has been modified. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void PortChanged (
   GrafPtr port
);
```

Parameters

port

A pointer to the `GrafPort` structure that you have changed.

Discussion

If your application has changed a `CGrafPort` structure, it must coerce the `CGrafPtr` so it will point to a `GrafPtr` before passing the pointer in the `port` parameter.

You generally should not directly change any of the `PixPat` structures specified in a `CGrafPort` structure, but instead use the `PenPixPat` and `BackPixPat` functions. However, if your application does change the content of a `PixPat` structure, it should call the `PixPatChanged` function and the `PortChanged` function.

If your application changes the `pmTable` field of the `PixMap` structure specified in the graphics port, your application should call `PortChanged`. If your application changes the content of the `ColorTable` structure referenced by the `pmTable` field, it should call `CTabChanged` also.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QDOffscreen.h`

PortSize

Changes the size of the port rectangle of the current graphics port (basic or color). (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void PortSize (
   short width,
   short height
);
```

Parameters

width

The width of the reset port rectangle.

height

The height of the reset port rectangle.

Discussion
The `PortSize` function is normally called only by the Window Manager. The `PortSize` function changes the size of the current graphics port's port rectangle. The upper-left corner of the port rectangle remains at its same location the width and height of the port rectangle are set to the given `width` and `height`. In other words, `PortSize` moves the lower-right corner of the port rectangle to a position relative to the upper-left corner.

The `PortSize` function doesn't change the clipping or visible region of the graphics port, nor does it affect the local coordinate system of the graphics port it changes only the width and height of the port rectangle. Remember that all drawing occurs only in the intersection of the boundary rectangle and the port rectangle, after being cropped to the visible region and the clipping region.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

ProtectEntry

Adds protection to or removes protection from an entry in the current `GDevice` data structure's color table. This function is used by system software and your application should not need to call it. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void ProtectEntry (
   short index,
   Boolean protect
);
```

Parameters
index
The index to the entry whose protection is to be changed.
protect
A Boolean value: specify `true` to protect the entry, `false` to remove protection.

Discussion
A protected entry can not be changed by other applications. `ProtectEntry` returns a protection error in `QDErr` if you attempt to protect an already protected entry. However, it can remove protection from any entry, even an already unprotected one.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

Pt2Rect

Determines the smallest rectangle that encloses two given points.

```
void Pt2Rect (
   Point pt1,
   Point pt2,
   Rect *dstRect
);
```

Parameters

pt1

The first of two points to enclose.

pt2

The second of two points to enclose.

dstRect

On return, a pointer to the smallest rectangle that can enclose them.

Discussion

If the points or rectangles supplied to this function are defined in a graphics port other than your current graphics port, you must convert them to the local coordinate system of your current graphics port. You can accomplish this by using the `SetPort` function to change to the graphics port containing the points or rectangles, using the `LocalGlobal` function to convert their locations to global coordinates, using `SetPort` to return to your starting graphics port, and then using the `GlobalToLocal` function to convert the locations of points or rectangles to the local coordinates of your current graphics port.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`QuickdrawAPI.h`

PtInRect

Determines whether a pixel below is enclosed in a rectangle.

```
Boolean PtInRect (
    Point pt,
    const Rect * r
);
```

Parameters

pt

The point to test.

r

The rectangle to test.

Return Value

`TRUE` if the pixel below and to the right of the point specified in the `pt` parameter is enclosed in the rectangle specified in the `r` parameter. `FALSE` if it is not.

Discussion
If the points or rectangles supplied to this function are defined in a graphics port other than your current graphics port, you must convert them to the local coordinate system of your current graphics port. You can accomplish this by using the `SetPort` function to change to the graphics port containing the points or rectangles, using the `LocalGlobal` function to convert their locations to global coordinates, using `SetPort` to return to your starting graphics port, and then using the `GlobalToLocal` function to convert the locations of points or rectangles to the local coordinates of your current graphics port.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`QuickdrawAPI.h`

PtInRgn

Determines whether a pixel is within a region.

```
Boolean PtInRgn (
   Point pt,
   RgnHandle rgn
);
```

Parameters

pt
The point whose pixel is to be checked.

rgn
A handle to the region to test.

Return Value
`TRUE` if the pixel below and to the right of the point specified in the `pt` parameter is within the region whose handle is specified in the `rgn` parameter. `FALSE` if it is not.

Discussion
If the points or rectangles supplied to this function are defined in a graphics port other than your current graphics port, you must convert them to the local coordinate system of your current graphics port. You can accomplish this by using the `SetPort` function to change to the graphics port containing the points or rectangles, using the `LocalGlobal` function to convert their locations to global coordinates, using `SetPort` to return to your starting graphics port, and then using the `GlobalToLocal` function to convert the locations of points or rectangles to the local coordinates of your current graphics port.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

PtToAngle

Calculates an angle between a vertical line pointing straight up from the center of a rectangle and a line from the center to a given point.

```
void PtToAngle (
   const Rect *r,
   Point pt,
   short *angle
);
```

Parameters

r

The rectangle to examine.

pt

The point to which an angle is to be calculated.

angle

On return, a pointer to the resulting angle.

The result returned in the `angle` parameter is specified in degrees from 0 to 359, measured clockwise from 12 o'clock, with 90 at 3 o'clock, 180 at 6 o'clock, and 270 at 9 o'clock. Other angles are measured relative to the rectangle. If the line to the given point goes through the upper-right corner of the rectangle, the angle returned is 45, even if the rectangle is not square if it goes through the lower-right corner, the angle is 135, and so on.

The angle returned can be used as input to one of the functions that manipulate arcs and wedges, in "Drawing Arcs and Wedges".

Discussion

If the points or rectangles supplied to this function are defined in a graphics port other than your current graphics port, you must convert them to the local coordinate system of your current graphics port. You can accomplish this by using the `SetPort` function to change to the graphics port containing the points or rectangles, using the `LocalGlobal` function to convert their locations to global coordinates, using `SetPort` to return to your starting graphics port, and then using the `GlobalToLocal` function to convert the locations of points or rectangles to the local coordinates of your current graphics port.

QuickdrawAPI.h

QDBeginCGContext

Returns a Quartz 2D drawing environment associated with a graphics port.

```
OSStatus QDBeginCGContext (
   CGrafPtr inPort,
   CGContextRef *outContext
);
```

Parameters

port

A color graphics port in which to draw. Offscreen graphics worlds with pixel depths of 1, 2, 4, and 8 are not supported. When using Quartz 2D to draw in a offscreen graphics world, alpha information is always ignored.

contextPtr

A pointer to your storage for a Quartz context. Upon completion, `contextPtr` points to a context associated with the port. The context matches the port's pixel depth, width, and height. Otherwise the context is in a default state and does not necessarily match other port attributes such as foreground color, background color, or clip region.

You should not retain or release the context. When you are finished using the context, you should call `QDEndCGContext` (page 2758).

Return Value
A result code. If `noErr`, the context was successfully initiated.

Discussion
Applications running in Mac OS X can use Quartz 2D to draw in a QuickDraw graphics port. When you call this function, you obtain a Quartz context that's associated with the specified port. To improve performance, contexts returned by this function are cached and reused during subsequent calls whenever possible.

Each block of Quartz 2D drawing code in your application should be surrounded by calls to this function and `QDEndCGContext` (page 2758). Nested calls to this function for the same graphics port are not permitted—that is, for a given port you should not call this function more than once without an intervening call to `QDEndCGContext` (page 2758).

While the Quartz context is in use, all Quickdraw imaging operations in the associated graphics port are disabled. This is done because the operations would fail during printing.

For information about how to use a Quartz context, see *Quartz 2D Programming Guide*.

Availability
Available in Mac OS X v10.1 and later.
Not available to 64-bit applications.

);
```

Return Value

Availability
Available in Mac OS X v10.1 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
QuickdrawAPI.h

QDDone

Determines whether QuickDraw has completed drawing in a given graphics port. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
Boolean QDDone (
   GrafPtr port
);
```

Parameters

port

The GrafPort structure for a graphics port in which your application has begun drawing; if you pass NULL, QDDone tests all open graphics ports.

Return Value
TRUE if all drawing operations have finished in the graphics port specified in the port parameter, FALSE if any remain to be executed. If you pass NULL in the port parameter, then QDDone returns TRUE only if drawing operations have completed in all ports.

Discussion
The QDDone function may be useful if a graphics accelerator is present and operating asynchronously. You can use it to ensure that all drawing is done before issuing new drawing commands, and to avoid the possibility that the new drawing operations might be overlaid by previously issued but unexecuted operations.

Special Considerations

If a graphics port draws a clock or some other continuously operating drawing process, QDDone may never return TRUE.

To determine whether all drawing in a color graphics port has completed, you must coerce its CGrafPort structure to a GrafPort structure, which you pass in the port parameter.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
QDOffscreen.h

QDEndCGContext

Terminates a Quartz 2D drawing environment associated with a graphics port.

```
OSStatus QDEndCGContext (
   CGrafPtr inPort,
   CGContextRef *inoutContext
);
```

Parameters

port

A graphics port specified in a preceding call to `QDBeginCGContext` (page 2756).

contextPtr

A pointer to the context obtained in the preceding call to `QDBeginCGContext` (page 2756) for the port. Upon completion, the storage pointed to by `contextPtr` is set to `NULL`.

Return Value
A result code. If `noErr`, the context is terminated.

Discussion
After you finish using Quartz 2D to draw in a graphics port, you should call this function to terminate the context. For more information, see `QDBeginCGContext` (page 2756).

Before calling this function, you should do one of the following:

- Call `CGContextSynchronize` (page 136) to mark the affected areas of the port for update.
- Call `CGContextFlush` (page 95) to immediately update the destination device.

Availability
Available in Mac OS X v10.1 and later.
Not available to 64-bit applications.

Related Sample Code
CarbonSketch

Declared In
`QuickdrawAPI.h`

QDError

Obtains a result code from the last applicable QuickDraw function that you called. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
short QDError (
   void
);
```

Return Value
The error result. On a system with only basic QuickDraw, `QDError` always returns `noErr`.

Discussion
The `QDError` function is helpful in determining whether insufficient memory caused a drawing operation - particularly those involving regions, polygons, pictures, and images copied with `CopyBits` - to fail.

Basic QuickDraw uses stack space for work buffers. For complex operations such as depth conversion, dithering, and image resizing, stack space may not be sufficient. QuickDraw attempts to get temporary memory from other parts of the system. If that is still not enough, `QDError` returns the `nsStackErr` error. If your application receives this result, reduce the memory required by the operation.

When you structure drawing operations in an open region, the resulting region description may overflow the 64 KB limit. In this case, `QDError` returns `regionTooBigError`. Since the resulting region is potentially corrupt, the `CloseRgn` function returns an empty region if it detects `QDError` has returned `regionTooBigError`. A similar error, `rgnTooBigErr`, occurs when using the `BitMapToRegion` function to convert a bitmap to a region.

The `BitMapToRegion` function also generates the `pixmapTooDeepErr` error if a `PixMap` structure is supplied that is greater than 1 bit per pixel. You may be able to recover from this problem by coercing your `PixMap` structure into a 1-bit `PixMap` structure and calling the `BitMapToRegion` function again.

Special Considerations

The `QDError` function does not report errors returned by basic QuickDraw.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

QDFlushPortBuffer

Calls the Quartz compositor to flush all new drawing in a Carbon window to the display. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void QDFlushPortBuffer (
   CGrafPtr port,
   RgnHandle region
);
```

Parameters

port

A window port. If the port has no back buffer, or if the port is an offscreen or printing port, this function does nothing.

region

An update region. Under normal conditions, you should pass `NULL` to avoid the overhead of additional region operations.

Discussion

In Mac OS X, drawing in a window port updates a back buffer associated with the window. Updates to this buffer are accumulated in a list called the dirty region.

The back buffer is automatically flushed to the display each time through the event loop. When the event loop does not get control soon enough—for example, during an animation sequence—you can call this function to flush the port buffer to the device immediately.

When you call this function, there are several different execution paths:

1. If the `region` parameter is `NULL`, the dirty region is flushed—along with any Quartz 2D drawing operations marked for update by calls to `CGContextSynchronize` (page 136)—and the dirty region is set to empty.

2. If the `region` parameter specifies an update region, the intersection of the dirty region and the update region is flushed—along with any Quartz 2D drawing operations marked for update by calls to `CGContextSynchronize` (page 136)—and the flushed region is subtracted from the dirty region.

Availability

   CGrafPtr port,
   RgnHandle region
);
```

Return Value

Availability
Available in Mac OS X v10.2 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
QuickdrawAPI.h

QDPictCreateWithProvider

Creates a QDPict picture, using QuickDraw picture data supplied with a Quartz data provider.

```
QDPictRef QDPictCreateWithProvider (
   CGDataProviderRef provider
);
```

Parameters

provider

A Quartz data provider that supplies QuickDraw picture data. The picture data must begin at either the first byte or the 513th byte in the data provider. The picture bounds must not be an empty rectangle.

QuickDraw retains the data provider you pass in, and you may safely release it after this function returns.

Return Value
A new QDPict picture, or NULL if the picture data is not valid. The initial retain count is 1. After you finish using the picture, you should release it by calling QDPictRelease (page 2769).

Discussion
This function creates a QDPict picture that you can draw in a Quartz context. For general information about QDPict pictures, see QDPictRef (page 2877).

Availability
Available in Mac OS X v10.1 and later.
Not available to 64-bit applications.

Declared In
QDPictToCGContext.h

QDPictCreateWithURL

Creates a QDPict picture, using QuickDraw picture data specified with a Core Foundation URL.

```
QDPictRef QDPictCreateWithURL (
   CFURLRef url
);
```

Parameters

url

A Core Foundation URL that specifies a PICT file containing the QuickDraw picture data. The picture header data must begin at either the first byte or the 513th byte in the PICT file. The picture bounds must not be an empty rectangle.

Return Value

A new QDPict picture, or `NULL` if the picture data is not valid. The initial retain count is 1. After you finish using the picture, you should release it by calling `QDPictRelease` (page 2769).

Discussion

This function creates a QDPict picture that you can draw in a Quartz context. For general information about QDPict pictures, see `QDPictRef` (page 2877).

Availability

Available in Mac OS X v10.1 and later.

Not available to 64-bit applications.

Declared In

`QDPictToCGContext.h`

QDPictDrawToCGContext

Draws a QuickDraw picture in a Quartz context.

```
OSStatus QDPictDrawToCGContext (
   CGContextRef ctx,
   CGRect rect,
   QDPictRef pictRef
);
```

Parameters

context

The Quartz context in which to draw.

rect

The rectangular area in which to draw the picture. You should specify the origin and size of this rectangle in user space units. The origin is the lower left corner of the picture when drawn. If necessary, the picture is scaled to fit inside this rectangle. To get unscaled results, you should pass the rectangle returned by `QDPictGetBounds` (page 2768). For additional information about scaling, see the discussion below.

picture

A QDPict picture.

Return Value

A result code. A non-zero result indicates that the picture was not successfully drawn.

Discussion
This function converts the picture data in a QDPict picture into an equivalent sequence of Quartz 2D graphics operations. Conceptually this is the same processing path taken when an application running in Mac OS X draws into a QuickDraw printing port.

When drawing a QDPict picture in a Quartz context, there are two ways to change the horizontal or vertical scale of the picture:

- Construct the drawing rectangle (see the `rect` parameter) by applying the change of scale to the bounds rectangle returned by `QDPictGetBounds` (page 2768). In this case, QuickDraw scales all the graphic elements in the picture except for patterns—the same behavior as `DrawPicture` (page 2610).
- Prior to calling `QDPictDrawToCGContext`, apply the change of scale to the current transformation matrix in the Quartz context—for example, by calling `CGContextScaleCTM` (page 105). In this case, QuickDraw scales the entire picture including patterns.

In a bitmap-based context, the picture is rendered into the bitmap. In a PDF-based context, the picture is converted into a PDF content stream. If the picture uses transfer modes such as `srcXor` that do not have an analog in Quartz 2D, the PDF representation may not match the original exactly.

Availability
Available in Mac OS X v10.1 and later.
Not available to 64-bit applications.

Declared In
`QDPictToCGContext.h`

QDPictGetBounds

Returns the intended location and size of a QDPict picture.

```
CGRect QDPictGetBounds (
   QDPictRef pictRef
);
```

Parameters
picture
A QDPict picture.

Return Value
A Quartz rectangle that represents the intended location and size of the picture. The rectangle is in default user space with one unit = 1/72 inch, and the origin is the lower-left corner of the picture.

Discussion
If the native resolution in the picture data is not 72 pixels per inch, the bounding rectangle returned by this function is scaled as follows:

```
width = width in pixels * 72 / horizontal resolution
height = height in pixels * 72 / vertical resolution
```

Availability
Available in Mac OS X v10.1 and later.
Not available to 64-bit applications.

Declared In
QDPictToCGContext.h

QDPictGetResolution

Returns the horizontal and vertical resolution of a QDPict picture.

```
void QDPictGetResolution (
   QDPictRef pictRef,
   float *xRes,
   float *yRes
);
```

Parameters

picture
A QDPict picture.

xRes
A pointer to your storage for a return value. Upon completion, the value is the picture's horizontal resolution in pixels per inch.

yRes
A pointer to your storage for a return value. Upon completion, the value is the picture's vertical resolution in pixels per inch.

Discussion
This function returns resolution data that you can use—together with the rectangle returned by `QDPictGetBounds` (page 2768)—to compute the picture's size in pixels.

Availability
Available in Mac OS X v10.1 and later.
Not available to 64-bit applications.

Declared In
QDPictToCGContext.h

QDPictRelease

Releases a QDPict picture.

```
void QDPictRelease (
   QDPictRef pictRef
);
```

Parameters

picture
A QDPict picture which you created or retained.

Discussion
After you finish using a QDPict picture that you created or retained, you should call this function to release the picture. If the picture's retain count becomes 0, this function frees the picture and any associated resources such as the picture's data provider.

Availability
Available in Mac OS X v10.1 and later.

Not available to 64-bit applications.

Declared In
QDPictToCGContext.h

QDPictRetain

Retains a QDPict picture.

```
QDPictRef QDPictRetain (
   QDPictRef pictRef
);
```

Parameters

picture
A QDPict picture.

Return Value
The retained picture.

Discussion
You should call this function when you obtain a QDPict picture that you did not create and you want to retain the picture for later use. When you no longer need the retained picture, you should call `QDPictRelease` (page 2769) to release it.

Availability
Available in Mac OS X v10.1 and later.
Not available to 64-bit applications.

Declared In
QDPictToCGContext.h

QDRegionToRects

```
OSStatus QDRegionToRects (
   RgnHandle rgn,
   QDRegionParseDirection dir,
   RegionToRectsUPP proc,
   void *userData
);
```

Return Value

Availability
Available in Mac OS X v10.0 and later.

Declared In
QuickdrawAPI.h

QDRegisterNamedPixMapCursor

(Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
OSStatus QDRegisterNamedPixMapCursor (

```
UInt32 QDSwapTextFlags (
   UInt32 newFlags
);
```

Availability
Available in Mac OS X v10.2 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

QDUnregisterNamedPixMapCursor

(Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
OSStatus QDUnregisterNamedPixMapCursor (
   const char name[128]
);
```

Return Value

Availability
Available in Mac OS X v10.3 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

Random

Obtains a pseudorandom integer. (Deprecated in Mac OS X v10.4. Use the Standard C Library `random(3)` function instead.)

```
short Random (
   void
);
```

Return Value
A pseudorandom integer, uniformly distributed in the range -32767 to 32767.

Discussion
The value `Random` returns depends solely on the global variable `randSeed`, which the QuickDraw `InitGraf` function initializes to 1. Each time the `Random` function executes, it uses a numerical algorithm to change the value of `randSeed` to prevent it from returning the same value each time it is called.

To prevent your application from generating the same sequence of pseudo-random numbers each time it is executed, initialize the `randSeed` global variable, when your application starts up, to a volatile long word variable such as the current date and time. If you would like to generate the same sequence of pseudo-random numbers twice, on the other hand, simply set `randSeed` to the same value before calling `Random` for each sequence.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

RealColor

Determines whether a given `RGBColor` data structure exists in the current device's color table. This function is used by system software and your application should not need to call it. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
Boolean RealColor (
   const RGBColor *color
);
```

Parameters
color

The `RGBColor` data structure to be tested.

Discussion
The `RealColor` function determines whether the color is available in the current `GDevice` data structure's CLUT, basing its search on the current resolution of the inverse table. For example, if the current value of the `iTabRes` field is 4, `RealColor` returns `true` if there exists a color that exactly matches the top 4 bits of red, green, and blue. (See the `iTabRes` field of the inverse table, `ITab` (page 2863).)

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
QuickdrawAPI.h

RectInRgn

Determines whether a rectangle intersects a region.

```
Boolean RectInRgn (
   const Rect *r,
   RgnHandle rgn
);
```

Parameters

r

The rectangle to check for intersection.

rgn

A handle to the region to check.

Return Value
TRUE if the rectangle specified in the r parameter intersects the region whose handle is specified in the rgn parameter. The RectInRgn function returns TRUE if the intersection encloses at least 1 bit or FALSE if it does not.

Discussion
If the points or rectangles supplied to this function are defined in a graphics port other than your current graphics port, you must convert them to the local coordinate system of your current graphics port. You can accomplish this by using the SetPort function to change to the graphics port containing the points or rectangles, using the LocalGlobal function to convert their locations to global coordinates, using SetPort to return to your starting graphics port, and then using the GlobalToLocal function to convert the locations of points or rectangles to the local coordinates of your current graphics port.

Special Considerations

The RectInRgn function sometimes returns TRUE when the rectangle merely intersects the region's bounding rectangle. If you need to know exactly whether a given rectangle intersects the actual region, use RectRgn (page 2776) to set the rectangle to a region, and call SectRgn (page 2786) to see whether the two regions intersect. If the result of SectRgn is an empty region, then the rectangle does not intersect the region.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
QuickdrawAPI.h

RectRgn

Changes the structure of an existing region to that of a rectangle.

```
void RectRgn (
   RgnHandle rgn,
   const Rect *r
);
```

Parameters

rgn

A handle to the region to restructure as a rectangle.

r

The rectangle structure to use.

Discussion

The `RectRgn` function destroys the previous structure of the `SetRectRgn` function, and it then sets the new structure to a rectangle that you specify in the `r` parameter.

As an alternative to the `RectRgn` function, use the `SetRectRgn` function, which accepts as parameters four coordinates instead of a rectangle.

If the points or rectangles supplied to this function are defined in a graphics port other than your current graphics port, you must convert them to the local coordinate system of your current graphics port. You can accomplish this by using the `SetPort` function to change to the graphics port containing the points or rectangles, using the `LocalGlobal` function to convert their locations to global coordinates, using `SetPort` to return to your starting graphics port, and then using the `GlobalToLocal` function to convert the locations of points or rectangles to the local coordinates of your current graphics port.

Special Considerations

The `RectRgn` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Related Sample Code

HideMenuBar

QTCarbonShell

Declared In

`QuickdrawAPI.h`

ReserveEntry

Reserves or removes reservation from an entry in the current `GDevice` data structure's color table. This function is used by system software and your application should not need to call it. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void ReserveEntry (
   short index,
   Boolean reserve
);
```

Parameters

index

The index to the entry.

reserve

`True` to reserve the entry, `false` to remove the reservation.

Discussion

A reserved entry cannot be matched by another application's search function, and `Color2Index` (or other functions that depend on it such as `RGBForeColor`, `RGBBackColor`, and `SetCPixel`) never return that entry to another client. You could use this function to selectively protect a color for color table animation.

The `ReserveEntry` function copies the low byte of the `gdID` field of the current `GDevice` data structure into the low byte of the `ColorSpec.value` field of the color table when reserving an entry, and leaves the high byte alone. `ReserveEntry` acts like selective protection and does not allow any changes if the current `gdID` field is different than the one in the `ColorSpec.value` field of the reserved entry. If a requested match is already reserved, `ReserveEntry` returns a protection error. It can remove reservation from any entry, even if a requested match is already not reserved.

Carbon Porting Notes

This function does nothing useful on Mac OS X.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

RestoreEntries

Restores a selection of color table entries. This function is used by system software and your application should not need to call it. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void RestoreEntries (
   CTabHandle srcTable,
   CTabHandle dstTable,
   ReqListRec *selection
);
```

Parameters

srcTable

The color table containing entries to be restored.

dstTable

The color table in which to restore the entries. If `dstTable` is `NULL`, or points to the current `GDevice` data structure's color table, `RestoreEntries` changes the device's color table and the hardware CLUT to these new colors.

selection

A pointer to the ReqListRec (page 2882) data structure. The entries to be restored are enumerated as offsets into a ColorTable data structure, not the contents of the ColorSpec.value field.

Discussion
The RestoreEntries function does not rebuild the inverse table.

If a request is beyond the end of the destination color table, RestoreEntries sets that position in the requestList data structure to colReqErr, and returns an error. RestoreEntries assumes that the color table specified by the srcTable parameter and the request list specified by the selection parameter have the same number of entries.

RestoreEntries does not change the color table's seed, so no invalidation occurs (which may cause RGBForeColor to act strangely). RestoreEntries ignores protection and reservation of color table entries.

You generally should use the Palette Manager to give your application its own set of colors; use of RestoreEntries should be limited to special-purpose applications. RestoreEntries allows you to change a color table without changing its ctSeed field. You can execute the application code and then use RestoreEntries to put the original colors back in. However, in some cases things in the background may appear in the wrong colors, since they were never redrawn. To avoid this, your application must build its own new inverse table and redraw the background. If you then use RestoreEntries, you should call the CTabChanged function to clean up correctly.

Carbon Porting Notes

This function does nothing useful on Mac OS X.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
QuickdrawAPI.h

RGBBackColor

Changes the background color. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void RGBBackColor (
   const RGBColor *color
);
```

Parameters

color

An RGBColor structure.

Discussion
If the current port is defined by a CGrafPort structure, QuickDraw supplies its rgbBkColor field with the RGB value that you specify in the color parameter, and places the pixel value most closely matching that color in the bkColor field. For indexed devices, the pixel value is an index to the current device's CLUT. F or direct devices, the value is the 16-bit or 32-bit equivalent to the RGB value.

If the current port is defined by a `GrafPort` structure, basic QuickDraw supplies its `fgColor` field with a color value determined by taking the high bit of each of the red, green, and blue components of the color that you supply in the `color` parameter. Basic QuickDraw uses that 3-bit number to select a color from its eight-color system.

You can also use Palette Manager functions to set the background color.

To determine the current background color, use the `GetBackColor` (page 2634) function.

Because a pixel pattern already contains color, QuickDraw ignores the background color and foreground colors when your application draws with a pixel pattern. Use the `PenPixPat` function to assign a pixel pattern to the foreground pattern used by the graphics pen. Use the `BackPixPat` function to assign a pixel pattern as the background pattern for the current color graphics port. Use the `FillCRect`, `FillCOval`, `FillCRoundRect`, `FillCArc`, `FillCRgn`, and `FillCPoly` functions to fill shapes with a pixel pattern.

Special Considerations

The `RGBBackColor` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

RGBForeColor

Changes the color of the "ink" used for framing and painting. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void RGBForeColor (
   const RGBColor *color
);
```

Parameters

color

An `RGBColor` structure.

Discussion

If the current port is defined by a `CGrafPort` structure, QuickDraw supplies its `rgbFgColor` field with the RGB value that you specify in the `color` parameter, and places the pixel value most closely matching that color in the `fgColor` field. For indexed devices, the pixel value is an index to the current device's CLUT. For direct devices, the value is the 16-bit or 32-bit equivalent to the RGB value.

If the current port is defined by a `GrafPort` structure, basic QuickDraw supplies its `fgColor` field with a color value determined by taking the high bit of each of the red, green, and blue components of the color that you supply in the `color` parameter. Basic QuickDraw uses that 3-bit number to select a color from its eight-color system.

You can also use Palette Manager functions to set the foreground color.

To determine the current foreground color, use the `GetForeColor` (page 2639) function.

QuickDraw ignores the foreground and background colors when your application draws with a pixel pattern. Assign a pixel pattern to the foreground pattern used by the graphics pen; by using the `BackPixPat` function to assign a pixel pattern as the background pattern for the current color graphics port; and by using the `FillCRect`, `FillCOval`, `FillCRoundRect`, `FillCArc`, `FillCRgn`, and `FillCPoly` functions to fill shapes with a pixel pattern.

Special Considerations

The `RGBForeColor` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.

SaveEntries

Saves a selection of color table entries. This function is used by system software and your application should not need to call it. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void SaveEntries (
   CTabHandle srcTable,
   CTabHandle resultTable,
   ReqListRec *selection
);
```

Parameters

srcTable
The color table containing entries to be saved. If you supply `NULL`, `SaveEntries` uses the current device's color table as the source.

resultTable

The color table in which to save the entries.

selection

A pointer to the ReqListRec (page 2882) data structure. The entries to be set are enumerated as offsets into a ColorTable data structure, not the contents of the ColorSpec.value field.) If an entry is not present in srcTable, then SaveEntries sets that position of the selection parameter to colReqErr, and that position of resultTable contains random values.

Discussion

If SaveEntries can not find one or more entries, then it posts an error code to QDError; however, for every entry in selection which is not colReqErr, the values in resultTable are valid. SaveEntries assumes that the color table specified by the srcTable parameter and the request list specified by the selection parameter have the same number of entries.

The output of SaveEntries is the same as the input for RestoreEntries, except for the order.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

QuickdrawAPI.h

ScalePt

Scales a height and width according to the proportions of two rectangles.

