This collection of documents provides the API reference for the Application Services framework, which includes several services—such as Quartz 2D and Mac OS X accessibility features—that are essential to Carbon applications. (The Quartz 2D API is defined in the Core Graphics interfaces, which begin with the letters "CG.") The Application Services framework also includes support for a number of legacy technologies—such as QuickDraw and the Font Manager—that have been superseded with newer technologies like Quartz 2D and ATSUI.

Introduction

Opaque Types

CGBitmapContext Reference

Derived From:	`CGContextRef` (page 137)
Framework:	ApplicationServices/ApplicationServices.h
Declared in	CGBitmapContext.h
Companion guide	Quartz 2D Programming Guide

Overview

The CGBitmapContext header file defines functions that create and operate on a Quartz bitmap graphics context. A bitmap graphics context is a type of `CGContextRef` (page 137) that you can use for drawing bits to memory. The functions in this reference operate only on Quartz bitmap graphics contexts created using the functionCGBitmapContextCreate (page 24).

The number of components for each pixel in a bitmap graphics context is specified by a color space (defined by a `CGColorSpaceRef` (page 56), which includes RGB, grayscale, and CMYK, and which also may specify a destination color profile). The bitmap graphics context specifies whether the bitmap should contain an alpha channel, and how the bitmap is generated.

Functions by Task

Creating Bitmap Contexts

`CGBitmapContextCreate` (page 24)
Creates a bitmap graphics context.

`CGBitmapContextCreateImage` (page 25)
Creates and returns a Quartz image from the pixel data in a bitmap graphics context.

Getting Information About Bitmap Contexts

These functions return the values of attributes specified when a bitmap context is created.

`CGBitmapContextGetBitmapInfo` (page 26)
Obtains the bitmap information associated with a bitmap graphics context.

`CGBitmapContextGetAlphaInfo` (page 26)
Returns the alpha information associated with the context, which indicates how a bitmap context handles the alpha component.

`CGBitmapContextGetBitsPerComponent` (page 27)
Returns the bits per component of a bitmap context.

`CGBitmapContextGetBitsPerPixel` (page 27)
Returns the bits per pixel of a bitmap context.

`CGBitmapContextGetBytesPerRow` (page 28)
Returns the bytes per row of a bitmap context.

`CGBitmapContextGetColorSpace` (page 28)
Returns the color space of a bitmap context.

`CGBitmapContextGetData` (page 28)
Returns a pointer to the image data associated with a bitmap context.

`CGBitmapContextGetHeight` (page 29)
Returns the height in pixels of a bitmap context.

`CGBitmapContextGetWidth` (page 29)
Returns the width in pixels of a bitmap context.

Functions

CGBitmapContextCreate

Creates a bitmap graphics context.

```
CGContextRef CGBitmapContextCreate (
   void *data,
   size_t width,
   size_t height,
   size_t bitsPerComponent,
   size_t bytesPerRow,
   CGColorSpaceRef colorspace,
   CGBitmapInfo bitmapInfo
);
```

Parameters

data
A pointer to the destination in memory where the drawing is to be rendered. The size of this memory block should be at least `(bytesPerRow*height)` bytes.

Starting in Mac OS X v10.3, you can pass `NULL` if you don't care where the data is stored. This frees you from managing your own memory, which reduces memory leak issues. Quartz has more flexibility when it manages data storage for you. For example, it's possible for Quartz to use OpenGL for rendering if it takes care of the memory.

width
The width, in pixels, of the required bitmap.

height
The height, in pixels, of the required bitmap.

bitsPerComponent
The number of bits to use for each component of a pixel in memory. For example, for a 32-bit pixel format and an RGB color space, you would specify a value of 8 bits per component. For more information about supported pixel formats, see *Quartz 2D Programming Guide*.

bytesPerRow
The number of bytes of memory to use per row of the bitmap.

colorspace
The color space to use for the bitmap context. Note that indexed color spaces are not supported for bitmap graphics contexts.

bitmapInfo
A `CGBitmapInfo` constant that specifies whether the bitmap should contain an alpha channel and its relative location in a pixel, along with whether the components are floating-point or integer values. (See *CGImage Reference* for a description `CGBitmapInfo` constants.) In *Quartz 2D Programming Guide*, see "Creating a Bitmap Graphics Context" (in the *Graphics Contexts* chapter) for the color space, bits per pixel, bits per pixel component, and bitmap information constant combinations that you can use when creating a bitmap context with `CGBitmapContextCreate`.

Return Value
A new bitmap context, or `NULL` if a context could not be created. You are responsible for releasing this object using `CGContextRelease` (page 102).

Discussion
When you call this function, Quartz creates a bitmap drawing environment—that is, a bitmap context—to your specifications. When you draw into this context, Quartz renders your drawing as bitmapped data in the specified block of memory.

The pixel format for a new bitmap context is determined by three parameters—the number of bits per component, the color space, and an alpha option (expressed as a `CGBitmapInfo` (page 227) constant). The alpha value determines the opacity of a pixel when it is drawn.

Availability
Available in Mac OS X version 10.0 and later.

Related Sample Code
CarbonSketch

Declared In
`CGBitmapContext.h`

CGBitmapContextCreateImage

Creates and returns a Quartz image from the pixel data in a bitmap graphics context.

```
CGImageRef CGBitmapContextCreateImage (
   CGContextRef c
);
```

Parameters

c
A bitmap graphics context.

Return Value
A CGImage object that contains a snapshot of the bitmap graphics context or `NULL` if the image is not created.

Discussion
The CGImage object returned by this function is created by a copy operation. Subsequent changes to the bitmap graphics context do not affect the contents of the returned image. In some cases the copy operation actually follows copy-on-write semantics, so that the actual physical copy of the bits occur only if the underlying

data in the bitmap graphics context is modified. As a consequence, you may want to use the resulting image and release it before you perform additional drawing into the bitmap graphics context. In this way, you can avoid the actual physical copy of the data.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGBitmapContext.h`

CGBitmapContextGetAlphaInfo

Returns the alpha information associated with the context, which indicates how a bitmap context handles the alpha component.

```
CGImageAlphaInfo CGBitmapContextGetAlphaInfo (
   CGContextRef c
);
```

Parameters

context

A bitmap context.

Return Value
A bitmap information constant. If the specified context is not a bitmap context, `kCGImageAlphaNone` (page 226) is returned. See `CGImageAlphaInfo` (renamed to `CGBitmapInfo` in Mac OS X v10.4) for more information about values.

Discussion
Every bitmap context contains an attribute that specifies whether the bitmap contains an alpha component, and how it is generated. The alpha component determines the opacity of a pixel when it is drawn.

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CGBitmapContext.h`

CGBitmapContextGetBitmapInfo

Obtains the bitmap information associated with a bitmap graphics context.

```
CGBitmapInfo CGBitmapContextGetBitmapInfo (
   CGContextRef c
);
```

Parameters

c

A bitmap graphics context.

Return Value
The bitmap info of the bitmap graphics context or `0` if `c` is not a bitmap graphics context. See *CGImage Reference* for a description of the `CGBitmapInfo` (page 227) constants that can be returned.

Discussion
The `CGBitmapInfo` data returned by the function specifies whether the bitmap contains an alpha channel and how the alpha channel is generated, along with whether the components are floating-point or integer.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGBitmapContext.h`

CGBitmapContextGetBitsPerComponent

Returns the bits per component of a bitmap context.

```
size_t CGBitmapContextGetBitsPerComponent (
   CGContextRef c
);
```

Parameters

context
The bitmap context to examine.

Return Value
The number of bits per component in the specified context, or `0` if the context is not a bitmap context.

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CGBitmapContext.h`

CGBitmapContextGetBitsPerPixel

Returns the bits per pixel of a bitmap context.

```
size_t CGBitmapContextGetBitsPerPixel (
   CGContextRef c
);
```

Parameters

context
The bitmap context to examine.

Return Value
The number of bits per pixel in the specified context, or `0` if the context is not a bitmap context.

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CGBitmapContext.h`

CGBitmapContextGetBytesPerRow

Returns the bytes per row of a bitmap context.

```
size_t CGBitmapContextGetBytesPerRow (
   CGContextRef c
);
```

Parameters

context

The bitmap context to examine.

Return Value

The number of bytes per row of the specified context, or `0` if the context is not a bitmap context.

Availability

Available in Mac OS X version 10.2 and later.

Declared In

`CGBitmapContext.h`

CGBitmapContextGetColorSpace

Returns the color space of a bitmap context.

```
CGColorSpaceRef CGBitmapContextGetColorSpace (
   CGContextRef c
);
```

Parameters

context

The bitmap context to examine.

Return Value

The color space of the specified context, or `NULL` if the context is not a bitmap context. You are responsible for retaining and releasing this object as necessary.

Availability

Available in Mac OS X version 10.2 and later.

Declared In

`CGBitmapContext.h`

CGBitmapContextGetData

Returns a pointer to the image data associated with a bitmap context.

```
void * CGBitmapContextGetData (
   CGContextRef c
);
```

Parameters

context

The bitmap context to examine.

Return Value
A pointer to the specified bitmap context's image data, or `NULL` if the context is not a bitmap context.

Availability
Available in Mac OS X version 10.2 and later.

Related Sample Code
CarbonSketch

Declared In
`CGBitmapContext.h`

CGBitmapContextGetHeight

Returns the height in pixels of a bitmap context.

```
size_t CGBitmapContextGetHeight (
   CGContextRef c
);
```

Parameters

context
The bitmap context to examine.

Return Value
The height in pixels of the specified context, or `0` if the context is not a bitmap context.

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CGBitmapContext.h`

CGBitmapContextGetWidth

Returns the width in pixels of a bitmap context.

```
size_t CGBitmapContextGetWidth (
   CGContextRef c
);
```

Parameters

context
The bitmap context to examine.

Return Value
The width in pixels of the specified context, or `0` if the context is not a bitmap context.

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CGBitmapContext.h`

CGColor Reference

Derived From:	CFType
Framework:	ApplicationServices/ApplicationServices.h
Declared in	CGColor.h
Companion guide	Quartz 2D Programming Guide

Overview

The `CGColorRef` opaque type contains a set of components (such as red, green, and blue) that uniquely define a color, and a color space that specifies how those components should be interpreted. Quartz color objects provide a fast and convenient way to manage and set colors, especially colors that are used repeatedly. Quartz drawing operations use color objects for setting fill and stroke colors, managing alpha, and setting color with a pattern.

See also these related references: *CGContext Reference*, *CGColorSpace Reference*, and *CGPattern Reference*.

Functions by Task

Getting a Constant Color

`CGColorGetConstantColor` (page 38)
Returns a color object that represents a constant color.

Retaining and Releasing Color Objects

`CGColorRelease` (page 40)
Decrements the retain count of a Quartz color.

`CGColorRetain` (page 40)
Increments the retain count of a Quartz color.

Creating Quartz Colors

`CGColorCreate` (page 32)
Creates a Quartz color using a list of intensity values (including alpha) and an associated color space.

`CGColorCreateCopy` (page 33)
Creates a copy of an existing Quartz color.

`CGColorCreateGenericGray` (page 35)
Creates a color in the Generic gray color space.

`CGColorCreateGenericRGB` (page 35)
Creates a color in the Generic RGB color space.

`CGColorCreateGenericCMYK` (page 34)
Creates a color in the Generic CMYK color space.

`CGColorCreateCopyWithAlpha` (page 33)
Creates a copy of an existing Quartz color, substituting a new alpha value.

`CGColorCreateWithPattern` (page 36)
Creates a Quartz color using a list of intensity values (including alpha), a pattern color space, and a pattern.

Getting Information about Quartz Colors

`CGColorEqualToColor` (page 36)
Indicates whether two colors are equal.

`CGColorGetAlpha` (page 37)
Returns the value of the alpha component associated with a Quartz color.

`CGColorGetColorSpace` (page 37)
Returns the color space associated with a Quartz color.

`CGColorGetComponents` (page 38)
Returns the values of the color components (including alpha) associated with a Quartz color.

`CGColorGetNumberOfComponents` (page 38)
Returns the number of color components (including alpha) associated with a Quartz color.

`CGColorGetPattern` (page 39)
Returns the pattern associated with a Quartz color in a pattern color space.

`CGColorGetTypeID` (page 39)
Returns the Core Foundation type identifier for a Quartz color data type.

Functions

CGColorCreate

Creates a Quartz color using a list of intensity values (including alpha) and an associated color space.

```
CGColorRef CGColorCreate (
   CGColorSpaceRef colorspace,
   const CGFloat components[]
);
```

Parameters

colorspace

A color space for the new color. Quartz retains this object; upon return, you may safely release it.

components

An array of intensity values describing the color. The array should contain *n*+1 values that correspond to the *n* color components in the specified color space, followed by the alpha component. Each component value should be in the range appropriate for the color space. Values outside this range will be clamped to the nearest correct value.

Return Value

A new Quartz color. You are responsible for releasing this object using `CGColorRelease` (page 40).

Availability

Available in Mac OS X version 10.3 and later.

Declared In

`CGColor.h`

CGColorCreateCopy

Creates a copy of an existing Quartz color.

```
CGColorRef CGColorCreateCopy (
   CGColorRef color
);
```

Parameters

color

A Quartz color.

Return Value

A copy of the specified color. You are responsible for releasing this object using `CGColorRelease` (page 40).

Availability

Available in Mac OS X version 10.3 and later.

Declared In

`CGColor.h`

CGColorCreateCopyWithAlpha

Creates a copy of an existing Quartz color, substituting a new alpha value.

```
CGColorRef CGColorCreateCopyWithAlpha (
   CGColorRef color,
   CGFloat alpha
);
```

Parameters

color

The Quartz color to copy.

alpha

A value that specifies the desired opacity of the copy. Values outside the range `[0,1]` are clamped to `0` or `1`.

Return Value
A copy of the specified color, using the specified alpha value. You are responsible for releasing this object using `CGColorRelease` (page 40).

Availability
Available in Mac OS X version 10.3 and later.

Declared In
`CGColor.h`

CGColorCreateGenericCMYK

Creates a color in the Generic CMYK color space.

```
CGColorRef CGColorCreateGenericCMYK(
    CGFloat cyan,
    CGFloat magenta,
    CGFloat yellow,
    CGFloat black,
    CGFloat alpha
);
```

Parameters

cyan

A cyan value (`0.0` - `1.0`).

magenta

A magenta value (`0.0` - `1.0`).

yellow

A yellow value (`0.0` - `1.0`).

black

A black value (`0.0` - `1.0`).

alpha

An alpha value (0.0 - 1.0).

Return Value
A color object.

Availability
Available in Mac OS X v10.5 and later.

Declared In
CGColor.h

CGColorCreateGenericGray

Creates a color in the Generic gray color space.

```
CGColorRef CGColorCreateGenericGray(
    CGFloat gray,
    CGFloat alpha
);
```

Parameters

gray
A grayscale value (0.0 - 1.0).

alpha
An alpha value (0.0 - 1.0).

Return Value
A color object.

Availability
Available in Mac OS X v10.5 and later.

Declared In
CGColor.h

CGColorCreateGenericRGB

Creates a color in the Generic RGB color space.

```
CGColorRef CGColorCreateGenericRGB(
    CGFloat red,
    CGFloat green,
    CGFloat blue,
    CGFloat alpha
);
```

Parameters

red
A red component value (0.0 - 1.0).

green
A green component value (0.0 - 1.0).

blue
A blue component value (0.0 - 1.0).

alpha
An alpha value (0.0 - 1.0).

Return Value
A color object.

Availability
Available in Mac OS X v10.5 and later.

Related Sample Code
CALayerEssentials

Declared In
CGColor.h

CGColorCreateWithPattern

Creates a Quartz color using a list of intensity values (including alpha), a pattern color space, and a pattern.

```
CGColorRef CGColorCreateWithPattern (
   CGColorSpaceRef colorspace,
   CGPatternRef pattern,
   const CGFloat components[]
);
```

Parameters

colorspace
A pattern color space for the new color. Quartz retains the color space you pass in. On return, you may safely release it.

pattern
A pattern for the new color object. Quartz retains the pattern you pass in. On return, you may safely release it.

components
An array of intensity values describing the color. The array should contain `n + 1` values that correspond to the `n` color components in the specified color space, followed by the alpha component. Each component value should be in the range appropriate for the color space. Values outside this range will be clamped to the nearest correct value.

Return Value
A new Quartz color. You are responsible for releasing this object using `CGColorRelease` (page 40).

Availability
Available in Mac OS X version 10.3 and later.

Declared In
CGColor.h

CGColorEqualToColor

Indicates whether two colors are equal.

```
bool CGColorEqualToColor (
   CGColorRef color1,
   CGColorRef color2
);
```

Parameters

color1
The first Quartz color to compare.

color2
The second Quartz color to compare.

Return Value
A Boolean value that, if `true`, indicates that the specified colors are equal. If the colors are not equal, the value is `false`.

Discussion
Two colors are equal if they have equal color spaces and numerically equal color components.

Availability
Available in Mac OS X version 10.3 and later.

Declared In
`CGColor.h`

CGColorGetAlpha

Returns the value of the alpha component associated with a Quartz color.

```
CGFloat CGColorGetAlpha (
   CGColorRef color
);
```

Parameters

color

A Quartz color.

Return Value
An alpha intensity value in the range `[0,1]`. The value represents the opacity of the color.

Availability
Available in Mac OS X version 10.3 and later.

Declared In
`CGColor.h`

CGColorGetColorSpace

Returns the color space associated with a Quartz color.

```
CGColorSpaceRef CGColorGetColorSpace (
   CGColorRef color
);
```

Parameters

color

A Quartz color.

Return Value
The Quartz color space for the specified color. You are responsible for retaining and releasing it as needed.

Availability
Available in Mac OS X version 10.3 and later.

Declared In
`CGColor.h`

CGColorGetComponents

Returns the values of the color components (including alpha) associated with a Quartz color.

```
const CGFloat * CGColorGetComponents (
   CGColorRef color
);
```

Parameters

color

A Quartz color.

Return Value

An array of intensity values for the color components (including alpha) associated with the specified color. The size of the array is one more than the number of components of the color space for the color.

Availability

Available in Mac OS X version 10.3 and later.

Declared In

CGColor.h

CGColorGetConstantColor

Returns a color object that represents a constant color.

```
CGColorRef CGColorGetConstantColor(
    CFStringRef colorName
);
```

Parameters

colorName

A color name. You can pass any of the "Constant Colors" (page 41) constant.

Return Value

A color object.

Discussion

As `CGColorGetConstantColor` is not a "Copy" or "Create" function, it does not necessarily return a new reference each time it's called. As a consequence, you should not release the returned value. However, colors returned from `CGColorGetConstantColor` can be retained and released in a properly nested fashion, just as any other Core Foundation type can.

Availability

Available in Mac OS X v10.5 and later.

Declared In

CGColor.h

CGColorGetNumberOfComponents

Returns the number of color components (including alpha) associated with a Quartz color.

```
size_t CGColorGetNumberOfComponents (
   CGColorRef color
);
```

Parameters

color

A Quartz color.

Return Value

The number of color components (including alpha) associated with the specified color. This number is one more than the number of components of the color space for the color.

Availability

Available in Mac OS X version 10.3 and later.

Declared In

`CGColor.h`

CGColorGetPattern

Returns the pattern associated with a Quartz color in a pattern color space.

```
CGPatternRef CGColorGetPattern (
   CGColorRef color
);
```

Parameters

color

A Quartz color.

Return Value

The pattern for the specified color. You are responsible for retaining and releasing the pattern as needed.

Availability

Available in Mac OS X version 10.3 and later.

Declared In

`CGColor.h`

CGColorGetTypeID

Returns the Core Foundation type identifier for a Quartz color data type.

```
CFTypeID CGColorGetTypeID (
   void
);
```

Return Value

The Core Foundation type identifier for `CGColorRef`.

Availability

Available in Mac OS X version 10.3 and later.

Declared In

`CGColor.h`

CGColorRelease

Decrements the retain count of a Quartz color.

```
void CGColorRelease (
    CGColorRef color
);
```

Parameters

color

The Quartz color to release.

Discussion

This function is equivalent to `CFRelease`, except that it does not cause an error if the `color` parameter is `NULL`.

Availability

Available in Mac OS X version 10.3 and later.

Related Sample Code

CALayerEssentials

Declared In

`CGColor.h`

CGColorRetain

Increments the retain count of a Quartz color.

```
CGColorRef CGColorRetain (
    CGColorRef color
);
```

Parameters

color

The Quartz color to retain.

Return Value

The same color you passed in as the *color* parameter.

Discussion

This function is equivalent to `CFRetain`, except that it does not cause an error if the `color` parameter is `NULL`.

Availability

Available in Mac OS X version 10.3 and later.

Declared In

`CGColor.h`

Data Types

CGColorRef

An opaque type that represents a color used in Quartz 2D drawing.

```
typedef struct CGColor *CGColorRef;
```

Discussion
`CGColorRef` is the fundamental data type used internally by Quartz to represent colors. CGColor objects. and the functions that operate on them, provide a fast and convenient way of managing and setting colors directly, especially colors that are reused (such as black for text).

In Mac OS X version 10.3 and later, `CGColorRef` is derived from `CFTypeRef` and inherits the properties that all Core Foundation types have in common. For more information, see CFType Reference.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`CGColor.h`

Constants

Constant Colors

Commonly used colors.

```
const CFStringRef kCGColorWhite;
const CFStringRef kCGColorBlack;
const CFStringRef kCGColorClear;
```

Constants

`kCGColorWhite`
The white color in the Generic gray color space.
Available in Mac OS X v10.5 and later.
Declared in `CGColor.h`.

`kCGColorBlack`
The black color in the Generic gray color space.
Available in Mac OS X v10.5 and later.
Declared in `CGColor.h`.

`kCGColorClear`
The clear color in the Generic gray color space.
Available in Mac OS X v10.5 and later.
Declared in `CGColor.h`.

Declared In
`CGColor.h`

Overview

The `CGColorSpaceRef` opaque type encapsulates color space information that is used to specify how Quartz interprets color information. A color space specifies how color values are interpreted. A color space is multi-dimensional, and each dimension represents a specific color component. For example, the colors in an RGB color space have three dimensions or components—red, green, and blue. The intensity of each component is represented by floating point values—their range and meaning depends on the color space in question.

Different types of devices (scanners, monitors, printers) operate within different color spaces (RGB, CMYK, grayscale). Additionally, two devices of the same type (for example, color displays from different manufacturers) may operate within the same kind of color space, yet still produce a different range of colors, or gamut. Color spaces that are correctly specified ensure that an image has a consistent appearance regardless of the output device.

Quartz supports several kinds of color spaces:

- Calibrated color spaces ensure that colors appear the same when displayed on different devices. The visual appearance of the color is preserved, as far as the capabilities of the device allow.
- Device-dependent color spaces are tied to the system of color representation of a particular device. Device color spaces are not recommended when high-fidelity color preservation is important.
- Special color spaces—indexed and pattern. An indexed color space contains a color table with up to 256 entries and a base color space to which the color table entries are mapped. Each entry in the color table specifies one color in the base color space. A pattern color space is used when stroking or filling with a pattern. Pattern color spaces are supported in Mac OS X version 10.1 and later.

Functions by Task

Creating Device-Independent Color Spaces

`CGColorSpaceCreateCalibratedGray` (page 45)
Creates a calibrated grayscale color space.

`CGColorSpaceCreateCalibratedRGB` (page 46)
Creates a calibrated RGB color space.

`CGColorSpaceCreateICCBased` (page 49)
Creates a device-independent color space that is defined according to the ICC color profile specification.

`CGColorSpaceCreateLab` (page 50)
Creates a device-independent color space that is relative to human color perception, according to the CIE L*a*b* standard.

Creating Generic or Device-Dependent Color Spaces

In Mac OS X v10.4 and later, the color space returned by each of these functions is no longer device-dependent and is replaced by a generic counterpart.

`CGColorSpaceCreateDeviceCMYK` (page 47)
Creates a device-dependent CMYK color space.

`CGColorSpaceCreateDeviceGray` (page 48)
Creates a device-dependent grayscale color space.

`CGColorSpaceCreateDeviceRGB` (page 48)
Creates a device-dependent RGB color space.

`CGColorSpaceCreateWithPlatformColorSpace` (page 52)
Creates a platform-specific color space.

Creating Special Color Spaces

`CGColorSpaceCreateIndexed` (page 50)
Creates an indexed color space, consisting of colors specified by a color lookup table.

`CGColorSpaceCreatePattern` (page 51)
Creates a pattern color space.

`CGColorSpaceCreateWithName` (page 52)
Creates a specified type of Quartz color space.

Getting Information About Color Spaces

`CGColorSpaceCopyICCProfile` (page 45)
Returns a copy of the ICC profile of the provided color space.

`CGColorSpaceGetNumberOfComponents` (page 54)
Returns the number of color components in a color space.

`CGColorSpaceGetTypeID` (page 55)
Returns the Core Foundation type identifier for Quartz color spaces.

`CGColorSpaceGetModel` (page 54)
Returns the color space model of the provided color space.

`CGColorSpaceGetBaseColorSpace` (page 53)
Returns the base color space of a pattern or indexed color space.

`CGColorSpaceGetColorTableCount` (page 54)
Returns the number of entries in the color table of an indexed color space.

`CGColorSpaceGetColorTable` (page 53)
Copies the entries in the color table of an indexed color space.

Retaining and Releasing Color Spaces

`CGColorSpaceRelease` (page 55)
Decrements the retain count of a color space.

`CGColorSpaceRetain` (page 56)
Increments the retain count of a color space.

Functions

CGColorSpaceCopyICCProfile

Returns a copy of the ICC profile of the provided color space.

```
CFDataRef CGColorSpaceCopyICCProfile(
    CGColorSpaceRef space
);
```

Parameters

space
The color space whose ICC profile you want to obtain.

Return Value
The ICC profile or `NULL` if the color space does not have an ICC profile.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`CGColorSpace.h`

CGColorSpaceCreateCalibratedGray

Creates a calibrated grayscale color space.

```
CGColorSpaceRef CGColorSpaceCreateCalibratedGray (
   const CGFloat whitePoint[3],
   const CGFloat blackPoint[3],
   CGFloat gamma
);
```

Parameters

whitePoint

An array of 3 numbers specifying the tristimulus value, in the CIE 1931 XYZ-space, of the diffuse white point.

blackPoint

An array of 3 numbers specifying the tristimulus value, in CIE 1931 XYZ-space, of the diffuse black point.

gamma

The gamma value appropriate to the imaging device.

Return Value

A new calibrated gray color space. You are responsible for releasing this object by calling `CGColorSpaceRelease` (page 55). If unsuccessful, returns `NULL`.

Discussion

Creates a device-independent grayscale color space that represents colors relative to a reference white point. This white point is based on the whitest light that can be generated by the output device. Colors in a device-independent color space should appear the same when displayed on different devices, to the extent that the capabilities of the device allow.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CGColorSpace.h`

CGColorSpaceCreateCalibratedRGB

Creates a calibrated RGB color space.

```
CGColorSpaceRef CGColorSpaceCreateCalibratedRGB (
   const CGFloat whitePoint[3],
   const CGFloat blackPoint[3],
   const CGFloat gamma[3],
   const CGFloat matrix[9]
);
```

Parameters

whitePoint

An array of 3 numbers specifying the tristimulus value, in the CIE 1931 XYZ-space, of the diffuse white point.

blackPoint

An array of 3 numbers specifying the tristimulus value, in CIE 1931 XYZ-space, of the diffuse black point.

gamma

An array of 3 numbers specifying the gamma for the red, green, and blue components of the color space.

matrix

An array of 9 numbers specifying the linear interpretation of the gamma-modified RGB values of the color space with respect to the final XYZ representation.

Return Value
A new calibrated RGB color space. You are responsible for releasing this object by calling `CGColorSpaceRelease` (page 55). If unsuccessful, returns `NULL`.

Discussion
Creates a device-independent RGB color space that represents colors relative to a reference white point. This white point is based on the whitest light that can be generated by the output device. Colors in a device-independent color space should appear the same when displayed on different devices, to the extent that the capabilities of the device allow.

For color spaces that require a detailed gamma, such as the piecewise transfer function used in sRGB or ITU-R BT.709, you may want to use the function `CGColorSpaceCreateICCBased` (page 49) instead, because it can accurately represent these gamma curves.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGColorSpace.h`

CGColorSpaceCreateDeviceCMYK

Creates a device-dependent CMYK color space.

```
CGColorSpaceRef CGColorSpaceCreateDeviceCMYK (
   void
);
```

Return Value
A device-dependent CMYK color space. You are responsible for releasing this object by calling `CGColorSpaceRelease` (page 55). If unsuccessful, returns `NULL`.

Discussion
In Mac OS X v10.4 and later, this color space is no longer device-dependent and is replaced by the generic counterpart—`kCGColorSpaceGenericCMYK`—described in "`Color Space Names`" (page 57). If you use this function in Mac OS X v10.4 and later, colors are mapped to the generic color spaces. If you want to bypass color matching, use the color space of the destination context.

Colors in a device-dependent color space are not transformed or otherwise modified when displayed on an output device—that is, there is no attempt to maintain the visual appearance of a color. As a consequence, colors in a device color space often appear different when displayed on different output devices. For this reason, device color spaces are not recommended when color preservation is important.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGColorSpace.h`

CGColorSpaceCreateDeviceGray

Creates a device-dependent grayscale color space.

```
CGColorSpaceRef CGColorSpaceCreateDeviceGray (
   void
);
```

Return Value
A device-dependent gray color space. You are responsible for releasing this object by calling `CGColorSpaceRelease` (page 55). If unsuccessful, returns `NULL`.

Discussion
In Mac OS X v10.4 and later, this color space is no longer device-dependent and is replaced by the generic counterpart—`kCGColorSpaceGenericGray`—described in "Color Space Names" (page 57). If you use this function in Mac OS X v10.4 and later, colors are mapped to the generic color spaces. If you want to bypass color matching, use the color space of the destination context.

Colors in a device-dependent color space are not transformed or otherwise modified when displayed on an output device—that is, there is no attempt to maintain the visual appearance of a color. As a consequence, colors in a device color space often appear different when displayed on different output devices. For this reason, device color spaces are not recommended when color preservation is important.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGColorSpace.h`

CGColorSpaceCreateDeviceRGB

Creates a device-dependent RGB color space.

```
CGColorSpaceRef CGColorSpaceCreateDeviceRGB (
   void
);
```

Return Value
A device-dependent RGB color space. You are responsible for releasing this object by calling `CGColorSpaceRelease` (page 55). If unsuccessful, returns `NULL`.

Discussion
In Mac OS X v10.4 and later, this color space is no longer device-dependent and is replaced by the generic counterpart—`kCGColorSpaceGenericRGB`—described in "Color Space Names" (page 57). If you use this function in Mac OS X v10.4 and later, colors are mapped to the generic color spaces. If you want to bypass color matching, use the color space of the destination context.

Colors in a device-dependent color space are not transformed or otherwise modified when displayed on an output device—that is, there is no attempt to maintain the visual appearance of a color. As a consequence, colors in a device color space often appear different when displayed on different output devices. For this reason, device color spaces are not recommended when color preservation is important.

Availability
Available in Mac OS X v10.0 and later.

Declared In
CGColorSpace.h

CGColorSpaceCreateICCBased

Creates a device-independent color space that is defined according to the ICC color profile specification.

```
CGColorSpaceRef CGColorSpaceCreateICCBased (
   size_t nComponents,
   const CGFloat *range,
   CGDataProviderRef profile,
   CGColorSpaceRef alternate
);
```

Parameters

nComponents
The number of color components in the color space defined by the ICC profile data. This must match the number of components actually in the ICC profile and must equal 1, 3, or 4.

range
An array of numbers that specify the minimum and maximum valid values of the corresponding color components. The size of the array is two times the number of components. If `c[k]` is the `k`th color component, the valid range is range`[2*k]` ≤ `c[k]` ≤ range`[2*k+1]`.

profile
A data provider that supplies the ICC profile.

alternateSpace
An alternate color space to use in case the ICC profile is not supported. The alternate color space must have `nComponents` color components. You must supply an alternate color space. If this parameter is `NULL`, then the function returns `NULL`.

Return Value
A new ICC-based color space object. You are responsible for releasing this object by calling `CGColorSpaceRelease` (page 55). If unsuccessful, returns `NULL`.

Discussion
This function creates an ICC-based color space from an ICC color profile, as defined by the International Color Consortium. ICC profiles define the reproducible color gamut (the range of colors supported by a device) and other characteristics of a particular output device, providing a way to accurately transform the color space of one device to the color space of another. The ICC profile is usually provided by the manufacturer of the device. Additionally, some color monitors and printers contain electronically embedded ICC profile information, as do some bitmap formats such as TIFF. Colors in a device-independent color space should appear the same when displayed on different devices, to the extent that the capabilities of the device allow.

You may want to use this function for a color space that requires a detailed gamma, such as the piecewise transfer function used in sRGB or ITU-R BT.709, because this function can accurately represent these gamma curves.

Availability
Available in Mac OS X v10.0 and later.

Declared In
CGColorSpace.h

CGColorSpaceCreateIndexed

Creates an indexed color space, consisting of colors specified by a color lookup table.

```
CGColorSpaceRef CGColorSpaceCreateIndexed (
   CGColorSpaceRef baseSpace,
   size_t lastIndex,
   const unsigned char *colorTable
);
```

Parameters

baseSpace

The color space on which the color table is based.

lastIndex

The maximum valid index value for the color table. The value must be less than or equal to 255.

colorTable

An array of `m*(lastIndex+1)` bytes, where `m` is the number of color components in the base color space. Each byte is an unsigned integer in the range `0` to `255` that is scaled to the range of the corresponding color component in the base color space.

Return Value

A new indexed color space object. You are responsible for releasing this object by calling `CGColorSpaceRelease` (page 55). If unsuccessful, returns `NULL`.

Discussion

An indexed color space contains a color table with up to 255 entries, and a base color space to which the color table entries are mapped. Each entry in the color table specifies one color in the base color space. A value in an indexed color space is treated as an index into the color table of the color space. The data in the table is in meshed format. (For example, for an RGB color space RGB, RGB, RGB, and so on.)

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CGColorSpace.h`

CGColorSpaceCreateLab

Creates a device-independent color space that is relative to human color perception, according to the CIE L*a*b* standard.

```
CGColorSpaceRef CGColorSpaceCreateLab (
   const CGFloat whitePoint[3],
   const CGFloat blackPoint[3],
   const CGFloat range[4]
);
```

Parameters

whitePoint

An array of 3 numbers that specify the tristimulus value, in the CIE 1931 XYZ-space, of the diffuse white point.

blackPoint

An array of 3 numbers that specify the tristimulus value, in CIE 1931 XYZ-space, of the diffuse black point.

range

An array of 4 numbers that specify the range of valid values for the a* and b* components of the color space. The a* component represents values running from green to red, and the b* component represents values running from blue to yellow.

Return Value
A new L*a*b* color space. You are responsible for releasing this object by calling `CGColorSpaceRelease` (page 55). If unsuccessful, returns `NULL`.

Discussion
The CIE L*a*b* space is a nonlinear transformation of the Munsell color notation system (a system which specifies colors by hue, value, and saturation—or "chroma"—values), designed to match perceived color difference with quantitative distance in color space. The L* component represents the lightness value, the a* component represents values running from green to red, and the b* component represents values running from blue to yellow. This roughly corresponds to the way the human brain is thought to decode colors. Colors in a device-independent color space should appear the same when displayed on different devices, to the extent that the capabilities of the device allow.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGColorSpace.h`

CGColorSpaceCreatePattern

Creates a pattern color space.

```
CGColorSpaceRef CGColorSpaceCreatePattern (
   CGColorSpaceRef baseSpace
);
```

Parameters

baseSpace

For masking patterns, the underlying color space that specifies the colors to be painted through the mask. For colored patterns, you should pass `NULL`.

Return Value
A new pattern color space. You are responsible for releasing this object by calling `CGColorSpaceRelease` (page 55). If unsuccessful, returns `NULL`.

Discussion
For information on creating and using patterns, see *Quartz 2D Programming Guide* and *CGPattern Reference*. Quartz retains the color space you pass in. Upon return, you may safely release it by calling `CGColorSpaceRelease` (page 55).

Availability
Available in Mac OS X v10.1 and later.

Declared In
`CGColorSpace.h`

CGColorSpaceCreateWithName

Creates a specified type of Quartz color space.

```
CGColorSpaceRef CGColorSpaceCreateWithName (
   CFStringRef name
);
```

Parameters

name

A color space name. See "Color Space Names" (page 57) for a list of the valid Quartz-defined names.

Return Value

A new generic color space. You are responsible for releasing this object by calling CGColorSpaceRelease (page 55). If unsuccessful, returns NULL.

Discussion

You can use this function to create a generic color space. For more information, see "Color Space Names" (page 57).

Prior to Mac OS X v10.4, you could pass this function one of the constants defined in "Named Color Spaces (Deprecated)" (page 60). As of Mac OS X v10.4, this function returns a generic color space even if you pass is one of the deprecated named color spaces.

Availability

Available in Mac OS X v10.2 and later.

Declared In

CGColorSpace.h

CGColorSpaceCreateWithPlatformColorSpace

Creates a platform-specific color space.

```
CGColorSpaceRef CGColorSpaceCreateWithPlatformColorSpace (
   void *platformColorSpaceReference
);
```

Parameters

platformColorSpace

A generic pointer to a platform-specific color space. In Mac OS X, pass a CMProfileRef—a ColorSync profile. Quartz uses this pointer (and the underlying information) only during the function call.

Return Value

A new color space. You are responsible for releasing this object by calling CGColorSpaceRelease (page 55). If unsuccessful, returns NULL.

Discussion

Colors in a device-dependent color space are not transformed or otherwise modified when displayed on an output device—that is, there is no attempt to maintain the visual appearance of a color. As a consequence, colors in a device color space often appear different when displayed on different output devices. For this reason, device color spaces are not recommended when color preservation is important.

Availability

Available in Mac OS X v10.1 and later.

Related Sample Code
CarbonSketch

Declared In
`CGColorSpace.h`

CGColorSpaceGetBaseColorSpace

Returns the base color space of a pattern or indexed color space.

```
CGColorSpace CGColorSpaceGetBaseColorSpace(
    CGColorSpaceRef space
);
```

Parameters

space

A color space object for a pattern or indexed color space.

Return Value
The base color space if the `space` parameter is a pattern or indexed color space; otherwise, `NULL`.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`CGColorSpace.h`

CGColorSpaceGetColorTable

Copies the entries in the color table of an indexed color space.

```
void CGColorSpaceGetColorTable(
        CGColorSpaceRef space,
        unsigned char *table);
);
```

Parameters

space

A color space object for an indexed color space.

table

The array pointed to by table should be at least as large as the number of entries in the color table. On output, the array contains the table data in the same format as that passed to `CGColorSpaceCreateIndexed` (page 50).

Discussion
This function does nothing if the color space is not an indexed color space. To determine whether a color space is an indexed color space, call the function `CGColorSpaceGetModel` (page 54).

Availability
Available in Mac OS X v10.5 and later.

See Also
`CGColorSpaceGetColorTableCount` (page 54)

Declared In
CGColorSpace.h

CGColorSpaceGetColorTableCount

Returns the number of entries in the color table of an indexed color space.

```
size_t CGColorSpaceGetColorTableCount(
    CGColorSpaceRef space
);
```

Parameters

space
A color space object for an indexed color space.

Return Value
The number of entries in the color table of the `space` parameter if the color space is an indexed color space; otherwise, returns `0`.

Availability
Available in Mac OS X v10.5 and later.

See Also
`CGColorSpaceGetColorTable` (page 53)

Declared In
CGColorSpace.h

CGColorSpaceGetModel

Returns the color space model of the provided color space.

```
CGColorSpaceModel CGColorSpaceGetModel(
    CGColorSpaceRef space
);
```

Parameters

space
A color space object.

Return Value
One of the constants described in "Color Space Models" (page 57).

Availability
Available in Mac OS X v10.5 and later.

Declared In
CGColorSpace.h

CGColorSpaceGetNumberOfComponents

Returns the number of color components in a color space.

```
size_t CGColorSpaceGetNumberOfComponents (
   CGColorSpaceRef cs
);
```

Parameters

cs

The Quartz color space to examine.

Return Value

The number of color components in the specified color space, not including the alpha value. For example, for an RGB color space, `CGColorSpaceGetNumberOfComponents` returns a value of `3`.

Discussion

A color space defines an n-dimensional space whose dimensions (or components) represent intensity values. For example, you specify colors in RGB space as three intensity values: red, green, and blue. You can use the `CGColorSpaceGetNumberOfComponents` function to obtain the number of components in a given color space.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CGColorSpace.h`

CGColorSpaceGetTypeID

Returns the Core Foundation type identifier for Quartz color spaces.

```
CFTypeID CGColorSpaceGetTypeID (
   void
);
```

Return Value

The identifier for the opaque type `CGColorSpaceRef` (page 56).

Availability

Available in Mac OS X v10.2 and later.

Declared In

`CGColorSpace.h`

CGColorSpaceRelease

Decrements the retain count of a color space.

```
void CGColorSpaceRelease (
   CGColorSpaceRef cs
);
```

Parameters

cs

The Quartz color space to release.

Discussion

This function is equivalent to `CFRelease`, except that it does not cause an error if the `cs` parameter is `NULL`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGColorSpace.h`

CGColorSpaceRetain

Increments the retain count of a color space.

```
CGColorSpaceRef CGColorSpaceRetain (
   CGColorSpaceRef cs
);
```

Parameters

cs

The Quartz color space to retain.

Return Value
The same color space you passed in as the *cs* parameter.

Discussion
This function is equivalent to `CFRetain`, except that it does not cause an error if the `cs` parameter is `NULL`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGColorSpace.h`

Data Types

CGColorSpaceRef

An opaque type that encapsulates color space information.

```
typedef struct CGColorSpace *CGColorSpaceRef;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGColorSpace.h`

Constants

Color Space Names

Convenience constants for commonly used color spaces.

```
CFStringRef kCGColorSpaceGenericGray
CFStringRef kCGColorSpaceGenericRGB
CFStringRef kCGColorSpaceGenericCMYK
CFStringRef kCGColorSpaceGenericRGBLinear
CFStringRef kCGColorSpaceAdobeRGB1998
CFStringRef kCGColorSpaceSRGB
```

Constants

`kCGColorSpaceGenericGray`
The name of the generic gray color space.

`kCGColorSpaceGenericRGB`
The name of the generic RGB color space.

`kCGColorSpaceGenericCMYK`
The name of the generic CMYK color space.

`kCGColorSpaceGenericRGBLinear`
The name of the generic linear RGB color space. This is the same as `kCGColorSpaceGenericRGB` (page 57), but with a gamma equal to `1.0`.

`kCGColorSpaceAdobeRGB1998`
The name of the Adobe RGB (1998) color space. For more information, see "Adobe RGB (1998) Color Image Encoding", Version 2005-05, Adobe Systems Inc. (http://www.adobe.com).

`kCGColorSpaceSRGB`
The name of the SRGB color space.

Discussion

A color space name constant can be passed as a parameter to the function `CGColorSpaceCreateWithName` (page 52). These color spaces replace `"Named Color Spaces (Deprecated)"` (page 60), which are deprecated in Mac OS X v10.4.

Declared In

`CGColorSpace.h`

Color Space Models

Models for color spaces.

```
enum CGColorSpaceModel {
    kCGColorSpaceModelUnknown = -1,
    kCGColorSpaceModelMonochrome,
    kCGColorSpaceModelRGB,
    kCGColorSpaceModelCMYK,
    kCGColorSpaceModelLab,
    kCGColorSpaceModelDeviceN,
    kCGColorSpaceModelIndexed,
    kCGColorSpaceModelPattern
};
typedef int32_t CGColorSpaceModel;
```

Constants

`kCGColorSpaceModelUnknown`
An unknown color space model.
Available in Mac OS X v10.5 and later.
Declared in `CGColorSpace.h`.

`kCGColorSpaceModelMonochrome`
A monochrome color space model.
Available in Mac OS X v10.5 and later.
Declared in `CGColorSpace.h`.

`kCGColorSpaceModelRGB`
An RGB color space model.
Available in Mac OS X v10.5 and later.
Declared in `CGColorSpace.h`.

`kCGColorSpaceModelCMYK`
A CMYK color space model.
Available in Mac OS X v10.5 and later.
Declared in `CGColorSpace.h`.

`kCGColorSpaceModelLab`
A Lab color space model.
Available in Mac OS X v10.5 and later.
Declared in `CGColorSpace.h`.

`kCGColorSpaceModelDeviceN`
A DeviceN color space model.
Available in Mac OS X v10.5 and later.
Declared in `CGColorSpace.h`.

`kCGColorSpaceModelIndexed`
An indexed color space model.
Available in Mac OS X v10.5 and later.
Declared in `CGColorSpace.h`.

`kCGColorSpaceModelPattern`
A pattern color space model.
Available in Mac OS X v10.5 and later.
Declared in `CGColorSpace.h`.

Declared In
`CGColorSpace.h`

Color Rendering Intents

Handling options for colors that are not located within the destination color space of a graphics context.

```
enum CGColorRenderingIntent {
    kCGRenderingIntentDefault,
    kCGRenderingIntentAbsoluteColorimetric,
    kCGRenderingIntentRelativeColorimetric,
    kCGRenderingIntentPerceptual,
    kCGRenderingIntentSaturation
};
typedef enum CGColorRenderingIntent CGColorRenderingIntent;
```

Constants

`kCGRenderingIntentDefault`
The default rendering intent for the graphics context.

Available in Mac OS X v10.0 and later.

Declared in `CGColorSpace.h`.

`kCGRenderingIntentAbsoluteColorimetric`
Map colors outside of the gamut of the output device to the closest possible match inside the gamut of the output device. This can produce a clipping effect, where two different color values in the gamut of the graphics context are mapped to the same color value in the output device's gamut. Unlike the relative colorimetric, absolute colorimetric does not modify colors inside the gamut of the output device.

Available in Mac OS X v10.0 and later.

Declared in `CGColorSpace.h`.

`kCGRenderingIntentRelativeColorimetric`
Map colors outside of the gamut of the output device to the closest possible match inside the gamut of the output device. This can produce a clipping effect, where two different color values in the gamut of the graphics context are mapped to the same color value in the output device's gamut. The relative colorimetric shifts all colors (including those within the gamut) to account for the difference between the white point of the graphics context and the white point of the output device.

Available in Mac OS X v10.0 and later.

Declared in `CGColorSpace.h`.

`kCGRenderingIntentPerceptual`
Preserve the visual relationship between colors by compressing the gamut of the graphics context to fit inside the gamut of the output device. Perceptual intent is good for photographs and other complex, detailed images.

Available in Mac OS X v10.0 and later.

Declared in `CGColorSpace.h`.

`kCGRenderingIntentSaturation`
Preserve the relative saturation value of the colors when converting into the gamut of the output device. The result is an image with bright, saturated colors. Saturation intent is good for reproducing images with low detail, such as presentation charts and graphs.

Available in Mac OS X v10.0 and later.

Declared in `CGColorSpace.h`.

Discussion
The rendering intent specifies how Quartz should handle colors that are not located within the gamut of the destination color space of a graphics context. It determines the exact method used to map colors from one color space to another. If you do not explicitly set the rendering intent by calling the function `CGContextSetRenderingIntent` (page 120), the graphics context uses the relative colorimetric rendering intent, except when drawing sampled images.

Declared In
`CGColorSpace.h`

Named Color Spaces (Deprecated)

Color spaces used in the Preferences application.

```
#define kCGColorSpaceUserCMYK CFSTR("kCGColorSpaceUserCMYK")
#define kCGColorSpaceUserGray CFSTR("kCGColorSpaceUserGray")
#define kCGColorSpaceUserRGB CFSTR("kCGColorSpaceUserRGB")
```

Constants

`kCGColorSpaceUserCMYK`
A user-defined CMYK color space.

`kCGColorSpaceUserGray`
A user-defined gray color space.

`kCGColorSpaceUserRGB`
A user-defined RGB color space.

Discussion
These constants are deprecated in Mac OS X v10.4. Instead use "`Color Space Names`" (page 57).

The named color spaces are user-configurable in the "Default Profiles for Documents" pane, located in Mac OS 10.2 in the ColorSync preference panel, and in Mac OS 10.3 in the Displays Color Preference panel. See also `CGColorSpaceCreateWithName` (page 52).

Availability
Available in Mac OS X v10.2 and later but deprecated in Mac OS X v10.4.

Declared In
`CGColorSpace.h`

CGContext Reference

Derived From:	*CFType Reference*
Framework:	ApplicationServices/ApplicationServices.h
Declared in	CGContext.h
Companion guide	Quartz 2D Programming Guide

Overview

The `CGContextRef` opaque type represents a Quartz 2D drawing destination. A graphics context contains drawing parameters and all device-specific information needed to render the paint on a page to the destination, whether the destination is a window in an application, a bitmap image, a PDF document, or a printer. You can obtain a graphics context by using Quartz graphics context creation functions or by using higher-level functions provided in the Carbon, Cocoa, or Printing frameworks. Quartz provides creation functions for various flavors of Quartz graphics contexts including bitmap images and PDF. The Carbon and Cocoa frameworks provide functions for obtaining window graphics contexts. The Printing framework provides functions that obtain a graphics context appropriate for the destination printer.

Functions by Task

Managing Graphics Contexts

`CGContextFlush` (page 95)
Forces all pending drawing operations in a window context to be rendered immediately to the destination device.

`CGContextGetTypeID` (page 99)
Returns the type identifier for Quartz graphics contexts.

`CGContextRelease` (page 102)
Decrements the retain count of a graphics context.

`CGContextRetain` (page 103)
Increments the retain count of a graphics context.

`CGContextSynchronize` (page 136)
Marks a window context for update.

Saving and Restoring the Current Graphics State

`CGContextSaveGState` (page 104)
Pushes a copy of the current graphics state onto the graphics state stack for the context.

`CGContextRestoreGState` (page 103)
Sets the current graphics state to the state most recently saved.

Getting and Setting Graphics State Parameters

`CGContextGetInterpolationQuality` (page 97)
Returns the current level of interpolation quality for a graphics context.

`CGContextSetFlatness` (page 113)
Sets the accuracy of curved paths in a graphics context.

`CGContextSetInterpolationQuality` (page 116)
Sets the level of interpolation quality for a graphics context.

`CGContextSetLineCap` (page 116)
Sets the style for the endpoints of lines drawn in a graphics context.

`CGContextSetLineDash` (page 117)
Sets the pattern for dashed lines in a graphics context.

`CGContextSetLineJoin` (page 118)
Sets the style for the joins of connected lines in a graphics context.

`CGContextSetLineWidth` (page 118)
Sets the line width for a graphics context.

`CGContextSetMiterLimit` (page 119)
Sets the miter limit for the joins of connected lines in a graphics context.

`CGContextSetPatternPhase` (page 119)
Sets the pattern phase of a context.

`CGContextSetFillPattern` (page 112)
Sets the fill pattern in the specified graphics context.

`CGContextSetRenderingIntent` (page 120)
Sets the rendering intent in the current graphics state.

`CGContextSetShouldAntialias` (page 124)
Sets anti-aliasing on or off for a graphics context.

`CGContextSetShouldSmoothFonts` (page 124)
Enables or disables font smoothing in a graphics context.

`CGContextSetStrokePattern` (page 126)
Sets the stroke pattern in the specified graphics context.

`CGContextSetBlendMode` (page 107)
Sets how Quartz composites sample values for a graphics context.

`CGContextSetAllowsAntialiasing` (page 106)
Sets whether or not to allow anti-aliasing for a graphics context.

Constructing Paths

These functions are used to define the geometry of the current path.

`CGContextAddArc` (page 68)
Adds an arc of a circle to the current path, using a center point, radius, and end point.

`CGContextAddArcToPoint` (page 69)
Adds an arc of a circle to the current path, using a radius and tangent points.

`CGContextAddCurveToPoint` (page 70)
Appends a cubic Bézier curve from the current point, using the provided control points and end point .

`CGContextAddLines` (page 72)
Adds a sequence of connected straight-line segments to the current path.

`CGContextAddLineToPoint` (page 73)
Appends a straight line segment from the current point to the provided point .

`CGContextAddPath` (page 73)
Adds a previously created Quartz path object to the current path in a graphics context.

`CGContextAddQuadCurveToPoint` (page 74)
Appends a quadratic Bézier curve from the current point, using a control point and an end point you specify.

`CGContextAddRect` (page 75)
Adds a rectangular path to the current path.

`CGContextAddRects` (page 75)
Adds a set rectangular paths to the current path.

`CGContextBeginPath` (page 76)
Creates a new empty path in a graphics context.

`CGContextClosePath` (page 81)
Closes and terminates an open path.

`CGContextMoveToPoint` (page 100)
Begins a new path at the point you specify.

`CGContextAddEllipseInRect` (page 71)
Adds an ellipse that fits inside the specified rectangle.

Painting Paths

These functions are used to stroke along or fill in the current path.

`CGContextClearRect` (page 78)
Paints a transparent rectangle.

`CGContextDrawPath` (page 87)
Draws the current path using the provided drawing mode.

`CGContextEOFillPath` (page 93)
Paints the area within the current path, using the even-odd fill rule.

`CGContextFillPath` (page 94)
Paints the area within the current path, using the nonzero winding number rule.

`CGContextFillRect` (page 94)
Paints the area contained within the provided rectangle, using the fill color in the current graphics state.

`CGContextFillRects` (page 95)
Paints the areas contained within the provided rectangles, using the fill color in the current graphics state.

`CGContextFillEllipseInRect` (page 93)
Paints the area of the ellipse that fits inside the provided rectangle, using the fill color in the current graphics state.

`CGContextStrokePath` (page 134)
Paints a line along the current path.

`CGContextStrokeRect` (page 134)
Paints a rectangular path.

`CGContextStrokeRectWithWidth` (page 135)
Paints a rectangular path, using the specified line width.

`CGContextReplacePathWithStrokedPath` (page 102)
Replaces the path in the graphics context with the stroked version of the path.

`CGContextStrokeEllipseInRect` (page 133)
Strokes an ellipse that fits inside the specified rectangle.

`CGContextStrokeLineSegments` (page 133)
Strokes a sequence of line segments.

Getting Information About Paths

`CGContextIsPathEmpty` (page 100)
Indicates whether the current path contains any subpaths.

`CGContextGetPathCurrentPoint` (page 98)
Returns the current point in a non-empty path.

`CGContextGetPathBoundingBox` (page 97)
Returns the smallest rectangle that contains the current path.

`CGContextPathContainsPoint` (page 101)
Checks to see whether the specified point is contained in the current path.

Modifying Clipping Paths

`CGContextClip` (page 79)
Modifies the current clipping path, using the nonzero winding number rule.

`CGContextEOClip` (page 92)
Modifies the current clipping path, using the even-odd rule.

`CGContextClipToRect` (page 80)
Sets the clipping path to the intersection of the current clipping path with the area defined by the specified rectangle.

`CGContextClipToRects` (page 81)
Sets the clipping path to the intersection of the current clipping path with the region defined by an array of rectangles.

`CGContextGetClipBoundingBox` (page 96)
Returns the bounding box of a clipping path.

`CGContextClipToMask` (page 79)
Maps a mask into the specified rectangle and intersects it with the current clipping area of the graphics context.

Setting Color, Color Space, and Shadow Values

`CGContextSetAlpha` (page 107)
Sets the opacity level for objects drawn in a graphics context.

`CGContextSetCMYKFillColor` (page 108)
Sets the current fill color to a value in the DeviceCMYK color space.

`CGContextSetFillColor` (page 111)
Sets the current fill color.

`CGContextSetCMYKStrokeColor` (page 110)
Sets the current stroke color to a value in the DeviceCMYK color space.

`CGContextSetFillColorSpace` (page 111)
Sets the fill color space in a graphics context.

`CGContextSetFillColorWithColor` (page 112)
Sets the current fill color in a graphics context, using a Quartz color.

`CGContextSetGrayFillColor` (page 114)
Sets the current fill color to a value in the DeviceGray color space.

`CGContextSetGrayStrokeColor` (page 115)
Sets the current stroke color to a value in the DeviceGray color space.

`CGContextSetRGBFillColor` (page 120)
Sets the current fill color to a value in the DeviceRGB color space.

`CGContextSetRGBStrokeColor` (page 121)
Sets the current stroke color to a value in the DeviceRGB color space.

`CGContextSetShadow` (page 122)
Enables shadowing in a graphics context.

`CGContextSetShadowWithColor` (page 123)
Enables shadowing with color a graphics context.

`CGContextSetStrokeColor` (page 125)
Sets the current stroke color.

`CGContextSetStrokeColorSpace` (page 125)
Sets the stroke color space in a graphics context.

`CGContextSetStrokeColorWithColor` (page 126)
Sets the current stroke color in a context, using a Quartz color.

Transforming User Space

These functions allow you to examine and change the current transformation matrix (CTM) in a graphics context.

`CGContextConcatCTM` (page 82)
: Transforms the user coordinate system in a context using a specified matrix.

`CGContextGetCTM` (page 96)
: Returns the current transformation matrix.

`CGContextRotateCTM` (page 104)
: Rotates the user coordinate system in a context.

`CGContextScaleCTM` (page 105)
: Changes the scale of the user coordinate system in a context.

`CGContextTranslateCTM` (page 136)
: Changes the origin of the user coordinate system in a context.

Using Transparency Layers

`CGContextBeginTransparencyLayer` (page 77)
: Begins a transparency layer.

`CGContextBeginTransparencyLayerWithRect` (page 78)
: Begins a transparency layer whose contents are bounded by the specified rectangle.

`CGContextEndTransparencyLayer` (page 92)
: Ends a transparency layer.

Drawing an Image to a Graphics Context

`CGContextDrawTiledImage` (page 90)
: Repeatedly draws an image, scaled to the provided rectangle, to fill the current clip region.

`CGContextDrawImage` (page 86)
: Draws an image into a graphics context.

Drawing PDF Content to a Graphics Context

`CGContextDrawPDFDocument` (page 88)
: Draws a page of a PDF document into a graphics context.

`CGContextDrawPDFPage` (page 88)
: Draws a page in the current user space of a PDF context.

Drawing With a Gradient

`CGContextDrawLinearGradient` (page 86)
: Paints a gradient fill that varies along the line defined by the provided starting and ending points.

`CGContextDrawRadialGradient` (page 89)
Paints a gradient fill that varies along the area defined by the provided starting and ending circles.

Drawing With a Shading

`CGContextDrawShading` (page 90)
Fills the clipping path of a context with the specified shading.

Setting Up a Page-Based Graphics Context

`CGContextBeginPage` (page 76)
Starts a new page in a page-based graphics context.

`CGContextEndPage` (page 91)
Ends the current page in a page-based graphics context.

Drawing Glyphs

`CGContextShowGlyphs` (page 129)
Displays an array of glyphs at the current text position.

`CGContextShowGlyphsAtPoint` (page 129)
Displays an array of glyphs at a position you specify.

`CGContextShowGlyphsWithAdvances` (page 130)
Draws an array of glyphs with varying offsets.

`CGContextShowGlyphsAtPositions` (page 130)
Draws glyphs at the provided position.

Drawing Text

`CGContextGetTextMatrix` (page 98)
Returns the current text matrix.

`CGContextGetTextPosition` (page 99)
Returns the location at which text is drawn.

`CGContextSelectFont` (page 106)
Sets the font and font size in a graphics context.

`CGContextSetCharacterSpacing` (page 108)
Sets the current character spacing.

`CGContextSetFont` (page 113)
Sets the platform font in a graphics context.

`CGContextSetFontSize` (page 114)
Sets the current font size.

`CGContextSetTextDrawingMode` (page 127)
Sets the current text drawing mode.

`CGContextSetTextMatrix` (page 127)
Sets the current text matrix.

`CGContextSetTextPosition` (page 128)
Sets the location at which text is drawn.

`CGContextShowText` (page 131)
Displays a character array at the current text position, a point specified by the current text matrix.

`CGContextShowTextAtPoint` (page 132)
Displays a character string at a position you specify.

Converting Between Device Space and User Space

`CGContextGetUserSpaceToDeviceSpaceTransform` (page 100)
Returns an affine transform that maps user space coordinates to device space coordinates.

`CGContextConvertPointToDeviceSpace` (page 83)
Returns a point that is transformed from user space coordinates to device space coordinates.

`CGContextConvertPointToUserSpace` (page 83)
Returns a point that is transformed from device space coordinates to user space coordinates.

`CGContextConvertSizeToDeviceSpace` (page 85)
Returns a size that is transformed from user space coordinates to device space coordinates.

`CGContextConvertSizeToUserSpace` (page 85)
Returns a size that is transformed from device space coordinates to user space coordinates

`CGContextConvertRectToDeviceSpace` (page 84)
Returns a rectangle that is transformed from user space coordinate to device space coordinates.

`CGContextConvertRectToUserSpace` (page 84)
Returns a rectangle that is transformed from device space coordinate to user space coordinates.

Functions

CGContextAddArc

Adds an arc of a circle to the current path, using a center point, radius, and end point.

```
void CGContextAddArc (
   CGContextRef c,
   CGFloat x,
   CGFloat y,
   CGFloat radius,
   CGFloat startAngle,
   CGFloat endAngle,
   int clockwise
);
```

Parameters

context
A graphics context.

x
The x-value, in user space coordinates, for the center of the arc.

y
The y-value, in user space coordinates, for the center of the arc.

radius
The radius of the arc, in user space coordinates.

startAngle
The angle to the starting point of the arc, measured in radians from the positive x-axis.

endAngle
The angle to the end point of the arc, measured in radians from the positive x-axis.

clockwise
Pass `1` to draw the arc clockwise; `0` otherwise.

Discussion
When you call this function, Quartz builds an arc of a circle centered on the point you provide. The arc is of the specified radius and extends between the start and end point. (You can also use `CGContextAddArc` as a convenient way to draw a circle, by setting the start point to `0` and the end point to `2*Pi`.)

If the current path already contains a subpath, Quartz additionally appends a straight line segment from the current point to the starting point of the arc. If the current path is empty, Quartz creates a new subpath for the arc and does not add the initial straight line segment.

After adding the arc, the current point is reset to the end point of arc (the second tangent point).

Availability
Available in Mac OS X version 10.0 and later.

See Also
`CGContextAddArcToPoint` (page 69)

Related Sample Code
CarbonSketch

Declared In
`CGContext.h`

CGContextAddArcToPoint

Adds an arc of a circle to the current path, using a radius and tangent points.

```
void CGContextAddArcToPoint (
   CGContextRef c,
   CGFloat x1,
   CGFloat y1,
   CGFloat x2,
   CGFloat y2,
   CGFloat radius
);
```

Parameters

context
A graphics context whose current path is not empty.

x1

The x-value, in user space coordinates, for the end point of the first tangent line. The first tangent line is drawn from the current point to (x1,y1).

y1

The y-value, in user space coordinates, for the end point of the first tangent line. The first tangent line is drawn from the current point to (x1,y1).

x2

The x-value, in user space coordinates, for the end point of the second tangent line. The second tangent line is drawn from (x1,y1) to (x2,y2).

y2

The y-value, in user space coordinates, for the end point of the second tangent line. The second tangent line is drawn from (x1,y1) to (x2,y2).

radius

The radius of the arc, in user space coordinates.

Discussion

This function draws an arc that is tangent to the line from the current point to `(x1,y1)` and to the line from `(x1,y1)` to *(x2,y2)*. The start and end points of the arc are located on the first and second tangent lines, respectively. The start and end points of the arc are also the "tangent points" of the lines.

If the current point and the first tangent point of the arc (the starting point) are not equal, Quartz appends a straight line segment from the current point to the first tangent point. After adding the arc, the current point is reset to the end point of arc (the second tangent point).

Availability

Available in Mac OS X version 10.0 and later.

`CGContext.h`

CGContextAddCurveToPoint

Appends a cubic Bézier curve from the current point, using the provided control points and end point .

```
void CGContextAddCurveToPoint (
   CGContextRef c,
   CGFloat cp1x,
   CGFloat cp1y,
   CGFloat cp2x,
   CGFloat cp2y,
   CGFloat x,
   CGFloat y
);
```

Parameters

context

A graphics context whose current path is not empty.

cp1x

The x-value, in user space coordinates, for the first control point of the curve.

cp1y

The y-value, in user space coordinates, for the first control point of the curve.

cp2x

The x-value, in user space coordinates, for the second control point of the curve.

cp2y

The y-value, in user space coordinates, for the second control point of the curve.

x

The x-value, in user space coordinates, at which to end the curve.

y

The y-value, in user space coordinates, at which to end the curve.

Discussion

This function appends a cubic curve to the current path. After adding the segment, the current point is reset from the beginning of the new segment to the end point of that segment.

Availability

Available in Mac OS X version 10.0 and later.

See Also

`CGContextAddQuadCurveToPoint` (page 74)

`CGContextAddArcToPoint` (page 69)

Declared In

`CGContext.h`

CGContextAddEllipseInRect

Adds an ellipse that fits inside the specified rectangle.

```
void CGContextAddEllipseInRect (
   CGContextRef context,
   CGRect rect
);
```

Parameters

context

A graphics context.

rect

A rectangle that defines the area for the ellipse to fit in.

Discussion
The ellipse is approximated by a sequence of Bézier curves. Its center is the midpoint of the rectangle defined by the `rect` parameter. If the rectangle is square, then the ellipse is circular with a radius equal to one-half the width (or height) of the rectangle. If the `rect` parameter specifies a rectangular shape, then the major and minor axes of the ellipse are defined by the width and height of the rectangle.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGContext.h`

CGContextAddLines

Adds a sequence of connected straight-line segments to the current path.

```
void CGContextAddLines (
   CGContextRef c,
   const CGPoint points[],
   size_t count
);
```

Parameters

context

A graphics context .

points

An array of values that specify the start and end points of the line segments to draw. Each point in the array specifies a position in user space. The first point is the array specifies the initial starting point.

count

The number of elements in the `points` array.

Discussion
This is a convenience function that adds a sequence of connected line segments to the current path in a graphics context. Quartz connects each point in the array with the subsequent point in the array, using straight line segments.

On return, the current point is the last point in the array. This function does not automatically close the path created by the line segments. If you want to close the path, you must call `CGContextClosePath` (page 81).

Availability
Available in Mac OS X version 10.0 and later.

See Also
`CGContextAddLineToPoint` (page 73)

Declared In
`CGContext.h`

CGContextAddLineToPoint

Appends a straight line segment from the current point to the provided point .

```
void CGContextAddLineToPoint (
   CGContextRef c,
   CGFloat x,
   CGFloat y
);
```

Parameters

context

A graphics context whose current path is not empty.

x

The x-value, in user space coordinates, for the end of the line segment.

y

The y-value, in user space coordinates, for the end of the line segment.

Discussion

After adding the line segment, the current point is reset from the beginning of the new line segment to the endpoint of that line segment.

Availability

Available in Mac OS X version 10.0 and later.

`CGContext.h`

CGContextAddPath

Adds a previously created Quartz path object to the current path in a graphics context.

```
void CGContextAddPath (
   CGContextRef context,
   CGPathRef path
);
```

Parameters

context

A graphics context .

path

A previously created Quartz path object. See *CGPath Reference*.

Discussion
Quartz applies the current transformation matrix (CTM) to the points in the new path before they are added to the current path in the graphics context.

Availability
Available in Mac OS X version 10.2 and later.

Related Sample Code

`CGContext.h`

CGContextAddQuadCurveToPoint

Appends a quadratic Bézier curve from the current point, using a control point and an end point you specify.

```
void CGContextAddQuadCurveToPoint (
   CGContextRef c,
   CGFloat cpx,
   CGFloat cpy,
   CGFloat x,
   CGFloat y
);
```

Parameters

context
A graphics context whose current path is not empty.

cpx
The x-coordinate of the user space for the control point of the curve.

cpy
The y-coordinate of the user space for the control point of the curve.

x
The x-coordinate of the user space at which to end the curve.

y
The y-coordinate of the user space at which to end the curve.

Discussion
This function appends a quadratic curve to the current subpath. After adding the segment, the current point is reset from the beginning of the new segment to the end point of that segment.

Availability
Available in Mac OS X version 10.0 and later.

CGContextAddRects

Adds a set rectangular paths to the current path.

```
void CGContextAddRects (
   CGContextRef c,
   const CGRect rects[],
   size_t count
);
```

Parameters

context

A graphics context.

rects

An array of rectangles, specified in user space coordinates.

count

The number of rectangles in the `rects` array.

Availability

Available in Mac OS X version 10.0 and later.

See Also

CGContextAddRect (page 75)

Declared In

CGContext.h

CGContextBeginPage

Starts a new page in a page-based graphics context.

```
void CGContextBeginPage (
   CGContextRef c,
   const CGRect *mediaBox
);
```

Parameters

context

A page-based graphics context such as a PDF context. If you specify a context that does not support multiple pages, this function does nothing.

mediaBox

A Quartz rectangle defining the bounds of the new page, expressed in units of the default user space, or `NULL`. These bounds supersede any supplied for the media box when you created the context. If you pass `NULL`, Quartz uses the rectangle you supplied for the media box when the graphics context was created.

Discussion

When using a graphics context that supports multiple pages, you should call this function together with `CGContextEndPage` (page 91) to delineate the page boundaries in the output. In other words, each page should be bracketed by calls to `CGContextBeginPage` and `CGContextEndPage`. Quartz ignores all drawing operations performed outside a page boundary in a page-based context.

Availability

Available in Mac OS X version 10.0 and later.

Related Sample Code

CarbonSketch

Declared In

`CGContext.h`

CGContextBeginPath

Creates a new empty path in a graphics context.

```
void CGContextBeginPath (
   CGContextRef c
);
```

Parameters

context

A graphics context.

Discussion

A graphics context can have only a single path in use at any time. If the specified context already contains a current path when you call this function, Quartz replaces the previous current path with the new path. In this case, Quartz discards the old path and any data associated with it.

The current path is not part of the graphics state. Consequently, saving and restoring the graphics state has no effect on the current path.

Availability
Available in Mac OS X version 10.0 and later.

See Also
`CGContextClosePath` (page 81)

Related Sample Code
CarbonSketch
HID Calibrator
HID Explorer

Declared In
`CGContext.h`

CGContextBeginTransparencyLayer

Begins a transparency layer.

```
void CGContextBeginTransparencyLayer (
   CGContextRef context,
   CFDictionaryRef auxiliaryInfo
);
```

Parameters

context
A graphics context.

auxiliaryInfo
A dictionary that specifies any additional information, or `NULL`.

Discussion
Until a corresponding call to `CGContextEndTransparencyLayer` (page 92), all subsequent drawing operations in the specified context are composited into a fully transparent backdrop (which is treated as a separate destination buffer from the context).

After a call to `CGContextEndTransparencyLayer`, the result is composited into the context using the global alpha and shadow state of the context. This operation respects the clipping region of the context.

After a call to this function, all of the parameters in the graphics state remain unchanged with the exception of the following:

- The global alpha is set to `1`.
- The shadow is turned off.

Ending the transparency layer restores these parameters to their previous values. Quartz maintains a transparency layer stack for each context, and transparency layers may be nested.

Tip: For best performance, make sure that you set the smallest possible clipping area for the objects in the transparency layer prior to calling `CGContextBeginTransparencyLayer`.

Availability
Available in Mac OS X version 10.3 and later.

Declared In
CGContext.h

CGContextBeginTransparencyLayerWithRect

Begins a transparency layer whose contents are bounded by the specified rectangle.

```
void CGContextBeginTransparencyLayerWithRect(CGContextRef context, CGRect rect,
CFDictionaryRef auxiliaryInfo);
```

Parameters

context
A graphics context.

rect
The rectangle, specified in user space, that bounds the transparency layer.

auxiliaryInfo
A dictionary that specifies any additional information, or NULL.

Discussion
This function is identical to CGContextBeginTransparencyLayer (page 77) except that the content of the transparency layer is within the bounds of the provided rectangle.

Availability
Available in Mac OS X v10.5 and later.

Declared In
CGContext.h

CGContextClearRect

Paints a transparent rectangle.

```
void CGContextClearRect (
   CGContextRef c,
   CGRect rect
);
```

Parameters

context
The graphics context in which to paint the rectangle.

rect
The rectangle, in user space coordinates.

Discussion
If the provided context is a window or bitmap context, Quartz effectively clears the rectangle. For other context types, Quartz fills the rectangle in a device-dependent manner. However, you should not use this function in contexts other than window or bitmap contexts.

Availability
Available in Mac OS X version 10.0 and later.

Related Sample Code
CarbonSketch

Declared In
`CGContext.h`

CGContextClip

Modifies the current clipping path, using the nonzero winding number rule.

```
void CGContextClip (
   CGContextRef c
);
```

Parameters

context

A graphics context that contains a path. If the context does not have a current path, the function does nothing.

Discussion
The function uses the nonzero winding number rule to calculate the intersection of the current path with the current clipping path. Quartz then uses the path resulting from the intersection as the new current clipping path for subsequent painting operations.

Unlike the current path, the current clipping path is part of the graphics state. Therefore, to re-enlarge the paintable area by restoring the clipping path to a prior state, you must save the graphics state before you clip and restore the graphics state after you've completed any clipped drawing.

After determining the new clipping path, the function resets the context's current path to an empty path.

See also`CGContextEOClip` (page 92)

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`CGContext.h`

CGContextClipToMask

Maps a mask into the specified rectangle and intersects it with the current clipping area of the graphics context.

```
void CGContextClipToMask (
   CGContextRef c,
   CGRect rect,
   CGImageRef mask
);
```

Parameters

c

A graphics context.

rect

The rectangle to map the `mask` parameter to.

mask

An image or an image mask. If `mask` is an image, then it must be in the DeviceGray color space, may not have an alpha component, and may not be masked by an image mask or masking color.

Discussion
If the *mask* parameter is an image mask, then Quartz clips in a manner identical to the behavior seen with the function `CGContextDrawImage`—the mask indicates an area to be left unchanged when drawing. The source samples of the image mask determine which points of the clipping area are changed, acting as an "inverse alpha" value. If the value of a source sample in the image mask is `S`, then the corresponding point in the current clipping area is multiplied by an alpha value of (`1-S`). For example, if `S` is `1` then the point in the clipping area becomes transparent. If `S` is `0`, the point in the clipping area is unchanged.

If the *mask* parameter is an image, then *mask* acts like an alpha mask and is blended with the current clipping area. The source samples of mask determine which points of the clipping area are changed. If the value of the source sample in mask is `S`, then the corresponding point in the current clipping area is multiplied by an alpha of `S`. For example, if `S` is `0`, then the point in the clipping area becomes transparent. If `S` is `1`, the point in the clipping area is unchanged.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGContext.h`

CGContextClipToRect

Sets the clipping path to the intersection of the current clipping path with the area defined by the specified rectangle.

```
void CGContextClipToRect (
   CGContextRef c,
   CGRect rect
);
```

Parameters

context

The graphics context for which to set the clipping path.

rect

A `CGRect` value that specifies, in the user space, the location and dimensions of the rectangle to be used in determining the new clipping path.

Discussion
This function sets the specified graphics context's clipping region to the area which intersects both the current clipping path and the specified rectangle.

After determining the new clipping path, the `CGContextClipToRect` function resets the context's current path to an empty path.

See also `CGContextClipToRects` (page 81).

Availability
Available in Mac OS X version 10.0 and later.

Declared In
CGContext.h

CGContextClipToRects

Sets the clipping path to the intersection of the current clipping path with the region defined by an array of rectangles.

```
void CGContextClipToRects (
   CGContextRef c,
   const CGRect rects[],
   size_t count
);
```

Parameters

context
The graphics context for which to set the clipping path.

rects
An array of rectangles. The locations and dimensions of the rectangles are specified in the user space coordinate system.

count
The total number of array entries in the `rects` parameter.

Discussion
This function sets the clipping path to the intersection of the current clipping path and the region within the specified rectangles.

After determining the new clipping path, the function resets the context's current path to an empty path.

See also `CGContextClipToRect` (page 80).

Availability
Available in Mac OS X version 10.0 and later.

Declared In
CGContext.h

CGContextClosePath

Closes and terminates an open path.

```
void CGContextClosePath (
   CGContextRef c
);
```

Parameters

context
A graphics context.

Discussion
If a path is open, this function closes and terminate the path. Quartz closes a path by drawing a straight line that connects the current point to the starting point. If the current point and the starting point are the same, you must still call this function to close the path. After Quartz terminates the path, the current point is no longer defined. If there is no open path, this function does nothing.

When you fill or clip an open path, Quartz implicitly closes the subpath for you.

Availability
Available in Mac OS X version 10.0 and later.

HID Explorer

Declared In
`CGContext.h`

CGContextConcatCTM

Transforms the user coordinate system in a context using a specified matrix.

```
void CGContextConcatCTM (
   CGContextRef c,
   CGAffineTransform transform
);
```

Parameters

context
A graphics context.

transform
The transformation matrix to apply to the specified context's current transformation matrix.

Discussion
When you call the function `CGContextConcatCTM`, it concatenates (that is, it combines) two matrices, by multiplying them together. The order in which matrices are concatenated is important, as the operations are not commutative. When you call `CGContextConcatCTM`, the resulting CTM in the context is: `CTMnew = transform * CTMcontext.`

Availability
Available in Mac OS X version 10.0 and later.

Related Sample Code
CarbonSketch

Declared In
`CGContext.h`

CGContextConvertPointToDeviceSpace

Returns a point that is transformed from user space coordinates to device space coordinates.

```
CGPoint CGContextConvertPointToDeviceSpace (
   CGContextRef c,
   CGPoint point
);
```

Parameters

c

A graphics context.

point

The point, in user space coordinates, to transform.

Return Value

The coordinates of the point in device space coordinates.

Availability

Available in Mac OS X v10.4 and later.

See Also

CGContextConvertPointToUserSpace (page 83)

Declared In

CGContext.h

CGContextConvertPointToUserSpace

Returns a point that is transformed from device space coordinates to user space coordinates.

```
CGPoint CGContextConvertPointToUserSpace (
   CGContextRef c,
   CGPoint point
);
```

Parameters

c

A graphics context.

point

The point, in device space coordinates, to transform.

Return Value

The coordinates of the point in user space coordinates.

Availability

Available in Mac OS X v10.4 and later.

See Also

CGContextConvertPointToDeviceSpace (page 83)

Declared In

CGContext.h

CGContextConvertRectToDeviceSpace

Returns a rectangle that is transformed from user space coordinate to device space coordinates.

```
CGRect CGContextConvertRectToDeviceSpace (
   CGContextRef c,
   CGRect rect
);
```

Parameters

context

A graphics context.

rect

The rectangle, in user space coordinates, to transform.

Return Value

The rectangle in device space coordinates.

Discussion

In general affine transforms do not preserve rectangles. As a result, this function returns the smallest rectangle that contains the transformed corner points of the rectangle.

Availability

Available in Mac OS X v10.4 and later.

See Also

CGContextConvertRectToUserSpace (page 84)

Declared In

CGContext.h

CGContextConvertRectToUserSpace

Returns a rectangle that is transformed from device space coordinate to user space coordinates.

```
CGRect CGContextConvertRectToUserSpace (
   CGContextRef c,
   CGRect rect
);
```

Parameters

context

A graphics context.

rect

The rectangle, in device space coordinates, to transform.

Return Value

The rectangle in user space coordinates.

Discussion

In general, affine transforms do not preserve rectangles. As a result, this function returns the smallest rectangle that contains the transformed corner points of the rectangle.

Availability

Available in Mac OS X v10.4 and later.

CGContextConvertSizeToDeviceSpace

Returns a size that is transformed from user space coordinates to device space coordinates.

```
CGSize CGContextConvertSizeToDeviceSpace (
   CGContextRef c,
   CGSize size
);
```

Parameters

c
A graphics context.

size
The size, in user space coordinates, to transform.

Return Value
The size in device space coordinates.

Availability
Available in Mac OS X v10.4 and later.

CGContextConvertSizeToUserSpace

Returns a size that is transformed from device space coordinates to user space coordinates

```
CGSize CGContextConvertSizeToUserSpace (
   CGContextRef c,
   CGSize size
);
```

Parameters

context
A graphics context.

size
The size, in device space coordinates, to transform.

Return Value
The size in user space coordinates.

Availability
Available in Mac OS X v10.4 and later.

See Also
CGContextConvertSizeToDeviceSpace (page 85)

Declared In
CGContext.h

CGContextDrawImage

Draws an image into a graphics context.

```
void CGContextDrawImage (
   CGContextRef c,
   CGRect rect,
   CGImageRef image
);
```

Parameters

context
The graphics context in which to draw the image.

rect
The location and dimensions in user space of the bounding box in which to draw the image.

image
The image to draw.

Discussion
Quartz scales the image—disproportionately, if necessary—to fit the bounds specified by the `rect` parameter.

Availability
Available in Mac OS X version 10.0 and later.

Related Sample Code
CarbonCocoa_PictureCursor
WhackedTV

Declared In
CGContext.h

CGContextDrawLinearGradient

Paints a gradient fill that varies along the line defined by the provided starting and ending points.

```
void CGContextDrawLinearGradient(
    CGContextRef context,
    CGGradientRef gradient,
    CGPoint startPoint,
    CGPoint endPoint,
    CGGradientDrawingOptions options
);
```

Parameters

context
A Quartz graphics context.

gradient
A CGGradient object.

startPoint
The coordinate that defines the starting point of the gradient.

endPoint
The coordinate that defines the ending point of the gradient.

options
Option flags (kCGGradientDrawsBeforeStartLocation (page 207) or kCGGradientDrawsAfterEndLocation (page 207)) that control whether the fill is extended beyond the starting or ending point.

Discussion
The color at location 0 in the CGGradient object is mapped to the starting point. The color at location 1 in the CGGradient object is mapped to the ending point. Colors are linearly interpolated between these two points based on the location values of the gradient. The option flags control whether the gradient is drawn before the start point or after the end point.

Availability
Available in Mac OS X v10.5 and later.

Declared In
CGContext.h

CGContextDrawPath

Draws the current path using the provided drawing mode.

```
void CGContextDrawPath (
   CGContextRef c,
   CGPathDrawingMode mode
);
```

Parameters

context
A graphics context that contains a path to paint.

mode
A path drawing mode constant—kCGPathFill, kCGPathEOFill, kCGPathStroke, kCGPathFillStroke, or kCGPathEOFillStroke. For a discussion of these constants, see *CGPath Reference*.

Discussion
This function draws the current path using the specified drawing mode. If the current path contains several disjoint portions (or subpaths), Quartz fills each one independently. Any subpath that you did not explicitly close by calling CGContextClosePath (page 81) is closed implicitly by the fill routines.

Availability
Available in Mac OS X version 10.0 and later.

See Also
CGContextFillPath (page 94)
CGContextEOFillPath (page 93)
CGContextStrokePath (page 134)

Related Sample Code
CarbonSketch

Declared In
CGContext.h

CGContextDrawPDFDocument

Draws a page of a PDF document into a graphics context.

```
void CGContextDrawPDFDocument (
   CGContextRef c,
   CGRect rect,
   CGPDFDocumentRef document,
   int page
);
```

Parameters

context
The graphics context in which to draw the PDF page.

rect
A `CGRect` value that specifies the dimensions and location of the area in which to draw the PDF page, in units of the user space. When drawn, Quartz scales the media box of the page to fit the rectangle you specify.

document
The PDF document to draw.

page
A value that specifies the PDF page number to draw. If the specified page does not exist, the function does nothing.

Special Considerations

For applications running in Mac OS X version 10.3 and later, it is recommended that you replace this function with `CGContextDrawPDFPage` (page 88). If you do so, and want to specify the drawing rectangle, you should use `CGPDFPageGetDrawingTransform` (page 355) to get an appropriate transform, concatenate it with the current transformation matrix, clip to the rectangle, and then call `CGContextDrawPDFPage` (page 88).

Availability
Available in Mac OS X version 10.0 and later.

Declared In
CGContext.h

CGContextDrawPDFPage

Draws a page in the current user space of a PDF context.

```
void CGContextDrawPDFPage (
   CGContextRef c,
   CGPDFPageRef page
);
```

Parameters

context

The graphics context in which to draw the PDF page.

page

A Quartz PDF page.

Discussion

This function works in conjunction with the opaque type `CGPDFPageRef` to draw individual pages into a PDF context.

For applications running in Mac OS X version 10.3 and later, this function is recommended as a replacement for the older function `CGContextDrawPDFDocument`.

Availability

Available in Mac OS X version 10.3 and later.

Related Sample Code

CarbonSketch

Declared In

`CGContext.h`

CGContextDrawRadialGradient

Paints a gradient fill that varies along the area defined by the provided starting and ending circles.

```
void CGContextDrawRadialGradient(
    CGContextRef context,
    CGGradientRef gradient,
    CGPoint startCenter,
    CGFloat startRadius,
    CGPoint endCenter,
    CGFloat endRadius,
    CGGradientDrawingOptions options
);
```

Parameters

context

A Quartz graphics context.

gradient

A CGGradient object.

startCenter

The coordinate that defines the center of the starting circle.

startRadius

The radius of the starting circle.

endCenter

The coordinate that defines the center of the ending circle.

endRadius
The radius of the ending circle.

options
Option flags (`kCGGradientDrawsBeforeStartLocation` (page 207) or `kCGGradientDrawsAfterEndLocation` (page 207)) that control whether the gradient is drawn before the starting circle or after the ending circle.

Discussion
The color at location 0 in the CGGradient object is mapped to the circle defined by `startCenter` and `startRadius`. The color at location 1 in the CGGradient object is mapped to the circle defined by `endCenter` and `endRadius`. Colors are linearly interpolated between the starting and ending circles based on the location values of the gradient. The option flags control whether the gradient is drawn before the start point or after the end point.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`CGContext.h`

CGContextDrawShading

Fills the clipping path of a context with the specified shading.

```
void CGContextDrawShading (
   CGContextRef c,
   CGShadingRef shading
);
```

Parameters

context
The graphics context in which to draw the shading.

shading
A Quartz shading. Quartz retains this object; upon return, you may safely release it.

Discussion
In Mac OS X v10.5 and later, the preferred way to draw gradients is to use a CGGradient object. See *CGGradient Reference*.

Availability
Available in Mac OS X v10.2 and later.

See Also
`CGContextDrawLinearGradient` (page 86)
`CGContextDrawRadialGradient` (page 89)

Declared In
`CGContext.h`

CGContextDrawTiledImage

Repeatedly draws an image, scaled to the provided rectangle, to fill the current clip region.

```
void CGContextDrawTiledImage(
    CGContextRef context,
    CGRect rect,
    CGImageRef image
);
```

Parameters

context

The graphics context in which to draw the image.

rect

A rectangle that specifies the tile size. Quartz scales the image—disproportionately, if necessary—to fit the bounds specified by the `rect` parameter.

image

The image to draw.

Discussion

Quartz draws the scaled image starting at the origin of user space, then moves to a new point (horizontally by the width of the tile and/or vertically by the height of the tile), draws the scaled image, moves again, draws again, and so on, until the current clip region is tiled with copies of the image. Unlike patterns, the image is tiled in user space, so transformations applied to the CTM affect the final result.

Availability

Available in Mac OS X v10.5 and later.

Declared In

`CGContext.h`

CGContextEndPage

Ends the current page in a page-based graphics context.

```
void CGContextEndPage (
   CGContextRef c
);
```

Parameters

context

A page-based graphics context.

Discussion

When using a graphics context that supports multiple pages, you should call this function to terminate drawing in the current page.

For more information, see `CGContextBeginPage` (page 76).

Availability

Available in Mac OS X version 10.0 and later.

Related Sample Code

CarbonSketch

Declared In

`CGContext.h`

CGContextEndTransparencyLayer

Ends a transparency layer.

```
void CGContextEndTransparencyLayer (
   CGContextRef context
);
```

Parameters

context

A graphics context.

Discussion

See the discussion for `CGContextBeginTransparencyLayer` (page 77).

Availability

Available in Mac OS X version 10.3 and later.

Declared In

`CGContext.h`

CGContextEOClip

Modifies the current clipping path, using the even-odd rule.

```
void CGContextEOClip (
   CGContextRef c
);
```

Parameters

context

A graphics context containing a path. If the context does not have a current path, the function does nothing.

Discussion

The function uses the even-odd rule to calculate the intersection of the current path with the current clipping path. Quartz then uses the path resulting from the intersection as the new current clipping path for subsequent painting operations.

Unlike the current path, the current clipping path is part of the graphics state. Therefore, to re-enlarge the paintable area by restoring the clipping path to a prior state, you must save the graphics state before you clip and restore the graphics state after you've completed any clipped drawing.

After determining the new clipping path, the function resets the context's current path to an empty path.

See also `CGContextClip` (page 79).

Availability

Available in Mac OS X version 10.0 and later.

Related Sample Code

CarbonSketch

Declared In

`CGContext.h`

CGContextEOFillPath

Paints the area within the current path, using the even-odd fill rule.

```
void CGContextEOFillPath (
   CGContextRef c
);
```

Parameters

context

A graphics context that contains a path to fill.

Discussion

If the current path contains several disjoint portions (or subpaths), Quartz fills each one independently. Any subpath that you did not explicitly close by calling `CGContextClosePath` (page 81) is closed implicitly by the fill routines.

Availability

Available in Mac OS X version 10.0 and later.

CGContextFillEllipseInRect

Paints the area of the ellipse that fits inside the provided rectangle, using the fill color in the current graphics state.

```
void CGContextFillEllipseInRect (
   CGContextRef context,
   CGRect rect
);
```

Parameters

context

A graphics context.

rect

A rectangle that defines the area for the ellipse to fit in.

Availability

Available in Mac OS X v10.4 and later.

Related Sample Code

HID Calibrator

HID Config Save

HID Explorer

Declared In
CGContext.h

CGContextFillPath

Paints the area within the current path, using the nonzero winding number rule.

```
void CGContextFillPath (
   CGContextRef c
);
```

Parameters

context
A graphics context that contains a path to fill.

Discussion
If the current path contains several disjoint portions (or subpaths), Quartz fills each one independently. Any subpath that you did not explicitly close by calling CGContextClosePath (page 81) is closed implicitly by the fill routines.

Availability
Available in Mac OS X version 10.0 and later.

See Also

CGContextStrokePath (page 134)
CGContextDrawPath (page 87)

Declared In
CGContext.h

CGContextFillRect

Paints the area contained within the provided rectangle, using the fill color in the current graphics state.

```
void CGContextFillRect (
   CGContextRef c,
   CGRect rect
);
```

Parameters

context
A graphics context.

rect
A rectangle, in user space coordinates.

Discussion
As a side effect when you call this function, Quartz clears the current path.

Availability
Available in Mac OS X version 10.0 and later.

See Also
CGContextFillRects (page 95)

Related Sample Code
CALayerEssentials
CarbonSketch
HID Calibrator
HID Explorer

Declared In
CGContext.h

CGContextFillRects

Paints the areas contained within the provided rectangles, using the fill color in the current graphics state.

```
void CGContextFillRects (
   CGContextRef c,
   const CGRect rects[],
   size_t count
);
```

Parameters

context
A graphics context .

rects
An array of rectangles, in user space coordinates.

count
The number rectangles in the `rects` array.

Discussion
As a side effect when you call this function, Quartz clears the current path.

Availability
Available in Mac OS X version 10.0 and later.

See Also
CGContextFillRect (page 94)

Declared In
CGContext.h

CGContextFlush

Forces all pending drawing operations in a window context to be rendered immediately to the destination device.

```
void CGContextFlush (
   CGContextRef c
);
```

Parameters

context

The window context to flush. If you pass a PDF context or a bitmap context, this function does nothing.

Discussion

When you call this function, Quartz immediately flushes the current drawing to the destination device (for example, a screen). Because the system software flushes a context automatically at the appropriate times, calling this function could have an adverse effect on performance. Under normal conditions, you do not need to call this function.

Availability

Available in Mac OS X version 10.0 and later.

Declared In

`CGContext.h`

CGContextGetClipBoundingBox

Returns the bounding box of a clipping path.

```
CGRect CGContextGetClipBoundingBox (
   CGContextRef c
);
```

Parameters

context

The graphics context to modify.

Return Value

The bounding box of the clipping path, specified in user space.

Discussion

The bounding box is the smallest rectangle completely enclosing all points in the clipping path, including control points for any Bezier curves in the path.

Availability

Available in Mac OS X version 10.3 and later.

Related Sample Code

CALayerEssentials

Declared In

`CGContext.h`

CGContextGetCTM

Returns the current transformation matrix.

```
CGAffineTransform CGContextGetCTM (
   CGContextRef c
);
```

Parameters

context

A graphics context.

Return Value
The transformation matrix for the current graphics state of the specified context.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
CGContext.h

CGContextGetInterpolationQuality

Returns the current level of interpolation quality for a graphics context.

```
CGInterpolationQuality CGContextGetInterpolationQuality (
   CGContextRef c
);
```

Parameters

context

The graphics context to examine.

Return Value
The current level of interpolation quality.

Discussion
Interpolation quality is a graphics state parameter that provides a hint for the level of quality to use for image interpolation (for example, when scaling the image). Not all contexts support all interpolation quality levels.

Availability
Available in Mac OS X version 10.1 and later.

See Also
CGContextSetInterpolationQuality (page 116)

Declared In
CGContext.h

CGContextGetPathBoundingBox

Returns the smallest rectangle that contains the current path.

```
CGRect CGContextGetPathBoundingBox (
   CGContextRef c
);
```

Parameters

context

The graphics context, containing a path, to examine.

Return Value

A `CGRect` value that specifies the dimensions and location, in user space, of the bounding box of the path. If there is no path, the function returns `CGRectNull`.

Discussion

The bounding box is the smallest rectangle completely enclosing all points in a path, including control points for Bézier cubic and quadratic curves.

Availability

Available in Mac OS X version 10.0 and later.

Declared In

`CGContext.h`

CGContextGetPathCurrentPoint

Returns the current point in a non-empty path.

```
CGPoint CGContextGetPathCurrentPoint (
   CGContextRef c
);
```

Parameters

context

The graphics context containing the path to examine.

Return Value

A `CGPoint` value that specifies the location, in user space, of current point in the context's path. If there is no path, the function returns `CGPointZero`.

Availability

Available in Mac OS X version 10.0 and later.

Declared In

`CGContext.h`

CGContextGetTextMatrix

Returns the current text matrix.

```
CGAffineTransform CGContextGetTextMatrix (
   CGContextRef c
);
```

Parameters

context

The graphics context for which to obtain the text matrix.

Return Value

The current text matrix.

Availability

Available in Mac OS X version 10.0 and later.

Declared In

CGContext.h

CGContextGetTextPosition

Returns the location at which text is drawn.

```
CGPoint CGContextGetTextPosition (
   CGContextRef c
);
```

Parameters

context

The graphics context from which to obtain the current text position.

Return Value

Returns a `CGPoint` value that specifies the x and y values at which text is to be drawn, in user space coordinates.

Availability

Available in Mac OS X version 10.0 and later.

Declared In

CGContext.h

CGContextGetTypeID

Returns the type identifier for Quartz graphics contexts.

```
CFTypeID CGContextGetTypeID (
   void
);
```

Return Value

The identifier for the opaque type `CGContextRef` (page 137).

Availability

Available in Mac OS X version 10.2 and later.

Declared In

CGContext.h

CGContextGetUserSpaceToDeviceSpaceTransform

Returns an affine transform that maps user space coordinates to device space coordinates.

```
CGAffineTransform CGContextGetUserSpaceToDeviceSpaceTransform (
   CGContextRef c
);
```

Parameters

c

A graphics context.

Return Value

The affine transforms that maps the user space of the graphics context to the device space.

Availability

Available in Mac OS X v10.4 and later.

Declared In

`CGContext.h`

CGContextIsPathEmpty

Indicates whether the current path contains any subpaths.

```
bool CGContextIsPathEmpty (
   CGContextRef c
);
```

Parameters

context

The graphics context containing the path to examine.

Return Value

Returns `1` if the context's path contains no subpaths, otherwise returns `0`.

Availability

Available in Mac OS X version 10.0 and later.

Declared In

`CGContext.h`

CGContextMoveToPoint

Begins a new path at the point you specify.

```
void CGContextMoveToPoint (
   CGContextRef c,
   CGFloat x,
   CGFloat y
);
```

Parameters

context

A graphics context.

x
The x-value, in user space coordinates, for the point.

y
The y-value, in user space coordinates, for the point.

Discussion
This point you specifies becomes the current point. It defines the starting point of the next line segment.

Availability
Available in Mac OS X version 10.0 and later.

Related Sample Code
CALayerEssentials
CarbonSketch
HID Calibrator
HID Explorer

Declared In
`CGContext.h`

CGContextPathContainsPoint

Checks to see whether the specified point is contained in the current path.

```
bool CGContextPathContainsPoint (
   CGContextRef context,
   CGPoint point,
   CGPathDrawingMode mode
);
```

Parameters

context
A graphics context.

point
The point to check, specified in user space units.

mode
A path drawing mode—`kCGPathFill`, `kCGPathEOFill`, `kCGPathStroke`, `kCGPathFillStroke`, or `kCGPathEOFillStroke`. See `CGPathDrawingMode` for more information on these modes.

Return Value
Returns `true` if `point` is inside the current path of the graphics context; `false` otherwise.

Discussion
A point is contained within the path of a graphics context if the point is inside the painted region when the path is stroked or filled with opaque colors using the specified path drawing mode. A point can be inside a path only if the path is explicitly closed by calling the function `CGContextClosePath` (page 81), for paths drawn directly to the current context, or `CGPathCloseSubpath` (page 271), for paths first created as `CGPath` objects and then drawn to the current context.

Availability
Available in Mac OS X v10.4 and later.

Declared In
CGContext.h

CGContextRelease

Decrements the retain count of a graphics context.

```
void CGContextRelease (
   CGContextRef c
);
```

Parameters

context
The graphics context to release.

Discussion
This function is equivalent to `CFRelease`, except that it does not cause an error if the `context` parameter is `NULL`.

Availability
Available in Mac OS X version 10.0 and later.

Related Sample Code
CarbonSketch

Declared In
CGContext.h

CGContextReplacePathWithStrokedPath

Replaces the path in the graphics context with the stroked version of the path.

```
void CGContextReplacePathWithStrokedPath (
   CGContextRef c
);
```

Parameters

c
A graphics context.

Discussion
Quartz creates a stroked path using the parameters of the current graphics context. You can use this path in the same way you use the path of any context. For example, you can clip to the stroked version of a path by calling this function followed by a call to the function `CGContextClip` (page 79).

Availability
Available in Mac OS X v10.4 and later.

Declared In
CGContext.h

CGContextRestoreGState

Sets the current graphics state to the state most recently saved.

```
void CGContextRestoreGState (
   CGContextRef c
);
```

Parameters

context

The graphics context whose state you want to modify.

Discussion

Quartz removes the graphics state that is at the top of the stack so that the most recently saved state becomes the current graphics state.

Availability

Available in Mac OS X version 10.0 and later.

See Also

`CGContextSaveGState` (page 104)

Related Sample Code

CarbonSketch

HID Calibrator

Declared In

`CGContext.h`

CGContextRetain

Increments the retain count of a graphics context.

```
CGContextRef CGContextRetain (
   CGContextRef c
);
```

Parameters

context

The graphics context to retain.

Return Value

The same graphics context you passed in as the `context` parameter.

Discussion

This function is equivalent to `CFRetain`, except that it does not cause an error if the `context` parameter is `NULL`.

Availability

Available in Mac OS X version 10.0 and later.

Declared In

`CGContext.h`

CGContextRotateCTM

Rotates the user coordinate system in a context.

```
void CGContextRotateCTM (
   CGContextRef c,
   CGFloat angle
);
```

Parameters

context

A graphics context.

angle

The angle, in radians, by which to rotate the coordinate space of the specified context. (Positive values rotate counterclockwise.)

Availability

Available in Mac OS X version 10.0 and later.

Declared In

`CGContext.h`

CGContextSaveGState

Pushes a copy of the current graphics state onto the graphics state stack for the context.

```
void CGContextSaveGState (
   CGContextRef c
);
```

Parameters

context

The graphics context whose current graphics state you want to save.

Discussion

Each graphics context maintains a stack of graphics states. Note that not all aspects of the current drawing environment are elements of the graphics state. For example, the current path is not considered part of the graphics state and is therefore not saved when you call the `CGContextSaveGState` function. The graphics state parameters that *are* saved are:

- CTM (current transformation matrix)
- clip region
- image interpolation quality
- line width
- line join
- miter limit
- line cap
- line dash
- flatness
- should anti-alias

- rendering intent
- fill color space
- stroke color space
- fill color
- stroke color
- alpha value
- font
- font size
- character spacing
- text drawing mode
- shadow parameters
- the pattern phase
- the font smoothing parameter
- blend mode

To restore your drawing environment to a previously saved state, you can use the function `CGContextRestoreGState` (page 103).

Availability
Available in Mac OS X version 10.0 and later.

Related Sample Code

CGContextScaleCTM

Changes the scale of the user coordinate system in a context.

```
void CGContextScaleCTM (
   CGContextRef c,
   CGFloat sx,
   CGFloat sy
);
```

Parameters

context
A graphics context.

sx
The factor by which to scale the x-axis of the coordinate space of the specified context.

sy
The factor by which to scale the y-axis of the coordinate space of the specified context.

Availability
Available in Mac OS X version 10.0 and later.

CarbonSketch

Declared In
CGContext.h

CGContextSelectFont

Sets the font and font size in a graphics context.

```
void CGContextSelectFont (
   CGContextRef c,
   const char *name,
   CGFloat size,
   CGTextEncoding textEncoding
);
```

Parameters

context
The graphics context for which to set the font and font size.

name
A null-terminated string that contains the PostScript name of the font to set.

size
A value that specifies the font size to set, in text space units.

textEncoding
A `CGTextEncoding` value that specifies the encoding used for the font. For a description of the available values, see "Text Encodings" (page 146).

Discussion
For information about when to use this function, see `CGContextShowText` (page 131) and `CGContextShowTextAtPoint` (page 132).

Availability
Available in Mac OS X version 10.0 and later.

Related Sample Code
HID Calibrator

Declared In
CGContext.h

CGContextSetAllowsAntialiasing

Sets whether or not to allow anti-aliasing for a graphics context.

```
void CGContextSetAllowsAntialiasing (
   CGContextRef context,
   bool allowsAntialiasing
);
```

Parameters

context

A graphics context.

allowsAntialiasing

A Boolean value that specifies whether or not to allow antialiasing. Pass `true` to allow antialiasing; `false` otherwise. This parameter is not part of the graphics state.

Discussion

Quartz performs antialiasing for a graphics context if both the `allowsAntialiasing` parameter and the graphics state parameter `shouldAntialias` are `true`.

Availability

Available in Mac OS X v10.4 and later.

Declared In

`CGContext.h`

CGContextSetAlpha

Sets the opacity level for objects drawn in a graphics context.

```
void CGContextSetAlpha (
   CGContextRef c,
   CGFloat alpha
);
```

Parameters

context

The graphics context for which to set the current graphics state's alpha value parameter.

alpha

A value that specifies the opacity level. Values can range from `0.0` (transparent) to `1.0` (opaque). Values outside this range are clipped to `0.0` or `1.0`.

Discussion

This function sets the alpha value parameter for the specified graphics context. To clear the contents of the drawing canvas, you should use the function `CGContextClearRect` (page 78).

Availability

Available in Mac OS X version 10.0 and later.

Declared In

`CGContext.h`

CGContextSetBlendMode

Sets how Quartz composites sample values for a graphics context.

```
void CGContextSetBlendMode (
   CGContextRef context,
   CGBlendMode mode
);
```

Parameters

context

The graphics context to modify.

mode

A blend mode. See "Blend Modes" (page 137) for a list of the constants you can supply.

Availability
Available in Mac OS X v10.4 and later.

Declared In
CGContext.h

CGContextSetCharacterSpacing

Sets the current character spacing.

```
void CGContextSetCharacterSpacing (
   CGContextRef c,
   CGFloat spacing
);
```

Parameters

context

The graphics context for which to set the character spacing.

spacing

A value that represents the amount of additional space to place between glyphs, in text space coordinates.

Discussion
Quartz adds the additional space to the advance between the origin of one character and the origin of the next character. For information about the text coordinate system, see `CGContextSetTextMatrix` (page 127).

Availability
Available in Mac OS X version 10.0 and later.

Declared In
CGContext.h

CGContextSetCMYKFillColor

Sets the current fill color to a value in the DeviceCMYK color space.

```
void CGContextSetCMYKFillColor (
   CGContextRef c,
   CGFloat cyan,
   CGFloat magenta,
   CGFloat yellow,
   CGFloat black,
   CGFloat alpha
);
```

Parameters

context

The graphics context for which to set the current fill color.

cyan

The cyan intensity value for the color to set. The DeviceCMYK color space permits the specification of a value ranging from 0.0 (does not absorb the secondary color) to 1.0 (fully absorbs the secondary color).

magenta

The magenta intensity value for the color to set. The DeviceCMYK color space permits the specification of a value ranging from 0.0 (does not absorb the secondary color) to 1.0 (fully absorbs the secondary color).

yellow

The yellow intensity value for the color to set. The DeviceCMYK color space permits the specification of a value ranging from 0.0 (does not absorb the secondary color) to 1.0 (fully absorbs the secondary color).

black

The black intensity value for the color to set. The DeviceCMYK color space permits the specification of a value ranging from 0.0 (does not absorb the secondary color) to 1.0 (fully absorbs the secondary color).

alpha

A value that specifies the opacity level. Values can range from `0.0` (transparent) to `1.0` (opaque). Values outside this range are clipped to `0.0` or `1.0`.

Discussion

Quartz provides convenience functions for each of the device color spaces that allow you to set the fill or stroke color space and the fill or stroke color with one function call.

When you call this function, two things happen:

- Quartz sets the current fill color space to DeviceCMYK.
- Quartz sets the current fill color to the value specified by the `cyan`, `magenta`, `yellow`, `black`, and `alpha` parameters.

See also `CGContextSetCMYKStrokeColor` (page 110).

Availability

Available in Mac OS X version 10.0 and later.

Declared In

`CGContext.h`

CGContextSetCMYKStrokeColor

Sets the current stroke color to a value in the DeviceCMYK color space.

```
void CGContextSetCMYKStrokeColor (
   CGContextRef c,
   CGFloat cyan,
   CGFloat magenta,
   CGFloat yellow,
   CGFloat black,
   CGFloat alpha
);
```

Parameters

context

The graphics context for which to set the current stroke color.

cyan

The cyan intensity value for the color to set. The DeviceCMYK color space permits the specification of a value ranging from `0.0` (does not absorb the secondary color) to `1.0` (fully absorbs the secondary color).

magenta

The magenta intensity value for the color to set. The DeviceCMYK color space permits the specification of a value ranging from `0.0` (does not absorb the secondary color) to `1.0` (fully absorbs the secondary color).

yellow

The yellow intensity value for the color to set. The DeviceCMYK color space permits the specification of a value ranging from `0.0` (does not absorb the secondary color) to `1.0` (fully absorbs the secondary color).

black

The black intensity value for the color to set. The DeviceCMYK color space permits the specification of a value ranging from `0.0` (does not absorb the secondary color) to `1.0` (fully absorbs the secondary color).

alpha

A value that specifies the opacity level. Values can range from `0.0` (transparent) to `1.0` (opaque). Values outside this range are clipped to `0.0` or `1.0`.

Discussion

When you call this function, two things happen:

- Quartz sets the current stroke color space to DeviceCMYK.
- Quartz sets the current stroke color to the value specified by the `cyan`, `magenta`, `yellow`, `black`, and `alpha` parameters.

See also `CGContextSetCMYKFillColor` (page 108).

Availability

Available in Mac OS X version 10.0 and later.

Declared In

`CGContext.h`

CGContextSetFillColor

Sets the current fill color.

```
void CGContextSetFillColor (
   CGContextRef c,
   const CGFloat components[]
);
```

Parameters

context

The graphics context for which to set the current fill color.

components

An array of intensity values describing the color to set. The number of array elements must equal the number of components in the current fill color space, plus an additional component for the alpha value.

Discussion

The current fill color space must not be a pattern color space. For information on setting the fill color when using a pattern color space, see `CGContextSetFillPattern` (page 112). Note that the preferred API to use is now `CGContextSetFillColorWithColor` (page 112).

Availability

Available in Mac OS X version 10.0 and later.

Related Sample Code

CarbonSketch

Declared In

`CGContext.h`

CGContextSetFillColorSpace

Sets the fill color space in a graphics context.

```
void CGContextSetFillColorSpace (
   CGContextRef c,
   CGColorSpaceRef colorspace
);
```

Parameters

context

The graphics context for which to set the fill color space.

colorspace

The new fill color space. Quartz retains this object; upon return, you may safely release it.

Discussion

As a side effect of this function, Quartz assigns an appropriate initial value to the fill color, based on the specified color space. To change this value, call `CGContextSetFillColor` (page 111). Note that the preferred API to use is now `CGContextSetFillColorWithColor` (page 112).

Availability

Available in Mac OS X version 10.0 and later.

Related Sample Code
CarbonSketch

Declared In
`CGContext.h`

CGContextSetFillColorWithColor

Sets the current fill color in a graphics context, using a Quartz color.

```
void CGContextSetFillColorWithColor (
   CGContextRef c,
   CGColorRef color
);
```

Parameters

context
The graphics context for which to set the fill color.

color
The new fill color.

Discussion
See also `CGContextSetFillColor` (page 111).

Availability
Available in Mac OS X version 10.3 and later.

Related Sample Code
CALayerEssentials

Declared In
`CGContext.h`

CGContextSetFillPattern

Sets the fill pattern in the specified graphics context.

```
void CGContextSetFillPattern (
   CGContextRef c,
   CGPatternRef pattern,
   const CGFloat components[]
);
```

Parameters

context
The graphics context to modify.

pattern
A fill pattern. Quartz retains this object; upon return, you may safely release it.

components

If the pattern is an uncolored (or a masking) pattern, pass an array of intensity values that specify the color to use when the pattern is painted. The number of array elements must equal the number of components in the base space of the fill pattern color space, plus an additional component for the alpha value.

If the pattern is a colored pattern, pass an alpha value.

Discussion

The current fill color space must be a pattern color space. Otherwise, the result of calling this function is undefined. If you want to set a fill color, not a pattern, then call the function `CGContextSetFillColorWithColor` (page 112).

Availability

Available in Mac OS X version 10.1 and later.

Declared In

`CGContext.h`

CGContextSetFlatness

Sets the accuracy of curved paths in a graphics context.

```
void CGContextSetFlatness (
   CGContextRef c,
   CGFloat flatness
);
```

Parameters

context

The graphics context to modify.

flatness

The largest permissible distance, measured in device pixels, between a point on the true curve and a point on the approximated curve.

Discussion

This function controls how accurately curved paths are rendered. Setting the flatness value to less than `1.0` renders highly accurate curves, but lengthens rendering times.

In most cases, you should not change the flatness value. Customizing the flatness value for the capabilities of a particular output device impairs the ability of your application to render to other devices.

Availability

Available in Mac OS X version 10.0 and later.

Declared In

`CGContext.h`

CGContextSetFont

Sets the platform font in a graphics context.

```
void CGContextSetFont (
   CGContextRef c,
   CGFontRef font
);
```

Parameters

context

The graphics context for which to set the font.

font

A Quartz font.

Discussion

For information about when to use this function, see `CGFontCreateWithPlatformFont` (page 183).

Availability

Available in Mac OS X version 10.0 and later.

Declared In

`CGContext.h`

CGContextSetFontSize

Sets the current font size.

```
void CGContextSetFontSize (
   CGContextRef c,
   CGFloat size
);
```

Parameters

context

A graphics context.

size

A font size, expressed in text space units.

Availability

Available in Mac OS X version 10.0 and later.

Declared In

`CGContext.h`

CGContextSetGrayFillColor

Sets the current fill color to a value in the DeviceGray color space.

```
void CGContextSetGrayFillColor (
   CGContextRef c,
   CGFloat gray,
   CGFloat alpha
);
```

Parameters

context

The graphics context for which to set the current fill color.

gray

A value that specifies the desired gray level. The DeviceGray color space permits the specification of a value ranging from `0.0` (absolute black) to `1.0` (absolute white). Values outside this range are clamped to `0.0` or `1.0`.

alpha

A value that specifies the opacity level. Values can range from `0.0` (transparent) to `1.0` (opaque). Values outside this range are clipped to `0.0` or `1.0`.

Discussion
When you call this function, two things happen:

- Quartz sets the current fill color space to DeviceGray.
- Quartz sets the current fill color to the value you specify in the `gray` and `alpha` parameters.

See also `CGContextSetGrayStrokeColor` (page 115).

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`CGContext.h`

CGContextSetGrayStrokeColor

Sets the current stroke color to a value in the DeviceGray color space.

```
void CGContextSetGrayStrokeColor (
   CGContextRef c,
   CGFloat gray,
   CGFloat alpha
);
```

Parameters

context

The graphics context for which to set the current stroke color.

gray

A value that specifies the desired gray level. The DeviceGray color space permits the specification of a value ranging from `0.0` (absolute black) to `1.0` (absolute white). Values outside this range are clamped to `0.0` or `1.0`.

alpha

A value that specifies the opacity level. Values can range from `0.0` (transparent) to `1.0` (opaque). Values outside this range are clipped to `0.0` or `1.0`.

Discussion
When you call this function, two things happen:

- Quartz sets the current stroke color space to DeviceGray. The DeviceGray color space is a single-dimension space in which color values are specified solely by the intensity of a gray value (from absolute black to absolute white).
- Quartz sets the current stroke color to the value you specify in the `gray` and `alpha` parameters.

See also `CGContextSetGrayFillColor` (page 114).

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`CGContext.h`

CGContextSetInterpolationQuality

Sets the level of interpolation quality for a graphics context.

```
void CGContextSetInterpolationQuality (
   CGContextRef c,
   CGInterpolationQuality quality
);
```

Parameters

context
The graphics context to modify.

quality
A `CGInterpolationQuality` constant that specifies the required level of interpolation quality. For possible values, see "`Interpolation Qualities`" (page 142).

Discussion
Interpolation quality is merely a hint to the context—not all contexts support all interpolation quality levels.

Availability
Available in Mac OS X version 10.1 and later.

See Also
`CGContextGetInterpolationQuality` (page 97)

Declared In
`CGContext.h`

CGContextSetLineCap

Sets the style for the endpoints of lines drawn in a graphics context.

```
void CGContextSetLineCap (
   CGContextRef c,
   CGLineCap cap
);
```

Parameters

context

The graphics context to modify.

cap

A line cap style constant—`kCGLineCapButt` (page 143) (the default), `kCGLineCapRound` (page 143), or `kCGLineCapSquare` (page 143). See "`Line Cap Styles`" (page 143).

Availability
Available in Mac OS X version 10.0 and later.

Related Sample Code
CarbonSketch

Declared In
`CGContext.h`

CGContextSetLineDash

Sets the pattern for dashed lines in a graphics context.

```
void CGContextSetLineDash (
   CGContextRef c,
   CGFloat phase,
   const CGFloat lengths[],
   size_t count
);
```

Parameters

context

The graphics context to modify.

phase

A value that specifies how far into the dash pattern the line starts, in units of the user space. For example, passing a value of `3` means the line is drawn with the dash pattern starting at three units from its beginning. Passing a value of `0` draws a line starting with the beginning of a dash pattern.

lengths

An array of values that specify the lengths of the painted segments and unpainted segments, respectively, of the dash pattern—or `NULL` for no dash pattern.

For example, passing an array with the values `[2,3]` sets a dash pattern that alternates between a 2-user-space-unit-long painted segment and a 3-user-space-unit-long unpainted segment. Passing the values `[1,3,4,2]` sets the pattern to a 1-unit painted segment, a 3-unit unpainted segment, a 4-unit painted segment, and a 2-unit unpainted segment.

count

If the `lengths` parameter specifies an array, pass the number of elements in the array. Otherwise, pass `0`.

Availability
Available in Mac OS X version 10.0 and later.

Related Sample Code
CarbonSketch

Declared In
`CGContext.h`

CGContextSetLineJoin

Sets the style for the joins of connected lines in a graphics context.

```
void CGContextSetLineJoin (
   CGContextRef c,
   CGLineJoin join
);
```

Parameters

context
The graphics context to modify.

join
A line join value—`kCGLineJoinMiter` (page 144) (the default), `kCGLineJoinRound` (page 144), or `kCGLineJoinBevel` (page 144). See `"Line Joins"` (page 144).

Availability
Available in Mac OS X version 10.0 and later.

Related Sample Code
CarbonSketch

Declared In
`CGContext.h`

CGContextSetLineWidth

Sets the line width for a graphics context.

```
void CGContextSetLineWidth (
   CGContextRef c,
   CGFloat width
);
```

Parameters

context
The graphics context to modify.

width
The new line width to use, in user space units. The value must be greater than `0`.

Discussion
The default line width is `1` unit. When stroked, the line straddles the path, with half of the total width on either side.

Availability
Available in Mac OS X version 10.0 and later.

Related Sample Code
CarbonSketch

Declared In
`CGContext.h`

CGContextSetMiterLimit

Sets the miter limit for the joins of connected lines in a graphics context.

```
void CGContextSetMiterLimit (
   CGContextRef c,
   CGFloat limit
);
```

Parameters

context
The graphics context to modify.

limit
The miter limit to use.

Discussion
If the current line join style is set to `kCGLineJoinMiter` (see `CGContextSetLineJoin` (page 118)), Quartz uses the miter limit to determine whether the lines should be joined with a bevel instead of a miter. Quartz divides the length of the miter by the line width. If the result is greater than the miter limit, Quartz converts the style to a bevel.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`CGContext.h`

CGContextSetPatternPhase

Sets the pattern phase of a context.

```
void CGContextSetPatternPhase (
   CGContextRef c,
   CGSize phase
);
```

Parameters

context
The graphics context to modify.

phase
A pattern phase, specified in user space.

Discussion
The pattern phase is a translation that Quartz applies prior to drawing a pattern in the context. The pattern phase is part of the graphics state of a context, and the default pattern phase is `(0,0)`. Setting the pattern phase has the effect of temporarily changing the pattern matrix of any pattern you draw. For example, setting the context's pattern phase to `(2,3)` has the effect of moving the start of pattern cell tiling to the point `(2,3)` in default user space.

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CGContext.h`

CGContextSetRenderingIntent

Sets the rendering intent in the current graphics state.

```
void CGContextSetRenderingIntent (
   CGContextRef c,
   CGColorRenderingIntent intent
);
```

Parameters

context
The graphics context to modify.

intent
A rendering intent constant—`kCGRenderingIntentDefault` (page 59), `kCGRenderingIntentAbsoluteColorimetric` (page 59), `kCGRenderingIntentRelativeColorimetric` (page 59), `kCGRenderingIntentPerceptual` (page 59), or `kCGRenderingIntentSaturation` (page 59). For a discussion of these constants, see *CGColorSpace Reference*.

Discussion
The rendering intent specifies how Quartz should handle colors that are not located within the gamut of the destination color space of a graphics context. If you do not explicitly set the rendering intent, Quartz uses perceptual rendering intent for drawing sampled images and relative colorimetric rendering intent for all other drawing.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`CGContext.h`

CGContextSetRGBFillColor

Sets the current fill color to a value in the DeviceRGB color space.

```
void CGContextSetRGBFillColor (
   CGContextRef c,
   CGFloat red,
   CGFloat green,
   CGFloat blue,
   CGFloat alpha
);
```

Parameters

context

The graphics context for which to set the current fill color.

red

The red intensity value for the color to set. The DeviceRGB color space permits the specification of a value ranging from `0.0` (zero intensity) to `1.0` (full intensity).

green

The green intensity value for the color to set. The DeviceRGB color space permits the specification of a value ranging from `0.0` (zero intensity) to `1.0` (full intensity).

blue

The blue intensity value for the color to set. The DeviceRGB color space permits the specification of a value ranging from `0.0` (zero intensity) to `1.0` (full intensity).

alpha

A value that specifies the opacity level. Values can range from `0.0` (transparent) to `1.0` (opaque). Values outside this range are clipped to `0.0` or `1.0`.

Discussion

When you call this function, two things happen:

- Quartz sets the current fill color space to DeviceRGB.
- Quartz sets the current fill color to the value specified by the `red`, `green`, `blue`, and `alpha` parameters.

See also `CGContextSetRGBStrokeColor` (page 121).

Availability

Available in Mac OS X version 10.0 and later.

Declared In

`CGContext.h`

CGContextSetRGBStrokeColor

Sets the current stroke color to a value in the DeviceRGB color space.

```
void CGContextSetRGBStrokeColor (
   CGContextRef c,
   CGFloat red,
   CGFloat green,
   CGFloat blue,
   CGFloat alpha
);
```

Parameters

context

The graphics context for which to set the current stroke color.

red

The red intensity value for the color to set. The DeviceRGB color space permits the specification of a value ranging from `0.0` (zero intensity) to `1.0` (full intensity).

green

The green intensity value for the color to set. The DeviceRGB color space permits the specification of a value ranging from `0.0` (zero intensity) to `1.0` (full intensity).

blue

The blue intensity value for the color to set. The DeviceRGB color space permits the specification of a value ranging from `0.0` (zero intensity) to `1.0` (full intensity).

alpha

A value that specifies the opacity level. Values can range from `0.0` (transparent) to `1.0` (opaque). Values outside this range are clipped to `0.0` or `1.0`.

Discussion

When you call this function, two things happen:

- Quartz sets the current stroke color space to DeviceRGB.
- Quartz sets the current stroke color to the value specified by the `red`, `green`, `blue`, and `alpha` parameters.

See also `CGContextSetRGBFillColor` (page 120).

Availability

Available in Mac OS X version 10.0 and later.

Declared In

`CGContext.h`

CGContextSetShadow

Enables shadowing in a graphics context.

```
void CGContextSetShadow (
   CGContextRef context,
   CGSize offset,
   CGFloat blur
);
```

Parameters

context

A graphics context.

offset

Specifies a translation of the context's coordinate system, to establish an offset for the shadow (`{0,0}` specifies a light source immediately above the screen).

blur

A non-negative number specifying the amount of blur.

Discussion

Shadow parameters are part of the graphics state in a context. After shadowing is set, all objects drawn are shadowed using a black color with 1/3 alpha (i.e., RGBA = `{0, 0, 0, 1.0/3.0}`) in the DeviceRGB color space.

To turn off shadowing:

- Use the standard save/restore mechanism for the graphics state.
- Use `CGContextSetShadowWithColor` (page 123) to set the shadow color to a fully transparent color (or pass `NULL` as the color).

Availability

Available in Mac OS X version 10.3 and later.

Declared In

`CGContext.h`

CGContextSetShadowWithColor

Enables shadowing with color a graphics context.

```
void CGContextSetShadowWithColor (
   CGContextRef context,
   CGSize offset,
   CGFloat blur,
   CGColorRef color
);
```

Parameters

context

The graphics context to modify.

offset

Specifies a translation in base-space.

blur

A non-negative number specifying the amount of blur.

color
Specifies the color of the shadow, which may contain a non-opaque alpha value. If `NULL`, then shadowing is disabled.

Discussion
See also `CGContextSetShadow` (page 122).

Availability
Available in Mac OS X version 10.3 and later.

Declared In
`CGContext.h`

CGContextSetShouldAntialias

Sets anti-aliasing on or off for a graphics context.

```
void CGContextSetShouldAntialias (
   CGContextRef c,
   bool shouldAntialias
);
```

Parameters

context
The graphics context to modify.

shouldAntialias
A Boolean value that specifies whether anti-aliasing should be turned on. Anti-aliasing is turned on by default when a window or bitmap context is created. It is turned off for other types of contexts.

Discussion
Anti-aliasing is a graphics state parameter.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`CGContext.h`

CGContextSetShouldSmoothFonts

Enables or disables font smoothing in a graphics context.

```
void CGContextSetShouldSmoothFonts (
   CGContextRef c,
   bool shouldSmoothFonts
);
```

Parameters

context
The graphics context to modify.

shouldSmoothFonts
A Boolean value that specifies whether to enable font smoothing.

Discussion
There are cases, such as rendering to a bitmap, when font smoothing is not appropriate and should be disabled. Note that some contexts (such as PostScript contexts) do not support font smoothing.

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CGContext.h`

CGContextSetStrokeColor

Sets the current stroke color.

```
void CGContextSetStrokeColor (
   CGContextRef c,
   const CGFloat components[]
);
```

Parameters

context

The graphics context for which to set the current stroke color.

components

An array of intensity values describing the color to set. The number of array elements must equal the number of components in the current stroke color space, plus an additional component for the alpha value.

Discussion
The current stroke color space must not be a pattern color space. For information on setting the stroke color when using a pattern color space, see `CGContextSetStrokePattern` (page 126). Note that the preferred API is now `CGContextSetStrokeColorWithColor` (page 126).

Availability
Available in Mac OS X version 10.0 and later.

Related Sample Code
CarbonSketch

`CGContext.h`

CGContextSetStrokeColorSpace

Sets the stroke color space in a graphics context.