```
void ScalePt (
   Point *pt,
   const Rect *srcRect,
   const Rect *dstRect
);
```

Parameters

pt

On input, a pointer to an initial height and width (specified in the two fields of a Point structure) to scale; on return, vertical and horizontal scaling factors derived by multiplying the height and width by ratios of the height and width of the rectangle in the srcRect parameter to the height and width of the rectangle in the dstRect parameter.

You do not pass coordinates in this parameter. Instead, you pass an initial height to scale in the v (or vertical) field of the Point structure, and you pass an initial width to scale in the h (or horizontal) field.

The ScalePt function scales these measurements by multiplying the initial height by the ratio of the height of the rectangle you specify in the dstRect parameter to the height of the rectangle you specify in the srcRect parameter, and by multiplying the initial width by the ratio of the width of the dstRect rectangle to the width of the srcRect rectangle.

srcRect

A rectangle. The ratio of this rectangle's height to the height of the rectangle in the dstRect parameter provides the vertical scaling factor, and the ratio of this rectangle's width to the width of the rectangle in the dstRect parameter provides the horizontal scaling factor.

dstRect

A rectangle compared to the rectangle in the `srcRect` parameter to determine vertical and horizontal scaling factors.

Discussion

The `ScalePt` function produces horizontal and vertical scaling factors from the proportions of two rectangles. Use `ScalePt`, for example, to scale the dimensions of the graphics pen.

Where the width of the `dstRect` rectangle is twice the width of the `srcRect` rectangle, and its height is three times the height of `srcRect`, `ScalePt` scales the width of the graphics pen from 3 to 6 and scales its height from 2 to 6.

Special Considerations

The minimum value `ScalePt` returns is (1,1).

If the points or rectangles supplied to this function are defined in a graphics port other than your current graphics port, you must convert them to the local coordinate system of your current graphics port. You can accomplish this by using the `SetPort` function to change to the graphics port containing the points or rectangles, using the `LocalGlobal` function to convert their locations to global coordinates, using `SetPort` to return to your starting graphics port, and then using the `GlobalToLocal` function to convert the locations of points or rectangles to the local coordinates of your current graphics port.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`QuickdrawAPI.h`

ScreenRes

Determines the resolution of the main device. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void ScreenRes (
   short *scrnHRes,
   short *scrnVRes
);
```

Parameters

scrnHRes

On return, the number of horizontal pixels per inch displayed by the current device.

scrnVRes

On return, the number of vertical pixels per inch displayed by the current device.

Discussion

To determine the resolutions of all available graphics devices, examine their `GDevice` (page 2859) structures. The horizontal and vertical resolutions for a graphics device are stored in the `hRes` and `vRes` fields, respectively, of the `PixMap` structure for the device's `GDevice` structure.

Currently, QuickDraw and the Printing Manager always assume a screen resolution of 72 dpi.

Do not use the actual screen resolution as a scaling factor when drawing into a printing graphics port. Instead, always use 72 dpi as the scaling factor. See the Printing Manager documentation for more information about drawing into a printing graphics port.

`QuickdrawAPI.h`

ScrollRect

Scroll the pixels of a specified portion of a basic graphics port's bitmap (or a color graphics port's pixel map). (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void ScrollRect (
   const Rect *r,
   short dh,
   short dv,
   RgnHandle updateRgn
);
```

Parameters

r
The pointer to the rectangle defining the area to be scrolled.

dh
The horizontal distance to be scrolled.

dv
The vertical distance to be scrolled.

updateRgn
A handle to the region of the window that needs to be updated.

Discussion
The `ScrollRect` function shifts pixels that are inside the specified rectangle of the current graphics port. No other pixels or the bits they represent are affected. The pixels are shifted a distance of `dh` horizontally and `dv` vertically. The positive directions are to the right and down. The pixels that are shifted out of the specified rectangle are not displayed, and the bits they represent are not saved. It is up to your application to save this data.

The empty area created by the scrolling is filled with the graphics port's background pattern, and the update region is changed to this filled area.

The `ScrollRect` function doesn't change the local coordinate system of the graphics port it simply moves the rectangle specified in the `r` parameter to different coordinates. Notice that `ScrollRect` doesn't move the graphics pen or the clipping region. However, because the document has moved, they're in different positions relative to the document.

By creating an update region for the window, `ScrollRect` forces an update event. After using `ScrollRect`, your application should use its own window-updating code to draw into the update region of the window.

The `ScrollRect` function may move or purge memory blocks in the application heap. Your application should not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

`QuickdrawAPI.h`

SectRect

Determines whether two rectangles intersect.

```
Boolean SectRect (
   const Rect *src1,
   const Rect *src2,
   Rect *dstRect
);
```

Parameters

src1
The first of two rectangles to test for intersection.

src2
The second of two rectangles to test for intersection.

dstRect
On return, a pointer to the rectangle marking the intersection of the first two rectangles.

Return Value
`TRUE` if the specified rectangles intersect or `FALSE` if they do not.

Discussion
The `SectRect` function calculates the rectangle that delineates the intersection of the two rectangles you specify in the `src1` and `src2` parameters. Rectangles that touch at a line or a point are not considered intersecting, because their intersection rectangle (actually, in this case, an intersection line or point) does not enclose any pixels in the bit image.

If the rectangles do not intersect, the destination rectangle is set to (0,0,0,0). The `SectRect` function works correctly even if one of the source rectangles is also the destination.

If the points or rectangles supplied to this function are defined in a graphics port other than your current graphics port, you must convert them to the local coordinate system of your current graphics port. You can accomplish this by using the `SetPort` function to change to the graphics port containing the points or rectangles, using the `LocalGlobal` function to convert their locations to global coordinates, using `SetPort` to return to your starting graphics port, and then using the `GlobalToLocal` function to convert the locations of points or rectangles to the local coordinates of your current graphics port.

SectRgn

Calculates the intersection of two regions.

```
void SectRgn (
   RgnHandle srcRgnA,
   RgnHandle srcRgnB,
   RgnHandle dstRgn
);
```

Parameters
srcRgnA

A handle to the first of two regions whose intersection is to be determined.

srcRgnB

A handle to the second of two regions whose intersection is to be determined.

dstRgn

On return, a handle to the region holding the intersection area. If the regions do not intersect, or one of the regions is empty, `SectRgn` sets the destination to the empty region defined by the rectangle (0,0,0,0).

The `SectRgn` function does not create a destination region; you must have already allocated memory for it by using the `NewRgn` (page 2726) function.

The destination region may be one of the source regions, if desired.

Discussion

The SectRgn procedure calculates the intersection of the two regions whose handles you pass in the srcRgnA and srcRgnB parameters, and it places the intersection in the region whose handle you pass in the dstRgn parameter. If the regions do not intersect, or one of the regions is empty, SectRgn sets the destination to the empty region defined by the rectangle (0,0,0,0).

The SectRgn procedure does not create a destination region; you must have already allocated memory for it by using the NewRgn function.

The destination region may be one of the source regions, if desired.

Special Considerations

The `SectRgn` function may temporarily use heap space that's twice the size of the two input regions.

The `SectRgn` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

`QuickdrawAPI.h`

SeedCFill

Determines how far filling will extend to pixels matching the color of a particular pixel. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void SeedCFill (
   const BitMap *srcBits,
   const BitMap *dstBits,
   const Rect *srcRect,
   const Rect *dstRect,
   short seedH,
   short seedV,
   ColorSearchUPP matchProc,
   long matchData
);
```

Parameters

srcBits

The source image. If the image is in a pixel map, you must coerce its `PixMap` structure to a `BitMap` structure.

dstBits
On return, the destination mask.

srcRect
The rectangle of the source image.

dstRect
The rectangle of the destination image.

seedH
The horizontal position of the seed point.

seedV
The vertical position of the seed point.

matchProc
An optional color search function.

matchData
Data for the optional color search function.

Discussion
The `SeedCFill` function generates a mask showing where the pixels in an image can be filled from a starting point, like the paint pouring from the MacPaint paint-bucket tool. This mask is a bitmap filled with 1's to indicate all pixels adjacent to a seed point whose colors do not exactly match the `RGBColor` structure for the pixel at the seed point. You can then use this mask with the `CopyBits`, `CopyMask`, and `CopyDeepMask` functions.

You specify a source image in the `srcBits` parameter and, in the `srcRect` parameter, specify a rectangle within that source image. You specify where to begin seeding in the `seedH` and `seedV` parameters, which must be the horizontal and vertical coordinates of a point in the local coordinate system of the source bitmap. By default, the 1's returned in the mask indicate all pixels adjacent to the seed point whose pixel values do not exactly match the pixel value of the pixel at the seed point. To use this default, set the `matchProc` and `matchData` parameters to 0.

In generating the mask, `SeedCFill` uses the `CopyBits` function to convert the source image to a 1-bit mask. The `SeedCFill` function installs a default color search function that returns 0 if the pixel value matches that of the seed point all other pixel values return 1's.

The `SeedCFill` function does not scale so the source and destination rectangles must be the same size. Calls to `SeedCFill` are not clipped to the current port and are not stored into QuickDraw pictures.

To customize `SeedCFill`, write your own color search function and point to it in the `matchProc` parameter; `SeedCFill` will then use your function instead of the default.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

SeedFill

Determines how far filling will extend from a seeding point. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void SeedFill (
   const void *srcPtr,
   void *dstPtr,
   short srcRow,
   short dstRow,
   short height,
   short words,
   short seedH,
   short seedV
);
```

Parameters

srcPtr

A pointer to the source bit image.

dstPtr

On input, a pointer to the destination bit image; upon return, a pointer to the bitmap containing the resulting mask.

srcRow

Row width of the source bitmap.

dstRow

Row width of the destination bitmap.

height

Height (in pixels) of the fill rectangle.

words

Width (in words) of the fill rectangle.

seedH

The horizontal offset (in pixels) at which to begin filling the destination bit image.

seedV

The vertical offset (in pixels) at which to begin filling the destination bit image.

Discussion

The `SeedFill` function produces a mask showing where bits in an image can be filled from a starting point, like the paint pouring from the MacPaint paint-bucket tool. The `SeedFill` returns this mask in the `dstPtr` parameter. This mask is a bitmap filled with 1's only where the pixels in the source image can be filled. You can then use this mask with the `CopyBits`, `CopyMask`, and `CopyDeepMask` functions.

Point to the bit image you want to fill with the `srcPtr` parameter, which can point to the image's base address or a word boundary within the image. Specify a pixel height and word width with the `height` and `words` parameters to define a fill rectangle that delimits the area you want to fill. The fill rectangle can be the entire bit image or a subset of it. Point to a destination image with the `dstPtr` parameter. Specify the row widths of the source and destination bitmaps (their `rowBytes` values) with the `srcRow` and `dstRow` parameters. (The bitmaps can be different sizes, but they must be large enough to contain the fill rectangle at the origins specified by the `srcPtr` and `dstPtr` parameters.)

You specify where to begin filling with the `seedH` and `seedV` parameters: they specify a horizontal and vertical offset in pixels from the origin of the image pointed to by the `srcPtr` parameter. The `SeedFill` function calculates contiguous pixels from that point out to the boundaries of the fill rectangle, and it stores the result in the bit image pointed to by the `dstPtr` parameter.

Calls to `SeedFill` are not clipped to the current port and are not stored into QuickDraw pictures.

`QuickdrawAPI.h`

SetCCursor

Specifies a color cursor for display on the screen. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void SetCCursor (
   CCrsrHandle cCrsr
);
```

Parameters

cCrsr
A handle to the color cursor to be displayed.

Discussion
At the time the cursor is set, it is expanded to the current screen depth so that it can be drawn rapidly. You must call `GetCCursor` before you call `SetCCursor`; however, you can make several subsequent calls to `SetCCursor` once `GetCCursor` creates the `CCrsr` structure.

If your application has changed the cursor's data or its color table, it must also invalidate the `crsrXValid` and `crsrID` fields of the `CCrsr` structure before calling `SetCCursor`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

SetClientID

Sets the `gdID` field in the current `GDevice` data structure to identify this client program to its search and complement functions. This function is used by system software and your application should not need to call it. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void SetClientID (
   short id
);
```

Parameters

id
The ID to be set in the device data structure.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

SetClip

Changes the clipping region of the current graphics port (basic or color) to a region you specify. (**Deprecated.** Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void SetClip (
   RgnHandle rgn
);
```

Parameters

rgn

A handle to a region. The `SetClip` function makes this region the clipping region of the current graphics port. The `SetClip` function doesn't change the region handle, but instead affects the clipping region itself.

Discussion
Since `SetClip` copies the specified region into the current graphics port's clipping region, any subsequent changes you make to the region specified in the `rgn` parameter do not affect the clipping region of the graphics port.

The initial clipping region of a graphics port is an arbitrarily large rectangle. You can set the clipping region to any arbitrary region, to aid you in drawing inside the graphics port—for example, to avoid drawing over scroll bars when drawing into a window, you could define a clipping region that excludes the scroll bars.

You can use the `GetClip` and `SetClip` functions to preserve the current clipping region: use `GetClip` to save the current port's clipping region, and use `SetClip` to restore it.

All other system software functions preserve the current clipping region.

The `SetClip` function may move or purge memory blocks in the application heap. Your application should not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ImageCompression.k.h`

SetCPixel

Sets the color of an individual pixel to the color that most closely matches the RGB color that you specify in the `cPix` parameter. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void SetCPixel (
   short h,
   short v,
   const RGBColor *cPix
);
```

Parameters

h

The horizontal coordinate of the point at the upper-left corner of the pixel.

v

The vertical coordinate of the point at the upper-left corner of the pixel.

cPix

An `RGBColor` structure.

Discussion

On an indexed color system, the `SetCPixel` function sets the pixel value to the index of the best-matching color in the current device's CLUT. In a direct environment, the `SetCPixel` function sets the pixel value to a 16-bit or 32-bit direct pixel value.

To determine the color of an individual pixel, use the `GetCPixel` (page 2636) function.

Special Considerations

The `SetCPixel` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

SetCursor

Sets the current cursor. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void SetCursor (
    const Cursor * crsr
);
```

Parameters

crsr

A `Cursor` (page 2854) structure for the cursor to be displayed.

Discussion

If the cursor is hidden, it remains hidden and attains its new appearance only when it's uncovered. If the cursor is already visible, it changes to the new appearance immediately.

You need to use the `InitCursor` (page 2671) function to initialize the standard arrow cursor and make it visible on the screen before you call `SetCursor` to change the cursor's appearance.

To display a color cursor, use the `SetCCursor` (page 2790) function.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In

```
OSErr SetCursorComponent (
   ComponentInstance ci
);
```

Return Value

Carbon Porting Notes

This function is not implemented on Mac OS X.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

SetDeviceAttribute

Sets the attribute bits of a `GDevice` structure. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void SetDeviceAttribute (
   GDHandle gdh,
   short attribute,
   Boolean value
);
```

Parameters

gdh
A handle to a `GDevice` structure.

attribute
One of the specific constants, which represent bits in the `gdFlags` field of a `GDevice` structure. See GDevice (page 2859) for the values you can use in this parameter.

value
A value of either 0 or 1 for the flag bit specified in the `attribute` parameter.

Discussion
For the graphics device specified in the `gdh` parameter, the `SetDeviceAttribute` function sets the flag bit specified in the `attribute` parameter to the value specified in the `value` parameter.

Your application should never directly change the `gdFlags` field of the `GDevice` structure; instead, use only the `SetDeviceAttribute` function.

Special Considerations

The `SetDeviceAttribute` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

SetEmptyRgn

Sets an existing region to be empty.

```
void SetEmptyRgn (
   RgnHandle rgn
);
```

Parameters

rgn
A handle to the region to be made empty.

Discussion
The `SetEmptyRgn` function destroys the previous structure of the region whose handle you pass in the `rgn` parameter; it then sets the new structure to the empty region defined by the rectangle (0,0,0,0).

Special Considerations

The `SetEmptyRgn` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

SetEntries

Sets a group of color table entries for the current `GDevice` data structure. This function is used by system software and your application should not need to call it. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void SetEntries (
   short start,
   short count,
   CSpecArray aTable
);
```

Parameters

start

The index of the first entry to be changed.

count

The number of entries to be changed. Note that all values are zero-based; for example, to set three entries, pass 2 in the count parameter.

aTable

An array of `ColorSpec` data structures containing the colors to be used. Directly specify a `cSpecArray` structure, not the beginning of a color table. The `ColorSpec.value` fields of the entries must be in the logical range for the target device's assigned pixel depth. Thus, with a 4-bit pixel size, the `ColorSpec.value` fields should be in the range 1 to 15. With an 8-bit pixel size, the range is 0 to 255.

Discussion

Instead of using `SetEntries`, you should use the Palette Manager function `SetEntryColor` to allow your application to run in a multiscreen or multitasking environment.

The `SetEntries` positional information works in logical space rather than in the actual memory space used by the hardware. Requesting a change at the fourth position in the color table may not modify the fourth color table entry in the hardware, but it does correctly change the color on the screen for any pixels with a value of 4 in the video card. The `SetEntries` mode characterized by a start position and a length is called sequence mode. In this case, `SetEntries` sequentially loads new colors into the hardware in the same order as they appear in the `aTable` parameter, copies the `clientID` fields for changed color table entries from the current `GDevice` data structure's `gdID` field, and ignores the `ColorSpec.value` fields.

The other `SetEntries` mode is called index mode. It allows the `cSpecArray` structure to specify where the data will be installed on an entry-by-entry basis. To use this mode, pass –1 for the start position, with a valid count and a pointer to the `cSpecArray` data structure. Each entry is installed into the color table at the position specified by the `ColorSpec.value` field of each entry in the `cSpecArray` data structure. In the current `GDevice` data structure's color table, the `ColorSpec.value` fields of all changed entries are assigned the `GDevice` data structure's `gdID` value.

When the Color Manager changes color table entries, it invalidates all cached fonts, and changes the color table's seed number so that the next drawing operation triggers the Color Manager to rebuild the inverse table. If any of the requested entries are protected or out of range, the Color Manager returns a protection error, and nothing happens. The Color Manager changes a reserved entry only if the current `gdID` field of the current `GDevice` data structure matches the low byte of the intended `ColorSpec.value` field in the color table.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

SetGDevice

Sets a `GDevice` structure as the current device. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void SetGDevice (
   GDHandle gd
);
```

Parameters

gd

A handle to a `GDevice` structure.

Discussion

Your application won't generally need to use this function, because when your application draws into a window on one or more screens, Color QuickDraw automatically switches `GDevice` structures as appropriate; and when your application needs to draw into an offscreen graphics world, it can use the `SetGWorld` function to set the graphics port as well as the `GDevice` structure for the offscreen environment. However, if your application uses the `SetPort` function instead of the `SetGWorld` function to set the graphics port to or from an offscreen graphics world, then your application must use `SetGDevice` in conjunction with `SetPort`.

A handle to the currently active device is kept in the global variable `TheGDevice`.

Special Considerations

The `SetGDevice` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

SetGWorld

Changes the current graphics port (basic, color, or offscreen). (**Deprecated.** Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void SetGWorld (
   CGrafPtr port,
   GDHandle gdh
);
```

Parameters

port

A pointer to an offscreen graphics world, color graphics port, or basic graphics port. Specify values of type `GrafPtr`, `CGrafPtr`, or `GWorldPtr`, depending on whether you want to set the current graphics port to be a basic graphics port, color graphics port, or offscreen graphics world. Any drawing your application performs then occurs in this graphics port.

gdh

A handle to a `GDevice` structure. If you pass a pointer to an offscreen graphics world in the `port` parameter, set this parameter to `NULL`, because `SetGWorld` ignores this parameter and sets the current device to the device attached to the offscreen graphics world.

Discussion
The `SetGWorld` function sets the current graphics port to the one specified by the `port` parameter and—unless you set the current graphics port to be an offscreen graphics world—sets the current device to that specified by the `gdh` parameter.

Special Considerations

The `SetGWorld` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.

`ImageCompression.k.h`

SetOrigin

Changes the coordinates of the window origin of the port rectangle of the current graphics port (basic or color). (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void SetOrigin (
   short h,
   short v
);
```

Parameters

h

The horizontal coordinate of the upper-left corner of the port rectangle.

v

The vertical coordinate of the upper-left corner of the port rectangle.

Discussion
The `SetOrigin` function changes the coordinates of the upper-left corner of the current graphics port's port rectangle to the values supplied by the `h` and `v` parameters. All other points in the current graphics port's local coordinate system are calculated from this point. All subsequent drawing and calculation functions use the new coordinate system.

The `SetOrigin` function does not affect the screen; it does, however, affect where subsequent drawing inside the graphics port appears. The `SetOrigin` function does not offset the coordinates of the clipping region or the graphics pen, which therefore change position on the screen (unlike the boundary rectangle, port rectangle, and visible region, which don't change position onscreen).

Because `SetOrigin` does not move the window's clipping region, use the `GetClip` function to store your clipping region immediately after your first call to `SetOrigin`—if you use clipping regions in your windows. Before calling your own window-drawing function, use the `ClipRect` function to define a new clipping region—to avoid drawing over your scroll bars, for example. After calling your own window-drawing function, use the `SetClip` function to restore the original clipping region. You can then call `SetOrigin` again to restore the window origin to a horizontal coordinate of 0 and a vertical coordinate of 0 with your original clipping region intact.

All other functions in the Macintosh Toolbox and Operating System preserve the local coordinate system of the current graphics port. The `SetOrigin` function is useful for readjusting the coordinate system after a scrolling operation.

Note that the Window Manager and Control Manager always assume the window's upper-left point has a horizontal coordinate of 0 and a vertical coordinate of 0 when they draw in a window. Therefore, if you use `SetOrigin` to change the window origin, be sure to use `SetOrigin` again to return the window origin to a horizontal coordinate of 0 and a vertical coordinate of 0 before using any Window Manager or Control Manager functions.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

`QuickdrawAPI.h`

SetPenState

Restores the state of the graphics pen that was saved with the `GetPenState` function. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void SetPenState (
   const PenState *pnState
);
```

Parameters

`pnState`

A `PenState` structure previously created with the `GetPenState` function. The `SetPenState` function sets the graphics pen's location, size, pattern, and pattern mode in the current graphics port to the values stored in this structure.

Discussion
This pen-manipulation function uses the local coordinate system of the current graphics port. Remember that each graphics port has its own pen, the state of which is stored in several fields of its `GrafPort` or `CGrafPort` structure. If you draw in one graphics port, change to another, and return to the first, the pen for the first graphics port has the same state as when you left it.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

SetPixelsState

Restores an offscreen pixel image to the state that you saved with the `GetPixelsState` function. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void SetPixelsState (
   PixMapHandle pm,
   GWorldFlags state
);
```

Parameters

pm

A handle to an offscreen pixel map.

state

Flags, which you usually save with the `GetPixelsState` function. You can use either of the constants `pixelsPurgeable` or `pixelsLocked here`.

Because only an unlocked memory block can be purged, `SetPixelsState` calls the `UnlockPixels` (page 2829) and `AllowPurgePixels` (page 2573) functions if the `state` parameter specifies the `pixelsPurgeable` flag. If the `state` parameter does not specify the `pixelsPurgeable` flag, `SetPixelsState` makes the base address for the offscreen pixel image unpurgeable.

If the `state` parameter does not specify the `pixelsLocked` flag, `SetPixelsState` allows the base address for the offscreen pixel image to be moved.

Discussion

The `SetPixelsState` function changes the state of the memory allocated for an offscreen pixel image to the state indicated in the `state` parameter.

After using `GetPixelsState` and before using `SetPixelsState`, your application can temporarily alter the offscreen graphics world by using the `AllowPurgePixels` (page 2573) function to temporarily mark the memory block for its offscreen pixel map as purgeable, the `NoPurgePixels` (page 2729) function to make it unpurgeable, the `LockPixels` (page 2704) function to prevent it from being moved, and the `UnlockPixels` (page 2829) function to unlock it.

Special Considerations

The `SetPixelsState` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QDOffscreen.h`

SetPort

Changes the current graphics port (basic or color). (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
virtual void SetPort (
   void *port
);
```

Parameters

port

A pointer to a `GrafPort` structure. Typically, you pass a pointer to a `GrafPort` structure that you previously saved with the `GetPort` function. The `SetPort` function sets this structure to be the current graphics port.

Discussion

All QuickDraw drawing functions affect the bitmap of, and use the local coordinate system of, the current graphics port. Each graphics port has its own graphics pen and text characteristics, which remain unchanged when the graphics port isn't selected as the current graphics port.

When your application runs in Color QuickDraw or uses offscreen graphics worlds, it should use the `SetGWorld` function instead of `SetPort`. The `SetGWorld` function restores the current graphics port for basic and color graphics ports as well as offscreen graphics worlds.

SetPortBits

Sets the bitmap for the current basic graphics port. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void SetPortBits (
   const BitMap *bm
);
```

Parameters

bm

A pointer to the `BitMap` structure to set for the current graphics port. Be sure to prepare all fields of the `BitMap` structure before you call `SetPortBits`.

Discussion

You should never need to use this function. This function, created for early versions of QuickDraw, allows you to perform all normal drawing and calculations on a buffer other than the screen—for example, copying a small offscreen image onto the screen with the `CopyBits` function. However, instead of using `SetPortBits`, you should use the more powerful offscreen graphics capabilities.

Declared In
`QuickdrawAPI.h`

SetPortPix

Sets the pixel map for the current color graphics port. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void SetPortPix (
   PixMapHandle pm
);
```

Parameters

pm

A handle to the `PixMap` structure.

Discussion
The `SetPortPix` function replaces the `portPixMap` field of the current `CGrafPort` structure with the handle you specify in the `pm` parameter.

Typically, your application does not need to call this function.

The `SetPortPix` function is analogous to the basic QuickDraw function `SetPortBits`, which sets the bitmap for the current basic graphics port. The `SetPortPix` function has no effect when used with a basic graphics port. Similarly, `SetPortBits` has no effect when used with a color graphics port.

Both `SetPortPix` and `SetPortBits` allow you to perform drawing and calculations on a buffer other than the screen. However, instead of using these functions, use the offscreen graphics capabilities.

`QuickdrawAPI.h`

SetPt

Assigns two coordinates to a point.

```
void SetPt (
   Point *pt,
   short h,
   short v
);
```

Parameters

pt

A pointer to the point to be given new coordinates. On return, this point is assigned the horizontal coordinate you specify in the `h` parameter and the vertical coordinate you specify in the `v` parameter.

h

The horizontal value of the new coordinates.

v

The vertical value of the new coordinates.

Discussion
The SetPt procedure assigns the horizontal coordinate specified in the h parameter and the vertical coordinate specified in the v parameter to the point returned in the pt parameter.

Availability
Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

SetRect

Assigns coordinates to a rectangle.

```
void SetRect (
    Rect * r,
    short left,
    short top,
    short right,
    short bottom
);
```

Parameters

r
A pointer to the rectangle to set.

left
The horizontal coordinate of the new upper-left corner of the rectangle.

top
The vertical coordinate of the new upper-left corner of the rectangle.

right
The horizontal coordinate of the new lower-right corner of the rectangle.

bottom
The vertical coordinate of the new lower-right corner of the rectangle.

Discussion
The `SetRect` function assigns the coordinates you specify in the `left`, `top`, `right`, and `bottom` parameters to the rectangle that you specify in the `r` parameter. This function is provided to help you shorten your program text. If you want a more readable text, at the expense of source text length, you can instead assign integers (or points) directly into the fields of a `Rect` structure.

You can use a rectangle to specify locations and sizes for various graphics operations.

If the points or rectangles supplied to this function are defined in a graphics port other than your current graphics port, you must convert them to the local coordinate system of your current graphics port. You can accomplish this by using the `SetPort` function to change to the graphics port containing the points or rectangles, using the `LocalGlobal` function to convert their locations to global coordinates, using `SetPort` to return to your starting graphics port, and then using the `GlobalToLocal` function to convert the locations of points or rectangles to the local coordinates of your current graphics port.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`QuickdrawAPI.h`

SetRectRgn

Changes the structure of an existing region to that of a rectangle.

```
void SetRectRgn (
    RgnHandle rgn,
    short left,
    short top,
    short right,
    short bottom
);
```

Parameters

rgn
A handle to the region to restructure as a rectangle.

left
The horizontal coordinate of the upper-left corner of the rectangle to set as the new region.

top
The vertical coordinate of the upper-left corner of the rectangle to set as the new region.

right
The horizontal coordinate of the lower-right corner of the rectangle to set as the new region.

bottom
The vertical coordinate of the lower-right corner of the rectangle to set as the new region.

Discussion
The `SetRectRgn` function destroys the previous structure of the region whose handle you pass in the `rgn` parameter, and it then sets the new structure to the rectangle that you specify in the `left`, `top`, `right`, and `bottom` parameters. If you specify an empty rectangle (that is, `right` is greater than or equal to `left` or `bottom = top`), the `SetRectRgn` function sets the region to the empty region defined by the rectangle (0,0,0,0).

As an alternative to the `SetRectRgn` function, you can change the structure of an existing region to that of a rectangle by using the `RectRgn` (page 2776) function, which accepts as a parameter a rectangle instead of four coordinates.

If the points or rectangles supplied to this function are defined in a graphics port other than your current graphics port, you must convert them to the local coordinate system of your current graphics port. You can accomplish this by using the `SetPort` function to change to the graphics port containing the points or rectangles, using the `LocalGlobal` function to convert their locations to global coordinates, using `SetPort` to return to your starting graphics port, and then using the `GlobalToLocal` function to convert the locations of points or rectangles to the local coordinates of your current graphics port.

Special Considerations

The `SetRectRgn` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

SetStdCProcs

Obtains a `CQDProcs` structure with fields that point to QuickDraw's standard low-level functions, which you can modify to change QuickDraw's standard low-level behavior. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void SetStdCProcs (
   CQDProcs *procs
);
```

Parameters

procs

Upon completion, a `CQDProcs` structure with fields that point to QuickDraw's standard low-level functions. You can change one or more fields to point to your own functions and then set the color graphics port to use this modified `CQDProcs` (page 2852) structure.

Discussion
For each shape that QuickDraw can draw, certain functions perform basic graphics operations on the shape: framing, painting, erasing, inverting, and filling. These functions, in turn, call a low-level drawing function for the shape.

The `grafProcs` field determines which low-level functions are called. If that field contains a value of `NULL`, the standard functions are called. You can set the `grafProcs` field to point to a structure of pointers to your own functions, and either completely override the standard ones or call them after your functions have modified their parameters as necessary.

The `SetStdCProcs` function sets all the fields of the `CQDProcs` structure to point to the standard functions. You can then reset the ones with which you are concerned.

The functions you install in the `CDQProcs` structure must have the same calling sequences as the standard basic QuickDraw functions.

When drawing in a color graphics port, your application must always use `SetStdCProcs` instead of `SetStdProcs`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

SetStdProcs

Obtains a `QDProcs` structure with fields that point to basic QuickDraw's standard low-level functions, which you can modify to point to your own functions. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void SetStdProcs (
   QDProcs *procs
);
```

Parameters

procs

On return, a pointer to a `QDProcs` structure with fields that point to basic QuickDraw's standard low-level functions. You can change one or more fields of this structure to point to your own functions and then set the basic graphics port to use this modified `QDProcs` structure. By changing these pointers, you can install your own functions, and either completely override the standard ones or call them after your functions have modified their parameters as necessary.

Discussion
The functions you install in this `QDProcs` structure must have the same calling sequences as the standard functions.

Special Considerations

The Color QuickDraw function `SetStdCProcs` is analogous to the `SetStdProcs` function, which you should use with computers that support only basic QuickDraw. When drawing in a color graphics port, your application must always use `SetStdCProcs` instead of `SetStdProcs`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

ShieldCursor

Hides the cursor in a rectangle.

```
void ShieldCursor (
   const Rect *shieldRect,
   Point offsetPt
);
```

Parameters

shieldRect

A rectangle in which the cursor is hidden whenever the cursor intersects the rectangle. The rectangle may be specified in global or local coordinates. If you are using global coordinates, pass (0,0) in the `offsetPt` parameter. If you are using the local coordinates of a graphics port, pass the coordinates for the upper-left corner of the graphics port's boundary rectangle in the `offsetPt` parameter.

offsetPt

A point value for the offset of the rectangle. Like the basic QuickDraw function `LocalToGlobal`, the `ShieldCursor` function offsets the coordinates of the rectangle by the coordinates of this point.

Discussion

If the cursor and the given rectangle intersect, `ShieldCursor` hides the cursor. If they do not intersect, the cursor remains visible while the mouse is not moving, but is hidden when the mouse moves. Use this function with a feature such as QuickTime to display content in a specified rectangle. When a QuickTime movie is animating, the cursor should not be visible in front of the movie.

The `ShieldCursor` function decrements the cursor level and should be balanced by a call to the `ShowCursor` function.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

ShowCursor

Displays a cursor hidden by the `HideCursor` or `ShieldCursor` functions.

```
void ShowCursor (
   void
);
```

Discussion

`ShowCursor` increments the cursor level, which has been decremented by the `HideCursor` (page 2668) or `ShieldCursor` (page 2813) function and displays the cursor on the screen when the level is 0. A call to the `ShowCursor` function balances each previous call to the `HideCursor` or `ShieldCursor` function. The level is not incremented beyond 0, so extra calls to `ShowCursor` have no effect.

Low-level interrupt-driven functions link the cursor with the mouse position, so that if the cursor level is 0 and visible, the cursor automatically follows the mouse.

If the cursor has been changed with the `SetCursor` (page 2792) function while hidden, `ShowCursor` displays the new cursor.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
Simple DrawSprocket

Declared In
`QuickdrawAPI.h`

ShowPen

Changes the ink of a graphics pen from invisible to visible, making pen drawing appear on the screen. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void ShowPen (
   void
);
```

Discussion
`ShowPen` is called by the functions `CloseRgn` (page 2582) , `ClosePoly` (page 2581) , and `ClosePicture`.

The `ShowPen` function increments the `pnVis` field of the current graphics port. For 0 or positive values, the pen drawing shows on the screen.

For example, if you have used the `HidePen` function to decrement the `pnVis` field from 0 to –1, use the `ShowPen` function to make its value 0 so that QuickDraw resumes drawing on the screen. Subsequent calls to `ShowPen` increment `pnVis` beyond 0, so every call to `ShowPen` should be balanced by a call to `HidePen`.

This pen-manipulation function uses the local coordinate system of the current graphics port. Remember that each graphics port has its own pen, the state of which is stored in several fields of its `GrafPort` or `CGrafPort` structure. If you draw in one graphics port, change to another, and return to the first, the pen for the first graphics port has the same state as when you left it.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

SlopeFromAngle

Converts an angle value to a slope value.

```
Fixed SlopeFromAngle (
   short angle
);
```

Parameters

angle

The angle, expressed in clockwise degrees from 12 o'clock and treated MOD 180. (90 degrees is thus at 3 o'clock and –90 degrees is at 9 o'clock.

Return Value

The slope corresponding to the angle specified in the angle parameter. Slopes are defined as Dx/Dy, the horizontal change divided by the vertical change between any two points on a line with the given angle. The negative y-axis is defined as being at 12 o'clock, and the positive y-axis at 6 o'clock. The x-axis is defined as usual, with the positive side defined as being at 3 o'clock.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

QuickdrawAPI.h

StdArc

QuickDraw's standard low-level function for drawing an arc or a wedge. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void StdArc (
   GrafVerb verb,
   const Rect *r,
   short startAngle,
   short arcAngle
);
```

Parameters

verb

The action to perform. See "Verb Constants" (page 2904).

r

The rectangle to contain the arc.

startAngle

The beginning angle.

arcAngle

The ending angle.

Discussion

Using the action specified in the verb parameter, the StdArc function draws an arc or wedge of the oval that fits inside the rectangle specified in the r parameter. The arc or wedge is bounded by the radii specified in the startAngle and arcAngle parameters.

You should only call this low-level function from your customized QuickDraw functions.

Special Considerations

The `StdArc` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

StdBits

QuickDraw's standard low-level function for transferring bits and pixels. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void StdBits (
   const BitMap *srcBits,
   const Rect *srcRect,
   const Rect *dstRect,
   short mode,
   RgnHandle maskRgn
);
```

Parameters

srcBits

A pointer to a bitmap or pixel map containing the image to copy.

srcRect

A pointer to the source rectangle.

dstRect

The destination rectangle.

mode

The source mode for the copy.

maskRgn

A handle to a region acting as a mask for the transfer.

Discussion

The `StdBits` function transfers a bit or pixel image between the bitmap or pixel map specified in the `srcBits` parameter and bitmap of the current graphics port, just as if the `CopyBits` function were called with the same parameters and with a destination bitmap equal to (* `thePort).portBits`.

You should only call this low-level function from your customized QuickDraw functions.

See `CopyBits` (page 2584) for a discussion of the destination bitmap and of the `srcBits`, `srcRect`, `dstRect`, `mode`, and `maskRgn` parameters

Special Considerations

The `StdBits` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

StdComment

QuickDraw's standard low-level function for processing a picture comment. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void StdComment (
   short kind,
   short dataSize,
   Handle dataHandle
);
```

Parameters

kind
The type of comment.

dataSize
The size of additional data, in bytes.

dataHandle
A handle to additional data.

Discussion
If there's no additional data for the comment, the value of the `dataHandle` parameter is `NULL` and the value of the `dataSize` parameter is 0. The `StdComment` function simply ignores the comment.

You should only call this low-level function from your customized QuickDraw functions.

Special Considerations

The `StdComment` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

StdGetPic

QuickDraw's standard low-level function for retrieving information from the definition of a picture. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void StdGetPic (
   void *dataPtr,
   short byteCount
);
```

Parameters

dataPtr

On return, a pointer to the collected picture data.

byteCount

The size of the picture data.

Discussion

The `StdGetPic` function retrieves from the definition of the currently open picture the next number of bytes as specified in the `byteCount` parameter.

You should only call this low-level function from your customized QuickDraw functions.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

StdLine

QuickDraw's standard low-level function for drawing a line. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void StdLine (
   Point newPt
);
```

Parameters

newPt

The point to which to draw the line.

Discussion

The `StdLine` function draws a line from the current pen location to the location (in local coordinates) specified in the `newPt` parameter.

You should only call this low-level function from your customized QuickDraw functions.

Special Considerations

The `StdLine` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
QuickdrawAPI.h

StdOpcode

(Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void StdOpcode (
   const Rect *fromRect,
   const Rect *toRect,
   UInt16 opcode,
   SInt16 version
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
QuickdrawAPI.h

StdOval

QuickDraw's standard low-level function for drawing an oval. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void StdOval (
   GrafVerb verb,
   const Rect *r
);
```

Parameters

verb
The action to perform. See "Verb Constants" (page 2904).

r
The rectangle to contain the oval.

Discussion
The `StdOval` function draws an oval inside the given rectangle specified in the `r` parameter according to the action specified in the `verb` parameter.

You should only call this low-level function from your customized QuickDraw functions.

Special Considerations

The `StdOval` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

StdPoly

QuickDraw's standard low-level function for drawing a polygon. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void StdPoly (
   GrafVerb verb,
   PolyHandle poly
);
```

Parameters

verb

The action to perform. See "Verb Constants" (page 2904).

poly

A handle to the polygon data.

Discussion
The `StdPoly` function draws the polygon specified in the `poly` parameter according to the action specified in the `verb` parameter.

You should only call this low-level function from your customized QuickDraw functions.

Special Considerations

The `StdPoly` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

StdPutPic

QuickDraw's standard low-level function for saving information as the definition of a picture. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void StdPutPic (
   const void *dataPtr,
   short byteCount
);
```

Parameters

dataPtr

A pointer to the collected picture data.

byteCount

The size of the picture data.

Discussion
The `StdPutPic` function saves as the definition of the currently open picture the drawing commands stored in the data structure pointed to by the `dataPtr` parameter, starting with the first byte and continuing for the next number of bytes as specified in the `byteCount` parameter.

You should only call this low-level function from your customized QuickDraw functions.

Special Considerations

The `StdPutPic` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

StdRect

QuickDraw's standard low-level function for drawing a rectangle. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void StdRect (
   GrafVerb verb,
   const Rect *r
);
```

Parameters

verb
The action to perform. See "Verb Constants" (page 2904).

r
The rectangle to draw.

Discussion
The `StdRect` function draws the rectangle specified in the `r` parameter according to the action specified in the `verb` parameter.

You should only call this low-level function from your customized QuickDraw functions.

Special Considerations

The `StdRect` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

StdRgn

QuickDraw's standard low-level function for drawing a region. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void StdRgn (
   GrafVerb verb,
   RgnHandle rgn
);
```

Parameters

verb

The action to perform. See "Verb Constants" (page 2904).

rgn

A handle to the region data.

Discussion

The `StdRgn` function draws the region specified in the `rgn` parameter according to the action specified in the `verb` parameter.

You should only call this low-level function from your customized QuickDraw functions.

Special Considerations

The `StdRgn` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

StdRRect

QuickDraw's standard low-level function for drawing a rounded rectangle. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void StdRRect (
   GrafVerb verb,
   const Rect *r,
   short ovalWidth,
   short ovalHeight
);
```

Parameters

verb

The action to perform. See "Verb Constants" (page 2904).

r

The rectangle to draw.

ovalWidth

The width diameter for the corner oval.

ovalHeight

The height diameter for the corner oval.

Discussion

The `StdRRect` function draws the rounded rectangle specified in the `r` parameter according to the action specified in the `verb` parameter. The `ovalWidth` and `ovalHeight` parameters specify the diameters of curvature for the corners.

You should only call this low-level function from your customized QuickDraw functions.

Special Considerations

The `StdRRect` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

StuffHex

Sets byte values into memory. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void StuffHex (
   void *thingPtr,
   ConstStr255Param s
);
```

Parameters

thingPtr

A pointer to any data structure in memory. If `thingPtr` is an odd address, then `thingPtr` is interpreted as pointing to the next word boundary.

s

A string of characters representing hexadecimal digits. All characters in this string must be hexadecimal digits (0, 1, 2, 3, 4, 5, 6, 7, 8, 9, A, B, C, D, E, F). Otherwise, `StuffHex` may set bytes in the data structure pointed to by `thingPtr` to arbitrary values. If there are an odd number of characters in the string, the last character is ignored.

Discussion

The `StuffHex` function sets bytes in memory beginning with that byte specified by the parameter `thingPtr`. The total number of bytes set is equivalent to half the length of the string, ignoring the last character if the number of characters is odd.

Each byte to be set corresponds to two characters in the string. These characters should represent hexadecimal digits. For example, the string ‘`D41A`’ results in 2 bytes being set to the values $D4 and $1A, respectively.

To copy a range of bytes from one memory location to another, you should ordinarily use the Memory Manager function, `BlockMove`.

Special Considerations

The `StuffHex` function does no range checking to ensure that bytes being set are within the bounds of a certain data structure. If you do not use `StuffHex` carefully, you may change memory in the partition of your application or another application in unpredictable ways.

Although the `StuffHex` function sets the value of individual bytes, it does not move relocatable blocks. Thus, you can call it at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

SubPt

Subtracts the coordinates of one point from another.

```
void SubPt (
   Point src,
   Point *dst
);
```

Parameters

`src`

A point, the coordinates of which are to be subtracted from the coordinates of the point specified in the `dst` parameter.

`dst`

The address of a point. Upon completion, the coordinates of this point contain the differences between the coordinates of the two points specified in the entry parameters.

If you pass `NULL` in the `dst` parameter, this function sets the `QDError` result code to `paramErr` and returns.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`QuickdrawAPI.h`

SwapPortPicSaveHandle

(Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
Handle SwapPortPicSaveHandle (
   CGrafPtr port,
   Handle inPicSaveHdl
);
```

(Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
Handle SwapPortRegionSaveHandle (
   CGrafPtr port,
   Handle inRegionSaveHdl
);
```

Availability
Available in Mac OS X v10.2 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

SyncCGContextOriginWithPort

Synchronizes the origin in a Quartz context with the lower-left corner of the associated graphics port. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
OSStatus SyncCGContextOriginWithPort (
   CGContextRef inContext,
   CGrafPtr port
);
```

Parameters

context

A Quartz context associated with a graphics port. You can obtain such a context by calling `QDBeginCGContext` (page 2756).

port

The graphics port associated with the context.

Return Value

A result code. If `noErr`, the context's origin was successfully changed.

Discussion

If you're using Quartz 2D to draw in a graphics port and `SetOrigin` (page 2797) is called to change the port's origin, you can call this function to maintain the correspondence between the context's origin and the lower-left corner of the `portBounds` rectangle.

When you call this function:

1. The current transformation matrix (CTM) is reset to its default values. Any changes you made to the CTM prior to calling this function are lost.
2. The CTM is translated to establish the new origin, taking the port's current origin into account.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

TestDeviceAttribute

Determines whether the flag bit for an attribute has been set in the `gdFlags` field of a `GDevice` structure. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
Boolean TestDeviceAttribute (
   GDHandle gdh,
   short attribute
);
```

Parameters

gdh

A handle to a `GDevice` structure.

attribute

One of the specific constants, which represent bits in the `gdFlags` field of a `GDevice` structure. See "Device Attribute Constants" (page 2887) for a description of the values you can use in this parameter.

Return Value

`TRUE` if the bit of the graphics device attribute specified in the `attribute` parameter is set to 1. Otherwise, `TestDeviceAttribute` returns `FALSE`.

Discussion

Use the `SetDeviceAttribute` (page 2793) function to change any of the flags tested by the `TestDeviceAttribute` function.

Special Considerations

The `TestDeviceAttribute` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

UnionRect

Calculates the smallest rectangle that encloses two rectangles.

```
void UnionRect (
    const Rect * src1,
    const Rect * src2,
    Rect * dstRect
);
```

Parameters

src1

The first of two rectangles to enclose.

src2

The second of two rectangles to enclose.

dstRect

On return, a pointer to the smallest rectangle that encloses both of the rectangles you specify in the `src1` and `src2` parameters. One of the source rectangles may also be the destination.

Discussion
If the points or rectangles supplied to this function are defined in a graphics port other than your current graphics port, you must convert them to the local coordinate system of your current graphics port. You can accomplish this by using the `SetPort` function to change to the graphics port containing the points or rectangles, using the `LocalGlobal` function to convert their locations to global coordinates, using `SetPort` to return to your starting graphics port, and then using the `GlobalToLocal` function to convert the locations of points or rectangles to the local coordinates of your current graphics port.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`QuickdrawAPI.h`

UnionRgn

Calculates the union of two regions.

```
void UnionRgn (
    RgnHandle srcRgnA,
    RgnHandle srcRgnB,
    RgnHandle dstRgn
);
```

Parameters

srcRgnA
A handle to the first of two regions whose union is to be determined.

srcRgnB
A handle to the second of two regions whose union is to be determined.

dstRgn
On return, a handle to the region holding the resulting union area. If both regions are empty, `UnionRgn` sets the destination to the empty region defined by the rectangle (0,0,0,0).

The `UnionRgn` function does not create the destination region; you must have already allocated memory for it by using the `NewRgn` (page 2726) function.

The destination region may be one of the source regions, if desired.

Discussion
The UnionRgn procedure calculates the union of the two regions whose handles you pass in the srcRgnA and srcRgnB parameters, and it places the union in the region whose handle you pass in the dstRgn parameter. If both regions are empty, UnionRgn sets the destination to the empty region defined by the rectangle (0,0,0,0).

Special Considerations

The `UnionRgn` function may temporarily use heap space that's twice the size of the two input regions.

The `UnionRgn` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
QuickdrawAPI.h

UnlockPixels

Allows the Memory Manager to move the base address for the offscreen pixel map that you specify in the pm parameter. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void UnlockPixels (
   PixMapHandle pm
);
```

Parameters

pm

A handle to an offscreen pixel map. Pass the same handle that you passed previously to the LockPixels function.

Discussion
To ensure the integrity of the data in a pixel image, call LockPixels before drawing into or copying from a pixel map; then, to prevent heap fragmentation, call UnlockPixels as soon as your application finishes drawing to and copying from the offscreen pixel map.

The baseAddr field of the PixMap structure for an offscreen graphics world contains a handle instead of a pointer (which is what the baseAddr field for an onscreen pixel map contains). The LockPixels function dereferences the PixMap handle into a pointer. When you use the UnlockPixels function, the handle is recovered.

You don't need to call UnlockPixels if LockPixels returns FALSE, because LockPixels doesn't lock the memory for a pixel image if that memory has been purged. However, calling UnlockPixels on purged memory does no harm.

Special Considerations

The UnlockPixels function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Related Sample Code
QTCarbonShell

Declared In
QDOffscreen.h

UnlockPortBits

Releases a previously acquired lock on the back buffer for a Carbon window. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
OSErr UnlockPortBits (
   GrafPtr port
);
```

Parameters

port

A window port specified in a previous call to `LockPortBits` (page 2705).

Return Value
A result code. If `noErr`, the corresponding lock is released.

Discussion
For more information about this function, see `LockPortBits` (page 2705).

In Mac OS 9, this function does nothing and returns `noErr`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Related Sample Code
QTCarbonShell

Declared In
`QuickdrawAPI.h`

UnpackBits

Decompresses a data buffer containing data compressed by `PackBits`. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
void UnpackBits (
   Ptr *srcPtr,
   Ptr *dstPtr,
   short dstBytes
);
```

Parameters

srcPtr

On entry, a pointer to the first byte of a buffer of data to be decompressed. On exit, a pointer to the first byte following the compressed data.

dstPtr

On entry, a pointer to the first byte in which to store decompressed data. On exit, a pointer to the first byte following the decompressed data.

dstBytes

The number of bytes of the data before compression. Use `PackBits` to compress data structures of a fixed size that you can then pass in this parameter to `UnpackBits`, or store with the compressed data the original size of the uncompressed data.

Discussion
Because your application must allocate memory for the source and destination buffers, `UnpackBits` does not move relocatable blocks. Thus, you can call it at interrupt time.

Because `UnpackBits` changes the values of the `srcPtr` and `dstPtr` parameters, you should pass to `UnpackBits` only copies of the pointers to the source and destination buffers. This allows you to access the beginning of the source and destination buffers after `UnpackBits` returns. Also, if the source or destination buffer is stored in an unlocked, relocatable block, this technique prevents `UnpackBits` from changing the value of a master pointer, which would make the original handle invalid.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

UpdateGWorld

Changes the pixel depth, boundary rectangle, or color table for an existing offscreen graphics world. (Deprecated in Mac OS X v10.4. Use Quartz 2D instead; see *Quartz Programming Guide for QuickDraw Developers*.)

```
GWorldFlags UpdateGWorld (
   GWorldPtr *offscreenGWorld,
   short pixelDepth,
   const Rect *boundsRect,
   CTabHandle cTable,
   GDHandle aGDevice,
   GWorldFlags flags
);
```

Parameters

offscreenGWorld
On input, a pointer to an existing offscreen graphics world; upon completion, the pointer to the updated offscreen graphics world.

pixelDepth
The pixel depth of the offscreen world; possible depths are 1, 2, 4, 8, 16, and 32 bits per pixel. If you specify 0 in this parameter, `UpdateGWorld` rescans the device list and uses the depth of the screen with the greatest pixel depth among all screens whose boundary rectangles intersect the rectangle that you specify in the `boundsRect` parameter. If you specify 0 in this parameter, `UpdateGWorld` also copies the `GDevice` structure from this device to create an offscreen `GDevice` structure. The `UpdateGWorld` function ignores the value you supply for this parameter if you specify a `GDevice` structure in the `aGDevice` parameter.

boundsRect
The boundary rectangle and port rectangle for the offscreen pixel map. This also becomes the boundary rectangle for the `GDevice` structure, if `NewGWorld` creates one. If you specify 0 in the `pixelDepth` parameter, `NewGWorld` interprets the boundaries in global coordinates, with which it determines which screens intersect the rectangle. (`NewGWorld` then uses the pixel depth, color table, and `GDevice` structure from the screen with the greatest pixel depth from among all screens whose boundary rectangles intersect this rectangle.) Typically, your application supplies this parameter with the port rectangle for the onscreen window into which your application will copy the pixel image from this offscreen world.

cTable

A handle to a `ColorTable` structure. If you pass `NULL` in this parameter, `UpdateGWorld` uses the default color table for the pixel depth that you specify in the `pixelDepth` parameter; if you set the `pixelDepth` parameter to 0, `UpdateGWorld` copies and uses the color table of the graphics device with the greatest pixel depth among all graphics devices whose boundary rectangles intersect the rectangle that you specify in the `boundsRect` parameter. The `UpdateGWorld` function ignores the value you supply for this parameter if you specify a `GDevice` structure in the `aGDevice` parameter.

aGDevice

As an option, a handle to a `GDevice` structure whose pixel depth and color table you want to use for the offscreen graphics world. To use the pixel depth and color table that you specify in the `pixelDepth` and `cTable` parameters, set this parameter to `NULL`.

flags

Options available to your application. You can set a combination of the flags `clipPix`, `stretchPix`, and `ditherPix`. If you don't wish to use any of these flags, specify 0. However, you should pass either `clipPix` or `stretchPix` to ensure that the pixel map is updated to reflect the new color table. See GWorldFlags (page 2863) for a description of the values you can use here.

Return Value

`UpdateGWorld` returns the `gwFlagErr` flag if `UpdateGWorld` was unsuccessful; in this case, the offscreen graphics world is left unchanged. Use the `QDError` function to help you determine why `UpdateGWorld` failed.

Discussion

You should call `UpdateGWorld` after every update event and whenever your windows move or change size.

If the `LockPixels` (page 2704) function reports that the Memory Manager has purged the base address for the offscreen pixel image, use `UpdateGWorld` to reallocate its memory. Then, reconstruct the pixel image or draw directly in a window instead of preparing the image in an offscreen graphics world.

The `UpdateGWorld` function uses the following algorithm when updating the offscreen pixel image:

1. If the color table that you specify in the `cTable` parameter is different from the previous color table, or if the color table associated with the `GDevice` structure that you specify in the `aGDevice` parameter is different, Color QuickDraw maps the pixel values in the offscreen pixel map to the new color table.
2. If the value you specify in the `pixelDepth` parameter differs from the previous pixel depth, Color QuickDraw translates the pixel values in the offscreen pixel image to those for the new pixel depth.
3. If the rectangle you specify in the `boundsRect` parameter differs from, but has the same size as, the previous boundary rectangle, QuickDraw realigns the pixel image to the screen for optimum performance for the `CopyBits` function.
4. If the rectangle you specify in the `boundsRect` parameter is smaller than the previous boundary rectangle and you specify the `clipPix` flag, the pixel image is clipped along the bottom and right edges.
5. If the rectangle you specify in the `boundsRect` parameter is bigger than the previous boundary rectangle and you specify the `clipPix` flag, the bottom and right edges of the pixel image are undefined.
6. If the rectangle you specify in the `boundsRect` parameter is smaller than the previous boundary rectangle and you specify the `stretchPix` flag, the pixel image is reduced to the new size.
7. If the rectangle you specify in the `boundsRect` parameter is bigger than the previous boundary rectangle and you specify the `stretchPix` flag, the pixel image is stretched to the new size.

8. If the Memory Manager purged the base address for the offscreen pixel image, `UpdateGWorld` reallocates the memory, but the pixel image is lost. You must reconstruct it.

Special Considerations

The `UpdateGWorld` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QDOffscreen.h`

XorRgn

Calculates the difference between the union and the intersection of two regions.

```
void XorRgn (
    RgnHandle srcRgnA,
    RgnHandle srcRgnB,
    RgnHandle dstRgn
);
```

Parameters

srcRgnA

A handle to the first of two regions to compare.

srcRgnB

A handle to the second of two regions to compare.

dstRgn

On return, a handle to the region holding the result.

This does not create the destination region; you must have already allocated memory for it by using the `NewRgn` (page 2726) function.

If the regions are coincident, `XorRgn` sets the destination region to the empty region defined by the rectangle (0,0,0,0).

Discussion

The XorRgn procedure calculates the difference between the union and the intersection of the regions whose handles you pass in the srcRgnA and srcRgnB parameters and places the result in the region whose handle you pass in the dstRgn parameter.

Special Considerations

The `XorRgn` function may temporarily use heap space that's twice the size of the two input regions.

The `XorRgn` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

Callbacks

ColorComplementProcPtr

Defines a pointer to a color inversion callback function that overrides the Color Manager's color inversion method.

```
typedef Boolean (*ColorComplementProcPtr) (
    RGBColor * rgb
);
```

If you name your function `MyColorComplementProc`, you would declare it like this:

```
Boolean ColorComplementProcPtr (
    RGBColor * rgb
);
```

Parameters

rgb

A pointer to the `RGBColor` data structure. Change it to reflect the inverted value.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`QuickdrawTypes.h`

ColorSearchProcPtr

Defines a pointer to a color search callback function that overrides the Color Manager's code for inverse table mapping.

```
typedef Boolean (*ColorSearchProcPtr) (
    RGBColor * rgb,
    long * position
);
```

If you name your function `MyColorSearchProc`, you would declare it like this:

```
Boolean ColorSearchProcPtr (
    RGBColor * rgb,
    long * position
);
```

Parameters

rgb

A pointer to the `RGBColor` data structure passed to your search function. Your function should set the `ColorSpec.value` field to the index corresponding to the color indicated here.

position

A pointer to the index of the best-mapping color your function finds.

Return Value

`True` if your function succeeds, `false` if your function cannot find a match.

Discussion

Your `MyColorSearchCallback` function should examine the `RGBColor` data structure passed to it by the Color Manager and return the index to the best-mapping color in the current `GDevice` data structure.

The Color Manager specifies the desired color in the `RGBColor` field of a `ColorSpec` data structure and passes it by a pointer on the stack. Your function should return the corresponding index in the `ColorSpec.value` field. If your function cannot handle the search, return `false` as the function value, and pass the `RGBColor` data structure back to the Color Manager in the `rgb` parameter.

The Color Manager calls each search function in the list until one returns the Boolean value `true`. If no search function installed in the linked list returns `true`, the Color Manager calls the default search function.

Availability

Available in Mac OS X v10.0 and later.

`QuickdrawTypes.h`

CustomXFerProcPtr

```
typedef void (*CustomXFerProcPtr) (
    CustomXFerRecPtr info
);
```

If you name your function `MyCustomXFerProc`, you would declare it like this:

```
void CustomXFerProcPtr (
    CustomXFerRecPtr info
);
```

Availability

Available in Mac OS X v10.0 and later.

Declared In

`QuickdrawAPI.h`

DeviceLoopDrawingProcPtr

```
typedef void (*DeviceLoopDrawingProcPtr) (
    short depth,
    short deviceFlags,
    GDHandle targetDevice,
    long userData
);
```

If you name your function `MyDeviceLoopDrawingProc`, you would declare it like this:

```
void DeviceLoopDrawingProcPtr (
    short depth,
    short deviceFlags,
    GDHandle targetDevice,
    long userData
);
```

Parameters

depth

The pixel depth of the graphics device.

deviceFlags

Constants which represent bits that are set to 1 in the `gdFlags` field of the `GDevice` structure for the current device. See "Device Attribute Constants" (page 2887) for a description of the values which you can receive in this parameter.

targetDevice

A handle to the `GDevice` (page 2859) structure for the current device.

userData

A value that your application supplies to the `DeviceLoop` function, which in turn passes the value to your drawing function for whatever purpose you deem useful.

Discussion

For each video device that intersects a drawing region that you define (generally, the update region of a window), `DeviceLoop` calls your drawing function. Your drawing function should analyze the pixel depth passed in the `depth` parameter and the values passed in the `deviceFlags` parameter, and then draw in a manner that is optimized for the current device.

When highlighting, for example, your application might invert black and white when drawing onto a 1-bit video device but use magenta as the highlight color when drawing onto a color video device. In this case, even were your window to span both a black-and-white and a color screen, the user sees the selection inverted on the black-and-white screen, while magenta would be used to highlight the selection on the color screen.

You must provide a pointer to your `MyDeviceLoopDrawingCallback` function in the `drawingProc` parameter for `DeviceLoop`.

Availability

Available in Mac OS X v10.0 and later.