```
void CGContextSetStrokeColorSpace (
   CGContextRef c,
   CGColorSpaceRef colorspace
);
```

Parameters

context

The graphics context for the new stroke color space.

colorspace
The new stroke color space. Quartz retains this object; upon return, you may safely release it.

Discussion
As a side effect when you call this function, Quartz assigns an appropriate initial value to the stroke color, based on the color space you specify. To change this value, call `CGContextSetStrokeColor` (page 125). Note that the preferred API is now `CGContextSetStrokeColorWithColor` (page 126).

Available in Mac OS X version 10.3 and later.

Declared In
`CGContext.h`

CGContextSetStrokePattern

Sets the stroke pattern in the specified graphics context.

```
void CGContextSetStrokePattern (
   CGContextRef c,
   CGPatternRef pattern,
   const CGFloat components[]
);
```

Parameters

context
The graphics context to modify.

pattern

A pattern for stroking. Quartz retains this object; upon return, you may safely release it.

components

If the specified pattern is an uncolored (or masking) pattern, pass an array of intensity values that specify the color to use when the pattern is painted. The number of array elements must equal the number of components in the base space of the stroke pattern color space, plus an additional component for the alpha value.

If the specified pattern is a colored pattern, pass an alpha value.

Discussion

The current stroke color space must be a pattern color space. Otherwise, the result of calling this function is undefined. If you want to set a stroke color, not a stroke pattern, then call the function `CGContextSetStrokeColorWithColor` (page 126).

Availability

Available in Mac OS X version 10.1 and later.

Declared In

`CGContext.h`

CGContextSetTextDrawingMode

Sets the current text drawing mode.

```
void CGContextSetTextDrawingMode (
   CGContextRef c,
   CGTextDrawingMode mode
);
```

Parameters

context

A graphics context.

mode

A text drawing mode (such as `kCGTextFill` (page 145) or `kCGTextStroke` (page 145)) that specifies how Quartz renders individual glyphs in a graphics context. See "`Text Drawing Modes`" (page 144) for a complete list.

Availability

Available in Mac OS X version 10.0 and later.

Declared In

`CGContext.h`

CGContextSetTextMatrix

Sets the current text matrix.

```
void CGContextSetTextMatrix (
   CGContextRef c,
   CGAffineTransform t
);
```

Parameters

context

A graphics context.

transform

The text matrix to set.

Discussion

The text matrix specifies the transform from text space to user space. To produce the final text rendering matrix that is used to actually draw the text on the page, Quartz concatenates the text matrix with the current transformation matrix and other parameters from the graphics state.

Note that the text matrix is *not* a part of the graphics state—saving or restoring the graphics state has no effect on the text matrix. The text matrix is an attribute of the graphics context, not of the current font.

Availability

Available in Mac OS X version 10.0 and later.

Related Sample Code

HID Calibrator

Declared In

`CGContext.h`

CGContextSetTextPosition

Sets the location at which text is drawn.

```
void CGContextSetTextPosition (
   CGContextRef c,
   CGFloat x,
   CGFloat y
);
```

Parameters

context

A graphics context.

x

A value for the x-coordinate at which to draw the text, in user space coordinates.

y

A value for the y-coordinate at which to draw the text.

Availability

Available in Mac OS X version 10.0 and later.

Declared In

`CGContext.h`

CGContextShowGlyphs

Displays an array of glyphs at the current text position.

```
void CGContextShowGlyphs (
   CGContextRef c,
   const CGGlyph g[],
   size_t count
);
```

Parameters

context

The graphics context in which to display the glyphs.

glyphs

An array of glyphs to display.

count

The total number of glyphs passed in the `g` parameter.

Discussion

This function displays an array of glyphs at the current text position, a point specified by the current text matrix.

See also `CGContextShowGlyphsAtPoint` (page 129), `CGContextShowText` (page 131), `CGContextShowTextAtPoint` (page 132), and `CGContextShowGlyphsWithAdvances` (page 130).

Availability

Available in Mac OS X version 10.0 and later.

Declared In

`CGContext.h`

CGContextShowGlyphsAtPoint

Displays an array of glyphs at a position you specify.

```
void CGContextShowGlyphsAtPoint (
   CGContextRef c,
   CGFloat x,
   CGFloat y,
   const CGGlyph glyphs[],
   size_t count
);
```

Parameters

context

The graphics context in which to display the glyphs.

x

A value for the x-coordinate of the user space at which to display the glyphs.

y

A value for the y-coordinate of the user space at which to display the glyphs.

glyphs

An array of glyphs to display.

count
The total number of glyphs passed in the `glyphs` parameter.

Discussion
This function displays an array of glyphs at the specified position in the text space.

See also `CGContextShowText` (page 131), `CGContextShowGlyphs` (page 129), `CGContextShowGlyphs` (page 129), and `CGContextShowGlyphsWithAdvances` (page 130).

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`CGContext.h`

CGContextShowGlyphsAtPositions

Draws glyphs at the provided position.

```
void CGContextShowGlyphsAtPositions(
    CGContextRef context,
    const CGGlyph glyphs[],
    const CGPoint positions[],
    size_t count
);
```

Parameters
context
The graphics context in which to display the glyphs.

glyphs
An array of Quartz glyphs.

positions
The positions for the glyphs. Each item in this array matches with the glyph at the corresponding index in the `glyphs` array. The position of each glyph is specified in text space, and, as a consequence, is transformed through the text matrix to user space.

count
The number of items in the `glyphs` array.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`CGContext.h`

CGContextShowGlyphsWithAdvances

Draws an array of glyphs with varying offsets.

```
void CGContextShowGlyphsWithAdvances (
   CGContextRef c,
   const CGGlyph glyphs[],
   const CGSize advances[],
   size_t count
);
```

Parameters

context

The graphics context in which to display the glyphs.

glyphs

An array of Quartz glyphs.

advances

An array of offset values associated with each glyph in the array. Each value specifies the offset from the previous glyph's origin to the origin of the corresponding glyph. Offsets are specified in user space.

count

The number of glyphs in the specified array.

Discussion

This function draws an array of glyphs at the current point specified by the text matrix.

See also `CGContextShowText` (page 131), `CGContextShowGlyphs` (page 129), and `CGContextShowGlyphs` (page 129), and `CGContextShowGlyphsAtPoint` (page 129).

Availability

Available in Mac OS X version 10.3 and later.

Declared In

`CGContext.h`

CGContextShowText

Displays a character array at the current text position, a point specified by the current text matrix.

```
void CGContextShowText (
   CGContextRef c,
   const char *string,
   size_t length
);
```

Parameters

context

A graphics context.

string

An array of characters to draw.

length

The length of the array specified in the `bytes` parameter.

Discussion
Quartz uses font data provided by the system to map each byte of the array through the encoding vector of the current font to obtain the glyph to display. Note that the font must have been set using `CGContextSelectFont` (page 106). Don't use `CGContextShowTextAtPoint` in conjunction with `CGContextSetFont` (page 113).

Availability
Available in Mac OS X version 10.0 and later.

See Also
`CGContextShowTextAtPoint` (page 132)
`CGContextShowGlyphs` (page 129)
`CGContextShowGlyphsAtPoint` (page 129)
`CGContextShowGlyphsWithAdvances` (page 130)

Declared In
`CGContext.h`

CGContextShowTextAtPoint

Displays a character string at a position you specify.

```
void CGContextShowTextAtPoint (
   CGContextRef c,
   CGFloat x,
   CGFloat y,
   const char *string,
   size_t length
);
```

Parameters

context
A graphics context .

x
A value for the x-coordinate of the text space at which to display the text.

y
A value for the y-coordinate of the text space at which to display the text.

string
An array of characters to draw.

length
The length of the array specified in the `bytes` parameter.

Discussion
Quartz uses font data provided by the system to map each byte of the array through the encoding vector of the current font to obtain the glyph to display. Note that the font must have been set using `CGContextSelectFont` (page 106). Don't use `CGContextShowTextAtPoint` in conjunction with `CGContextSetFont` (page 113).

Availability
Available in Mac OS X version 10.0 and later.

HID Calibrator

Declared In
CGContext.h

CGContextStrokeEllipseInRect

Strokes an ellipse that fits inside the specified rectangle.

```
void CGContextStrokeEllipseInRect (
   CGContextRef context,
   CGRect rect
);
```

Parameters

context
A graphics context.

rect
A rectangle that defines the area for the ellipse to fit in.

Availability
Available in Mac OS X v10.4 and later.

Declared In
CGContext.h

CGContextStrokeLineSegments

Strokes a sequence of line segments.

```
void CGContextStrokeLineSegments (
   CGContextRef c,
   const CGPoint points[],
   size_t count
);
```

Parameters

c
A graphics context.

points
An array of points, organized as pairs—the starting point of a line segment followed by the ending point of a line segment. For example, the first point in the array specifies the starting position of the first line, the second point specifies the ending position of the first line, the third point specifies the starting position of the second line, and so forth.

count

The number of points in the `points` array.

Discussion
This function is equivalent to the following code:

```
CGContextBeginPath (context);
for (k = 0; k < count; k += 2) {
    CGContextMoveToPoint(context, s[k].x, s[k].y);
    CGContextAddLineToPoint(context, s[k+1].x, s[k+1].y);
}
CGContextStrokePath(context);
```

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGContext.h`

CGContextStrokePath

Paints a line along the current path.

```
void CGContextStrokePath (
   CGContextRef c
);
```

Parameters

context

A graphics context.

Discussion
Quartz uses the line width and stroke color of the graphics state to paint the path. As a side effect when you call this function, Quartz clears the current path.

Availability
Available in Mac OS X version 10.0 and later.

CGContextStrokeRect

Paints a rectangular path.

```
void CGContextStrokeRect (
   CGContextRef c,
   CGRect rect
);
```

Parameters

context

A graphics context .

rect

A rectangle, specified in user space coordinates.

Discussion
Quartz uses the line width and stroke color of the graphics state to paint the path.

Availability
Available in Mac OS X version 10.0 and later.

See Also
`CGContextStrokeRectWithWidth` (page 135)

Related Sample Code
CarbonSketch
HID Calibrator
HID Config Save

Declared In
`CGContext.h`

CGContextStrokeRectWithWidth

Paints a rectangular path, using the specified line width.

```
void CGContextStrokeRectWithWidth (
   CGContextRef c,
   CGRect rect,
   CGFloat width
);
```

Parameters

context

A graphics context.

rect

A rectangle, in user space coordinates.

width

A value, in user space units, that is greater than zero. This value does not affect the line width values in the current graphics state.

Discussion
Aside from the line width value, Quartz uses the current attributes of the graphics state (such as stroke color) to paint the line. The line straddles the path, with half of the total width on either side. As a side effect when you call this function, Quartz clears the current path.

Availability
Available in Mac OS X version 10.0 and later.

See Also
CGContextStrokeRect (page 134)

Declared In
CGContext.h

CGContextSynchronize

Marks a window context for update.

```
void CGContextSynchronize (
   CGContextRef c
);
```

Parameters

context

The window context to synchronize. If you pass a PDF context or a bitmap context, this function does nothing.

Discussion
When you call this function, all drawing operations since the last update are flushed at the next regular opportunity. Under normal conditions, you do not need to call this function.

Availability
Available in Mac OS X version 10.0 and later.

Related Sample Code
CarbonSketch

Declared In
CGContext.h

CGContextTranslateCTM

Changes the origin of the user coordinate system in a context.

```
void CGContextTranslateCTM (
   CGContextRef c,
   CGFloat tx,
   CGFloat ty
);
```

Parameters

context

A graphics context.

tx

The amount to displace the x-axis of the coordinate space, in units of the user space, of the specified context.

ty

The amount to displace the y-axis of the coordinate space, in units of the user space, of the specified context.

Availability
Available in Mac OS X version 10.0 and later.

Related Sample Code
CarbonSketch

`CGContext.h`

Constants

Blend Modes

Compositing operations for images.

```
enum CGBlendMode {
    kCGBlendModeNormal,
    kCGBlendModeMultiply,
    kCGBlendModeScreen,
    kCGBlendModeOverlay,
    kCGBlendModeDarken,
    kCGBlendModeLighten,
    kCGBlendModeColorDodge,
    kCGBlendModeColorBurn,
    kCGBlendModeSoftLight,
    kCGBlendModeHardLight,
    kCGBlendModeDifference,
    kCGBlendModeExclusion,
    kCGBlendModeHue,
    kCGBlendModeSaturation,
    kCGBlendModeColor,
    kCGBlendModeLuminosity,
    kCGBlendModeClear,
    kCGBlendModeCopy,
    kCGBlendModeSourceIn,
    kCGBlendModeSourceOut,
    kCGBlendModeSourceAtop,
    kCGBlendModeDestinationOver,
    kCGBlendModeDestinationIn,
    kCGBlendModeDestinationOut,
    kCGBlendModeDestinationAtop,
    kCGBlendModeXOR,
    kCGBlendModePlusDarker,
    kCGBlendModePlusLighter
};
typedef enum CGBlendMode CGBlendMode;
```

Constants

`kCGBlendModeNormal`

Paints the source image samples over the background image samples.

Available in Mac OS X v10.4 and later.

Declared in `CGContext.h`.

`kCGBlendModeMultiply`

Multiplies the source image samples with the background image samples. This results in colors that are at least as dark as either of the two contributing sample colors.

Available in Mac OS X v10.4 and later.

Declared in `CGContext.h`.

`kCGBlendModeScreen`

Multiplies the inverse of the source image samples with the inverse of the background image samples. This results in colors that are at least as light as either of the two contributing sample colors.

Available in Mac OS X v10.4 and later.

Declared in `CGContext.h`.

`kCGBlendModeOverlay`
: Either multiplies or screens the source image samples with the background image samples, depending on the background color. The result is to overlay the existing image samples while preserving the highlights and shadows of the background. The background color mixes with the source image to reflect the lightness or darkness of the background.

  Available in Mac OS X v10.4 and later.

  Declared in `CGContext.h`.

`kCGBlendModeDarken`
: Creates the composite image samples by choosing the darker samples (either from the source image or the background). The result is that the background image samples are replaced by any source image samples that are darker. Otherwise, the background image samples are left unchanged.

  Available in Mac OS X v10.4 and later.

  Declared in `CGContext.h`.

`kCGBlendModeLighten`
: Creates the composite image samples by choosing the lighter samples (either from the source image or the background). The result is that the background image samples are replaced by any source image samples that are lighter. Otherwise, the background image samples are left unchanged.

  Available in Mac OS X v10.4 and later.

  Declared in `CGContext.h`.

`kCGBlendModeColorDodge`
: Brightens the background image samples to reflect the source image samples. Source image sample values that specify black do not produce a change.

  Available in Mac OS X v10.4 and later.

  Declared in `CGContext.h`.

`kCGBlendModeColorBurn`
: Darkens the background image samples to reflect the source image samples. Source image sample values that specify white do not produce a change.

  Available in Mac OS X v10.4 and later.

  Declared in `CGContext.h`.

`kCGBlendModeSoftLight`
: Either darkens or lightens colors, depending on the source image sample color. If the source image sample color is lighter than 50% gray, the background is lightened, similar to dodging. If the source image sample color is darker than 50% gray, the background is darkened, similar to burning. If the source image sample color is equal to 50% gray, the background is not changed. Image samples that are equal to pure black or pure white produce darker or lighter areas, but do not result in pure black or white. The overall effect is similar to what you'd achieve by shining a diffuse spotlight on the source image. Use this to add highlights to a scene.

  Available in Mac OS X v10.4 and later.

  Declared in `CGContext.h`.

`kCGBlendModeHardLight`
: Either multiplies or screens colors, depending on the source image sample color. If the source image sample color is lighter than 50% gray, the background is lightened, similar to screening. If the source image sample color is darker than 50% gray, the background is darkened, similar to multiplying. If the source image sample color is equal to 50% gray, the source image is not changed. Image samples that are equal to pure black or pure white result in pure black or white. The overall effect is similar to what you'd achieve by shining a harsh spotlight on the source image. Use this to add highlights to a scene.

  Available in Mac OS X v10.4 and later.

  Declared in `CGContext.h`.

`kCGBlendModeDifference`
: Subtracts either the source image sample color from the background image sample color, or the reverse, depending on which sample has the greater brightness value. Source image sample values that are black produce no change; white inverts the background color values.

  Available in Mac OS X v10.4 and later.

  Declared in `CGContext.h`.

`kCGBlendModeExclusion`
: Produces an effect similar to that produced by `kCGBlendModeDifference`, but with lower contrast. Source image sample values that are black don't produce a change; white inverts the background color values.

  Available in Mac OS X v10.4 and later.

  Declared in `CGContext.h`.

`kCGBlendModeHue`
: Uses the luminance and saturation values of the background with the hue of the source image.

  Available in Mac OS X v10.4 and later.

  Declared in `CGContext.h`.

`kCGBlendModeSaturation`
: Uses the luminance and hue values of the background with the saturation of the source image. Areas of the background that have no saturation (that is, pure gray areas) don't produce a change.

  Available in Mac OS X v10.4 and later.

  Declared in `CGContext.h`.

`kCGBlendModeColor`
: Uses the luminance values of the background with the hue and saturation values of the source image. This mode preserves the gray levels in the image. You can use this mode to color monochrome images or to tint color images.

  Available in Mac OS X v10.4 and later.

  Declared in `CGContext.h`.

`kCGBlendModeLuminosity`
: Uses the hue and saturation of the background with the luminance of the source image. This mode creates an effect that is inverse to the effect created by `kCGBlendModeColor`.

  Available in Mac OS X v10.4 and later.

  Declared in `CGContext.h`.

`kCGBlendModeClear`
`R = 0`

Available in Mac OS X v10.5 and later.

Declared in `CGContext.h`.

`kCGBlendModeCopy`
`R = S`

Available in Mac OS X v10.5 and later.

Declared in `CGContext.h`.

`kCGBlendModeSourceIn`
`R = S*Da`

Available in Mac OS X v10.5 and later.

Declared in `CGContext.h`.

`kCGBlendModeSourceOut`
`R = S*(1 - Da)`

Available in Mac OS X v10.5 and later.

Declared in `CGContext.h`.

`kCGBlendModeSourceAtop`
`R = S*Da + D*(1 - Sa)`

Available in Mac OS X v10.5 and later.

Declared in `CGContext.h`.

`kCGBlendModeDestinationOver`
`R = S*(1 - Da) + D`

Available in Mac OS X v10.5 and later.

Declared in `CGContext.h`.

`kCGBlendModeDestinationIn`
`R = D*Sa`

Available in Mac OS X v10.5 and later.

Declared in `CGContext.h`.

`kCGBlendModeDestinationOut`
`R = D*(1 - Sa)`

Available in Mac OS X v10.5 and later.

Declared in `CGContext.h`.

`kCGBlendModeDestinationAtop`
`R = S*(1 - Da) + D*Sa`

Available in Mac OS X v10.5 and later.

Declared in `CGContext.h`.

`kCGBlendModeXOR`
`R = S*(1 - Da) + D*(1 - Sa)`. This XOR mode is only nominally related to the classical bitmap XOR operation, which is not supported by Quartz 2D.

Available in Mac OS X v10.5 and later.

Declared in `CGContext.h`.

`kCGBlendModePlusDarker`
`R = MAX(0, (1 - D) + (1 - S))`

Available in Mac OS X v10.5 and later.

Declared in `CGContext.h`.

`kCGBlendModePlusLighter`
`R = MIN(1, S + D)`

Available in Mac OS X v10.5 and later.

Declared in `CGContext.h`.

Discussion
The blend mode constants introduced in Mac OS X v10.5 represent the Porter-Duff blend modes. The symbols in the equations for these blend modes are:

- R is the premultiplied result
- S is the source color, and includes alpha
- D is the destination color, and includes alpha
- Ra, Sa, and Da are the alpha components of R, S, and D

You can find more information on blend modes, including examples of images produced using them, and many mathematical descriptions of the modes, in *PDF Reference, Fourth Edition*, Version 1.5, Adobe Systems, Inc. If you are a former QuickDraw developer, it may be helpful for you to think of blend modes as an alternative to transfer modes

For examples of using blend modes see "Setting Blend Modes" and "Using Blend Modes With Images" in *Quartz 2D Programming Guide*.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGContext.h`

Interpolation Qualities

Levels of interpolation quality for rendering an image.

```
enum CGInterpolationQuality {
    kCGInterpolationDefault,
    kCGInterpolationNone,
    kCGInterpolationLow,
    kCGInterpolationHigh
};
typedef enum CGInterpolationQuality CGInterpolationQuality;
```

Constants
`kCGInterpolationDefault`

The default level of quality.

Available in Mac OS X v10.1 and later.

Declared in `CGContext.h`.

`kCGInterpolationNone`
No interpolation.

Available in Mac OS X v10.1 and later.

Declared in `CGContext.h`.

`kCGInterpolationLow`
A low level of interpolation quality. This setting may speed up image rendering.

Available in Mac OS X v10.1 and later.

Declared in `CGContext.h`.

`kCGInterpolationHigh`
A high level of interpolation quality. This setting may slow down image rendering.

Available in Mac OS X v10.1 and later.

Declared in `CGContext.h`.

Discussion
You use the function `CGContextSetInterpolationQuality` (page 116) to set the interpolation quality in a graphics context.

Declared In
`CGContext.h`

Line Cap Styles

Styles for rendering the endpoint of a stroked line.

```
enum CGLineCap {
    kCGLineCapButt,
    kCGLineCapRound,
    kCGLineCapSquare
};
typedef enum CGLineCap CGLineCap;
```

Constants
`kCGLineCapButt`
A line with a squared-off end. Quartz draws the line to extend only to the exact endpoint of the path. This is the default.

Available in Mac OS X v10.0 and later.

Declared in `CGContext.h`.

`kCGLineCapRound`
A line with a rounded end. Quartz draws the line to extend beyond the endpoint of the path. The line ends with a semicircular arc with a radius of 1/2 the line's width, centered on the endpoint.

Available in Mac OS X v10.0 and later.

Declared in `CGContext.h`.

`kCGLineCapSquare`
A line with a squared-off end. Quartz extends the line beyond the endpoint of the path for a distance equal to half the line width.

Available in Mac OS X v10.0 and later.

Declared in `CGContext.h`.

Discussion
A line cap specifies the method used by `CGContextStrokePath` (page 134) to draw the endpoint of the line. To change the line cap style in a graphics context, you use the function `CGContextSetLineCap` (page 116).

Declared In
`CGContext.h`

Line Joins

Junction types for stroked lines.

```
enum CGLineJoin {
    kCGLineJoinMiter,
    kCGLineJoinRound,
    kCGLineJoinBevel
};
typedef enum CGLineJoin CGLineJoin;
```

Constants

`kCGLineJoinMiter`
A join with a sharp (angled) corner. Quartz draws the outer sides of the lines beyond the endpoint of the path, until they meet. If the length of the miter divided by the line width is greater than the miter limit, a bevel join is used instead. This is the default. To set the miter limit, see `CGContextSetMiterLimit` (page 119)

Available in Mac OS X v10.0 and later.

Declared in `CGContext.h`.

`kCGLineJoinRound`
A join with a rounded end. Quartz draws the line to extend beyond the endpoint of the path. The line ends with a semicircular arc with a radius of 1/2 the line's width, centered on the endpoint.

Available in Mac OS X v10.0 and later.

Declared in `CGContext.h`.

`kCGLineJoinBevel`
A join with a squared-off end. Quartz draws the line to extend beyond the endpoint of the path, for a distance of 1/2 the line's width.

Available in Mac OS X v10.0 and later.

Declared in `CGContext.h`.

Discussion
A line join specifies how `CGContextStrokePath` (page 134) draws the junction between connected line segments. To set the line join style in a graphics context, you use the function `CGContextSetLineJoin` (page 118).

Declared In
`CGContext.h`

Text Drawing Modes

Modes for rendering text.

```
enum CGTextDrawingMode {
    kCGTextFill,
    kCGTextStroke,
    kCGTextFillStroke,
    kCGTextInvisible,
    kCGTextFillClip,
    kCGTextStrokeClip,
    kCGTextFillStrokeClip,
    kCGTextClip
};
typedef enum CGTextDrawingMode CGTextDrawingMode;
```

Constants

`kCGTextFill`
Perform a fill operation on the text.
Available in Mac OS X v10.0 and later.
Declared in `CGContext.h`.

`kCGTextStroke`
Perform a stroke operation on the text.
Available in Mac OS X v10.0 and later.
Declared in `CGContext.h`.

`kCGTextFillStroke`
Perform fill, then stroke operations on the text.
Available in Mac OS X v10.0 and later.
Declared in `CGContext.h`.

`kCGTextInvisible`
Do not draw the text, but do update the text position.
Available in Mac OS X v10.0 and later.
Declared in `CGContext.h`.

`kCGTextFillClip`
Perform a fill operation, then intersect the text with the current clipping path.
Available in Mac OS X v10.0 and later.
Declared in `CGContext.h`.

`kCGTextStrokeClip`
Perform a stroke operation, then intersect the text with the current clipping path.
Available in Mac OS X v10.0 and later.
Declared in `CGContext.h`.

`kCGTextFillStrokeClip`
Perform fill then stroke operations, then intersect the text with the current clipping path.
Available in Mac OS X v10.0 and later.
Declared in `CGContext.h`.

`kCGTextClip`
Specifies to intersect the text with the current clipping path. This mode does not paint the text.
Available in Mac OS X v10.0 and later.
Declared in `CGContext.h`.

Discussion
You provide a text drawing mode constant to the function `CGContextSetTextDrawingMode` (page 127) to set the current text drawing mode for a graphics context. Text drawing modes determine how Quartz renders individual glyphs onscreen. For example, you can set a text drawing mode to draw text filled in or outlined (stroked) or both. You can also create special effects with the text clipping drawing modes, such as clipping an image to a glyph shape.

Declared In
`CGContext.h`

Text Encodings

Text encodings for fonts.

```
enum CGTextEncoding {
    kCGEncodingFontSpecific,
    kCGEncodingMacRoman
};
typedef enum CGTextEncoding CGTextEncoding;
```

Constants

`kCGEncodingFontSpecific`
The built-in encoding of the font.

Available in Mac OS X v10.0 and later.

Declared in `CGContext.h`.

`kCGEncodingMacRoman`
The MacRoman encoding. MacRoman is an ASCII variant originally created for use in the Mac OS, in which characters 127 and lower are ASCII, and characters 128 and higher are non-English characters and symbols.

Available in Mac OS X v10.0 and later.

Declared in `CGContext.h`.

Discussion
For more information on setting the font in a graphics context, see `CGContextSelectFont` (page 106).

Declared In
`CGContext.h`

CGDataConsumer Reference

Derived From:	CFType
Framework:	ApplicationServices/ApplicationServices.h
Declared in	CGDataConsumer.h
Companion guide	Quartz 2D Programming Guide

Overview

The `CGDataConsumerRef` opaque type abstracts the data-writing task and eliminates the need for applications to manage data through a raw memory buffer. You can use data consumer objects to write image or PDF data and all, except for `CGDataConsumerCreateWithCFData` (page 148), are available in Mac OS X v10.0 or later.

If your application runs in Mac OS X v10.4 or later, you should use CGImageDestination objects rather than data consumers. See *CGImageDestination Reference*.

Functions by Task

Creating Data Consumers

`CGDataConsumerCreate` (page 148)
Creates a data consumer that uses callback functions to write data.

`CGDataConsumerCreateWithURL` (page 149)
Creates a data consumer that writes data to a location specified by a URL.

`CGDataConsumerCreateWithCFData` (page 148)
Creates a data consumer that writes to a CFData object.

Getting the CFType ID

`CGDataConsumerGetTypeID` (page 149)
Returns the Core Foundation type identifier for Quartz data consumers.

Retaining and Releasing Data Consumers

`CGDataConsumerRelease` (page 150)
Decrements the retain count of a data consumer.

`CGDataConsumerRetain` (page 150)
Increments the retain count of a data consumer.

Functions

CGDataConsumerCreate

Creates a data consumer that uses callback functions to write data.

```
CGDataConsumerRef CGDataConsumerCreate (
   void *info,
   const CGDataConsumerCallbacks *callbacks
);
```

Parameters

info
A pointer to data of any type or `NULL`. When Quartz calls the functions specified in the `callbacks` parameter, it passes this pointer as the `info` parameter.

callbacks
A pointer to a `CGDataConsumerCallbacks` structure that specifies the callback functions you implement to copy data sent to the consumer and to handle the consumer's basic memory management. For a complete description, see `CGDataConsumerCallbacks` (page 152).

Return Value
A new data consumer object. You are responsible for releasing this object using `CGDataConsumerRelease` (page 150).

Availability
Available in Mac OS X version 10.0 and later.

Related Sample Code
CarbonSketch

Declared In
`CGDataConsumer.h`

CGDataConsumerCreateWithCFData

Creates a data consumer that writes to a CFData object.

```
CGDataConsumerRef CGDataConsumerCreateWithCFData (
   CFMutableDataRef data
);
```

Parameters

data

The CFData object to write to.

Return Value

A new data consumer object. You are responsible for releasing this object using `CGDataConsumerRelease` (page 150).

Discussion

You can use this function when you need to represent Quartz data as a CFData type. For example, you might create a CFData object that you then copy to the pasteboard.

Availability

Available in Mac OS X v10.4 and later.

Declared In

`CGDataConsumer.h`

CGDataConsumerCreateWithURL

Creates a data consumer that writes data to a location specified by a URL.

```
CGDataConsumerRef CGDataConsumerCreateWithURL (
   CFURLRef url
);
```

Parameters

url

A CFURL object that specifies the data destination.

Return Value

A new data consumer object. You are responsible for releasing this object using `CGDataConsumerRelease` (page 150).

Availability

Available in Mac OS X version 10.0 and later.

Declared In

`CGDataConsumer.h`

CGDataConsumerGetTypeID

Returns the Core Foundation type identifier for Quartz data consumers.

```
CFTypeID CGDataConsumerGetTypeID (
   void
);
```

Return Value

The Core Foundation identifier for the opaque type `CGDataConsumerRef` (page 153).

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CGDataConsumer.h`

CGDataConsumerRelease

Decrements the retain count of a data consumer.

```
void CGDataConsumerRelease (
   CGDataConsumerRef consumer
);
```

Parameters

consumer
The data consumer to release.

Discussion
This function is equivalent to `CFRelease`, except that it does not cause an error if the `consumer` parameter is `NULL`.

Availability
Available in Mac OS X version 10.0 and later.

Related Sample Code
CarbonSketch

Declared In
`CGDataConsumer.h`

CGDataConsumerRetain

Increments the retain count of a data consumer.

```
CGDataConsumerRef CGDataConsumerRetain (
   CGDataConsumerRef consumer
);
```

Parameters

consumer
The data consumer to retain.

Return Value
The same data consumer you passed in as the `consumer` parameter.

Discussion
This function is equivalent to `CFRetain`, except that it does not cause an error if the `consumer` parameter is `NULL`.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`CGDataConsumer.h`

Callbacks

CGDataConsumerPutBytesCallback

Copies data from a Quartz-supplied buffer into a data consumer.

```
size_t (*CGDataConsumerPutBytesCallback) (
    void *info,
    const void *buffer,
    size_t count
);
```

If you name your function `MyConsumerPutBytes`, you would declare it like this:

```
size_t MyConsumerPutBytes (
    void *info,
    const void *buffer,
    size_t count
);
```

Parameters

info
: A generic pointer to private data shared among your callback functions. This is the pointer supplied to `CGDataConsumerCreate` (page 148).

buffer
: The Quartz-supplied buffer from which you copy the specified number of bytes.

count
: The number of bytes to copy.

Return Value
The number of bytes copied. If no more data can be written to the consumer, you should return `0`.

Discussion
When Quartz is ready to send data to the consumer, your function is called. It should copy the specified number of bytes from `buffer` into some resource under your control—for example, a file.

For information on how to associate your callback function with a data consumer, see `CGDataConsumerCreate` (page 148) and `CGDataConsumerCallbacks` (page 152).

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGDataConsumer.h`

CGDataConsumerReleaseInfoCallback

Releases any private data or resources associated with the data consumer.

```
void (*CGDataConsumerReleaseInfoCallback) (
    void *info
);
```

If you name your function `MyConsumerReleaseInfo`, you would declare it like this:

```
void MyConsumerReleaseInfo (
    void *info
);
```

Parameters

info

A generic pointer to private data shared among your callback functions. This is the same pointer you supplied to `CGDataConsumerCreate` (page 148).

Discussion

When Quartz frees a data consumer that has an associated release function, the release function is called.

For information on how to associate your callback function with a data consumer, see `CGDataConsumerCreate` (page 148) and `CGDataConsumerCallbacks` (page 152).

Availability

Available in Mac OS X v10.4 and later.

Declared In

`CGDataConsumer.h`

Data Types

CGDataConsumerCallbacks

A structure that contains pointers to callback functions that manage the copying of data for a data consumer.

```
struct CGDataConsumerCallbacks {
 CGDataConsumerPutBytesCallback putBytes;
 CGDataConsumerReleaseInfoCallback releaseConsumer;
};
typedef struct CGDataConsumerCallbacks CGDataConsumerCallbacks;
```

Fields

`putBytes`

A pointer to a function that copies data to the data consumer. For more information, see `CGDataConsumerPutBytesCallback` (page 151).

`releaseConsumer`

A pointer to a function that handles clean-up for the data consumer, or `NULL`. For more information, see `CGDataConsumerReleaseInfoCallback` (page 152)

Discussion
The functions specified by the `CGDataConsumerCallbacks` structure are responsible for copying data that Quartz sends to your consumer and for handling the consumer's basic memory management. You supply a `CGDataConsumerCallbacks` structure to the function `CGDataConsumerCreate` (page 148) to create a data consumer.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGDataConsumer.h`

CGDataConsumerRef

An opaque type that handles the storage of data supplied by Quartz functions.

```
typedef struct CGDataConsumer *CGDataConsumerRef;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGDataConsumer.h`

CGDataProvider Reference

Derived From:	*CFType Reference*
Framework:	ApplicationServices/ApplicationServices.h
Declared in	CGDataProvider.h

Overview

The CGDataProvider header file declares a data type that supplies Quartz functions with data. Data provider objects abstract the data-access task and eliminate the need for applications to manage data through a raw memory buffer.

For information on how to use CGDataProvider functions, see *Quartz 2D Programming Guide* Programming Guide.

See also *CGDataConsumer Reference*.

Functions

CGDataProviderCopyData

Returns a copy of the provider's data.

```
CFDataRef CGDataProviderCopyData(
   CGDataProviderRef provider
);
```

Parameters

provider

The data provider whose data you want to copy.

Return Value

A new data object containing a copy of the provider's data. You are responsible for releasing this object.

Availability

Available in Mac OS X v10.5 and later.

Declared In

CGDataProvider.h

CGDataProviderCreate

Creates a Quartz sequential-access data provider. (Deprecated in Mac OS X v10.5.)

```
CGDataProviderRef CGDataProviderCreate (
   void *info,
   const CGDataProviderCallbacks *callbacks
);
```

Parameters

info

A pointer to data of any type or `NULL`. When Quartz calls the functions specified in the `callbacks` parameter, it sends each of the functions this data.

callbacks

A pointer to a `CGDataProviderCallbacks` structure that specifies the callback functions you implement to handle the data provider's basic memory management. For a complete description, see `CGDataProviderCallbacks` (page 170).

Return Value

A new data provider. You are responsible for releasing this object using `CGDataProviderRelease` (page 161).

Discussion

You use this function to create a sequential-access data provider that uses callback functions to read data from your program in a stream.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Declared In

`CGDataProvider.h`

CGDataProviderCreateDirect

Creates a Quartz direct-access data provider.

```
CGDataProviderRef CGDataProviderCreateDirect (
   void *info,
   off_t size,
   const CGDataProviderDirectCallbacks *callbacks
);
```

Parameters

info

A pointer to data of any type or `NULL`. When Quartz calls the functions specified in the `callbacks` parameter, it sends each of the functions this pointer.

size

The number of bytes of data to provide.

callbacks

A pointer to a `CGDataProviderDirectCallbacks` structure that specifies the callback functions you implement to handle the data provider's basic memory management.

Return Value
A new data provider. You are responsible for releasing this object using `CGDataProviderRelease` (page 161).

Discussion
You use this function to create a direct-access data provider that uses callback functions to read data from your program in a single block.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`CGDataProvider.h`

CGDataProviderCreateDirectAccess

Creates a Quartz direct-access data provider. (Deprecated in Mac OS X v10.5.)

```
CGDataProviderRef CGDataProviderCreateDirectAccess (
   void *info,
   size_t size,
   const CGDataProviderDirectAccessCallbacks *callbacks
);
```

Parameters

info
A pointer to data of any type or `NULL`. When Quartz calls the functions specified in the `callbacks` parameter, it sends each of the functions this pointer.

size
A value that specifies the number of bytes that the data provider contains.

callbacks
A pointer to a `CGDataProviderDirectAccessCallbacks` structure that specifies the callback functions you implement to handle the data provider's basic memory management. For a complete description, see `CGDataProviderDirectAccessCallbacks` (page 171).

Return Value
A new data provider. You are responsible for releasing this object using `CGDataProviderRelease` (page 161).

Discussion
You use this function to create a direct-access data provider that uses callback functions to read data from your program in a single block.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In
`CGDataProvider.h`

CGDataProviderCreateSequential

Creates a Quartz sequential-access data provider.

```
CGDataProviderRef CGDataProviderCreateSequential (
   void *info,
   const CGDataProviderSequentialCallbacks *callbacks
);
```

Parameters

info

A pointer to data of any type or `NULL`. When Quartz calls the functions specified in the `callbacks` parameter, it sends each of the functions this pointer.

callbacks

A pointer to a `CGDataProviderSequentialCallbacks` structure that specifies the callback functions you implement to handle the data provider's basic memory management.

Return Value

A new data provider. You are responsible for releasing this object using `CGDataProviderRelease` (page 161).

Discussion

You use this function to create a sequential-access data provider that uses callback functions to read data from your program in a single block.

Availability

Available in Mac OS X v10.5 and later.

Declared In

`CGDataProvider.h`

CGDataProviderCreateWithCFData

Creates a Quartz data provider that reads from a CFData object.

```
CGDataProviderRef CGDataProviderCreateWithCFData (
   CFDataRef data
);
```

Parameters

data

The CFData object to read from.

Return Value

A new data provider. You are responsible for releasing this object using `CGDataProviderRelease` (page 161).

Discussion

You can use this function when you need to represent Quartz data as a CFData type. For example, you might create a CFData object when reading data from the pasteboard.

Availability

Available in Mac OS X v10.4 and later.

Declared In

`CGDataProvider.h`

CGDataProviderCreateWithData

Creates a Quartz direct-access data provider that uses data your program supplies.

```
CGDataProviderRef CGDataProviderCreateWithData (
   void *info,
   const void *data,
   size_t size,
   CGDataProviderReleaseDataCallback releaseData
);
```

Parameters

info

A pointer to data of any type, or `NULL`. When Quartz calls the function specified in the `releaseData` parameter, Quartz sends it this pointer as its first argument.

data

A pointer to the array of data that the provider contains.

size

A value that specifies the number of bytes that the data provider contains.

releaseData

A pointer to a release callback for the data provider, or `NULL`. Your release function is called when Quartz frees the data provider. For more information, see `CGDataProviderReleaseDataCallback` (page 166).

Return Value

A new data provider. You are responsible for releasing this object using `CGDataProviderRelease` (page 161).

Discussion

You use this function to create a direct-access data provider that uses callback functions to read data from your program an entire block at one time.

Availability

Available in Mac OS X v10.0 and later.

Related Sample Code

CarbonSketch

Declared In

`CGDataProvider.h`

CGDataProviderCreateWithFilename

Creates a Quartz direct-access data provider that uses a file to supply data.

```
CGDataProviderRef CGDataProviderCreateWithFilename(
   const char *filename
);
```

Parameters

filename

The full or relative pathname to use for the data provider. When you supply Quartz data via the provider, it reads the data from the specified file.

Return Value
A new data provider or `NULL` if the file could not be opened. You are responsible for releasing this object using `CGDataProviderRelease` (page 161).

Discussion
You use this function to create a direct-access data provider that supplies data from a file. When you supply Quartz with a direct-access data provider, Quartz obtains data from your program in a single block.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGDataProvider.h`

CGDataProviderCreateWithURL

Creates a Quartz direct-access data provider that uses a URL to supply data.

```
CGDataProviderRef CGDataProviderCreateWithURL (
   CFURLRef url
);
```

Parameters

url

A CFURL object to use for the data provider. When you supply Quartz data via the provider, it reads the data from the URL address.

Return Value
A new data provider or `NULL` if the data from the URL could not be accessed. You are responsible for releasing this object using `CGDataProviderRelease` (page 161).

Discussion
You use this function to create a direct-access data provider that supplies data from a URL. When you supply Quartz with a direct-access data provider, Quartz obtains data from your program in a single entire block.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGDataProvider.h`

CGDataProviderGetTypeID

Returns the Core Foundation type identifier for Quartz data providers.

```
CFTypeID CGDataProviderGetTypeID (
   void
);
```

Return Value
The identifier for the opaque type `CGDataProviderRef` (page 170).

Availability
Available in Mac OS X v10.2 and later.

Declared In
CGDataProvider.h

CGDataProviderRelease

Decrements the retain count of a data provider.

```
void CGDataProviderRelease (
   CGDataProviderRef provider
);
```

Parameters

provider
The data provider to release.

Discussion
This function is equivalent to `CFRelease`, except that it does not cause an error if the `provider` parameter is `NULL`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
CGDataProvider.h

CGDataProviderRetain

Increments the retain count of a data provider.

```
CGDataProviderRef CGDataProviderRetain (
   CGDataProviderRef provider
);
```

Parameters

provider
The data provider to retain.

Return Value
The same data provider you passed in as the `provider` parameter.

Discussion
This function is equivalent to `CFRetain`, except that it does not cause an error if the `provider` parameter is `NULL`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
CGDataProvider.h

Callbacks by Task

Sequential-Access Data Provider Callbacks

`CGDataProviderGetBytesCallback` (page 165)
A callback function that copies from a provider data stream into a Quartz-supplied buffer.

`CGDataProviderReleaseInfoCallback` (page 167)
A callback function that releases any private data or resources associated with the data provider.

`CGDataProviderRewindCallback` (page 168)
A callback function that moves the current position in the data stream back to the beginning.

`CGDataProviderSkipBytesCallback` (page 168)
A callback function that advances the current position in the data stream supplied by the provider.

`CGDataProviderSkipForwardCallback` (page 169)
A callback function that advances the current position in the data stream supplied by the provider.

Direct-Access Data Provider Callbacks

`CGDataProviderGetBytePointerCallback` (page 162)
A callback function that returns a generic pointer to the provider data.

`CGDataProviderGetBytesAtOffsetCallback` (page 163)
A callback function that copies data from the provider into a Quartz buffer.

`CGDataProviderReleaseBytePointerCallback` (page 166)
A callback function that releases the pointer Quartz obtained by calling `CGDataProviderGetBytePointerCallback` (page 162).

`CGDataProviderReleaseDataCallback` (page 166)
A callback function that releases data you supply to the function `CGDataProviderCreateWithData` (page 159).

`CGDataProviderGetBytesAtPositionCallback` (page 164)
A callback function that copies data from the provider into a Quartz buffer.

Callbacks

CGDataProviderGetBytePointerCallback

A callback function that returns a generic pointer to the provider data.

```
const void * (*CGDataProviderGetBytePointerCallback) (
   void *info
);
```

If you name your function `MyProviderGetBytePointer`, you would declare it like this:

```
void *MyProviderGetBytePointer (
```

```
    void *info
);
```

Parameters

info

A generic pointer to private data shared among your callback functions. This is the same pointer you supplied to `CGDataProviderCreateDirectAccess` (page 157).

Return Value

A generic pointer to your provider data. By suppling this pointer, you are giving Quartz read-only access to both the pointer and the underlying provider data. You must not move or modify the provider data until Quartz calls your `CGDataProviderReleaseBytePointerCallback` (page 166) function.

Discussion

When Quartz needs direct access to your provider data, this function is called.

For information on how to associate your function with a direct-access data provider, see `CGDataProviderCreateDirectAccess` (page 157) and `CGDataProviderDirectAccessCallbacks` (page 171).

Availability

Available in Mac OS X v10.3 and later.

Declared In

`CGDataProvider.h`

CGDataProviderGetBytesAtOffsetCallback

A callback function that copies data from the provider into a Quartz buffer.

```
typedef size_t (*CGDataProviderGetBytesAtOffsetCallback) (
    void *info,
    void *buffer,
    size_t offset,
    size_t count
);
```

If you name your function `MyProviderGetBytesWithOffset`, you would declare it like this:

```
size_t MyProviderGetBytesWithOffset (
    void *info,
    void *buffer,
    size_t offset,
    size_t count
);
```

Parameters

info

A generic pointer to private data shared among your callback functions. This is the same pointer you supplied to `CGDataProviderCreateDirectAccess` (page 157).

buffer

The Quartz-supplied buffer into which you copy the specified number of bytes.

offset
Specifies the relative location in the data provider at which to begin copying data.

count
The number of bytes to copy.

Return Value
The number of bytes copied. If no more data can be written to the buffer, you should return 0.

Discussion
When Quartz is ready to receive data from the provider, your function is called.

For information on how to associate your function with a direct-access data provider, see `CGDataProviderCreateDirectAccess` (page 157) and `CGDataProviderDirectAccessCallbacks` (page 171).

Availability
Available in Mac OS X v10.3 and later.

Declared In
`CGDataProvider.h`

CGDataProviderGetBytesAtPositionCallback

A callback function that copies data from the provider into a Quartz buffer.

```
typedef size_t (*CGDataProviderGetBytesAtPositionCallback) (
    void *info,
    void *buffer,
    off_t position,
    size_t count
);
```

If you name your function `MyProviderGetBytesAtPosition`, you would declare it like this:

```
size_t MyProviderGetBytesAtPosition (
    void *info,
    void *buffer,
    off_t position,
    size_t count
);
```

Parameters

info
A generic pointer to private data shared among your callback functions. This is the same pointer you supplied to `CGDataProviderCreateDirect` (page 156).

buffer
The Quartz-supplied buffer into which you copy the specified number of bytes.

position
Specifies the relative location in the data provider at which to begin copying data.

count
The number of bytes to copy.

Return Value
The number of bytes copied. If no more data can be written to the buffer, you should return 0.

Discussion
When Quartz is ready to receive data from the provider, your function is called.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`CGDataProvider.h`

CGDataProviderGetBytesCallback

A callback function that copies from a provider data stream into a Quartz-supplied buffer.

```
size_t (*CGDataProviderGetBytesCallback) (
    void *info,
    void *buffer,
    size_t count
);
```

If you name your function `MyProviderGetBytes`, you would declare it like this:

```
size_t MyProviderGetBytes (
    void *info,
    void *buffer,
    size_t count
);
```

Parameters

info
A generic pointer to private data shared among your callback functions. This is the same pointer you supplied to `CGDataProviderCreate` (page 156).

buffer
The Quartz-supplied buffer into which you copy the specified number of bytes.

count
The number of bytes to copy.

Return Value
The number of bytes copied. If no more data can be written to the buffer, you should return `0`.

Discussion
When Quartz is ready to receive data from the provider data stream, your function is called. It should copy the specified number of bytes into `buffer`.

For information on how to associate your callback function with a data provider, see `CGDataProviderCreate` (page 156) and `CGDataProviderCallbacks` (page 170).

Availability
Available in Mac OS X v10.3 and later.

Declared In
CGDataProvider.h

CGDataProviderReleaseBytePointerCallback

A callback function that releases the pointer Quartz obtained by calling CGDataProviderGetBytePointerCallback (page 162).

```
typedef void (*CGDataProviderReleaseBytePointerCallback) (
    void *info,
    const void *pointer
);
```

If you name your function MyProviderReleaseBytePointer, you would declare it like this:

```
void MyProviderReleaseBytePointer (
    void *info,
    const void *pointer
);
```

Parameters

info

A generic pointer to private data shared among your callback functions. This is the same pointer you supplied to CGDataProviderCreateDirectAccess (page 157).

pointer

A pointer to your provider data. This is the same pointer you returned in CGDataProviderGetBytePointerCallback (page 162).

Discussion
When Quartz no longer needs direct access to your provider data, your function is called. You may safely modify, move, or release your provider data at this time.

For information on how to associate your function with a direct-access data provider, see CGDataProviderCreateDirectAccess (page 157) and CGDataProviderDirectAccessCallbacks (page 171).

Availability
Available in Mac OS X v10.3 and later.

Declared In
CGDataProvider.h

CGDataProviderReleaseDataCallback

A callback function that releases data you supply to the function CGDataProviderCreateWithData (page 159).

```
typedef void (*CGDataProviderReleaseDataCallback) (
    void *info,
    const void *data
    size_t size
);
```

If you name your function `MyProviderReleaseData`, you would declare it like this:

```
void MyProviderReleaseData (
    void *info,
    const void *data
    size_t size
);
```

Parameters

info

A generic pointer to private data shared among your callback functions. This is the same pointer you supplied to `CGDataProviderCreateWithData` (page 159).

data

A pointer to your provider data.

size

The size of the data.

Discussion

When Quartz no longer needs direct access to your provider data, your function is called. You may safely modify, move, or release your provider data at this time.

Availability

Available in Mac OS X v10.5 and later.

Declared In

`CGDataProvider.h`

CGDataProviderReleaseInfoCallback

A callback function that releases any private data or resources associated with the data provider.

```
void (*CGDataProviderReleaseInfoCallback) (
    void *info
);
```

If you name your function `MyProviderReleaseInfo`, you would declare it like this:

```
void MyProviderReleaseInfo (
    void *info
);
```

Parameters

info

A generic pointer to private information shared among your callback functions. This is the same pointer you supplied to `CGDataProviderCreate` (page 156).

Discussion

When Quartz frees a data provider that has an associated release function, the release function is called.

For information on how to associate your callback function with a data provider, see `CGDataProviderCreate` (page 156) and `CGDataProviderCallbacks` (page 170).

Availability

Available in Mac OS X v10.3 and later.

Declared In

`CGDataProvider.h`

CGDataProviderRewindCallback

A callback function that moves the current position in the data stream back to the beginning.

```
void (*CGDataProviderRewindCallback) (
    void *info
);
```

If you name your function `MyProviderRewind`, you would declare it like this:

```
void MyProviderRewind (
    void *info
);
```

Parameters

info

A generic pointer to private data shared among your callback functions. This is the same pointer you supplied to `CGDataProviderCreate` (page 156).

Discussion

When Quartz needs to read from the beginning of the provider's data stream, your function is called.

For information on how to associate your callback function with a data provider, see `CGDataProviderCreate` (page 156) and `CGDataProviderCallbacks` (page 170).

Availability

Available in Mac OS X v10.3 and later.

Declared In

`CGDataProvider.h`

CGDataProviderSkipBytesCallback

A callback function that advances the current position in the data stream supplied by the provider.

```
void (*CGDataProviderSkipBytesCallback) (
    void *info,
    size_t count
);
```

If you name your function `MyProviderSkipBytes`, you would declare it like this:

```
void MyProviderSkipBytes (
    void *info,
    size_t count
);
```

Parameters

info

A generic pointer to private data shared among your callback functions. This is the same pointer you supplied to `CGDataProviderCreate` (page 156).

count

The number of bytes to skip.

Discussion

When Quartz needs to advance forward in the provider's data stream, your function is called.

For information on how to associate your callback function with a data provider, see `CGDataProviderCreate` (page 156) and `CGDataProviderCallbacks` (page 170).

Availability

Available in Mac OS X v10.3 and later.

Declared In

`CGDataProvider.h`

CGDataProviderSkipForwardCallback

A callback function that advances the current position in the data stream supplied by the provider.

```
off_t (*CGDataProviderSkipForwardCallback) (
    void *info,
    off_t count
);
```

If you name your function `MyProviderSkipForwardBytes`, you would declare it like this:

```
off_t MyProviderSkipForwardBytes (
    void *info,
    off_t count
);
```

Parameters

info

A generic pointer to private data shared among your callback functions. This is the same pointer you supplied to `CGDataProviderCreate` (page 156).

count
The number of bytes to skip.

Return Value
The number of bytes that were actually skipped.

Discussion
When Quartz needs to advance forward in the provider's data stream, your function is called.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`CGDataProvider.h`

Data Types

CGDataProviderRef

Defines an opaque type that supplies Quartz with data.

```
typedef struct CGDataProvider *CGDataProviderRef;
```

Discussion
Some Quartz routines supply blocks of data to your program. Rather than reading through a raw memory buffer, data provider objects of type `CGDataProviderRef` allow you to supply Quartz functions with data.

In Mac OS X version 10.2 and later, `CGDataProviderRef` is derived from `CFTypeRef` and inherits the properties that all Core Foundation types have in common. For more information, see *CFType Reference*.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGDataProvider.h`

CGDataProviderCallbacks

Defines a structure containing pointers to client-defined callback functions that manage the sending of data for a sequential-access data provider.

```
struct CGDataProviderCallbacks {
    CGDataProviderGetBytesCallback getBytes;
    CGDataProviderSkipBytesCallback skipBytes;
    CGDataProviderRewindCallback rewind;
    CGDataProviderReleaseInfoCallback releaseProvider;
};
typedef struct CGDataProviderCallbacks CGDataProviderCallbacks;
```

Fields

`getBytes`

A pointer to a function that copies data from the provider. For more information, see `CGDataProviderGetBytesCallback` (page 165).

`skipBytes`

A pointer to a function that Quartz calls to advance the stream of data supplied by the provider. For more information, see `CGDataProviderSkipBytesCallback` (page 168).

`rewind`

A pointer to a function Quartz calls to return the provider to the beginning of the data stream. For more information, see `CGDataProviderRewindCallback` (page 168).

`releaseProvider`

A pointer to a function that handles clean-up for the data provider, or `NULL`. For more information, see `CGDataProviderReleaseInfoCallback` (page 167).

Discussion

The functions specified by the `CGDataProviderCallbacks` structure are responsible for sequentially copying data to a memory buffer for Quartz to use. The functions are also responsible for handling the data provider's basic memory management. You supply a `CGDataProviderCallbacks` structure to the function `CGDataProviderCreate` (page 156) to create a sequential-access data provider.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CGDataProvider.h`

CGDataProviderDirectAccessCallbacks

Defines pointers to client-defined callback functions that manage the sending of data for a direct-access data provider.

```
struct CGDataProviderDirectAccessCallbacks {
    CGDataProviderGetBytePointerCallback getBytePointer;
    CGDataProviderReleaseBytePointerCallback releaseBytePointer;
    CGDataProviderGetBytesAtOffsetCallback getBytes;
    CGDataProviderReleaseInfoCallback releaseProvider;
};
typedef struct CGDataProviderDirectAccessCallbacks
CGDataProviderDirectAccessCallbacks;
```

Fields

`getBytePointer`

A pointer to a function that returns a pointer to the provider's data. For more information, see `CGDataProviderGetBytePointerCallback` (page 162).

releaseBytePointer
: A pointer to a function that Quartz calls to release a pointer to the provider's data. For more information, see CGDataProviderReleaseBytePointerCallback (page 166).

getBytes
: A pointer to a function that copies data from the provider. For more information, see CGDataProviderGetBytesAtOffsetCallback (page 163).

releaseProvider
: A pointer to a function that handles clean-up for the data provider, or NULL. For more information, see CGDataProviderReleaseInfoCallback (page 167).

Discussion

You supply a CGDataProviderDirectAccessCallbacks structure to the function CGDataProviderCreateDirectAccess (page 157) to create a data provider for direct access. The functions specified by the CGDataProviderDirectAccessCallbacks structure are responsible for copying data a block at a time to a memory buffer for Quartz to use. The functions are also responsible for handling the data provider's basic memory management. For the callback to work, one of the getBytePointer and getBytes parameters must be non-NULL. If both are non-NULL, then getBytePointer is used to access the data.

Availability

Available in Mac OS X v10.0 and later.

Declared In

CGDataProvider.h

CGDataProviderDirectCallbacks

Defines pointers to client-defined callback functions that manage the sending of data for a direct-access data provider.

```
struct CGDataProviderDirectCallbacks {
     unsigned int version;
    CGDataProviderGetBytePointerCallback getBytePointer;
    CGDataProviderReleaseBytePointerCallback releaseBytePointer;
    CGDataProviderGetBytesAtPositionCallback getBytesAtPosition;
    CGDataProviderReleaseInfoCallback releaseInfo;
};
typedef struct CGDataProviderDirectCallbacks  CGDataProviderDirectCallbacks;
```

Fields

version
: The version of this structure. It should be set to 0.

getBytePointer
: A pointer to a function that returns a pointer to the provider's data. For more information, see CGDataProviderGetBytePointerCallback (page 162).

releaseBytePointer
: A pointer to a function that Quartz calls to release a pointer to the provider's data. For more information, see CGDataProviderReleaseBytePointerCallback (page 166).

getBytesAtPosition
: A pointer to a function that copies data from the provider.

releaseInfo
A pointer to a function that handles clean-up for the data provider, or NULL. For more information, see CGDataProviderReleaseInfoCallback (page 167).

Discussion
You supply a CGDataProviderDirectCallbacks structure to the function CGDataProviderCreateDirect (page 156) to create a data provider for direct access. The functions specified by the CGDataProviderDirectCallbacks structure are responsible for copying data a block at a time to a memory buffer for Quartz to use. The functions are also responsible for handling the data provider's basic memory management. For the callback to work, one of the getBytePointer and getBytesAtPosition parameters must be non-NULL. If both are non-NULL, then getBytePointer is used to access the data.

Availability
Available in Mac OS X v10.5 and later.

Declared In
CGDataProvider.h

CGDataProviderSequentialCallbacks

Defines a structure containing pointers to client-defined callback functions that manage the sending of data for a sequential-access data provider.

```
struct CGDataProviderSequentialCallbacks {
    unsigned int version;
    CGDataProviderGetBytesCallback getBytes;
    CGDataProviderSkipForwardCallback skipForward;
    CGDataProviderRewindCallback rewind;
    CGDataProviderReleaseInfoCallback releaseInfo;
};
typedef struct CGDataProviderSequentialCallbacks CGDataProviderSequentialCallbacks;
```

Fields
version
The version of this structure. It should be set to 0.

getBytes
A pointer to a function that copies data from the provider. For more information, see CGDataProviderGetBytesCallback (page 165).

skipForward
A pointer to a function that Quartz calls to advance the stream of data supplied by the provider.

rewind
A pointer to a function Quartz calls to return the provider to the beginning of the data stream. For more information, see CGDataProviderRewindCallback (page 168).

releaseInfo
A pointer to a function that handles clean-up for the data provider, or NULL. For more information, see CGDataProviderReleaseInfoCallback (page 167).

Discussion
The functions specified by the CGDataProviderSequentialCallbacks structure are responsible for sequentially copying data to a memory buffer for Quartz to use. The functions are also responsible for handling the data provider's basic memory management. You supply a CGDataProviderCallbacks structure to the function CGDataProviderCreateSequential (page 157) to create a sequential-access data provider.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`CGDataProvider.h`

CGFont Reference

Derived From:	CFType
Framework:	ApplicationServices/ApplicationServices.h
Declared in	CGFont.h
Companion guide	Quartz 2D Programming Guide

Overview

The `CGFontRef` opaque type encapsulates font information. A font is a set of shapes or glyphs associated with a character set. A glyph can represent a single character (such as 'b'), more than one character (such as the "fi" ligature), or a special character such as a space. Quartz retrieves the glyphs for the font from ATS (Apple Type Services) and paints the glyphs based on the relevant parameters of the current graphics state.

Quartz provides a limited, low-level interface for drawing text. For information on text-drawing functions, see *CGContext Reference*. For full Unicode and text-layout support, use the services provided by Core Text or ATSUI).

Functions by Task

Retaining and Releasing a CGFont Object

`CGFontRelease` (page 190)
Decrements the retain count of a Quartz font.

`CGFontRetain` (page 191)
Increments the retain count of a Quartz font.

Creating a CGFont Object

`CGFontCreateWithDataProvider` (page 182)
Creates a font object from data supplied from a data provider.

`CGFontCreateWithFontName` (page 183)
Creates a font object corresponding to the font specified by a PostScript or full name.

`CGFontCreateCopyWithVariations` (page 181)
Creates a copy of a font using a variation specification dictionary.

`CGFontCreateWithPlatformFont` (page 183)
Creates a font object from an Apple Type Services (ATS) font.

Working With PostScript Fonts

`CGFontCopyPostScriptName` (page 178)
Obtains the PostScript name of a font.

`CGFontCanCreatePostScriptSubset` (page 177)
Determines whether Quartz can create a subset of the font in PostScript format.

`CGFontCreatePostScriptSubset` (page 182)
Creates a subset of the font in the specified PostScript format.

`CGFontCreatePostScriptEncoding` (page 181)
Creates a PostScript encoding of a font.

Working With Font Tables

`CGFontCopyTableTags` (page 179)
Returns an array of tags that correspond to the font tables for a font.

`CGFontCopyTableForTag` (page 179)
Returns the font table that corresponds to the provided tag.

Getting Font Information

`CGFontGetTypeID` (page 189)
Returns the Core Foundation type identifier for Quartz fonts.

`CGFontCopyVariationAxes` (page 180)
Returns an array of the variation axis dictionaries for a font.

`CGFontCopyVariations` (page 180)
Returns the variation specification dictionary for a font.

`CGFontCopyFullName` (page 177)
Returns the full name associated with a font object.

`CGFontGetAscent` (page 184)
Returns the ascent of a font.

`CGFontGetDescent` (page 185)
Returns the descent of a font.

`CGFontGetLeading` (page 188)
Returns the leading of a font.

`CGFontGetCapHeight` (page 184)
Returns the cap height of a font.

`CGFontGetXHeight` (page 190)
Returns the x-height of a font.

`CGFontGetFontBBox` (page 185)
Returns the bounding box of a font.

`CGFontGetItalicAngle` (page 188)
Returns the italic angle of a font.

`CGFontGetStemV` (page 189)
Returns the thickness of the dominant vertical stems of glyphs in a font.

`CGFontGetGlyphBBoxes` (page 187)
Get the bounding box of each glyph in an array.

`CGFontGetGlyphWithGlyphName` (page 187)
Returns the glyph for the font name associated with the specified font object.

`CGFontCopyGlyphNameForGlyph` (page 178)
Returns the glyph name associated with a font object.

`CGFontGetNumberOfGlyphs` (page 188)
Returns the number of glyphs in a font.

`CGFontGetGlyphAdvances` (page 186)
Gets the bound box of each glyph in the provided array.

`CGFontGetUnitsPerEm` (page 190) Deprecated in Mac OS X v10.5
Returns the number of glyph space units per em for the provided font.