`QuickdrawTypes.h`

QDTxMeasProcPtr

```
typedef short (*QDTxMeasProcPtr) (
    short byteCount,
    const void * textAddr,
    Point * numer,
    Point * denom,
    FontInfo * info
);
```

If you name your function `MyQDTxMeasProc`, you would declare it like this:

```
short QDTxMeasProcPtr (
    short byteCount,
    const void * textAddr,
    Point * numer,
    Point * denom,
    FontInfo * info
);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`QuickdrawTypes.h`

RegionToRectsProcPtr

```
typedef OSStatus (*RegionToRectsProcPtr) (
    UInt16 message,
    RgnHandle rgn,
    const Rect * rect,
    void * refCon
);
```

If you name your function `MyRegionToRectsProc`, you would declare it like this:

```
OSStatus RegionToRectsProcPtr (
    UInt16 message,
    RgnHandle rgn,
    const Rect * rect,
    void * refCon
);
```

Return Value

Availability
Available in Mac OS X v10.0 and later.

Declared In
`QuickdrawAPI.h`

Data Types

BitMap

```
struct BitMap {
    Ptr baseAddr;
    short rowBytes;
    Rect bounds;
};
typedef struct BitMap BitMap;
typedef BitMap * BitMapPtr;
```

Fields
`baseAddr`
: A pointer to the beginning of the bit image.

`rowBytes`
: The offset in bytes from one row of the image to the next. The value of the `rowBytes` field must be less than $4000.

`bounds`
: The bitmap's boundary rectangle by default, the entire main screen.

Discussion
A bitmap, which is a data structure of type `BitMap`, defines a bit image in terms of the QuickDraw coordinate plane. (A bit image is a collection of bits in memory that form a grid.)

A bitmap has three parts: a pointer to a bit image, the row width of that image, and a boundary rectangle that links the local coordinate system of a graphics port to QuickDraw's global coordinate system and defines the area of the bit image into which QuickDraw can draw.

The width of the boundary rectangle determines how many bits of one row are logically owned by the bitmap. This width must not exceed the number of bits in each row of the bit image. The height of the boundary rectangle determines how many rows of the image are logically owned by the bitmap. The number of rows enclosed by the boundary rectangle must not exceed the number of rows in the bit image.

The boundary rectangle defines the local coordinate system used by the port rectangle for a graphics port (described next). The upper-left corner (which for a window is called the window origin) of the port rectangle usually has a vertical coordinate of 0 and a horizontal coordinate of 0, although you can use the function `SetOrigin` (page 2797) to change the coordinates of the window origin.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`QuickdrawTypes.h`

Bits16

```
typedef short Bits16[16];
```

Discussion
The `Bits16` array is used by the `Cursor` (page 2854) structure to hold a black-and-white, 16-by-16 pixel square image.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`QuickdrawTypes.h`

CCrsr

```
struct CCrsr {
    short crsrType;
    PixMapHandle crsrMap;
    Handle crsrData;
    Handle crsrXData;
    short crsrXValid;
    Handle crsrXHandle;
    Bits16 crsr1Data;
    Bits16 crsrMask;
    Point crsrHotSpot;
    long crsrXTable;
    long crsrID;
};
typedef struct CCrsr CCrsr;
typedef CCrsr * CCrsrPtr;
```

Fields

`crsrType`
The type of cursor. Possible values are $8000 for a black-and-white cursor and $8001 for a color cursor.

`crsrMap`
A handle to the `PixMap` structure defining the cursor's characteristics. When the screen depth is greater than 2 bits per pixel, the `crsrMap` field and the `crsrData` field define the image. The pixels within the mask replace the destination pixels. Color QuickDraw transfers the pixels outside the mask into the destination pixels using the XOR Boolean transfer mode. Therefore, if pixels outside the mask are white, the destination pixels aren't changed. If pixels outside the mask are all black, the destination pixels are inverted. All other values outside of the mask cause unpredictable results.

`crsrData`
A handle to the cursor's pixel data. To work properly, a color cursor's image should contain white pixels `(R=G= B=$FFFF)` for the transparent part of the image, and black pixels `(R=G=B=$0000)` for the part of the image to be inverted, in addition to the other colors in the cursor's image. Thus, to define a cursor that contains two colors, it's necessary to use a 2-bit cursor image (that is, a four-color image.

`crsrXData`
A handle to the expanded pixel image used internally by Color QuickDraw.

`crsrXValid`
The depth of the expanded cursor image. If you change the cursor's data or color table, set this field to 0 to cause the cursor to be re-expanded. Never set it to any other values.

`crsrXHandle`
Reserved for future use.

`crsr1Data`
A 16-by-16 pixel image with a pixel depth of 1 to be displayed when the cursor is on screens with pixel depths of 1 or 2 bits.

`crsrMask`
The cursor's mask data. QuickDraw uses the mask to crop the cursor's outline into a background color or pattern. QuickDraw then draws the cursor into this shape. The same 1-bit mask is used with images specified by the `crsrData` and `crsr1Data` fields.

`crsrHotSpot`
The cursor's hot spot.

`crsrXTable`
Reserved for future use.

`crsrID`
The color table seed for the cursor.

Discussion
Your application typically does not create `CCrsr` structures. Although you can create a `CCrsr` structure, it is usually easier to create a color cursor in a color cursor resource, 'crsr'.

A color cursor is a 256-pixel color image in a 16-by-16 pixel square defined in a color cursor (`'crsr'`) resource. When your application uses the `GetCCursor` function to get a color cursor from a `'crsr'` resource, `GetCCursor` loads the resource into memory as a `CCrsr` structure. Your application can then display the color cursor by using the `SetCCursor` (page 2790) function.

`CCrsr` is substantially different from the `Cursor` structure. The fields `crsr1Data`, `crsrMask`, and `crsrHotSpot` in the `CCrsr` structure are the only ones that have counterparts in the `Cursor` structure.

The first four fields of the `CCrsr` structure are similar to the first four fields of the `PixPat` record, and are used in the same manner by QuickDraw.

The display of a cursor involves a relationship between a mask, stored in the `crsrMask` field with the same format used for 1-bit cursor masks, and an image. There are two possible sources for a color cursor's image. When the cursor is on a screen whose depth is 1 or 2 bits per pixel, the image for the cursor is taken from the `crsr1Data` field, which contains bitmap cursor data, similar to the bitmap in a `'CURS'` resource.

ColorSpec

```
struct ColorSpec {
    short value;
    RGBColor rgb;
};
typedef struct ColorSpec ColorSpec;
typedef ColorSpec * ColorSpecPtr;
```

Fields

`value`

The pixel value assigned by QuickDraw for the color specified in the `rgb` field of this structure. QuickDraw assigns a pixel value based on the capabilities of the user's screen. For indexed devices, the pixel value is an index number assigned by QuickDraw to the closest color available on the indexed device for direct devices, this value expresses the best available red, green, and blue values for the color on the direct device.

`rgb`

An `RGBColor` (page 2882) structure that fully specifies the color whose approximation QuickDraw specifies in the `value` field.

Discussion
When creating a `PixMap` (page 2869) structure for an indexed device, QuickDraw creates a `ColorTable` structure that defines the best colors available for the pixel image on that graphics device. QuickDraw also stores a `ColorTable` structure for the currently available colors in the graphics device's CLUT.

One of the fields in a `ColorTable` structure requires a value of type `cSpecArray`, which is defined as an array of `ColorSpec` structures. Typically, your application never needs to create `ColorTable` structures or `ColorSpec` structures. For completeness, the data structure of type `ColorSpec` is shown here.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`IOMacOSTypes.h`

ColorTable

```
struct ColorTable {
    long ctSeed;
    short ctFlags;
    short ctSize;
    CSpecArray ctTable;
};
typedef struct ColorTable ColorTable;
typedef ColorTable * CTabPtr;
typedef CTabPtr * CTabHandle;
```

Fields

`ctSeed`

Identifies a particular instance of a color table. QuickDraw uses the `ctSeed` value to compare an indexed device's color table with its associated inverse table (a table it uses for fast color lookup). When the color table for a graphics device has been changed, QuickDraw needs to rebuild the inverse table.

`ctFlags`

Flags that distinguish pixel map color tables from color tables in `GDevice` structures.

`ctSize`

One less than the number of entries in the table.

`ctTable`

An array of `ColorSpec` (page 2850) entries, each containing a pixel value and a color specified by an `RGBColor` structure.

Discussion

When creating a `PixMap` (page 2869) structure for a particular graphics device, QuickDraw creates a `ColorTable` structure that defines the best colors available for the pixel image on that particular graphics device. QuickDraw also creates a `ColorTable` structure of all available colors for use by the CLUT on indexed devices.

Typically, your application needs to create `ColorTable` structures only if it uses the Palette Manager.

Your application should never need to directly change the fields of a `ColorTable` structure. If you find it absolutely necessary for your application to do so, immediately use the `CTabChanged` (page 2593) function to notify QuickDraw that your application has changed the `ColorTable` structure.

Availability

Available in Mac OS X v10.0 and later.

CProcRec

```
struct CProcRec {
    Handle nxtComp;
    ColorComplementUPP compProc;
};
typedef struct CProcRec CProcRec;
typedef CProcRec * CProcPtr;
```

Fields

`nxtComp`

A handle to the next `CPRocRec` data structure in the list.

`compProc`

A pointer to a complement function, as described in `ColorComplementProcPtr` (page 2834).

Discussion

The `CProcRec` data structure contains a pointer to a custom complement function and a pointer to the next complement function in the list.

Availability

Available in Mac OS X v10.0 and later.

    UniversalProcPtr newProc6;
};
typedef struct CQDProcs CQDProcs;
typedef CQDProcs * CQDProcsPtr;
```

Fields

`textProc`

A pointer to the low-level function that draws text. The standard QuickDraw function is the `StdText` function.

`lineProc`
: A pointer to the low-level function that draws lines. The standard QuickDraw function is the `StdLine` function.

`rectProc`
: A pointer to the low-level function that draws rectangles. The standard QuickDraw function is the `StdRect` function.

`rRectProc`
: A pointer to the low-level function that draws rounded rectangles. The standard QuickDraw function is the `StdRRect` function.

`ovalProc`
: A pointer to the low-level function that draws ovals. The standard QuickDraw function is the `StdOval` function.

`arcProc`
: A pointer to the low-level function that draws arcs. The standard QuickDraw function is the `StdArc` function.

`polyProc`
: A pointer to the low-level function that draws polygons. The standard QuickDraw function is the `StdPoly` function.

`rgnProc`
: A pointer to the low-level function that draws regions. The standard QuickDraw function is the `StdRgn` function.

`bitsProc`
: A pointer to the low-level function that copies bitmaps. The standard QuickDraw function is the `StdBits` function.

`commentProc`
: A pointer to the low-level function for processing a picture comment. The standard QuickDraw function is the `StdComment` function.

`txMeasProc`
: A pointer to the low-level function for measuring text width. The standard QuickDraw function is the `StdTxMeas` function.

`getPicProc`
: A pointer to the low-level function for retrieving information from the definition of a picture. The standard QuickDraw function is the `StdGetPic` function.

`putPicProc`
: A pointer to the low-level function for saving information as the definition of a picture. The standard QuickDraw function is the `StdPutPic` function.

`opcodeProc`
: Reserved for future use.

`newProc1`
: Reserved for future use.

`glyphsProc`
: Reserved for future use.

`printerStatusProc`
: Reserved for future use.

`newProc4`
: Reserved for future use.

`newProc5`
Reserved for future use.

`newProc6`
Reserved for future use.

Discussion
Use the `CQDProcs` structure only if you customize one or more of QuickDraw's standard low-level drawing functions. Use the `SetStdCProcs` (page 2811) function to create a `CQDProcs` structure.

Availability
Available in Mac OS X v10.0 and later.

`QuickdrawTypes.h`

Cursor

```
struct Cursor {
    Bits16 data;
    Bits16 mask;
    Point hotSpot;
};
typedef struct Cursor Cursor;
typedef Cursor * CursPtr;
```

Fields
`data`
Cursor image data, which must begin on a word boundary.

`mask`
The cursor's mask. QuickDraw uses the mask to crop the cursor's outline into a background color or pattern. QuickDraw then draws the cursor into this shape.

`hotSpot`
A point in the image that aligns a point (not a bit) in the image with the mouse location on the screen. Whenever the user moves the mouse, the low-level interrupt-driven mouse functions move the cursor. When the user clicks, the Event Manager function `WaitNextEvent` reports the location of the cursor's hot spot in global coordinates.

Discussion
Your application typically does not create `Cursor` structures. Although you can create a `Cursor` structure and its associated `Bits16` array in your program code, it is usually easier to create a black-and-white cursor in a cursor resource,'CURS'.

A cursor is a 256-pixel, black-and-white image in a 16-by-16 pixel square. When your application uses the `GetCursor` (page 2638) function to get a cursor from a `'CURS'` resource, `GetCursor` loads the resource into memory as a `Cursor` structure. Your application then displays the color cursor by using the `SetCursor` (page 2792) function.

The cursor appears on the screen as a 16-by-16 pixel square. The appearance of each bit if the square is determined by the corresponding bits in the data and the mask and, if the mask bit is 0, by the pixel under the cursor. The four possible combinations of values for the data bit and the mask bit are:

- Data bit 0, Mask bit 1. The resulting pixel on the screen is white.
- Data bit 1, Mask bit 1. The resulting pixel on the screen is black.
- Data bit 0, Mask bit 0. The resulting pixel on the screen is the same as the pixel under the cursor.
- Data bit 1, Mask bit 0. The resulting pixel on the screen is the inverse of the pixel under the cursor.

Notice that if all mask bits are 0, the cursor is completely transparent, in that the image under the cursor can still be viewed. Pixels under the white part of the cursor appear unchanged; under the black part of the cursor, black pixels show through as white.

Basic QuickDraw supplies a predefined cursor in the global variable named `arrow`; this is the standard arrow cursor.

Availability
Available in Mac OS X v10.0 and later.

GDevice

```
struct GDevice {
    short gdRefNum;
    short gdID;
    short gdType;
    ITabHandle gdITable;
    short gdResPref;
    SProcHndl gdSearchProc;
    CProcHndl gdCompProc;
    short gdFlags;
    PixMapHandle gdPMap;
    long gdRefCon;
    GDHandle gdNextGD;
    Rect gdRect;
    long gdMode;
    short gdCCBytes;
    short gdCCDepth;
    Handle gdCCXData;
    Handle gdCCXMask;
    long gdReserved;
};
typedef struct GDevice GDevice;
typedef GDevice * GDPtr;
typedef GDPtr * GDHandle;
```

Fields

`gdRefNum`
The reference number of the driver for the screen associated with the video device. For most video devices, this information is set at system startup time.

`gdID`
Reserved. If you create your own `GDevice` structure, set this field to 0.

`gdType`
The general type of graphics device. See "Graphics Device Type Constants" (page 2891) for a description of the values which you can use in this field.

`gdITable`
A handle to the inverse table for color mapping.

`gdResPref`
The preferred resolution for inverse tables.

`gdSearchProc`
A handle to the list of search functions. Its value is `NULL` for the default function.

`gdCompProc`
A handle to a list of complement functions. Its value is `NULL` for the default function.

`gdFlags`
The `GDevice` structure's attributes. To set the attribute bits in the `gdFlags` field, use the `SetDeviceAttribute` (page 2793) function. Do not set `gdFlags` directly in the `GDevice` structure.

`gdPMap`
: A handle to a `PixMap` structure giving the dimension of the image buffer, along with the characteristics of the graphics device (resolution, storage format, color depth, and color table). For `GDevice` structures, the high bit of the global variable

```
(((**TheGDevice).**gdPMap).**pmTable).ctFlags
```

is always set.

`gdRefCon`
: A value used by system software to pass device-related parameters. Since a graphics device is shared, do not store data here.

`gdNextGD`
: A handle to the next graphics device in the device list. If this is the last graphics device in the device list, the field contains 0.

`gdRect`
: The boundary rectangle of the graphics device represented by the `GDevice` structure. The main screen has the upper-left corner of the rectangle set to (0,0). All other graphics devices are relative to this point.

`gdMode`
: The current setting for the graphics device mode. This value is passed to the video driver to set its pixel depth and to specify color or black and white; applications do not need this information.

`gdCCBytes`
: The `rowBytes` value of the expanded cursor. Your application should not change this field.

`gdCCDepth`
: The depth of the expanded cursor. Your application should not change this field.

`gdCCXData`
: A handle to the cursor's expanded data. Your application should not change this field.

`gdCCXMask`
: A handle to the cursor's expanded mask. Your application should not change this field.

`gdReserved`
: Reserved for future expansion; it must be set to 0 for future compatibility.

Discussion

Color QuickDraw stores state information for video devices and offscreen graphics worlds in `GDevice` structures. When the system starts up, it allocates and initializes one handle to a `GDevice` structure for each video device it finds. When you use the Offscreen Graphics Devices function, `NewGWorld`, Color QuickDraw automatically creates a `GDevice` structure for the new offscreen graphics world. The system links these `GDevice` structures in a list, called the device list. (You can find a handle to the first element in the device list in the global variable `DeviceList`.) By default, the `GDevice` structure corresponding to the first video device found is marked as the current device. All other graphics devices in the list are initially marked as inactive.

When the user moves a window or creates a window on another screen, and your application draws into that window, Color QuickDraw automatically makes the video device for that screen the current device. Color QuickDraw stores that information in the global variable `TheGDevice`.

`GDevice` structures that correspond to video devices have drivers associated with them. These drivers can be used to change the mode of the video device from black and white to color and to change the pixel depth. Application-created `GDevice` structures usually don't require drivers.

Your application should never need to directly change the fields of a `GDevice` structure. If you find it absolutely necessary for your application to so, immediately use the `GDeviceChanged` function to notify QuickDraw that your application has changed the `GDevice` structure.

`QuickdrawTypes.h`

GrafVars

```
struct GrafVars {
    RGBColor rgbOpColor;
    RGBColor rgbHiliteColor;
    Handle pmFgColor;
    short pmFgIndex;
    Handle pmBkColor;
    short pmBkIndex;
    short pmFlags;
};
typedef struct GrafVars GrafVars;
typedef GrafVars * GVarPtr;
```

Fields

`rgbOpColor`
The color for the arithmetic transfer operations `addPin`, `subPin`, and `blend`.

`rgbHiliteColor`
The highlight color for this graphics port.

`pmFgColor`
A handle to the palette that contains the foreground color.

`pmFgIndex`
The index value into the palette for the foreground color.

`pmBkColor`
A handle to the palette that contains the background color.

`pmBkIndex`
The index value into the palette for the background color.

`pmFlags`
Flags private to the Palette Manager.

Discussion

The `GrafVars` structure contains color information in addition to that in the `CGrafPort` structure, of which it is logically a part; the information is used by QuickDraw and the Palette Manager.

Availability

Available in Mac OS X v10.0 and later.

GWorldFlags

```
typedef unsigned long GWorldFlags;
```

Discussion
Several functions expect or return values defined by the `GWorldFlags` data type. See "Graphics World Flags" (page 2891) for a detailed description of these flags.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`QDOffscreen.h`

GWorldPtr

Defines a pointer to a structure that your application can use to refer to an offscreen graphics world.

```
typedef CGrafPtr GWorldPtr;
```

Discussion
An offscreen graphics world in color QuickDraw contains a `CGrafPort` structure—and its handles to associated `PixMap` and `ColorTable` structures—that describes an offscreen graphics port and contains references to a `GDevice` structure and other state information. The actual data structure for an offscreen graphics world is kept private to allow for future extensions. However, when your application uses the `NewGWorld` function to create an offscreen world, `NewGWorld` returns a pointer of type `GWorldPtr` by which your application refers to the offscreen graphics world.

On computers lacking color QuickDraw, `GWorldPtr` points to an extension of the `GrafPort` structure.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`QDOffscreen.h`

ITab

```
struct ITab {
    long iTabSeed;
    short iTabRes;
    Byte iTTable[1];
};
typedef struct ITab ITab;
typedef ITab * ITabPtr;
typedef ITabPtr * ITabHandle;
```

Fields

`iTabSeed`
The `iTabSeed` value, initially set from the corresponding CLUT's `ctSeed` field. If at any time these do not match, then the color table was changed, and the inverse table needs to be rebuilt.

`iTabRes`
The resolution of this inverse table.

`iTTable`
An array of index values. The size of the `iTabTable` field in bytes is `23*iTabRes`.

Discussion
The `ITab` data structure contains the inverse table information that the Color Manager uses for fast mapping of RGB color values.

MacRegion

```
struct MacRegion {
    UInt16 rgnSize;
    Rect rgnBBox;
};
typedef struct MacRegion MacRegion;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`QuickdrawTypes.h`

MatchRec

```
struct MatchRec {
    unsigned short red;
    unsigned short green;
    unsigned short blue;
    long matchData;
};
typedef struct MatchRec MatchRec;
```

Fields

`red`
Red value of the seed.

`green`
Green value of the seed.

`blue`
Blue value of the seed.

`matchData`
The value passed in the `matchData` parameter of the `SeedCFill` or `CalcCMask` function.

Discussion

When `SeedCFill` (page 2787) or `CalcCMask` (page 2577) calls your color search function, the `GDRefCon` field of the current `GDevice` structure contains a pointer to a `MatchRec` structure. This structure contains the RGB value of the seed pixel or seed color for which your color search function searches.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`QuickdrawTypes.h`

OpenCPicParams

```
struct OpenCPicParams {
    Rect srcRect;
    Fixed hRes;
    Fixed vRes;
    short version;
    short reserved1;
    long reserved2;
};
typedef struct OpenCPicParams OpenCPicParams;
```

Fields

`srcRect`
The optimal bounding rectangle for the resolution indicated by the `hRes` and `vRes` fields. When you later call the `DrawPicture` (page 2610) function to play back the saved picture, specify a destination rectangle and `DrawPicture` scales the picture so that it is completely aligned with the destination rectangle.

`hRes`
The best horizontal resolution for the picture. A value of $00480000 specifies a horizontal resolution of 72 dpi.

`vRes`
: The best vertical resolution for the picture. A value of $00480000 specifies a vertical resolution of 72 dpi.

`version`
: Always set this field to –2.

`reserved1`
: Reserved; set to 0.

`reserved2`
: Reserved; set to 0.

Discussion
When you use the `OpenCPicture` function to begin creating a picture, you must pass it information in an `OpenCPicParams` structure. This structure provides a simple mechanism for specifying resolutions when creating images. For example, applications that create pictures from scanned images can specify resolutions higher than 72 dpi for these pictures in `OpenCPicParams` structures.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`QuickdrawTypes.h`

Pattern

```
struct Pattern {
    UInt8 pat[8];
};
typedef struct Pattern Pattern;
typedef Pattern * PatPtr;
typedef PatPtr * PatHandle;
```

Discussion
Your application typically does not create `Pattern` structures. Although you can create `Pattern` structures in your program code, it is usually easier to create bit patterns using the pattern, 'PAT', or pattern list, 'PAT#', resource.

A bit pattern is a 64-bit image, organized as an 8-by-8 bit square, that defines a repeating design or tone. When a pattern is drawn, it is aligned so that adjacent areas of the same pattern in the same graphics port form a continuous, coordinated pattern. QuickDraw provides predefined patterns in global variables named `white`, `black`, `gray`, `ltGray`, and `dkGray`. The row width of a pattern is 1 byte.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`QuickdrawTypes.h`

PenState

```
struct PenState {
    Point pnLoc;
    Point pnSize;
    short pnMode;
    Pattern pnPat;
};
typedef struct PenState PenState;
```

Fields

`pnLoc`

For the current graphics port at the time the `GetPenState` function was called, the value of that graphics port's `pnLoc` field. This value is the point where QuickDraw begins drawing next. The location of the graphics pen is a point in the graphics port's coordinate system, not a pixel in a bit image. The upper-left corner of the pen is at the pen location the graphics pen hangs below and to the right of this point.

`pnSize`

For the current graphics port at the time the `GetPenState` function was called, the value of that graphics port's `pnSize` field. The graphics pen is rectangular in shape, and its width and height are specified by the values in the `pnSize` field. The default size is a 1-by-1 bit square; the width and height can range from 0 by 0 to 32,767 by 32,767. If either the pen width or the pen height is 0, the pen does not draw. Heights or widths of less than 0 are undefined.

`pnMode`

The pattern mode—that is, for the current graphics port at the time the `GetPenState` function was called, the value of that graphics port's `pnMode` field. This value determines how the pen pattern is to affect what's already in the bit image when lines or shapes are drawn. When the graphics pen draws, QuickDraw first determines what bits in the bit image are affected, finds their corresponding bits in the pattern, and then transfers the bits from the pattern into the image according to this mode, which specifies one of eight Boolean transfer operations. The resulting bit is stored into its proper place in the bit image.

`pnPat`

For the current graphics port at the time the `GetPenState` function was called, the pen pattern for that graphics port. This pattern determines how the bits under the graphics pen are affected when lines or shapes are drawn.

Discussion

The `GetPenState` (page 2647) function saves the location, size, pattern, and pattern mode of the graphics pen for the current graphics port in a `PenState` structure, which is a data structure of type `PenState`. After changing the graphics pen as necessary, you can later restore these pen states with the `SetPenState` (page 2798) function.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`QuickdrawTypes.h`

Picture

```
struct Picture {
    short picSize;
    Rect picFrame;
};
typedef struct Picture Picture;
typedef Picture * PicPtr;
typedef PicPtr * PicHandle;
```

Fields

`picSize`

The size of the rest of this structure for a version 1 picture. To maintain compatibility with the version 1 picture format, the `picSize` field was not changed for the version 2 picture or extended version 2 formats. The information in this field is used only for version 1 pictures, which cannot exceed 32 KB in size. Because version 2 and extended version 2 pictures can be much larger than the 32 KB limit imposed by the 2-byte `picSize` field, you should use the Memory Manager function `GetHandleSize` to determine the size of a picture in memory; you should use the File Manager function `PBGetFInfo` to determine the size of a picture in a `'PICT'` file; and you should use the Resource Manager function `GetMaxResourceSize` to determine the size of a `'PICT'` resource.

`picFrame`

The bounding rectangle for the picture defined in the rest of this structure. The `DrawPicture` function uses this rectangle to scale the picture if you draw it into a destination rectangle of a different size.

Discussion

When you use the `OpenCPicture` (page 2734) or `OpenPicture` (page 2736) function, QuickDraw begins collecting your subsequent drawing commands in a `Picture` structure. (You use the `ClosePicture` function to complete a picture definition.) When you use the `GetPicture` (page 2648) function to retrieve a picture stored in a resource, `GetPicture` reads the resource into memory as a `Picture` structure. By using the `DrawPicture` (page 2610) procedure, you can draw onscreen the picture defined by the commands stored in the `Picture` structure.

A picture opcode is a number that the `DrawPicture` function uses to determine what object to draw or what mode to change for subsequent drawing. Generally, do not read or write this picture data directly. Instead, use the `OpenCPicture` (or `OpenPicture`), `ClosePicture`, and `DrawPicture` functions to process these opcodes.

The `Picture` structure can also contain picture comments. Created by applications using the `PicComment` function, picture comments contain data or commands for special processing by output devices, such as PostScript printers.

You can use File Manager functions to save the picture in a file of type `'PICT'`, you can use Resource Manager functions to save the picture in a resource of type `'PICT'`, and you can use the Scrap Manager function `PutScrap` to store the picture in `'PICT'` scrap format.

Availability

Available in Mac OS X v10.0 and later.

`QuickdrawTypes.h`

PixelType

```
typedef SInt8 PixelType;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`QuickdrawTypes.h`

PixMap

```
struct PixMap {
    Ptr baseAddr;
    short rowBytes;
    Rect bounds;
    short pmVersion;
    short packType;
    long packSize;
    Fixed hRes;
    Fixed vRes;
    short pixelType;
    short pixelSize;
    short cmpCount;
    short cmpSize;
    long planeBytes;
    CTabHandle pmTable;
    long pmReserved;
};
typedef struct PixMap PixMap;
typedef PixMap * PixMapPtr;
typedef PixMapPtr * PixMapHandle;
```

Fields

`baseAddr`

For an onscreen pixel image, a pointer to the first byte of the image. For optimal performance, this should be a multiple of 4. The pixel image that appears on a screen is normally stored on a graphics card rather than in main memory.

Note that the `baseAddr` field of the `PixMap` structure for an offscreen graphics world contains a handle instead of a pointer. You must use the `GetPixBaseAddr` function to obtain a pointer to the `PixMap` structure for an offscreen graphics world. Your application should never directly access the `baseAddr` field of the `PixMap` structure for an offscreen graphics world.

`rowBytes`

The offset in bytes from one row of the image to the next. The value must be even, less than $4000, and for best performance it should be a multiple of 4. The high 2 bits of `rowBytes` are used as flags. If bit 15 = 1, the data structure pointed to is a `PixMap` structure; otherwise it is a `BitMap` structure.

`bounds`

The boundary rectangle, which links the local coordinate system of a graphics port to QuickDraw's global coordinate system and defines the area of the bit image into which QuickDraw can draw. By default, the boundary rectangle is the entire main screen. Do not use the value of this field to determine the size of the screen instead use the value of the `gdRect` field of the `GDevice` structure for the screen.

`pmVersion`
: The version number of QuickDraw that created this `PixMap` structure. The value of `pmVersion` is normally 0. If `pmVersion` is 4, QuickDraw treats the `PixMap` structure's `baseAddr` field as 32-bit clean. All other flags are private. Most applications never need to set this field.

`packType`
: The packing algorithm used to compress image data. QuickDraw currently supports a `packType` of 0, which means no packing, and values of 1 to 4 for packing direct pixels.

`packSize`
: The size of the packed image in bytes. When the `packType` field contains the value 0, this field is always set to 0.

`hRes`
: The horizontal resolution of the pixel image in pixels per inch. This value is of type `Fixed`; by default, the value here is $00480000 (for 72 pixels per inch).

`vRes`
: The vertical resolution of the pixel image in pixels per inch. This value is of type `Fixed`; by default, the value here is $00480000 (for 72 pixels per inch).

`pixelType`
: The storage format for a pixel image. Indexed pixels are indicated by a value of 0. Direct pixels are specified by a value of `RGBDirect`, or 16. In the `PixMap` structure of the `GDevice` structure for a direct device, this field is set to the constant `RGBDirect` when the screen depth is set.

`pixelSize`
: Pixel depth; that is, the number of bits used to represent a pixel. Indexed pixels can have sizes of 1, 2, 4, and 8 bits; direct pixel sizes are 16 and 32 bits.

`cmpCount`
: The number of components used to represent a color for a pixel. With indexed pixels, each pixel is a single value representing an index in a color table, and therefore this field contains the value 1—the index is the single component. With direct pixels, each pixel contains three components—one integer each for the intensities of red, green, and blue—so this field contains the value 3.

`cmpSize`
: The size in bits of each component for a pixel. QuickDraw expects that the sizes of all components are the same, and that the value of the `cmpCount` field multiplied by the value of the `cmpSize` field is less than or equal to the value in the `pixelSize` field.

  For an indexed pixel value, which has only one component, the value of the `cmpSize` field is the same as the value of the `pixelSize` field—that is, 1, 2, 4, or 8.

  For direct pixels there are two additional possibilities:

  - A 16-bit pixel, which has three components, has a `cmpSize` value of 5. This leaves an unused high-order bit, which QuickDraw sets to 0.
  - A 32-bit pixel, which has three components (red, green, and blue), has a `cmpSize` value of 8. This leaves an unused high-order byte, which QuickDraw sets to 0.

  Generally, therefore, your application should clear the memory for the image to 0 before creating a 16-bit or 32-bit image. The Memory Manager functions `NewHandleClear` and `NewPtrClear` assist you in allocating pre-zeroed memory.