Functions

CGFontCanCreatePostScriptSubset

Determines whether Quartz can create a subset of the font in PostScript format.

```
bool CGFontCanCreatePostScriptSubset (
   CGFontRef font,
   CGFontPostScriptFormat format
);
```

Parameters

font
A font object.

Return Value

Returns `true` if a subset in the PostScript format can be created for the font; `false` otherwise.

Discussion

For more information on PostScript format, see *Adobe Type 1 Font Format*, which is available from http://partners.adobe.com/.

Availability

Available in Mac OS X v10.4 and later.

Declared In

`CGFont.h`

CGFontCopyFullName

Returns the full name associated with a font object.

```
CFStringRef CGFontCopyFullName (
    CGFontRef font
);
```

Parameters

font

A font object.

Return Value
The full name associated with the font.

Availability
Available in Mac OS X version 10.5 and later.

Declared In
CGFont.h

CGFontCopyGlyphNameForGlyph

Returns the glyph name associated with a font object.

```
CFStringRef CGFontCopyGlyphNameForGlyph (
    CGFontRef font
);
```

Parameters

font

A font object.

Return Value
A glyph name, or `NULL` if there isn't a glyph associated with the font object.

Availability
Available in Mac OS X version 10.5 and later.

Declared In
CGFont.h

CGFontCopyPostScriptName

Obtains the PostScript name of a font.

```
CFStringRef CGFontCopyPostScriptName (
   CGFontRef font
);
```

Parameters

font

A font object.

Return Value
The PostScript name of the font.

Discussion

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGFont.h`

CGFontCopyTableForTag

Returns the font table that corresponds to the provided tag.

```
CFDataRef CGFontCopyTableForTag(
    CGFontRef font,
    uint32_t tag
);
```

Parameters

font
A font object.

tag
The tag for the table you want to obtain.

Return Value
The font table that corresponds to the tag, or `NULL` if no such table exists.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`CGFont.h`

CGFontCopyTableTags

Returns an array of tags that correspond to the font tables for a font.

```
CFArrayRef CGFontCopyTableTags(
    CGFontRef font
);
```

Parameters

font
A CGFont object.

Return Value
An array of font table tags.

Discussion
Each entry in the returned array is a four-byte value that represents a single TrueType or OpenType font table tag. To obtain a tag at index `k` in a manner that is appropriate for 32-bit and 64-bit architectures, you need to use code similar to the following:

```
tag = (uint32_t)(uintptr_t)CFArrayGetValue(table, k);
```

Availability
Available in Mac OS X v10.5 and later.

Declared In
`CGFont.h`

CGFontCopyVariationAxes

Returns an array of the variation axis dictionaries for a font.

```
CFArrayRef CGFontCopyVariationAxes (
   CGFontRef font
);
```

Parameters

font
A CGFont object.

Return Value
An array of the variation axis dictionaries. Returns `NULL` if the font doesn't support variations.

Discussion
A variation axis is a range included in a font by the font designer that allows a font to produce different type styles. Each variation axis dictionary contains key-value pairs that specify the variation axis name and the minimum, maximum, and default values for that variation axis.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGFont.h`

CGFontCopyVariations

Returns the variation specification dictionary for a font.

```
CFDictionaryRef CGFontCopyVariations (
   CGFontRef font
);
```

Parameters

font
A font object.

Return Value
The variation specification dictionary for the font. Returns `NULL` if the font doesn't support variations.

Discussion
The variation specification dictionary contains keys that correspond to the variation axis names of the font. Each key is a variation axis name. The value for each key is the value specified for that particular variation axis represented as a CFNumber object.

Availability
Available in Mac OS X v10.4 and later.

Declared In
CGFont.h

CGFontCreateCopyWithVariations

Creates a copy of a font using a variation specification dictionary.

```
CGFontRef CGFontCreateCopyWithVariations (
   CGFontRef font,
   CFDictionaryRef variations
);
```

Parameters

font

The Quartz font to copy.

variations

A variation specification dictionary that contains keys corresponding to the variation axis names of the font. Each key in the dictionary is a variation axis name. The value for each key is the value specified for that particular variation axis represented as a CFNumber object. If a variation axis name is not specified in `variations`, then the current value from `font` is used.

Return Value
The font object.

Availability
Available in Mac OS X v10.4 and later.

Declared In
CGFont.h

CGFontCreatePostScriptEncoding

Creates a PostScript encoding of a font.

```
CFDataRef CGFontCreatePostScriptEncoding (
   CGFontRef font,
   const CGGlyph encoding[256]
);
```

Parameters

font

A CGFont object.

encoding

The encoding to use.

Return Value
A PostScript encoding of the font that contains glyphs in the specified encoding.

Discussion
For more information on PostScript format, see *Adobe Type 1 Font Format*, which is available from http://partners.adobe.com/.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGFont.h`

CGFontCreatePostScriptSubset

Creates a subset of the font in the specified PostScript format.

```
CFDataRef CGFontCreatePostScriptSubset (
   CGFontRef font,
   CFStringRef subsetName,
   CGFontPostScriptFormat format,
   const CGGlyph glyphs[],
   size_t count,
   const CGGlyph encoding[256]
);
```

Parameters

font
A font object.

subsetName
The name of the subset.

format
The PostScript format of the font.

glyphs
An array that contains the glyphs in the subset.

count
The number of glyphs specified by the `glyphs` array.

encoding
The default encoding for the subset. You can pass `NULL` if you do not want to specify an encoding.

Return Value
A subset of the font created from the supplied parameters.

Discussion
For more information on PostScript format, see *Adobe Type 1 Font Format*, which is available from http://partners.adobe.com/.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGFont.h`

CGFontCreateWithDataProvider

Creates a font object from data supplied from a data provider.

```
CGFontRef CGFontCreateWithDataProvider (
    CGDataProviderRef provider
);
```

Parameters

provider

A data provider.

Return Value

The font object or `NULL` if the font can't be created. You are responsible for releasing this object using `CGFontRelease` (page 190).

Discussion

Before drawing text in a Quartz context, you must set the font in the current graphics state by calling the function `CGContextSetFontSize` (page 114).

Availability

Available in Mac OS X version 10.5 and later.

Declared In

`CGFont.h`

CGFontCreateWithFontName

Creates a font object corresponding to the font specified by a PostScript or full name.

```
CGFontRef CGFontCreateWithFontName (
    CFStringRef name
);
```

Parameters

name

The PostScript or full name of a font.

Return Value

The font object or `NULL` if the font can't be created. You are responsible for releasing this object using `CGFontRelease` (page 190).

Discussion

Before drawing text in a Quartz context, you must set the font in the current graphics state by calling the function `CGContextSetFont` (page 113).

Availability

Available in Mac OS X version 10.5 and later.

Declared In

`CGFont.h`

CGFontCreateWithPlatformFont

Creates a font object from an Apple Type Services (ATS) font.

```
CGFontRef CGFontCreateWithPlatformFont (
   void *platformFontReference
);
```

Parameters

platformFontReference

A generic pointer to a font object. The font should be of a type appropriate to the platform on which your program is running. For Mac OS X, you should pass a pointer to an ATS font.

Return Value

The font object, or `NULL` if the platform font could not be located. You are responsible for releasing this object using `CGFontRelease` (page 190).

Discussion

Before drawing text in a Quartz context, you must set the font in the current graphics state. For ATS Fonts, call this function to create a Quartz font, and pass it to `CGContextSetFont` (page 113).

Availability

Available in Mac OS X version 10.0 and later.

Declared In

`CGFont.h`

CGFontGetAscent

Returns the ascent of a font.

```
int CGFontGetAscent (
    CGFontRef font
);
```

Parameters

font

A font object.

Return Value

The ascent of the font.

Discussion

The ascent is the maximum distance above the baseline of glyphs in a font. The value is specified in glyph space units.

Availability

Available in Mac OS X version 10.5 and later.

Declared In

`CGFont.h`

CGFontGetCapHeight

Returns the cap height of a font.

```
int CGFontGetCapHeight (
    CGFontRef font
);
```

Parameters

font

A font object.

Return Value
The cap height of the font.

Discussion
The cap height is the distance above the baseline of the top of flat capital letters of glyphs in a font. The value is specified in glyph space units.

Availability
Available in Mac OS X version 10.5 and later.

Declared In
`CGFont.h`

CGFontGetDescent

Returns the descent of a font.

```
int CGFontGetDescent (
    CGFontRef font
);
```

Parameters

font

A font object.

Return Value
The descent of the font .

Discussion
The descent is the maximum distance below the baseline of glyphs in a font. The value is specified in glyph space units.

Availability
Available in Mac OS X version 10.5 and later.

Declared In
`CGFont.h`

CGFontGetFontBBox

Returns the bounding box of a font.

```
CGRect CGFontGetFontBBox (
    CGFontRef font
);
```

Parameters

font

A font object.

Return Value
The bounding box of the font.

Discussion
The font bounding box is the union of all of the bounding boxes for all the glyphs in a font. The value is specified in glyph space units.

Availability
Available in Mac OS X version 10.5 and later.

Declared In
`CGFont.h`

CGFontGetGlyphAdvances

Gets the bound box of each glyph in the provided array.

```
bool CGFontGetGlyphAdvances (
    CGFontRef font,
    const CGGlyph glyphs[],
    size_t count,
    int advances[]
);
```

Parameters

font

The font object associated with the provided glyphs.

glyphs

An array of glyphs.

count

The number of glyphs in the array.

advances

On output, an array of of advances for the provided glyphs.

Return Value
`TRUE` unless the advances can't be provided for some reason.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`CGFont.h`

CGFontGetGlyphBBoxes

Get the bounding box of each glyph in an array.

```
bool CGFontGetGlyphBBoxes (
    CGFontRef font,
    const CGGlyph glyphs[],
    size_t count,
    CGRect bboxes[]
);
```

Parameters

font

A font object.

glyphs

A array of glyphs.

count

The number of items in the `glyphs` array.

bboxes

On return, the bounding boxes for each glyph.

Return Value

`false` if bounding boxes can't be retrieved for any reason; `true` otherwise.

Availability

Available in Mac OS X version 10.5 and later.

Declared In

`CGFont.h`

CGFontGetGlyphWithGlyphName

Returns the glyph for the font name associated with the specified font object.

```
CGGlyph CGFontGetGlyphWithGlyphName (
    CGFontRef font
);
```

Parameters

font

A font object.

Return Value

A glyph, or `0` if there isn't a name associated with the font object.

Availability

Available in Mac OS X version 10.5 and later.

Declared In

`CGFont.h`

CGFontGetItalicAngle

Returns the italic angle of a font.

```
CGFloat CGFontGetItalicAngle (
    CGFontRef font
);
```

Parameters

font

A font object.

Return Value

The italic angle of the font, measured in degrees counter-clockwise from the vertical.

Availability

Available in Mac OS X version 10.5 and later.

Declared In

CGFont.h

CGFontGetLeading

Returns the leading of a font.

```
int CGFontGetLeading (
    CGFontRef font
);
```

Parameters

font

A font object.

Return Value

The leading of the font.

Discussion

The leading is the spacing between consecutive lines of text in a font. The value is specified in glyph space units.

Availability

Available in Mac OS X version 10.5 and later.

Declared In

CGFont.h

CGFontGetNumberOfGlyphs

Returns the number of glyphs in a font.

```
size_t CGFontGetNumberOfGlyphs (
    CGFontRef font
);
```

Parameters

font

A `CGFont` object.

Return Value
The number of glyphs in the provided font.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`CGFont.h`

CGFontGetStemV

Returns the thickness of the dominant vertical stems of glyphs in a font.

```
CGFloat CGFontGetItalicAngle (
    CGFontRef font
);
```

Parameters

font

A font object.

Return Value
The thickness of the dominant vertical stems of glyphs in a font.

Availability
Available in Mac OS X version 10.5 and later.

Declared In
`CGFont.h`

CGFontGetTypeID

Returns the Core Foundation type identifier for Quartz fonts.

```
CFTypeID CGFontGetTypeID (
   void
);
```

Return Value
The Core Foundation identifier for the opaque type `CGFontRef` (page 191).

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CGFont.h`

CGFontGetUnitsPerEm

Returns the number of glyph space units per em for the provided font.

```
int CGFontGetUnitsPerEm (
    CGFontRef font
);
```

Parameters

font

A `CGFont` object.

Return Value
The number of glyph space units per em for the provided font.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`CGFont.h`

CGFontGetXHeight

Returns the x-height of a font.

```
int CGFontGetXHeight (
    CGFontRef font
);
```

Parameters

font

A font object.

Return Value
The x-height of the font.

Discussion
The x-height is the distance above the baseline of the top of flat, non-ascending lowercase letters (such as `x`) of glyphs in a font. The value is specified in glyph space units.

Availability
Available in Mac OS X version 10.5 and later.

Declared In
`CGFont.h`

CGFontRelease

Decrements the retain count of a Quartz font.

```
void CGFontRelease (
   CGFontRef font
);
```

Parameters

font

The Quartz font to release.

Discussion

This function is equivalent to `CFRelease`, except that it does not cause an error if the `font` parameter is `NULL`.

Availability

Available in Mac OS X version 10.0 and later.

Declared In

`CGFont.h`

CGFontRetain

Increments the retain count of a Quartz font.

```
CGFontRef CGFontRetain (
   CGFontRef font
);
```

Parameters

font

The Quartz font to retain.

Return Value

The same font you specified in the `font` parameter.

Discussion

This function is equivalent to `CFRetain`, except that it does not cause an error if the `font` parameter is `NULL`.

Availability

Available in Mac OS X version 10.0 and later.

Declared In

`CGFont.h`

Data Types

CGFontRef

An opaque type that encapsulates font information.

```
typedef struct CGFont *CGFontRef;
```

Availability

Available in Mac OS X v10.0 and later.

Declared In
`CGFont.h`

CGFontIndex

An index into a font table.

```
typedef unsigned short CGFontIndex;
```

Discussion
This integer type provides an additional way to specify a glyph identifier. `CGFontIndex` is equivalent to `CGGlyph` (page 192), and you can use constants of either type interchangeably.

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CGFont.h`

CGGlyph

An index into the internal glyph table of a font.

```
typedef unsigned short CGGlyph;
```

Discussion
When drawing text, you typically specify a sequence of characters. However, Quartz also allows you to use `CGGlyph` values to specify glyphs. In either case, Quartz renders the text using font data provided by the Apple Type Services (ATS) framework.

You provide `CGGlyph` values to the functions `CGContextShowGlyphs` (page 129) and `CGContextShowGlyphsAtPoint` (page 129). These functions display an array of glyphs at the current text position or at a position you specify, respectively.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGFont.h`

Constants

CGFontPostScriptFormat

Possible formats for a PostScript font subset.

```
enum CGFontPostScriptFormat {
    kCGFontPostScriptFormatType1 = 1,
    kCGFontPostScriptFormatType3 = 3,
    kCGFontPostScriptFormatType42 = 42
};
typedef enum CGFontPostScriptFormat CGFontPostScriptFormat;
```

Constants

`kCGFontPostScriptFormatType1`

This is documented in *Adobe Type 1 Font Format*, which is available from http://partners.adobe.com/.

Available in Mac OS X v10.4 and later.

Declared in `CGFont.h`.

`kCGFontPostScriptFormatType3`

This is documented in *PostScript Language Reference, 3rd edition*, which is available from http://partners.adobe.com/.

Available in Mac OS X v10.4 and later.

Declared in `CGFont.h`.

`kCGFontPostScriptFormatType42`

This is documented in *Adobe Technical Note 5012, The Type 42 Font Format Specification*, which is available from http://partners.adobe.com/.

Available in Mac OS X v10.4 and later.

Declared in `CGFont.h`.

Availability

Available in Mac OS X v10.4 and later.

Declared In

`CGFont.h`

Font Table Index Values

Possible values for an index into a font table.

```
enum {
    kCGFontIndexMax = ((1 << 16) - 2),
    kCGFontIndexInvalid = ((1 << 16) - 1),
    kCGGlyphMax = kCGFontIndexMax
};
```

Constants

`kCGFontIndexMax`

The maximum allowed value for `CGFontIndex` (page 192).

Available in Mac OS X v10.1 and later.

Declared in `CGFont.h`.

`kCGFontIndexInvalid`

An invalid font index (a value which never represents a valid glyph).

Available in Mac OS X v10.1 and later.

Declared in `CGFont.h`.

`kCGGlyphMax`
The same as `kCGFontIndexMax`.

Available in Mac OS X v10.1 and later.

Declared in `CGFont.h`.

Discussion
See `CGFontIndex` (page 192).

Declared In
`CGFont.h`

Font Variation Axis Keys

Keys used for a font variation axis dictionary.

```
const CFStringRef kCGFontVariationAxisName
const CFStringRef kCGFontVariationAxisMinValue
const CFStringRef kCGFontVariationAxisMaxValue
const CFStringRef kCGFontVariationAxisDefaultValue
```

Constants
`kCGFontVariationAxisName`
The key used to obtain the variation axis name from a variation axis dictionary. The value obtained with this key is a `CFStringRef` that specifies the name of the variation axis.

Available in Mac OS X v10.4 and later.

Declared in `CGFont.h`.

`kCGFontVariationAxisMinValue`
The key used to obtain the minimum variation axis value from a variation axis dictionary. The value obtained with this key is a `CFNumberRef` that specifies the minimum value of the variation axis.

Available in Mac OS X v10.4 and later.

Declared in `CGFont.h`.

`kCGFontVariationAxisMaxValue`
The key used to obtain the maximum variation axis value from a variation axis dictionary. The value obtained with this key is a `CFNumberRef` that specifies the maximum value of the variation axis.

Available in Mac OS X v10.4 and later.

Declared in `CGFont.h`.

`kCGFontVariationAxisDefaultValue`
The key used to obtain the default variation axis value from a variation axis dictionary. The value obtained with this key is a `CFNumberRef` that specifies the default value of the variation axis.

Available in Mac OS X v10.4 and later.

Declared in `CGFont.h`.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGFont.h`

CGFunction Reference

Derived From:	CFType
Framework:	ApplicationServices/ApplicationServices.h
Declared in	CGFunction.h
Companion guide	Quartz 2D Programming Guide

Overview

The `CGFunctionRef` opaque type provides a general facility for defining and using callback functions. These functions can take an arbitrary number of floating-point input values and pass back an arbitrary number of floating-point output values.

Quartz uses CGFunction objects to implement shadings. *CGShading Reference* describes the parameters and semantics required for the callbacks used by CGFunction objects.

Functions by Task

Creating a CGFunction Object

`CGFunctionCreate` (page 196)
Creates a Quartz function.

Retaining and Releasing CGFunction Objects

`CGFunctionRelease` (page 197)
Decrements the retain count of a function object.

`CGFunctionRetain` (page 197)
Increments the retain count of a function object.

Getting the CFType ID

`CGFunctionGetTypeID` (page 197)
Returns the type identifier for Quartz function objects.

Functions

CGFunctionCreate

Creates a Quartz function.

```
CGFunctionRef CGFunctionCreate (
   void *info,
   size_t domainDimension,
   const CGFloat *domain,
   size_t rangeDimension,
   const CGFloat *range,
   const CGFunctionCallbacks *callbacks
);
```

Parameters

info

A pointer to user-defined storage for data that you want to pass to your callbacks. You need to make sure that the data persists for as long as it's needed, which can be beyond the scope in which the Quartz function is used.

domainDimension

The number of inputs.

domain

An array of (`2*domainDimension`) floats used to specify the valid intervals of input values. For each `k` from `0` to `(domainDimension - 1)`, `domain[2*k]` must be less than or equal to `domain[2*k+1]`, and the `k`th input value will be clipped to lie in the interval `domain[2*k] ≤ input[k] ≤ domain[2*k+1]`. If this parameter is `NULL`, then the input values are not clipped.

rangeDimension

The number of outputs.

range

An array of `(2*rangeDimension)` floats that specifies the valid intervals of output values. For each `k` from `0` to `(rangeDimension - 1)`, `range[2*k]` must be less than or equal to `range[2*k+1]`, and the `k`th output value will be clipped to lie in the interval `range[2*k] ≤ output[k] ≤ range[2*k+1]`. If this parameter is `NULL`, then the output values are not clipped.

callbacks

A pointer to a callback function table. This table should contain pointers to the callbacks you provide to implement the semantics of this Quartz function. Quartz makes a copy of your table, so, for example, you could safely pass in a pointer to a structure on the stack.

Return Value

The new Quartz function. You are responsible for releasing this object using `CGFunctionRelease` (page 197).

Availability

Available in Mac OS X version 10.2 and later.

Declared In

`CGFunction.h`

CGFunctionGetTypeID

Returns the type identifier for Quartz function objects.

```
CFTypeID CGFunctionGetTypeID (
    void
);
```

Return Value
The identifier for the opaque type `CGFunctionRef` (page 199).

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CGFunction.h`

CGFunctionRelease

Decrements the retain count of a function object.

```
void CGFunctionRelease (
   CGFunctionRef function
);
```

Parameters

`function`
The function object to release.

Discussion
This function is equivalent to `CFRelease`, except that it does not cause an error if the `function` parameter is `NULL`.

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CGFunction.h`

CGFunctionRetain

Increments the retain count of a function object.

```
CGFunctionRef CGFunctionRetain (
   CGFunctionRef function
);
```

Parameters

`function`
The same function object you passed in as the `function` parameter.

Return Value

Discussion
This function is equivalent to `CFRetain`, except that it does not cause an error if the `function` parameter is `NULL`.

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CGFunction.h`

Callbacks

CGFunctionEvaluateCallback

Performs custom operations on the supplied input data to produce output data.

```
typedef void (*CGFunctionEvaluateCallback) (
    void *info,
    const float *inData,
    float *outData
);
```

If you name your function `MyCGFunctionEvaluate`, you would declare it like this:

```
void MyCGFunctionEvaluate (
    void *info,
    const float *inData,
    float *outData
);
```

Parameters

info

The `info` parameter passed to `CGFunctionCreate` (page 196).

inData

An array of floats. The size of the array is that specified by the `domainDimension` parameter passed to the `CGFunctionCreate` (page 196) function.

outData

An array of floats. The size of the array is that specified by the `rangeDimension` parameter passed to the `CGFunctionCreate` (page 196) function.

Discussion
The callback you write is responsible for implementing the calculation of output values from the supplied input values. For example, if you want to implement a simple "squaring" function of one input argument to one output argument, your evaluation function might be:

```
void evaluateSquare(void *info, const float *inData, float *outData)
{
    outData[0] = inData[0] * inData[0];
}
```

Availability
Available in Mac OS X v10.2 and later.

Declared In
CGFunction.h

CGFunctionReleaseInfoCallback

Performs custom clean-up tasks when Quartz deallocates a CGFunction object.

```
typedef void (*CGFunctionReleaseInfoCallback) (
    void *info
);
```

If you name your function `MyCGFunctionReleaseInfo`, you would declare it like this:

```
void MyCGFunctionReleaseInfo (
    void *info
);
```

Parameters

info

The `info` parameter passed to `CGFunctionCreate` (page 196).

Availability
Available in Mac OS X v10.2 and later.

Declared In
CGFunction.h

Data Types

CGFunctionRef

An opaque type that represents a callback function.

```
typedef struct CGFunction *CGFunctionRef;
```

Availability
Available in Mac OS X version 10.2 and later.

Declared In
CGFunction.h

CGFunctionCallbacks

A structure that contains callbacks needed by a CGFunction object.

```
struct CGFunctionCallbacks
{
  unsigned int version;
  CGFunctionEvaluateCallback evaluate;
  CGFunctionReleaseInfoCallback releaseInfo
};

typedef struct CGFunctionCallbacks CGFunctionCallbacks;
```

Fields

`version`

The structure version number. For this structure, the version should be `0`.

`evaluate`

The callback that evaluates the function.

`releaseInfo`

If non-`NULL`, the callback used to release the `info` parameter passed to `CGFunctionCreate` (page 196).

Availability

Available in Mac OS X v10.2 and later.

Declared In

`CGFunction.h`

CGGLContext Reference

Derived From:	`CGContextRef` (page 137)
Framework:	ApplicationServices/ApplicationServices.h
Declared in	CGGLContext.h
Companion guide	Quartz 2D Programming Guide

Overview

The CGGLContext header file defines functions that create and update a graphics context for OpenGL drawing. A CGGLContext context is a type of `CGContextRef` (page 137) that is used for OpenGL content. However, its use is not recommended.

Functions

CGGLContextCreate

Creates a Quartz graphics context from an OpenGL context.

```
CGContextRef CGGLContextCreate (
   void *glContext,
   CGSize size,
   CGColorSpaceRef colorspace
);
```

Parameters

glContext

The context that the OpenGL system uses to manage OpenGL drawing.

size

The dimensions of the OpenGL viewport rectangle.

colorspace

An RGB color space that serves as the destination space when rendering device-independent colors. If `NULL`, Quartz uses the default RGB color space. Quartz retains the color space you pass in; on return, you may safely release it.

Return Value

A new Quartz graphics context. You are responsible for releasing this object by calling `CGContextRelease` (page 102).

Discussion
The use of this function is not recommended.

Creates a Quartz context from the OpenGL context `glContext`. The context establishes an OpenGL viewport rectangle with dimensions specified by the `size` parameter by calling `glViewport(3G)`. If non-`NULL`, the `colorspace` parameter should be an RGB profile that specifies the destination space when rendering device-independent colors.

Availability
Available in Mac OS X version 10.3 and later.

Declared In
`CGGLContext.h`

CGGLContextUpdateViewportSize

Updates the size of the viewport associated with an OpenGL context.

```
void CGGLContextUpdateViewportSize (
   CGContextRef c,
   CGSize size
);
```

Parameters

context
A Quartz graphics context obtained by calling `CGGLContextCreate` (page 201).

size
The new dimensions of the OpenGL viewport.

Discussion
The use of this function is not recommended.

You should call this function whenever the size of the associated OpenGL context changes.

Availability
Available in Mac OS X version 10.3 and later.

Declared In
`CGGLContext.h`

CGGradient Reference

Derived From:	CFType
Framework:	ApplicationServices/ApplicationServices.h
Declared in	CGGradient.h
Companion guide	Quartz 2D Programming Guide

Overview

A gradient defines a smooth transition between colors across an area. The `CGGradientRef` opaque type, and the functions that operate on it, make creating and using radial and axial gradient fills an easy task. A CGGradient object has a color space, two or more colors, and a location for each color. The color space cannot be a pattern or indexed color space, otherwise it can be any Quartz color space (`CGColorSpaceRef` (page 56)).

Colors can be provided as component values (such as red, green, blue) or as Quartz color objects (`CGColorRef` (page 41)). In Quartz, component can vary from 0.0 to 1.0, designating the proportion of the component present in the color.

A location is a normalized value. When it comes time to paint the gradient, Quartz maps the normalized location values to the points in coordinate space that you provide.

If you want more precise control over gradients, or if your application runs in versions of Mac OS X that are earlier than v10.5, see *CGShading Reference*.

Functions by Task

Creating a CGGradient Object

`CGGradientCreateWithColorComponents` (page 204)
Creates a CGGradient object from a color space and the provided color components and locations.

`CGGradientCreateWithColors` (page 205)
Creates a CGGradient object from a color space and the provided color objects and locations.

Retaining and Releasing a CGGradient Object

`CGGradientRelease` (page 206)
Decrements the retain count of a CGGradient object.

`CGGradientRetain` (page 206)
Increments the retain count of a CGGradient object.

Getting the Type ID for a CGGradient Object

`CGGradientGetTypeID` (page 206)
Returns the Core Foundation type identifier for CGGradient objects.

Functions

CGGradientCreateWithColorComponents

Creates a CGGradient object from a color space and the provided color components and locations.

```
CGGradientRef CGGradientCreateWithColorComponents(
    CGColorSpaceRef space,
    const CGFloat components[],
    const CGFloat locations[],
    size_t count
);
```

Parameters

space
The color space to use for the gradient. You cannot use a pattern or indexed color space.

components
The color components for each color that defines the gradient. The components should be in the color space specified by `space`. If you are unsure of the number of components, you can call the function `CGColorSpaceGetNumberOfComponents` (page 54).

The number of items in this array should be the product of `count` and the number of components in the color space. For example, if the color space is an RGBA color space and you want to use two colors in the gradient (one for a starting location and another for an ending location), then you need to provide 8 values in `components`—red, green, blue, and alpha values for the first color, followed by red, green, blue, and alpha values for the second color.

locations
The location for each color provided in `components`. Each location must be a `CGFloat` value in the range of 0 to 1, inclusive. If 0 and 1 are not in the `locations` array, Quartz uses the colors provided that are closest to 0 and 1 for those locations.

If `locations` is `NULL`, the first color in `colors` is assigned to location `0`, the last color in`colors` is assigned to location `1`, and intervening colors are assigned locations that are at equal intervals in between.

count
The number of locations provided in the `locations` parameters.

Return Value
A CGGradient object.

Availability
Available in Mac OS X v10.5 and later.

See Also
`CGContextDrawLinearGradient` (page 86)
`CGContextDrawRadialGradient` (page 89)

Declared In
`CGGradient.h`

CGGradientCreateWithColors

Creates a CGGradient object from a color space and the provided color objects and locations.

```
CGGradientRef CGGradientCreateWithColors(
    CGColorSpaceRef space,
    CFArrayRef colors,
    const CGFloat locations[]
);
```

Parameters

space

The color space to use for the gradient. You cannot use a pattern or indexed color space.

colors

A non-empty array of CGColor objects that should be in the color space specified by `space`. If `space` is not `NULL`, each color will be converted (if necessary) to that color space and the gradient will drawn in that color space. Otherwise, each color will be converted to and drawn in the GenericRGB color space.

locations

The location for each color provided in `colors`; each location must be a `CGFloat` value in the range of 0 to 1, inclusive. If 0 and 1 are not in the `locations` array, Quartz uses the colors provided that are closest to 0 and 1 for those locations.

If `locations` is `NULL`, the first color in `colors` is assigned to location `0`, the last color in`colors` is assigned to location `1`, and intervening colors are assigned locations that are at equal intervals in between.

The `locations` array should contain the same number of items as the `colors` array.

Return Value
A CGGradient object.

Availability
Available in Mac OS X v10.5 and later.

See Also
`CGContextDrawLinearGradient` (page 86)
`CGContextDrawRadialGradient` (page 89)

Declared In
`CGGradient.h`

CGGradientGetTypeID

Returns the Core Foundation type identifier for CGGradient objects.

```
CFTypeID CGGradientGetTypeID (
   void
);
```

Return Value
The Core Foundation identifier for the opaque type `CGGradientRef`.

Availability
Available in Mac OS X version 10.5 and later.

Declared In
`CGGradient.h`

CGGradientRelease

Decrements the retain count of a CGGradient object.

```
void CGGradientRelease (
   CGGradientRef gradient
);
```

Parameters
gradient
The gradient object to release.

Discussion
This function is equivalent to `CFRelease`, except that it does not cause an error if the *gradient* parameter is `NULL`.

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CGGradient.h`

CGGradientRetain

Increments the retain count of a CGGradient object.

```
CGGradientRef CGGradientRetain(
   CGGradientRef gradient
);
```

Parameters
gradient
The gradient object to retain.

Return Value
The same gradient object that you passed in as the `gradient` parameter.

Discussion
This function is equivalent to `CFRetain`, except that it does not cause an error if the `gradient` parameter is `NULL`.

Availability
Available in Mac OS X version 10.5 and later.

Declared In
`CGGradient.h`

Data Types

CGGradientRef

An opaque type that represents a Quartz gradient.

```
typedef struct CGGradient *CGGradientRef;
```

Availability
Available in Mac OS X v10.5 and later.

Declared In
`CGGradient.h`

Constants

Gradient Drawing Options

Drawing locations for gradients.

```
enum {
    kCGGradientDrawsBeforeStartLocation = (1 << 0),
    kCGGradientDrawsAfterEndLocation = (1 << 1)
};
typedef enum CGGradientDrawingOptions CGGradientDrawingOptions;
```

Constants

`kCGGradientDrawsBeforeStartLocation`
The fill should extend beyond the starting location. The color that extends beyond the starting point is the solid color defined by the CGGradient object to be at location 0.

Available in Mac OS X v10.5 and later.

Declared in `CGGradient.h`.

`kCGGradientDrawsAfterEndLocation`
The fill should extend beyond the ending location. The color that extends beyond the ending point is the solid color defined by the CGGradient object to be at location 1.

Available in Mac OS X v10.5 and later.

Declared in `CGGradient.h`.

Declared In
`CGGradient.h`

CGImage Reference

Derived From:	*CFType Reference*
Framework:	ApplicationServices/ApplicationServices.h
Declared in	CGImage.h
Companion guide	Quartz 2D Programming Guide

Overview

The `CGImageRef` opaque type represents bitmap images and bitmap image masks, based on sample data that you supply. A bitmap (or sampled) image is a rectangular array of pixels, with each pixel representing a single sample or data point in a source image.

Functions by Task

Creating Bitmap Images

`CGImageCreate` (page 211)
Creates a bitmap image from data supplied by a data provider.

`CGImageCreateCopy` (page 212)
Creates a copy of a bitmap image.

`CGImageCreateCopyWithColorSpace` (page 213)
Create a copy of a bitmap image, replacing its colorspace.

`CGImageCreateWithJPEGDataProvider` (page 214)
Creates a bitmap image using JPEG-encoded data supplied by a data provider.

`CGImageCreateWithPNGDataProvider` (page 216)
Creates a Quartz bitmap image using PNG-encoded data supplied by a data provider.

`CGImageCreateWithImageInRect` (page 213)
Creates a bitmap image using the data contained within a subregion of an existing bitmap image.

`CGImageCreateWithMask` (page 215)
Creates a bitmap image from an existing image and an image mask.

`CGImageCreateWithMaskingColors` (page 215)
Creates a bitmap image by masking an existing bitmap image with the provided color values.

Creating an Image Mask

`CGImageMaskCreate` (page 223)
Creates a bitmap image mask from data supplied by a data provider.

Retaining and Releasing Images

`CGImageRetain` (page 225)
Increments the retain count of a bitmap image.

`CGImageRelease` (page 224)
Decrements the retain count of a bitmap image.

Getting the CFType ID

`CGImageGetTypeID` (page 222)
Returns the type identifier for Quartz bitmap images.

Getting Information About an Image

`CGImageGetAlphaInfo` (page 217)
Returns the alpha channel information for a bitmap image.

`CGImageGetBitmapInfo` (page 217)
Returns the bitmap information for a bitmap image.

`CGImageGetBitsPerComponent` (page 218)
Returns the number of bits allocated for a single color component of a bitmap image.

`CGImageGetBitsPerPixel` (page 218)
Returns the number of bits allocated for a single pixel in a bitmap image.

`CGImageGetBytesPerRow` (page 219)
Returns the number of bytes allocated for a single row of a bitmap image.

`CGImageGetColorSpace` (page 219)
Return the color space for a bitmap image.

`CGImageGetDataProvider` (page 220)
Returns the data provider for a bitmap image.

`CGImageGetDecode` (page 220)
Returns the decode array for a bitmap image.

`CGImageGetHeight` (page 220)
Returns the height of a bitmap image.

`CGImageGetShouldInterpolate` (page 221)
Returns the interpolation setting for a bitmap image.

`CGImageGetRenderingIntent` (page 221)
Returns the rendering intent setting for a bitmap image.

`CGImageGetWidth` (page 222)
Returns the width of a bitmap image.

`CGImageIsMask` (page 223)
Returns whether a bitmap image is an image mask.

Functions

CGImageCreate

Creates a bitmap image from data supplied by a data provider.

```
CGImageRef CGImageCreate (
   size_t width,
   size_t height,
   size_t bitsPerComponent,
   size_t bitsPerPixel,
   size_t bytesPerRow,
   CGColorSpaceRef colorspace,
   CGBitmapInfo bitmapInfo,
   CGDataProviderRef provider,
   const CGFloat decode[],
   bool shouldInterpolate,
   CGColorRenderingIntent intent
);
```

Parameters

width
The width, in pixels, of the required image.

height
The height, in pixels, of the required image

bitsPerComponent
The number of bits for each component in a source pixel. For example, if the source image uses the RGBA-32 format, you would specify 8 bits per component.

bitsPerPixel
The total number of bits in a source pixel. This value must be at least `bitsPerComponent` times the number of components per pixel.

bytesPerRow
The number of bytes of memory for each horizontal row of the bitmap.

colorspace
The color space for the image. Quartz retains the color space you pass in; on return, you may safely release it.

bitmapInfo
A `CGBitmapInfo` constant that specifies whether the bitmap should contain an alpha channel and its relative location in a pixel, along with whether the components are floating-point or integer values.

provider
The source of data for the bitmap. For information about supported data formats, see the discussion below. Quartz retains this object; on return, you may safely release it.

decode

The decode array for the image. If you do not want to allow remapping of the image's color values, pass `NULL` for the decode array. For each color component in the image's color space, a decode array provides a pair of values denoting the upper and lower limits of a range. For example, the decode array for a source image in the RGB color space would contain six entries total, consisting of one pair each for red, green, and blue. When the image is rendered, Quartz uses a linear transform to map the original component value into a relative number within your designated range that is appropriate for the destination color space.

shouldInterpolate

A Boolean value that specifies whether interpolation should occur. The interpolation setting specifies whether Quartz should apply a pixel-smoothing algorithm to the image. Without interpolation, the image may appear jagged or pixelated when drawn on an output device with higher resolution than the image data.

intent

A rendering intent constant that specifies how Quartz should handle colors that are not located within the gamut of the destination color space of a graphics context. The rendering intent determines the exact method used to map colors from one color space to another. For descriptions of the defined rendering-intent constants, see `Color Rendering Intents` (page 59).

Return Value
A new Quartz bitmap image. You are responsible for releasing this object by calling `CGImageRelease` (page 224).

Discussion
The data provider should provide raw data that matches the format specified by the other input parameters. To use encoded data (for example, from a file specified by a URL-based data provider), see `CGImageCreateWithJPEGDataProvider` (page 214) and `CGImageCreateWithPNGDataProvider` (page 216). In Mac OS X version 10.3 and later, you can also use the QuickTime function `GraphicsImportCreateCGImage` to decode an image file in any supported format and create a CGImage, in a single operation.

For information on supported pixel formats, see *Quartz 2D Programming Guide*.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`CGImage.h`

CGImageCreateCopy

Creates a copy of a bitmap image.

```
CGImageRef CGImageCreateCopy (
   CGImageRef image
);
```

Parameters

image

The image to copy.

Return Value
An copy of the image specified by the `image` parameter.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGImage.h`

CGImageCreateCopyWithColorSpace

Create a copy of a bitmap image, replacing its colorspace.

```
CGImageRef CGImageCreateCopyWithColorSpace (
   CGImageRef image,
   CGColorSpaceRef colorspace
);
```

Parameters

image
The graphics image to copy.

colorspace
The destination color space. The number of components in this color space must be the same as the number in the specified image.

Return Value
A new Quartz image that is a copy of the image passed as the `image` parameter but with its color space replaced by that specified by the `colorspace` parameter. Returns `NULL` if `image` is an image mask, or if the number of components of `colorspace` is not the same as the number of components of the colorspace of `image`. You are responsible for releasing this object using `CGImageRelease` (page 224).

Availability
Available in Mac OS X version 10.3 and later.

Declared In
`CGImage.h`

CGImageCreateWithImageInRect

Creates a bitmap image using the data contained within a subregion of an existing bitmap image.

```
CGImageRef CGImageCreateWithImageInRect (
   CGImageRef image,
   CGRect rect
);
```

Parameters

image
The image to extract the subimage from.

rect
A rectangle whose coordinates specify the area to create an image from.

Return Value
A CGImage object that specifies a subimage of the image. If the `rect` parameter defines an area that is not in the image, returns `NULL`.

Discussion
Quartz performs these tasks to create the subimage:

- Adjusts the area specified by the `rect` parameter to integral bounds by calling the function `CGRectIntegral`.
- Intersects the result with a rectangle whose origin is `(0,0)` and size is equal to the size of the image specified by the `image` parameter.
- References the pixels within the resulting rectangle, treating the first pixel within the rectangle as the origin of the subimage.

If `W` and `H` are the width and height of image, respectively, then the point `(0,0)` corresponds to the first pixel of the image data. The point `(W-1, 0)` is the last pixel of the first row of the image data while `(0, H-1)` is the first pixel of the last row of the image data and `(W-1, H-1)` is the last pixel of the last row of the image data.

The resulting image retains a reference to the original image, which means you may release the original image after calling this function.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGImage.h`

CGImageCreateWithJPEGDataProvider

Creates a bitmap image using JPEG-encoded data supplied by a data provider.

```
CGImageRef CGImageCreateWithJPEGDataProvider (
   CGDataProviderRef source,
   const CGFloat decode[],
   bool shouldInterpolate,
   CGColorRenderingIntent intent
);
```

Parameters

source
A data provider supplying JPEG-encoded data.

decode
The decode array for the image. Typically a decode array is unnecessary, and you should pass `NULL`.

shouldInterpolate
A Boolean value that specifies whether interpolation should occur. The interpolation setting specifies whether Quartz should apply a pixel-smoothing algorithm to the image.

intent
A `CGColorRenderingIntent` constant that specifies how Quartz should handle colors that are not located within the gamut of the destination color space of a graphics context.

Return Value
A new Quartz bitmap image. You are responsible for releasing this object by calling `CGImageRelease` (page 224).

Availability
Available in Mac OS X version 10.1 and later.

Declared In
`CGImage.h`

CGImageCreateWithMask

Creates a bitmap image from an existing image and an image mask.

```
CGImageRef CGImageCreateWithMask (
   CGImageRef image,
   CGImageRef mask
);
```

Parameters

image

The image to apply the `mask` parameter to. This image must not be an image mask and may not have an image mask or masking color associated with it.

mask

A mask. If the mask is an image, it must be in the DeviceGray color space, must not have an alpha component, and may not itself be masked by an image mask or a masking color. If the mask is not the same size as the image specified by the `image` parameter, then Quartz scales the mask to fit the image.

Return Value
An image created by masking `image` with `mask`. You are responsible for releasing this object by calling `CGImageRelease` (page 224).

Discussion
The resulting image depends on whether the `mask` parameter is an image mask or an image. If the `mask` parameter is an image mask, then the source samples of the image mask act as an inverse alpha value. That is, if the value of a source sample in the image mask is S, then the corresponding region in `image` is blended with the destination using an alpha value of (1-S). For example, if S is 1, then the region is not painted, while if S is 0, the region is fully painted.

If the `mask` parameter is an image, then it serves as an alpha mask for blending the image onto the destination. The source samples of `mask`' act as an alpha value. If the value of the source sample in mask is S, then the corresponding region in image is blended with the destination with an alpha of S. For example, if S is 0, then the region is not painted, while if S is 1, the region is fully painted.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGImage.h`

CGImageCreateWithMaskingColors

Creates a bitmap image by masking an existing bitmap image with the provided color values.

```
CGImageRef CGImageCreateWithMaskingColors (
   CGImageRef image,
   const CGFloat components[]
);
```

Parameters

image

The image to mask. This parameter may not be an image mask, may not already have an image mask or masking color associated with it, and cannot have an alpha component.

components

An array of color components that specify a color or range of colors to mask the image with. The array must contain 2N values { min[1], max[1], ... min[N], max[N] } where N is the number of components in color space of `image`. Each value in `components` must be a valid image sample value. If `image` has integer pixel components, then each value must be in the range [0 .. 2**`bitsPerComponent` - 1] (where `bitsPerComponent` is the number of bits/component of `image`). If `image` has floating-point pixel components, then each value may be any floating-point number which is a valid color component.

Return Value

An image created by masking `image` with the colors specified in the `components` array. You are responsible for releasing this object by calling `CGImageRelease` (page 224).

Discussion

Any image sample with color value {c[1], ... c[N]} where min[i] <= c[i] <= max[i] for 1 <= i <= N is masked out (that is, not painted). This means that anything underneath the unpainted samples, such as the current fill color, shows through.

Availability

Available in Mac OS X v10.4 and later.

Declared In

`CGImage.h`

CGImageCreateWithPNGDataProvider

Creates a Quartz bitmap image using PNG-encoded data supplied by a data provider.

```
CGImageRef CGImageCreateWithPNGDataProvider (
   CGDataProviderRef source,
   const CGFloat decode[],
   bool shouldInterpolate,
   CGColorRenderingIntent intent
);
```

Parameters

source

A data provider supplying PNG-encoded data.

decode

The decode array for the image. Typically a decode array is unnecessary, and you should pass `NULL`.

shouldInterpolate

A Boolean value that specifies whether interpolation should occur. The interpolation setting specifies whether Quartz should apply a pixel-smoothing algorithm to the image.

intent

A `CGColorRenderingIntent` constant that specifies how Quartz should handle colors that are not located within the gamut of the destination color space of a graphics context.

Return Value
A new Quartz bitmap image. You are responsible for releasing this object by calling `CGImageRelease` (page 224).

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CGImage.h`

CGImageGetAlphaInfo

Returns the alpha channel information for a bitmap image.

```
CGImageAlphaInfo CGImageGetAlphaInfo (
   CGImageRef image
);
```

Parameters

image

The image to examine.

Return Value
A `CGImageAlphaInfo` constant that specifies (1) whether the bitmap contains an alpha channel, (2) where the alpha bits are located in the image data, and (3) whether the alpha value is premultiplied. For possible values, see "Constants" (page 226). The function returns `kCGImageAlphaNone` if the `image` parameter refers to an image mask.

Discussion
The alpha value is what determines the opacity of a pixel when it is drawn.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`CGImage.h`

CGImageGetBitmapInfo

Returns the bitmap information for a bitmap image.

```
CGBitmapInfo CGImageGetBitmapInfo (
   CGImageRef image
);
```

Parameters

image

An image.

Return Value
The bitmap information associated with an image.

Discussion
This function returns a constant that specifies:

- The type of bitmap data—floating point or integer. You use the constant `kCGBitmapFloatComponents` to extract this information.
- Whether an alpha channel is in the data, and if so, how the alpha data is stored. You use the constant `kCGBitmapAlphaInfoMask` to extract the alpha information. Alpha information is specified as one of the constants listed in "Alpha Information for Images" (page 226).

You can extract the alpha information

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGImage.h`

CGImageGetBitsPerComponent

Returns the number of bits allocated for a single color component of a bitmap image.

```
size_t CGImageGetBitsPerComponent (
   CGImageRef image
);
```

Parameters

image
The image to examine.

Return Value
The number of bits used in memory for each color component of the specified bitmap image (or image mask). Possible values are 1, 2, 4, or 8. For example, for a 16-bit RGB(A) colorspace, the function would return a value of 4 bits per color component.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`CGImage.h`

CGImageGetBitsPerPixel

Returns the number of bits allocated for a single pixel in a bitmap image.

```
size_t CGImageGetBitsPerPixel (
   CGImageRef image
);
```

Parameters

image
The image to examine.

Return Value
The number of bits used in memory for each pixel of the specified bitmap image (or image mask).

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`CGImage.h`

CGImageGetBytesPerRow

Returns the number of bytes allocated for a single row of a bitmap image.

```
size_t CGImageGetBytesPerRow (
   CGImageRef image
);
```

Parameters

image
The image to examine.

Return Value
The number of bytes used in memory for each row of the specified bitmap image (or image mask).

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`CGImage.h`

CGImageGetColorSpace

Return the color space for a bitmap image.

```
CGColorSpaceRef CGImageGetColorSpace (
   CGImageRef image
);
```

Parameters

image
The image to examine.

Return Value
The source color space for the specified bitmap image, or `NULL` if the image is an image mask. You are responsible for retaining and releasing the color space as necessary.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`CGImage.h`

CGImageGetDataProvider

Returns the data provider for a bitmap image.

```
CGDataProviderRef CGImageGetDataProvider (
   CGImageRef image
);
```

Parameters

image

The image to examine.

Return Value

The data provider for the specified bitmap image (or image mask). You are responsible for retaining and releasing the data provider as necessary.

Availability

Available in Mac OS X version 10.0 and later.

Declared In

`CGImage.h`

CGImageGetDecode

Returns the decode array for a bitmap image.

```
const CGFloat * CGImageGetDecode (
   CGImageRef image
);
```

Parameters

image

The image to examine.

Return Value

The decode array for a bitmap image (or image mask). See the discussion for a description of possible return values.

Discussion

For a bitmap image or image mask, for each color component in the source color space, the decode array contains a pair of values denoting the upper and lower limits of a range. When the image is rendered, Quartz uses a linear transform to map the original component value into a relative number, within the designated range, that is appropriate for the destination color space. If remapping of the image's color values is not allowed, the returned value will be `NULL`.

Availability

Available in Mac OS X version 10.0 and later.

Declared In

`CGImage.h`

CGImageGetHeight

Returns the height of a bitmap image.

```
size_t CGImageGetHeight (
   CGImageRef image
);
```

Parameters

image

The image to examine.

Return Value
The height in pixels of the bitmap image (or image mask).

Availability
Available in Mac OS X version 10.0 and later.

Related Sample Code
CarbonCocoa_PictureCursor

Declared In
`CGImage.h`

CGImageGetRenderingIntent

Returns the rendering intent setting for a bitmap image.

```
CGColorRenderingIntent CGImageGetRenderingIntent (
   CGImageRef image
);
```

Parameters

image

The image to examine.

Return Value
Returns the `CGColorRenderingIntent` constant that specifies how Quartz should handle colors that are not located within the gamut of the destination color space of a graphics context in which the image is drawn. If the image is an image mask, this function returns `kCGRenderingIntentDefault`.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`CGImage.h`

CGImageGetShouldInterpolate

Returns the interpolation setting for a bitmap image.

```
bool CGImageGetShouldInterpolate (
   CGImageRef image
);
```

Parameters

image

The image to examine.

Return Value
Returns `1` if interpolation is enabled for the specified bitmap image (or image mask), otherwise, returns `0`.

Discussion
The interpolation setting specifies whether Quartz should apply an edge-smoothing algorithm to the associated image.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`CGImage.h`

CGImageGetTypeID

Returns the type identifier for Quartz bitmap images.

```
CFTypeID CGImageGetTypeID (
   void
);
```

Return Value
The identifier for the opaque type `CGImageRef` (page 225).

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CGImage.h`

CGImageGetWidth

Returns the width of a bitmap image.

```
size_t CGImageGetWidth (
   CGImageRef image
);
```

Parameters
image
The image to examine.

Return Value
The width, in pixels, of the specified bitmap image (or image mask).

Availability
Available in Mac OS X version 10.0 and later.

Related Sample Code
CarbonCocoa_PictureCursor

Declared In
`CGImage.h`

CGImageIsMask

Returns whether a bitmap image is an image mask.

```
bool CGImageIsMask (
   CGImageRef image
);
```

Parameters

image

The image to examine.

Return Value

A Boolean value that indicates whether the image passed in the `image` parameter is an image mask (`true` indicates that the image is an image mask).

Availability

Available in Mac OS X version 10.0 and later.

Declared In

`CGImage.h`

CGImageMaskCreate

Creates a bitmap image mask from data supplied by a data provider.

```
CGImageRef CGImageMaskCreate (
   size_t width,
   size_t height,
   size_t bitsPerComponent,
   size_t bitsPerPixel,
   size_t bytesPerRow,
   CGDataProviderRef provider,
   const CGFloat decode[],
   bool shouldInterpolate
);
```

Parameters

width

The width, in pixels, of the required image mask.

height

The height, in pixels, of the required image mask.

bitsPerComponent

The number of significant masking bits in a source pixel. For example, if the source image is an 8-bit mask, you specify 8 bits per component. Image masks must be 1, 2, 4, or 8 bits per component.

bitsPerPixel

The total number of bits in a source pixel.

bytesPerRow

The number of bytes to use for each horizontal row of the image mask.

provider

The data source for the image mask.

decode

Typically a decode array is unnecessary, and you should pass `NULL`.

shouldInterpolate

A Boolean value that specifies whether interpolation should occur. The interpolation setting specifies whether Quartz should apply an edge-smoothing algorithm to the image mask.

Return Value
A Quartz bitmap image mask. You are responsible for releasing this object by calling `CGImageRelease` (page 224).

Discussion
A Quartz bitmap image mask is used the same way an artist uses a silkscreen, or a sign painter uses a stencil. The bitmap represents a mask through which a color is transferred. The bitmap itself does not have a color. It gets its color from the fill color currently set in the graphics state.

When you draw into a context with a bitmap image mask, Quartz uses the mask to determine where and how the current fill color is applied to the image rectangle. Each sample value in the mask specifies how much of the current fill color is masked out at a specific location. Effectively, the sample value specifies the opacity of the mask. Larger values represent greater opacity and hence less color applied to the page.

Image masks must be 1, 2, 4, or 8 bits per component. For a 1-bit mask, a sample value of `1` specifies sections of the mask that are masked out; these sections block the current fill color. A sample value of `0` specifies sections of the mask that are not masked out; these sections show the current fill color of the graphics state when the mask is painted. You can think of the sample values as an inverse alpha. That is, a value of `1` is transparent and `0` is opaque.

For image masks that are 2, 4, or 8 bits per component, each component is mapped to a range of 0 to 1 by scaling using this formula:

```
1/(2^bits per component - 1)
```

For example, a 4-bit mask has values that range from 0 to 15. These values are scaled by 1/15 so that each component ranges from 0 to 1. Component values that rescale to 0 or 1 behave the same way as they behave for 1-bit image masks. Values that scale to between 0 and 1 act as an inverse alpha. That is, the fill color is painted as if it has an alpha value of (`1 - MaskSampleValue`). For example, if the sample value of an 8-bit mask scales to `0.8`, the current fill color is painted as if it has an alpha value of `0.2`, that is (`1-0.8`).

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`CGImage.h`

CGImageRelease

Decrements the retain count of a bitmap image.

```
void CGImageRelease (
   CGImageRef image
);
```

Parameters

image

The image to release.

Discussion
This function is equivalent to `CFRelease`, except that it does not cause an error if the `image` parameter is `NULL`.

Availability
Available in Mac OS X version 10.0 and later.

Related Sample Code
WhackedTV

Declared In
`CGImage.h`

CGImageRetain

Increments the retain count of a bitmap image.

```
CGImageRef CGImageRetain (
   CGImageRef image
);
```

Parameters

image
The image to retain.

Return Value
The same image you passed in as the `image` parameter.

Discussion
This function is equivalent to `CFRetain`, except that it does not cause an error if the `image` parameter is `NULL`.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`CGImage.h`

Data Types

CGImageRef

An opaque type that encapsulates bitmap image information.

```
typedef struct CGImage *CGImageRef;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGImage.h`

Constants

Alpha Information for Images

Storage options for alpha component data.

```
enum CGImageAlphaInfo {
    kCGImageAlphaNone,
    kCGImageAlphaPremultipliedLast,
    kCGImageAlphaPremultipliedFirst,
    kCGImageAlphaLast,
    kCGImageAlphaFirst,
    kCGImageAlphaNoneSkipLast,
    kCGImageAlphaNoneSkipFirst
};
typedef enum CGImageAlphaInfo CGImageAlphaInfo;
```

Constants

`kCGImageAlphaFirst`

The alpha component is stored in the most significant bits of each pixel. For example, non-premultiplied ARGB.

Available in Mac OS X v10.0 and later.

Declared in `CGImage.h`.

`kCGImageAlphaLast`

The alpha component is stored in the least significant bits of each pixel. For example, non-premultiplied RGBA.

Available in Mac OS X v10.0 and later.

Declared in `CGImage.h`.

`kCGImageAlphaNone`

There is no alpha channel. If the total size of the pixel is greater than the space required for the number of color components in the color space, the least significant bits are ignored. This value is equivalent to `kCGImageAlphaNoneSkipLast`.

Available in Mac OS X v10.0 and later.

Declared in `CGImage.h`.

`kCGImageAlphaNoneSkipFirst`

There is no alpha channel. If the total size of the pixel is greater than the space required for the number of color components in the color space, the most significant bits are ignored.

Available in Mac OS X v10.0 and later.

Declared in `CGImage.h`.

`kCGImageAlphaOnly`

There is no color data, only an alpha channel.

Available in Mac OS X v10.3 and later.

Declared in `CGImage.h`.

`kCGImageAlphaNoneSkipLast`
: There is no alpha channel. If the total size of the pixel is greater than the space required for the number of color components in the color space, the least significant bits are ignored. This value is equivalent to `kCGImageAlphaNone`.

  Available in Mac OS X v10.0 and later.

  Declared in `CGImage.h`.

`kCGImageAlphaPremultipliedFirst`
: The alpha component is stored in the most significant bits of each pixel and the color components have already been multiplied by this alpha value. For example, premultiplied ARGB.

  Available in Mac OS X v10.0 and later.

  Declared in `CGImage.h`.

`kCGImageAlphaPremultipliedLast`
: The alpha component is stored in the least significant bits of each pixel and the color components have already been multiplied by this alpha value. For example, premultiplied RGBA.

  Available in Mac OS X v10.0 and later.

  Declared in `CGImage.h`.

Discussion
A `CGImageAlphaInfo` constant specifies (1) whether a bitmap contains an alpha channel, (2) where the alpha bits are located in the image data, and (3) whether the alpha value is premultiplied. You can obtain a `CGImageAlphaInfo` constant for an image by calling the function `CGImageGetAlphaInfo` (page 217). (You provide a `CGBitmapInfo` constant to the function `CGImageCreate` (page 211), part of which is a `CGImageAlphaInfo` constant.)

Quartz accomplishes alpha blending by combining the color components of the source image with the color components of the destination image using the linear interpolation formula, where "source" is one color component of one pixel of the new paint and "destination" is one color component of the background image.

Quartz supports premultiplied alpha only for images. You should not premultiply any other color values specified in Quartz.

Declared In
`CGImage.h`

Image Bitmap Information

Component information for a bitmap image.

```
enum {
    kCGBitmapAlphaInfoMask = 0x1F,
    kCGBitmapFloatComponents = (1 << 8),

    kCGBitmapByteOrderMask = 0x7000,
    kCGBitmapByteOrderDefault = (0 << 12),
    kCGBitmapByteOrder16Little = (1 << 12),
    kCGBitmapByteOrder32Little = (2 << 12),
    kCGBitmapByteOrder16Big = (3 << 12),
    kCGBitmapByteOrder32Big = (4 << 12)
};
typedef uint32_t CGBitmapInfo;
```

```
#ifdef __BIG_ENDIAN__
    kCGBitmapByteOrder16Host kCGBitmapByteOrder16Big
    kCGBitmapByteOrder32Host kCGBitmapByteOrder32Big
#else
    kCGBitmapByteOrder16Host kCGBitmapByteOrder16Little
    kCGBitmapByteOrder32Host kCGBitmapByteOrder32Little
#endif
```

Constants

`kCGBitmapAlphaInfoMask`
The alpha information mask. Use this to extract alpha information that specifies whether a bitmap contains an alpha channel and how the alpha channel is generated.

Available in Mac OS X v10.4 and later.

Declared in `CGImage.h`.

`kCGBitmapFloatComponents`
The components of a bitmap are floating-point values.

Available in Mac OS X v10.4 and later.

Declared in `CGImage.h`.

`kCGBitmapByteOrderMask`
The byte ordering of pixel formats.

Available in Mac OS X v10.4 and later.

Declared in `CGImage.h`.

`kCGBitmapByteOrderDefault`
The default byte order.

Available in Mac OS X v10.4 and later.

Declared in `CGImage.h`.

`kCGBitmapByteOrder16Little`
16-bit, little endian format.

Available in Mac OS X v10.4 and later.

Declared in `CGImage.h`.

`kCGBitmapByteOrder32Little`
32-bit, little endian format.

Available in Mac OS X v10.4 and later.

Declared in `CGImage.h`.

`kCGBitmapByteOrder16Big`
16-bit, big endian format.

Available in Mac OS X v10.4 and later.

Declared in `CGImage.h`.

`kCGBitmapByteOrder32Big`
32-bit, big endian format.

Available in Mac OS X v10.4 and later.

Declared in `CGImage.h`.

`kCGBitmapByteOrder16Host`
16-bit, host endian format.

`kCGBitmapByteOrder32Host`
32-bit, host endian format.

Discussion
Applications that store pixel data in memory using ARGB format must take care in how they read data. If the code is not written correctly, it's possible to misread the data which leads to colors or alpha that appear wrong. The Quartz byte order constants specify the byte ordering of pixel formats. To specify byte ordering to Quartz use a bitwise OR operator to combine the appropriate constant with the `bitmapInfo` parameter.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGImage.h`

CGImageDestination Reference

Derived From:	CFType
Framework:	ApplicationServices/ImageIO
Declared in	CGImageDestination.h
Companion guide	Quartz 2D Programming Guide

Overview

CGImageDestination objects, available in Mac OS X v10.4 or later, abstract the data-writing task. An image destination can represent a single image or multiple images. It can contain thumbnail images as well as properties for each image.

The functions described in this reference can write data to three kinds of destinations: a URL, a `CFData` object, and a data consumer. After creating a CGImageDestination object for the appropriate destination, you can add image data and set image properties. When you are finished adding data, call the function `CGImageDestinationFinalize` to write the image data and properties to the URL, `CFData` object, or data consumer.

Functions by Task

Creating Image Destinations

`CGImageDestinationCreateWithDataConsumer` (page 234)
Creates an image destination that writes to the specified data consumer.

`CGImageDestinationCreateWithData` (page 234)
Creates an image destination that writes to a Core Foundation mutable data object.

`CGImageDestinationCreateWithURL` (page 235)
Creates an image destination that writes to a location specified by a URL.

Adding Images

`CGImageDestinationAddImage` (page 232)
Adds an image to an image destination.

`CGImageDestinationAddImageFromSource` (page 233)
Adds an image from an image source to an image destination.

Getting Type Identifiers

`CGImageDestinationCopyTypeIdentifiers` (page 233)
Returns an array of the uniform type identifiers (UTIs) that are supported for image destinations.

`CGImageDestinationGetTypeID` (page 236)
Returns the unique type identifier of an image destination opaque type.

Setting Properties

`CGImageDestinationSetProperties` (page 236)
Applies one or more properties to all images in an image destination.

Finalizing an Image Destination

`CGImageDestinationFinalize` (page 235)
Writes image data and properties to the data, URL, or data consumer associated with the image destination.

Functions

CGImageDestinationAddImage

Adds an image to an image destination.

```
void CGImageDestinationAddImage (
    CGImageDestinationRef idst,
    CGImageRef image,
    CFDictionaryRef properties
);
```

Parameters

idst
An image destination

image
The image to add.

properties
An optional dictionary that specifies the properties of the added image. The dictionary can contain any of the properties described in "Destination Properties" (page 237) or the image properties described in *CGImageProperties Reference*.

Discussion
The function logs an error if you add more images than what you specified when you created the image destination.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
CGImageDestination.h

CGImageDestinationAddImageFromSource

Adds an image from an image source to an image destination.