`planeBytes`
: The offset in bytes from one drawing plane to the next. This field is set to 0.

`pmTable`
: A handle to a `ColorTable` structure for the colors in this pixel map.

`pmReserved`
Reserved for future expansion. This field must be set to 0 for future compatibility.

Discussion
The `PixMap` structure contains information about the dimensions, contents, storage format, depth, resolution, and color usage of a pixel image. The pixel map for a window's color graphics port always consists of the pixel depth, color table, and boundary rectangle of the main screen, even if the window is created on or moved to an entirely different screen.

Availability
Available in Mac OS X v10.0 and later.

`QuickdrawTypes.h`

PixPat

```
struct PixPat {
    short patType;
    PixMapHandle patMap;
    Handle patData;
    Handle patXData;
    short patXValid;
    Handle patXMap;
    Pattern pat1Data;
};
typedef struct PixPat PixPat;
typedef PixPat * PixPatPtr;
typedef PixPatPtr * PixPatHandle;
```

Fields
`patType`
The pattern's type. The value 0 specifies a basic QuickDraw bit pattern, the value 1 specifies a full-color pixel pattern, and the value 2 specifies an RGB pattern.

`patMap`
A handle to a `PixMap` (page 2869) structure that describes the pattern's pixel image. The `PixMap` structure can contain indexed or direct pixels.

`patData`
A handle to the pattern's pixel image.

`patXData`
A handle to an expanded pixel image used internally by QuickDraw.

`patXValid`
A flag that, when set to –1, invalidates the expanded data.

`patXMap`
Reserved for use by QuickDraw.

`pat1Data`
A bit pattern to be used when this pattern is drawn into a `GrafPort` structure. The `NewPixPat` (page 2720) function sets this field to 50 percent gray.

Discussion
Your application typically does not create `PixPat` structures. Although you can create such structures in your program code, it is usually easier to create pixel patterns using the pixel pattern resource, `'ppat'`.

When used for a color graphics port, the basic QuickDraw functions `PenPat` and `BackPat` store pixel patterns in, respectively, the `pnPixPat` and `bkPixPat` fields of the `CGrafPort` structure and set the `patType` field of the `PixPat` field to 0 to indicate that the `PixPat` structure contains a bit pattern. Such patterns are limited to 8-by-8 pixel dimensions and, instead of being drawn in black and white, are always drawn using the colors specified in the `CGrafPort` structure's `rgbFgColor` and `rgbBkColor` fields, respectively.

In a full-color pixel pattern, the `patType` field contains the value 1, and the pattern's dimensions, depth, resolution, set of colors, and other characteristics are defined by a `PixMap` structure, referenced by the handle in the `patMap` field of the `PixPat` structure. Full-color pixel patterns contain color tables that describe the colors they use. Generally such a color table contains one entry for each color used in the pattern. For instance, if your pattern has five colors, you would probably create a 4 bits per pixel pattern that uses pixel values 0–4, and a color table with five entries, numbered 0–4, that contain the RGB specifications for those pixel values.

However, if you don't specify a color table for a pixel value, QuickDraw assigns a color to that pixel value. The largest unassigned pixel value becomes the foreground color the smallest unassigned pixel value is assigned the background color. Remaining unassigned pixel values are given colors that are evenly distributed between the foreground and background.

For instance, in the color table mentioned above, pixel values 5–15 are unused. Assume that the foreground color is black and the background color is white. Pixel value 15 is assigned the foreground color, black pixel value 5 is assigned the background color, white the nine pixel values between them are assigned evenly distributed shades of gray. If the `PixMap` structure's color table is set to `NULL`, all pixel values are determined by blending the foreground and background colors.

Full-color pixel patterns are not limited to a fixed size: their height and width can be any power of 2, as specified by the height and width of the boundary rectangle for the `PixMap` structure specified in the `patMap` field. A pattern 8 bits wide, which is the size of a bit pattern, has a row width of just 1 byte, contrary to the usual rule that the `rowBytes` field must be even. Read this pattern type into memory using the `GetPixPat` (page 2651) function, and set it using the `PenPixPat` (page 2747) or `BackPixPat` (page 2576) functions.

The pixel map specified in the `patMap` field of the `PixPat` structure defines the pattern's characteristics. The `baseAddr` field of the `PixMap` structure for that pixel map is ignored. For a full-color pixel pattern, the actual pixel image defining the pattern is stored in the handle in the `patData` field of the `PixPat` structure. The pattern's pixel depth need not match that of the pixel map into which it's transferred the depth is adjusted automatically when the pattern is drawn. QuickDraw maintains a private copy of the pattern's pixel image, expanded to the current screen depth and aligned to the current graphics port, in the `patXData` field of the `PixPat` structure.

In an RGB pixel pattern, the `patType` field contains the value 2. Using the `MakeRGBPat` (page 2706) function, your application can specify the exact color it wants to use. QuickDraw selects a pattern to approximate that color. In this way, your application can effectively increase the color resolution of the screen. RGB pixel patterns are particularly useful for dithering: mixing existing colors together to create the illusion of a third color that's unavailable on an indexed device. The `MakeRGBPat` function aids in this process by constructing a dithered pattern to approximate a given absolute color. An RGB pixel pattern can display 125 different patterns on a 4-bit screen, or 2197 different patterns on an 8-bit screen.

An RGB pixel pattern has an 8-by-8 pixel pattern that is 2 bits deep. For an RGB pixel pattern, the `RGBColor` structure that you specify to the `MakeRGBPat` function defines the image; there is no image data.

Your application should never need to directly change the fields of a `PixPat` structure. If you find it absolutely necessary for your application to so, immediately use the `PixPatChanged` (page 2750) function to notify QuickDraw that your application has changed the `PixPat` structure.

Polygon

```
typedef MacPolygon Polygon;
```

Discussion
After you use the `OpenPoly` function to create a polygon, QuickDraw begins collecting the line-drawing information you provide into a `MacPolygon` structure. The `OpenPoly` function returns a handle to the newly allocated `MacPolygon` structure. Thereafter, your application normally refers to your new polygon by this handle, because QuickDraw functions such as `FramePoly` and `PaintPoly` expect a handle to a `Polygon` as their first parameter.

A polygon is defined by a sequence of connected lines. A `MacPolygon` structure consists of two fixed-length fields followed by a variable-length array of points: the starting point followed by each successive point to which a line is drawn.

Your application typically does not need to create a `MacPolygon` structure.

QDPictRef

Defines an opaque data type that represents a QuickDraw picture in the Quartz 2D graphics environment.

```
typedef struct QDPict * QDPictRef;
```

Discussion
This opaque type is used to draw QuickDraw picture data in a Quartz context. (Quartz 2D defines an analogous opaque type called `CGPDFDocumentRef` (page 340) which is used to draw PDF data in a Quartz context.) An instance of the `QDPictRef` type is called a **QDPict picture**. There are two ways to create a QDPict picture:

- You can call `QDPictCreateWithProvider` (page 2766), passing in a Quartz data provider for the picture data. Typically the source of this data is a `'PICT'` resource.
- You can call `QDPictCreateWithURL` (page 2767), passing in a Core Foundation URL that specifies a file with picture data in the data fork.

Both functions verify that picture header information is present, starting at either byte 1 or byte 513 of the picture data.

To draw a QDPict picture in a Quartz context, you call `QDPictDrawToCGContext` (page 2767). To get the bounds or native resolution of a QDPict picture, you call `QDPictGetBounds` (page 2768) or `QDPictGetResolution` (page 2769).

When you draw a QDPict picture in a PDF context, you can save the drawing in a PDF file. This is the recommended way to convert QuickDraw pictures into single-page PDF documents.

These additional sources of information may be helpful:

- The sample Carbon program *CGDrawPicture* shows how to use this opaque type to draw QuickDraw pictures in a Quartz context.
- For general information about QuickDraw pictures and the PICT graphics format, see Chapter 7 in *Inside Macintosh: Imaging With QuickDraw*.

QDProcs

```
struct QDProcs {
    QDTextUPP textProc;
    QDLineUPP lineProc;
    QDRectUPP rectProc;
    QDRRectUPP rRectProc;
    QDOvalUPP ovalProc;
    QDArcUPP arcProc;
    QDPolyUPP polyProc;
    QDRgnUPP rgnProc;
    QDBitsUPP bitsProc;
    QDCommentUPP commentProc;
    QDTxMeasUPP txMeasProc;
    QDGetPicUPP getPicProc;
    QDPutPicUPP putPicProc;
};
typedef struct QDProcs QDProcs;
typedef QDProcs * QDProcsPtr;
```

Fields

`textProc`
A pointer to the low-level function that draws text. The standard QuickDraw function is the `StdText` function.

`lineProc`
A pointer to the low-level function that draws lines. The standard QuickDraw function is the `StdLine` (page 2818) function.

`rectProc`
A pointer to the low-level function that draws rectangles. The standard QuickDraw function is the `StdRect` (page 2821) function.

`rRectProc`
: A pointer to the low-level function that draws rounded rectangles. The standard QuickDraw function is the `StdRRect` (page 2822) function.

`ovalProc`
: A pointer to the low-level function that draws ovals. The standard QuickDraw function is the `StdOval` (page 2819) function.

`arcProc`
: A pointer to the low-level function that draws arcs. The standard QuickDraw function is the `StdArc` (page 2815) function.

`polyProc`
: A pointer to the low-level function that draws polygons. The standard QuickDraw function is the `StdPoly` (page 2820) function.

`rgnProc`
: A pointer to the low-level function that draws regions. The standard QuickDraw function is the `StdRgn` (page 2822) function.

`bitsProc`
: A pointer to the low-level function that copies bitmaps. The standard QuickDraw function is the `StdBits` (page 2816) function.

`commentProc`
: A pointer to the low-level function for processing a picture comment. The standard QuickDraw function is the `StdComment` (page 2817) function.

`txMeasProc`
: A pointer to the low-level function for measuring text width. The standard QuickDraw function is the `StdTxMeas` function.

`getPicProc`
: A pointer to the low-level function for retrieving information from the definition of a picture. The standard QuickDraw function is the `StdGetPic` (page 2817) function.

`putPicProc`
: A pointer to the low-level function for saving information as the definition of a picture. The standard QuickDraw function is the `StdPutPic` (page 2820) function.

Discussion
You need to use the `QDProcs` structure only if you customize one or more of QuickDraw's low-level drawing functions. Use `SetStdProcs` (page 2812) to create a `QDProcs` structure.

The `QDProcs` structure contains pointers to low-level drawing functions. You can change the fields of this structure to point to functions of your own devising.

ReqListRec

```
struct ReqListRec {
    short reqLSize;
    short reqLData[1];
};
typedef struct ReqListRec ReqListRec;
```

Fields

`reqLSize`

The size of this `ReqListRec` data structure minus one.

`reqLData`

An array of integers representing offsets into a color table.

Discussion

The `ReqListRec` data structure is a parameter to the `SaveEntries` function by which you can describe color table entries to be saved.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`QuickdrawTypes.h`

RGBColor

```
struct RGBColor {
    unsigned short red;
    unsigned short green;
    unsigned short blue;
};
typedef struct RGBColor RGBColor;
typedef RGBColor * RGBColorPtr;
```

Fields

`red`

An unsigned integer specifying the red value of the color.

`green`

An unsigned integer specifying the green value of the color.

`blue`

An unsigned integer specifying the blue value of the color.

Discussion

You usually specify a color to QuickDraw by creating an `RGBColor` structure in which you assign the red, green, and blue values of the foreground color. For example, when you want to set the foreground color for drawing, you create an `RGBColor` structure that defines the foreground color you desire; then you pass that structure as a parameter to the `RGBForeColor` function.

In an `RGBColor` structure, three 16-bit unsigned integers give the intensity values for the three additive primary colors.

Availability

Available in Mac OS X v10.0 and later.

Declared In
IOMacOSTypes.h

RgnHandle

An opaque type that represents a QuickDraw region.

```
typedef struct OpaqueRgnHandle * RgnHandle;
```

Discussion
A region is an arbitrary area or set of areas on the QuickDraw coordinate plane. The outline of a region should be one or more closed loops.

Availability
Available in Mac OS X v10.0 and later.

Declared In
QuickdrawTypes.h

SProcRec

```
struct SProcRec {
    Handle nxtSrch;
    ColorSearchUPP srchProc;
};
typedef struct SProcRec SProcRec;
typedef SProcRec * SProcPtr;
```

Fields
nxtSrch
A handle to the next SProcRec data structure in the chain of search functions.
srchProc
A pointer to a custom search function (described in ColorSearchProcPtr (page 2834)).

Discussion
The SProcRec data structure contains a pointer to a custom search function and a handle to the next SProcRec data structure in the function list.

Availability
Available in Mac OS X v10.0 and later.

Declared In
QuickdrawTypes.h

WindowPtr

An opaque type that represents a window.

```
typedef struct OpaqueWindowPtr * WindowPtr;
```

Discussion
This is a Window Manager data type, defined in QuickDraw for historical reasons. Its role in Mac OS X is to serve as the basis for the widely used WindowRef data type.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`QuickdrawTypes.h`

xColorSpec

```
struct xColorSpec {
    short value;
    RGBColor rgb;
    short xalpha;
};
typedef struct xColorSpec xColorSpec;
typedef xColorSpec * xColorSpecPtr;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`QuickdrawTypes.h`

xCSpecArray

```
typedef xColorSpec xCSpecArray[1];
```

Availability
Available in Mac OS X v10.0 and later.

`QuickdrawTypes.h`

Constants

chunky

```
enum {
    chunky = 0,
    chunkyPlanar = 1,
    planar = 2
};
```

Color Constants

```
enum {
    blackColor = 33,
    whiteColor = 30,
    redColor = 205,
    greenColor = 341,
    blueColor = 409,
    cyanColor = 273,
    magentaColor = 137,
    yellowColor = 69
};
```

Constants

`blackColor`
Represents black.
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawTypes.h`.

`whiteColor`
Represents white.
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawTypes.h`.

`redColor`
Represents red.
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawTypes.h`.

`greenColor`
Represents green.
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawTypes.h`.

`blueColor`
Represents blue.
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawTypes.h`.

`cyanColor`
Represents cyan.
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawTypes.h`.

`magentaColor`
Represents magenta.
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawTypes.h`.

`yellowColor`
Represents yellow.
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawTypes.h`.

Discussion
These constants are used in the `color` parameter of the `ForeColor` (page 2628) and `BackColor` (page 2574) functions to specify one of the eight basic QuickDraw colors.

colorXorXFer

```
enum {
    colorXorXFer = 52,
    noiseXFer = 53,
    customXFer = 54
};
```

Cursor ID Constants

```
enum {
    sysPatListID = 0,
    iBeamCursor = 1,
    crossCursor = 2,
    plusCursor = 3,
    watchCursor = 4
};
```

Constants
`iBeamCursor`
The I-beam cursor; to select text
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawTypes.h`.

`crossCursor`
The crosshairs cursor; to draw graphics
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawTypes.h`.

`plusCursor`
The plus sign cursor; to select cells

Available in Mac OS X v10.0 and later.

Declared in `QuickdrawTypes.h`.

`watchCursor`
The wristwatch cursor; to indicate a short operation in progress

Available in Mac OS X v10.0 and later.

Declared in `QuickdrawTypes.h`.

Discussion
When passing a value to the `Show_Cursor` function, use the `Cursors` data type to represent the kind of cursor to show.

cursorDoesAnimate

```
enum {
    cursorDoesAnimate = 1L << 0,
    cursorDoesHardware = 1L << 1,
    cursorDoesUnreadableScreenBits = 1L << 2
};
```

Device Attribute Constants

```
enum {
    interlacedDevice = 2,
    hwMirroredDevice = 4,
    roundedDevice = 5,
    hasAuxMenuBar = 6,
    burstDevice = 7,
    ext32Device = 8,
    ramInit = 10,
    mainScreen = 11,
    allInit = 12,
    screenDevice = 13,
    noDriver = 14,
    screenActive = 15,
    hiliteBit = 7,
    pHiliteBit = 0,
    defQDColors = 127,
    RGBDirect = 16,
    baseAddr32 = 4
};
```

Constants
`burstDevice`
If this bit is set to 1, the graphics device supports block transfer.

Available in Mac OS X v10.0 and later.

Declared in `QuickdrawTypes.h`.

`ext32Device`
If this bit is set to 1, the graphics device must be used in 32-bit mode.
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawTypes.h`.

`ramInit`
If this bit is set to 1, the graphics device has been initialized from RAM.
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawTypes.h`.

`mainScreen`
If this bit is set to 1,the graphics device is the main screen.
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawTypes.h`.

`allInit`
If this bit is set to 1, all graphics devices were initialized from the `'scrn'` resource.
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawTypes.h`.

`screenDevice`
If this bit is set to 1, the graphics device is a screen.
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawTypes.h`.

`noDriver`
If this bit is set to 1, the `GDevice` structure has no driver.
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawTypes.h`.

`screenActive`
If this bit is set to 1, the graphics device is active.
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawTypes.h`.

Discussion
These constants are used in the `attribute` parameters of the `SetDeviceAttribute` (page 2793) and `TestDeviceAttribute` (page 2826) functions, and in the `deviceFlags` parameter of the `DeviceLoopDrawingProcPtr` (page 2836) callback. These constants represent the `GDevice` structure's attributes, as bits in the `gdFlags` field.

Device Loop Flags

```
enum {
    singleDevices = 1 << singleDevicesBit,
    dontMatchSeeds = 1 << dontMatchSeedsBit,
    allDevices = 1 << allDevicesBit
};
```

Constants

`singleDevices`

If this flag is not set, `DeviceLoop` calls your drawing function only once for each set of similar graphics devices, and the first one found is passed as the target device. (It is assumed to be representative of all the similar graphics devices.) If you set the `singleDevices` flag, then `DeviceLoop` does not group similar graphics devices, (that is, those having identical pixel depths, black-and-white or color settings, and matching color table seeds), when it calls your drawing function.

Available in Mac OS X v10.0 and later.

Declared in `QuickdrawTypes.h`.

`dontMatchSeeds`

If you set the `dontMatchSeeds` flag, then `DeviceLoop` does not consider the `ctSeed` field of `ColorTable` structures for graphics devices when comparing them; `DeviceLoop` ignores this flag if you set the `singleDevices` flag.

Available in Mac OS X v10.0 and later.

Declared in `QuickdrawTypes.h`.

`allDevices`

If you set the `allDevices` flag, `DeviceLoop` ignores the `drawingRgn` parameter and calls your drawing function for every device. The value of the current graphics port's `visRgn` field is not affected when you set this flag.

Available in Mac OS X v10.0 and later.

Declared in `QuickdrawTypes.h`.

Discussion

When you use the `DeviceLoop` (page 2597) function, you can change its default behavior by using the `flags` parameter to specify one or more members of the set of flags defined by the `DeviceLoopFlags` data type. If you want to use the default behavior of `DeviceLoop`, specify 0 in the `flags` parameter.

deviceIsIndirect

```
enum {
    deviceIsIndirect = (1L << 0),
    deviceNeedsLock = (1L << 1),
    deviceIsStatic = (1L << 2),
    deviceIsExternalBuffer = (1L << 3),
    deviceIsDDSurface = (1L << 4),
    deviceIsDCISurface = (1L << 5),
    deviceIsGDISurface = (1L << 6),
    deviceIsAScreen = (1L << 7),
    deviceIsOverlaySurface = (1L << 8)
};
```

Drag Constraint Constants

When passed to the `DragControl` function, specify how a user can move a control.

```
enum {
    kNoConstraint = 0,
    kVerticalConstraint = 1,
    kHorizontalConstraint = 2
};
```

Constants

`kNoConstraint`
No constraint.
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawTypes.h`.

`kVerticalConstraint`
Constrain movement to horizontal axis only.
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawTypes.h`.

`kHorizontalConstraint`
Constrain movement to vertical axis only.
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawTypes.h`.

Graphics Device Type Constants

```
enum {
    picLParen = 0,
    picRParen = 1,
    clutType = 0,
    fixedType = 1,
    directType = 2,
    gdDevType = 0
};
```

Constants

`clutType`
Represents a CLUT device--that is, one with colors mapped with a color lookup table.
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawTypes.h`.

`fixedType`
Represents a fixed colors device --that is, the color lookup table can't be changed.
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawTypes.h`.

`directType`
Represents a device with direct RGB colors.
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawTypes.h`.

`gdDevType`
If this bit is set to 0, the graphics device is black and white; if it is set to 1, the graphics device supports color.
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawTypes.h`.

Discussion
These constants represent the general type of graphics device for the `gdType` field of the `GDevice` (page 2859) structure.

Graphics World Flags

Specify additional information passed to and from `NewGWorld` (page 2715) and related functions in parameters of type `GWorldFlags` (page 2863).

```
enum {
    pixPurge = 1L << pixPurgeBit,
    noNewDevice = 1L << noNewDeviceBit,
    useTempMem = 1L << useTempMemBit,
    keepLocal = 1L << keepLocalBit,
    useDistantHdwrMem = 1L << useDistantHdwrMemBit,
    useLocalHdwrMem = 1L << useLocalHdwrMemBit,
    pixelsPurgeable = 1L << pixelsPurgeableBit,
    pixelsLocked = 1L << pixelsLockedBit,
    kNativeEndianPixMap = 1L << nativeEndianPixMapBit,
    kAllocDirectDrawSurface = 1L << 14,
    mapPix = 1L << mapPixBit,
    newDepth = 1L << newDepthBit,
    alignPix = 1L << alignPixBit,
    newRowBytes = 1L << newRowBytesBit,
    reallocPix = 1L << reallocPixBit,
    clipPix = 1L << clipPixBit,
    stretchPix = 1L << stretchPixBit,
    ditherPix = 1L << ditherPixBit,
    gwFlagErr = 1L << gwFlagErrBit
};
```

Constants

`pixPurge`

If you specify this flag for the `flags` parameter of the `NewGWorld` function, `UpdateGWorld` (page 2831) makes the base address for the offscreen pixel image purgeable.

Available in Mac OS X v10.0 and later.

Declared in `QDOffscreen.h`.

`noNewDevice`

If you specify this flag for the `flags` parameter of the `UpdateGWorld` (page 2831) function, `NewGWorld` does not create a new offscreen `GDevice` structure; instead, `NewGWorld` uses either the `GDevice` structure you specify or the `GDevice` structure for a video card on the user's system.

Available in Mac OS X v10.0 and later.

Declared in `QDOffscreen.h`.

`useTempMem`

If you specify this in the `flags` parameter of the `UpdateGWorld` (page 2831) function, `NewGWorld` creates the base address for an offscreen pixel image in temporary memory. You generally should not use this flag. You should use temporary memory only for fleeting purposes and only with the `GetPixelsState` (page 2651) function so that other applications can launch.

Available in Mac OS X v10.0 and later.

Declared in `QDOffscreen.h`.

`keepLocal`

If you specify this in the `flags` parameter of the `UpdateGWorld` (page 2831) function, `NewGWorld` creates a pixel image in Macintosh main memory where it cannot be cached to a graphics accelerator card.

If you specify this in the flags parameter of `GetPixelsState` (page 2651), `UpdateGWorld` keeps the offscreen pixel image in Macintosh main memory.

Available in Mac OS X v10.0 and later.

Declared in `QDOffscreen.h`.

`pixelsPurgeable`
: If you specify this in the `state` parameter of the `UpdateGWorld` (page 2831) function, `SetPixelsState` makes the base address for an offscreen pixel map purgeable. If you use the `SetPixelsState` function without passing it this flag, then `SetPixelsState` makes the base address for an offscreen pixel map unpurgeable. If the `GetPixelsState` (page 2651) function returns this flag, then the base address for an offscreen pixel is purgeable.

Available in Mac OS X v10.0 and later.

Declared in `QDOffscreen.h`.

`pixelsLocked`
: If you specify this flag for the `state` parameter of the `SetPixelsState` function, `SetPixelsState` locks the base address for an offscreen pixel image. If you use the `SetPixelsState` function without passing it this flag, then `SetPixelsState` unlocks the offscreen pixel image. If the `GetPixelsState` function returns this flag, then the base address for an offscreen pixel is locked.

Available in Mac OS X v10.0 and later.

Declared in `QDOffscreen.h`.

`kNativeEndianPixMap`
: By default, the function `NewGWorld` (page 2715) allocates pixel buffers with big-endian byte ordering regardless of the system architecture. If this flag is passed in the `flags` parameter of `NewGWorld`, the pixel format will be set to `k32ARGBPixelFormat` or `k16BE555PixelFormat` on a PowerPC system, and to `k32BGRAPixelFormat` or `k16LE555PixelFormat` on an Intel system, for depths 32 or 16, respectively. Note that `NewGWorld` is the only function where this flag is observed; `NewGWorldFromPtr` (page 2718) and `UpdateGWorld` (page 2831) ignore it.

Available in Mac OS X v10.3 and later.

Declared in `QDOffscreen.h`.

`mapPix`
: If the `UpdateGWorld` (page 2831) function returns this flag, then it remapped the colors in the offscreen pixel map to a new color table.

Available in Mac OS X v10.0 and later.

Declared in `QDOffscreen.h`.

`newDepth`
: If the `UpdateGWorld` function returns this flag, then it translated the offscreen pixel map to a different pixel depth.

Available in Mac OS X v10.0 and later.

Declared in `QDOffscreen.h`.

`alignPix`
: If the `UpdateGWorld` function returns this flag, then it realigned the offscreen pixel image to an onscreen window.

Available in Mac OS X v10.0 and later.

Declared in `QDOffscreen.h`.

`newRowBytes`
: If the `UpdateGWorld` function returns this flag, then it changed the `rowBytes` field of the `PixMap` structure for the offscreen graphics world.

Available in Mac OS X v10.0 and later.

Declared in `QDOffscreen.h`.

`reallocPix`
: If the `UpdateGWorld` function returns this flag, then it reallocated the base address for the offscreen pixel image. Your application should then reconstruct the pixel image or draw directly in a window instead of preparing the image in an offscreen graphics world.

  Available in Mac OS X v10.0 and later.

  Declared in `QDOffscreen.h`.

`clipPix`
: If you specify this flag in the `flags` parameter of the `UpdateGWorld` (page 2831) function, then `UpdateGWorld` updates and clips the pixel image to the new boundary rectangle specified. If the `UpdateGWorld` function returns this flag, then it clipped the pixel image.

  Available in Mac OS X v10.0 and later.

  Declared in `QDOffscreen.h`.

`stretchPix`
: If you specify this flag in the `flags` parameter of the `UpdateGWorld` (page 2831) function, then `UpdateGWorld` updates and stretches or shrinks the pixel image to the new boundary rectangle specified. If the `UpdateGWorld` function returns this flag, then it stretched or shrank the offscreen image.

  Available in Mac OS X v10.0 and later.

  Declared in `QDOffscreen.h`.

`ditherPix`
: If you specify this flag in the `flags` parameter of the `UpdateGWorld` (page 2831) function, then `UpdateGWorld` dithers the pixel image to the new boundary rectangle specified. Include this flag with the `clipPix` or `stretchPix` flag. If the `UpdateGWorld` function returns this flag, then it dithered the offscreen image.

  Available in Mac OS X v10.0 and later.

  Declared in `QDOffscreen.h`.

`gwFlagErr`
: If the `UpdateGWorld` function returns this flag, then it was unsuccessful and the offscreen graphics world was left unchanged.

  Available in Mac OS X v10.0 and later.

  Declared in `QDOffscreen.h`.

invalColReq

```
enum {
    invalColReq = -1
};
```

italicBit

```
enum {
    italicBit = 1,

    transparent = 36
};
```

Constants

`srcCopy`

For basic graphics ports, force the destination pixel black where the source pixel is black; where the source pixel is white, force the destination pixel white.

For color graphics ports, determines how close the color of the source pixel is to black, and assigns this relative amount of foreground color to the destination pixel. Determines how close the color of the source pixel is to white, and assigns this relative amount of background color to the destination pixel.

Available in Mac OS X v10.0 and later.

Declared in `QuickdrawTypes.h`.

`srcOr`

For basic graphics ports, forces the destination pixel black if the source pixel is black; where the source pixel is white, leaves the destination pixel unaltered.

For color graphics ports, determines how close the color of the source pixel is to black, and assigns this relative amount of foreground color to the destination pixel.

Available in Mac OS X v10.0 and later.

Declared in `QuickdrawTypes.h`.

`srcXor`

For basic and color graphics ports, inverts destination pixel where the source pixel is black. For a basic graphics port, where the source pixel is white, leaves the destination pixel unaltered.

For a color graphics port, for a colored destination pixel, uses the complement of its color if the pixel is direct, or inverts its index if the pixel is indexed.

Available in Mac OS X v10.0 and later.

Declared in `QuickdrawTypes.h`.

`srcBic`

For a basic graphics port, forces destination pixel white where source pixel is black; where source pixel is white, leaves the destination pixel unaltered.

For a color graphics port, determines how close the color of the source pixel is to black, and assigns this relative amount of background color to the destination pixel.

Available in Mac OS X v10.0 and later.

Declared in `QuickdrawTypes.h`.

`notSrcCopy`

For a basic graphics port, forces the destination pixel white where the source pixel is black; where the source pixel is white, forces the destination pixel black.

For a color graphics port, determines how close the color of the source pixel is to black, and assigns this relative amount of background color to the destination pixel. Determines how close the color of the source pixel is to white, and assigns this relative amount of foreground color to the destination pixel.

Available in Mac OS X v10.0 and later.

Declared in `QuickdrawTypes.h`.

`notSrcOr`

For a basic graphics port, leaves the destination pixel unaltered where the source pixel is black; where the source pixel is white, forces the destination pixel black.

For a color graphics port, determines how close the color of the source pixel is to white, and assigns this relative amount of foreground color to the destination pixel.

Available in Mac OS X v10.0 and later.

Declared in `QuickdrawTypes.h`.

`notSrcXor`

For basic and color graphics ports, where the source pixel is white, inverts the destination pixel. For a basic graphics port, where the source pixel is black, leaves the destination pixel unaltered.

For a color graphics port, for a colored destination pixel, uses the complement of its color if the pixel is direct, or inverts its index if the pixel is indexed.

Available in Mac OS X v10.0 and later.

Declared in `QuickdrawTypes.h`.

`notSrcBic`

For a basic graphics port, where the source pixel is black, leaves the destination pixel unaltered; where the source pixel is white, forces the destination pixel white.

For a color graphics port, determines how close the color of the source pixel is to white, and assigns this relative amount of background color to the destination pixel.

Available in Mac OS X v10.0 and later.

Declared in `QuickdrawTypes.h`.

`patCopy`

Where the pattern pixel is black, applies foreground color to the destination pixel; where the pattern pixel is white, applies background color to the destination pixel.

Available in Mac OS X v10.0 and later.

Declared in `QuickdrawTypes.h`.

`patOr`

Where the pattern pixel is black, inverts the destination pixel; where the pattern pixel is white, leaves the destination pixel unaltered.

Available in Mac OS X v10.0 and later.

Declared in `QuickdrawTypes.h`.

`patXor`

Where the pattern pixel is black, inverts the destination pixel; where the pattern pixel is white, leaves the destination pixel unaltered.

Available in Mac OS X v10.0 and later.

Declared in `QuickdrawTypes.h`.

`patBic`

Where the pattern pixel is black, applies the background color to destination pixel; where the pattern pixel is white, leaves the destination pixel unaltered.

Available in Mac OS X v10.0 and later.

Declared in `QuickdrawTypes.h`.

`notPatCopy`

Where the pattern pixel is black, applies background color to destination pixel; where the pattern pixel is white, applies foreground color to the destination pixel

Available in Mac OS X v10.0 and later.

Declared in `QuickdrawTypes.h`.

`notPatOr`

Where the pattern pixel is black, leaves the destination pixel unaltered; where the pattern pixel is white, applies foreground color to the destination pixel

Available in Mac OS X v10.0 and later.

Declared in `QuickdrawTypes.h`.

`notPatXor`

Where the pattern pixel is black, leaves the destination pixel unaltered; where the pattern pixel is white, inverts the destination pixel

Available in Mac OS X v10.0 and later.

Declared in `QuickdrawTypes.h`.

`notPatBic`

Where the pattern pixel is black, leaves the destination pixel unaltered; where the pattern pixel is white, applies background color to the destination pixel.

Available in Mac OS X v10.0 and later.

Declared in `QuickdrawTypes.h`.

`grayishTextOr`

Draws dimmed text on the screen. You can use it for black-and-white or color graphics ports. The `grayishTextOr` transfer mode is not considered a standard transfer mode because currently it is not stored in pictures, and printing with it is undefined. (It does not pass through the QuickDraw bottleneck functions.)

Available in Mac OS X v10.0 and later.

Declared in `QuickdrawTypes.h`.

`hilite`

Adds highlighting to the source or pattern mode. With highlighting, QuickDraw replaces the background color with the highlight color when your application copies images between graphics ports. This has the visual effect of using a highlighting pen to select the object. (The global variable `HiliteRGB` is read from parameter RAM when the machine starts. Basic graphics ports use the color stored in the `HiliteRGB` global variable as the highlight color. Color graphics ports default to the `HiliteRGB` global variable, but can be overridden by the `HiliteColor` function.)

For text, specifies that the caret position should be determined according to the primary line direction, based on the value of `SysDirection`.

Available in Mac OS X v10.0 and later.

Declared in `QuickdrawTypes.h`.

`blend`

Replaces the destination pixel with a blend of the source and destination pixel colors. If the destination is a bitmap or 1-bit pixel map, reverts to `srcCopy` mode.

Available in Mac OS X v10.0 and later.

Declared in `QuickdrawTypes.h`.

`addPin`

Replaces the destination pixel with the sum of the source and destination pixel colors-- up to a maximum allowable values. If the destination is a bitmap or 1-bit pixel map, reverts to `srcBic` mode.

Available in Mac OS X v10.0 and later.

Declared in `QuickdrawTypes.h`.

`addOver`

Replaces the destination pixel with the sum of the source and destination pixel colors, except if the value of the red, green, or blue component exceeds 65,536, then `addOver` subtracts 65,536 from that value. If the destination is a bitmap or 1-bit pixel map, reverts to `srcXor` mode.

Available in Mac OS X v10.0 and later.

Declared in `QuickdrawTypes.h`.

`subPin`

Replaces the destination pixel with the difference of the source and destination pixel colors, but not less than a minimum allowable value. If the destination is a bitmap or 1-bit pixel map, reverts to `srcOr` mode.

Available in Mac OS X v10.0 and later.

Declared in `QuickdrawTypes.h`.

`addMax`

Compares the source and destination pixels, and replaces the destination pixel with the color containing the greater saturation of each of the RGB components. If the destination is a bitmap or 1-bit pixel map, reverts to `srcBic` mode.

Available in Mac OS X v10.0 and later.

Declared in `QuickdrawTypes.h`.

`subOver`

Replaces the destination pixel with the difference of the source and destination pixel colors, except if the value of the red, green, or blue component is less than 0, then it adds the negative result to 65,536. if the destination is a bitmap or 1-bit pixel map, revert to `srcXor` mode.

Available in Mac OS X v10.0 and later.

Declared in `QuickdrawTypes.h`.

`adMin`

Compares the source and destination pixels, and replaces the destination pixel with the color containing the lesser saturation of each of the RGB components. If the destination is a bitmap or 1-bit pixel map, reverts to `srcOr` mode.

Available in Mac OS X v10.0 and later.

Declared in `QuickdrawTypes.h`.

`ditherCopy`

On computers running System 7, you can add dithering to any source mode by adding this constant or the value it represents to the source mode.

Dithering is a technique that mixes existing colors to create the effect of additional colors. It also improves images that you shrink or that you copy from a direct pixel device to an indexed device.

Available in Mac OS X v10.0 and later.

Declared in `QuickdrawTypes.h`.

`transparent`

Replaces the destination pixel with the source pixel if the source pixel is not equal to the background color. The `transparent` mode replaces the destination pixel with the source pixel if the source pixel isn't equal to the background color. This mode is most useful in 8-bit, 4-bit, or 2-bit color modes.

Available in Mac OS X v10.0 and later.

Declared in `QuickdrawTypes.h`.

Discussion

`CopyBits` (page 2584) uses the source and arithmetic transfer mode constants in the `mode` parameter to specify the manner in which pixels are transferred from a source pixel map to a destination pixel map.

`PenMode` (page 2744) uses the pattern mode constants in the `mode` parameter to specify source modes for transferring the bits from a source bitmap to a destination bitmap.

The `TextMode` function uses these constants to set the transfer mode in the graphics port `txMode` field.

The transfer mode determines the interplay between what an application is drawing (the source) and what already exists on the display device (the destination), resulting in the text display.

There are two basic kinds of modes: pattern (`pat`) and source (`src`).

The pattern mode constants are `patCopy`, `patOr`, `patXor`, `patBic`, `notPatCopy`, `notPatOr`, `notPatXor`, and `notPatBic`.

Source is the kind that you use for drawing text. There are four basic Boolean operations: `Copy`, `Or`, `Xor`, and `Bic` (bit clear), each of which has an inverse variant in which the source is inverted before the transfer, yielding eight operations in all. Basic QuickDraw supports these eight transfer modes. Color QuickDraw interprets the source mode constants differently than basic QuickDraw does. Color QuickDraw enables your application to achieve color effects within those basic transfer modes, and offers an additional set of transfer modes that perform arithmetic operations on the RGB values of the source and destination pixels. Other transfer modes are `grayishTextOr`, `transparent` mode, and text mask mode.

The arithmetic transfer modes are `addOver`, `addPin`, `subOver`, `subPin`, `addMax`, `adMax`, `adMin`, and `blend`. For color, the arithmetic modes change the destination pixels by performing arithmetic operations on the source and destination pixels. Arithmetic transfer modes calculate pixel values by adding, subtracting, or averaging the RGB components of the source and destination pixels. They are most useful for 8-bit color, but they work on 4-bit and 2-bit color also. When the destination bitmap is one bit deep, the mode reverts to the basic transfer mode that best approximates the arithmetic mode requested.

Verb Constants

```
enum {
    frame = kQDGrafVerbFrame,
    paint = kQDGrafVerbPaint,
    erase = kQDGrafVerbErase,
    invert = kQDGrafVerbInvert,
    fill = kQDGrafVerbFill
};
```

Constants

`frame`
Specifies the frame action.
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawTypes.h`.

`paint`
Specifies the paint action.
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawTypes.h`.

`erase`
Specifies the erase action.
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawTypes.h`.

`invert`
Specifies the invert action.
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawTypes.h`.

`fill`
Specifies the fill action.
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawTypes.h`.

Discussion

When you use the `StdRect` (page 2821), `StdRRect` (page 2822), `StdOval` (page 2819), `StdArc` (page 2815), `StdPoly` (page 2820), or `StdRgn` (page 2822) functions, these constants are used in the `verb` parameter to specify the type of action taken by those low-level drawing functions.

Result Codes

The table below lists the result codes specific to QuickDraw.

Result Code	Value	Description
`updPixMemErr`	-125	Insufficient memory to update a pixmap. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
noMemForPictPlaybackErr	-145	Insufficient memory for drawing the picture. Available in Mac OS X v10.0 and later.
pixMapTooDeepErr	-148	Pixel map is deeper than 1 bit per pixel. Available in Mac OS X v10.0 and later.
nsStackErr	-149	Insufficient stack Available in Mac OS X v10.0 and later.
cMatchErr	-150	Color2Index failed to find an index. Available in Mac OS X v10.0 and later.
cTempMemErr	-151	Failed to allocate memory for temporary structures. Available in Mac OS X v10.0 and later.
cNoMemErr	-152	Failed to allocate memory for structures. Available in Mac OS X v10.0 and later.
cRangeErr	-153	Range error on color table requests. Available in Mac OS X v10.0 and later.
cProtectErr	-154	ColorTable structure entry protection violation. Available in Mac OS X v10.0 and later.
cDevErr	-155	Invalid type of graphics device. Available in Mac OS X v10.0 and later.
cResErr	-156	Invalid resolution for MakeITable. Available in Mac OS X v10.0 and later.
cDepthErr	-157	Invalid pixel depth. Available in Mac OS X v10.0 and later.
rgnTooBigErr	-500	Bitmap too large to convert to a region. Available in Mac OS X v10.0 and later.
kQDNoPalette	-3950	Available in Mac OS X v10.2 and later.
kQDNoColorHWCursorSupport	-3951	Available in Mac OS X v10.2 and later.
kQDCursorAlreadyRegistered	-3952	Available in Mac OS X v10.2 and later.
kQDCursorNotRegistered	-3953	Available in Mac OS X v10.2 and later.
kQDCorruptPICTDataErr	-3954	Available in Mac OS X v10.2 and later.

QuickDraw Text Reference (Not Recommended)

Framework: ApplicationServices/ApplicationServices.h

Declared in QuickdrawText.h

Important: The information in this document is obsolete and should not be used for new development.

Overview

You can use the QuickDraw text routines to measure and draw text ranging in complexity from a single glyph to a line of justified text containing multiple languages and styles. In addition to measuring and drawing text, the QuickDraw text routines also help you to determine which characters to highlight and where to position the caret to mark the insertion point. These routines translate pixel locations into byte offsets and vice versa.

To understand the routines described in this document, it is helpful to be familiar with the other parts of QuickDraw. It is also helpful to be familiar with the Font Manager, because of the close relationship between QuickDraw and the Font Manager. To understand the tasks involved in text layout, you should also be acquainted with the Text Utilities and the Script Manager.

Carbon supports the majority of QuickDraw Text.

Functions by Task

Determining the Caret Position, and Selecting and Highlighting Text

`CharToPixel` (page 2911) Deprecated in Mac OS X v10.4

Returns the screen pixel width from the left edge of a text segment to the glyph of the character whose byte offset you specify. (Deprecated. Use ATSUI instead.)

`HiliteText` (page 2921) Deprecated in Mac OS X v10.4

Finds all the characters between two byte offsets in a text segment whose glyphs are to be highlighted. (Deprecated. Use ATSUI instead.)

`PixelToChar` (page 2927) Deprecated in Mac OS X v10.4

Returns the byte offset of a character in a style run, or part of a style run, whose onscreen glyph is nearest the place where the user clicked the mouse. (Deprecated. Use ATSUI instead.)

Drawing Text

`DrawChar` (page 2914) Deprecated in Mac OS X v10.4
Draws the glyph for a single 1-byte character at the current pen location in the current graphics port. (Deprecated. Use ATSUI or Quartz instead.)

`DrawJustified` (page 2915) Deprecated in Mac OS X v10.4
Draws the specified text at the current pen location in the current graphics port, taking into account the adjustment necessary to condense or extend the text by the slop value, appropriately for the script system. (Deprecated. Use ATSUI instead.)

`DrawString` (page 2917) Deprecated in Mac OS X v10.4
Draws the text of the specified Pascal string at the pen location in the current graphics port (`GrafPort` or `CGrafPort`). (Deprecated. Use ATSUI or Quartz instead.)

`DrawText` (page 2918) Deprecated in Mac OS X v10.4
Draws the specified text at the current pen location in the current graphics port. (Deprecated. Use ATSUI or Quartz instead.)

`StandardGlyphs` (page 2933) Deprecated in Mac OS X v10.4
This obsolete function doesn't do anything in Mac OS X. (Deprecated. Use ATSUI to render Unicode text.)

`StdText` (page 2933) Deprecated in Mac OS X v10.4
Draws text from an arbitrary structure in memory. (Deprecated. Use ATSUI or Quartz instead.)

`stdtext` (page 2934) Deprecated in Mac OS X v10.4
Draws text from an arbitrary structure in memory. (Deprecated. Use ATSUI or Quartz instead.)

Laying Out a Line of Text

`GetFormatOrder` (page 2920) Deprecated in Mac OS X v10.4
Determines the display order of style runs for a line of text containing multiple style runs with mixed directions. (Deprecated. Use ATSUI instead.)

`PortionLine` (page 2930) Deprecated in Mac OS X v10.4
Determines the correct proportion of extra space to apply to the specified style run in a line of justified text; that is, how to distribute the total slop value for a line among the style runs on that line. (Deprecated. Use ATSUI instead.)

`VisibleLength` (page 2944) Deprecated in Mac OS X v10.4
Calculates the length, in bytes, of a given text segment, excluding trailing white space. (Deprecated. Use ATSUI instead.)

Measuring Text

`CharWidth` (page 2913) Deprecated in Mac OS X v10.4
Returns the width (horizontel extension), in pixels, of the specified character. (Deprecated. Use ATSUI instead.)

`MeasureJustified` (page 2923) Deprecated in Mac OS X v10.4
Calculates, for text that is expanded, condensed, or scaled, the onscreen width in pixels from the left edge of the text segment to the glyph of the character. (Deprecated. Use ATSUI instead.)

`MeasureText` (page 2925) Deprecated in Mac OS X v10.4
Calculates the width of the character's glyph in pixels from the left edge of the text segment. (Deprecated. Use ATSUI instead.)

`StdTxMeas` (page 2934) Deprecated in Mac OS X v10.4
Measures the width of scaled or unscaled text. (Deprecated. Use ATSUI instead.)

`StringWidth` (page 2936) Deprecated in Mac OS X v10.4
Returns the length, in pixels, of the specified text string. (Deprecated. Use ATSUI instead.)

`TextWidth` (page 2941) Deprecated in Mac OS X v10.4
Returns the length, in pixels, of the specified text. (Deprecated. Use ATSUI instead.)

Setting Text Characteristics

`CharExtra` (page 2910) Deprecated in Mac OS X v10.4
Specifies, for a color graphics port (`CGrafPort`), the number of pixels by which to widen (or narrow) the glyphs of each nonspace character in a style run. (Deprecated. Use ATSUI instead.)

`GetFontInfo` (page 2919) Deprecated in Mac OS X v10.4
Returns information about the current graphics port's font, taking into account the style and size in which the glyphs are to be drawn. (Deprecated. Use ATSUI instead.)

`SpaceExtra` (page 2932) Deprecated in Mac OS X v10.4
Specifies the number of pixels by which to widen (or narrow) each space in a style run to be drawn in the current graphics port. (Deprecated. Use ATSUI instead.)

`TextFace` (page 2939) Deprecated in Mac OS X v10.4
Sets the style of the font in which the text is to be drawn in the current graphics port. (Deprecated. Use ATSUI or Quartz instead.)

`TextFont` (page 2939) Deprecated in Mac OS X v10.4
Sets the font of the current graphics port in which the text is to be rendered. (Deprecated. Use ATSUI or Quartz instead.)

`TextMode` (page 2940) Deprecated in Mac OS X v10.4
Sets the transfer mode for drawing text in the current graphics port. (Deprecated. Use ATSUI or Quartz instead.)

`TextSize` (page 2941) Deprecated in Mac OS X v10.4
Sets the font size for text drawn in the current graphics port to the specified number of points. (Deprecated. Use ATSUI or Quartz instead.)

Truncating Strings and Breaking Lines

`StyledLineBreak` (page 2937) Deprecated in Mac OS X v10.4
Returns the proper location to break a line of text, taking into account script and language considerations, making use of tables in the string-manipulation (`'itl2'`) resource in its computations. (Deprecated. Use ATSUI instead.)

`TruncString` (page 2943) Deprecated in Mac OS X v10.4
Ensures that a Pascal string fits into the specified pixel width, by truncating the string as necessary. This function makes use of the current script and font. (Deprecated. Use CFString instead.)

`TruncText` (page 2943) Deprecated in Mac OS X v10.4
: Ensures that a text string fits into the specified pixel width, by truncating the string as necessary. This function makes use of the current script and font. (Deprecated. Use CFString instead.)

Working With Universal Procedure Pointers

`DisposeStyleRunDirectionUPP` (page 2914) Deprecated in Mac OS X v10.4
: Disposes of a universal procedure pointer (UPP) to a style run direction callback. (Deprecated. Use ATSUI to handle style runs.)

`InvokeStyleRunDirectionUPP` (page 2922) Deprecated in Mac OS X v10.4
: Calls your style run direction callback. (Deprecated. Use ATSUI to handle style runs.)

`NewStyleRunDirectionUPP` (page 2927) Deprecated in Mac OS X v10.4
: Creates a new universal procedure pointer (UPP) to a style run direction callback. (Deprecated. Use ATSUI to handle style runs.)

Functions

CharExtra

Specifies, for a color graphics port (`CGrafPort`), the number of pixels by which to widen (or narrow) the glyphs of each nonspace character in a style run. (Deprecated in Mac OS X v10.4. Use ATSUI instead.)

```
void CharExtra (
   Fixed extra
);
```

Parameters

extra
: The amount (in pixels or decimal fractions of a pixel) to widen (or narrow) each glyph other than the space character in a range of text.

Discussion

The `CharExtra` function sets the value of the `chExtra` field of the color graphics port structure. This field contains a number that is in 4.12 fractional notation: four bits of signed integer followed by 12 bits of fraction. The `CharExtra` function uses the value of the `txSize` field, so you must call `TextSize` to set the font size of the text before you call `CharExtra`.

The initial setting is 0. You can pass a negative value for the `extra` parameter, but be careful not to narrow glyphs so much that the text is unreadable. The measuring and drawing functions use the value in this field when an application calls them to measure or draw text. The `CharExtra` function is available only for color graphic ports.

Do not use `CharExtra` for script systems that include zero-width characters, such as diacritical marks, because intercharacter space is added to all glyphs, separating the diacritical mark from the glyph of the character. Do not use it for script systems that include contextual forms, such as ligatures or conjunct characters, which would not be represented properly were intercharacter space added to these glyphs. For example, you should not use `CharExtra` for the Devanagari or Arabic languages, whose text is drawn as connected glyphs, or with the Sonata font because it includes zero-width characters.

The 2-byte script systems use the `chExtra` field value properly.

To ensure future compatibility and benefit from any enhancements, always use this function to modify the `chExtra` field, rather than directly change the field value.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawText.h`

CharToPixel

Returns the screen pixel width from the left edge of a text segment to the glyph of the character whose byte offset you specify. (Deprecated in Mac OS X v10.4. Use ATSUI instead.)

```
short CharToPixel (
   Ptr textBuf,
   long textLength,
   Fixed slop,
   long offset,
   short direction,
   JustStyleCode styleRunPosition,
   Point numer,
   Point denom
);
```

Parameters

`textBuf`

A pointer to the beginning of the text segment.

`textLength`

The length in bytes of the entire text segment pointed to by `textBuf`. The `CharToPixel` function requires the context of the complete text in order to determine the correct value.

`slop`

The amount of slop for the text to be drawn. A positive value extends the text segment; a negative value condenses the text segment.

The value of this parameter is the number of pixels by which the width of the text segment is to be changed, after the text has been scaled. The `slop` is a signed value that specifies how smuch the text is to be extended or condensed. The `slop` is derived from the calculations made using the proportion returned from the `PortionLine` function for a style run. To measure or draw text that is not to be extended or condensed, pass a `slop` value of 0.

`offset`

The offset from `textBuf` to the character within the text segment whose display pixel location is to be measured. For 2-byte script systems, if the character whose position is to be measured is 2 bytes long, this is the offset of the first byte.

direction

This parameter specifies whether `CharToPixel` is to return the caret position for a character with a direction of left-to-right or right-to-left. A direction value of `hilite` indicates that `CharToPixel` is to use the caret position for the character direction that matches the primary line direction as specified by the `SysDirection` global variable.

styleRunPosition

The position on the line of this style run. The style run can be the only one on the line, the leftmost on the line, the rightmost on the line, or one between two other style runs.

This parameter specifies the position of the style run on the display line. It is used to determine the proportion of total slop to apply to a style run, measure or draw a line of justified text, identify where to break a line of text, and determine the caret position to mark an insertion point or highlight text.

The style run position parameter is meaningful only for those script systems that use intercharacter spacing for justification. For all other script systems, the parameter exists for future extensibility. Although the style run position parameter is not used, for example, for justifying text in the Roman script system, to allow for future compatibility, you should always specify the appropriate value for it for all calls that take it.

For those script systems that do use intercharacter spacing, space between style runs may be allocated differently depending upon whether the style run is leftmost, rightmost, or between two other style runs. For example, depending on the script system, if a style run occurs at the beginning or end of a line, extra space may not be added to the outer edge of the outermost glyph, whereas if a style run is interior to a line, all of the glyphs of the text may be treated the same: extra space is allocated to both sides of every glyph including those at either end of the style run.

The current implementations of simple script systems such as Roman and Cyrillic do not justify a line of text by changing the width of nonspace characters. Instead, they rely solely on the use of space characters: the same amount of extra width is added to (or subtracted from) every space whether the space is at the beginning or end of the line or interior to it.

See "Style Run Position Constants" (page 2951) for a list of the constants you can supply.

numer

A point giving the numerator for the horizontal and vertical scaling factors.

Both `numer` and `denom` are point values: `numer` specifies the numerator for the horizontal and vertical scaling factors, and `denom` specifies the denominator for the horizontal and vertical scaling factors. Together, these values specify the scaling factors for the text: `numer.v` over `denom.v` gives the vertical scaling (height), and `numer.h` over `denom.h` gives the horizontal scaling factors (width). You need to specify values for `numer` and `denom` even if you are not scaling the text. For unscaled text, you can specify scaling factors of 1, 1.

denom

A point giving the denominator for the horizontal and vertical scaling factors.

Return Value

The screen pixel width from the left edge of a text segment to the glyph of the character whose byte offset you specify.

Discussion

You use `CharToPixel` to find the onscreen pixel location at which to draw a caret and to identify the selection points for highlighting. The `CharToPixel` function returns the horizontal distance in pixels from the start of the range of text beginning with the byte offset at `textBuf` to the glyph corresponding to the character whose byte offset is specified by the `offset` parameter. The pixel location is relative to the beginning of the text segment, not the left margin of the display line. To get the actual display line pixel location of the glyph relative to the left margin, you add the pixel value that `CharToPixel` returns to the pixel location at

the end of the previous style run (on the left) in display order. In other words, you need to know the length of the text in pixels on the display line up to the beginning of the range of text that you call `CharToPixel` for, and then you add in the screen pixel width that `CharToPixel` returns.

You specify a value for `textLen` that is equal to the entire visible part of the style run on a line and includes trailing spaces if and only if they are displayed. They may not be displayed, for example, for the last style run in memory order, which is part of the line. Do not confuse the `textLen` parameter with the `offset`, which is the byte offset of the character within the text segment whose pixel location `CharToPixel` is to return.

If you use `CharToPixel` to get a caret position to mark the insertion point, you specify a value of `leftCaret` or `rightCaret` for the `direction` parameter. You can use the value of the `PixelToChar leadingEdge` flag to determine the `direction` parameter value.

If the `leadingEdge` flag is `FALSE`, you base the value of the `direction` parameter on the direction of the character at the byte offset in memory that precedes the one that `PixelToChar` returns; if `leadingEdge` is `TRUE`, you base the value of the `direction` parameter on the direction of the character at the byte offset that `PixelToChar` returns. If there isn't a character at the byte offset, you base the value of the `direction` parameter on the primary line direction as determined by the `SysDirection` global variable.

Be sure to pass the same values for `styleRunPosition` and the scaling factors (`numer` and `denom`) to `CharToPixel` that you pass to any of the other justification functions for this style run.

The `CharToPixel` function works with text in all script systems. For 1-byte contextual script systems, `CharToPixel` calculates the widths of any ligatures, reversals, and compound characters that need to be drawn.

Note that `textLen` is the number of bytes to be drawn, not the number of characters. Because 2-byte script systems also include characters consisting of only one byte, do not simply multiply the number of characters by 2 to determine this value; you must determine and specify the correct number of bytes.

Special Considerations

The `CharToPixel` function may move memory; do not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawText.h`

CharWidth

Returns the width (horizontel extension), in pixels, of the specified character. (Deprecated in Mac OS X v10.4. Use ATSUI instead.)

```
short CharWidth (
   CharParameter ch
);
```

Parameters

ch

The character whose width is to be measured.

Return Value
The width (horizontel extension), in pixels, of the specified character.

Discussion
The `CharWidth` function includes the effects of the stylistic variations for the text set in the current graphics port. If you change any of these attributes after determining the glyph width but before actually drawing it, the predetermined width may not be correct. For a space character, `CharWidth` also includes the effect of `SpaceExtra`. For a nonspace character, `CharWidth` includes the effect of `CharExtra`.

Because it takes a single-byte value as the `ch` parameter, `CharWidth` works only for 1-byte simple script systems.

A series of calls to `CharWidth` in a contextual 1-byte font may give incorrect results, because the width of a text segment may be different from the sum of its individual character widths. In that case, to measure a line of text you should call `TextWidth`.

Do not use the `CharWidth` function for 2-byte script systems. If you want to measure the width of a single glyph in a 2-byte font, you should use `TextWidth`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

`QuickdrawText.h`

DisposeStyleRunDirectionUPP

Disposes of a universal procedure pointer (UPP) to a style run direction callback. (Deprecated in Mac OS X v10.4. Use ATSUI to handle style runs.)

```
void DisposeStyleRunDirectionUPP (
   StyleRunDirectionUPP userUPP
);
```

Parameters
userUPP

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`QuickdrawText.h`

DrawChar

Draws the glyph for a single 1-byte character at the current pen location in the current graphics port. (Deprecated in Mac OS X v10.4. Use ATSUI or Quartz instead.)

```
void DrawChar (
   CharParameter ch
);
```

Parameters

ch

The character code whose glyph is to be drawn.

Discussion

The `DrawChar` function draws a single character's glyph and then advances the pen by the width of the glyph. If the glyph isn't in the font, the font's missing symbol is drawn.

If you're drawing more than one character, it's faster to make one `DrawString` or `DrawText` call rather than a series of `DrawChar` calls.

Because it takes a single-byte value as the `ch` parameter, `DrawChar` works only for 1-byte script systems. If you want to draw the glyph of a single character in a 2-byte script, call either `DrawText`, `DrawString`, or `DrawJustified`.

A series of calls to `DrawChar` in a 1-byte complex script system can give incorrect results because a text string is not always a simple concatenation of a series of characters. In a contextual script, two different glyphs may be used to represent a single character in its contextual form and alone. To draw a sequence of text in a 1-byte complex script system, use `DrawText`, `DrawString`, or `DrawJustified` instead.

For 1-byte complex scripts, you can use `DrawChar` for special purposes, such as to include the isolated glyph of a character in a book's index, for example, to show a single glyph as it exists apart from contextual transformations.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawText.h`

DrawJustified

Draws the specified text at the current pen location in the current graphics port, taking into account the adjustment necessary to condense or extend the text by the slop value, appropriately for the script system. (Deprecated in Mac OS X v10.4. Use ATSUI instead.)