```
void CGImageDestinationAddImageFromSource (
    CGImageDestinationRef idst,
    CGImageSourceRef isrc,
    size_t index,
    CFDictionaryRef properties
);
```

Parameters

idst
An image destination.

isrc
An image source.

index
An index that specifies the location of the image in the image source. The index is zero-based.

properties
A dictionary that specifies properties to overwrite or add to the source image properties. If a key in `properties` has the value `kCFNull`, the corresponding property in the image destination is removed. The dictionary can contain any of the properties described in "Destination Properties" (page 237) or the image properties described in *CGImageProperties Reference*.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
CGImageDestination.h

CGImageDestinationCopyTypeIdentifiers

Returns an array of the uniform type identifiers (UTIs) that are supported for image destinations.

```
CFArrayRef CGImageDestinationCopyTypeIdentifiers (
    void
);
```

Return Value
Returns an array of the UTIs that are supported for image destinations. See Uniform Type Identifiers Overview for a list of system-declared and third-party UTIs that can be returned.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
CGImageDestination.h

CGImageDestinationCreateWithData

Creates an image destination that writes to a Core Foundation mutable data object.

```
CGImageDestinationRef CGImageDestinationCreateWithData (
    CFMutableDataRef data,
    CFStringRef type,
    size_t count,
    CFDictionaryRef options
);
```

Parameters

data

The data object to write to. For more information on data objects, see *CFData Reference* and Data Objects.

type

The uniform type identifier (UTI) of the resulting image file. See *Uniform Type Identifiers Overview* for a list of system-declared and third-party UTIs.

count

The number of images (not including thumbnail images) that the image file will contain.

options

Reserved for future use. Pass `NULL`.

Return Value

An image destination. You are responsible for releasing this object using `CFRelease`.

Availability

Available in Mac OS X version 10.4 and later.

Declared In

`CGImageDestination.h`

CGImageDestinationCreateWithDataConsumer

Creates an image destination that writes to the specified data consumer.

```
CGImageDestinationRef CGImageDestinationCreateWithDataConsumer (
    CGDataConsumerRef consumer,
    CFStringRef type,
    size_t count,
    CFDictionaryRef options
);
```

Parameters

consumer

The data consumer to write to. For information on data consumers see *CGDataConsumer Reference* and *Quartz 2D Programming Guide*.

type

The uniform type identifier (UTI) of the resulting image file. See *Uniform Type Identifiers Overview* for a list of system-declared and third-party UTIs.

count

The number of images (not including thumbnail images) that the image file will contain.

options
Reserved for future use. Pass `NULL`.

Return Value
An image destination. You are responsible for releasing this object using `CFRelease`.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`CGImageDestination.h`

CGImageDestinationCreateWithURL

Creates an image destination that writes to a location specified by a URL.

```
CGImageDestinationRef CGImageDestinationCreateWithURL (
    CFURLRef url,
    CFStringRef type,
    size_t count,
    CFDictionaryRef options
);
```

Parameters

url
The URL to write to. If the URL already exists, the data at this location is overwritten.

type
The UTI (uniform type identifier) of the resulting image file. See *Uniform Type Identifiers Overview* for a list of system-declared and third-party UTIs.

count
The number of images (not including thumbnail images) that the image file will contain.

options
Reserved for future use. Pass `NULL`.

Return Value
An image destination. You are responsible for releasing this object using `CFRelease`.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`CGImageDestination.h`

CGImageDestinationFinalize

Writes image data and properties to the data, URL, or data consumer associated with the image destination.

```
bool CGImageDestinationFinalize (
   CGImageDestinationRef idst
);
```

Parameters

idst

An image destination.

Return Value
Returns `true` if the image is successfully written; `false` otherwise.

Discussion
You must call this function or the output of the image destination will not be valid. After calling this function, no additional data can be added to the image destination.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`CGImageDestination.h`

CGImageDestinationGetTypeID

Returns the unique type identifier of an image destination opaque type.

```
CFTypeID CGImageDestinationGetTypeID (
    void
);
```

Return Value
Returns the Core Foundation type ID for an image destination.

Discussion
A type identifier is an integer that identifies the opaque type to which a Core Foundation object belongs. You use type IDs in various contexts, such as when you are operating on heterogeneous collections.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`CGImageDestination.h`

CGImageDestinationSetProperties

Applies one or more properties to all images in an image destination.

```
void CGImageDestinationSetProperties (
    CGImageDestinationRef idst,
    CFDictionaryRef properties
);
```

Parameters

idst

An image destination.

properties
A dictionary that contains the properties to apply. You can set any of the properties described in "Destination Properties" (page 237) or the image properties described in *CGImageProperties Reference*.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
CGImageDestination.h

Data Types

CGImageDestinationRef

An opaque type that represents an image destination.

```
typedef struct CGImageDestination *CGImageDestinationRef;
```

Availability
Available in Mac OS X v10.4 and later.

Declared In
CGImageDestination.h

Constants

Destination Properties

Properties for a single image in an image destination.

```
const CFStringRef kCGImageDestinationLossyCompressionQuality
const CFStringRef kCGImageDestinationBackgroundColor
```

Constants
kCGImageDestinationLossyCompressionQuality
The desired compression quality to use when writing to an image destination. If present, the value associated with this key must be a `CFNumberRef` data type in the range `0.0` to `1.0`. A value of `1.0` specifies to use lossless compression if destination format supports it. A value of 0.0 implies to use maximum compression.

Available in Mac OS X v10.4 and later.

Declared in `CGImageDestination.h`.

`kCGImageDestinationBackgroundColor`

The desired background color to composite against when writing an image that has an alpha component to a destination format that does not support alpha. If present, the value associated with this key must be a `CGColorRef` (page 41) data type without an alpha component of its own. If not present, and if a background color is needed, a white color is used.

Available in Mac OS X v10.4 and later.

Declared in `CGImageDestination.h`.

Declared In
`CGImageDestination.h`

CGImageSource Reference

Derived From:	CFType
Framework:	ApplicationServices/ImageIO
Declared in	CGImageSource.h
Companion guides	Quartz 2D Programming Guide CGImage Reference

Overview

CGImageSource objects, available in Mac OS X v10.4 or later, abstract the data-reading task. An image source can read image data from a URL, a `CFData` object, or a data consumer.

After creating a CGImageSource object for the appropriate source, you can obtain images, thumbnails, image properties, and other image information using CGImageSource functions.

Functions by Task

Creating an Image Source

`CGImageSourceCreateWithDataProvider` (page 244)
Creates an image source that reads data from the specified data provider.

`CGImageSourceCreateWithData` (page 244)
Creates an image source that reads from a Core Foundation data object.

`CGImageSourceCreateWithURL` (page 245)
Creates an image source that reads from a location specified by a URL.

Creating Images From an Image Source

`CGImageSourceCreateImageAtIndex` (page 242)
Creates a CGImage object for the image data associated with the specified index in an image source.

`CGImageSourceCreateThumbnailAtIndex` (page 243)
Creates a thumbnail image of the image located at a specified location in an image source.

`CGImageSourceCreateIncremental` (page 242)
Create an incremental image source.

Updating an Image Source

`CGImageSourceUpdateData` (page 248)
Updates an incremental image source with new data.

`CGImageSourceUpdateDataProvider` (page 248)
Updates an incremental image source with a new data provider.

Getting Information From an Image Source

`CGImageSourceGetTypeID` (page 247)
Returns the unique type identifier of an image source opaque type.

`CGImageSourceGetType` (page 247)
Returns the uniform type identifier of the source container.

`CGImageSourceCopyTypeIdentifiers` (page 241)
Returns an array of uniform type identifiers (UTIs) that are supported for image sources.

`CGImageSourceGetCount` (page 245)
Returns the number of images (not including thumbnails) in the image source.

`CGImageSourceCopyProperties` (page 240)
Returns the properties of the image source.

`CGImageSourceCopyPropertiesAtIndex` (page 241)
Returns the properties of the image at a specified location in an image source.

`CGImageSourceGetStatus` (page 246)
Return the status of an image source.

`CGImageSourceGetStatusAtIndex` (page 246)
Returns the current status of an image that is at a specified location in an image source.

Functions

CGImageSourceCopyProperties

Returns the properties of the image source.

```
CFDictionaryRef CGImageSourceCopyProperties (
   CGImageSourceRef isrc,
   CFDictionaryRef options
);
```

Parameters

isrc
An image source.

options
A dictionary you can use to request additional options. See "Image Source Option Dictionary Keys" (page 250) for the keys you can supply.

Return Value
A dictionary that contains the properties associated with the image source container. See *CGImageProperties Reference* for a list of properties that can be in the dictionary.

Discussion
These properties apply to the container in general but not necessarily to any individual image contained in the image source.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`CGImageSource.h`

CGImageSourceCopyPropertiesAtIndex

Returns the properties of the image at a specified location in an image source.

```
CFDictionaryRef CGImageSourceCopyPropertiesAtIndex (
   CGImageSourceRef isrc,
   size_t index,
   CFDictionaryRef options
);
```

Parameters

isrc
An image source.

index
The index of the image whose properties you want to obtain. The index is zero-based.

options
A dictionary you can use to request additional options. See "Image Source Option Dictionary Keys" (page 250) for the keys you can supply.

Return Value
A dictionary that contains the properties associated with the image. See *CGImageProperties Reference* for a list of properties that can be in the dictionary.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`CGImageSource.h`

CGImageSourceCopyTypeIdentifiers

Returns an array of uniform type identifiers (UTIs) that are supported for image sources.

```
CFArrayRef CGImageSourceCopyTypeIdentifiers (
   void
);
```

Return Value
Returns an array of the UTIs that are supported for image sources.

Discussion
See Uniform Type Identifiers Overview for a list of system-declared and third-party UTIs.

Availability
Available in Mac OS X version 10.4 and later.

Related Sample Code
CarbonCocoa_PictureCursor

Declared In
`CGImageSource.h`

CGImageSourceCreateImageAtIndex

Creates a CGImage object for the image data associated with the specified index in an image source.

```
CGImageRef CGImageSourceCreateImageAtIndex (
   CGImageSourceRef isrc,
   size_t index,
   CFDictionaryRef options
);
```

Parameters

isrc

An image source.

index

The index that specifies the location of the image. The index is zero-based.

options

A dictionary that specifies additional creation options. See "`Image Source Option Dictionary Keys`" (page 250) for the keys you can supply.

Return Value
Returns a CGImage object. You are responsible for releasing this object using `CGImageRelease` (page 224).

Availability
Available in Mac OS X version 10.4 and later.

Related Sample Code
CarbonCocoa_PictureCursor

Declared In
`CGImageSource.h`

CGImageSourceCreateIncremental

Create an incremental image source.

```
CGImageSourceRef CGImageSourceCreateIncremental (
   CFDictionaryRef options
);
```

Parameters

options

A dictionary that specifies additional creation options. See "Image Source Option Dictionary Keys" (page 250) for the keys you can supply.

Return Value

Returns an image source object. You are responsible for releasing this object using `CFRelease`.

Discussion

The function `CGImageSourceCreateIncremental` creates an empty image source container to which you can add data later by calling the functions `CGImageSourceUpdateDataProvider` or `CGImageSourceUpdateData`. You don't provide data when you call this function.

An incremental image is an image that is created in chunks, similar to the way large images viewed over the web are loaded piece by piece.

Availability

Available in Mac OS X version 10.4 and later.

Declared In

`CGImageSource.h`

CGImageSourceCreateThumbnailAtIndex

Creates a thumbnail image of the image located at a specified location in an image source.

```
CGImageRef CGImageSourceCreateThumbnailAtIndex (
   CGImageSourceRef isrc,
   size_t index,
   CFDictionaryRef options
);
```

Parameters

isrc

An image source.

index

The index that specifies the location of the image. The index is zero-based.

options

A dictionary that specifies additional creation options. See "Image Source Option Dictionary Keys" (page 250) for the keys you can supply.

Return Value

A CGImage object. You are responsible for releasing this object using `CGImageRelease` (page 224).

Discussion

If the image source is a PDF, this function creates a 72 dpi image of the PDF page specified by the index that you pass. You must, however, pass an options dictionary that contains either the `kCGImageSourceCreateThumbnailFromImageIfAbsent` or `kCGImageSourceCreateThumbnailFromImageAlways` keys, with the value of the key set to `TRUE`.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`CGImageSource.h`

CGImageSourceCreateWithData

Creates an image source that reads from a Core Foundation data object.

```
CGImageSourceRef CGImageSourceCreateWithData (
   CFDataRef data,
   CFDictionaryRef options
);
```

Parameters

data

The data object to read from. For more information on data objects, see *CFData Reference* and Data Objects.

options

A dictionary that specifies additional creation options. See "`Image Source Option Dictionary Keys`" (page 250) for the keys you can supply.

Return Value
An image source. You are responsible for releasing this object using `CFRelease`.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`CGImageSource.h`

CGImageSourceCreateWithDataProvider

Creates an image source that reads data from the specified data provider.

```
CGImageSourceRef CGImageSourceCreateWithDataProvider (
   CGDataProviderRef provider,
   CFDictionaryRef options
);
```

Parameters

provider

The data provider to read from. For more information on data providers, see *CGDataProvider Reference* and *Quartz 2D Programming Guide*.

options

A dictionary that specifies additional creation options. See "`Image Source Option Dictionary Keys`" (page 250) for the keys you can supply.

Return Value
An image source. You are responsible for releasing this object using `CFRelease`.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`CGImageSource.h`

CGImageSourceCreateWithURL

Creates an image source that reads from a location specified by a URL.

```
CGImageSourceRef CGImageSourceCreateWithURL (
   CFURLRef url,
   CFDictionaryRef options
);
```

Parameters

url

The URL to read from.

options

A dictionary that specifies additional creation options. See "Image Source Option Dictionary Keys" (page 250) for the keys you can supply.

Return Value
An image source. You are responsible for releasing this object using `CFRelease`.

Availability
Available in Mac OS X version 10.4 and later.

Related Sample Code
CarbonCocoa_PictureCursor

Declared In
`CGImageSource.h`

CGImageSourceGetCount

Returns the number of images (not including thumbnails) in the image source.

```
size_t CGImageSourceGetCount (
   CGImageSourceRef isrc
);
```

Parameters

isrc

An image source.

Return Value
The number of images. If the image source is a multilayered PSD file, the function returns `1`.

Discussion
This function does not extract the layers of a PSD file.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
CGImageSource.h

CGImageSourceGetStatus

Return the status of an image source.

```
CGImageSourceStatus CGImageSourceGetStatus (
   CGImageSourceRef isrc
);
```

Parameters

isrc
An image source.

Return Value
Returns the current status of the image source. See "Image Source Status" (page 249) for a list of possible values.

Discussion
The status is particularly informative for incremental image sources, but may also be used by clients that provide non-incremental data.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
CGImageSource.h

CGImageSourceGetStatusAtIndex

Returns the current status of an image that is at a specified location in an image source.

```
CGImageSourceStatus CGImageSourceGetStatusAtIndex (
   CGImageSourceRef isrc,
   size_t index
);
```

Parameters

isrc
An image source.

index
The index of the image whose status you want to obtain. The index is zero-based.

Return Value
Returns the current status of the image. See "Image Source Status" (page 249) for a list of possible values.

Discussion
The status is particularly informative for incremental image sources, but may also be used by clients that provide non-incremental data.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
CGImageSource.h

CGImageSourceGetType

Returns the uniform type identifier of the source container.

```
CFStringRef CGImageSourceGetType (
   CGImageSourceRef isrc
);
```

Parameters

isrc
An image source.

Return Value
The uniform type identifier of the image.

Discussion
The uniform type identifier (UTI) of the source container can be different from the type of the images in the container. For example, the `.icns` format supports embedded `JPEG2000`. The type of the source container is `"com.apple.icns"` but type of the images is `JPEG2000`.

See Uniform Type Identifier Concepts for a list of system-declared and third-party UTIs.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
CGImageSource.h

CGImageSourceGetTypeID

Returns the unique type identifier of an image source opaque type.

```
CFTypeID CGImageSourceGetTypeID (
   void
);
```

Return Value
Returns the Core Foundation type ID for an image source.

Discussion
A type identifier is an integer that identifies the opaque type to which a Core Foundation object belongs. You use type IDs in various contexts, such as when you are operating on heterogeneous collections. Note that a CFType ID is different from a uniform type identifier (UTI).

Availability
Available in Mac OS X version 10.4 and later.

Declared In
CGImageSource.h

CGImageSourceUpdateData

Updates an incremental image source with new data.

```
void CGImageSourceUpdateData (
   CGImageSourceRef isrc,
   CFDataRef data,
   bool final
);
```

Parameters

isrc

An image source.

data

The data to add to the image source. Each time you call the function `CGImageSourceUpdateData`, the `data` parameter must contain all of the image file data accumulated so far.

final

A value that specifies whether the data is the final set. Pass `true` if it is, `false` otherwise.

Availability

Available in Mac OS X version 10.4 and later.

Declared In

`CGImageSource.h`

CGImageSourceUpdateDataProvider

Updates an incremental image source with a new data provider.

```
void CGImageSourceUpdateDataProvider (
   CGImageSourceRef isrc,
   CGDataProviderRef provider,
   bool final
);
```

Parameters

isrc

An image source.

provider

The new data provider. The new data provider must provide all the previous data supplied to the image source plus any additional new data.

final

A value that specifies whether the data is the final set. Pass `true` if it is, `false` otherwise.

Availability

Available in Mac OS X version 10.4 and later.

Declared In

`CGImageSource.h`

Data Types

CGImageSourceRef

An opaque type that represents an image source.

```
typedef struct CGImageSource *CGImageSourceRef;
```

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGImageSource.h`

Constants

Image Source Status

Status states for images and image sources.

```
enum CGImageSourceStatus {
    kCGImageStatusUnexpectedEOF = -5,
    kCGImageStatusInvalidData = -4,
    kCGImageStatusUnknownType = -3,
    kCGImageStatusReadingHeader = -2,
    kCGImageStatusIncomplete = -1,
    kCGImageStatusComplete = 0
};
typedef enum CGImageSourceStatus CGImageSourceStatus;
```

Constants

`kCGImageStatusUnexpectedEOF`
The end of the file was encountered unexpectedly.
Available in Mac OS X v10.4 and later.
Declared in `CGImageSource.h`.

`kCGImageStatusInvalidData`
The data is not valid.
Available in Mac OS X v10.4 and later.
Declared in `CGImageSource.h`.

`kCGImageStatusUnknownType`
The image is an unknown type.
Available in Mac OS X v10.4 and later.
Declared in `CGImageSource.h`.

`kCGImageStatusReadingHeader`
In the process of reading the header.

Available in Mac OS X v10.4 and later.

Declared in `CGImageSource.h`.

`kCGImageStatusIncomplete`
The operation is not complete

Available in Mac OS X v10.4 and later.

Declared in `CGImageSource.h`.

`kCGImageStatusComplete`
The operation is complete.

Available in Mac OS X v10.4 and later.

Declared in `CGImageSource.h`.

Discussion
These status values are returned by the functions `CGImageSourceGetStatus` (page 246) and `CGImageSourceGetStatusAtIndex` (page 246).

Declared In
`CGImageSource.h`

Image Source Option Dictionary Keys

Keys that you can include in the options dictionary to create an image source.

```
CFStringRef kCGImageSourceTypeIdentifierHint;
CFStringRef kCGImageSourceShouldAllowFloat;
CFStringRef kCGImageSourceShouldCache;
CFStringRef kCGImageSourceCreateThumbnailFromImageIfAbsent;
CFStringRef kCGImageSourceCreateThumbnailFromImageAlways;
CFStringRef kCGImageSourceThumbnailMaxPixelSize;
CFStringRef kCGImageSourceCreateThumbnailWithTransform
```

Constants
`kCGImageSourceTypeIdentifierHint`
The best guess of the uniform type identifier (UTI) for the format of the image source file. If specified, the value of this key must be a CFString object. This key can be provided in the options dictionary when you create a CGImageSource object.

Available in Mac OS X v10.4 and later.

Declared in `CGImageSource.h`.

`kCGImageSourceShouldAllowFloat`
Whether the image should be returned as a CGImage object that uses floating-point values, if supported by the file format. CGImage objects that use extended-range floating-point values may require additional processing to render in a pleasing manner. The value of this key must be a CFBoolean value. The default value is `kCFBooleanFalse`.

Available in Mac OS X v10.4 and later.

Declared in `CGImageSource.h`.

`kCGImageSourceShouldCache`
: Whether the image should be cached in a decoded form. The value of this key must be a CFBoolean value. The default value is `kCFBooleanTrue`. This key can be provided in the options dictionary that you can pass to the functions `CGImageSourceCopyPropertiesAtIndex` (page 241) and `CGImageSourceCreateImageAtIndex` (page 242).

  Available in Mac OS X v10.4 and later.

  Declared in `CGImageSource.h`.

`kCGImageSourceCreateThumbnailFromImageIfAbsent`
: Whether a thumbnail should be automatically created for an image if a thumbnail isn't present in the image source file. The thumbnail is created from the full image, subject to the limit specified by `kCGImageSourceThumbnailMaxPixelSize`. If a maximum pixel size isn't specified, then the thumbnail is the size of the full image, which in most cases is not desirable. This key must be a CFBoolean value. The default value is `kCFBooleanFalse`. This key can be provided in the options dictionary that you pass to the function `CGImageSourceCreateThumbnailAtIndex` (page 243).

  Available in Mac OS X v10.4 and later.

  Declared in `CGImageSource.h`.

`kCGImageSourceCreateThumbnailFromImageAlways`
: Whether a thumbnail should be created from the full image even if a thumbnail is present in the image source file. The thumbnail is created from the full image, subject to the limit specified by `kCGImageSourceThumbnailMaxPixelSize`. If a maximum pixel size isn't specified, then the thumbnail is the size of the full image, which probably isn't what you want. This key must be a CFBoolean value. The default value is `kCFBooleanFalse`. This key can be provided in the options dictionary that you can pass to the function `CGImageSourceCreateThumbnailAtIndex` (page 243).

  Available in Mac OS X v10.4 and later.

  Declared in `CGImageSource.h`.

`kCGImageSourceThumbnailMaxPixelSize`
: The maximum width and height in pixels of a thumbnail. If this key is not specified, the width and height of a thumbnail is not limited and thumbnails may be as big as the image itself. If present, this key must be a CFNumber value. This key can be provided in the options dictionary that you pass to the function `CGImageSourceCreateThumbnailAtIndex` (page 243).

  Available in Mac OS X v10.4 and later.

  Declared in `CGImageSource.h`.

`kCGImageSourceCreateThumbnailWithTransform`
: Whether the thumbnail should be rotated and scaled according to the orientation and pixel aspect ratio of the full image. The value of this key must be a CFBoolean value. The default value is `kCFBooleanFalse`.

  Available in Mac OS X v10.4 and later.

  Declared in `CGImageSource.h`.

Discussion

Except for `kCGImageSourceTypeIdentifierHint`, which you use when creating an image source, these constants specify options that you can set when creating an image from image source. Each constant is a key; you must supply the appropriate value when you add this option to the options dictionary.

Declared In

`CGImageSource.h`

CGLayer Reference

Derived From:	CFType
Framework:	ApplicationServices/ApplicationServices.h
Declared in	CGLayer.h

Overview

CGLayer objects are useful for offscreen drawing and can be used in much the same way that a bitmap context can be used. In fact, a CGLayer object is a much better representation than a bitmap context.

Using CGLayer objects can improve performance, particularly when you need to capture a piece of drawing that you stamp repeatedly (using the same scale factor and orientation). Quartz can cache CGLayer objects to the video card, making drawing a CGLayer to a destination much faster than rendering the equivalent image constructed from a bitmap context.

A CGLayer object is created relative to a graphics context. Although layer uses this graphics context as a reference for initialization, you are not restricted to drawing the layer to this graphics context. You can draw the layer to other graphics contexts, although any limitations of the original context are imposed. For example, if you create a CGLayer object using a bitmap context, the layer is rendered as a bitmap when drawn to any other graphics context.

You can use a CGLayer when you want to apply a shadow to a group of objects (such as a group of circles) rather than to individual objects.

Use these layers in your code whenever you can, especially when:

- You need to reuse a filled or stroked shape.
- You are building a scene and at least some of it can be reused. Put the reusable drawing in its own CGLayer.

Any CG object that you draw repeatedly—including CGPath, CGShading, and CGPDFPage—benefit from improved performance if you draw it to a CGLayer object.

Functions by Task

Creating Layer Objects

`CGLayerCreateWithContext` (page 255)
Creates a CGLayer object that is associated with a graphics context.

Drawing Layer Content

`CGContextDrawLayerInRect` (page 255)
Draws the contents of a CGLayer object into the specified rectangle.

`CGContextDrawLayerAtPoint` (page 254)
Draws the contents of a CGLayer object at the specified point.

Retaining and Releasing Layers

`CGLayerRelease` (page 257)
Decrements the retain count of a CGLayer object.

`CGLayerRetain` (page 258)
Increments the retain count of a CGLayer object.

Getting the CFType ID for a Layer

`CGLayerGetTypeID` (page 257)
Returns the unique type identifier used for CGLayer objects.

Getting Layer Information

`CGLayerGetSize` (page 257)
Returns the width and height of a CGLayer object.

`CGLayerGetContext` (page 256)
Returns the graphics context associated with a CGLayer object.

Functions

CGContextDrawLayerAtPoint

Draws the contents of a CGLayer object at the specified point.

```
void CGContextDrawLayerAtPoint (
   CGContextRef context,
   CGPoint point,
   CGLayerRef layer
);
```

Parameters

context
The graphics context associated with the layer.

point
The location, in current user space coordinates, to use as the origin for the drawing.

layer
The layer whose contents you want to draw.

Discussion
Calling the function `CGContextDrawLayerAtPoint` is equivalent to calling the function `CGContextDrawLayerInRect` with a rectangle that has its origin at `point` and its size equal to the size of the layer.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`CGLayer.h`

CGContextDrawLayerInRect

Draws the contents of a CGLayer object into the specified rectangle.

```
void CGContextDrawLayerInRect (
   CGContextRef context,
   CGRect rect,
   CGLayerRef layer
);
```

Parameters
context
The graphics context associated with the layer.

rect
The rectangle, in current user space coordinates, to draw to.

layer
The layer whose contents you want to draw.

Discussion
The contents are scaled, if necessary, to fit into the rectangle.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`CGLayer.h`

CGLayerCreateWithContext

Creates a CGLayer object that is associated with a graphics context.

```
CGLayerRef CGLayerCreateWithContext (
    CGContextRef context,
    CGSize size,
    CFDictionaryRef auxiliaryInfo
);
```

Parameters

context

The graphics context you want to create the layer relative to. The layer uses this graphics context as a reference for initialization.

size

The size, in default user space units, of the layer relative to the graphics context.

auxiliaryInfo

Reserved for future use. Pass `NULL`.

Return Value

A CGLayer object. You are responsible for releasing this object using the function `CGLayerRelease` (page 257) when you no longer need the layer.

Discussion

After you create a CGLayer object, you should reuse it whenever you can to facilitate the Quartz caching strategy. Quartz caches any objects that are reused, including CGLayer objects. Objects that are reused frequently remain in the cache. In contrast, objects that are used once in a while may be moved in and out of the cache according to their frequency of use. If you don't reuse CGLayer objects, Quartz won't cache them. This means that you lose an opportunity to improve the performance of your application.

Availability

Available in Mac OS X version 10.4 and later.

Declared In

`CGLayer.h`

CGLayerGetContext

Returns the graphics context associated with a CGLayer object.

```
CGContextRef CGLayerGetContext (
    CGLayerRef layer
);
```

Parameters

layer

The layer whose graphics context you want to obtain.

Return Value

The graphics context associated with the layer.

Discussion

The context that's returned is the context for the layer itself, not the context that you specified when you created the layer.

Availability

Available in Mac OS X version 10.4 and later.

Declared In
CGLayer.h

CGLayerGetSize

Returns the width and height of a CGLayer object.

```
CGSize CGLayerGetSize (
    CGLayerRef layer
);
```

Parameters

layer
The layer whose width and height you want to obtain.

Return Value
The width and height of the layer, in default user space coordinates.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
CGLayer.h

CGLayerGetTypeID

Returns the unique type identifier used for CGLayer objects.

```
CFTypeID CGLayerGetTypeID (
    void
);
```

Return Value
The type identifier for CGLayer objects.

Discussion
A type identifier is an integer that identifies the opaque type to which a Core Foundation object belongs. You use type IDs in various contexts, such as when you are operating on heterogeneous collections.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
CGLayer.h

CGLayerRelease

Decrements the retain count of a CGLayer object.

```
void CGLayerRelease (
    CGLayerRef layer
);
```

Parameters

layer

The layer to release.

Discussion

This function is equivalent to calling `CFRelease (layer)` except that it does not crash (as `CFRetain` does) if the `layer` parameter is `null`.

Availability

Available in Mac OS X version 10.4 and later.

Declared In

`CGLayer.h`

CGLayerRetain

Increments the retain count of a CGLayer object.

```
CGLayerRef CGLayerRetain (
    CGLayerRef layer
);
```

Parameters

layer

The layer to retain.

Return Value

The same layer you passed in as the `layer` parameter.

Discussion

This function is equivalent to calling `CFRetain (layer)` except that it does not crash (as `CFRetain` does) if the `layer` parameter is `null`.

Availability

Available in Mac OS X version 10.4 and later.

Declared In

`CGLayer.h`

Data Types

CGLayerRef

An opaque type used for offscreen drawing.

```
typedef struct CGLayer *CGLayerRef;
```

Availability

Available in Mac OS X v10.4 and later.

Declared In
`CGLayer.h`

CGPath Reference

Derived From:	CFType
Framework:	ApplicationServices/ApplicationServices.h
Declared in	CGPath.h
Companion guide	Quartz 2D Programming Guide

Overview

A **graphics path** is a description of a 2D geometric scene using sequences of lines and Bézier curves. `CGPathRef` defines an opaque type that represents an immutable graphics path. `CGMutablePathRef` defines an opaque type that represents a mutable graphics path. To draw using a Quartz path, you need to add the path to a graphics context—see `CGContextAddPath` (page 73).

Each figure in a scene may be described by a **subpath**. A subpath has an ordered set of **path elements**, that represent single steps in the construction of a subpath. (For example, `MoveToPoint (bottom left)` and `AddLineToPoint (bottom right)` are path elements.) A subpath also maintains state information, including a **starting point** and a **current point**. When drawing a path, Quartz traverses each subpath using its path elements and its state.

The lines and curves in a subpath are always connected, but they do not necessarily form a closed figure. Furthermore, subpaths do not need to be connected to each other. For example, you could use a graphics path to draw the outlines of a sequence of text characters.

Functions by Task

Creating and Managing Paths

`CGPathCreateMutable` (page 273)
Creates a mutable graphics path.

`CGPathCreateMutableCopy` (page 273)
Creates a mutable copy of an existing graphics path.

`CGPathCreateCopy` (page 272)
Creates an immutable copy of a graphics path.

`CGPathRelease` (page 277)
Decrements the retain count of a graphics path.

`CGPathRetain` (page 277)
Increments the retain count of a graphics path.

Modifying Quartz Paths

`CGPathAddArc` (page 263)
Appends an arc to a mutable graphics path, possibly preceded by a straight line segment.

`CGPathAddArcToPoint` (page 264)
Appends an arc to a mutable graphics path, possibly preceded by a straight line segment.

`CGPathAddCurveToPoint` (page 265)
Appends a Bézier curve to a mutable graphics path.

`CGPathAddLines` (page 267)
Appends an array of new line segments to a mutable graphics path.

`CGPathAddLineToPoint` (page 267)
Appends a line segment to a mutable graphics path.

`CGPathAddPath` (page 268)
Appends a path to a mutable graphics path.

`CGPathAddQuadCurveToPoint` (page 268)
Appends a quadratic curve to a mutable graphics path.

`CGPathAddRect` (page 269)
Appends a rectangle to a mutable graphics path.

`CGPathAddRects` (page 270)
Appends an array of rectangles to a mutable graphics path.

`CGPathApply` (page 271)
For each element in a graphics path, calls a custom applier function.

`CGPathMoveToPoint` (page 276)
Starts a new subpath at a specified location in a mutable graphics path.

`CGPathCloseSubpath` (page 271)
Closes and completes a subpath in a mutable graphics path.

`CGPathAddEllipseInRect` (page 266)
Adds to a path an ellipse that fits inside a rectangle.

Getting Information about Quartz Paths

`CGPathEqualToPath` (page 274)
Indicates whether two graphics paths are equivalent.

`CGPathGetBoundingBox` (page 274)
Returns the bounding box of a graphics path.

`CGPathGetCurrentPoint` (page 274)
Returns the current point in a graphics path.

`CGPathGetTypeID` (page 275)
Returns the Core Foundation type identifier for Quartz graphics paths.

`CGPathIsEmpty` (page 275)
Indicates whether or not a graphics path is empty.

`CGPathIsRect` (page 276)
Indicates whether or not a graphics path represents a rectangle.

`CGPathContainsPoint` (page 272)
Checks whether a point is contained in a graphics path.

Functions

CGPathAddArc

Appends an arc to a mutable graphics path, possibly preceded by a straight line segment.

```
void CGPathAddArc (
   CGMutablePathRef path,
   const CGAffineTransform *m,
   CGFloat x,
   CGFloat y,
   CGFloat radius,
   CGFloat startAngle,
   CGFloat endAngle,
   bool clockwise
);
```

Parameters

path
The mutable graphics path to change.

m
A pointer to an affine transformation matrix, or `NULL` if no transformation is needed. If specified, Quartz applies the transformation to the arc before it is added to the path.

x
The x-coordinate of the center point of the arc.

y
The y-coordinate of the center point of the arc.

r
The radius of the arc.

startAngle
The angle (in radians) from horizontal that determines the starting point of the arc.

endAngle
The angle (in radians) from horizontal that determines the ending point of the arc.

clockwise
A Boolean value that specifies whether or not to draw the arc in the clockwise direction; `true` specifies clockwise.

Discussion
An arc is a segment of a circle with radius r centered at a point `(x,y)`. When you call this function, you provide the center point, radius, and two angles in radians. Quartz uses this information to determine the end points of the arc, and then approximates the new arc using a sequence of cubic Bézier curves. The `clockwise` parameter determines the direction in which the arc is drawn.

A transformation may be applied to the Bézier curves before they are added to the path. If no transform is needed, the second argument should be `NULL`.

If the specified path already contains a subpath, Quartz implicitly adds a line connecting the current point to the beginning of the arc. If the path is empty, Quartz creates a new subpath for the arc and does not add the initial straight line segment.

The ending point of the arc becomes the new current point of the path.

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CGPath.h`

CGPathAddArcToPoint

Appends an arc to a mutable graphics path, possibly preceded by a straight line segment.

```
void CGPathAddArcToPoint (
   CGMutablePathRef path,
   const CGAffineTransform *m,
   CGFloat x1,
   CGFloat y1,
   CGFloat x2,
   CGFloat y2,
   CGFloat radius
);
```

Parameters

path

The mutable path to change. The path must not be empty.

m

A pointer to an affine transformation matrix, or `NULL` if no transformation is needed. If specified, Quartz applies the transformation to the arc before it is added to the path.

x1

The x-coordinate of the user space for the end point of the first tangent line. The first tangent line is drawn from the current point to `(x1,y1)`.

y1

The y-coordinate of the user space for the end point of the first tangent line. The first tangent line is drawn from the current point to `(x1,y1)`.

x2

The x-coordinate of the user space for the end point of the second tangent line. The second tangent line is drawn from `(x1,y1)` to `(x2,y2)`.

y2

The y-coordinate of the user space for the end point of the second tangent line. The second tangent line is drawn from `(x1,y1)` to `(x2,y2)`.

radius

The radius of the arc, in user space coordinates.

Discussion

This function uses a sequence of cubic Bézier curves to draw an arc that is tangent to the line from the current point to (x1,y1) and to the line from (x1,y1) to (x2,y2). The start and end points of the arc are located on the first and second tangent lines, respectively. The start and end points of the arc are also the "tangent points" of the lines.

If the current point and the first tangent point of the arc (the starting point) are not equal, Quartz appends a straight line segment from the current point to the first tangent point. After adding the arc, the current point is reset to the end point of the arc (the second tangent point).

For another way to draw an arc in a path, see `CGPathAddArc` (page 263).

Availability

Available in Mac OS X version 10.2 and later.

Declared In

`CGPath.h`

CGPathAddCurveToPoint

Appends a Bézier curve to a mutable graphics path.

```
void CGPathAddCurveToPoint (
   CGMutablePathRef path,
   const CGAffineTransform *m,
   CGFloat cp1x,
   CGFloat cp1y,
   CGFloat cp2x,
   CGFloat cp2y,
   CGFloat x,
   CGFloat y
);
```

Parameters

path

The mutable path to change. The path must not be empty.

m

A pointer to an affine transformation matrix, or `NULL` if no transformation is needed. If specified, Quartz applies the transformation to the curve before it is added to the path.

cx1

The x-coordinate of the first control point.

cy1

The y-coordinate of the first control point.

cx2

The x-coordinate of the second control point.

cy2
The y-coordinate of the second control point.

x
The x-coordinate of the end point of the curve.

y
The y-coordinate of the end point of the curve.

Discussion
Appends a cubic Bézier curve from the current point in a path to the specified location using two control points, after an optional transformation. Before returning, this function updates the current point to the specified location `(x,y)`.

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CGPath.h`

CGPathAddEllipseInRect

Adds to a path an ellipse that fits inside a rectangle.

```
void CGPathAddEllipseInRect (
   CGMutablePathRef path,
   const CGAffineTransform *m,
   CGRect rect
);
```

Parameters

path
The path to modify.

m
An affine transform to apply to the ellipse, or `NULL` if you don't want to transform the ellipse.

rect
A rectangle to enclose the ellipse.

Discussion
The ellipse is approximated by a sequence of Bézier curves. Its center is the midpoint of the rectangle defined by the `rect` parameter. If the rectangle is square, then the ellipse is circular with a radius equal to one-half the width (or height) of the rectangle. If the `rect` parameter specifies a rectangular shape, then the major and minor axes of the ellipse are defined by the width and height of the rectangle.

The ellipse forms a complete subpath of the path—that is, the ellipse drawing starts with a move-to operation and ends with a close-subpath operation, with all moves oriented in the clockwise direction. If you supply an affine transform, then the constructed Bézier curves that define the ellipse are transformed before they are added to the path.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGPath.h`

CGPathAddLines

Appends an array of new line segments to a mutable graphics path.

```
void CGPathAddLines (
   CGMutablePathRef path,
   const CGAffineTransform *m,
   const CGPoint points[],
   size_t count
);
```

Parameters

path

The mutable path to change.

m

A pointer to an affine transformation matrix, or `NULL` if no transformation is needed. If specified, Quartz applies the transformation to the lines before adding them to the path.

points

An array of points that specifies the line segments to add.

count

The number of elements in the array.

Discussion

This is a convenience function that adds a sequence of connected line segments to a path, using the following operation:

```
CGPathMoveToPoint (path, m, points[0].x, points[0].y);
for (k = 1; k < count; k++) {
    CGPathAddLineToPoint (path, m, points[k].x, points[k].y);
}
```

Availability

Available in Mac OS X version 10.2 and later.

Declared In

`CGPath.h`

CGPathAddLineToPoint

Appends a line segment to a mutable graphics path.

```
void CGPathAddLineToPoint (
   CGMutablePathRef path,
   const CGAffineTransform *m,
   CGFloat x,
   CGFloat y
);
```

Parameters

path

The mutable path to change. The path must not be empty.

m

A pointer to an affine transformation matrix, or `NULL` if no transformation is needed. If specified, Quartz applies the transformation to the line before it is added to the path.

x
The x-coordinate of the end point of the line.

y
The y-coordinate of the end point of the line.

Discussion
Before returning, this function updates the current point to the specified location `(x,y)`.

Availability
Available in Mac OS X version 10.2 and later.

Related Sample Code
CALayerEssentials

Declared In
`CGPath.h`

CGPathAddPath

Appends a path to a mutable graphics path.

```
void CGPathAddPath (
   CGMutablePathRef path1,
   const CGAffineTransform *m,
   CGPathRef path2
);
```

Parameters

path1
The mutable path to change.

m
A pointer to an affine transformation matrix, or `NULL` if no transformation is needed. If specified, Quartz applies the transformation to `path2` before it is added to `path1`.

path2
The path to add.

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CGPath.h`

CGPathAddQuadCurveToPoint

Appends a quadratic curve to a mutable graphics path.

```
void CGPathAddQuadCurveToPoint (
   CGMutablePathRef path,
   const CGAffineTransform *m,
   CGFloat cpx,
   CGFloat cpy,
   CGFloat x,
   CGFloat y
);
```

Parameters

path

The mutable path to change. The path must not be empty.

m

A pointer to an affine transformation matrix, or `NULL` if no transformation is needed. If specified, Quartz applies the transformation to the curve before adding it to the path.

cx

The x-coordinate of the control point.

cy

The y-coordinate of the control point.

x

The x-coordinate of the end point of the curve.

y

The y-coordinate of the end point of the curve.

Discussion

Before returning, this function updates the current point to the specified location `(x, y)`.

Availability

Available in Mac OS X version 10.2 and later.

Declared In

`CGPath.h`

CGPathAddRect

Appends a rectangle to a mutable graphics path.

```
void CGPathAddRect (
   CGMutablePathRef path,
   const CGAffineTransform *m,
   CGRect rect
);
```

Parameters

path

The mutable path to change.

m

A pointer to an affine transformation matrix, or `NULL` if no transformation is needed. If specified, Quartz applies the transformation to the rectangle before adding it to the path.

rect

The rectangle to add.

Discussion
This is a convenience function that adds a rectangle to a path, using the following sequence of operations:

```
// start at origin
CGPathMoveToPoint (path, m, CGRectGetMinX(rect), CGRectGetMinY(rect));

// add bottom edge
CGPathAddLineToPoint (path, m, CGRectGetMaxX(rect), CGRectGetMinY(rect));

// add right edge
CGPathAddLineToPoint (path, m, CGRectGetMaxX(rect), CGRectGetMaxY(rect);

// add top edge
CGPathAddLineToPoint (path, m, CGRectGetMinX(rect), CGRectGetMaxY(rect));

// add left edge and close
CGPathCloseSubpath (path);
```

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CGPath.h`

CGPathAddRects

Appends an array of rectangles to a mutable graphics path.

```
void CGPathAddRects (
   CGMutablePathRef path,
   const CGAffineTransform *m,
   const CGRect rects[],
   size_t count
);
```

Parameters

path
The mutable path to change.

m
An affine transformation matrix, or `NULL` if no transformation is needed. If specified, Quartz applies the transformation to the rectangles before adding them to the path.

rects
The array of new rectangles to add.

count
The number of elements in the array.

Discussion
This is a convenience function that adds an array of rectangles to a path, using the following operation:

```
for (k = 0; k < count; k++) {
    CGPathAddRect (path, m, rects[k]);
}
```

Availability
Available in Mac OS X version 10.2 and later.

Declared In
CGPath.h

CGPathApply

For each element in a graphics path, calls a custom applier function.

```
void CGPathApply (
   CGPathRef path,
   void *info,
   CGPathApplierFunction function
);
```

Parameters

path
The path to which the function will be applied.

info
A pointer to the user data that Quartz will pass to the function being applied, or NULL.

function
A pointer to the function to apply. See CGPathApplierFunction (page 278) for more information.

Discussion
For each element in the specified path, Quartz calls the applier function, which can examine (but not modify) the element.

Availability
Available in Mac OS X version 10.2 and later.

Declared In
CGPath.h

CGPathCloseSubpath

Closes and completes a subpath in a mutable graphics path.

```
void CGPathCloseSubpath (
   CGMutablePathRef path
);
```

Parameters

path
The path to change.

Discussion
Appends a line from the current point in a path to the starting point of the current subpath and ends the subpath. On return, the current point is now the previous starting point.

Availability
Available in Mac OS X version 10.2 and later.

Related Sample Code
CALayerEssentials

Declared In
CGPath.h

CGPathContainsPoint

Checks whether a point is contained in a graphics path.

```
bool CGPathContainsPoint (
   CGPathRef path,
   const CGAffineTransform *m,
   CGPoint point,
   bool eoFill
);
```

Parameters

path

The path to evaluate the point against.

m

An affine transform. If `m` is not `NULL` then the point is transformed by this affine transform prior to determining whether the path contains the point.

point

The point to check.

eoFill

A Boolean value that, if `true`, specifies to use the even-odd fill rule to evaluate the painted region of the path. If `false`, the winding fill rule is used.

Return Value
Returns `true` if the point is contained in the path; `false` otherwise.

Discussion
A point is contained in a path if it is inside the painted region when the path is filled and the path is a closed path. You can call the function `CGPathCloseSubpath` to ensure that a path is closed.

Availability
Available in Mac OS X v10.4 and later.

Declared In
CGPath.h

CGPathCreateCopy

Creates an immutable copy of a graphics path.

```
CGPathRef CGPathCreateCopy (
   CGPathRef path
);
```

Parameters

path

The path to copy.

Return Value
A new, immutable copy of the specified path. You are responsible for releasing this object.

Availability
Available in Mac OS X version 10.2 and later.

Declared In
CGPath.h

CGPathCreateMutable

Creates a mutable graphics path.

```
CGMutablePathRef CGPathCreateMutable (
   void
);
```

Return Value
A new mutable path. You are responsible for releasing this object.

Availability
Available in Mac OS X version 10.2 and later.

Related Sample Code
CALayerEssentials

Declared In
CGPath.h

CGPathCreateMutableCopy

Creates a mutable copy of an existing graphics path.

```
CGMutablePathRef CGPathCreateMutableCopy (
   CGPathRef path
);
```

Parameters

path
The path to copy.

Return Value
A new, mutable, copy of the specified path. You are responsible for releasing this object.

Discussion
You can modify a mutable graphics path by calling the various CGPath geometry functions, such as CGPathAddArc (page 263), CGPathAddLineToPoint (page 267), and CGPathMoveToPoint (page 276).

Availability
Available in Mac OS X version 10.2 and later.

Declared In
CGPath.h

CGPathEqualToPath

Indicates whether two graphics paths are equivalent.

```
bool CGPathEqualToPath (
   CGPathRef path1,
   CGPathRef path2
);
```

Parameters

path1

The first path being compared.

path2

The second path being compared.

Return Value

A Boolean value that indicates whether or not the two specified paths contain the same sequence of path elements. If the paths are not the same, returns `false`.

Availability

Available in Mac OS X version 10.2 and later.

Declared In

`CGPath.h`

CGPathGetBoundingBox

Returns the bounding box of a graphics path.

```
CGRect CGPathGetBoundingBox (
   CGPathRef path
);
```

Parameters

path

The graphics path to evaluate.

Return Value

A rectangle that represents the bounding box of the specified path.

Discussion

The bounding box is the smallest rectangle completely enclosing all points in the path, including control points for Bézier and quadratic curves.

Availability

Available in Mac OS X version 10.2 and later.

Declared In

`CGPath.h`

CGPathGetCurrentPoint

Returns the current point in a graphics path.

```
CGPoint CGPathGetCurrentPoint (
   CGPathRef path
);
```

Parameters

path

The path to evaluate.

Return Value
The current point in the specified path.

Discussion
If the path is empty—that is, if it has no elements—this function returns `CGPointZero` (see `CGGeometry`). To determine whether a path is empty, use `CGPathIsEmpty` (page 275).

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CGPath.h`

CGPathGetTypeID

Returns the Core Foundation type identifier for Quartz graphics paths.

```
CFTypeID CGPathGetTypeID (
   void
);
```

Return Value
The Core Foundation identifier for the opaque type `CGPathRef` (page 278).

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CGPath.h`

CGPathIsEmpty

Indicates whether or not a graphics path is empty.

```
bool CGPathIsEmpty (
   CGPathRef path
);
```

Parameters

path

The path to evaluate.

Return Value
A Boolean value that indicates whether the specified path is empty.

Discussion
An empty path contains no elements.

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CGPath.h`

CGPathIsRect

Indicates whether or not a graphics path represents a rectangle.

```
bool CGPathIsRect (
   CGPathRef path,
   CGRect *rect
);
```

Parameters

path

The path to evaluate.

rect

On input, a pointer to an uninitialized rectangle. If the specified path represents a rectangle, on return contains a copy of the rectangle.

Return Value
A Boolean value that indicates whether the specified path represents a rectangle. If the path represents a rectangle, returns `true`.

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CGPath.h`

CGPathMoveToPoint

Starts a new subpath at a specified location in a mutable graphics path.

```
void CGPathMoveToPoint (
   CGMutablePathRef path,
   const CGAffineTransform *m,
   CGFloat x,
   CGFloat y
);
```

Parameters

path

The mutable path to change.

m

A pointer to an affine transformation matrix, or `NULL` if no transformation is needed. If specified, Quartz applies the transformation to the point before changing the path.

x

The x-coordinate of the new location.

y
The y-coordinate of the new location.

Discussion
This function initializes the starting point and the current point to the specified location (x,y) after an optional transformation.

Availability
Available in Mac OS X version 10.2 and later.

Related Sample Code
CALayerEssentials

Declared In
`CGPath.h`

CGPathRelease

Decrements the retain count of a graphics path.

```
void CGPathRelease (
   CGPathRef path
);
```

Parameters
path
The graphics path to release.

Discussion
This function is equivalent to `CFRelease`, except that it does not cause an error if the `path` parameter is `NULL`.

Availability
Available in Mac OS X version 10.2 and later.

Related Sample Code
CALayerEssentials

Declared In
`CGPath.h`

CGPathRetain

Increments the retain count of a graphics path.

```
CGPathRef CGPathRetain (
   CGPathRef path
);
```

Parameters
path
The graphics path to retain.

Return Value
The same path you passed in as the `path` parameter.

Discussion
This function is equivalent to `CFRetain`, except that it does not cause an error if the `path` parameter is `NULL`.

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CGPath.h`

Callbacks

CGPathApplierFunction

Defines a callback function that can view an element in a graphics path.

```
typedef void (*CGPathApplierFunction) (
    void *info,
    const CGPathElement *element
);
```

If you name your function `MyCGPathApplierFunc`, you would declare it like this:

```
void MyCGPathApplierFunc (
   void *info,
  const CGPathElement *element
);
```

Discussion
See also `CGPathApply` (page 271).

Availability
Available in Mac OS X v10.2 and later.

Declared In
`CGPath.h`

Data Types

CGPathRef

An opaque type that represents an immutable graphics path.

```
typedef const struct CGPath *CGPathRef;
```

Availability
Available in Mac OS X v10.2 and later.

Declared In
CGPath.h

CGMutablePathRef

An opaque type that represents a mutable graphics path.

```
typedef struct CGPath *CGMutablePathRef;
```

Availability
Available in Mac OS X v10.2 and later.

Declared In
CGPath.h

CGPathElement

A data structure that provides information about a path element.

```
struct CGPathElement {
    CGPathElementType type;
    CGPoint * points;
};
typedef struct CGPathElement CGPathElement;
```

Fields
`type`
An element type (or operation).
`points`
An array of one or more points that serve as arguments.

Availability
Available in Mac OS X v10.2 and later.

Declared In
CGPath.h

Constants

Path Drawing Modes

Options for rendering a path.

```
enum CGPathDrawingMode {
    kCGPathFill,
    kCGPathEOFill,
    kCGPathStroke,
    kCGPathFillStroke,
    kCGPathEOFillStroke
};
typedef enum CGPathDrawingMode CGPathDrawingMode;
```

Constants

`kCGPathFill`
Render the area contained within the path using the non-zero winding number rule.
Available in Mac OS X v10.0 and later.
Declared in `CGContext.h`.

`kCGPathEOFill`
Render the area within the path using the even-odd rule.
Available in Mac OS X v10.0 and later.
Declared in `CGContext.h`.

`kCGPathStroke`
Render a line along the path.
Available in Mac OS X v10.0 and later.
Declared in `CGContext.h`.

`kCGPathFillStroke`
First fill and then stroke the path, using the nonzero winding number rule.
Available in Mac OS X v10.0 and later.
Declared in `CGContext.h`.

`kCGPathEOFillStroke`
First fill and then stroke the path, using the even-odd rule.
Available in Mac OS X v10.0 and later.
Declared in `CGContext.h`.

Discussion
You can pass a path drawing mode constant to the function `CGContextDrawPath` (page 87) to specify how Quartz should paint a graphics context's current path.

Path Element Types

The type of element found in a path.

```
enum CGPathElementType {
    kCGPathElementMoveToPoint,
    kCGPathElementAddLineToPoint,
    kCGPathElementAddQuadCurveToPoint,
    kCGPathElementAddCurveToPoint,
    kCGPathElementCloseSubpath
};
typedef enum CGPathElementType CGPathElementType;
```

Constants

`kCGPathElementMoveToPoint`
The path element that starts a new subpath. See the function `CGPathMoveToPoint` (page 276).

Available in Mac OS X v10.2 and later.

Declared in `CGPath.h`.

`kCGPathElementAddLineToPoint`
The path element that adds a line from the current point to the specified point. See the function `CGPathAddLineToPoint` (page 267).

Available in Mac OS X v10.2 and later.

Declared in `CGPath.h`.

`kCGPathElementAddQuadCurveToPoint`
The path element that adds a quadratic curve from the current point to the specified point. See the function `CGPathAddQuadCurveToPoint` (page 268).

Available in Mac OS X v10.2 and later.

Declared in `CGPath.h`.

`kCGPathElementAddCurveToPoint`
The path element that adds a cubic curve from the current point to the specified point. See the function `CGPathAddCurveToPoint` (page 265).

Available in Mac OS X v10.2 and later.

Declared in `CGPath.h`.

`kCGPathElementCloseSubpath`
The path element that closes and completes a subpath. See the function `CGPathCloseSubpath` (page 271).

Available in Mac OS X v10.2 and later.

Declared in `CGPath.h`.

Discussion
For more information about paths, see `CGPathRef` (page 278).

CGPattern Reference

Derived From:	CFType
Framework:	ApplicationServices/ApplicationServices.h
Declared in	CGPattern.h
Companion guide	Quartz 2D Programming Guide

Overview

The `CGPatternRef` opaque type represents a pattern that you can use to stroke along or fill in a graphics path. Quartz tiles the pattern cell for you, based on parameters you specify when you call `CGPatternCreate` (page 284).

To create a dashed line, see `CGContextSetLineDash` (page 117) in *CGContext Reference*.

Functions by Task

Creating a Pattern

`CGPatternCreate` (page 284)
Creates a pattern object.

Getting the CFType ID

`CGPatternGetTypeID` (page 285)
Returns the type identifier for Quartz patterns.

Retaining and Releasing a Pattern

`CGPatternRetain` (page 286)
Increments the retain count of a Quartz pattern.

`CGPatternRelease` (page 285)
Decrements the retain count of a Quartz pattern.

Functions

CGPatternCreate

Creates a pattern object.

```
CGPatternRef CGPatternCreate (
   void *info,
   CGRect bounds,
   CGAffineTransform matrix,
   CGFloat xStep,
   CGFloat yStep,
   CGPatternTiling tiling,
   bool isColored,
   const CGPatternCallbacks *callbacks
);
```

Parameters

info

A pointer to private storage used by your pattern drawing function, or `NULL`. For more information, see the discussion below.

bounds

The bounding box of the pattern cell, specified in pattern space. (Pattern space is an abstract space that maps to the default user space by the transformation matrix you specify with the `matrix` parameter.) The drawing done in your pattern drawing function is clipped to this rectangle.

matrix

A matrix that represents a transform from pattern space to the default user space of the context in which the pattern is used. If no transform is needed, pass the identity matrix.

xStep

The horizontal displacement between cells, specified in pattern space. For no additional horizontal space between cells (so that each pattern cells abuts the previous pattern cell in the horizontal direction), pass the width of the pattern cell.

yStep

The vertical displacement between cells, specified in pattern space. For no additional vertical space between cells (so that each pattern cells abuts the previous pattern cell in the vertical direction), pass the height of the pattern cell.

tiling

A `CGPatternTiling` constant that specifies the desired tiling method. For more information about tiling methods, see "Tiling Patterns" (page 289).

isColored

If you want to draw your pattern using its own intrinsic color, pass `true`. If you want to draw an uncolored (or masking) pattern that uses the fill or stroke color in the graphics state, pass `false`.

callbacks

A pointer to a pattern callback function table—your pattern drawing function is an entry in this table. See `CGPatternCallbacks` (page 288) for more information about callback function tables for patterns.

Return Value

A new Quartz pattern. You are responsible for releasing this object using `CGPatternRelease` (page 285).

Discussion
Quartz calls your drawing function at the appropriate time to draw the pattern cell. A pattern cell must be invariant—that is, the pattern cell should be drawn exactly the same way each time the drawing function is called.

The appearance of a pattern cell is unaffected by changes in the graphics state of the context in which the pattern is used.

See `CGPatternDrawPatternCallback` (page 286) for more information about pattern drawing functions.

Availability
Available in Mac OS X version 10.1 and later.

Declared In
`CGPattern.h`

CGPatternGetTypeID

Returns the type identifier for Quartz patterns.

```
CFTypeID CGPatternGetTypeID (
    void
);
```

Return Value
The identifier for the opaque type `CGPatternRef` (page 288).

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CGPattern.h`

CGPatternRelease

Decrements the retain count of a Quartz pattern.

```
void CGPatternRelease (
   CGPatternRef pattern
);
```

Parameters
pattern
The pattern to release.

Discussion
This function is equivalent to `CFRelease`, except that it does not cause an error if the *pattern* parameter is `NULL`.

Availability
Available in Mac OS X version 10.1 and later.

Declared In
`CGPattern.h`

CGPatternRetain

Increments the retain count of a Quartz pattern.

```
CGPatternRef CGPatternRetain (
   CGPatternRef pattern
);
```

Parameters

pattern

The pattern to retain.

Return Value

The same pattern you passed in as the `pattern` parameter.

Discussion

This function is equivalent to `CFRetain`, except that it does not cause an error if the `pattern` parameter is `NULL`.

Availability

Available in Mac OS X version 10.1 and later.

Declared In

`CGPattern.h`

Callbacks

CGPatternDrawPatternCallback

Draws a pattern cell.

```
typedef void (*CGPatternDrawPatternCallback) (
   void * info,
    CGContextRef context
);
```

If you name your function `MyDrawPattern`, you would declare it like this:

```
void MyDrawPattern (
    void * info,
    CGContextRef context
);
```

Parameters

info

A generic pointer to private data associated with the pattern. This is the same pointer you supplied to `CGPatternCreate` (page 284).

context

The graphics context for drawing the pattern cell.

Discussion
When a pattern is used to stroke or fill a graphics path, Quartz calls your custom drawing function at the appropriate time to draw the pattern cell. The cell should be drawn exactly the same way each time the drawing function is called.

In a drawing function associated with an uncolored pattern, you should not attempt to set a stroke or fill color or color space—if you do so, the result is undefined.

To learn how to associate your drawing function with a Quartz pattern, see `CGPatternCreate` (page 284) and `CGPatternCallbacks` (page 288).

Availability
Available in Mac OS X v10.2 and later.

Declared In
`CGPattern.h`

CGPatternReleaseInfoCallback

Release private data or resources associated with the pattern.

```
typedef void (*CGPatternReleaseInfoCallback) (
    void * info
);
```

If you name your function `MyCGPatternReleaseInfo`, you would declare it like this:

```
void MyCGPatternReleaseInfo (
    void * info
);
```

Parameters

info

A generic pointer to private data shared among your callback functions. This is the same pointer you supplied to `CGPatternCreate` (page 284).

Discussion
Quartz calls your release function when it frees your pattern object.

To learn how to associate your release function with a Quartz pattern, see `CGPatternCreate` (page 284) and `CGPatternCallbacks` (page 288).

Availability
Available in Mac OS X v10.2 and later.

Declared In
`CGPattern.h`

Data Types

CGPatternRef

An opaque type that represents a pattern.

```
typedef struct CGPattern * CGPatternRef;
```

Availability
Available in Mac OS X v10.1 and later.

Declared In
`CGPattern.h`

CGPatternCallbacks

A structure that holds a version and two callback functions for drawing a custom pattern.

```
struct CGPatternCallbacks {
    unsigned int version;
    CGPatternDrawPatternCallback drawPattern;
    CGPatternReleaseInfoCallback releaseInfo;
};
typedef struct CGPatternCallbacks CGPatternCallbacks;
```

Fields

`version`
: The version of the structure passed in as a parameter to the `CGPatternCreate` (page 284). For this version of the structure, you should set this value to zero.

`drawPattern`
: A pointer to a custom function that draws the pattern. For information about this callback function, see `CGPatternDrawPatternCallback` (page 286).

`releaseInfo`
: An optional pointer to a custom function that's invoked when the pattern is released. `CGPatternReleaseInfoCallback` (page 287).

Discussion
You supply a `CGPatternCallbacks` structure to the function `CGPatternCreate` (page 284) to create a data provider for direct access. The functions specified by the `CGPatternCallbacks` structure are responsible for drawing the pattern and for handling the pattern's memory management.

Availability
Available in Mac OS X v10.1 and later.

Declared In
`CGPattern.h`

Constants

Tiling Patterns

Different methods for rendering a tiled pattern.

```
enum CGPatternTiling {
    kCGPatternTilingNoDistortion,
    kCGPatternTilingConstantSpacingMinimalDistortion,
    kCGPatternTilingConstantSpacing
};
typedef enum CGPatternTiling CGPatternTiling;
```

Constants

`kCGPatternTilingNoDistortion`

The pattern cell is not distorted when painted. The spacing between pattern cells may vary by as much as 1 device pixel.

Available in Mac OS X v10.1 and later.

Declared in `CGPattern.h`.

`kCGPatternTilingConstantSpacingMinimalDistortion`

Pattern cells are spaced consistently. The pattern cell may be distorted by as much as 1 device pixel when the pattern is painted.

Available in Mac OS X v10.1 and later.

Declared in `CGPattern.h`.

`kCGPatternTilingConstantSpacing`

Pattern cells are spaced consistently, as with `kCGPatternTilingConstantSpacingMinimalDistortion`. The pattern cell may be distorted additionally to permit a more efficient implementation.

Available in Mac OS X v10.1 and later.

Declared in `CGPattern.h`.

Declared In

`CGPattern.h`

CGPDFArray Reference

Derived From:	None
Framework:	ApplicationServices/ApplicationServices.h
Declared in	CGPDFArray.h
Companion guide	Quartz 2D Programming Guide

Overview

The CGPDFArray header file defines an opaque type that encapsulates a PDF array. A PDF array represents an array structure in a PDF document. PDF arrays may be heterogeneous—that is, they may contain any other PDF objects, including PDF strings, PDF dictionaries, and other PDF arrays.

Many CGPDFArray functions to retrieve values from a PDF array take the form:

```
bool CGPDFArrayGet<DataType> (
 CGPDFArrayRef array,
 size_t index,
 <DataType>Ref *value
);
```

These functions test the data type of the object at the specified index. If the object is not of the expected type, the function returns `false`. If the object is of the expected type, the function returns `true`, and the object is passed back in the `value` parameter.

This opaque type is not derived from CFType and therefore there are no functions for retaining and releasing it. CGPDFArray objects exist only as constituent parts of a CGPDFDocument object, and they are managed by their container.

Functions

CGPDFArrayGetArray

Returns whether an object at a given index in a PDF array is another PDF array and, if so, retrieves that array.