```
void DrawJustified (
   Ptr textPtr,
   long textLength,
   Fixed slop,
   JustStyleCode styleRunPosition,
   Point numer,
   Point denom
);
```

Parameters

textPtr

A pointer to the memory location of the beginning of the text to be drawn.

textLength

The number of bytes of text to be drawn.

Note that `textLength` is the number of bytes to be drawn, not the number of characters. Because 2-byte script systems also include characters consisting of only 1 byte, do not simply multiply the number of characters by 2 to determine this value; you must determine and specify the correct number of bytes.

slop

The amount of slop for the text to be drawn. A positive value extends the text segment; a negative value condenses the text segment. Pass the value assessed for this style run based on the proportion returned for it from `PortionLine`.

The value of this parameter is the number of pixels by which the width of the text segment is to be changed, after the text has been scaled. The `slop` is a signed value that specifies how much the text is to be extended or condensed. The `slop` is derived from the calculations made using the proportion returned from the `PortionLine` function for a style run. To measure or draw text that is not to be extended or condensed, pass a `slop` value of 0.

styleRunPosition

The position on the line of this style run. The style run can be the only one on the line, the leftmost on the line, the rightmost on the line, or one between two other style runs. Be sure to pass the same value that you pass to `PortionLine`.

This parameter specifies the position of the style run on the display line. It is used to determine the proportion of total slop to apply to a style run, measure or draw a line of justified text, identify where to break a line of text, and determine the caret position to mark an insertion point or highlight text.

The style run position parameter is meaningful only for those script systems that use intercharacter spacing for justification. For all other script systems, the parameter exists for future extensibility. Although the style run position parameter is not used, for example, for justifying text in the Roman script system, to allow for future compatibility, you should always specify the appropriate value for it for all calls that take it.

For those script systems that do use intercharacter spacing, space between style runs may be allocated differently depending upon whether the style run is leftmost, rightmost, or between two other style runs. For example, depending on the script system, if a style run occurs at the beginning or end of a line, extra space may not be added to the outer edge of the outermost glyph, whereas if a style run is interior to a line, all of the glyphs of the text may be treated the same: extra space is allocated to both sides of every glyph including those at either end of the style run.

The current implementations of simple script systems such as Roman and Cyrillic do not justify a line of text by changing the width of nonspace characters. Instead, they rely solely on the use of space characters: the same amount of extra width is added to (or subtracted from) every space whether the space is at the beginning or end of the line or interior to it.

See "Style Run Position Constants" (page 2951) for a list of the constants you can supply.

numer

A point giving the numerator for the horizontal and vertical scaling factors.

Both numer and denom are point values: numer specifies the numerator for the horizontal and vertical scaling factors, and denom specifies the denominator for the horizontal and vertical scaling factors. Together, these values specify the scaling factors for the text: numer.v over denom.v gives the vertical scaling (height), and numer.h over denom.h gives the horizontal scaling factors (width). You need to specify values for numer and denom even if you are not scaling the text. For unscaled text, you can specify scaling factors of 1, 1. Be sure to pass the same value that you pass to `PortionLine`.

denom

A point giving the denominator for the horizontal and vertical scaling factors. Be sure to pass the same value that you pass to `PortionLine`.

Discussion
The `DrawJustified` function is similar to the `DrawText` function, except that you use it to draw text that is expanded or condensed by the number of pixels specified by `slop`. The `DrawJustified` function is most commonly used to draw a line of justified text.

The `DrawJustified` function draws the specified text in the font, size, and style of the current graphics port, taking into account any scaling factors, and it distributes the slop appropriately for the script system. Regardless of the line direction of the text to be drawn, you place the pen at the left edge of the line before calling `DrawJustified` for the first style run. For all subsequent style runs on that line, QuickDraw advances the pen appropriately.

If `DrawJustified` changes the width of spaces, it temporarily resets the space extra (`spExtra`) value. It adds to the current value of the field, if any, the amount of extra space to be applied to each space character within the range of text in order to justify the text, based on calculations that take into account the slop value and all of the text characteristics. On exit, `DrawJustified` restores the original value.

The `DrawJustifie` d function works with text in all script systems. For example, to depict justified Arabic text, `DrawJustified` uses extension bars to create the additional width that is distributed as slop within a style run.

For 1-byte complex script systems, `DrawJustified` substitutes the proper ligatures, reversals, and compound characters as needed.

For 2-byte script systems that do not use space characters to delimit words, `DrawJustified` distributes the slop value in a manner appropriate to the script system. For script systems, such as Japanese, that use ideographic characters, `DrawJustified` distributes the additional screen pixel width appropriately for the text representation.

Special Considerations
The `DrawJustified` function may move memory; do not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawText.h`

DrawString

Draws the text of the specified Pascal string at the pen location in the current graphics port (`GrafPort` or `CGrafPort`). (Deprecated in Mac OS X v10.4. Use ATSUI or Quartz instead.)

```
void DrawString (
   ConstStr255Param s
);
```

Parameters
s
A Pascal string consisting of the text to be drawn.

Discussion
The `DrawString` function draws the string with its left edge at the current pen location, extending right. The final position of the pen location, after the text is drawn, is to the right of the rightmost glyph in the string. QuickDraw does not do any formatting, such as handling of carriage returns or line feeds.

Note that you can use `DrawString` only for a Pascal string containing a single style run.

QuickDraw temporarily stores on the stack all of the text you ask it to draw, even if the text is to be clipped. When drawing large font sizes or complex style variations, draw only what is visible on the screen. You can determine the number of characters whose corresponding glyphs actually fit on the screen by calling the `StringWidth` function to determine the length of the string before calling `DrawString`.

If you specify values in the graphics port `spExtra` or `chExtra` fields to change the width of space or nonspace characters, `DrawString` takes these values into account.

For right-to-left text, such as Hebrew or Arabic, QuickDraw draws the final (leftmost) glyph first, then moves to the right through all the glyphs, drawing the initial (rightmost) glyph last.

Note that you should not change the width of nonspace characters for 1-byte simple script systems with zero-width characters or 1-byte complex script systems. For more information, see `CharExtra` (page 2910).

For contextual script systems, `DrawString` substitutes the proper ligatures, reversals, and compound characters as needed. Inside a picture definition, `DrawString` can't have a `byteCount` greater than 255.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Simple DrawSprocket

Declared In
`QuickdrawText.h`

DrawText

Draws the specified text at the current pen location in the current graphics port. (Deprecated in Mac OS X v10.4. Use ATSUI or Quartz instead.)

```
void DrawText (
    const void * textBuf,
    short firstByte,
    short byteCount
);
```

Parameters

`textBuf`
A pointer to a buffer containing the text to be drawn.

`firstByte`
An offset from the start of the text buffer (`textBuf`) to the first byte of the text to be drawn.

byteCount

The number of bytes of text to be drawn. Inside a picture definition, `DrawText` cannot have a `byteCount` greater than 255.

For 2-byte script systems, note that `byteCount` is the number of bytes to be drawn, not the number of glyphs. Because 2-byte script systems also include characters consisting of only 1 byte, do not simply multiply the number of characters by 2 to determine this value; you must determine and specify the correct number of bytes.

Discussion

The `DrawText` function draws the text with the leftmost glyph at the current pen location, extending right. After QuickDraw draws the text, it sets the pen location to the right of the rightmost glyph.

QuickDraw temporarily stores on the stack all of the text you ask it to draw, even if the text is to be clipped. When drawing a range of text, it's best to draw only what is visible on the screen. If an entire text string does not fit on a line, truncate the text at a word boundary. If possible, avoid truncating within a style run. You can determine the number of characters whose glyphs actually fit on the screen by calling the `TextWidth` function before calling `DrawText`.

If you specify values in the graphics port `spExtra` and `chExtra` fields to change the width of nonspace and space characters, both `TextWidth` and `DrawText` take these values into account.

For 1-byte complex script systems, `DrawText` substitutes the proper ligatures, reversals, and compound characters as needed.

For right-to-left text, such as Hebrew or Arabic, QuickDraw draws the final (leftmost) glyph first, then moves to the right through all the characters, drawing the initial (rightmost) glyph last.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawText.h`

GetFontInfo

Returns information about the current graphics port's font, taking into account the style and size in which the glyphs are to be drawn. (Deprecated in Mac OS X v10.4. Use ATSUI instead.)

```
void GetFontInfo (
   FontInfo *info
);
```

Parameters

info

Pointer to a font information structure that contains the font measurement information, in integer values.

Discussion

The `GetFontInfo` function returns the ascent, descent, leading, and width of the largest glyph of the font in the text font, size, and style specified in the current graphics port. If the script system specified by the current graphics port `txFont` field has an associated font, as do Hebrew and Arabic, `GetFontInfo` returns combined information based on both fonts. This is to accommodate text written in the Roman script when

the primary script system is non-Roman. However, even if all of the text is written in a non-Roman script, if there is an associated font, `GetFontInfo` always bases its information on the combined fonts. You can determine the line height, in pixels, by adding the values of the ascent, descent, and leading fields.

The `GetFontInfo` function is similar to the Font Manager's `FontMetrics` function, except that the `GetFontInfo` function returns integer values. See `FontInfo` (page 2947) for a description of the structure and its fields.

`QuickdrawText.h`

GetFormatOrder

Determines the display order of style runs for a line of text containing multiple style runs with mixed directions. (Deprecated in Mac OS X v10.4. Use ATSUI instead.)

```
void GetFormatOrder (
   FormatOrderPtr ordering,
   short firstFormat,
   short lastFormat,
   Boolean lineRight,
   StyleRunDirectionUPP rlDirProc,
   Ptr dirParam
);
```

Parameters

ordering
A pointer to a format order array, with (`lastFormat - firstFormat + 1`) entries. The function fills the array with the display order of each style run. On exit, the array contains a permuted list of the numbers from `firstFormat` to `lastFormat`.

The first entry in the array is the number of the style run to draw first; this is the leftmost style run in display order. The last entry in the array is the number of the entry to draw last, the rightmost style run in display order.

Upon completion of the call, the `FormatOrder` (page 2948) array contains the numbers identifying the style runs in display order.

firstFormat
A number greater than or equal to 0 identifying the first style run in storage order that is part of the line for which you are calling `GetFormatOrder`.

lastFormat
A number greater than or equal to 0 identifying the last style run in storage order that is part of the line for which you are calling `GetFormatOrder`.

lineRight
A flag that you set to `TRUE` if the primary line direction is right-to-left.

rlDirProc

A pointer to a callback function that calculates the correct direction, given the style run identifier. The `GetFormatOrder` function calls the application-defined `rlDirProc` function for each identifier from `firstFormat` to `lastFormat`.

This function returns `TRUE` for right-to-left text direction and `FALSE` for left-to-right. Given `dirParam` and a style run identifier, the callback function should be able to determine the style run direction. For more information, see `StyleRunDirectionProcPtr` (page 2946).

dirParam

A pointer to a parameter block that contains the font and script information for each style run in the text. This parameter block is used by the application-supplied function.

Discussion

The `GetFormatOrder` function helps you determine how to draw text that contains multiple style runs with mixed directions. For mixed-directional text, after you determine where to break the line, you need to call `GetFormatOrder` to determine the display order. When you call `GetFormatOrder`, you supply a Boolean function, and reference it using the `rlDirProc` parameter. This function calculates the direction of each style run identified by number. Do not call `GetFormatOrder` if there is only one style run on the line.

You must index the style runs in storage order. You pass `GetFormatOrder` numbers identifying the first and last style runs of the line in storage order and the primary line direction. The `GetFormatOrder` function returns to you an equivalent sequence in display order.

If you do not explicitly define the primary line direction of the text, base the `lineRight` parameter on the value of the `SysDirection` global variable. (The `SysDirection` global variable is set to `-1` if the system direction is right to left, and 0 if the system direction is left to right.)

Declared In

`QuickdrawText.h`

HiliteText

Finds all the characters between two byte offsets in a text segment whose glyphs are to be highlighted. (Deprecated in Mac OS X v10.4. Use ATSUI instead.)

```
void HiliteText (
   Ptr textPtr,
   short textLength,
   short firstOffset,
   short secondOffset,
   OffsetTable offsets
);
```

Parameters

textPtr

A pointer to a buffer that contains the text to be highlighted.

textLength

The length in bytes of the entire text segment pointed to by `textPtr`.

firstOffset
The byte offset from `textPtr` to the first character to be highlighted.

secondOffset
The byte offset from `textPtr` to the last character to be highlighted.

offsets
A table that, upon completion of the call, specifies the boundaries of the text to be highlighted.

Discussion
The `HiliteText` function returns three pairs of byte offsets that mark the onscreen ranges of text to be highlighted. This is because for bidirectional text, although the characters are contiguous in memory, their displayed glyphs can include up to three separate ranges of text.

The `HiliteText` function takes into account the fact that to highlight the complete range of text whose beginning and ending byte offsets you pass it, it must return byte offsets that encompass the glyphs of the first and last characters in the text segment. To determine the correct offset pairs, `HiliteText` relies on the primary line direction as specified by the `SysDirection` global variable.

Before calling `HiliteText`, you must set up an offset table (of type `OffsetTable`) in your application to hold the results. You can consider the offset table to be a set of three offset pairs.

If the two offsets in any pair are equal, the pair is empty and you can ignore it. Otherwise the pair identifies a run of characters whose glyphs are to be highlighted.

The offsets that `HiliteText` returns depend on the primary line direction as defined by the `SysDirection` global variable. If you change the value of `SysDirection`, `HiliteText` returns the offset that is meaningful according to the primary line direction for ambiguous offsets on the boundary of right-to-left and left-to-right text.

Special Considerations
The `HiliteText` function may move memory; do not call this function at interrupt time.

`QuickdrawText.h`

MeasureJustified

Calculates, for text that is expanded, condensed, or scaled, the onscreen width in pixels from the left edge of the text segment to the glyph of the character. (Deprecated in Mac OS X v10.4. Use ATSUI instead.)

```
void MeasureJustified (
   Ptr textPtr,
   long textLength,
   Fixed slop,
   Ptr charLocs,
   JustStyleCode styleRunPosition,
   Point numer,
   Point denom
);
```

Parameters

textPtr

A pointer to the memory location of the beginning of the text to be measured.

textLength

The number of bytes of text to be measured. The text length should equal the entire visible part of the text on a line, including trailing spaces if and only if they are displayed. Otherwise, the results for the last glyph on the line may be invalid.

slop

The amount of slop for the text to be drawn. A positive value extends the text segment; a negative value condenses the text segment.

The value of this parameter is the number of pixels by which the width of the text segment is to be changed, after the text has been scaled. The `slop` is a signed value that specifies how much the text is to be extended or condensed. The `slop` is derived from the calculations made using the proportion returned from the `PortionLine` function for a style run. To measure or draw text that is not to be extended or condensed, pass a `slop` value of 0.

charLocs

A pointer to an application-defined array of `textLength` + 1 integers.

styleRunPosition

The position on the line of this style run. The style run can be the only one on the line, the leftmost on the line, the rightmost on the line, or one between two other style runs.

This parameter specifies the position of the style run on the display line. It is used to determine the proportion of total slop to apply to a style run, measure or draw a line of justified text, identify where to break a line of text, and determine the caret position to mark an insertion point or highlight text.

The style run position parameter is meaningful only for those script systems that use intercharacter spacing for justification. For all other script systems, the parameter exists for future extensibility. Although the style run position parameter is not used, for example, for justifying text in the Roman script system, to allow for future compatibility, you should always specify the appropriate value for it for all calls that take it.

For those script systems that do use intercharacter spacing, space between style runs may be allocated differently depending upon whether the style run is leftmost, rightmost, or between two other style runs. For example, depending on the script system, if a style run occurs at the beginning or end of a line, extra space may not be added to the outer edge of the outermost glyph, whereas if a style run is interior to a line, all of the glyphs of the text may be treated the same: extra space is allocated to both sides of every glyph including those at either end of the style run.

The current implementations of simple script systems such as Roman and Cyrillic do not justify a line of text by changing the width of nonspace characters. Instead, they rely solely on the use of space characters: the same amount of extra width is added to (or subtracted from) every space whether the space is at the beginning or end of the line or interior to it.

See "Style Run Position Constants" (page 2951) for a list of the constants you can supply.

numer

A point giving the numerator for the horizontal and vertical scaling factors.

Both numer and denom are point values: numer specifies the numerator for the horizontal and vertical scaling factors, and denom specifies the denominator for the horizontal and vertical scaling factors. Together, these values specify the scaling factors for the text: `numer.v` over `denom.v` gives the vertical scaling (height), and `numer.h` over `denom.h` gives the horizontal scaling factors (width). You need to specify values for numer and denom even if you are not scaling the text. For unscaled text, you can specify scaling factors of 1, 1.

denom

A point giving the denominator for the horizontal and vertical scaling factors.

Discussion

The `MeasureJustified` function is similar to the `MeasureText` function, except that it is used to find the pixel location of a character's glyph in text that is expanded or condensed. The function calculates the onscreen pixel width of the glyph of each character, beginning from the left edge of the text segment, taking into account `slop` value, scaling, and style run position.

On return, the first element in the `charLocs` array contains 0 and the last element contains the total width of the text segment, when the primary line direction is left to right and the text is unidirectional. When the primary line direction is right to left and the text is unidirectional, the first element in the array contains the total width of the text segment, and the last element in the array contains 0. When the text is bidirectional, at a direction boundary, `MeasureJustified` selects the character whose direction maps to that of the primary line direction.

The `MeasureJustified` function returns the same results that an application would get if it called `CharToPixel` for each character with a direction parameter value of `hilite`. Using `MeasureJustified` to find the pixel location of a character's glyph is less efficient than using the `CharToPixel` function because the application must define the array pointed to by `charLocs`, and then walk the array after `MeasureText` returns the results.

The `MeasureJustified` function temporarily resets the space extra (`spExtra`) value, adding to the current value of the field, if any, the amount of extra space to be added to space characters in order to fully justify the text, based on calculations that take into account the slop value and all the text characteristics. On exit, `MeasureJustified` restores the original value.

Because `MeasureJustified` measures text in only the current font, style, and size, you need to call it once for each individual style run. For additional information about `MeasureJustified`, contact Developer Technical Support.

The `MeasureJustified` function works properly for text in all script systems. For 1-byte complex script systems, `MeasureJustified` calculates the widths of any ligatures, reversals, and compound characters that would need to be drawn.

Note that `textLength` is the number of bytes to be drawn, not the number of characters. Because 2-byte script systems also include characters consisting of only one byte, you should not simply multiply the number of characters by 2 to determine this value; the application must determine and specify the correct number of bytes.

Some 1-byte script system fonts may have zero-width characters, which are usually overlapping diacritical marks that typically follow the base character in memory. In this case, `MeasureJustified` measures both the glyph of the base character (the high-order, low-address byte) and the width of the diacritical mark. The `charLoc` array includes an entry for each, but both entries contain the same value.

For 1-byte complex script systems, `MeasureJustified` calculates the widths of any ligatures, reversals, compound characters, and character clusters that need to be drawn. For example, for an Arabic ligature, the entry that corresponds to the trailing edge of each character that is part of the ligature is the trailing edge of the entire ligature.

Special Considerations

The `MeasureJustified` function may move memory; do not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawText.h`

MeasureText

Calculates the width of the character's glyph in pixels from the left edge of the text segment. (Deprecated in Mac OS X v10.4. Use ATSUI instead.)

```
void MeasureText (
   short count,
   const void *textAddr,
   void *charLocs
);
```

Parameters

count

The number of bytes (as opposed to characters) to be measured. Because 2-byte script systems also include characters consisting of only one byte, do not simply multiply the number of characters by 2 to determine this value; you must determine and specify the correct number of bytes.

For 2-byte characters, the `charLocs` array contains two entries—one corresponding to each byte—but both entries contain the same pixel-width value.

textAddr

A pointer to the memory location of the beginning of the text to be measured. The value of `textAddr` must point directly to the first character whose glyph is to be measured.

charLocs

A pointer to an application-defined array of `count` + 1 integers. On return, the first element in the `charLocs` array contains 0 and the last element contains the total width of the text segment, when the primary line direction is left to right and the text is unidirectional.

When the primary line direction is right to left, and the text is unidirectional, the first element in the array contains the total width of the text segment, and the last element in the array contains 0. When the text is bidirectional, at a direction boundary, `MeasureText` selects the character whose direction maps to that of the primary line direction.

Discussion

Provides an array version of the `TextWidth` function. The `MeasureText` function calculates the onscreen pixel width of the glyph of each character, beginning from the left edge of the text segment. The function returns the same results that an application would get if it called `CharToPixel` for each character with a direction parameter value of `hilite`. Using `MeasureText` to find the pixel location of a character's glyph is less efficient than using the `CharToPixel` function because the application must define the array pointed to by `charLocs`, and then walk the array after `MeasureText` returns the results.

Because this function measures text in the font, style, and size of the current graphics port, you need to call it once for each individual style run in any line of text that contains multiple style runs.

Some fonts in 1-byte script systems may have zero-width characters, which are usually overlapping diacritical marks that typically follow the base character in memory. In this case, `MeasureText` measures both the glyph of the base character (the high-order, low-address byte) and the width of the diacritical mark. The `charLoc` array includes an entry for each, but both entries contain the same value.

For 1-byte complex script systems, `MeasureText` calculates the widths of any ligatures, reversals, compound characters, and character clusters that need to be drawn. For example, for an Arabic ligature, the entry that corresponds to the trailing edge of each character that is part of the ligature is the trailing edge of the entire ligature.

`QuickdrawText.h`

PixelToChar

Returns the byte offset of a character in a style run, or part of a style run, whose onscreen glyph is nearest the place where the user clicked the mouse. (Deprecated in Mac OS X v10.4. Use ATSUI instead.)

```
short PixelToChar (
   Ptr textBuf,
   long textLength,
   Fixed slop,
   Fixed pixelWidth,
   Boolean *leadingEdge,
   Fixed *widthRemaining,
   JustStyleCode styleRunPosition,
   Point numer,
   Point denom
);
```

Parameters

textBuf

A pointer to the start of the text segment.

textLength

The length in bytes of the entire text segment pointed to by `textBuf`. The `PixelToChar` function requires the context of the complete text segment in order to determine the correct value.

slop

The amount of slop for the text to be drawn. A positive value extends the text segment; a negative value condenses the text segment.

The value of this parameter is the number of pixels by which the width of the text segment is to be changed, after the text has been scaled. The `slop` is a signed value that specifies how much the text is to be extended or condensed. The `slop` is derived from the calculations made using the proportion returned from the `PortionLine` function for a style run. To measure or draw text that is not to be extended or condensed, pass a `slop` value of 0.

pixelWidth

The screen location of the glyph associated with the character whose byte offset is to be returned. The screen location is measured in pixels beginning from the left edge of the text segment for which you call `PixelToChar`.

leadingEdge

Pointer to a Boolean flag that, upon completion of the call, is set to `TRUE` if the pixel location is on the leading edge of the glyph, and `FALSE` if the pixel location is on the trailing edge of the glyph. The leading edge is the left side if the direction of the character that the glyph represents is left-to-right (such as a Roman character), and the right side if the character direction is right-to-left (such as an Arabic or a Hebrew letter).

widthRemaining

Pointer to a location that, upon completion of the call, contains –1 if the pixel location (specified by the `pixelWidth` parameter) falls within the style run (represented by the `textLen` bytes starting at `textBuf`). Otherwise, the location contains the amount of pixels by which the input pixel location (`pixelWidth`) extends beyond the right edge of the text for which you called `PixelToChar`.

styleRunPosition

The position on the line of this style run. The style run can be the only one on the line, the leftmost on the line, the rightmost on the line, or one between two other style runs.

This parameter specifies the position of the style run on the display line. It is used to determine the proportion of total slop to apply to a style run, measure or draw a line of justified text, identify where to break a line of text, and determine the caret position to mark an insertion point or highlight text.

The style run position parameter is meaningful only for those script systems that use intercharacter spacing for justification. For all other script systems, the parameter exists for future extensibility. Although the style run position parameter is not used, for example, for justifying text in the Roman script system, to allow for future compatibility, you should always specify the appropriate value for it for all calls that take it.

For those script systems that do use intercharacter spacing, space between style runs may be allocated differently depending upon whether the style run is leftmost, rightmost, or between two other style runs. For example, depending on the script system, if a style run occurs at the beginning or end of a line, extra space may not be added to the outer edge of the outermost glyph, whereas if a style run is interior to a line, all of the glyphs of the text may be treated the same: extra space is allocated to both sides of every glyph including those at either end of the style run.

The current implementations of simple script systems such as Roman and Cyrillic do not justify a line of text by changing the width of nonspace characters. Instead, they rely solely on the use of space characters: the same amount of extra width is added to (or subtracted from) every space whether the space is at the beginning or end of the line or interior to it.

See "Style Run Position Constants" (page 2951) for a list of the constants you can supply.

numer

A point giving the numerator for the horizontal and vertical scaling factors.

Both `numer` and `denom` are point values: `numer` specifies the numerator for the horizontal and vertical scaling factors, and `denom` specifies the denominator for the horizontal and vertical scaling factors. Together, these values specify the scaling factors for the text: `numer.v` over `denom.v` gives the vertical scaling (height), and `numer.h` over `denom.h` gives the horizontal scaling factors (width). You need to specify values for `numer` and `denom` even if you are not scaling the text. For unscaled text, you can specify scaling factors of 1, 1.

denom

A point giving the denominator for the horizontal and vertical scaling factors.

Return Value
The byte offset of a character in a style run, or part of a style run, whose onscreen glyph is nearest the place where the user clicked the mouse.

Discussion
You can use the information that `PixelToChar` returns for highlighting, word selection, and identifying the caret position. The `PixelToChar` function returns a byte offset and a Boolean value that describes whether the pixel location is on the leading edge or trailing edge of the glyph where the mouse-down event occurred. When the pixel location falls on a glyph that corresponds to one or more characters that are part of the text segment, the `PixelToChar` function uses the direction of the character or characters to determine which side of the glyph is the leading edge. (A glyph can represent more than one character, for example, for a ligature. Generally, if a glyph represents more than one character, all of the characters have the same text direction.)

If the pixel location is on the leading edge, `PixelToChar` returns the byte offset of the character whose glyph is at the pixel location. (If the glyph represents multiple characters, it returns the byte offset of the first of these characters in memory.) If the pixel location is on the trailing edge, `PixelToChar` returns the byte offset of the first character in memory following the character or characters represented by the glyph. If the pixel location is on the trailing edge of the glyph that corresponds to the last character in the text segment, `PixelToChar` returns a byte offset equal to the length of the text segment.

When the pixel location is before the leading edge of the first glyph in the displayed text segment, `PixelToChar` returns a leading edge value of `FALSE` and the byte offset of the first character. When the pixel location is after the trailing edge of the last glyph in the displayed text segment, `PixelToChar` returns a leading edge value of `TRUE` and the next byte offset in memory, the one after the last character in the text segment. If the primary line direction is left to right, before means to the left of all of the glyphs for the characters in the text segment, and after means to the right of all these glyphs. If the primary line direction is right to left, before and after hold the opposite meanings.

You also use the value of the `leadingEdge` flag to help determine the value of the `direction` parameter to pass to `CharToPixel`, which you call to get the caret position. If the `leadingEdge` flag is `FALSE`, you base the value of the `direction` parameter on the direction of the character at the byte offset in memory that precedes the one that `PixelToChar` returns; if `leadingEdge` is `TRUE`, you base the value of the `direction` parameter on the direction of the character at the byte offset that `PixelToChar` returns. If there isn't a character at the byte offset, you base the value of the `direction` parameter on the primary line direction as determined by the `SysDirection` global variable.

You specify a value for `textLen` that is equal to the entire visible part of the style run on a line and includes trailing spaces if and only if they are displayed. They may not be displayed, for example, for the last style run in memory order that is part of the current line.

Be sure to pass the same values for `styleRunPosition` and the scaling factors (`numer` and `denom`) to `PixelToChar` that you pass to any of the other justification functions for this style run.

You pass `PixelToChar` a pointer to the byte offset of the character in the text buffer that begins the text segment or style run containing the character whose glyph is at the pixel location. If you do not know which style run on the display line contains the character whose glyph is at the pixel location, you can loop through the style runs until you find the one that contains the pixel location. If the style run contains the character, `PixelToChar` returns its byte offset. If it doesn't, you can use the `widthRemaining` parameter value to help determine which style run contains the glyph at the pixel location.

If you pass `PixelToChar` the pixel width of the display line, you can use the returned value of `widthRemaining` to calculate the length of a style run. The `widthRemaining` parameter contains the length in pixels from the end of the style run for which you call `PixelToChar` to the end of the display line, in this

case, if the style run for which you call it does not include the byte offset whose glyph corresponds to the pixel location. You subtract the returned `widthRemaining` value from the screen pixel width of the display line to get the style run's length.

To truncate a line of text, you can use `PixelToChar` to find the byte offset of the character where the line should be broken. To return the correct byte offset associated with the pixel location of a mouse-down event when the text belongs to a right-to-left script system, the `PixelToChar` function reorders the text. If right-to-left text is reordered when you use `PixelToChar` to determine where to break a line, it returns the wrong byte offset. To get the correct result, you must turn off reordering before you call `PixelToCha` r. Remember to restore reordering after you have determined where to break the line.

The `PixelToChar` function works with text in all script systems, and for text that is justified or not. For contextual script systems, `PixelToChar` takes into account the widths of any ligatures, reversals, and compound characters that were created when the text was drawn.

Because 2-byte script systems also include characters consisting of only one byte, you should not simply multiply the number of characters by 2 to determine this value; you must determine and specify the correct number of bytes.

Special Considerations

The `PixelToChar` function may move memory; do not call this function at interrupt time.

`QuickdrawText.h`

PortionLine

Determines the correct proportion of extra space to apply to the specified style run in a line of justified text; that is, how to distribute the total slop value for a line among the style runs on that line. (Deprecated in Mac OS X v10.4. Use ATSUI instead.)

```
Fixed PortionLine (
   Ptr textPtr,
   long textLen,
   JustStyleCode styleRunPosition,
   Point numer,
   Point denom
);
```

Parameters

textPtr

A pointer to the style run.

textLen

The number of bytes in the text of the style run.

styleRunPosition

The position on the line of this style run. The style run can be the only one on the line, the leftmost on the line, the rightmost on the line, or one between two other style runs.

This parameter specifies the position of the style run on the display line. It is used to determine the proportion of total slop to apply to a style run, measure or draw a line of justified text, identify where to break a line of text, and determine the caret position to mark an insertion point or highlight text.

The style run position parameter is meaningful only for those script systems that use intercharacter spacing for justification. For all other script systems, the parameter exists for future extensibility. Although the style run position parameter is not used, for example, for justifying text in the Roman script system, to allow for future compatibility, you should always specify the appropriate value for it for all calls that take it.

For those script systems that do use intercharacter spacing, space between style runs may be allocated differently depending upon whether the style run is leftmost, rightmost, or between two other style runs. For example, depending on the script system, if a style run occurs at the beginning or end of a line, extra space may not be added to the outer edge of the outermost glyph, whereas if a style run is interior to a line, all of the glyphs of the text may be treated the same: extra space is allocated to both sides of every glyph including those at either end of the style run.

The current implementations of simple script systems such as Roman and Cyrillic do not justify a line of text by changing the width of nonspace characters. Instead, they rely solely on the use of space characters: the same amount of extra width is added to (or subtracted from) every space whether the space is at the beginning or end of the line or interior to it.

See "Style Run Position Constants" (page 2951) for a list of the constants you can supply.

numer

A point giving the numerator for the horizontal and vertical scaling factors.

Both `numer` and `denom` are point values: `numer` specifies the numerator for the horizontal and vertical scaling factors, and `denom` specifies the denominator for the horizontal and vertical scaling factors. Together, these values specify the scaling factors for the text: `numer.v` over `denom.v` gives the vertical scaling (height), and `numer.h` over `denom.h` gives the horizontal scaling factors (width). You need to specify values for `numer` and `denom` even if you are not scaling the text. For unscaled text, you can specify scaling factors of 1, 1.

denom

A point giving the denominator for the horizontal and vertical scaling factors.

Return Value
A number that represents the portion of the slop to be applied to the style run for which it is called.

Discussion
You use `PortionLine` in formatting a line of justified text. It helps you determine how to distribute the slop for a line among its style runs. When you know the total slop for a line of text, you need to determine what portion of it to attribute to each style run. To do this, you call the `PortionLine` function once for each style run on the line. The `PortionLine` function computes the portion of extra space for a style run, taking into account the font, size, style, and scaling factors of the style run. It returns a number that represents the portion of the slop to be applied to the style run for which it is called. You use the value that `PortionLine` returns to determine the percentage of slop that you should attribute to a style run.

To determine the percentage of slop to allocate to each style run, you compute what percentage each portion is of the sum of all portions. To determine the actual slop value in pixels for each style run, you apply the percentage to the total slop value. The following steps summarize this process:

1. Call `PortionLine` for each style run on the line.

2. Add the returned values together.

3. Calculate the percentage of the slop value for each style run using the ratio of the value returned by `PortionLine` for that style run and the total of the values returned for all of the style runs on the line.

4. Calculate the number of pixels to be added to each style run by multiplying the percentage of the slop for each style run by the total number of pixels.

Be sure to pass the same values for `styleRunPosition` and the scaling factors (`numer` and `denom`) to `PortionLine` that you pass to any of the other justification functions for this style run.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`QuickdrawText.h`

SpaceExtra

Specifies the number of pixels by which to widen (or narrow) each space in a style run to be drawn in the current graphics port. (Deprecated in Mac OS X v10.4. Use ATSUI instead.)

```
void SpaceExtra (
   Fixed extra
);
```

Parameters

extra

The amount (in pixels or binary fractions of a pixel) to widen (or narrow) each space in a style run on a line.

Discussion
The `SpaceExtra` function sets the value of the extra space (`spExtra`) field in the current graphics port structure. The initial setting is `0`. You can pass a negative value for the extra parameter, but be careful not to narrow spaces so much that the text is unreadable. The value you specify is added to the width of each space character in the style run. For those script systems that do not use spaces, any value set in the extra space field is ignored. For those script systems that use spaces as delimiters, if you do not want to justify a line of text using `DrawJustified`, you can use the `SpaceExtra` function to set a fixed number of pixels to be added to each space character, then call `DrawText` or `DrawString`.

When you use the justification functions (`MeasureJustified`, `DrawJustified`) to measure or draw justified text, they temporarily reset the extra space value. They add to the current value of the field, if any, the amount of extra space to be added to space characters in the specified text in order to justify the text, based on calculations that take into account the slop value for the range of text and all of the text characteristics. On exit, these functions restore the original value.

For a color graphics port (`CGrafPort`), you can use `SpaceExtra` by itself or in conjunction with the `CharExtra` function to format a line of text in the 1-byte simple or 2-byte script systems. You should not use `CharExtra` for 1-byte complex script systems.

To ensure future compatibility and benefit from any enhancements, always use this function to modify the `spExtra` field, rather than directly change the field value.

`QuickdrawText.h`

StdText

Draws text from an arbitrary structure in memory. (Deprecated in Mac OS X v10.4. Use ATSUI or Quartz instead.)

```
void StdText (
   short count,
   const void *textAddr,
   Point numer,
   Point denom
);
```

Parameters

count
The number of bytes of text to draw.

textAddr
A memory structure containing the text to draw.

numer
Scaling numerator.

denom
Scaling denominator.

Discussion
This is QuickDraw's standard low-level function for drawing text. The `StdText` function draws text from the arbitrary structure in memory specified by the `textBuf` parameter, starting from the first byte and continuing for the number of bytes specified in the `byteCount` parameter. The `numer` and `denom` parameters specify the scaling factor: `numer.v` over `denom.v` gives the vertical scaling, and `numer.h` over `denom.h` gives the horizontal scaling factor.

You should only call this low-level function from your customized QuickDraw functions.

Special Considerations

The `StdText` function may move or purge memory blocks in the application heap; do not call this function at interrupt time.

StdTxMeas

Measures the width of scaled or unscaled text. (Deprecated in Mac OS X v10.4. Use ATSUI instead.)

```
short StdTxMeas (
   short byteCount,
   const void *textAddr,
   Point *numer,
   Point *denom,
   FontInfo *info
);
```

Parameters

byteCount

The number of bytes to be counted.

textAddr

A pointer to the beginning of the text in memory.

numer

Pointer to a point giving the numerator for the horizontal and vertical scaling factors. For this function, `numer` and `denom` are reference parameters. On output, these parameters contain additional scaling to be applied to the text.

Both `numer` and `denom` are point values: `numer` specifies the numerator for the horizontal and vertical scaling factors, and `denom` specifies the denominator for the horizontal and vertical scaling factors. Together, these values specify the scaling factors for the text: `numer.v` over `denom.v` gives the vertical scaling (height), and `numer.h` over `denom.h` gives the horizontal scaling factors (width). You need to specify values for `numer` and `denom` even if you are not scaling the text. For unscaled text, you can specify scaling factors of 1, 1.

denom

Pointer to a point giving the denominator for the horizontal and vertical scaling factors.

info

Pointer to a font information structure that describes the current font.

Return Value

The width of the text stored in memory, beginning with the first character at `textAddr` and continuing for `byteCount` bytes.

Discussion

The `StdTxMeas` function is a QuickDraw bottleneck function that the QuickDraw text-measuring functions use extensively. The `StdTxMeas` function returns the width of the text stored in memory beginning with the first character at `textAddr` and continuing for `byteCount` bytes. You can call the `StdTxMeas` function directly, for example, to measure text that you want to explicitly scale, but not justify. You can also use `StdTxMeas` to get the font metrics for scaled text in order to determine the line height, instead of using `GetFontInfo`, which doesn't support scaling.

The high-level QuickDraw text functions provide most of the functionality needed to measure and draw text. However, if you need to call `StdTxMeas` directly, you must first check the graphics port `grafProcs` field to determine whether the bottleneck functions have been customized, and if so, you must call the customized function instead of the standard one. The bottleneck functions are always customized for printing.

If the `grafProcs` field contains `NULL`, the standard bottleneck functions have not been customized. If the `grafProcs` field contains a pointer, the standard bottleneck functions have been replaced by customized ones. This pointer (of type `QDProcPtr`) points to a `QDProc` structure, which contains fields that point to the bottleneck function to be used for a specific drawing function. If the standard bottleneck function has been customized, your application needs to use the customized function indicated by the `QDProc` structure field.

On input, you need to specify values for `numer` and `denom`, even if you are not scaling the text. You can specify 1,1 scaling factors, in this case, so that no scaling is applied. On return, `numer` and `denom` contain the additional scaling to be applied to the text.

The `StdTxtMeas` function returns output scaling factors that you need to apply to the text to get the right measurement if the Font Manager was not able to fully satisfy the scaling request. You can use the Toolbox Utilities' `FixRound` and `FixRatio` functions to help with this process.

The `StdTxMeas` function gives the correct results for all script systems. The `byteCount` parameter is the number of bytes of the text to be drawn, not characters. When specifying this value, consider that 2-byte script systems also include characters consisting of only one byte.

`QuickdrawText.h`

StringWidth

Returns the length, in pixels, of the specified text string. (Deprecated in Mac OS X v10.4. Use ATSUI instead.)

```
short StringWidth (
   ConstStr255Param s
);
```

Parameters

s

A Pascal string containing the text to be measured.

Return Value
The length, in pixels, of the specified text string.

Discussion
You should not call `StringWidth` to measure scaled text. Although `StringWidth` takes into account the graphics port structure settings, it does not accept scaling parameters, and therefore cannot determine the correct text width result for text to be drawn using scaling factor parameters.

If you specify values in the graphics port `spExtra` or `chExtra` fields to change the width of space or nonspace characters, `StringWidth` takes these values into account.

Because this function measures text in the font, style, and size of the current graphics port, you need to call it once for each individual style run in any line of text that contains multiple style runs.

The `StringWidth` function works with all script systems.

StyledLineBreak

Returns the proper location to break a line of text, taking into account script and language considerations, making use of tables in the string-manipulation (`'itl2'`) resource in its computations. (Deprecated in Mac OS X v10.4. Use ATSUI instead.)

```
StyledLineBreakCode StyledLineBreak (
   Ptr textPtr,
   SInt32 textLen,
   SInt32 textStart,
   SInt32 textEnd,
   SInt32 flags,
   Fixed *textWidth,
   SInt32 *textOffset
);
```

Parameters

`textPtr`
A pointer to the beginning of a script run on the current line to be broken.

`textLen`
The number of bytes in the script run on the current line to be broken.

`textStart`
A byte offset to the beginning of a style run within the script run.

When used with unformatted text, `textStart` can be 0, and `textEnd` is identical to `textLen`. With styled text, the interval between `textStart` and `textEnd` specifies a style run. The interval between `textPtr` and `textLen` specifies a script run. Note that the style runs in `StyledLineBreak` must be traversed in memory order, not in display order.

`textEnd`
A byte offset to the end of the style run within the script run.

`flags`
Reserved for future expansion; must be 0.

`textWidth`
A pointer to the maximum length of the displayed line in pixels. `StyledLineBreak` decrements this value for its own use. You are responsible for setting it before your first call to `StyledLineBreak` for a line.

`StyledLineBreak` automatically decrements the `textWidth` variable by the width of the style run for use on the next call. You need to set the value of `textWidth` before calling it to process a line.

textOffset

A pointer to the text offset value, which must be nonzero on your first call to `StyledLineBreak` for a line, and zero for subsequent calls to `StyledLineBreak` for that line. This value allows `StyledLineBreak` to differentiate between the first and subsequent calls, which is important when a long word is found (as described below).

The `textOffset` parameter must be nonzero for the first call on a line and zero for each call to the function on the line. This allows `StyledLineBreak` to act differently when a long word is encountered: if the word is in the first style run on the line, `StyledLineBreak` breaks the line on a character boundary within the word; if the word is in a subsequent style run on the line, `StyledLineBreak` breaks the line before the start of the word.

On output, `textOffset` is the count of bytes from `textPtr` to the location in the text string where the line break is to occur. When `StyledLineBreak` finds a line break, it sets the value of `textOffset` to the count of bytes that can be displayed starting at `textPtr`.

When `StyledLineBreak` is called for the second or subsequent style runs within a script run, the `textOffset` value at exit may be less than the `textStart` parameter (that is, it may specify a line break before the current style run).

Return Value
Indicates whether the function broke on a word boundary or a character boundary, or if the width extended beyond the edge of the text. See "Style Line Break Values" (page 2950) for a list of the constants that can be returned.

Discussion
The function `StyledLineBreak` breaks the line on a word boundary if possible and allows for multiscript runs and style runs on a single line.

Use the `StyledLineBreak` function when you are laying out lines in an environment that may include text from multiple scripts. To use this function, you need to understand how QuickDraw draws text.

You can only use the `StyledLineBreak` function when you have organized your text in script runs and style runs within each script run. This type of text organization is used by most text-processing applications that allow for multiscript text. Use this function when you are displaying text in a screen area to determine the best place to break each displayed line.

What you do is iterate through your text, a script run at a time starting from the first character past the end of the previous line. Use `StyledLineBreak` to check each style run in the script run (in memory order) until the function determines that it has arrived at a line break. As you loop through each style run, before calling `StyledLineBreak`, you must set the text values in the graphics port structure that are used by QuickDraw to measure the text. These include the font, font size, and font style of the style run.

If the current style run is included in a contiguous sequence of other style runs of the same script, then `textPtr` should point to the start of the first style run of the same script on the line, and `textLen` should include the last style run of the same script on the line. This is because word boundaries can extend across style runs, but not across script runs.

Although the offsets are in long integer values and the widths are in fixed values for future extensions, in the current version the long integer values are restricted to the integer range, and only the integer portion of the widths is used.

`StyledLineBreak` always chooses a line break for the last style run on the line in memory order as if all whitespace in that style run would be stripped. The `VisibleLength` function, which is a QuickDraw function used to eliminate trailing spaces from a style run before drawing it, can be called for the style run that is at

the display end of a line. This leads to a potential conflict when both functions are used with mixed-directional text: if the end of a line in memory order actually occurs in the middle of the displayed line, `StyledLineBreak` assumes that the whitespace is stripped from that run, but `VisibleLength` does not strip the characters.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawText.h`

TextFace

Sets the style of the font in which the text is to be drawn in the current graphics port. (Deprecated in Mac OS X v10.4. Use ATSUI or Quartz instead.)

```
void TextFace (
   StyleParameter face
);
```

Parameters

face

The style for text to be drawn in the current graphics port.

Discussion
The `TextFace` function sets the value for the style of the font in the text face (`txFace`) field of the current graphics port. The `Style` data type allows you to specify a set of one or more of the following predefined constants: `bold`, `italic`, `underline`, `outline`, `shadow`, `condense`, and `extend`. In Pascal, you specify the constants within square brackets. For example:

```
TextFace([bold]);
{bold}TextFace([bold,italic]);
{bold and italic}
```

The style is set to the empty set (`[]`) by default, which specifies plain.

To ensure future compatibility and benefit from any enhancements, always use this function to modify the `txFace` field, rather than directly change the field value.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawText.h`

TextFont

Sets the font of the current graphics port in which the text is to be rendered. (Deprecated in Mac OS X v10.4. Use ATSUI or Quartz instead.)

```
void TextFont (
   short font
);
```

Parameters

font

The font family ID. The initial font family ID is `0`, which represents the system font. The value that you specify for this field is either an integer or a constant. The range of integers currently defined are from `0` to `32767`. Currently, negative font family IDs are not supported, although they may be supported in the future.

The system font and application font have different font IDs and sizes on various script systems. However, the special designators `0` and `1` always map to the system font and the application font for the system script, respectively.

Discussion
The `TextFont` function sets the value of the graphics port text font (`txFont`) field. To ensure future compatibility and benefit from any enhancements, always use this function to modify the `txFont` field, rather than directly change the field value.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

TextMode

Sets the transfer mode for drawing text in the current graphics port. (Deprecated in Mac OS X v10.4. Use ATSUI or Quartz instead.)

```
void TextMode (
   short mode
);
```

Parameters

mode

The transfer mode to be used to draw the text.

Discussion
The `TextMode` function sets the transfer mode in the graphics port `txMode` field. The transfer mode determines the interplay between what an application is drawing (the source) and what already exists on the display device (the destination), resulting in the text display.

There are two basic kinds of modes: pattern (`pat`) and source (`src`). Source is the kind that you use for drawing text. There are four basic Boolean operations: `Copy`, `Or`, `Xor`, and `Bic` (bit clear), each of which has an inverse variant in which the source is inverted before the transfer, yielding eight operations in all. Original QuickDraw supports these eight transfer modes. Color QuickDraw enables your application to achieve color

effects within those basic transfer modes, and offers an additional set of transfer modes that perform arithmetic operations on the RGB values of the source and destination pixels. Other transfer modes are `grayishTextOr`, `transparent` mode, and text mask mode.

To ensure future compatibility and benefit from any enhancements, always use this function to modify the `txMode` field, rather than directly change the field value.

`QuickdrawText.h`

TextWidth

Returns the length, in pixels, of the specified text. (Deprecated in Mac OS X v10.4. Use ATSUI instead.)

```
short TextWidth (
   const void *textBuf,
   short firstByte,
   short byteCount
);
```

Parameters

textBuf

A pointer to a buffer that contains the text to be measured.

firstByte

An offset from `textBuf` to the first byte of the text to be measured.

byteCount

The number of bytes of text to be measured.

Return Value

The length, in pixels, of the specified text.

Discussion

You can use `TextWidth` to measure the screen pixel width of any text segment that has uniform character attributes. You can use it to measure the style runs in a line of text, whether you intend to draw the line using `DrawText` or `DrawJustified`. The `TextWidth` function takes into account the character attributes set in the graphics port. If you change any of these attributes after determining the text width but before actually drawing the text, the predetermined width may not be correct. For a space character, `TextWidth` also includes the effect of `SpaceExtra`. For a nonspace character, `TextWidth` includes the effect of `CharExtra`.

Because this function measures text in the font, style, and size of the current graphics port, you need to call it once for each individual style run in any line of text that contains multiple style runs.

The `TextWidth` function works with text in all script systems because the script management system modifies the function if necessary to give the proper results.

To draw justified lines of text that include multiple style runs, you calculate the amount of extra pixels, or slop, that remains to be distributed throughout the line. This process entails measuring the screen pixel width of each style run on the line: you can use `TextWidth` for this purpose.

For 1-byte complex script systems, `TextWidth` calculates the widths of any ligatures, reversals, and compound characters that need to be drawn.

Note that `byteCount` is the number of bytes to be measured, not the number of characters. Because 2-byte script systems also include characters consisting of only one byte, you should not simply multiply the number of characters by 2 to determine this value; you must determine and specify the correct number of bytes.

`QuickdrawText.h`

TruncString

Ensures that a Pascal string fits into the specified pixel width, by truncating the string as necessary. This function makes use of the current script and font. (Deprecated in Mac OS X v10.4. Use CFString instead.)

```
short TruncString (
   short width,
   Str255 theString,
   TruncCode truncWhere
);
```

Parameters

width

The number of pixels in which the string must be displayed in the current script and font.

theString

The Pascal string to be displayed. On output, contains a version of the string that has been truncated (if necessary) to fit in the number of pixels specified by `width`.

truncWhere

A constant that indicates where the string should be truncated. If you supply the `truncEnd` value, characters are truncated off the end of the string. If you supply the `truncMiddle` value, characters are truncated from the middle of the string; this is useful when displaying pathnames.

See "Truncation Positions" (page 2953) for a list of the constants you can supply.

Discussion

The `TruncString` function ensures that a Pascal string fits into the pixel width specified by the `width` parameter by modifying the string, if necessary, through truncation. `TruncString` uses the font script to determine how to perform truncation. If truncation occurs, `TruncString` inserts a truncation indicator, which is the ellipsis (…) in the Roman script system. You can specify which token to use for indicating truncation as the `tokenEllipsis` token type in the untoken table of a tokens (`'itl4'`) resource.

To determine the width of a string in the current font and script, use the QuickDraw `StringWidth` function.

Special Considerations

`TruncString` may move memory; your application should not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawText.h`

TruncText

Ensures that a text string fits into the specified pixel width, by truncating the string as necessary. This function makes use of the current script and font. (Deprecated in Mac OS X v10.4. Use CFString instead.)

```
short TruncText (
   short width,
   Ptr textPtr,
   short *length,
   TruncCode truncWhere
);
```

Parameters

width

The number of pixels in which the text string must be displayed in the current script and font.

textPtr

A pointer to the text string to be truncated. The text string can be up to 32 KB long.

length

On input, a pointer to a value containing the length, in bytes, of the text string to be truncated. On output, this value is updated to reflect the length of the (possibly) truncated text.

truncWhere

A constant that indicates where the text string should be truncated. You must set this parameter to one of the constants `truncEnd` or `truncMiddle`. If you supply the `truncEnd` value, characters are truncated off the end of the string. If you supply the `truncMiddle` value, characters are truncated from the middle of the string; this is useful when displaying pathnames.

See "Truncation Positions" (page 2953) for a list of the constants you can supply.

Discussion

You can use the `TruncText` function to ensure that a string defined by a pointer and a byte length fits into the specified pixel width, by truncating the string in a manner dependent on the font script.

`TruncText` uses the font script to determine how to perform truncation. If truncation occurs, `TruncText` inserts a truncation indicator which is the ellipsis (…) in the Roman script system. You can specify which token to use for indicating truncation as the `tokenEllipsis` token type in the untoken table of a tokens resource.

To determine the width of a string in the current font and script, use the QuickDraw `StringWidth` function.

Special Considerations

`TruncText` may move memory; your application should not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawText.h`

VisibleLength

Calculates the length, in bytes, of a given text segment, excluding trailing white space. (Deprecated in Mac OS X v10.4. Use ATSUI instead.)

```
long VisibleLength (
   Ptr textPtr,
   long textLength
);
```

Parameters

textPtr

A pointer to a text string.

textLength

The number of bytes in the text segment.

Return Value

The length, in bytes, of a given text segment, excluding trailing white space.

Discussion

The `VisibleLength` function determines how much of a style run to display, without displaying trailing spaces. You call `VisibleLength` for the last style run of a line in memory order. The last style run in memory order of the text constituting the line is not always the last style run in display order. For a line of unidirectional left-to-right text, the last style run in memory order is the rightmost style run in display order. For a line of unidirectional right-to-left text, the last style run in memory order is the leftmost style run in display order. However, if the text contains mixed directions, the last style run in memory order may be an interior style run in display order.

The text justification functions do not automatically exclude trailing spaces, so you pass them the value that `VisibleLength` returns as the length of the last style run in memory order.

The `VisibleLength` function behaves differently for various script systems. For simple script systems, such as Roman and Cryllic, and for 2-byte script systems, `VisibleLength` does not include in the byte count it returns trailing spaces that occur at the display end of the text segment. For 2-byte script systems, `VisibleLength` does not count them, whether they are 1-byte or 2-byte space characters.

For 1-byte complex script systems, `VisibleLength` does not include in the byte count that it returns spaces whose character direction is the same as the primary line direction. For 1-byte complex script systems that support bidirectional text, Roman spaces take on a character direction based on the primary line direction. If the Roman spaces then fall at the end of the text, `VisibleLength` does not include them in the returned byte count.

The purpose of `VisibleLength` is to trim off white space at the display end of the line. The `VisibleLength` function does not eliminate the white space by removing its character code from memory. Rather, it does not include white space characters in the count that it returns as the length of the range of text for which you call it.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

`QuickdrawText.h`

Callbacks

StyleRunDirectionProcPtr

Defines a pointer to a style run direction callback function that calculates, for a style run identified by number, the direction of that style run.

```
typedef Boolean (*StyleRunDirectionProcPtr)
(
    short styleRunIndex,
    void * dirParam
);
```

If you name your function `MyStyleRunDirectionProc`, you would declare it like this:

```
Boolean StyleRunDirectionProcPtr (
    short styleRunIndex,
    void * dirParam
);
```

Parameters

styleRunIndex

A value that identifies the style run whose direction is needed.

dirParam

A pointer to an application-defined parameter block that contains the font and script information for each style run in the text. The contents of this parameter block are used to determine the direction of the style run. Because of the relationship between the font family ID and the script code, the font family ID can be used to determine the text direction.

Return Value

A Boolean value that is `TRUE` for right-to-left text direction, `FALSE` for left-to-right.

Discussion

To fill the ordering array (type `FormatOrder`) for style runs on a line, the `GetFormatOrder` function calls `MyStyleRunDirectionCallback` for each style run numbered from `firstFormat` to `lastFormat`. `GetFormatOrder` passes `MyStyleRunDirectionCallback` a number identifying the style run in storage order, and a pointer to the parameter information block, `dirParam`, that contains the font and style information for the style run. Given `dirParam` and a style run identifier, the application-defined `MyStyleRunDirectionCallback` function should be able to determine the style run direction.

You should store your style run information in a way that makes it convenient for `MyStyleRunDirectionCallback`. One obvious way to do this is to declare a structure type for style runs that allows you to save things like font style, font family ID, script number, and so forth. You then can store these structures in an array. When the time comes for `GetFormatOrder` to fill the ordering array, `MyStyleRunDirectionCallback` can consult the style run array for direction information for each of the numbered style runs in turn.

For more information, see `GetFormatOrder` (page 2920).

When you provide the Component Manager with a pointer to your function, you should use a universal procedure pointer (UPP). The definition of the UPP data type for your file identification function is as follows:

```
typedef (StyleRunDirectionProcPtr) StyleRunDirectionUPP;
```

Before using your style run direction callback function, you must first create a new universal procedure pointer to it, using the `NewStyleRunDirectionUPP` function, as shown here:

```
StyleRunDirectionUPP MyStyleRunDirectionUPP;

MyStyleRunDirectionUPP = StyleRunDirectionUPP(&MyStyleRunDirectionCallback)
```

You then pass `MyStyleRunDirectionUPP` to the function `GetFormatOrder`. If you wish to call your own callback function, you can use the `InvokeStyleRunDirectionUPP` function:

```
direction = InvokeStyleRunDirectionUPP(styleRunIndex, &paramInfo,
MyStyleRunDirectionUPP)
```

When you are finished using your callback function, you should dispose of the universal procedure pointer associated with it, using the `DisposeStyleRunDirectionUPP` function.

```
DisposeStyleRunDirectionUPP(MyStyleRunDirectionUPP);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`QuickdrawText.h`

Data Types

FontInfo

Contains font metric information.

```
struct FontInfo {
    short ascent;
    short descent;
    short widMax;
    short leading;
};
typedef struct FontInfo FontInfo;
```

Fields

`ascent`
The measurement, in pixels, from the baseline to the ascent line of the font.

`descent`
The measurement, in pixels, from the baseline to the descent line of the font.

`widMax`
The width, in pixels, of the largest glyph in the font.

`leading`
The measurement, in pixels, from the descent line to the ascent line below it.

Discussion
The `FontInfo` data type defines a font information structure. The `GetFontInfo` (page 2919) function uses the font information structure to return measurement information based on the font of the current graphics port. If the current font has an associated font, as do Arabic and Hebrew, `GetFontInfo` returns information

based on both fonts. The font information structure contains the ascent, the descent, the width of the largest glyph, and the leading for a given font. The `StdTxMeas` (page 2934) function also uses a structure of type `FontInfo` to return information about the current font.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`QuickdrawText.h`

FormatOrder

Contains and array of display orders for style runs.

```
typedef  FormatOrder[1];
```

Discussion
The `GetFormatOrder` (page 2920) function fills the supplied format order array with the display order of each style run.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`QuickdrawText.h`

StyleRunDirectionUPP

Defines a universal procedure pointer to a style run direction callback.

```
typedef StyleRunDirectionProcPtr StyleRunDirectionUPP;
```

Discussion
For more information, see the description of the `StyleRunDirectionProcPtr` (page 2946) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`QuickdrawText.h`

Constants

Caret Direction Constants

Specify a caret position.

```
enum {
    leftCaret = 0,
    rightCaret = -1,
    kHilite = 1
};
```

Constants

`leftCaret`
Place caret for left-to-right text direction.
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawText.h`.

`rightCaret`
Place caret for right-to-left text direction.
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawText.h`.

`kHilite`
Specifies that the caret position should be determined according to the primary line direction, based on the value of `SysDirection`.
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawText.h`.

Discussion
You can use these constants to specify a value for `direction`, as used in the `CharToPixel` (page 2911) function.

Truncation Status Values

Returned as result codes for the functions `TruncString` and `TruncText`.

```
enum {
    notTruncated = 0,
    truncated = 1,
    truncErr = -1,
    smNotTruncated = 0,
    smTruncated = 1,
    smTruncErr = -1
};
```

Constants

`notTruncated`
Specifies that truncation is not necessary.
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawText.h`.

`truncated`
Specifies that truncation was performed.
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawText.h`.

`truncErr`
Specifies a general error occurred.
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawText.h`.

`smNotTruncated`
Specifies that truncation is not necessary. This is obsolete.
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawText.h`.

`smTruncated`
Specifies that truncation was performed. This is obsolete.
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawText.h`.

`smTruncErr`
Specifies a general error occurred. This is obsolete.
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawText.h`.

Style Line Break Values

Specify a line break.

```
typedef SInt8 StyledLineBreakCode;
enum {
    smBreakWord = 0,
    smBreakChar = 1,
    smBreakOverflow = 2
};
```

Constants

`smBreakWord`
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawText.h`.

`smBreakChar`
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawText.h`.

`smBreakOverflow`
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawText.h`.

Obsolete Caret Placement Values

Specify where to place a caret.

```
enum {
    smLeftCaret = 0,
    smRightCaret = -1,
    smHilite = 1
};
```

Constants

`smLeftCaret`
Specifies to place caret for left block. This is obsolete.
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawText.h`.

`smRightCaret`
Specifies to place caret for right block. This is obsolete.
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawText.h`.

`smHilite`
Specifies the direction is `TESysJust`. This is obsolete.
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawText.h`.

Style Run Position Constants

Specify style run positions.

```
typedef short JustStyleCode;
enum {
    onlyStyleRun = 0,
    leftStyleRun = 1,
    rightStyleRun = 2,
    middleStyleRun = 3,
    smOnlyStyleRun = 0,
    smLeftStyleRun = 1,
    smRightStyleRun = 2,
    smMiddleStyleRun = 3
};
```

Constants

`onlyStyleRun`
This is the only style run on the line.
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawText.h`.

`leftStyleRun`
This is the leftmost of multiple style runs on the line.
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawText.h`.

`rightStyleRun`
This is the rightmost of multiple style runs on the line
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawText.h`.

`middleStyleRun`
The line and this one is interior: neither leftmost nor rightmost.

Available in Mac OS X v10.0 and later.

Declared in `QuickdrawText.h`.

`smOnlyStyleRun`
This is obsolete.

Available in Mac OS X v10.0 and later.

Declared in `QuickdrawText.h`.

`smLeftStyleRun`
This is obsolete.

Available in Mac OS X v10.0 and later.

Declared in `QuickdrawText.h`.

`smRightStyleRun`
This is obsolete.

Available in Mac OS X v10.0 and later.

Declared in `QuickdrawText.h`.

`smMiddleStyleRun`
This is obsolete.

Available in Mac OS X v10.0 and later.

Declared in `QuickdrawText.h`.

Discussion
Use one of the following constants (defined as type `JustStyleCode`) in the `styleRunPosition` parameter for `PortionLine` (page 2930) `DrawJustified` (page 2915), `MeasureJustified` (page 2923), `CharToPixel` (page 2911), and `PixelToChar` (page 2927).

txFlag Constants

Specify constants for `txFlags`.

```
enum {
    tfAntiAlias = 1 << 0,
    tfUnicode = 1 << 1
};
```

Constants
`tfAntiAlias`
Available in Mac OS X v10.0 and later.

Declared in `QuickdrawText.h`.

`tfUnicode`
Available in Mac OS X v10.0 and later.

Declared in `QuickdrawText.h`.

Discussion
These used to be the pad field after `txFace`.

Truncation Positions

Specify where to truncate a string.

```
typedef  TruncCode;
enum {
    truncEnd = 0,
    truncMiddle = 0x4000,
    smTruncEnd = 0,
    smTruncMiddle = 0x4000
};
```

Constants

`truncEnd`
Truncate at end.
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawText.h`.

`truncMiddle`
Truncate in middle.
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawText.h`.

`smTruncEnd`
Truncate at end. This is obsolete.
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawText.h`.

`smTruncMiddle`
Truncate in middle. This is obsolete.
Available in Mac OS X v10.0 and later.
Declared in `QuickdrawText.h`.