```
bool CGPDFArrayGetArray (
   CGPDFArrayRef array,
   size_t index,
   CGPDFArrayRef *value
);
```

Parameters

array

A PDF array. If this parameter is not a valid PDF array, the behavior is undefined.

index

The index of the value to retrieve. If the index is outside the index space of the array (`0` to `N-1`, where `N` is the count of the array), the behavior is undefined.

value

On input, a pointer to a PDF array. If the value at the specified index is a PDF array, then on return that array, otherwise the value is unspecified.

Return Value
Returns `true` if there is a PDF array at the specified index, otherwise `false`.

Availability
Available in Mac OS X version 10.3 and later.

Declared In
`CGPDFArray.h`

CGPDFArrayGetBoolean

Returns whether an object at a given index in a PDF array is a PDF Boolean and, if so, retrieves that Boolean.

```
bool CGPDFArrayGetBoolean (
   CGPDFArrayRef array,
   size_t index,
   CGPDFBoolean *value
);
```

Parameters

array

A PDF array. If this parameter is not a valid PDF array, the behavior is undefined.

index

The index of the value to retrieve. If the index is outside the index space of `array` (`0` to `N-1`, where `N` is the count of `array`), the behavior is undefined.

value

On input, a pointer to a PDF Boolean. If the value at the specified index is a PDF Boolean, then on return that Boolean, otherwise the value is undefined.

Return Value
Returns `true` if there is a PDF Boolean at the specified index, otherwise `false`.

Availability
Available in Mac OS X version 10.3 and later.

Declared In
`CGPDFArray.h`

CGPDFArrayGetCount

Returns the number of items in a PDF array.

```
size_t CGPDFArrayGetCount (
   CGPDFArrayRef array
);
```

Parameters

array

A PDF array. If this parameter is not a valid PDF array, the behavior is undefined.

Return Value

Returns the number of items in the array.

Availability

Available in Mac OS X version 10.3 and later.

Declared In

`CGPDFArray.h`

CGPDFArrayGetDictionary

Returns whether an object at a given index in a PDF array is a PDF dictionary and, if so, retrieves that dictionary.

```
bool CGPDFArrayGetDictionary (
   CGPDFArrayRef array,
   size_t index,
   CGPDFDictionaryRef *value
);
```

Parameters

array

A PDF array. If this parameter is not a valid PDF array, the behavior is undefined.

index

The index of the value to retrieve. If the index is outside the index space of the array (`0` to `N-1`, where `N` is the count of the array), the behavior is undefined.

value

On input, a pointer to a PDF dictionary. If the value at the specified index is a PDF dictionary, then on return that dictionary, otherwise the value is undefined.

Return Value

Returns `true` if there is a PDF dictionary at the specified index, otherwise `false`.

Availability

Available in Mac OS X version 10.3 and later.

Declared In

`CGPDFArray.h`

CGPDFArrayGetInteger

Returns whether an object at a given index in a PDF array is a PDF integer and, if so, retrieves that object.

```
bool CGPDFArrayGetInteger (
   CGPDFArrayRef array,
   size_t index,
   CGPDFInteger *value
);
```

Parameters

array

A PDF array. If this parameter is not a valid PDF array, the behavior is undefined.

index

The index of the value to retrieve. If the index is outside the index space of the array (`0` to `N-1`, where `N` is the count of the array), the behavior is undefined.

value

On input, a pointer to a PDF integer. If the value at the specified index is a PDF integer value, then on return contains that value, otherwise the value is undefined.

Return Value
Returns `true` if there is a PDF integer at the specified index, otherwise `false`.

Availability
Available in Mac OS X version 10.3 and later.

Declared In
`CGPDFArray.h`

CGPDFArrayGetName

Returns whether an object at a given index in a PDF array is a PDF name reference (represented as a constant C string) and, if so, retrieves that name.

```
bool CGPDFArrayGetName (
   CGPDFArrayRef array,
   size_t index,
   const char **value
);
```

Parameters

array

A PDF array. If this parameter is not a valid PDF array, the behavior is undefined.

index

The index of the value to retrieve. If the index is outside the index space of the array (`0` to `N-1`, where `N` is the count of the array), the behavior is undefined.

value

An uninitialized pointer to a constant C string. If the value at the specified index is a reference to a PDF name (represented by a constant C string) then upon return, contains that value; otherwise the value is undefined.

Return Value
Returns `true` if there is an array of characters at the specified index, otherwise `false`.

Availability
Available in Mac OS X version 10.3 and later.

Declared In
CGPDFArray.h

CGPDFArrayGetNull

Returns whether an object at a given index in a Quartz PDF array is a PDF null.

```
bool CGPDFArrayGetNull (
   CGPDFArrayRef array,
   size_t index
);
```

Parameters

array

A PDF array. If this parameter is not a valid PDF array, the behavior is undefined.

index

The index of the value to retrieve. If the index is outside the index space of the array (`0` to `N-1`, where `N` is the count of the array), the behavior is undefined.

Return Value
Returns `true` if there is a PDF null at the specified index, otherwise `false`.

Availability
Available in Mac OS X version 10.3 and later.

Declared In
CGPDFArray.h

CGPDFArrayGetNumber

Returns whether an object at a given index in a PDF array is a PDF number and, if so, retrieves that object.

```
bool CGPDFArrayGetNumber (
   CGPDFArrayRef array,
   size_t index,
   CGPDFReal *value
);
```

Parameters

array

A PDF array. If this parameter is not a valid PDF array, the behavior is undefined.

index

The index of the value to retrieve. If the index is outside the index space of the array (`0` to `N-1`, where `N` is the count of the array), the behavior is undefined.

value

On input, a pointer to a PDF number. If the value at the specified index is a PDF number, then on return contains that value, otherwise the value is undefined.

Return Value
Returns `true` if there is a PDF number at the specified index, otherwise `false`.

Availability
Available in Mac OS X version 10.3 and later.

Declared In
CGPDFArray.h

CGPDFArrayGetObject

Returns whether an object at a given index in a PDF array is a PDF object and, if so, retrieves that object.

```
bool CGPDFArrayGetObject (
   CGPDFArrayRef array,
   size_t index,
   CGPDFObjectRef *value
);
```

Parameters

array
A PDF array. If this parameter is not a valid PDF array, the behavior is undefined.

index
The index of the value to retrieve. If the index is outside the index space of the array (`0` to `N-1`, where `N` is the count of the array), the behavior is undefined.

value
On input, a pointer to a PDF object. If the value at the specified index is a PDF object, then on return contains that object, otherwise the value is undefined.

Return Value
Returns `true` if there is a PDF object at the specified index, otherwise `false`.

Availability
Available in Mac OS X version 10.3 and later.

Declared In
CGPDFArray.h

CGPDFArrayGetStream

Returns whether an object at a given index in a PDF array is a PDF stream and, if so, retrieves that stream.

```
bool CGPDFArrayGetStream (
   CGPDFArrayRef array,
   size_t index,
   CGPDFStreamRef *value
);
```

Parameters

array
A PDF array. If this parameter is not a valid PDF array, the behavior is undefined.

index
The index of the value to retrieve. If the index is outside the index space of the array (`0` to `N-1`, where `N` is the count of the array), the behavior is undefined.

value
On input, a pointer to a PDF stream. If the value at the specified index is a PDF stream, then on return that stream, otherwise the value is undefined.

Return Value
Returns `true` if there is a PDF stream at the specified index, otherwise `false`.

Availability
Available in Mac OS X version 10.3 and later.

Declared In
`CGPDFArray.h`

CGPDFArrayGetString

Returns whether an object at a given index in a PDF array is a PDF string and, if so, retrieves that string.

```
bool CGPDFArrayGetString (
   CGPDFArrayRef array,
   size_t index,
   CGPDFStringRef *value
);
```

Parameters

array
A PDF array. If this parameter is not a valid PDF array, the behavior is undefined.

index
The index of the value to retrieve. If the index is outside the index space of the array (`0` to `N-1`, where `N` is the count of the array), the behavior is undefined.

value
On input, a pointer to a PDF string. If the value at the specified index is a PDF string, then on return that string, otherwise the value is undefined.

Return Value
Returns `true` if there is a PDF stream at the specified index, otherwise `false`.

Availability
Available in Mac OS X version 10.3 and later.

Declared In
`CGPDFArray.h`

Data Types

CGPDFArrayRef

An opaque type that encapsulates a PDF array.

```
typedef struct CGPDFArray *CGPDFArrayRef;
```

Availability
Available in Mac OS X v10.3 and later.

Declared In
`CGPDFArray.h`

CGPDFContentStream Reference

Derived From:	None
Framework:	ApplicationServices/ApplicationServices.h
Declared in	CGPDFContentStream.h
Companion guide	Quartz 2D Programming Guide

Overview

The `CGPDFContentStreamRef` opaque type provides access to the data that describes the appearance of a PDF page. A CGPDFContentStream object represents one or more PDF content streams for a page and their associated resource dictionaries. A PDF content stream is a sequential set of instructions that specifies how to paint items on a PDF page. A resource dictionary contains information needed by the content stream in order to decode the sequential instructions of the content stream.

CGPDFContentStream functions can retrieve both the content streams and the resource dictionaries associated with a PDF page.

This opaque type is not derived from CFType and therefore there are no functions for retaining and releasing it.

Functions by Task

Creating a PDF Content Stream Object

`CGPDFContentStreamCreateWithPage` (page 300)
Creates a content stream object from a PDF page object.

`CGPDFContentStreamCreateWithStream` (page 300)
Creates a PDF content stream object from an existing PDF content stream object.

Getting Data from a PDF Content Stream Object

`CGPDFContentStreamGetStreams` (page 301)
Gets the array of PDF content streams contained in a PDF content stream object.

`CGPDFContentStreamGetResource` (page 301)
Gets the specified resource from a PDF content stream object.

Retaining and Releasing a PDF Content Stream Object

`CGPDFContentStreamRetain` (page 302)
Increments the retain count of a PDF content stream object.

`CGPDFContentStreamRelease` (page 302)
Decrements the retain count of a PDF content stream object.

Functions

CGPDFContentStreamCreateWithPage

Creates a content stream object from a PDF page object.

```
CGPDFContentStreamRef CGPDFContentStreamCreateWithPage (
   CGPDFPageRef page
);
```

Parameters

page
A PDF page object.

Return Value
A new CGPDFContentStream object. You are responsible for releasing this object by calling the function `CGPDFContentStreamRelease`.

Discussion
A CGPDFContentStream object can contain more than one PDF content stream. To retrieve an array of the PDF content streams in the object, call the function `CGPDFContentStreamGetStreams` (page 301). To obtain the resources associated with a CGPDFContentStream object, call the function `CGPDFContentStreamGetResource` (page 301).

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`CGPDFContentStream.h`

CGPDFContentStreamCreateWithStream

Creates a PDF content stream object from an existing PDF content stream object.

```
CGPDFContentStreamRef CGPDFContentStreamCreateWithStream (
   CGPDFStreamRef stream,
   CGPDFDictionaryRef streamResources,
   CGPDFContentStreamRef parent
);
```

Parameters

stream
The PDF stream you want to create a content stream from.

streamResources
A PDF dictionary that contains the resources associated with the stream you want to retrieve.

parent
The content stream of the page on which *stream* appears. Supply the `parent` parameter when you create a content stream that's used within a page.

Return Value
A CGPDFContentStream object created from the `stream` parameter. You are responsible for releasing this object by calling the function `CGPDFContentStreamRelease` (page 302).

Discussion
You can use this function to get access to the contents of a form, pattern, Type3 font, or any PDF stream.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`CGPDFContentStream.h`

CGPDFContentStreamGetResource

Gets the specified resource from a PDF content stream object.

```
CGPDFObjectRef CGPDFContentStreamGetResource (
   CGPDFContentStreamRef cs,
   const char *category,
   const char *name
);
```

Parameters

cs
A CGPDFContentStream object.

category
A string that specifies the category of the resource you want to obtain.

name
A string that specifies the name of the resource you want to obtain.

Return Value
The resource dictionary.

Discussion
You can use this function to obtain resources used by the content stream, such as forms, patterns, color spaces, and fonts.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`CGPDFContentStream.h`

CGPDFContentStreamGetStreams

Gets the array of PDF content streams contained in a PDF content stream object.

```
CFArrayRef CGPDFContentStreamGetStreams (
   CGPDFContentStreamRef cs
);
```

Parameters

cs

A CGPDFContentStream object.

Return Value
The array of PDF content streams that make up the content stream object represented by the `cs` parameter.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`CGPDFContentStream.h`

CGPDFContentStreamRelease

Decrements the retain count of a PDF content stream object.

```
void CGPDFContentStreamRelease (
   CGPDFContentStreamRef cs
);
```

Parameters

cs

A PDF content stream.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`CGPDFContentStream.h`

CGPDFContentStreamRetain

Increments the retain count of a PDF content stream object.

```
CGPDFContentStreamRef CGPDFContentStreamRetain (
   CGPDFContentStreamRef cs
);
```

Parameters

cs

A PDF content stream.

Return Value
The same PDF content stream you passed in as the `cs` parameter.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`CGPDFContentStream.h`

Data Types

CGPDFContentStreamRef

An opaque type that provides access to the data that describes the appearance of a PDF page.

```
typedef struct CGPDFContentStream *CGPDFContentStreamRef;
```

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGPDFContentStream.h`

CGPDFContext Reference

Derived From:	`CGContextRef` (page 137)
Framework:	ApplicationServices/ApplicationServices.h
Declared in	CGPDFContext.h
Companion guide	Quartz 2D Programming Guide

Overview

The CGPDFContext header file defines functions that create and get information about a Quartz PDF context. A CGPDFContext object is a type of `CGContextRef` (page 137) that is used for drawing PDF content. The functions in this reference operate only on Quartz PDF graphics contexts created using the functions CGPDFContextCreate (page 307) or CGPDFContextCreateWithURL (page 308).

When you draw to the PDF context using CGContext functions the drawing operations are recorded in PDF format. The PDF commands that represent the drawing are written to the destination specified when you create the PDF graphics context.

Functions by Task

Creating a Context

`CGPDFContextCreate` (page 307)
Creates a PDF graphics context.

`CGPDFContextCreateWithURL` (page 308)
Creates a URL-based PDF graphics context.

Beginning and Ending Pages

`CGPDFContextBeginPage` (page 306)
Begins a new page in a PDF graphics context.

`CGPDFContextEndPage` (page 309)
Ends the current page in the PDF graphics context.

Working with Destinations

`CGPDFContextAddDestinationAtPoint` (page 306)
Sets a destination to jump to when a point in the current page of a PDF graphics context is clicked.

`CGPDFContextSetDestinationForRect` (page 309)
Sets a destination to jump to when a rectangle in the current PDF page is clicked.

`CGPDFContextSetURLForRect` (page 310)
Sets the URL associated with a rectangle in a PDF graphics context.

Closing a PDF Context

`CGPDFContextClose` (page 307)
Closes a PDF document.

Functions

CGPDFContextAddDestinationAtPoint

Sets a destination to jump to when a point in the current page of a PDF graphics context is clicked.

```
void CGPDFContextAddDestinationAtPoint (
    CGContextRef context,
    CFStringRef name,
    CGPoint point
);
```

Parameters

context
A PDF graphics context.

name
A destination name.

point
A location in the current page of the PDF graphics context.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGPDFContext.h`

CGPDFContextBeginPage

Begins a new page in a PDF graphics context.

```
void CGPDFContextBeginPage (
    CGContextRef context,
    CFDictionaryRef pageInfo
);
```

Parameters

context

A PDF graphics context.

pageInfo

A dictionary that contains key-value pairs that define the page properties.

Discussion

You must call the function `CGPDFContextEndPage` (page 309) to signal the end of the page.

Availability

Available in Mac OS X v10.4 and later.

Declared In

`CGPDFContext.h`

CGPDFContextClose

Closes a PDF document.

```
void CGPDFContextClose(
    CGContextRef context
);
```

Parameters

context

A PDF graphics context.

Discussion

After closing the context, all pending data is written to the context destination, and the PDF file is completed. No additional data can be written to the destination context after the PDF document is closed.

Availability

Available in Mac OS X v10.5 and later.

Declared In

`CGPDFContext.h`

CGPDFContextCreate

Creates a PDF graphics context.

```
CGContextRef CGPDFContextCreate (
   CGDataConsumerRef consumer,
   const CGRect *mediaBox,
   CFDictionaryRef auxiliaryInfo
);
```

Parameters

consumer

The data consumer to receive the PDF output data.

mediaBox

A pointer to a rectangle that defines the size and location of the PDF page, or `NULL`. The origin of the rectangle should typically be `(0,0)`. Quartz uses this rectangle as the default bounds of the page's media box. If you pass `NULL`, Quartz uses a default page size of 8.5 by 11 inches (612 by 792 points).

auxiliaryInfo

A dictionary that specifies any additional information to be used by the PDF context when generating the PDF file, or `NULL`. The dictionary is retained by the new context, so on return you may safely release it. See "Auxiliary Dictionary Keys" (page 310) for keys you can include in the dictionary.

Return Value

A new PDF context, or `NULL` if the context cannot be created. You are responsible for releasing this object using `CGContextRelease` (page 102).

Discussion

This function creates a PDF drawing environment to your specifications. When you draw into the new context, Quartz renders your drawing as a sequence of PDF drawing commands that are passed to the data consumer object.

Availability

Available in Mac OS X version 10.0 and later.

Related Sample Code

CarbonSketch

Declared In

`CGPDFContext.h`

CGPDFContextCreateWithURL

Creates a URL-based PDF graphics context.

```
CGContextRef CGPDFContextCreateWithURL (
   CFURLRef url,
   const CGRect *mediaBox,
   CFDictionaryRef auxiliaryInfo
);
```

Parameters

url

A Core Foundation URL that specifies where you want to place the resulting PDF file.

mediaBox

A rectangle that specifies the bounds of the PDF. The origin of the rectangle should typically be `(0,0)`. The `CGPDFContextCreateWithURL` function uses this rectangle as the default page media bounding box. If you pass `NULL`, `CGPDFContextCreateWithURL` uses a default page size of 8.5 by 11 inches (612 by 792 points).

auxiliaryInfo

A dictionary that specifies any additional information to be used by the PDF context when generating the PDF file, or `NULL`. The dictionary is retained by the new context, so on return you may safely release it.

Return Value
A new PDF context, or `NULL` if a context could not be created. You are responsible for releasing this object using `CGContextRelease` (page 102).

Discussion
When you call this function, Quartz creates a PDF drawing environment—that is, a graphics context—to your specifications. When you draw into the resulting context, Quartz renders your drawing as a series of PDF drawing commands stored in the specified location.

Availability
Available in Mac OS X version 10.0 and later.

Related Sample Code
CarbonSketch

Declared In
`CGPDFContext.h`

CGPDFContextEndPage

Ends the current page in the PDF graphics context.

```
void CGPDFContextEndPage (
    CGContextRef context
);
```

Parameters

context

A PDF graphics context.

Discussion
You can call `CGPDFContextEndPage` only after you call the function `CGPDFContextBeginPage` (page 306).

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGPDFContext.h`

CGPDFContextSetDestinationForRect

Sets a destination to jump to when a rectangle in the current PDF page is clicked.

```
void CGPDFContextSetDestinationForRect (
    CGContextRef context,
    CFStringRef name,
    CGRect rect
);
```

Parameters

context

A PDF graphics context.

name

A destination name.

rect

A rectangle that specifies an area of the current page of a PDF graphics context. The rectangle is specified in default user space (not device space).

Availability
Available in Mac OS X v10.4 and later.

Declared In
CGPDFContext.h

CGPDFContextSetURLForRect

Sets the URL associated with a rectangle in a PDF graphics context.

```
void CGPDFContextSetURLForRect (
   CGContextRef context,
   CFURLRef url,
   CGRect rect
);
```

Parameters

context

A PDF graphics context.

url

A CFURL object that specifies the destination of the contents associated with the rectangle.

rect

A rectangle specified in default user space (not device space).

Availability
Available in Mac OS X v10.4 and later.

Declared In
CGPDFContext.h

Constants

Auxiliary Dictionary Keys

Keys that used to set up a PDF context.

```
CFStringRef kCGPDFContextAuthor;
CFStringRef kCGPDFContextCreator;
CFStringRef kCGPDFContextTitle;
CFStringRef kCGPDFContextOwnerPassword;
CFStringRef kCGPDFContextUserPassword;
CFStringRef kCGPDFContextAllowsPrinting;
CFStringRef kCGPDFContextAllowsCopying;
CFStringRef kCGPDFContextOutputIntent;
CFStringRef kCGPDFContextOutputIntents;
CFStringRef kCGPDFContextSubject;
CFStringRef kCGPDFContextKeywords;
CFStringRef kCGPDFContextEncryptionKeyLength;
```

Constants

`kCGPDFContextAuthor`

The corresponding value is a string that represents the name of the person who created the document. This key is optional.

Available in Mac OS X v10.4 and later.

Declared in `CGPDFContext.h`.

`kCGPDFContextCreator`

The corresponding value is a string that represents the name of the application used to produce the document. This key is optional.

Available in Mac OS X v10.4 and later.

Declared in `CGPDFContext.h`.

`kCGPDFContextTitle`

The corresponding value is a string that represents the title of the document. This key is optional.

Available in Mac OS X v10.4 and later.

Declared in `CGPDFContext.h`.

`kCGPDFContextOwnerPassword`

The owner password of the PDF document. If this key is specified, the document is encrypted using the value as the owner password; otherwise, the document will not be encrypted. The value of this key must be a CFString object that can be represented in ASCII encoding. Only the first 32 bytes are used for the password. There is no default value for this key. If the value of this key cannot be represented in ASCII, the document is not created and the creation function returns `NULL`.

Available in Mac OS X v10.4 and later.

Declared in `CGPDFContext.h`.

`kCGPDFContextUserPassword`

The user password of the PDF document. If the document is encrypted, then the value of this key will be the user password for the document. If not specified, the user password is the empty string. The value of this key must be a CFString object that can be represented in ASCII encoding; only the first 32 bytes will be used for the password. If the value of this key cannot be represented in ASCII, the document is not created and the creation function returns `NULL`.

Available in Mac OS X v10.4 and later.

Declared in `CGPDFContext.h`.

`kCGPDFContextAllowsPrinting`

Whether the document allows printing when unlocked with the user password. The value of this key must be a CFBoolean value. The default value of this key is `kCFBooleanTrue`.

Available in Mac OS X v10.4 and later.

Declared in `CGPDFContext.h`.

`kCGPDFContextAllowsCopying`
Whether the document allows copying when unlocked with the user password. The value of this key must be a CFBoolean object. The default value of this key is `kCFBooleanTrue`.

Available in Mac OS X v10.4 and later.

Declared in `CGPDFContext.h`.

`kCGPDFContextOutputIntent`
The output intent `PDF/X`. This key is optional. If present, the value of this key must be a CFDictionary object. The dictionary is added to the `/OutputIntents` entry in the PDF file document catalog. The keys and values contained in the dictionary must match those specified in section 9.10.4 of the PDF 1.4 specification, ISO/DIS 15930-3 document published by ISO/TC 130, and Adobe Technical Note #5413.

Available in Mac OS X v10.4 and later.

Declared in `CGPDFContext.h`.

`kCGPDFContextOutputIntents`
Output intent dictionaries. This key is optional. If present, the value must be an array of one or more `kCGPDFContextOutputIntent` dictionaries. The array is added to the PDF document in the `/OutputIntents` entry in the PDF file's document catalog. Each dictionary in the array must be of form specified for the `kCGPDFContextOutputIntent` key, except that only the first dictionary in the array is required to contain the "S" key with a value of `GTS_PDFX`. If both the `kCGPDFContextOutputIntent` and `kCGPDFContextOutputIntents` keys are specified, the former is ignored.

Available in Mac OS X v10.4 and later.

Declared in `CGPDFContext.h`.

`kCGPDFContextSubject`
The subject of a document. Optional; if present, the value of this key must be a `CFString` object.

Declared in `CGPDFContext.h`.

Available in Mac OS X v10.5 and later.

`kCGPDFContextKeywords`
The keywords for this document. This key is optional. If the value of this key is a `CFString` object, the `/Keywords` entry will be the specified string. If the value of this key is a `CFArray` object, then it must be an array of `CFString` objects. The `/Keywords` entry will, in this case, be the concatenation of the specified strings separated by commas (" , "). In addition, an entry with the key `"/AAPL:Keywords"` is stored in the document information dictionary; its value is an array consisting of each of the specified strings. The value of this key must be in one of the above forms; otherwise, this key is ignored.

Declared in `CGPDFContext.h`.

Available in Mac OS X v10.5 and later.

`kCGPDFContextEncryptionKeyLength`
The encryption key length in bits; see Table 3.18 "Entries common to all encryption dictionaries", PDF Reference: Adobe PDF version 1.5 (4th ed.) for more information. Optional; if present, the value of this key must be a `CFNumber` object with value which is a multiple of 8 between 40 and 128, inclusive. If this key is absent or invalid, the encryption key length defaults to 40 bits.

Declared in `CGPDFContext.h`.

Available in Mac OS X v10.5 and later.

Discussion
For more information about using these keys in a PDF context, see `CGPDFContextCreate` (page 307) and `CGPDFContextCreateWithURL` (page 308).

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGPDFContext.h`

Box Dictionary Keys

Keys that specify various PDF boxes.

```
CFStringRef kCGPDFContextMediaBox
CFStringRef kCGPDFContextCropBox
CFStringRef kCGPDFContextBleedBox
CFStringRef kCGPDFContextTrimBox
CFStringRef kCGPDFContextArtBox
```

Constants

`kCGPDFContextMediaBox`
The media box for the document or for a given page. This key is optional. If present, the value of this key must be a CFData object that contains a `CGRect` (stored by value, not by reference).

Available in Mac OS X v10.4 and later.

Declared in `CGPDFContext.h`.

`kCGPDFContextCropBox`
The crop box for the document or for a given page. This key is optional. If present, the value of this key must be a CFData object that contains a `CGRect` (stored by value, not by reference).

Available in Mac OS X v10.4 and later.

Declared in `CGPDFContext.h`.

`kCGPDFContextBleedBox`
The bleed box for the document or for a given page. This key is optional. If present, the value of this key must be a CFData object that contains a `CGRect` (stored by value, not by reference).

Available in Mac OS X v10.4 and later.

Declared in `CGPDFContext.h`.

`kCGPDFContextTrimBox`
The trim box for the document or for a given page. This key is optional. If present, the value of this key must be a CFData object that contains a `CGRect` (stored by value, not by reference).

Available in Mac OS X v10.4 and later.

Declared in `CGPDFContext.h`.

`kCGPDFContextArtBox`
The art box for the document or for a given page. This key is optional. If present, the value of this key must be a CFData object that contains a `CGRect` (stored by value, not by reference).

Available in Mac OS X v10.4 and later.

Declared in `CGPDFContext.h`.

Discussion
For more information about using these keys in a PDF context, see `CGPDFContextCreate` (page 307) and `CGPDFContextCreateWithURL` (page 308).

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGPDFContext.h`

Output Intent Dictionary Keys

Keys to specify output intent options.

```
CFStringRef kCGPDFXOutputIntentSubtype;
CFStringRef kCGPDFXOutputConditionIdentifier;
CFStringRef kCGPDFXOutputCondition;
CFStringRef kCGPDFXRegistryName;
CFStringRef kCGPDFXInfo;
CFStringRef kCGPDFXDestinationOutputProfile;
```

Constants

`kCGPDFXOutputIntentSubtype`
The output intent subtype. This key is required. The value of this key must be a CFString object equal to `"GTS_PDFX"`; otherwise, the dictionary is ignored.

Available in Mac OS X v10.4 and later.

Declared in `CGPDFContext.h`.

`kCGPDFXOutputConditionIdentifier`
A string identifying the intended output device or production condition in a human- or machine-readable form. This key is required. The value of this key must be a CFString object. For best results, the string should be restricted to characters in the ASCII character set.

Available in Mac OS X v10.4 and later.

Declared in `CGPDFContext.h`.

`kCGPDFXOutputCondition`
A text string identifying the intended output device or production condition in a human- readable form. This key is optional. If present, the value of this key must be a CFString object.

Available in Mac OS X v10.4 and later.

Declared in `CGPDFContext.h`.

`kCGPDFXRegistryName`
A string identifying the registry in which the condition designated by `kCGPDFXOutputConditionIdentifier` is defined. This key is optional. If present, the value of this key must be a CFString object. For best results, the string should be lossless in ASCII encoding.

Available in Mac OS X v10.4 and later.

Declared in `CGPDFContext.h`.

`kCGPDFXInfo`
A human-readable text string containing additional information or comments about the intended target device or production condition. This key is required if the value of `kCGPDFXOutputConditionIdentifier` does not specify a standard production condition. It is optional otherwise. If present, the value of this key must be a CFString object.

Available in Mac OS X v10.4 and later.

Declared in `CGPDFContext.h`.

`kCGPDFXDestinationOutputProfile`

An ICC profile stream defining the transformation from the PDF document's source colors to output device colorants. This key is required if the value of `kCGPDFXOutputConditionIdentifier` does not specify a standard production condition. It is optional otherwise. If present, the value of this key must be an ICC-based color space specified as a `CGColorSpace` object.

Available in Mac OS X v10.4 and later.

Declared in `CGPDFContext.h`.

Discussion
For more information about using these keys in a PDF context, see `CGPDFContextCreate` (page 307) and `CGPDFContextCreateWithURL` (page 308).

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGPDFContext.h`

CGPDFDictionary Reference

Derived From:	None
Framework:	ApplicationServices/ApplicationServices.h

Companion guide	Quartz 2D Programming Guide

Overview

The `CGPDFDictionaryRef` opaque type encapsulates a PDF dictionary whose key-value pairs can specify any kind of PDF object, including another dictionary. Dictionary objects are the main building blocks of a PDF document. A key-value pair within a dictionary is called an entry. In a PDF dictionary, the key must be an array of characters. Within a given dictionary, the keys are unique—that is, no two keys in a single dictionary are equal (as determined by `strcmp`). The value associated with a key can be any kind of PDF object, including another dictionary. Dictionary objects are the main building blocks of a PDF document.

Many functions that retrieve values from a PDF dictionary take the form:

```
bool CGPDFDictionaryGet<DataType> (
 CGPDFDictionaryRef dictionary,
 const char *key,
 <DataType>Ref *value
);
```

These functions test whether there is an object associated with the specified key. If there is an object associated with the specified key, they test its data type. If there is no associated object, or if there is but it is not of the expected type, the function returns `false`. If there is an object associated with the specified key and it is of the expected type, the function returns `true` and the object is passed back in the `value` parameter.

This opaque type is not derived from CFType and therefore there are no functions for retaining and releasing it. CGPDFDictionary objects exist only as constituent parts of a CGPDFDocument object, and they are managed by their container.

Functions by Task

Applying a Function to All Entries

`CGPDFDictionaryApplyFunction` (page 318)
Applies a function to each entry in a dictionary.

Getting Data from a Dictionary

`CGPDFDictionaryGetArray` (page 319)
Returns whether there is a PDF array associated with a specified key in a PDF dictionary and, if so, retrieves that array.

`CGPDFDictionaryGetBoolean` (page 320)
Returns whether there is a PDF Boolean value associated with a specified key in a PDF dictionary and, if so, retrieves the Boolean value.

`CGPDFDictionaryGetCount` (page 320)
Returns the number of entries in a PDF dictionary.

`CGPDFDictionaryGetDictionary` (page 320)
Returns whether there is another PDF dictionary associated with a specified key in a PDF dictionary and, if so, retrieves that dictionary.

`CGPDFDictionaryGetInteger` (page 321)
Returns whether there is a PDF integer associated with a specified key in a PDF dictionary and, if so, retrieves that integer.

`CGPDFDictionaryGetName` (page 322)
Returns whether an object with a specified key in a PDF dictionary is a PDF name reference (represented as a constant C string) and, if so, retrieves that name.

`CGPDFDictionaryGetNumber` (page 322)
Returns whether there is a PDF number associated with a specified key in a PDF dictionary and, if so, retrieves that number.

`CGPDFDictionaryGetObject` (page 323)
Returns whether there is a PDF object associated with a specified key in a PDF dictionary and, if so, retrieves that object.

`CGPDFDictionaryGetStream` (page 323)
Returns whether there is a PDF stream associated with a specified key in a PDF dictionary and, if so, retrieves that stream.

`CGPDFDictionaryGetString` (page 324)
Returns whether there is a PDF string associated with a specified key in a PDF dictionary and, if so, retrieves that string.

Functions

CGPDFDictionaryApplyFunction

Applies a function to each entry in a dictionary.

```
void CGPDFDictionaryApplyFunction (
   CGPDFDictionaryRef dict,
   CGPDFDictionaryApplierFunction function,
   void *info
);
```

Parameters

dictionary

A PDF dictionary. If this parameter is not a valid PDF dictionary, the behavior is undefined.

function

The function to apply to each entry in the dictionary.

info

A pointer to contextual information to pass to the function.

Discussion

This function enumerates all of the entries in the dictionary, calling the function once for each. The current key, its associated value, and the contextual information are passed to the function (see also CGPDFDictionaryApplierFunction (page 324)).

Availability

Available in Mac OS X version 10.3 and later.

Declared In

`CGPDFDictionary.h`

CGPDFDictionaryGetArray

Returns whether there is a PDF array associated with a specified key in a PDF dictionary and, if so, retrieves that array.

```
bool CGPDFDictionaryGetArray (
   CGPDFDictionaryRef dict,
   const char *key,
   CGPDFArrayRef *value
);
```

Parameters

dictionary

A PDF dictionary. If this parameter is not a valid PDF dictionary, the behavior is undefined.

key

The key for the value to retrieve.

value

On input, an uninitialized pointer to a PDF array. If the value associated with the specified key is a PDF array, then on return contains that array; otherwise the value is unspecified.

Return Value

Returns `true` if there is a PDF array associated with the specified key; otherwise, `false`.

Availability

Available in Mac OS X version 10.3 and later.

Declared In

`CGPDFDictionary.h`

CGPDFDictionaryGetBoolean

Returns whether there is a PDF Boolean value associated with a specified key in a PDF dictionary and, if so, retrieves the Boolean value.

```
bool CGPDFDictionaryGetBoolean (
   CGPDFDictionaryRef dict,
   const char *key,
   CGPDFBoolean *value
);
```

Parameters

dictionary

A PDF dictionary. If this parameter is not a valid PDF dictionary, the behavior is undefined.

key

The key for the value to retrieve.

value

On input, a pointer to a PDF Boolean value. If the value associated with the specified key is a PDF Boolean value, then on return contains that value; otherwise the value is unspecified.

Return Value

Returns `true` if there is a PDF Boolean value associated with the specified key; otherwise, `false`.

Availability

Available in Mac OS X version 10.3 and later.

Declared In

`CGPDFDictionary.h`

CGPDFDictionaryGetCount

Returns the number of entries in a PDF dictionary.

```
size_t CGPDFDictionaryGetCount (
   CGPDFDictionaryRef dict
);
```

Parameters

dictionary

A PDF dictionary. If this parameter is not a valid PDF dictionary, the behavior is undefined.

Return Value

Returns the number of entries in the dictionary.

Availability

Available in Mac OS X version 10.3 and later.

Declared In

`CGPDFDictionary.h`

CGPDFDictionaryGetDictionary

Returns whether there is another PDF dictionary associated with a specified key in a PDF dictionary and, if so, retrieves that dictionary.

```
bool CGPDFDictionaryGetDictionary (
   CGPDFDictionaryRef dict,
   const char *key,
   CGPDFDictionaryRef *value
);
```

Parameters

dictionary

A PDF dictionary. If this parameter is not a valid PDF dictionary, the behavior is undefined.

key

The key for the value to retrieve.

value

On input, a pointer to a PDF dictionary. If the value associated with the specified key is a PDF dictionary, then on return contains that dictionary; otherwise the value is unspecified.

Return Value

Returns `true` if there is a PDF dictionary associated with the specified key; otherwise, `false`.

Availability

Available in Mac OS X version 10.3 and later.

Declared In

`CGPDFDictionary.h`

CGPDFDictionaryGetInteger

Returns whether there is a PDF integer associated with a specified key in a PDF dictionary and, if so, retrieves that integer.

```
bool CGPDFDictionaryGetInteger (
   CGPDFDictionaryRef dict,
   const char *key,
   CGPDFInteger *value
);
```

Parameters

dictionary

A PDF dictionary. If this parameter is not a valid PDF dictionary, the behavior is undefined.

key

The key for the value to retrieve.

value

On input, a pointer to a PDF integer. If the value associated with the specified key is a PDF integer, then on return contains that value; otherwise the value is unspecified.

Return Value

Returns `true` if there is a PDF integer associated with the specified key; otherwise, `false`.

Availability

Available in Mac OS X version 10.3 and later.

Declared In

`CGPDFDictionary.h`

CGPDFDictionaryGetName

Returns whether an object with a specified key in a PDF dictionary is a PDF name reference (represented as a constant C string) and, if so, retrieves that name.

```
bool CGPDFDictionaryGetName (
   CGPDFDictionaryRef dict,
   const char *key,
   const char **value
);
```

Parameters

dictionary

A PDF dictionary. If this parameter is not a valid PDF dictionary, the behavior is undefined.

key

The key for the value to retrieve.

value

On input, a pointer to a PDF name reference, represented as a constant C string. If the value associated with the specified key is a reference to a PDF name, then on return, the variable points to the name; otherwise, the value is undefined.

Return Value

Returns `true` if there is a character array associated with the specified key; otherwise, `false`.

Availability

Available in Mac OS X version 10.3 and later.

Declared In

`CGPDFDictionary.h`

CGPDFDictionaryGetNumber

Returns whether there is a PDF number associated with a specified key in a PDF dictionary and, if so, retrieves that number.

```
bool CGPDFDictionaryGetNumber (
   CGPDFDictionaryRef dict,
   const char *key,
   CGPDFReal *value
);
```

Parameters

dictionary

A PDF dictionary. If this parameter is not a valid PDF dictionary, the behavior is undefined.

key

The key for the value to retrieve.

value

On input, a pointer to a PDF number. If the value associated with the specified key is a PDF number (real or integer), then on return contains that value; otherwise the value is unspecified.

Return Value

Returns `true` if there is a PDF number associated with the specified key; otherwise, `false`.

Availability
Available in Mac OS X version 10.3 and later.

Declared In
`CGPDFDictionary.h`

CGPDFDictionaryGetObject

Returns whether there is a PDF object associated with a specified key in a PDF dictionary and, if so, retrieves that object.

```
bool CGPDFDictionaryGetObject (
   CGPDFDictionaryRef dict,
   const char *key,
   CGPDFObjectRef *value
);
```

Parameters

dictionary
A PDF dictionary. If this parameter is not a valid PDF dictionary, the behavior is undefined.

key
The key for the value to retrieve.

value
On input, a pointer to a PDF object. If the value associated with the specified key is a PDF object, then on return contains that object; otherwise the value is unspecified.

Return Value
Returns `true` if there is a PDF object associated with the specified key; otherwise, `false`.

Availability
Available in Mac OS X version 10.3 and later.

Declared In
`CGPDFDictionary.h`

CGPDFDictionaryGetStream

Returns whether there is a PDF stream associated with a specified key in a PDF dictionary and, if so, retrieves that stream.

```
bool CGPDFDictionaryGetStream (
   CGPDFDictionaryRef dict,
   const char *key,
   CGPDFStreamRef *value
);
```

Parameters

dictionary
A PDF dictionary. If this parameter is not a valid PDF dictionary, the behavior is undefined.

key
The key for the value to be retrieved.

value

On input, a pointer to a PDF stream. If the value associated with the specified key is a PDF stream, then on return contains that stream; otherwise, the value is unspecified.

Return Value
Returns `true` if there is a PDF stream associated with the specified key; otherwise, `false`.

Availability
Available in Mac OS X version 10.3 and later.

Declared In
`CGPDFDictionary.h`

CGPDFDictionaryGetString

Returns whether there is a PDF string associated with a specified key in a PDF dictionary and, if so, retrieves that string.

```
bool CGPDFDictionaryGetString (
   CGPDFDictionaryRef dict,
   const char *key,
   CGPDFStringRef *value
);
```

Parameters

dictionary

A PDF dictionary. If this parameter is not a valid PDF dictionary, the behavior is undefined.

key

The key for the value to retrieve.

value

On input, a pointer to a PDF string. If the value associated with the specified key is a PDF string, then on return contains that string; otherwise the value is unspecified.

Return Value
Returns `true` if there is a PDF string associated with the specified key; otherwise, `false`.

Availability
Available in Mac OS X version 10.3 and later.

Declared In
`CGPDFDictionary.h`

Callbacks

CGPDFDictionaryApplierFunction

Performs custom processing on a key-value pair from a PDF dictionary, using optional contextual information.

```
typedef void (*CGPDFDictionaryApplierFunction) (
   const char *key,
   CGPDFObjectRef value,
   void *info,
);
```

If you name your function `MyFunction`, you would declare it like this:

```
void MyFunction (
   const char *key,
   CGPDFObjectRef object,
   void *info
);
```

Parameters

key

The current key in the dictionary.

object

The value in the dictionary associated with the key.

info

The contextual information that your provided in the `info` parameter in `CGPDFDictionaryApplyFunction` (page 318).

Discussion

`CGPDFDictionaryApplierFunction` defines the callback for `CGPDFDictionaryApplyFunction`, that enumerates all of the entries in the dictionary, calling your custom applier function once for each entry. The current key, its associated value, and the contextual information are passed to your applier function using the `key`, `value`, and `info` parameters respectively.

Availability

Available in Mac OS X v10.3 and later.

Declared In

`CGPDFDictionary.h`

Data Types

CGPDFDictionaryRef

An opaque type that encapsulates a PDF dictionary.

```
typedef struct CGPDFDictionary *CGPDFDictionaryRef;
```

Availability

Available in Mac OS X v10.3 and later.

Declared In

`CGPDFDictionary.h`

CGPDFDocument Reference

Derived From:	CFType
Framework:	ApplicationServices/ApplicationServices.h
Declared in	CGPDFDocument.h
Companion guide	Quartz 2D Programming Guide

Overview

The `CGPDFDocumentRef` opaque type encapsulates a document that contains PDF (Portable Document Format) drawing information. PDF provides an efficient format for cross-platform exchange of documents with rich content. PDF files can contain multiple pages of images and text. A PDF document object contains all the information relating to a PDF document, including its catalog and contents.

Note that PDF documents may be encrypted, and that some operations may be restricted until a valid password is supplied—see the functions listed in "Managing Encryption" (page 328). Quartz also supports decrypting encrypted documents.

Quartz can both display and generate files that are compliant with the PDF standard. When imaging PDF files, `CGPDFDocumentRef` is the basic type used to represent a PDF document.

Functions by Task

Creating PDF Document Objects

`CGPDFDocumentCreateWithProvider` (page 330)
Creates a Quartz PDF document using a data provider.

`CGPDFDocumentCreateWithURL` (page 330)
Creates a Quartz PDF document using data specified by a URL.

Retaining and Releasing PDF Documents

`CGPDFDocumentRelease` (page 339)
Decrements the retain count of a PDF document.

`CGPDFDocumentRetain` (page 339)
Increments the retain count of a Quartz PDF document.

Getting the CFType ID for a PDF Document Object

`CGPDFDocumentGetTypeID` (page 337)
Returns the type identifier for Quartz PDF documents.

Getting Information About Quartz PDF Documents

`CGPDFDocumentGetCatalog` (page 332)
Returns the document catalog of a Quartz PDF document.

`CGPDFDocumentGetNumberOfPages` (page 335)
Returns the number of pages in a PDF document.

`CGPDFDocumentGetPage` (page 335)
Returns a page from a Quartz PDF document.

`CGPDFDocumentGetVersion` (page 337)
Returns the major and minor version numbers of a Quartz PDF document.

`CGPDFDocumentGetInfo` (page 334)
Gets the information dictionary for a PDF document.

`CGPDFDocumentGetID` (page 333)
Gets the file identifier for a PDF document.

Managing Encryption

`CGPDFDocumentAllowsCopying` (page 329)
Returns whether the specified PDF document allows copying.

`CGPDFDocumentAllowsPrinting` (page 329)
Returns whether a PDF document allows printing.

`CGPDFDocumentIsEncrypted` (page 338)
Returns whether the specified PDF file is encrypted.

`CGPDFDocumentIsUnlocked` (page 338)
Returns whether the specified PDF document is currently unlocked.

`CGPDFDocumentUnlockWithPassword` (page 340)
Unlocks an encrypted PDF document, if a valid password is supplied.

Getting Page Information

`CGPDFDocumentGetArtBox` (page 331) Deprecated in Mac OS X version 10.3 and later
Returns the art box of a page in a PDF document.

`CGPDFDocumentGetBleedBox` (page 331) Deprecated in Mac OS X version 10.3 and later
Returns the bleed box of a page in a PDF document.

`CGPDFDocumentGetCropBox` (page 333) Deprecated in Mac OS X version 10.3 and later
Returns the crop box of a page in a PDF document.

`CGPDFDocumentGetMediaBox` (page 334) Deprecated in Mac OS X version 10.3 and later
Returns the media box of a page in a PDF document.

`CGPDFDocumentGetRotationAngle` (page 336) Deprecated in Mac OS X version 10.3 and later
Returns the rotation angle of a page in a PDF document.

`CGPDFDocumentGetTrimBox` (page 336) Deprecated in Mac OS X version 10.3 and later
Returns the trim box of a page in a PDF document.

Functions

CGPDFDocumentAllowsCopying

Returns whether the specified PDF document allows copying.

```
bool CGPDFDocumentAllowsCopying (
   CGPDFDocumentRef document
);
```

Parameters

document
A PDF document.

Return Value

A Boolean that, if `true`, indicates that the document allows copying. If the value is `false`, the document does not allow copying.

Discussion

This function returns `true` if the specified PDF document allows copying. It returns `false` if the document is encrypted and the current password doesn't grant permission to perform copying.

Availability

Available in Mac OS X version 10.2 and later.

Declared In

`CGPDFDocument.h`

CGPDFDocumentAllowsPrinting

Returns whether a PDF document allows printing.

```
bool CGPDFDocumentAllowsPrinting (
   CGPDFDocumentRef document
);
```

Parameters

document
A PDF document.

Return Value

A Boolean that, if `true`, indicates that the document allows printing. If the value is `false`, the document does not allow printing.

Discussion

This function returns `true` if the specified PDF document allows printing. It returns `false` if the document is encrypted and the current password doesn't grant permission to perform printing.

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CGPDFDocument.h`

CGPDFDocumentCreateWithProvider

Creates a Quartz PDF document using a data provider.

```
CGPDFDocumentRef CGPDFDocumentCreateWithProvider (
   CGDataProviderRef provider
);
```

Parameters

provider

A data provider that supplies the PDF document data.

Return Value
A new Quartz PDF document, or `NULL` if a document can not be created. You are responsible for releasing the object using `CGPDFDocumentRelease` (page 339).

Discussion
Distributing individual pages of a PDF document to separate threads is not supported. If you want to use threads, consider creating a separate document for each thread and operating on a block of pages per thread.

Availability
Available in Mac OS X version 10.0 and later.

See Also
`CGContextDrawPDFDocument` (page 88)

Related Sample Code
CarbonSketch

Declared In
`CGPDFDocument.h`

CGPDFDocumentCreateWithURL

Creates a Quartz PDF document using data specified by a URL.

```
CGPDFDocumentRef CGPDFDocumentCreateWithURL (
   CFURLRef url
);
```

Parameters

url

The URL address at which the PDF document data is located.

Return Value
A new Quartz PDF document, or `NULL` if a document could not be created. You are responsible for releasing the object using `CGPDFDocumentRelease` (page 339).

Discussion
Distributing individual pages of a PDF document to separate threads is not supported. If you want to use threads, consider creating a separate document for each thread and operating on a block of pages per thread.

Availability
Available in Mac OS X version 10.0 and later.

See Also
`CGContextDrawPDFDocument` (page 88)

Declared In
`CGPDFDocument.h`

CGPDFDocumentGetArtBox

Returns the art box of a page in a PDF document. (Deprecated in Mac OS X version 10.3 and later.)

```
CGRect CGPDFDocumentGetArtBox (
   CGPDFDocumentRef document,
   int page
);
```

Parameters

document
The PDF document to examine.

page
An integer that specifies the number of the page to examine.

Return Value
A rectangle that represents the art box for the specified page, expressed in default PDF user space units (points).

Discussion
The replacement function for this one is `CGPDFPageGetBoxRect`, which gets the rectangle associated with a type of box (art, media, crop, bleed trim) that represents a content region or page dimensions of a PDF page. For more information see *CGPDFPage Reference*.

The art box defines the extent of the page's meaningful content (including potential white space) as intended by the document creator. The default value is the page's crop box.

Availability
Available in Mac OS X version 10.0 and later.
Deprecated in Mac OS X version 10.3 and later.

Declared In
`CGPDFDocument.h`

CGPDFDocumentGetBleedBox

Returns the bleed box of a page in a PDF document. (Deprecated in Mac OS X version 10.3 and later.)

```
CGRect CGPDFDocumentGetBleedBox (
   CGPDFDocumentRef document,
   int page
);
```

Parameters

document

The PDF document to examine.

page

An integer that specifies the number of the page to examine.

Return Value
A rectangle that represents the bleed box for the specified page, expressed in default PDF user space units (points).

Discussion
The replacement function for this one is `CGPDFPageGetBoxRect`, which gets the rectangle associated with a type of box (art, media, crop, bleed trim) that represents a content region or page dimensions of a PDF page. For more information see *CGPDFPage Reference*.

The bleed box defines the bounds to which the contents of the page should be clipped when output in a production environment. The default value is the page's crop box.

Availability
Available in Mac OS X version 10.0 and later.
Deprecated in Mac OS X version 10.3 and later.

Declared In
`CGPDFDocument.h`

CGPDFDocumentGetCatalog

Returns the document catalog of a Quartz PDF document.

```
CGPDFDictionaryRef CGPDFDocumentGetCatalog (
   CGPDFDocumentRef document
);
```

Parameters

document

A PDF document.

Return Value
The document catalog of the specified document.

Discussion
The entries in a PDF document catalog recursively describe the contents of the PDF document. You can access the contents of a PDF document catalog by calling the function `CGPDFDocumentGetCatalog`. For information on accessing PDF metadata, see *Quartz 2D Programming Guide*.

Availability
Available in Mac OS X version 10.3 and later.

Declared In
`CGPDFDocument.h`

CGPDFDocumentGetCropBox

Returns the crop box of a page in a PDF document. (Deprecated in Mac OS X version 10.3 and later.)

```
CGRect CGPDFDocumentGetCropBox (
   CGPDFDocumentRef document,
   int page
);
```

Parameters

document

The PDF document to examine.

page

An integer that specifies the number of the page to examine.

Return Value

A rectangle that represents the crop box for the specified page, expressed in default PDF user space units (points).

Discussion

The replacement function for this one is `CGPDFPageGetBoxRect`, which gets the rectangle associated with a type of box (art, media, crop, bleed trim) that represents a content region or page dimensions of a PDF page. For more information see *CGPDFPage Reference*.

The crop box defines the region to which the contents of the page are to be clipped (or cropped) when displayed or printed. Unlike the other boxes, the crop box has no defined meaning in terms of physical page geometry or intended use—it merely suggests where the page should be clipped.

Availability

Available in Mac OS X version 10.0 and later.

Deprecated in Mac OS X version 10.3 and later.

Declared In

`CGPDFDocument.h`

CGPDFDocumentGetID

Gets the file identifier for a PDF document.

```
CGPDFArrayRef CGPDFDocumentGetID (
   CGPDFDocumentRef document
);
```

Parameters

document

The document whose file identifier you want to obtain.

Return Value

Returns the file identifier for the document.

Discussion

A PDF file identifier is defined in the PDF specification as an array of two strings, the first of which is a permanent identifier that doesn't change even when the file is updated. The second string changes each time the file is updated. For more information, see *PDF Reference: Version 1.3 (Second Edition)*, Adobe Systems Incorporated.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGPDFDocument.h`

CGPDFDocumentGetInfo

Gets the information dictionary for a PDF document.

```
CGPDFDictionaryRef CGPDFDocumentGetInfo (
   CGPDFDocumentRef document
);
```

Parameters

document
The document whose dictionary you want to obtain.

Return Value
The information dictionary for the document.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGPDFDocument.h`

CGPDFDocumentGetMediaBox

Returns the media box of a page in a PDF document. (Deprecated in Mac OS X version 10.3 and later.)

```
CGRect CGPDFDocumentGetMediaBox (
   CGPDFDocumentRef document,
   int page
);
```

Parameters

document
The PDF document to examine.

page
An integer that specifies the number of the page to examine.

Return Value
A rectangle that represents the media box for the specified page, expressed in default PDF user space units (points).

Discussion
The replacement function for this one is `CGPDFPageGetBoxRect`, which gets the rectangle associated with a type of box (art, media, crop, bleed trim) that represents a content region or page dimensions of a PDF page. For more information see *CGPDFPage Reference*.

The media box defines the location and size of the physical medium on which the page is intended to be displayed or printed. For example, if the page size is 8.5 by 11 inches, this function returns the coordinate pairs `(0,0)` and `(612,792)`.

Availability
Available in Mac OS X version 10.0 and later.
Deprecated in Mac OS X version 10.3 and later.

Declared In
`CGPDFDocument.h`

CGPDFDocumentGetNumberOfPages

Returns the number of pages in a PDF document.

```
size_t CGPDFDocumentGetNumberOfPages (
   CGPDFDocumentRef document
);
```

Parameters

document
The PDF document to examine.

Return Value
The total number of pages in the PDF document.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`CGPDFDocument.h`

CGPDFDocumentGetPage

Returns a page from a Quartz PDF document.

```
CGPDFPageRef CGPDFDocumentGetPage (
   CGPDFDocumentRef document,
   size_t pageNumber
);
```

Parameters

document
A PDF document.

pageNumber
The number of the page requested.

Return Value
Return the PDF page corresponding to the specified page number, or `NULL` if no such page exists in the document. Pages are numbered starting at 1.

Availability
Available in Mac OS X version 10.3 and later.

Related Sample Code
CarbonSketch

Declared In
CGPDFDocument.h

CGPDFDocumentGetRotationAngle

Returns the rotation angle of a page in a PDF document. (Deprecated in Mac OS X version 10.3 and later.)

```
int CGPDFDocumentGetRotationAngle (
   CGPDFDocumentRef document,
   int page
);
```

Parameters

document

The PDF document to examine.

page

An integer that specifies the number of the page to examine.

Return Value
The rotation angle of the page, expressed in degrees. If the specified page does not exist, returns 0.

Discussion
The replacement function for this one is `CGPDFPageGetRotationAngle`. For more information see *CGPDFPage Reference*.

Availability
Available in Mac OS X version 10.0 and later.
Deprecated in Mac OS X version 10.3 and later.

Declared In
CGPDFDocument.h

CGPDFDocumentGetTrimBox

Returns the trim box of a page in a PDF document. (Deprecated in Mac OS X version 10.3 and later.)

```
CGRect CGPDFDocumentGetTrimBox (
   CGPDFDocumentRef document,
   int page
);
```

Parameters

document

The PDF document to examine.

page

A value specifying the number of the page to examine.

Return Value
Returns a rectangle that represents the trim box for the specified page, expressed in default PDF user space units (points).

Discussion
The replacement function for this one is `CGPDFPageGetBoxRect`, which gets the rectangle associated with a type of box (art, media, crop, bleed trim) that represents a content region or page dimensions of a PDF page. For more information see *CGPDFPage Reference*.

The trim box defines the intended dimensions of the finished page after trimming. It may be smaller than the media box, to allow for production-related content such as printing instructions, cut marks, or color bars. The default value is the page's crop box.

Availability
Available in Mac OS X version 10.0 and later.
Deprecated in Mac OS X version 10.3 and later.

Declared In
`CGPDFDocument.h`

CGPDFDocumentGetTypeID

Returns the type identifier for Quartz PDF documents.

```
CFTypeID CGPDFDocumentGetTypeID (
   void
);
```

Return Value
The identifier for the opaque type `CGPDFDocumentRef` (page 340).

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CGPDFDocument.h`

CGPDFDocumentGetVersion

Returns the major and minor version numbers of a Quartz PDF document.

```
void CGPDFDocumentGetVersion (
   CGPDFDocumentRef document,
   int *majorVersion,
   int *minorVersion
);
```

Parameters

document
A PDF document.

majorVersion
On return, contains the major version number of the document.

minorVersion
On return, contains the minor version number of the document.

Return Value
On return, the values of the `majorVersion` and `minorVersion` parameters are set to the major and minor version numbers of the document respectively.

Availability
Available in Mac OS X version 10.3 and later.

Declared In
`CGPDFDocument.h`

CGPDFDocumentIsEncrypted

Returns whether the specified PDF file is encrypted.

```
bool CGPDFDocumentIsEncrypted (
   CGPDFDocumentRef document
);
```

Parameters

document
A PDF document.

Return Value
A Boolean that, if `true`, indicates that the document is encrypted. If the value is `false`, the document is not encrypted.

Discussion
If the document is encrypted, a password must be supplied before certain operations are enabled. For more information, see `CGPDFDocumentUnlockWithPassword` (page 340).

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CGPDFDocument.h`

CGPDFDocumentIsUnlocked

Returns whether the specified PDF document is currently unlocked.

```
bool CGPDFDocumentIsUnlocked (
   CGPDFDocumentRef document
);
```

Parameters

document
A PDF document.

Return Value
A Boolean that, if `true`, indicates that the document is not locked. If the value is `false`, the document is locked.

Discussion
There are two possible reasons why a PDF document is unlocked:

- The document is not encrypted.
- The document is encrypted, and a valid password was previously specified using `CGPDFDocumentUnlockWithPassword` (page 340).

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CGPDFDocument.h`

CGPDFDocumentRelease

Decrements the retain count of a PDF document.

```
void CGPDFDocumentRelease (
    CGPDFDocumentRef document
);
```

Parameters

document
The PDF document to release.

Discussion
This function is equivalent to `CFRelease`, except that it does not cause an error if the `document` parameter is `NULL`.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`CGPDFDocument.h`

CGPDFDocumentRetain

Increments the retain count of a Quartz PDF document.

```
CGPDFDocumentRef CGPDFDocumentRetain (
    CGPDFDocumentRef document
);
```

Parameters

document
The PDF document to retain.

Return Value
The same document you passed in as the *document* parameter.

Discussion
This function is equivalent to `CFRetain`, except that it does not cause an error if the `document` parameter is `NULL`.

Availability
Available in Mac OS X version 10.0 and later.

Declared In
`CGPDFDocument.h`

CGPDFDocumentUnlockWithPassword

Unlocks an encrypted PDF document, if a valid password is supplied.

```
bool CGPDFDocumentUnlockWithPassword (
   CGPDFDocumentRef document,
   const char *password
);
```

Parameters

document

A PDF document.

password

A pointer to a string that contains the password.

Return Value
A Boolean that, if `true`, indicates that the document has been successfully unlocked. If the value is `false`, the document has not been unlocked.

Discussion
Given an encrypted PDF document and a password, this function does the following:

- Sets the lock state of the document, based on the validity of the password.
- Returns `true` if the document is unlocked.
- Returns `false` if the document cannot be unlocked with the specified password.

Unlocking a PDF document makes it possible to decrypt the document and perform other privileged operations. Different passwords enable different operations.

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CGPDFDocument.h`

Data Types

CGPDFDocumentRef

An opaque type that represents a PDF (Portable Document Format) document.

```
typedef struct CGPDFDocument * CGPDFDocumentRef;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CGPDFDocument.h`

CGPDFObject Reference

Derived From:	None
Framework:	ApplicationServices/ApplicationServices.h
Declared in	CGPDFObject.h
Companion guide	Quartz 2D Programming Guide

Overview

The `CGPDFObjectRef` opaque type represents PDF objects in a PDF document. PDF supports several basic types of object: Boolean values, integer and real numbers, strings, names, arrays, dictionaries, and streams. Most of these are represented in Quartz by corresponding specific types. A CGPDFObject can represent any of these types. You use CGPDFObject functions to determine the type of the object, and retrieve the object value if it is of an expected type.

This opaque type is not derived from CFType and therefore there are no functions for retaining and releasing it. CGPDFObject objects exist as constituent parts of a CGPDFDocument object, and are managed by their container.

Functions

CGPDFObjectGetType

Returns the PDF type identifier of an object.

```
CGPDFObjectType CGPDFObjectGetType (
   CGPDFObjectRef object
);
```

Parameters

object

A PDF object. If the value if not a PDF object, the behavior is unspecified.

Return Value

Returns the type of the `object` parameter. See "Data Types" (page 344).

Availability

Available in Mac OS X version 10.3 and later.

Declared In

`CGPDFObject.h`

CGPDFObjectGetValue

Returns whether an object is of a given type and if it is, retrieves its value.

```
bool CGPDFObjectGetValue (
   CGPDFObjectRef object,
   CGPDFObjectType type,
   void *value
);
```

Parameters

object

A PDF object.

type

A PDF object type.

value

If the `object` parameter is a PDF object of the specified type, then on return contains that object, otherwise the value is unspecified.

Return Value

Returns `true` if the specified object is a PDF object of the specified type, otherwise `false`.

Discussion

The function gets the value of the `object` parameter. If the type of `object` is equal to the type specified, then:

- If the `value` parameter is not a null pointer, then the value of `object` is copied to `value`, and the function returns `true`.
- If the `value` parameter is a null pointer, then the function simply returns `true`. This allows you to test whether `object` is of the type specified.

If the type of `object` is `kCGPDFObjectTypeInteger` and `type` is equal to `kCGPDFObjectTypeReal`, then the value of `object` is converted to floating point, the result copied to `value`, and the function returns `true`. If none of the preceding conditions is met, returns `false`.

Availability

Available in Mac OS X version 10.3 and later.

Declared In

`CGPDFObject.h`

Data Types

CGPDFObjectRef

An opaque type that contains information about a PDF object.

```
typedef union CGPDFObject *CGPDFObjectRef;
```

Availability

Available in Mac OS X v10.3 and later.

Declared In
CGPDFObject.h

CGPDFBoolean

A PDF Boolean value.

```
typedef unsigned char CGPDFBoolean;
```

Availability
Available in Mac OS X v10.3 and later.

Declared In
CGPDFObject.h

CGPDFInteger

A PDF integer value.

```
typedef long int CGPDFInteger;
```

Availability
Available in Mac OS X v10.3 and later.

Declared In
CGPDFObject.h

CGPDFReal

A PDF real value.

```
typedef CGFloat CGPDFReal;
```

Availability
Available in Mac OS X v10.3 and later.

Declared In
CGPDFObject.h

Constants

PDF Object Types

Types of PDF object.

```
enum CGPDFObjectType {
    kCGPDFObjectTypeNull = 1,
    kCGPDFObjectTypeBoolean,
    kCGPDFObjectTypeInteger,
    kCGPDFObjectTypeReal,
    kCGPDFObjectTypeName,
    kCGPDFObjectTypeString,
    kCGPDFObjectTypeArray,
    kCGPDFObjectTypeDictionary,
    kCGPDFObjectTypeStream
};typedef enum CGPDFObjectType CGPDFObjectType;
```

Constants

`kCGPDFObjectTypeNull`
The type for a PDF null.
Available in Mac OS X v10.3 and later.
Declared in `CGPDFObject.h`.

`kCGPDFObjectTypeBoolean`
The type for a PDF Boolean.
Available in Mac OS X v10.3 and later.
Declared in `CGPDFObject.h`.

`kCGPDFObjectTypeInteger`
The type for a PDF integer.
Available in Mac OS X v10.3 and later.
Declared in `CGPDFObject.h`.

`kCGPDFObjectTypeReal`
The type for a PDF real.
Available in Mac OS X v10.3 and later.
Declared in `CGPDFObject.h`.

`kCGPDFObjectTypeName`
Type for a PDF name.
Available in Mac OS X v10.3 and later.
Declared in `CGPDFObject.h`.

`kCGPDFObjectTypeString`
The type for a PDF string.
Available in Mac OS X v10.3 and later.
Declared in `CGPDFObject.h`.

`kCGPDFObjectTypeArray`
Type for a PDF array.
Available in Mac OS X v10.3 and later.
Declared in `CGPDFObject.h`.

`kCGPDFObjectTypeDictionary`
The type for a PDF dictionary.
Available in Mac OS X v10.3 and later.
Declared in `CGPDFObject.h`.

`kCGPDFObjectTypeStream`
The type for a PDF stream.

Available in Mac OS X v10.3 and later.

Declared in `CGPDFObject.h`.

Declared In
`CGPDFObject.h`

CGPDFOperatorTable Reference

Derived From:	None
Framework:	ApplicationServices/ApplicationServices.h
Declared in	CGPDFOperatorTable.h

Overview

A CGPDFOperatorTable object stores callback functions for PDF operators. You pass an operator table and a PDF content stream to a CGPDFScanner object. When the scanner parses a PDF operator, Quartz invokes your callback for that operator. See also *CGPDFScanner Reference* and *CGPDFContentStream Reference*.

Note: This opaque type is not derived from CFType and therefore you can't use the Core Foundation base functions on it, such as `CFRetain` and `CFRelease`. Memory management is handled by the specific functions `CGPDFOperatorTableRetain` (page 350) and `CGPDFOperatorTableRelease` (page 350).

For more about PDF operators, see the latest version of *PDF Reference*, Adobe Systems Incorporated.

Functions by Task

Creating a PDF Operator Table

`CGPDFOperatorTableCreate` (page 350)
Creates an empty PDF operator table.

Setting Callback Functions

`CGPDFOperatorTableSetCallback` (page 351)
Sets a callback function for a PDF operator.

Retaining and Releasing a PDF Operator Table

`CGPDFOperatorTableRetain` (page 350)
Increments the retain count of a CGPDFOperatorTable object.

`CGPDFOperatorTableRelease` (page 350)
Decrements the retain count of a CGPDFOperatorTable object.

Functions

CGPDFOperatorTableCreate

Creates an empty PDF operator table.

```
CGPDFOperatorTableRef CGPDFOperatorTableCreate (
   void
);
```

Return Value
An empty PDF operator table. You are responsible for releasing this object by calling `CGPDFOperatorTableRelease` (page 350).

Discussion
Call the function `CGPDFOperatorTableSetCallback` (page 351) to fill the operator table with callbacks.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`CGPDFOperatorTable.h`

CGPDFOperatorTableRelease

Decrements the retain count of a CGPDFOperatorTable object.

```
void CGPDFOperatorTableRelease (
   CGPDFOperatorTableRef table
);
```

Parameters
table
A PDF operator table.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`CGPDFOperatorTable.h`

CGPDFOperatorTableRetain

Increments the retain count of a CGPDFOperatorTable object.

```
CGPDFOperatorTableRef CGPDFOperatorTableRetain (
   CGPDFOperatorTableRef table
);
```

Parameters

table

A PDF operator table.

Return Value

The same PDF operator table you passed in as the `table` parameter.

Availability

Available in Mac OS X version 10.4 and later.

Declared In

`CGPDFOperatorTable.h`

CGPDFOperatorTableSetCallback

Sets a callback function for a PDF operator.

```
void CGPDFOperatorTableSetCallback (
   CGPDFOperatorTableRef table,
   const char *name,
   CGPDFOperatorCallback callback
);
```

Parameters

table

A PDF operator table.

name

The name of the PDF operator you want to set a callback for.

callback

The callback to invoke for the PDF operator specified by the `name` parameter.

Discussion

You call the function `CGPDFOperatorTableSetCallback` for each PDF operator for which you want to provide a callback. See Appendix A in the *PDF Reference, Second Edition*, version 1.3, Adobe Systems Incorporated for a summary of PDF operators.

Availability

Available in Mac OS X version 10.4 and later.

Declared In

`CGPDFOperatorTable.h`

Callbacks

CGPDFOperatorCallback

Performs custom processing for PDF operators.

```
typedef void (*CGPDFOperatorCallback)(
   CGPDFScannerRef scanner,
   void *info
);
```

If you name your function `MyCGPDFOperatorCallback`, you would declare it like this:

```
void MyCGPDFOperatorCallback (
   CGPDFScannerRef scanner,
   void *info
);
```

Parameters

scanner

A CGPDFScanner object. Quartz passes the scanner to your callback function. The scanner contains the PDF content stream that has the PDF operator that corresponds to this callback.

info

A pointer to data passed to the callback.

Discussion

Your callback function takes any action that's appropriate for your application. For example, if you want to count the number of inline images in a PDF but ignore the image data, you would set a callback for the `EI` operator. In your callback you would increment a counter for each call.

Availability

Available in Mac OS X v10.4 and later.

Declared In

`CGPDFOperatorTable.h`

Data Types

CGPDFOperatorTableRef

An opaque type that stores callback functions for PDF operators.

```
typedef struct CGPDFOperatorTable *CGPDFOperatorTableRef;
```

Availability

Available in Mac OS X v10.4 and later.

Declared In

`CGPDFOperatorTable.h`

CGPDFPage Reference

Derived From:	CFType
Framework:	ApplicationServices/ApplicationServices.h
Declared in	CGPDFPage.h
Companion guide	Quartz 2D Programming Guide

Overview

The `CGPDFPageRef` opaque type represents a page in a PDF document.

Functions by Task

Retaining and Releasing a PDF Page

`CGPDFPageRetain` (page 358)
Increments the retain count of a PDF page.

`CGPDFPageRelease` (page 357)
Decrements the retain count of a PDF page.

Getting the CFType ID

`CGPDFPageGetTypeID` (page 357)
Returns the CFType ID for PDF page objects.

Getting Page Information

`CGPDFPageGetBoxRect` (page 354)
Returns the rectangle that represents a type of box for a content region or page dimensions of a PDF page.

`CGPDFPageGetDictionary` (page 354)
Returns the dictionary of a PDF page.

`CGPDFPageGetDocument` (page 355)
Returns the document for a page.

`CGPDFPageGetDrawingTransform` (page 355)
Returns the affine transform that maps a box to a given rectangle on a PDF page.

`CGPDFPageGetPageNumber` (page 356)
Returns the page number of the specified PDF page.

`CGPDFPageGetRotationAngle` (page 357)
Returns the rotation angle of a PDF page.

Functions

CGPDFPageGetBoxRect

Returns the rectangle that represents a type of box for a content region or page dimensions of a PDF page.

```
CGRect CGPDFPageGetBoxRect (
   CGPDFPageRef page,
   CGPDFBox box
);
```

Parameters

page
A PDF page.

box
A `CGPDFBox` constant that specifies the type of box. For possible values, see "PDF Boxes" (page 359).

Return Value

Returns the rectangle associated with the type of box specified by the `box` parameter in the specified page.

Discussion

Returns the rectangle associated with the specified box in the specified page. This is the value of the corresponding entry (such as `/MediaBox`, `/ArtBox`, and so on) in the page's dictionary.

Availability

Available in Mac OS X v10.3 and later.

Related Sample Code

CarbonSketch

Declared In

`CGPDFPage.h`

CGPDFPageGetDictionary

Returns the dictionary of a PDF page.

```
CGPDFDictionaryRef CGPDFPageGetDictionary (
   CGPDFPageRef page
);
```

Parameters

page

A PDF page.

Return Value
Returns the PDF dictionary for the specified page.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`CGPDFPage.h`

CGPDFPageGetDocument

Returns the document for a page.

```
CGPDFDocumentRef CGPDFPageGetDocument (
   CGPDFPageRef page
);
```

Parameters

page

A PDF page.

Return Value
The PDF document with which the specified page is associated.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`CGPDFPage.h`

CGPDFPageGetDrawingTransform

Returns the affine transform that maps a box to a given rectangle on a PDF page.

```
CGAffineTransform CGPDFPageGetDrawingTransform (
   CGPDFPageRef page,
   CGPDFBox box,
   CGRect rect,
   int rotate,
   bool preserveAspectRatio
);
```

Parameters

page

A PDF page.

box

A `CGPDFBox` constant that specifies the type of box. For possible values, see "PDF Boxes" (page 359).

rect

A Quartz rectangle.

rotate

An integer, that must be a multiple of `90`, that specifies the angle by which the specified rectangle is rotated clockwise.

preserveAspectRatio

A Boolean value that specifies whether or not the aspect ratio should be preserved. A value of `true` specifies that the aspect ratio should be preserved.

Return Value
An affine transform that maps the box specified by the `box` parameter to the rectangle specified by the `rect` parameter.

Discussion
Quartz constructs the affine transform as follows:

- Computes the effective rectangle by intersecting the rectangle associated with `box` and the `/MediaBox` entry of the specified page.
- Rotates the effective rectangle according to the page's `/Rotate` entry.
- Centers the resulting rectangle on `rect`. If the value of the `rotate` parameter is non-zero, then the rectangle is rotated clockwise by rotate degrees. The value of `rotate` must be a multiple of 90.
- Scales the rectangle, if necessary, so that it coincides with the edges of `rect`. If the value of `preserveAspectRatio` parameter is `true`, then the final rectangle coincides with the edges of `rect` only in the more restrictive dimension.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`CGPDFPage.h`

CGPDFPageGetPageNumber

Returns the page number of the specified PDF page.

```
size_t CGPDFPageGetPageNumber (
   CGPDFPageRef page
);
```

Parameters

page

A PDF page.

Return Value
Returns the page number of the specified page.

Availability
Available in Mac OS X v10.3 and later.

Declared In
CGPDFPage.h

CGPDFPageGetRotationAngle

Returns the rotation angle of a PDF page.

```
int CGPDFPageGetRotationAngle (
   CGPDFPageRef page
);
```

Parameters

page
A PDF page.

Return Value
The rotation angle (in degrees) of the specified page. This is the value of the `/Rotate` entry in the page's dictionary.

Availability
Available in Mac OS X v10.3 and later.

Declared In
CGPDFPage.h

CGPDFPageGetTypeID

Returns the CFType ID for PDF page objects.

```
CFTypeID CGPDFPageGetTypeID (
   void
);
```

Return Value
Returns the Core Foundation type for a PDF page.

Availability
Available in Mac OS X v10.3 and later.

Declared In
CGPDFPage.h

CGPDFPageRelease

Decrements the retain count of a PDF page.

```
void CGPDFPageRelease (
   CGPDFPageRef page
);
```

Parameters

page
A PDF page.

Discussion
This function is equivalent to `CFRelease`, except that it does not cause an error if the `page` parameter is `NULL`.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`CGPDFPage.h`

CGPDFPageRetain

Increments the retain count of a PDF page.

```
CGPDFPageRef CGPDFPageRetain (
   CGPDFPageRef page
);
```

Parameters

page

A PDF page.

Return Value
The same page you passed in as the `page` parameter.

Discussion
This function is equivalent to `CFRetain`, except that it does not cause an error if the `page` parameter is `NULL`.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`CGPDFPage.h`

Data Types

CGPDFPageRef

An opaque type that represents a page in a PDF document.

```
typedef struct CGPDFPage *CGPDFPageRef;
```

Availability
Available in Mac OS X v10.3 and later.

Declared In
`CGPDFPage.h`

Constants

PDF Boxes

Box types for a PDF page.

```
enum CGPDFBox {
    kCGPDFMediaBox = 0,
    kCGPDFCropBox = 1,
    kCGPDFBleedBox = 2,
    kCGPDFTrimBox = 3,
    kCGPDFArtBox = 4
};
typedef enum CGPDFBox CGPDFBox;
```

Constants

`kCGPDFMediaBox`

The page media box—a rectangle, expressed in default user space units, that defines the boundaries of the physical medium on which the page is intended to be displayed or printed

Available in Mac OS X v10.3 and later.

Declared in `CGPDFPage.h`.

`kCGPDFCropBox`

The page crop box—a rectangle, expressed in default user space units, that defines the visible region of default user space. When the page is displayed or printed, its contents are to be clipped to this rectangle.

Available in Mac OS X v10.3 and later.

Declared in `CGPDFPage.h`.

`kCGPDFBleedBox`

The page bleed box—a rectangle, expressed in default user space units, that defines the region to which the contents of the page should be clipped when output in a production environment

Available in Mac OS X v10.3 and later.

Declared in `CGPDFPage.h`.

`kCGPDFTrimBox`

The page trim box—a rectangle, expressed in default user space units, that defines the intended dimensions of the finished page after trimming.

Available in Mac OS X v10.3 and later.

Declared in `CGPDFPage.h`.

`kCGPDFArtBox`

The page art box—a rectangle, expressed in default user space units, defining the extent of the page's meaningful content (including potential white space) as intended by the page's creator.

Available in Mac OS X v10.3 and later.

Declared in `CGPDFPage.h`.

Declared In

`CGPDFPage.h`

CGPDFScanner Reference

Derived From:	None
Framework:	ApplicationServices/ApplicationServices.h
Declared in	CGPDFScanner.h
Companion guide	Quartz 2D Programming Guide

Overview

The `CGPDFScannerRef` opaque type is used to parse a PDF content stream. You can set up the PDF scanner object to invoke callbacks when it encounters specific PDF operators in the stream.

This opaque type is not derived from CFType and therefore there are no functions for retaining and releasing it.

Functions by Task

Creating a PDF Scanner Object

`CGPDFScannerCreate` (page 362)
Creates a CGPDFScanner object.

Retaining and Releasing PDF Scanner Objects

`CGPDFScannerRetain` (page 368)
Increments the retain count of a scanner object.

`CGPDFScannerRelease` (page 367)
Decrements the retain count of a scanner object.

Parsing Content

`CGPDFScannerScan` (page 368)
Parses the content stream of a CGPDFScanner object.

`CGPDFScannerGetContentStream` (page 363)
Returns the content stream associated with a CGPDFScanner object.

Getting PDF Objects from the Scanner Stack

`CGPDFScannerPopObject` (page 366)
Retrieves an object from the scanner stack.

`CGPDFScannerPopBoolean` (page 364)
Retrieves a Boolean object from the scanner stack.

`CGPDFScannerPopInteger` (page 364)
Retrieves an integer object from the scanner stack.

`CGPDFScannerPopNumber` (page 365)
Retrieves a real value object from the scanner stack.

`CGPDFScannerPopName` (page 365)
Retrieves a character string from the scanner stack.

`CGPDFScannerPopString` (page 367)
Retrieves a string object from the scanner stack.

`CGPDFScannerPopArray` (page 363)
Retrieves an array object from the scanner stack.

`CGPDFScannerPopDictionary` (page 364)
Retrieves a PDF dictionary object from the scanner stack.

`CGPDFScannerPopStream` (page 366)
Retrieves a PDF stream object from the scanner stack.

Functions

CGPDFScannerCreate

Creates a CGPDFScanner object.

```
CGPDFScannerRef CGPDFScannerCreate (
   CGPDFContentStreamRef cs,
   CGPDFOperatorTableRef table,
   void *info
);
```

Parameters

cs
A CGPDFContentStream object. (See *CGPDFContentStream Reference*.)

table
A CGPDFOperatorTable object that contains callbacks for the PDF operators you want to handle.

info
A pointer to data you want passed to your CGPDFOperatorTable callback function. (See *CGPDFOperatorTable Reference*.)

Return Value
A CGPDFScanner object. You are responsible for releasing this object by calling the function `CGPDFScannerRelease`.

Discussion
When you want to parse the contents of the PDF stream, call the function `CGPDFScannerScan` (page 368).

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`CGPDFScanner.h`

CGPDFScannerGetContentStream

Returns the content stream associated with a CGPDFScanner object.

```
CGPDFContentStreamRef CGPDFScannerGetContentStream (
   CGPDFScannerRef scanner
);
```

Parameters

scanner
The scanner object whose content stream you want to obtain.

Return Value
Return the content stream associated with `scanner`.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`CGPDFScanner.h`

CGPDFScannerPopArray

Retrieves an array object from the scanner stack.

```
bool CGPDFScannerPopArray (
   CGPDFScannerRef scanner,
   CGPDFArrayRef *value
);
```

Parameters

scanner
A valid scanner object.

value
On output, points to the CGPDFArray object popped from the `scanner` stack.

Return Value
Returns `true` if `value` is retrieved successfully; `false` otherwise.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`CGPDFScanner.h`

CGPDFScannerPopBoolean

Retrieves a Boolean object from the scanner stack.

```
bool CGPDFScannerPopBoolean (
   CGPDFScannerRef scanner,
   CGPDFBoolean *value
);
```

Parameters

scanner

A valid scanner object.

value

On output, points to the CGPDFBoolean object popped from the `scanner` stack.

Return Value

Returns `true` if `value` is retrieved successfully; `false` otherwise.

Availability

Available in Mac OS X version 10.4 and later.

Declared In

`CGPDFScanner.h`

CGPDFScannerPopDictionary

Retrieves a PDF dictionary object from the scanner stack.

```
bool CGPDFScannerPopDictionary (
   CGPDFScannerRef scanner,
   CGPDFDictionaryRef *value
);
```

Parameters

scanner

A valid scanner object.

value

On output, points to the CGPDFDictionary object popped from the `scanner` stack.

Return Value

Returns `true` if `value` is retrieved successfully; `false` otherwise.

Availability

Available in Mac OS X version 10.4 and later.

Declared In

`CGPDFScanner.h`

CGPDFScannerPopInteger

Retrieves an integer object from the scanner stack.

```
bool CGPDFScannerPopInteger (
   CGPDFScannerRef scanner,
   CGPDFInteger *value
);
```

Parameters

scanner

A valid scanner object.

value

On output, points to the CGPDFInteger object popped from the `scanner` stack.

Return Value

Returns `true` if `value` is retrieved successfully; `false` otherwise.

Availability

Available in Mac OS X version 10.4 and later.

Declared In

`CGPDFScanner.h`

CGPDFScannerPopName

Retrieves a character string from the scanner stack.

```
bool CGPDFScannerPopName (
   CGPDFScannerRef scanner,
   const char **value
);
```

Parameters

scanner

A valid scanner object.

value

On output, points to the character string popped from the `scanner` stack.

Return Value

Returns `true` if `value` is retrieved successfully; `false` otherwise.

Availability

Available in Mac OS X version 10.4 and later.

Declared In

`CGPDFScanner.h`

CGPDFScannerPopNumber

Retrieves a real value object from the scanner stack.

```
bool CGPDFScannerPopNumber (
   CGPDFScannerRef scanner,
   CGPDFReal *value
);
```

Parameters

scanner

A valid scanner object.

value

On output, points to the CGPDFReal object popped from the `scanner` stack.

Return Value
Returns `true` if `value` is retrieved successfully; `false` otherwise.

Discussion
The number retrieved from the scanner can be a real value or an integer value. However, the result is always converted to a `CGPDFReal` data type.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`CGPDFScanner.h`

CGPDFScannerPopObject

Retrieves an object from the scanner stack.

```
bool CGPDFScannerPopObject (
   CGPDFScannerRef scanner,
   CGPDFObjectRef *value
);
```

Parameters

scanner

A valid scanner object.

value

On output, points to the object popped from the `scanner` stack.

Return Value
Returns `true` if `value` is retrieved successfully; `false` otherwise.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`CGPDFScanner.h`

CGPDFScannerPopStream

Retrieves a PDF stream object from the scanner stack.

```
bool CGPDFScannerPopStream (
   CGPDFScannerRef scanner,
   CGPDFStreamRef *value
);
```

Parameters

scanner

A valid scanner object.

value

On output, points to the CGPDFStream object popped from the `scanner` stack.

Return Value

Returns `true` if `value` is retrieved successfully; `false` otherwise.

Availability

Available in Mac OS X version 10.4 and later.

Declared In

`CGPDFScanner.h`

CGPDFScannerPopString

Retrieves a string object from the scanner stack.

```
bool CGPDFScannerPopString (
   CGPDFScannerRef scanner,
   CGPDFStringRef *value
);
```

Parameters

scanner

A valid scanner object.

value

On output, points to the CGPDFString object popped from the `scanner` stack.

Return Value

Returns `true` if `value` is retrieved successfully; `false` otherwise.

Availability

Available in Mac OS X version 10.4 and later.

Declared In

`CGPDFScanner.h`

CGPDFScannerRelease

Decrements the retain count of a scanner object.

```
void CGPDFScannerRelease (
   CGPDFScannerRef scanner
);
```

Parameters

scanner

The scanner object to release.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
CGPDFScanner.h

CGPDFScannerRetain

Increments the retain count of a scanner object.

```
CGPDFScannerRef CGPDFScannerRetain (
   CGPDFScannerRef scanner
);
```

Parameters

scanner

The scanner object to retain.

Return Value
The same scanner object passed to the function in the `scanner` parameter.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
CGPDFScanner.h

CGPDFScannerScan

Parses the content stream of a CGPDFScanner object.

```
bool CGPDFScannerScan (
   CGPDFScannerRef scanner
);
```

Parameters

scanner

The scanner object whose content stream you want to parse.

Return Value
Returns `true` if the entire stream is parsed successfully; `false` if parsing fails (for example, if the stream data is corrupted).

Discussion
The function `CGPDFScannerScan` parses the PDF content stream associated with the scanner. Each time Quartz parses a PDF operator for which you register a callback, Quartz invokes your callback.

Availability
Available in Mac OS X version 10.4 and later.

Declared In
`CGPDFScanner.h`

Data Types

CGPDFScannerRef

An opaque type used to parse a PDF content stream.

```
typedef struct CGPDFScanner *CGPDFScannerRef;
```

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CGPDFScanner.h`

CGPDFStream Reference

Derived From:	None
Framework:	ApplicationServices/ApplicationServices.h
Declared in	CGPDFStream.h
Companion guide	Quartz 2D Programming Guide

Overview

The `CGPDFStreamRef` opaque type represents a PDF stream. A PDF stream consists of a dictionary that describes a sequence of bytes. Streams typically represent objects with potentially large amounts of data, such as images and page descriptions.

This opaque type is not derived from CFType and therefore there are no functions for retaining and releasing it.

Functions

CGPDFStreamCopyData

Returns the data associated with a PDF stream.

```
CFDataRef CGPDFStreamCopyData (
   CGPDFStreamRef stream,
   CGPDFDataFormat *format
);
```

Parameters

stream

A PDF stream.

format

On return, contains a constant that specifies the format of the data returned—`CGPDFDataFormatRaw` (page 373), `CGPDFDataFormatJPEGEncoded` (page 373), or `CGPDFDataFormatJPEG2000` (page 373).

Return Value

A CFData object that contains a copy of the stream data. You are responsible for releasing this object.

Availability

Available in Mac OS X version 10.3 and later.

Declared In
CGPDFStream.h

CGPDFStreamGetDictionary

Returns the dictionary associated with a PDF stream.

```
CGPDFDictionaryRef CGPDFStreamGetDictionary (
   CGPDFStreamRef stream
);
```

Parameters

stream
A PDF stream.

Return Value
The PDF dictionary for the specified stream.

Availability
Available in Mac OS X version 10.3 and later.

Declared In
CGPDFStream.h

Data Types

CGPDFStream

An opaque type that represents a PDF stream.

```
typedef struct CGPDFStream *CGPDFStreamRef;
```

Availability
Available in Mac OS X v10.3 and later.

Declared In
CGPDFStream.h

Constants

CGPDFDataFormat

The encoding format of PDF data.

```
enum CGPDFDataFormat {
 CGPDFDataFormatRaw,
 CGPDFDataFormatJPEGEncoded,
 CGPDFDataFormatJPEG2000
};
typedef enum CGPDFDataFormat CGPDFDataFormat;
```

Constants

`CGPDFDataFormatRaw`

The data stream is not encoded.

Available in Mac OS X v10.3 and later.

Declared in `CGPDFStream.h`.

`CGPDFDataFormatJPEGEncoded`

The data stream is encoded in JPEG format.

Available in Mac OS X v10.3 and later.

Declared in `CGPDFStream.h`.

`CGPDFDataFormatJPEG2000`

The data stream is encoded in JPEG-2000 format.

Available in Mac OS X v10.4 and later.

Declared in `CGPDFStream.h`.

Availability

Available in Mac OS X version 10.3 and later.

Declared In

`CGPDFStream.h`

CGPDFString Reference

Derived From:	None
Framework:	ApplicationServices/ApplicationServices.h
Declared in	CGPDFString.h
Companion guide	Quartz 2D Programming Guide

Overview

The `CGPDFStringRef` opaque type represents a string in a PDF document A PDF string object of a series of bytes—unsigned integer values in the range 0 to 255. The string elements are not integer objects, but are stored in a more compact format. For more information on the representation of strings in PDF, see the latest version of *PDF Reference*, Adobe Systems Incorporated.

This opaque type is not derived from CFType and therefore there are no functions for retaining and releasing it. CGPDFString objects exist as constituent parts of a CGPDFDocument object, and are managed by their container.

Functions by Task

Converting PDF Strings

`CGPDFStringCopyTextString` (page 376)
Returns a CFString object that represents a PDF string as a text string.

`CGPDFStringCopyDate` (page 376)
Converts a string to a date.

Getting PDF String Data

`CGPDFStringGetBytePtr` (page 376)
Returns a pointer to the bytes of a PDF string.

`CGPDFStringGetLength` (page 377)
Returns the number of bytes in a PDF string.

Functions

CGPDFStringCopyDate

Converts a string to a date.

```
CFDateRef CGPDFStringCopyDate (
   CGPDFStringRef string
);
```

Parameters

string

The string to convert to a date.

Return Value

A CFDate object.

Discussion

The PDF specification defines a specific format for strings that represent dates. This function converts strings in that form to CFDate objects.

Availability

Available in Mac OS X version 10.4 and later.

Declared In

`CGPDFString.h`

CGPDFStringCopyTextString

Returns a CFString object that represents a PDF string as a text string.

```
CFStringRef CGPDFStringCopyTextString (
   CGPDFStringRef string
);
```

Parameters

string

A PDF string. If this value is `NULL`, it will cause an error.

Return Value

Returns a CFString object that represents the specified PDF string as a text string. You are responsible for releasing this object.

Availability

Available in Mac OS X version 10.3 and later.

Declared In

`CGPDFString.h`

CGPDFStringGetBytePtr

Returns a pointer to the bytes of a PDF string.

```
const unsigned char * CGPDFStringGetBytePtr (
   CGPDFStringRef string
);
```

Parameters

string

A PDF string.

Return Value

Returns a pointer to the bytes of the specified string. If the string is `NULL`, the function returns `NULL`.

Availability

Available in Mac OS X version 10.3 and later.

Declared In

`CGPDFString.h`

CGPDFStringGetLength

Returns the number of bytes in a PDF string.

```
size_t CGPDFStringGetLength (
   CGPDFStringRef string
);
```

Parameters

string

A PDF string.

Return Value

Returns the number of bytes referenced by the string, or `0` if the string is `NULL`.

Availability

Available in Mac OS X version 10.3 and later.

Declared In

`CGPDFString.h`

Data Types

CGPDFStringRef

An opaque data type that represents a string in a PDF document.

```
typedef struct CGPDFString *CGPDFStringRef;
```

Availability

Available in Mac OS X v10.3 and later.

Declared In

`CGPDFString.h`

CGPSConverter Reference

Derived From:	*CFType Reference*
Framework:	ApplicationServices/ApplicationServices.h
Declared in	CGPSConverter.h
Companion guide	Quartz 2D Programming Guide

Overview

`CGPSConverterRef` is an opaque type used to convert PostScript data to PDF data. The PostScript data is supplied by a data provider and written into a data consumer. When you create a PostScript converter object, you can supply callback functions for Quartz to invoke at various stages of the conversion process,

Functions

CGPSConverterAbort

Tells a PostScript converter to abort a conversion at the next available opportunity.

```
bool CGPSConverterAbort (
   CGPSConverterRef converter
);
```

Parameters

converter

A PostScript converter.

Return Value

A Boolean value that indicates whether the converter is currently converting data (`true` if it is).

Availability

Available in Mac OS X version 10.3 and later.

Declared In

`CGPSConverter.h`

CGPSConverterConvert

Uses a PostScript converter to convert PostScript data to PDF data.

```
bool CGPSConverterConvert (
   CGPSConverterRef converter,
   CGDataProviderRef provider,
   CGDataConsumerRef consumer,
   CFDictionaryRef options
);
```

Parameters

converter

A PostScript converter.

provider

A Quartz data provider that supplies PostScript data.

consumer

A Quartz data provider that will receive the resulting PDF data.

options

This parameter should be `NULL`; it is reserved for future expansion of the API.

Return Value

A Boolean value that indicates whether the PostScript conversion completed successfully (`true` if it did).

Discussion

The conversion is thread safe, however it is not possible to have more than one conversion job in process within a given address space or process. If a given thread is running a conversion and another thread starts a new conversion, the second conversion will block until the first conversion is complete.

Important: Although `CGPSConverterConvert` is thread safe (it uses locks to prevent more than one conversion at a time in the same process), it is not thread safe with respect to the Resource Manager. If your application uses the Resource Manager on a separate thread, you should either use locks to prevent `CGPSConverterConvert` from executing during your usage of the Resource Manager or you should perform your conversions using the Post Script converter in a separate process.

In general, you can avoid this issue by using nib files instead of Resource Manager resources.

Availability

Available in Mac OS X version 10.3 and later.

Declared In

`CGPSConverter.h`

CGPSConverterCreate

Creates a new PostScript converter.

```
CGPSConverterRef CGPSConverterCreate (
   void *info,
   const CGPSConverterCallbacks *callbacks,
   CFDictionaryRef options
);
```

Parameters

info

A pointer to the data that will be passed to the callbacks.

callbacks
A pointer to a PostScript converter callbacks structure that specifies the callbacks to be used during a conversion process.

options
This parameter should be `NULL`; it is reserved for future expansion of the API.

Return Value
A new PostScript converter, or `NULL` if a converter could not be created. You are responsible for releasing this object.

Availability
Available in Mac OS X version 10.3 and later.

Declared In
`CGPSConverter.h`

CGPSConverterGetTypeID

Returns the Core Foundation type identifier for PostScript converters.

```
CFTypeID CGPSConverterGetTypeID (
   void
);
```

Return Value
The Core Foundation identifier for the opaque type `CGPSConverterRef` (page 386).

Availability
Available in Mac OS X version 10.3 and later.

Declared In
`CGPSConverter.h`

CGPSConverterIsConverting

Checks whether the converter is currently converting data.

```
bool CGPSConverterIsConverting (
   CGPSConverterRef converter
);
```

Parameters
converter
A PostScript converter.

Return Value
Returns `true` that indicates if the conversion is in progress.

Availability
Available in Mac OS X version 10.3 and later.

Declared In
`CGPSConverter.h`

Callbacks by Task

Performing Custom Tasks at the Document Level

`CGPSConverterBeginDocumentCallback` (page 382)
Performs custom tasks at the beginning of a PostScript conversion process.

`CGPSConverterEndDocumentCallback` (page 383)
Performs custom tasks at the end of a PostScript conversion process.

Performing Custom Tasks at the Page Level

`CGPSConverterBeginPageCallback` (page 383)
Performs custom tasks at the beginning of each page in a PostScript conversion process.

`CGPSConverterEndPageCallback` (page 384)
Performs custom tasks at the end of each page of a PostScript conversion process.

Reporting Progress and Messages

`CGPSConverterProgressCallback` (page 385)
Reports progress periodically during a PostScript conversion process.

`CGPSConverterMessageCallback` (page 384)
Passes messages generated during a PostScript conversion process.

Performing Custom Clean-up Tasks

`CGPSConverterReleaseInfoCallback` (page 386)
Performs custom tasks when a PostScript converter is released.

Callbacks

CGPSConverterBeginDocumentCallback

Performs custom tasks at the beginning of a PostScript conversion process.

```
typedef void (*CGPSConverterBeginDocumentCallback)(void
*info);
```

If you name your function `MyConverterBeginDocument`, you would declare it like this:

```
size_t MyConverterBeginDocument (
    void *info
);
```

Parameters

info

A generic pointer to private data shared among your callback functions. This is the same pointer you supplied to `CGPSConverterCreate` (page 380).

Availability
Available in Mac OS X v10.3 and later.

Declared In
`CGPSConverter.h`

CGPSConverterBeginPageCallback

Performs custom tasks at the beginning of each page in a PostScript conversion process.

```
typedef void (*CGPSConverterBeginPageCallback)(void
*info, size_t pageNumber, CFDictionaryRef pageInfo);
```

If you name your function `MyConverterBeginDocument`, you would declare it like this:

```
void MyConverterBeginPage (
    void *info,
   size_t pageNumber,
   CFDictionaryRef pageInfo
);
```

Parameters

info

A generic pointer to private data shared among your callback functions. This is the same pointer you supplied to `CGPSConverterCreate` (page 380).

pageNumber

The current page number. Page numbers start at `1`.

pageInfo

A dictionary that contains contextual information about the page. This parameter is reserved for future API expansion, and is currently unused.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`CGPSConverter.h`

CGPSConverterEndDocumentCallback

Performs custom tasks at the end of a PostScript conversion process.

```
typedef void (*CGPSConverterEndDocumentCallback)(void
*info, bool success);
```

If you name your function `MyConverterEndDocument`, you would declare it like this:

```
void MyConverterEndDocument (
    void *info,
```

```
    bool success
);
```

Parameters

info

A generic pointer to private data shared among your callback functions. This is the same pointer you supplied to `CGPSConverterCreate` (page 380).

success

A Boolean value that indicates whether the PostScript conversion completed successfully (`true` if it did).

Availability
Available in Mac OS X v10.3 and later.

Declared In
`CGPSConverter.h`

CGPSConverterEndPageCallback

Performs custom tasks at the end of each page of a PostScript conversion process.

```
typedef void (*CGPSConverterEndPageCallback)(void
*info, size_t pageNumber, CFDictionaryRef pageInfo);
```

If you name your function `MyConverterEndPage`, you would declare it like this:

```
void MyConverterEndPage (
   void *info,
   size_t *pageNumber,
   CFDictionaryRef pageInfo
);
```

Parameters

info

A generic pointer to private data shared among your callback functions. This is the same pointer you supplied to `CGPSConverterCreate` (page 380).

pageNumber

The current page number. Page numbers start at `1`.

pageInfo

A dictionary that contains contextual information about the page. This parameter is reserved for future API expansion, and is currently unused.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`CGPSConverter.h`

CGPSConverterMessageCallback

Passes messages generated during a PostScript conversion process.

```
typedef void (*CGPSConverterMessageCallback)(void
*info, CFStringRef message);
```

If you name your function `MyConverterMessage`, you would declare it like this:

```
void MyConverterMessage (
    void *info,
   CFStringRef message
);
```

Parameters

info

A generic pointer to private data shared among your callback functions. This is the same pointer you supplied to `CGPSConverterCreate` (page 380).

message

A string containing the message from the PostScript conversion process.

Discussion

There are several kinds of message that might be sent during a conversion process. The most likely are font substitution messages, and any messages that the PostScript code itself generates. Any PostScript messages written to `stdout` are routed through this callback—typically these are debugging or status messages and, although uncommon, can be useful in debugging. In addition, there may be error messages if the document is malformed.

Availability

Available in Mac OS X v10.3 and later.

Declared In

`CGPSConverter.h`

CGPSConverterProgressCallback

Reports progress periodically during a PostScript conversion process.

```
typedef void (*CGPSConverterProgressCallback)(void
*info);
```

If you name your function `MyConverterProgress`, you would declare it like this:

```
void MyConverterProgress (
    void *info
);
```

Parameters

info

A generic pointer to private data shared among your callback functions. This is the same pointer you supplied to `CGPSConverterCreate` (page 380).

Availability

Available in Mac OS X v10.3 and later.

Declared In

`CGPSConverter.h`

CGPSConverterReleaseInfoCallback

Performs custom tasks when a PostScript converter is released.

```
typedef void (*CGPSConverterReleaseInfoCallback)(void
*info);
```

If you name your function `MyConverterReleaseInfo`, you would declare it like this:

```
void MyConverterReleaseInfo (
  void *info
);
```

Parameters

info

A generic pointer to private data shared among your callback functions. This is the same pointer you supplied to `CGPSConverterCreate` (page 380).

Availability

Available in Mac OS X v10.3 and later.

Declared In

`CGPSConverter.h`

Data Types

CGPSConverterRef

An opaque data type used to convert PostScript data to PDF data.

```
typedef struct CGPSConverter *CGPSConverterRef;
```

Availability

Available in Mac OS X v10.3 and later.

Declared In

`CGPSConverter.h`

CGPSConverterCallbacks

A structure for holding the callbacks provided when you create a PostScript converter object.

```
struct CGPSConverterCallbacks {
    unsigned int version;
    CGPSConverterBeginDocumentCallback beginDocument;
    CGPSConverterEndDocumentCallback endDocument;
    CGPSConverterBeginPageCallback beginPage;
    CGPSConverterEndPageCallback endPage;
    CGPSConverterProgressCallback noteProgress;
    CGPSConverterMessageCallback noteMessage;
    CGPSConverterReleaseInfoCallback releaseInfo;
};
typedef struct CGPSConverterCallbacks CGPSConverterCallbacks;
```

Fields

`version`
: The version number of the structure passed in as a parameter to the converter creation functions. The structure defined below is version `0`.

`beginDocument`
: The callback called at the beginning of the conversion of the PostScript document, or `NULL`.

`endDocument`
: The callback called at the end of conversion of the PostScript document, or `NULL`.

`beginPage`
: The callback called at the start of the conversion of each page in the PostScript document, or `NULL`.

`endPage`
: The callback called at the end of the conversion of each page in the PostScript document, or `NULL`.

`noteProgress`
: The callback called periodically during the conversion to indicate that conversion is proceeding, or `NULL`.

`noteMessage`
: The callback called to pass any messages that might result during the conversion, or `NULL`.

`releaseInfo`
: The callback called when the converter is deallocated, or `NULL`.

Availability

Available in Mac OS X v10.3 and later.

Declared In

`CGPSConverter.h`

CGShading Reference

Derived From:	CFType
Framework:	ApplicationServices/ApplicationServices.h
Declared in	CGShading.h
Companion guide	Quartz 2D Programming Guide

Overview

`CGShadingRef` is an opaque type used to define linear (axial) and radial gradient fills whose color transitions are controlled by a function (`CGFunctionRef` (page 199)) that you provide. Shading means to fill using a smooth transition between colors across an area. To paint with a Quartz shading, you call `CGContextDrawShading` (page 90). This function fills the current clipping path using the specified color gradient, calling your parametric function repeatedly as it draws

An alternative to using a CGShading object is to use the `CGGradientRef` (page 207) opaque type. For applications that run in Mac OS X v10.5 and later, CGGradient objects are much simpler to use. (See *CGGradient Reference*.)

Functions by Task

Creating Shading Objects

`CGShadingCreateAxial` (page 390)
Creates a shading object to use for axial shading.

`CGShadingCreateRadial` (page 391)
Creates a shading object to use for radial shading.

Retaining and Releasing Shading Objects

`CGShadingRetain` (page 392)
Increments the retain count of a shading object.

`CGShadingRelease` (page 392)
Decrements the retain count of a shading object.

Getting the CFType ID

`CGShadingGetTypeID` (page 391)
Returns the Core Foundation type identifier for Quartz shading objects.

Functions

CGShadingCreateAxial

Creates a shading object to use for axial shading.

```
CGShadingRef CGShadingCreateAxial (
   CGColorSpaceRef colorspace,
   CGPoint start,
   CGPoint end,
   CGFunctionRef function,
   bool extendStart,
   bool extendEnd
);
```

Parameters

colorspace
The color space in which color values are expressed. Quartz retains this object; upon return, you may safely release it.

start
The starting point of the axis, in the shading's target coordinate space.

end
The ending point of the axis, in the shading's target coordinate space.

function
A CGFunction object created by the function `CGFunctionCreate`. This object refers to your function for creating an axial shading. Quartz retains this object; upon return, you may safely release it.

extendStart
A Boolean value that specifies whether to extend the shading beyond the starting point of the axis.

extendEnd
A Boolean value that specifies whether to extend the shading beyond the ending point of the axis.

Return Value
A new Quartz axial shading. You are responsible for releasing this object using `CGShadingRelease` (page 392).

Discussion
An axial shading is a color blend that varies along a linear axis between two endpoints and extends indefinitely perpendicular to that axis. When you are ready to draw the shading, call the function `CGContextDrawShading` (page 90).

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CGShading.h`

CGShadingCreateRadial

Creates a shading object to use for radial shading.

```
CGShadingRef CGShadingCreateRadial (
   CGColorSpaceRef colorspace,
   CGPoint start,
   CGFloat startRadius,
   CGPoint end,
   CGFloat endRadius,
   CGFunctionRef function,
   bool extendStart,
   bool extendEnd
);
```

Parameters

colorspace
The color space in which color values are expressed. Quartz retains this object; upon return, you may safely release it.

start
The center of the starting circle, in the shading's target coordinate space.

startRadius
The radius of the starting circle, in the shading's target coordinate space.

end
The center of the ending circle, in the shading's target coordinate space.

endRadius
The radius of the ending circle, in the shading's target coordinate space.

function
A CGFunction object created by the function `CGFunctionCreate`. This object refers to your function for creating a radial shading. Quartz retains this object; upon return, you may safely release it.

extendStart
A Boolean value that specifies whether to extend the shading beyond the starting circle.

extendEnd
A Boolean value that specifies whether to extend the shading beyond the ending circle.

Return Value

A new Quartz radial shading. You are responsible for releasing this object using `CGShadingRelease` (page 392).

Discussion

A radial shading is a color blend that varies between two circles. To draw the shading, call the function `CGContextDrawShading` (page 90).

Availability

Available in Mac OS X version 10.2 and later.

Declared In

`CGShading.h`

CGShadingGetTypeID

Returns the Core Foundation type identifier for Quartz shading objects.

```
CFTypeID CGShadingGetTypeID (
   void
);
```

Return Value
The Core Foundation identifier for the opaque type `CGShadingRef` (page 393).

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CGShading.h`

CGShadingRelease

Decrements the retain count of a shading object.

```
void CGShadingRelease (
   CGShadingRef shading
);
```

Parameters

shading
The shading object to release.

Discussion
This function is equivalent to `CFRelease`, except that it does not cause an error if the *shading* parameter is `NULL`.

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CGShading.h`

CGShadingRetain

Increments the retain count of a shading object.

```
CGShadingRef CGShadingRetain (
   CGShadingRef shading
);
```

Parameters

shading
The shading object to retain.

Return Value
The same shading object you passed in as the `shading` parameter.

Discussion
This function is equivalent to `CFRetain`, except that it does not cause an error if the `shading` parameter is `NULL`.

Availability
Available in Mac OS X version 10.2 and later.

Declared In
`CGShading.h`

Data Types

CGShadingRef

An opaque type that represents a Quartz shading.

```
typedef struct CGShading *CGShadingRef;
```

Availability
Available in Mac OS X v10.2 and later.

Declared In
`CGShading.h`

Managers

Apple Event Manager Reference

Framework:	CoreServices/CoreServices.h, Carbon/Carbon.h
Declared in	AEDataModel.h AEHelpers.h AEMach.h AEObjects.h AEPackObject.h AERegistry.h AEUserTermTypes.h AppleEvents.h

Overview

The Apple Event Manager, a part of the Open Scripting Architecture (OSA), provides facilities for applications to send and respond to Apple events and to make their operations and data available to AppleScript scripts. For related API reference, see Open Scripting Architecture Reference.

An Apple event is a type of interprocess message that can specify complex operations and data. Apple events provide a data transport and event dispatching mechanism that can be used within a single application, between applications on the same computer, and between applications on different computers connected to a network.

Applications typically use Apple events to request services and information from other applications or to provide services and information in response to such requests. All applications that present a graphical interface to the user through the Human Interface Toolbox (Carbon applications) or the Cocoa application framework should be able to respond, if appropriate, to certain events sent by the Mac OS. These include the `open application` (or `launch`), `reopen`, `open documents`, `print documents`, and `quit` events.

Some Apple Event Manager functions are marked as being thread safe—for all other functions, you should call them only on the main thread.

For an overview of technologies that take advantage of the Apple Event Manager, see AppleScript Overview.

For information on working with Apple events, including events sent by the Mac OS, see "Responding to Apple Events" in Apple Events Programming Guide. For information about individual four-character codes used in Apple events, see *AppleScript Terminology and Apple Event Codes Reference*.

The Apple Event Manager is implemented by the AE framework, a subframework of the Core Services framework. You don't link directly with the AE framework—instead, you typically link with the Carbon framework, which includes it. Some AppleEvent definitions are only available to clients of the Carbon framework, which includes, for example, `AEInteraction.h` in the HIToolbox framework.

The AE framework does not force a connection to the window server. This allows daemons and startup items that work with Apple events to continue working across log outs.

Functions by Task

Adding Items to Descriptor Lists

`AEPutArray` (page 459)
Inserts the data for an Apple event array into a descriptor list, replacing any previous descriptors in the list.

`AEPutDesc` (page 461)
Adds a descriptor to any descriptor list, possibly replacing an existing descriptor in the list.

`AEPutPtr` (page 465)
Inserts data specified in a buffer into a descriptor list as a descriptor, possibly replacing an existing descriptor in the list.

Adding Parameters and Attributes to Apple Events and Apple Event Records

`AEPutAttributeDesc` (page 460)
Adds a descriptor and a keyword to an Apple event as an attribute.

`AEPutAttributePtr` (page 461)
Adds a pointer to data, a descriptor type, and a keyword to an Apple event as an attribute.

`AEPutKeyDesc` (page 462)
Inserts a descriptor and a keyword into an Apple event record as an Apple event parameter.

`AEPutKeyPtr` (page 463)
Inserts data, a descriptor type, and a keyword into an Apple event record as an Apple event parameter.

`AEPutParamDesc` (page 464)
Inserts a descriptor and a keyword into an Apple event or Apple event record as an Apple event parameter.

`AEPutParamPtr` (page 464)
Inserts data, a descriptor type, and a keyword into an Apple event or Apple event record as an Apple event parameter.

Coercing Descriptor Types

`AECoerceDesc` (page 413)
Coerces the data in a descriptor to another descriptor type and creates a descriptor containing the newly coerced data.

`AECoercePtr` (page 414)
Coerces data to a desired descriptor type and creates a descriptor containing the newly coerced data.

Counting the Items in Descriptor Lists

`AECountItems` (page 415)
Counts the number of descriptors in a descriptor list.

Creating an Apple Event

`AECreateAppleEvent` (page 416)
Creates an Apple event with several important attributes but no parameters.

Creating and Duplicating Descriptors

`AECreateDesc` (page 417)
Creates a new descriptor that incorporates the specified data.

`AECreateDescFromExternalPtr` (page 418)
Creates a new descriptor that uses a memory buffer supplied by the caller.

`AEDuplicateDesc` (page 426)
Creates a copy of a descriptor.

Creating, Calling, and Deleting Universal Procedure Pointers

`DisposeAECoerceDescUPP` (page 503)
Disposes of a universal procedure pointer to a function that coerces data stored in a descriptor.

`DisposeAECoercePtrUPP` (page 503)
Disposes of a universal procedure pointer to a function that coerces data stored in a buffer.

`DisposeAEDisposeExternalUPP` (page 503)
Disposes of a universal procedure pointer to a function that disposes of data supplied to the `AECreateDescFromExternalPtr` function.

`DisposeAEEventHandlerUPP` (page 504)
Disposes of a universal procedure pointer to an event handler function.

`DisposeAEFilterUPP` (page 504)
Disposes of a universal procedure pointer to an Apple event filter function.

`DisposeAEIdleUPP` (page 504)
Disposes of a universal procedure pointer to an Apple event idle function.

`DisposeOSLAccessorUPP` (page 504)
Disposes of a universal procedure pointer to an object accessor function.

`DisposeOSLAdjustMarksUPP` (page 505)
Disposes of a universal procedure pointer to an object callback adjust marks function.

`DisposeOSLCompareUPP` (page 505)
Disposes of a universal procedure pointer to an object callback comparison function.

`DisposeOSLCountUPP` (page 505)
Disposes of a universal procedure pointer to an object callback count function.

`DisposeOSLDisposeTokenUPP` (page 506)
Disposes of a universal procedure pointer to an object callback dispose token function.

`DisposeOSLGetErrDescUPP` (page 506)
Disposes of a universal procedure pointer to an object callback get error descriptor function.

`DisposeOSLGetMarkTokenUPP` (page 506)
Disposes of a universal procedure pointer to an object callback get mark function.

DisposeOSLMarkUPP (page 507)
Disposes of a universal procedure pointer to an object callback mark function.

InvokeAECoerceDescUPP (page 507)
Calls a universal procedure pointer to a function that coerces data stored in a descriptor.

InvokeAECoercePtrUPP (page 508)
Calls a universal procedure pointer to a function that coerces data stored in a buffer.

InvokeAEDisposeExternalUPP (page 508)
Calls a dispose external universal procedure pointer.

InvokeAEEventHandlerUPP (page 509)
Calls an event handler universal procedure pointer.

InvokeAEFilterUPP (page 509)
Calls an Apple event filter universal procedure pointer.

InvokeAEIdleUPP (page 509)
Calls an Apple event idle universal procedure pointer.

InvokeOSLAccessorUPP (page 510)
Calls an object accessor universal procedure pointer.

InvokeOSLAdjustMarksUPP (page 510)
Calls an object callback adjust marks universal procedure pointer.

InvokeOSLCompareUPP (page 511)
Calls an object callback comparison universal procedure pointer.

InvokeOSLCountUPP (page 511)
Calls an object callback count universal procedure pointer.

InvokeOSLDisposeTokenUPP (page 512)
Calls an object callback dispose token universal procedure pointer.

InvokeOSLGetErrDescUPP (page 512)
Calls an object callback get error descriptor universal procedure pointer.

InvokeOSLGetMarkTokenUPP (page 513)
Calls an object callback get mark universal procedure pointer.

InvokeOSLMarkUPP (page 513)
Calls an object callback mark universal procedure pointer.

NewAECoerceDescUPP (page 514)
Creates a new universal procedure pointer to a function that coerces data stored in a descriptor.

NewAECoercePtrUPP (page 514)
Creates a new universal procedure pointer to a function that coerces data stored in a buffer.

NewAEDisposeExternalUPP (page 514)
Creates a new universal procedure pointer to a function that disposes of data stored in a buffer.

NewAEEventHandlerUPP (page 515)
Creates a new universal procedure pointer to an event handler function.

NewAEFilterUPP (page 515)
Creates a new universal procedure pointer to an Apple event filter function.

NewAEIdleUPP (page 515)
Creates a new universal procedure pointer to an Apple event idle function.

NewOSLAccessorUPP (page 516)
Creates a new universal procedure pointer to an object accessor function.

NewOSLAdjustMarksUPP (page 516)
Creates a new universal procedure pointer to an object callback adjust marks function.

NewOSLCompareUPP (page 517)
Creates a new universal procedure pointer to an object callback comparison function.

NewOSLCountUPP (page 517)
Creates a new universal procedure pointer to an object callback count function.

NewOSLDisposeTokenUPP (page 517)
Creates a new universal procedure pointer to an object callback dispose token function.

NewOSLGetErrDescUPP (page 518)
Creates a new universal procedure pointer to an object callback get error descriptor function.

NewOSLGetMarkTokenUPP (page 518)
Creates a new universal procedure pointer to an object callback get mark function.

NewOSLMarkUPP (page 518)
Creates a new universal procedure pointer to an object callback mark function.

Creating Descriptor Lists and Apple Event Records

AECreateList (page 419)
Creates an empty descriptor list or Apple event record.

Creating Object Specifiers

CreateCompDescriptor (page 498)
Creates a comparison descriptor that specifies how to compare one or more Apple event objects with either another Apple event object or a descriptor.

CreateLogicalDescriptor (page 499)
Creates a logical descriptor that specifies a logical operator and one or more logical terms for the Apple Event Manager to evaluate.

CreateObjSpecifier (page 500)
Assembles an object specifier that identifies one or more Apple event objects, from other descriptors.

CreateOffsetDescriptor (page 501)
Creates an offset descriptor that specifies the position of an element in relation to the beginning or end of its container.

CreateRangeDescriptor (page 502)
Creates a range descriptor that specifies a series of consecutive elements in the same container.

Deallocating Memory for Descriptors

AEDisposeDesc (page 424)
Deallocates the memory used by a descriptor.

Deallocating Memory for Tokens

`AEDisposeToken` (page 425)
Deallocates the memory used by a token.

Deleting Descriptors

`AEDeleteItem` (page 422)
Deletes a descriptor from a descriptor list, causing all subsequent descriptors to move up one place.

`AEDeleteKeyDesc` (page 423)
Deletes a keyword-specified parameter from an Apple event record.

`AEDeleteParam` (page 423)
Deletes a keyword-specified parameter from an Apple event record.

Dispatching Apple Events

`AEProcessAppleEvent` (page 457)
Calls the handler, if one exists, for a specified Apple event.

Getting, Calling, and Removing Object Accessor Functions

`AECallObjectAccessor` (page 412)
Invokes the appropriate object accessor function for a specific desired type and container type.

`AEGetObjectAccessor` (page 441)
Gets an object accessor function from an object accessor dispatch table.

`AEInstallObjectAccessor` (page 451)
Adds or replaces an entry for an object accessor function to an object accessor dispatch table.

`AERemoveObjectAccessor` (page 470)
Removes an object accessor function from an object accessor dispatch table.

Getting Data or Descriptors From Apple Events and Apple Event Records

`AEGetAttributeDesc` (page 429)
Gets a copy of the descriptor for a specified Apple event attribute from an Apple event; typically used when your application needs to pass the descriptor on to another function.

`AEGetAttributePtr` (page 430)
Gets a copy of the data for a specified Apple event attribute from an Apple event; typically used when your application needs to work with the data directly.

`AEGetKeyDesc` (page 436)
Gets a copy of the descriptor for a keyword-specified Apple event parameter from an Apple event record

`AEGetKeyPtr` (page 437)
Gets a copy of the data for a specified Apple event parameter from an Apple event record.

AEGetParamDesc (page 443)
Gets a copy of the descriptor for a keyword-specified Apple event parameter from an Apple event or an Apple event record.

AEGetParamPtr (page 444)
Gets a copy of the data for a specified Apple event parameter from an Apple event or an Apple event record.

Getting Information About the Apple Event Manager

AEManagerInfo (page 454)
Provides information about the version of the Apple Event Manager currently available or the number of processes that are currently recording Apple events.

Getting Items From Descriptor Lists

AEGetArray (page 428)
Extracts data from an Apple event array created with the AEPutArray function and stores it as a standard array of fixed size items in the specified buffer.

AEGetNthDesc (page 439)
Copies a descriptor from a specified position in a descriptor list into a specified descriptor; typically used when your application needs to pass the extracted data to another function as a descriptor.

AEGetNthPtr (page 440)
Gets a copy of the data from a descriptor at a specified position in a descriptor list; typically used when your application needs to work with the extracted data directly.

Getting the Sizes and Descriptor Types of Descriptors

AESizeOfAttribute (page 482)
Gets the size and descriptor type of an Apple event attribute from a descriptor of type AppleEvent.

AESizeOfKeyDesc (page 483)
Gets the size and descriptor type of an Apple event parameter from a descriptor of type AERecord.

AESizeOfNthItem (page 484)
Gets the data size and descriptor type of the descriptor at a specified position in a descriptor list.

AESizeOfParam (page 485)
Gets the size and descriptor type of an Apple event parameter from a descriptor of type AERecord or AppleEvent.

Initializing the Object Support Library

AEObjectInit (page 455)
Initializes the Object Support Library.

AESetObjectCallbacks (page 480)
Specifies the object callback functions for your application.

Locating Processes on Remote Computers

Available starting in Mac OS X version v10.3, these functions allow you to locate processes on remote computers (a task supported by the PPCToolbox in Mac OS 9).

`AECreateRemoteProcessResolver` (page 420)
Creates an object for resolving a list of remote processes.

`AEDisposeRemoteProcessResolver` (page 424)
Disposes of an `AERemoteProcessResolverRef`.

`AERemoteProcessResolverGetProcesses` (page 466)
Returns an array of objects containing information about processes running on a remote machine.

`AERemoteProcessResolverScheduleWithRunLoop` (page 467)
Schedules a resolver for execution on a given run loop in a given mode.

Managing Apple Event Dispatch Tables

`AEGetEventHandler` (page 435)
Gets an event handler from an Apple event dispatch table.

`AEInstallEventHandler` (page 449)
Adds an entry for an event handler to an Apple event dispatch table.

`AERemoveEventHandler` (page 469)
Removes an event handler entry from an Apple event dispatch table.

Managing Coercion Handler Dispatch Tables

`AEGetCoercionHandler` (page 431)
Gets the coercion handler for a specified descriptor type.

`AEInstallCoercionHandler` (page 448)
Installs a coercion handler in either the application or system coercion handler dispatch table.

`AERemoveCoercionHandler` (page 468)
Removes a coercion handler from a coercion handler dispatch table.

Managing Special Handler Dispatch Tables

`AEGetSpecialHandler` (page 446)
Gets a specified handler from a special handler dispatch table.

`AEInstallSpecialHandler` (page 452)
Installs a callback function in a special handler dispatch table.

`AERemoveSpecialHandler` (page 471)
Removes a handler from a special handler dispatch table.

Operating On Descriptor Data

`AEGetDescData` (page 432)
Gets the data from the specified descriptor.

`AEGetDescDataSize` (page 434)
Gets the size, in bytes, of the data in the specified descriptor.

`AEGetDescDataRange` (page 433)
Retrieves a specified series of bytes from the specified descriptor.

`AEReplaceDescData` (page 472)
Copies the specified data into the specified descriptor, replacing any previous data.

Requesting More Time to Respond to Apple Events

`AEResetTimer` (page 472)
Resets the timeout value for an Apple event to its starting value.

Requesting User Interaction

`AEGetInteractionAllowed` (page 436)
Gets your application's current user interaction preferences for responding to an Apple event as a server application.

`AEInteractWithUser` (page 453)
Initiates interaction with the user when your application is a server application responding to an Apple event.

`AESetInteractionAllowed` (page 479)
Specifies user interaction preferences for responding to an Apple event when your application is the server application.

Resolving Object Specifiers

`AEResolve` (page 473)
Resolves an object specifier.

Sending an Apple Event

`AESend` (page 476)
Sends the specified Apple event.

Creating Apple Event Structures in Memory

`AEBuildAppleEvent` (page 408)
Constructs an entire Apple event in a single call.

AEBuildDesc (page 410)
Provides a facility for compiling AEBuild descriptor strings into Apple event descriptors (AEDesc).

AEBuildParameters (page 411)
Adds additional parameters or attributes to an existing Apple event.

AEPrintDescToHandle (page 456)
Provides a pretty printer facility for displaying the contents of Apple event descriptors.

vAEBuildAppleEvent (page 519)
Allows you to encapsulate calls to AEBuildAppleEvent in a wrapper routine.

vAEBuildDesc (page 520)
Allows you to encapsulate calls to AEBuildDesc in your own wrapper routines.

vAEBuildParameters (page 521)
Allows you to encapsulate calls to AEBuildParameters in your own stdarg-style wrapper routines, using techniques similar to those allowed by vsprintf.

Creating Apple Event Structures Using Streams

AEStreamClose (page 485)
Closes and deallocates an AEStreamRef.

AEStreamCloseDesc (page 486)
Marks the end of a descriptor in an AEStreamRef.

AEStreamCloseList (page 486)
Marks the end of a list of descriptors in an AEStreamRef.

AEStreamCloseRecord (page 487)
Marks the end of a record in an AEStreamRef.

AEStreamCreateEvent (page 487)
Creates a new Apple event and opens a stream for writing data to it.

AEStreamOpen (page 489)
Opens a new AEStreamRef for use in building a descriptor.

AEStreamOpenDesc (page 489)
Marks the beginning of a descriptor in an AEStreamRef.

AEStreamOpenEvent (page 490)
Opens a stream for an existing Apple event.

AEStreamOpenKeyDesc (page 490)
Marks the beginning of a key descriptor in an AEStreamRef.

AEStreamOpenList (page 491)
Marks the beginning of a descriptor list in an AEStreamRef.

AEStreamOpenRecord (page 491)
Marks the beginning of an Apple event record in an AEStreamRef.

AEStreamOptionalParam (page 492)
Designates a parameter in an Apple event as optional.

AEStreamSetRecordType (page 493)
Sets the type of the most recently created record in an AEStreamRef.

AEStreamWriteAEDesc (page 493)
Copies an existing descriptor into an AEStreamRef.

AEStreamWriteData (page 494)
Appends data to the current descriptor in an AEStreamRef.

AEStreamWriteDesc (page 494)
Appends the data for a complete descriptor to an AEStreamRef.

AEStreamWriteKey (page 495)
Marks the beginning of a keyword/descriptor pair for a descriptor in an AEStreamRef.

AEStreamWriteKeyDesc (page 496)
Writes a complete keyword/descriptor pair to an AEStreamRef.

Working With Lower Level Apple Event Functions

AEGetRegisteredMachPort (page 445)
Returns the Mach port (in the form of a mach_port_t) that was registered with the bootstrap server for this process.

AEDecodeMessage (page 421)
Decodes a Mach message and converts it into an Apple event and its related reply.

AESendMessage (page 478)
Sends an AppleEvent to a target process without some of the overhead required by AESend.

AEProcessMessage (page 458)
Decodes and dispatches a low level Mach message event to an event handler, including packaging and returning the reply to the sender.

Serializing Apple Event Data

AESizeOfFlattenedDesc (page 483)
Returns the amount of buffer space needed to store the descriptor after flattening it.

AEFlattenDesc (page 426)
Flattens the specified descriptor and stores the data in the supplied buffer.

AEUnflattenDesc (page 498)
Unflattens the data in the passed buffer and creates a descriptor from it.

Suspending and Resuming Apple Event Handling

AEGetTheCurrentEvent (page 447)
Gets the Apple event that is currently being handled.

AEResumeTheCurrentEvent (page 474)
Informs the Apple Event Manager that your application wants to resume the handling of a previously suspended Apple event or that it has completed the handling of the Apple event.

AESetTheCurrentEvent (page 481)
Specifies a current Apple event to take the place of the one your application has suspended.

AESuspendTheCurrentEvent (page 497)
Suspends the processing of the Apple event that is currently being handled.

Miscellaneous

`AECheckIsRecord` (page 413)
Determines whether a descriptor is truly an `AERecord`.

`AEInitializeDesc` (page 448)
Initializes a new descriptor.

Functions

AEBuildAppleEvent

Constructs an entire Apple event in a single call.

```
OSStatus AEBuildAppleEvent (
   AEEventClass theClass,
   AEEventID theID,
   DescType addressType,
   const void *addressData,
   Size addressLength,
   SInt16 returnID,
   SInt32 transactionID,
   AppleEvent *result,
   AEBuildError *error,
   const char *paramsFmt,
   ...
);
```

Parameters

theClass
The event class for the resulting Apple event. See `AEEventClass` (page 555).

theID
The event id for the resulting Apple event. See `AEEventID` (page 556).

addressType
The address type for the addressing information described in the next two parameters: usually one of `typeApplSignature`, `typeProcessSerialNumber`, or `typeKernelProcessID`. See `DescType` (page 560).

addressData
A pointer to the address information.

addressLength
The number of bytes pointed to by the `addressData` parameter.

returnID
The return ID for the created Apple event. If you pass a value of `kAutoGenerateReturnID`, the Apple Event Manager assigns the created Apple event a return ID that is unique to the current session. If you pass any other value, the Apple Event Manager assigns that value for the ID.

transactionID

The transaction ID for this Apple event. A transaction is a sequence of Apple events that are sent back and forth between the client and server applications, beginning with the client's initial request for a service. All Apple events that are part of a transaction must have the same transaction ID. You can specify the `kAnyTransactionID` constant if the Apple event is not one of a series of interdependent Apple events.

result

A pointer to a descriptor where the resulting descriptor should be stored. See `AppleEvent` (page 559) for a description of the data type.

error

A pointer to an `AEBuildError` structure where additional information about any errors that occur will be saved. This is an optional parameter and you can pass `NULL` if this information is not required. See `AEBuildError` (page 546) for a description of the data type.

paramsFmt

An AEBuild format string describing the AppleEvent record to be created. The format of these strings is described in Technical Note TN2106, AEBuild*, AEPrint*, and Friends. That technote also describes possible error return codes for syntax errors in the format string.

Return Value

A numeric result code indicating the success of the call. A value of `AEBuildSyntaxNoErr` (zero) means the call succeeded. You can use the *error* parameter to discover information about other errors. See "Apple Event Manager Result Codes" (page 636).

Discussion

IMPORTANT: Following the parameters described above, the `AEBuildAppleEvent` function takes a variable number of parameters as specified by the format string provided in the *paramsFmt* parameter.

This function and related "AEBuild" routines (including `AEBuildDesc` (page 410) and `AEBuildParameters` (page 411), and the variable-argument versions, `vAEBuildAppleEvent` (page 519), `vAEBuildDesc` (page 520), and `vAEBuildParameters` (page 521)) provide a very simple translation service for converting specially formatted strings into complex Apple event descriptors. Normally, creating complex Apple event descriptors requires a large number of calls to Apple event Manager routines to build up the descriptor piece by piece. The `AEBuildAppleEvent` function and related routines allow you to consolidate all of the calls required to construct a complex Apple event descriptor into a single system call that creates the desired structure as directed by a format string that you provide.

In many ways, the AEBuild routines are very much like the standard C library's `printf` suite of routines. The syntax for the format string that you provide is very simple and allows for the substitution of data items into the Apple event descriptors being created.

The `AEBuildAppleEvent` function is similar to `AECreateAppleEvent` (page 416), but in addition to creating the Apple event, it also constructs the parameters for the event from the last three arguments. You can use `AEBuildAppleEvent` to build an entire Apple event, or `AEBuildParameters` (page 411) to add additional parameters to an existing Apple event.

The syntax of the formatting string for an entire Apple event (as passed to `AEBuildAppleEvent`) is almost identical to that used to represent the contents of an Apple event, without the curly braces. The event is defined as a sequence of name-value pairs, with optional parameters preceded with a tilde (~) character. The syntax is described in Technical Note TN2106, AEBuild*, AEPrint*, and Friends.

It is important to note that the identifier for the direct parameter in an Apple event, specified by the constant `keyDirectObject`, is four minus signs (`'----'`). The minus sign has special meaning in AEBuild strings, and it should always be enclosed in single quotes when it is used to identify the direct parameter for an Apple event in a descriptor string.

Version Notes
Prior to Mac OS X version 10.3, `AEBuildAppleEvent` would fail if you supplied a data parameter with size greater than 32767 bytes.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEHelpers.h`

AEBuildDesc

Provides a facility for compiling AEBuild descriptor strings into Apple event descriptors (`AEDesc`).

```
OSStatus AEBuildDesc (
   AEDesc *dst,
   AEBuildError *error,
   const char *src,
   ...
);
```

Parameters

dst
: A pointer to a descriptor where the resulting descriptor should be stored. See `AEDesc` (page 546).

error
: A pointer to an `AEBuildError` structure where additional information about any errors that occur will be saved. This is an optional parameter and you can pass `NULL` if this information is not required. See `AEBuildError` (page 546).

src
: An *`AEBuild`* format string describing the descriptor to be created.

Return Value
A numeric result code indicating the success of the call. A value of `AEBuildSyntaxNoErr` (zero) means the call succeeded. You can use the *`error`* parameter to discover information about other errors. See also "Apple Event Manager Result Codes" (page 636).

Discussion
This function and related "AEBuild" routines provide a very simple translation service for converting specially formatted strings into complex Apple event descriptors. Normally, creating complex Apple event descriptors requires a large number of calls to Apple event Manager routines to build up the descriptor piece by piece. The `AEBuildDesc` function and related routines allow you to consolidate all of the calls required to construct a complex Apple event descriptor into a single system call that creates the desired structure as directed by a format string that you provide.

For additional information on using the AEBuild routines, see the descriptions for `AEBuildAppleEvent` (page 408) and `AEBuildParameters` (page 411).

Version Notes
Prior to Mac OS X version 10.3, `AEBuildDesc` would fail if you supplied a data parameter with size greater than 32767 bytes.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEHelpers.h`

AEBuildParameters

Adds additional parameters or attributes to an existing Apple event.

```
OSStatus AEBuildParameters (
   AppleEvent *event,
   AEBuildError *error,
   const char *format,
   ...
);
```

Parameters

event
The Apple event to which you are adding parameters. See `AppleEvent` (page 559).

error
A pointer to an `AEBuildError` structure where additional information about any errors that occur will be saved. This is an optional parameter and you can pass `NULL` if this information is not required. See `AEBuildError` (page 546).

format
An *AEBuild* format string describing the parameters to be created.

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
This function can be called more than once to add any desired number of parameters or attributes to an existing Apple event. The Apple event should already have been created through either a call to `AECreateAppleEvent` (page 416) or `AEBuildAppleEvent` (page 408).

This function and related "AEBuild" routines provide a very simple translation service for converting specially formatted strings into complex Apple event descriptors. Normally, creating complex Apple event descriptors requires a large number of calls to Apple event Manager routines to build up the descriptor piece by piece. The `AEBuildDesc` function and related routines allow you to consolidate all of the calls required to construct a complex Apple event descriptor into a single system call that creates the desired structure as directed by a format string that you provide.

For additional information on using the AEBuild routines, see the descriptions for `AEBuildAppleEvent` (page 408) and `AEBuildDesc` (page 410).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEHelpers.h`

AECallObjectAccessor

Invokes the appropriate object accessor function for a specific desired type and container type.

```
OSErr AECallObjectAccessor (
   DescType desiredClass,
   const AEDesc *containerToken,
   DescType containerClass,
   DescType keyForm,
   const AEDesc *keyData,
   AEDesc *token
);
```

Parameters

desiredClass

The type of the Apple event object requested. Some possible values are defined in "Object Class ID Constants" (page 599). See `DescType` (page 560).

containerToken

A pointer to the token that identifies the container for the desired object. (Token is defined in `AEDisposeToken` (page 425).) See `AEDesc` (page 546).

containerClass

The object class of the container for the desired objects. See `DescType` (page 560).

keyForm

The key form that specifies how to find the object within the container. Key form constants are described in "Key Form and Descriptor Type Object Specifier Constants" (page 590). See `DescType` (page 560).

keyData

A pointer to the key data that identifies the object within the container. The type of this data is form-specific. That is, `formName` typically has key data of type `typeText`. See `AEDesc` (page 546).

token

A pointer to a token. On return, a token specifying the desired object (or objects). Your application should dispose of this token when it is through with it by calling `AEDisposeToken` (page 425). See `AEDesc` (page 546).

Return Value

A result code. See "Apple Event Manager Result Codes" (page 636). `AECallObjectAccessor` returns any result codes returned by the object accessor function it calls.

Discussion

If you want your application to do some of the Apple event object resolution normally performed by the `AEResolve` (page 473) function, you can use `AECallObjectAccessor` to invoke an object accessor function. This might be useful, for example, if you have installed an object accessor function using `typeWildCard` for the `AEInstallObjectAccessor` function's `desiredClass` parameter and `typeAEList` for the `containerType` parameter. To return a list of tokens for a request like "line one of every window" the object accessor function can create an empty list, then call `AECallObjectAccessor` for each requested element, adding tokens for each element to the list one at a time.

The parameters of `AECallObjectAccessor` are identical to the parameters of an object accessor function, as described in `OSLAccessorProcPtr` (page 533) with one exception—the Apple Event Manager adds a reference constant parameter each time it calls the object accessor function.

You can also call a specific object accessor function directly through its universal procedure pointer with one of the invoke functions described in "Creating, Calling, and Deleting Universal Procedure Pointers" (page 399).

Version Notes
In Mac OS X, your application can not make an object callback function available to other applications by installing it in a system object accessor dispatch table.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEObjects.h`

AECheckIsRecord

Determines whether a descriptor is truly an `AERecord`.

```
Boolean AECheckIsRecord (
   const AEDesc *theDesc
);
```

Parameters

`theDesc`
A pointer to the descriptor to check.

Return Value
Returns `true` if the descriptor is an `AERecord` or an `AppleEvent`, `false` otherwise.

Version Notes
Thread safe starting in Mac OS X v10.2.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

AECoerceDesc

Coerces the data in a descriptor to another descriptor type and creates a descriptor containing the newly coerced data.

```
OSErr AECoerceDesc (
   const AEDesc *theAEDesc,
   DescType toType,
   AEDesc *result
);
```

Parameters

`theAEDesc`
A pointer to the descriptor containing the data to coerce. See `AEDesc` (page 546).

toType

The desired descriptor type of the resulting descriptor. For a list of AppleScript's predefined descriptor types, see "Descriptor Type Constants" (page 581). See `DescType` (page 560).

result

A pointer to a descriptor. On successful return, a descriptor containing the coerced data and matching the descriptor type specified in `toType`. On error, a null descriptor. If the function returns successfully, your application should call the `AEDisposeDesc` (page 424) function to dispose of the resulting descriptor after it has finished using it.

Return Value

A result code. See "Apple Event Manager Result Codes" (page 636). If `AECoerceDesc` returns a nonzero result code, it returns a null descriptor record (a descriptor record of type `typeNull`, which does not contain any data) unless the Apple Event Manager is not available because of limited memory.

Version Notes

See the Version Notes section for the `AECoercePtr` (page 414) function for information on when to use descriptor-based versus pointer-based coercion handlers starting in Mac OS X version 10.2.

Thread safe starting in Mac OS X v10.2.

Availability

Available in Mac OS X v10.0 and later.

Related Sample Code

CarbonSketch

Declared In

`AEDataModel.h`

AECoercePtr

Coerces data to a desired descriptor type and creates a descriptor containing the newly coerced data.

```
OSErr AECoercePtr (
   DescType typeCode,
   const void *dataPtr,
   Size dataSize,
   DescType toType,
   AEDesc *result
);
```

Parameters

typeCode

The descriptor type of the source data. For a list of AppleScript's predefined descriptor types, see "Descriptor Type Constants" (page 581). See `DescType` (page 560).

dataPtr

A pointer to the data to coerce.

dataSize

The length, in bytes, of the data to coerce.

toType

The desired descriptor type of the resulting descriptor. For a list of AppleScript's predefined descriptor types, see "Descriptor Type Constants" (page 581).

result

A pointer to a descriptor. On successful return, a descriptor containing the coerced data and matching the descriptor type specified in `toType`. On error, a null descriptor. If the function returns successfully, your application should call the `AEDisposeDesc` (page 424) function to dispose of the resulting descriptor after it has finished using it. See `AEDesc` (page 546).

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Version Notes
Starting in Mac OS X version 10.2, pointer-based coercion handlers are not called if the input type is "structured"—that is, if the type to be coerced is `typeAEList`, `typeAERecord`, or coerced `typeAERecord`. If you want to add a coercion handler for one of these types, it must be a descriptor-based handler. This does not mean you are required to use descriptor-based coercion handlers everywhere—for "flat" data types, such as `typeText`, pointer-based handlers are still fine.

Thread safe starting in Mac OS X v10.2.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

AECountItems

Counts the number of descriptors in a descriptor list.

```
OSErr AECountItems (
   const AEDescList *theAEDescList,
   long *theCount
);
```

Parameters

theAEDescList

A pointer to the descriptor list to count. See `AEDescList` (page 553).

theCount

A pointer to a count variable. On return, the number of descriptors in the specified descriptor list, which can be 0, if the list is empty.

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
Your application typically counts the descriptors in a descriptor list when it is extracting data from an Apple event. You can use the functions in "Getting Items From Descriptor Lists" to get an individual item from a descriptor list or to iterate through the items.

Version Notes
Thread safe starting in Mac OS X v10.2.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
QTCarbonShell

Declared In
`AEDataModel.h`

AECreateAppleEvent

Creates an Apple event with several important attributes but no parameters.

```
OSErr AECreateAppleEvent (
   AEEventClass theAEEventClass,
   AEEventID theAEEventID,
   const AEAddressDesc *target,
   AEReturnID returnID,
   AETransactionID transactionID,
   AppleEvent *result
);
```

Parameters

theAEEventClass

The event class of the Apple event to create. This parameter becomes accessible through the `keyEventClassAttr` attribute of the Apple event. Some event classes are described in "Event Class Constants" (page 585). See `AEEventClass` (page 555).

theAEEventID

The event ID of the Apple event to create. This parameter becomes accessible through the `keyEventIDAttr` attribute of the Apple event. Some event IDs are described in "Event ID Constants" (page 586). See `AEEventID` (page 556).

target

A pointer to an address descriptor. Before calling `AECreateAppleEvent`, you set the descriptor to identify the target (or server) application for the Apple event. This parameter becomes accessible through the `keyAddressAttr` attribute of the Apple event. See `AEAddressDesc` (page 551).

returnID

The return ID for the created Apple event. If you pass a value of `kAutoGenerateReturnID`, the Apple Event Manager assigns the created Apple event a return ID that is unique to the current session. If you pass any other value, the Apple Event Manager assigns that value for the ID. This parameter becomes accessible through the `keyReturnIDAttr` attribute of the Apple event. The return ID constant is described in "ID Constants for the AECreateAppleEvent Function" (page 589). See `AEReturnID` (page 558).

transactionID

The transaction ID for this Apple event. A transaction is a sequence of Apple events that are sent back and forth between the client and server applications, beginning with the client's initial request for a service. All Apple events that are part of a transaction must have the same transaction ID. You can specify the `kAnyTransactionID` constant if the Apple event is not one of a series of interdependent Apple events. This parameter becomes accessible through the `keyTransactionIDAttr` attribute of the Apple event. This transaction ID constant is described in "ID Constants for the AECreateAppleEvent Function" (page 589). See `AETransactionID` (page 559).

result

A pointer to an Apple event. On successful return, the new Apple event. On error, a null descriptor (one with descriptor type `typeNull`). If the function returns successfully, your application should call the `AEDisposeDesc` (page 424) function to dispose of the resulting Apple event after it has finished using it. See the `AppleEvent` (page 559) data type.

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
The `AECreateAppleEvent` function creates an empty Apple event. You can add parameters to the Apple event after you create it with the functions described in "Adding Parameters and Attributes to Apple Events and Apple Event Records" (page 398).

Version Notes
Thread safe starting in Mac OS X v10.2.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

AECreateDesc

Creates a new descriptor that incorporates the specified data.

```
OSErr AECreateDesc (
   DescType typeCode,
   const void *dataPtr,
   Size dataSize,
   AEDesc *result
);
```

Parameters

typeCode

The descriptor type for the new descriptor. For a list of AppleScript's predefined descriptor types, see "Descriptor Type Constants" (page 581). See `DescType` (page 560).

dataPtr

A pointer to the data for the new descriptor. This data is copied into a newly-allocated block of memory for the descriptor that is created. To minimize copying overhead, consider using `AECreateDescFromExternalPtr` (page 418).

dataSize

The length, in bytes, of the data for the new descriptor.

result

A pointer to a descriptor. On successful return, a descriptor that incorporates the data specified by the `dataPtr` parameter. On error, a null descriptor. If the function returns successfully, your application should call the `AEDisposeDesc` (page 424) function to dispose of the resulting descriptor after it has finished using it. See `AEDesc` (page 546).

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
While it is possible to create an Apple event descriptor or a descriptor list or a descriptor with the `AECreateDesc` function (assuming you have access to the raw data for an Apple event, list, or descriptor), you typically create these structured objects with their specific creation routines—`AECreateAppleEvent`, `AECreateList`, or `AECreateDesc`.

Version Notes
Thread safe starting in Mac OS X v10.2.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

AECreateDescFromExternalPtr

Creates a new descriptor that uses a memory buffer supplied by the caller.

```
OSStatus AECreateDescFromExternalPtr (
   OSType descriptorType,
   const void *dataPtr,
   Size dataLength,
   AEDisposeExternalUPP disposeCallback,
   SRefCon disposeRefcon,
   AEDesc *theDesc
);
```

Parameters

descriptorType
The descriptor type for the new descriptor.

dataPtr
A pointer to the data for the new descriptor. The memory that is pointed to cannot be a `Handle` (which may move in memory), cannot be modified by the caller, and must be preserved in place (and not freed), until the *disposeCallback* function is called.

If possible, the descriptor will be mapped into the address space of the recipient using shared memory, avoiding an actual memory copy.

The pointer that is passed in does not need to be aligned to any particular boundary, but is optimized to transfer data on a page boundary. You can get the current page size (4096 on all current Mac OS X systems) with the `getpagesize(3)` call. (Type `man 3 getpagesize` in a Terminal window for documentation.)

dataLength
The length, in bytes, of the data for the new descriptor.

disposeCallback
A universal procedure pointer to a dispose callback function of type `AEDisposeExternalProcPtr` (page 527). Your callback function will be called when the block of memory provided by `dataPtr` is no longer needed by the Apple Event Manager. The function can be called at any time, including during creation of the descriptor.

disposeRefcon

A reference constant the Apple Event Manager passes to the `disposeCallback` function whenever it calls the function. If your dispose function doesn't require a reference constant, pass 0 for this parameter.

theDesc

A pointer to a descriptor. On successful return, a descriptor that incorporates the data specified by the `dataPtr` parameter. On error, a null descriptor. If the function returns successfully, your application should call the `AEDisposeDesc` (page 424) function to dispose of the resulting descriptor after it has finished using it.

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
This function is different than `AECreateDesc` (page 417), in that it creates a descriptor that uses the data block provided by the caller "in place," rather than allocate a block of memory and copy the data to it. This function can provide dramatically improved performance if you're working with large chunks of data. It attempts to copy the descriptor to the address space of any recipient process using virtual memory APIs, avoiding an actual memory copy. For example, you might want to use this function to pass a large image in an Apple event.

You can use the `AEGetDescDataRange` (page 433) function to access a specific section of a large block of data.

Version Notes
Thread safe starting in Mac OS X v10.2.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`AEDataModel.h`

AECreateList

Creates an empty descriptor list or Apple event record.

```
OSErr AECreateList (
   const void *factoringPtr,
   Size factoredSize,
   Boolean isRecord,
   AEDescList *resultList
);
```

Parameters

factoringPtr

A pointer to the data at the beginning of each descriptor that is the same for all descriptors in the list. If there is no common data, or if you decide not to isolate the common data, pass `NULL` as the value of this parameter.

factoredSize

The size of the common data. If there is no common data, or if you decide not to isolate the common data, pass 0 as the value of this parameter. (See the Discussion section for more information.)

isRecord

A Boolean value that specifies the kind of list to create. Pass a value of `TRUE` to create an Apple event record (a data structure of type `AERecord` (page 557)) or `FALSE` to create a descriptor list.

resultList

A pointer to a descriptor list variable. On successful return, the descriptor list or Apple event record that the `AECreateList` function creates. On error, a null descriptor. See `AEDescList` (page 553).

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
The `AECreateList` function creates an empty descriptor list or Apple event record. You can use the functions described in "Adding Items to Descriptor Lists" to populate the list as part of creating an Apple event. After sending the Apple event with the `AESend` (page 476) function, you should dispose of the descriptor list with the `AEDisposeDesc` (page 424) function when you no longer need it.

If you intend to use a descriptor list for a factored Apple event array, you must provide, in the `factoringPtr` parameter, a pointer to the data shared by all items in the array and, in the `factoredSize` parameter, the size of the common data. The common data must be 4, 8, or more than 8 bytes in length because it always consists of (a) the descriptor type (4 bytes) (b) the descriptor type (4 bytes) and the size of each item's data (4 bytes) or (c) the descriptor type (4 bytes), the size of each item's data (4 bytes), and some portion of the data itself (1 or more bytes).

For information about data types used with Apple event arrays, see "Apple Event Manager Data Types" (page 545).

Version Notes
The *factoringPtr* and *factoredSize* parameters are not supported in Mac OS X v10.2 and later. You should pass `NULL` and zero, respectively, for these parameters.

Thread safe starting in Mac OS X v10.2.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

AECreateRemoteProcessResolver

Creates an object for resolving a list of remote processes.

```
AERemoteProcessResolverRef AECreateRemoteProcessResolver (
   CFAllocatorRef allocator,
   CFURLRef url
);
```

Parameters

allocator

An object that is used to allocates and deallocate any Core Foundation types created or returned by this API. You can pass `kCFAllocatorDefault` to get the default allocation behavior. The allocator is based on `CFAllocatorRef`, an opaque data type described in the Core Foundation Reference Documentation.

url

A `CFURL` reference identifying the remote host and port on which to look for processes. See the Core Foundation Reference Documentation for a description of the `CFURLRef` data type.

Return Value
An `AERemoteProcessResolverRef` (page 557), which must be disposed of with `AEDisposeRemoteProcessResolver` (page 424). A resolver can only be used one time; once it has obtained a list of remote processes from a server, or gotten an error, it can no longer be scheduled. To retrieve a new list of processes, create a new instance of this object.

Discussion
You supply this function with the URL for a remote host and port; it returns a reference to a resolver object. To obtain a list of remote processes from the resolver, you can query it synchronously with `AERemoteProcessResolverGetProcesses` (page 466), which blocks until the request completes (either successfully or with an error).

If asynchronous behavior is desired, you can optionally use `AERemoteProcessResolverScheduleWithRunLoop` (page 467) to schedule the resolver asynchronously on a run loop. If so, you supply a callback routine (see `AERemoteProcessResolverCallback` (page 532)) that is executed when the resolver completes. To obtain information about the remote processes, you will again have to call `AERemoteProcessResolverGetProcesses` (page 466).

A resolver can only be used once; once it has fetched the data or gotten an error it can no longer be scheduled. The data obtained by the resolver is a `CFArrayRef` of `CFDictionaryRef` objects. For information on the format of the returned remote process information, see the description of the function result for the function `AERemoteProcessResolverGetProcesses` (page 466), and also "Remote Process Dictionary Keys" (page 602).

Version Notes
Thread safe starting in Mac OS X v10.3.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`AppleEvents.h`

AEDecodeMessage

Decodes a Mach message and converts it into an Apple event and its related reply.

```
OSStatus AEDecodeMessage (
   mach_msg_header_t *header,
   AppleEvent *event,
   AppleEvent *reply
);
```

Parameters

header

A pointer to a Mach message header for the event to be decoded.

event

A pointer to a null Apple event descriptor (one with descriptor type `typeNull`). On successful completion, contains the decoded Apple event. If the function returns successfully, your application should call the `AEDisposeDesc` (page 424) function to dispose of the resulting descriptor after it has finished using it.

reply

A pointer to a null Apple event descriptor. On successful completion, contains the reply event from the decoded Apple event. To send the reply, you use the following:

```
AESendMessage(reply, NULL, kAENoReply, kAEDefaultTimeout);
```

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
The Apple Event Manager provides the following functions (on Mac OS X only) for working with Apple events at a lower level: `AEGetRegisteredMachPort` (page 445), `AEDecodeMessage`, `AESendMessage` (page 478), and `AEProcessMessage` (page 458). See the descriptions for those functions for more information on when you might use them.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEMach.h`

AEDeleteItem

Deletes a descriptor from a descriptor list, causing all subsequent descriptors to move up one place.

```
OSErr AEDeleteItem (
   AEDescList *theAEDescList,
   long index
);
```

Parameters

theAEDescList

A pointer to the descriptor list containing the descriptor to delete. See `AEDescList` (page 553).

index

A one-based positive integer indicating the position of the descriptor to delete. `AEDeleteItem` returns an error if you pass zero, a negative number, or a value that is out of range.

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Version Notes
Thread safe starting in Mac OS X v10.2.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

AEDeleteKeyDesc

Deletes a keyword-specified parameter from an Apple event record.

```
OSErr AEDeleteKeyDesc (
    AERecord *theAERecord,
    AEKeyword theAEKeyword
);
```

Parameters

theAERecord

A pointer to the Apple event record to delete the parameter from.

theAEKeyword

The keyword that specifies the parameter to delete. Some keyword constants are described in "Keyword Parameter Constants" (page 595). See `AEKeyword` (page 556).

Return Value

A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion

This function is declared as a macro that invokes `AEDeleteParam` (page 423), which can operate on an Apple event or an Apple event record. See the Discussion for that function for more information.

Version Notes

See `AEDeleteParam` (page 423).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`AEDataModel.h`

AEDeleteParam

Deletes a keyword-specified parameter from an Apple event record.

```
OSErr AEDeleteParam (
   AppleEvent *theAppleEvent,
   AEKeyword theAEKeyword
);
```

Parameters

theAppleEvent

A pointer to the Apple event or Apple event record to delete the parameter from. See `AppleEvent` (page 559).

theAEKeyword

The keyword that specifies the parameter to delete. Some keyword constants are described in "Keyword Parameter Constants" (page 595). See `AEKeyword` (page 556).

Return Value

A result code. See "Apple Event Manager Result Codes" (page 636).

Version Notes

Thread safe starting in Mac OS X v10.2.

Availability
Available in Mac OS X v10.0 and later.

Declared In
AEDataModel.h

AEDisposeDesc

Deallocates the memory used by a descriptor.

```
OSErr AEDisposeDesc (
   AEDesc *theAEDesc
);
```

Parameters

theAEDesc

A pointer to the descriptor to deallocate. On return, a null descriptor. If you pass a null descriptor in this parameter, AEDisposeDesc returns noErr. See AEDesc (page 546).

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636). As currently implemented, AEDisposeDesc always returns noErr.

Discussion
The AEDisposeDesc function deallocates the memory used by a descriptor. After calling this method, the descriptor becomes an empty descriptor with a type of typeNULL. Because all Apple event structures (except for keyword-specified descriptors) are descriptors, you can use AEDisposeDesc for any of them.

Do not call AEDisposeDesc on a descriptor obtained from another Apple Event Manager function (such as the reply event from a call to AESend (page 476)) unless that function returns successfully.

Special Considerations

If the AEDesc might contain an OSL token, dispose of it with AEDisposeToken (page 425).

Version Notes
Thread safe starting in Mac OS X v10.2.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
CarbonSketch
QTCarbonShell

Declared In
AEDataModel.h

AEDisposeRemoteProcessResolver

Disposes of an AERemoteProcessResolverRef.

```
void AEDisposeRemoteProcessResolver (
   AERemoteProcessResolverRef ref
);
```

Parameters

ref

The `AERemoteProcessResolverRef` (page 557) to dispose of. Acquired from a previous call to `AECreateRemoteProcessResolver` (page 420).

Discussion
If this resolver is currently scheduled on a run loop, it is unscheduled, and the asynchronous callback is not executed.

Version Notes
Thread safe starting in Mac OS X v10.3.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`AppleEvents.h`

AEDisposeToken

Deallocates the memory used by a token.

```
OSErr AEDisposeToken (
   AEDesc *theToken
);
```

Parameters

theToken

A pointer to the token to dispose of. On successful return, the pointer is set to the null descriptor. See `AEDesc` (page 546).

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
Your application calls the `AEResolve` (page 473) function to resolve an object specifier, with the help of the object accessor functions described in "Object Accessor Callbacks" and the application object callback functions described in "Object Callback Functions".

When `AEResolve` returns a final token to your event handler as the result of the resolution of an object specifier, your application must deallocate the memory used by the token. When your application calls the `AEDisposeToken` function, the Apple Event Manager first calls your application's token disposal function, if you have provided one. The token disposal function is described in `OSLDisposeTokenProcPtr` (page 539).

If you haven't provided a token disposal function, or if your application's token disposal function returns `errAEEventNotHandled` as the function result, the Apple Event Manager calls the system token disposal function if one is available. If there is no system token disposal function or the function returns `errAEEventNotHandled` as the function result, the Apple Event Manager calls the `AEDisposeDesc` function to dispose of the token.

Version Notes
In Mac OS X, your application can not make an object callback function available to other applications by installing it in a system object accessor dispatch table.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEObjects.h`

AEDuplicateDesc

Creates a copy of a descriptor.

```
OSErr AEDuplicateDesc (
   const AEDesc *theAEDesc,
   AEDesc *result
);
```

Parameters

theAEDesc

A pointer to the descriptor to duplicate. See `AEDesc` (page 546).

result

A pointer to a descriptor. On return, the descriptor contains a copy of the descriptor specified by the `theAEDesc` parameter. If the function returns successfully, your application should call the `AEDisposeDesc` (page 424) function to dispose of the resulting descriptor after it has finished using it.

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
It is common for applications to send Apple events that have one or more attributes or parameters in common. For example, if you send a series of Apple events to the same application, the address attribute is the same. In these cases, the most efficient way to create the necessary Apple events is to make a template Apple event that you can then copy—by calling the `AEDuplicateDesc` function—as needed. You then fill in or change the remaining parameters and attributes of the copy, send the copy by calling the `AESend` (page 476) function and, after `AESend` returns a result code, dispose of the copy by calling `AEDisposeDesc` (page 424). You can use this approach to prepare structures of type `AEDesc` (page 546), `AEDescList` (page 553), `AERecord` (page 557), and `AppleEvent` (page 559).

Version Notes
Thread safe starting in Mac OS X v10.2.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

AEFlattenDesc

Flattens the specified descriptor and stores the data in the supplied buffer.

```
OSStatus AEFlattenDesc (
   const AEDesc *theAEDesc,
   Ptr buffer,
   Size bufferSize,
   Size *actualSize
);
```

Parameters

theAEDesc

A pointer to the descriptor to be flattened. See `AEDesc` (page 546).

buffer

A pointer to memory, allocated by the application, where the flattened data will be stored. See the *bufferSize* parameter for information on how large a buffer you should allocate.

bufferSize

The size of the buffer pointed to by buffer. Prior to calling `AEFlattenDesc`, you call the `AESizeOfFlattenedDesc` (page 483) function to determine the required size of the buffer for the flatten operation.

If *bufferSize* is too small, `AEFlattenDesc` returns `errAEBufferTooSmall` and doesn't store any data in the buffer.

actualSize

A pointer to a size variable. On return, the variable contains the actual size of the flattened data. You can specify `NULL` for this parameter if you do not care about the returned size.

Return Value

A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion

Flattening a descriptor serializes the data it contains. That is, it reduces a complex, possibly deeply nested structure to a series of bytes that can conveniently be stored. The descriptor can be reconstituted from the stored bytes with the `AEUnflattenDesc` (page 498) function.

Applications can be scriptable and work with Apple events without needing to flatten and unflatten descriptors. Flattening is a special-purpose capability that is useful in circumstances where it may be convenient to store data by saving and restoring a descriptor, rather than having to manually extract the data from it, store the data as a separate step, then manually recreate the descriptor (if necessary). For example, you might use flattening to store a preference setting received through an Apple event.

Flattening and unflattening should work without loss of data on descriptors that represent `AEDesc`, `AEList`, and `AERecord` structures. You can also use the process with `AppleEvent` descriptors. However, keep in mind that Apple events may contain attributes that are relevant only to a running process, and these attributes may not keep their meaning when the event is reconstituted.

Flattening and unflattening works across OS versions, including between Mac OS 9 and Mac OS X.

Flattening is endian-neutral. That is, you can save flattened data on a machine that is either big-endian or little-endian, then retrieve and unflatten the data on either type of machine, without any special steps by your application.

Version Notes

Thread safe starting in Mac OS X v10.2.

Availability

Available in Mac OS X v10.0 and later.

Declared In
AEDataModel.h

AEGetArray

Extracts data from an Apple event array created with the AEPutArray function and stores it as a standard array of fixed size items in the specified buffer.

```
OSErr AEGetArray (
   const AEDescList *theAEDescList,
   AEArrayType arrayType,
   AEArrayDataPointer arrayPtr,
   Size maximumSize,
   DescType *itemType,
   Size *itemSize,
   long *itemCount
);
```

Parameters

theAEDescList

A pointer to the descriptor list to get the array from. If the array is of type kAEDataArray, kAEPackedArray, or kAEHandleArray, the descriptor list must be factored. A factored descriptor list is one in which the Apple Event Manager automatically isolates the data that is common to all the elements of the list so that the common data only appears in the list once. To create a factored descriptor list, you call the AECreateList (page 419) function and specify the data that is common to all elements in the descriptor array. See the Discussion section for related information. See AEDescList (page 553).

arrayType

The Apple event array type to convert. Pass one of the constants: described in "Data Array Constants" (page 580). See AEArrayType (page 552).

arrayPtr

A pointer to a buffer, allocated and disposed of by your application, for storing the array. The size in bytes must be at least as large as the value you pass in the maximumSize parameter. On return, the buffer contains the array of fixed-size items. See AEArrayDataPointer (page 551).

maximumSize

The maximum length, in bytes, of the expected data. The AEGetArray function will not return more data than you specify in this parameter.

itemType

A pointer to a descriptor type. On return, for arrays of type kAEDataArray, kAEPackedArray, or kAEHandleArray, the descriptor type of the items in the returned array. The AEGetArray function doesn't supply a value in itemType for arrays of type kAEDescArray and kAEKeyDescArray because they may contain descriptors of different types. Possible descriptor types are listed in "Descriptor Type Constants" (page 581). See DescType (page 560).

itemSize

A pointer to a size variable. On return, for arrays of type kAEDataArray or kAEPackedArray, the size (in bytes) of each item in the returned array. You don't get an item size for arrays of type kAEDescArray, kAEKeyDescArray, or kAEHandleArray because descriptors and handles (though not the data they point to) have a known size.

itemCount

A pointer to a size variable. On return, the number of items in the returned array.

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
The `AEGetArray` function uses a buffer identified by the pointer in the `arrayPtr` parameter to store the converted data for the Apple event array specified by the `theAEDescList` parameter. For example, `AEGetArray` may convert an array of descriptors of type `typeLongInteger` into a simple array of integer values or an array of descriptors of type `typeFSS` into an array of file specification records.

Even if the descriptor list that contains the array is factored, the converted data for each array item includes the data common to all the descriptors in the list. The Apple Event Manager automatically reconstructs the common data for each item when you call `AEGetArray`.

For information about creating and factoring descriptor lists for Apple event arrays, see `AECreateList` (page 419). For information about adding an Apple event array to a descriptor list, see `AEPutArray` (page 459).

Version Notes
Thread safe starting in Mac OS X v10.2.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

AEGetAttributeDesc

Gets a copy of the descriptor for a specified Apple event attribute from an Apple event; typically used when your application needs to pass the descriptor on to another function.

```
OSErr AEGetAttributeDesc (
   const AppleEvent *theAppleEvent,
   AEKeyword theAEKeyword,
   DescType desiredType,
   AEDesc *result
);
```

Parameters

theAppleEvent
A pointer to the Apple event to get the attribute descriptor from. See `AppleEvent` (page 559).

theAEKeyword
The keyword that specifies the desired attribute. Some keyword constants are described in "Keyword Attribute Constants" (page 593). See `AEKeyword` (page 556).

result
A pointer to a descriptor. On successful return, a copy of the specified Apple event attribute, coerced, if necessary, to the descriptor type specified in `desiredType`. On error, a null descriptor. If the function returns successfully, your application should call the `AEDisposeDesc` (page 424) function to dispose of the resulting descriptor after it has finished using it. See `AEDesc` (page 546).

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
To get Apple event attribute data for your application to use directly, call `AEGetAttributePtr` (page 430). To get a descriptor for an Apple event attribute to pass on to another Apple Event Manager routine, call `AEGetAttributeDesc`.

Version Notes
Thread safe starting in Mac OS X v10.2.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

AEGetAttributePtr

Gets a copy of the data for a specified Apple event attribute from an Apple event; typically used when your application needs to work with the data directly.

```
OSErr AEGetAttributePtr (
   const AppleEvent *theAppleEvent,
   AEKeyword theAEKeyword,
   DescType desiredType,
   DescType *typeCode,
   void *dataPtr,
   Size maximumSize,
   Size *actualSize
);
```

Parameters

theAppleEvent

A pointer to the Apple event to get the attribute data from. See `AppleEvent` (page 559).

theAEKeyword

The keyword that specifies the desired attribute. Some keyword constants are described in "Keyword Attribute Constants" (page 593). See `AEKeyword` (page 556).

desiredType

The desired descriptor type for the copied data. For a list of AppleScript's predefined descriptor types, see "Descriptor Type Constants" (page 581).

If the descriptor specified by the `theAEKeyword` parameter is not of the desired type, `AEGetAttributePtr` attempts to coerce the data to this type. However, if you pass a value of `typeWildCard`, no coercion is performed, and the descriptor type of the returned data is the same as the descriptor type of the Apple event attribute.

On return, you can determine the actual descriptor type by examining the `typeCode` parameter.

See `DescType` (page 560).

typeCode

A pointer to a descriptor type. On return, specifies the descriptor type of the attribute data pointed to by `dataPtr`. The returned type is either the same as the type specified by the `desiredType` parameter or, if the desired type was type wildcard, the true type of the descriptor. For a list of AppleScript's predefined descriptor types, see "Descriptor Type Constants" (page 581). See `DescType` (page 560).

dataPtr

A pointer to a buffer, local variable, or other storage location, created and disposed of by your application. The size in bytes must be at least as large as the value you pass in the `maximumSize` parameter. On return, contains the attribute data.

maximumSize

The maximum length, in bytes, of the expected attribute data. The `AEGetAttributePtr` function will not return more data than you specify in this parameter.

actualSize

A pointer to a size variable. On return, the length, in bytes, of the data for the specified Apple event attribute. If this value is larger than the value you passed in the `maximumSize` parameter, the buffer pointed to by `dataPtr` was not large enough to contain all of the data for the attribute, though `AEGetAttributePtr` does not write beyond the end of the buffer. If the buffer was too small, you can resize it and call `AEGetAttributePtr` again.

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
To get Apple event attribute data for your application to use directly, call `AEGetAttributePtr`. To get a descriptor for an Apple event attribute to pass on to another Apple Event Manager routine, call `AEGetAttributeDesc` (page 429).

Before calling `AEGetAttributePtr`, you can call the `AESizeOfAttribute` (page 482) function to determine a size for the `dataPtr` buffer. However, unless you specify `typeWildCard` for the `desiredType` parameter, `AEGetAttributePtr` may coerce the data, which may cause the size of the data to change.

Version Notes
Thread safe starting in Mac OS X v10.2.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

AEGetCoercionHandler

Gets the coercion handler for a specified descriptor type.

```
OSErr AEGetCoercionHandler (
   DescType fromType,
   DescType toType,
   AECoercionHandlerUPP *handler,
   SRefCon *handlerRefcon,
   Boolean *fromTypeIsDesc,
   Boolean isSysHandler
);
```

Parameters

fromType

The descriptor type of the data coerced by the handler. For a list of AppleScript's predefined descriptor types, see "Descriptor Type Constants" (page 581). See `DescType` (page 560).

toType
The descriptor type of the resulting data. For a list of AppleScript's predefined descriptor types, see "Descriptor Type Constants" (page 581).

handler
A universal procedure pointer. On return, a pointer to the specified handler, if a coercion table entry exists that exactly matches the values supplied in the parameters `fromType` and `toType`. See `AECoercionHandlerUPP` (page 552).

handlerRefcon
A pointer to a reference constant. On return, the reference constant from the coercion table entry for the specified coercion handler. The Apple Event Manager passes this reference constant to the handler each time it calls the handler. The reference constant may have a value of 0.

fromTypeIsDesc
A pointer to a Boolean value. The `AEGetCoercionHandler` function returns a value of `TRUE` in this parameter if the coercion handler expects the data as a descriptor or `FALSE`, if the coercion handler expects a pointer to the data.

isSysHandler
Specifies the coercion table to get the handler from. Pass `TRUE` to get the handler from the system coercion table or `FALSE` to get the handler from your application's coercion table. Use of the system coercion table is not recommended.

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Version Notes
Thread safe starting in Mac OS X v10.2.

Your application should not install a coercion handler in a system coercion handler dispatch table with the goal that the handler will get called when other applications perform coercions—this won't work in Mac OS X. For more information, see "Writing and Installing Coercion Handlers" in Apple Events Programming Guide.

In Mac OS 7.1 through 9.x and Mac OS X version v10.2 and later, `AEGetCoercionHandler` returns `errAEHandlerNotInstalled` when there's not an exact match, even if a wildcard handler is installed that could handle the coercion. Mac OS X version v10.0.x and v10.1.x will return the wildcard handler.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

AEGetDescData

Gets the data from the specified descriptor.

```
OSErr AEGetDescData (
   const AEDesc *theAEDesc,
   void *dataPtr,
   Size maximumSize
);
```

Parameters

theAEDesc

A pointer to the descriptor to get the data from. See `AEDesc` (page 546).

dataPtr

A pointer to a buffer, local variable, or other storage location created and disposed of by your application. The size in bytes should be the same as the value you pass in the `maximumSize` parameter. On return, contains the data from the descriptor.

maximumSize

The length, in bytes, of the expected descriptor data. The `AEGetDescData` function will not return more data than you specify in this parameter. You typically determine the maximum size by calling `AEGetDescDataSize` (page 434).

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
Your application can call `AEGetDescDataSize` (page 434) to get the size, in bytes, of the data in a descriptor, allocate a buffer or variable of that size, then call `AEGetDescData` to get the data.

This function works only with value descriptors created by `AECreateDesc` (page 417). You cannot get the data of an `AERecord` (page 557) or `AEDescList` (page 553), for example.

Version Notes
Thread safe starting in Mac OS X v10.2.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
CarbonSketch
QTCarbonShell

Declared In
`AEDataModel.h`

AEGetDescDataRange

Retrieves a specified series of bytes from the specified descriptor.

```
OSStatus AEGetDescDataRange (
   const AEDesc *dataDesc,
   void *buffer,
   Size offset,
   Size length
);
```

Parameters

dataDesc

A pointer to the descriptor to get the data from. See `AEDesc` (page 546).

buffer

A pointer to a buffer, local variable, or other storage location created and disposed of by your application. The size in bytes should be at least as large as the value you pass in the `length` parameter. On return, contains the specified data from the descriptor.

offset

The zero-based offset to the data to be retrieved from the descriptor.

length

The number of bytes of contiguous data to retrieve.

Return Value

A result code. If the requested `offset` and `length` are such that they do not fit entirely within the descriptor's data, `AEGetDescDataRange` returns `errAEBufferTooSmall`. See also "Apple Event Manager Result Codes" (page 636).

Discussion

This function is valid only for value type descriptors (such as `typeUTF8Text`). You can use this function when you know the precise location of a subset of data within the descriptor. For example, if the descriptor contains a block of your private data, you might retrieve just a particular chunk you need at a known offset, representing an image, a string, or some other data type. Or if a descriptor contains an RGB color, you can access just the blue field.

When used in conjunction with `AECreateDescFromExternalPtr` (page 418), `AEGetDescDataRange` can provide greatly improved performance, especially when working with large blocks of data.

Availability

Available in Mac OS X v10.2 and later.

Declared In

`AEDataModel.h`

AEGetDescDataSize

Gets the size, in bytes, of the data in the specified descriptor.

```
Size AEGetDescDataSize (
   const AEDesc *theAEDesc
);
```

Parameters

theAEDesc

A pointer to the descriptor to obtain the data size for. See `AEDesc` (page 546).

Return Value

Returns the size, in bytes, of the data in the specified descriptor.

Discussion
This function works only with value descriptors created by `AECreateDesc` (page 417). You cannot get the data size of an `AERecord` (page 557) or `AEDescList` (page 553), for example.

Version Notes
Thread safe starting in Mac OS X v10.2.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

AEGetEventHandler

Gets an event handler from an Apple event dispatch table.

```
OSErr AEGetEventHandler (
   AEEventClass theAEEventClass,
   AEEventID theAEEventID,
   AEEventHandlerUPP *handler,
   SRefCon *handlerRefcon,
   Boolean isSysHandler
);
```

Parameters

theAEEventClass

The event class for the desired handler. See `AEEventClass` (page 555).

theAEEventID

The event ID for the desired handler. See `AEEventID` (page 556).

handler

A universal procedure pointer. On return, a pointer to the specified handler, if a dispatch table entry exists that exactly matches the values supplied in the parameters `theAEEventClass` and `theAEEventID`.

If you use the `typeWildCard` constant for either or both of these parameters, `AEGetEventHandler` will return an error unless an entry exists that specifies `typeWildCard` in exactly the same way. For example, if you specify `typeWildCard` in both the `theAEEventClass` parameter and the `theAEEventID` parameter, the Apple Event Manager will not return the first handler for any event class and event ID in the dispatch table; instead, it will only return a handler if an entry exists that specifies type `typeWildCard` for both the event class and the event ID.

For an explanation of wildcard values, see the Discussion section for `AEInstallEventHandler` (page 449).

See `AEEventHandlerUPP` (page 555).

handlerRefcon

A pointer to a reference constant. On return, the reference constant from the dispatch table entry for the specified handler. The reference constant may have a value of 0.

isSysHandler

Specifies the Apple event dispatch table to get the handler from. Pass `TRUE` to get the handler from the system dispatch table or `FALSE` to get the handler from your application's dispatch table. See Version Notes for related information.

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Version Notes
Thread safe starting in Mac OS X v10.2.

Your application should not install a handler in a system dispatch table with the goal that the handler will get called when other applications receive events—this won't work in Mac OS X. For more information, see "The System Dispatch Table" in "Apple Event Dispatching" in Apple Events Programming Guide.

In Mac OS 7.1 through 9.x and Mac OS X version v10.2 and later, `AEGetEventHandler` returns `errAEHandlerNotInstalled` when there's not an exact match, even if a wildcard handler is installed that could handle the event. Mac OS X version v10.0.x and v10.1.x will return the wildcard handler.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AppleEvents.h`

AEGetInteractionAllowed

Gets your application's current user interaction preferences for responding to an Apple event as a server application.

```
OSErr AEGetInteractionAllowed (
   AEInteractAllowed *level
);
```

Parameters

level

A pointer to an interaction level variable. On return, the variable specifies the current user interaction level, matching one of the values described in "User Interaction Level Constants" (page 605).

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
The current user interaction preference for responding to an Apple event is set either by default (to `kAEInteractWithLocal`) or by a previous call to `AESetInteractionAllowed` (page 479).

For additional information on interaction level, see `AESend` (page 476) and `"AESendMode"` (page 566).

See also `AEInteractWithUser` (page 453).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEInteraction.h`

AEGetKeyDesc

Gets a copy of the descriptor for a keyword-specified Apple event parameter from an Apple event record

```
OSErr AEGetKeyDesc (
    AERecord *theAERecord,
    AEKeyword theAEKeyword,
    DescType desiredType,
    AEDesc *result
);
```

Parameters

theAERecord

A pointer to the Apple event record to get the parameter descriptor from.

theAEKeyword

A keyword that specifies the desired Apple event parameter. Some keyword constants are described in "Keyword Parameter Constants" (page 595). See `AEKeyword` (page 556).

desiredType

The descriptor type for the desired Apple event parameter. For a list of AppleScript's predefined descriptor types, see "Descriptor Type Constants" (page 581).

If the requested Apple event parameter is not of the desired type, the Apple Event Manager attempts to coerce it to the desired type. However, if you pass a value of `typeWildCard`, no coercion is performed, and the descriptor type of the returned descriptor is the same as the descriptor type of the Apple event parameter.

See `DescType` (page 560).

result

A pointer to a descriptor. On successful return, a copy of the descriptor for the specified Apple event parameter, coerced, if necessary, to the descriptor type specified by the `desiredType` parameter. On error, a null descriptor. If the function returns successfully, your application should call the `AEDisposeDesc` (page 424) function to dispose of the resulting descriptor after it has finished using it. See `AEDesc` (page 546).

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
This function is declared as a macro that invokes `AEGetParamDesc` (page 443), which can operate on an Apple event or an Apple event record. See the Discussion for that function for more information.

Version Notes
See `AEGetParamDesc` (page 443).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

AEGetKeyPtr

Gets a copy of the data for a specified Apple event parameter from an Apple event record.

```
OSErr AEGetKeyPtr (
    AERecord *theAERecord,
    AEKeyword theAEKeyword,
    DescType desiredType,
    DescType *actualType,
    void *dataPtr,
    Size maximumSize,
    Size *actualSize
);
```

Parameters

theAERecord

A pointer to the Apple event record to get the parameter data from.

theAEKeyword

The keyword that specifies the desired Apple event record parameter. Some keyword constants are described in "Keyword Parameter Constants" (page 595).

desiredType

The desired descriptor type for the copied data. For a list of AppleScript's predefined descriptor types, see "Descriptor Type Constants" (page 581).

If the descriptor specified by the `theAEKeyword` parameter is not of the desired type, `AEGetKeyPtr` attempts to coerce the data to this type. However, if the desired type is `typeWildCard`, no coercion is performed.

On return, you can determine the actual descriptor type by examining the `typeCode` parameter.

typeCode

A pointer to a descriptor type. On return, specifies the descriptor type of the data pointed to by `dataPtr`. The returned type is either the same as the type specified by the `desiredType` parameter or, if the desired type was type wildcard, the true type of the descriptor. Specify `NULL` if you do not care about this return value. For a list of AppleScript's predefined descriptor types, see "Descriptor Type Constants" (page 581).

dataPtr

A pointer to a buffer, local variable, or other storage location created and disposed of by your application. The size in bytes must be at least as large as the value you pass in the `maximumSize` parameter. On return, contains the parameter data. Specify `NULL` if you do not care about this return value.

maximumSize

The maximum length, in bytes, of the expected Apple event record parameter data. The `AEGetKeyPtr` function will not return more data than you specify in this parameter.

actualSize

A pointer to a variable of type `Size`. On return, the length, in bytes, of the data for the specified Apple event record parameter. If this value is larger than the value you passed in the `maximumSize` parameter, the buffer pointed to by `dataPtr` was not large enough to contain all of the data for the parameter, though `AEGetKeyPtr` does not write beyond the end of the buffer. If the buffer was too small, you can resize it and call `AEGetKeyPtr` again. Specify `NULL` if you do not care about this return value.

Return Value

A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion

This function is declared as a macro that invokes `AEGetParamPtr` (page 444), which can operate on an Apple event or an Apple event record. See the Discussion for that function for more information.

Version Notes
See AEGetParamPtr (page 444).

Availability
Available in Mac OS X v10.0 and later.

Declared In
AEDataModel.h

AEGetNthDesc

Copies a descriptor from a specified position in a descriptor list into a specified descriptor; typically used when your application needs to pass the extracted data to another function as a descriptor.

```
OSErr AEGetNthDesc (
   const AEDescList *theAEDescList,
   long index,
   DescType desiredType,
   AEKeyword *theAEKeyword,
   AEDesc *result
);
```

Parameters

theAEDescList

A pointer to the descriptor list to get the descriptor from. See AEDescList (page 553).

index

A one-based positive integer indicating the position of the descriptor to get. AEGetNthDesc returns an error if you pass zero, a negative number, or a value that is out of range.

desiredType

The desired descriptor type for the descriptor to copy. For a list of AppleScript's predefined descriptor types, see "Descriptor Type Constants" (page 581).

If the descriptor specified by the index parameter is not of the desired type, AEGetNthDesc attempts to coerce it to this type. However, if you pass a value of typeWildCard, no coercion is performed, and the descriptor type of the copied descriptor is the same as the descriptor type of the original descriptor.

See DescType (page 560).

theAEKeyword

A pointer to a keyword. On successful return, the keyword for the specified descriptor, if you are getting data from a list of keyword-specified descriptors; otherwise, AEGetNthDesc returns the value typeWildCard. Some keyword constants are described in "Keyword Attribute Constants" (page 593) and "Keyword Parameter Constants" (page 595). See AEKeyword (page 556).

result

A pointer to a descriptor. On successful return, a copy of the descriptor specified by the index parameter, coerced, if necessary, to the descriptor type specified by the desiredType parameter. On error, a null descriptor. If the function returns successfully, your application should call the AEDisposeDesc (page 424) function to dispose of the resulting descriptor after it has finished using it. See AEDesc (page 546).

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
If the Nth descriptor in the list is itself an Apple event record and the desired type is not wildcard, record, or list, `AEGetNthDesc` will fail with an `errAECoercionFailed` error. This behavior prevents coercion problems.

You may find the `AEGetNthPtr` (page 440) function convenient for retrieving data for direct use in your application, as it includes automatic coercion.

Version Notes
Thread safe starting in Mac OS X v10.2.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

AEGetNthPtr

Gets a copy of the data from a descriptor at a specified position in a descriptor list; typically used when your application needs to work with the extracted data directly.

```
OSErr AEGetNthPtr (
   const AEDescList *theAEDescList,
   long index,
   DescType desiredType,
   AEKeyword *theAEKeyword,
   DescType *typeCode,
   void *dataPtr,
   Size maximumSize,
   Size *actualSize
);
```

Parameters

theAEDescList

A pointer to the descriptor list that contains the descriptor. See `AEDescList` (page 553).

index

A one-based positive integer indicating the position in the descriptor list of the descriptor to get the data from. `AEGetNthPtr` returns an error if you pass zero, a negative number, or a value that is out of range.

desiredType

The desired descriptor type for the copied data. For a list of AppleScript's predefined descriptor types, see "Descriptor Type Constants" (page 581).

If the descriptor specified by the `index` parameter is not of the desired type, `AEGetNthPtr` attempts to coerce the data to this type. If you pass a value of `typeWildCard`, no coercion is performed, and the descriptor type of the copied data is the same as the descriptor type of the original descriptor.

See `DescType` (page 560).

theAEKeyword

A pointer to a keyword. On return, the keyword for the specified descriptor, if you are getting data from a list of keyword-specified descriptors; otherwise, `AEGetNthPtr` returns the value `typeWildCard`. Some keyword constants are described in "Keyword Attribute Constants" (page 593) and "Keyword Parameter Constants" (page 595). See `AEKeyword` (page 556).

typeCode

A pointer to a descriptor type. On return, specifies the descriptor type of the data pointed to by `dataPtr`. For a list of AppleScript's predefined descriptor types, see "Descriptor Type Constants" (page 581).

dataPtr

A pointer to a buffer, local variable, or other storage location created and disposed of by your application. The size in bytes must be at least as large as the value you pass in the `maximumSize` parameter. On return, contains the data from the descriptor at the position in the descriptor list specified by the `index` parameter.

maximumSize

The maximum length, in bytes, of the expected data. The `AEGetNthPtr` function will not return more data than you specify in this parameter.

actualSize

A pointer to a size variable. On return, the length, in bytes, of the data for the specified descriptor. If this value is larger than the value of the `maximumSize` parameter, the buffer pointed to by `dataPtr` was not large enough to contain all of the data for the descriptor, though `AEGetNthPtr` does not write beyond the end of the buffer. If the buffer was too small, you can resize it and call `AEGetNthPtr` again.

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
The `AEGetNthPtr` function uses a buffer to return the data for a specified descriptor from a specified descriptor list. The function attempts to coerce the descriptor to the descriptor type specified by the `desiredType` parameter.

Before calling `AEGetNthPtr`, you can call the `AESizeOfNthItem` (page 484) function to determine a size for the `dataPtr` buffer. However, unless you specify `typeWildCard` for the `desiredType` parameter, `AESizeOfNthItem` may coerce the data, which may cause the size of the data to change. If you are using `AEGetNthPtr` to iterate through a list of descriptors of the same type with a fixed size, such as a list of descriptors of type `typeFSS`, you can get the size once, allocate a buffer, and reuse it for each call.

The order of items in an Apple event record may change after an insertion or deletion. In addition, duplicating an Apple event record is not guaranteed to preserve the item order.

Version Notes
Thread safe starting in Mac OS X v10.2.

Availability
Available in Mac OS X v10.0 and later.

QTCarbonShell
QTMetaData

Declared In
`AEDataModel.h`

AEGetObjectAccessor

Gets an object accessor function from an object accessor dispatch table.

```
OSErr AEGetObjectAccessor (
   DescType desiredClass,
   DescType containerType,
   OSLAccessorUPP *accessor,
   SRefCon *accessorRefcon,
   Boolean isSysHandler
);
```

Parameters

desiredClass

The object class of the Apple event objects located by the object accessor function to get. Pass the value `typeWildCard` to get an object accessor function whose entry in an object accessor dispatch table specifies `typeWildCard` as the object class. Pass the value `cProperty` to get an object accessor function whose entry in an object accessor dispatch table specifies `cProperty` (a constant used to specify a property of any object class). Some other possible values are defined in "Object Class ID Constants" (page 599). See `DescType` (page 560).

containerType

The descriptor type of the token that identifies the container for the objects located by the requested accessor function. (Token is defined in `AEDisposeToken` (page 425).) Pass the value `typeWildCard` to get an object accessor function whose entry in an object accessor dispatch table specifies `typeWildCard` as the descriptor type of the token used to specify the container type. See `DescType` (page 560).

accessor

A universal procedure pointer. On return, a pointer to the requested object accessor function, if an object accessor dispatch table entry exists that exactly matches the values supplied in the parameters `desiredClass` and `containerType`. See `OSLAccessorUPP` (page 560).

accessorRefcon

A pointer to a reference constant. On return, points to the reference constant from the object accessor dispatch table entry for the specified object accessor function. The reference constant may have a value of 0.

isSysHandler

Specifies the object accessor dispatch table to get the object accessor function from. Pass `TRUE` to get the object accessor function from the system object accessor dispatch table or `FALSE` to get the object accessor function from your application's object accessor dispatch table. Use of the system object accessor dispatch table is not recommended.

Return Value

A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion

Calling `AEGetObjectAccessor` does not remove the object accessor function from an object accessor dispatch table.

Version Notes

In Mac OS X, your application can not make an object callback function available to other applications by installing it in a system object accessor dispatch table.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`AEObjects.h`

AEGetParamDesc

Gets a copy of the descriptor for a keyword-specified Apple event parameter from an Apple event or an Apple event record.

```
OSErr AEGetParamDesc (
   const AppleEvent *theAppleEvent,
   AEKeyword theAEKeyword,
   DescType desiredType,
   AEDesc *result
);
```

Parameters

theAppleEvent

A pointer to the Apple event to get the parameter descriptor from.

theAEKeyword

A keyword that specifies the desired Apple event parameter. Some keyword constants are described in "Keyword Parameter Constants" (page 595).

desiredType

The descriptor type for the desired Apple event parameter. For a list of AppleScript's predefined descriptor types, see "Descriptor Type Constants" (page 581).

If the requested Apple event parameter is not of the desired type, the Apple Event Manager attempts to coerce it to the desired type. However, if you pass a value of `typeWildCard`, no coercion is performed, and the descriptor type of the returned descriptor is the same as the descriptor type of the Apple event parameter.

result

A pointer to a descriptor. On successful return, a copy of the descriptor for the specified Apple event parameter, coerced, if necessary, to the descriptor type specified by the `desiredType` parameter. On error, a null descriptor. If the function returns successfully, your application should call the `AEDisposeDesc` (page 424) function to dispose of the resulting descriptor after it has finished using it.

Return Value

A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion

You typically call `AEGetParamDesc` to get a descriptor for an Apple event parameter to pass on to another Apple Event Manager routine. To get Apple event parameter data for your application to use directly, call `AEGetParamPtr` (page 444).

If the actual parameter you are getting with `AEGetParamDesc` is a record, you can only request it as a `typeAERecord`, `typeAEList`, or `typeWildcard`. For any other type, `AEGetParamDesc` will return `errAECoercionFail`.

Version Notes

Thread safe starting in Mac OS X v10.2.

Availability

Available in Mac OS X v10.0 and later.

Related Sample Code

QTCarbonShell

Declared In
`AEDataModel.h`

AEGetParamPtr

Gets a copy of the data for a specified Apple event parameter from an Apple event or an Apple event record.

```
OSErr AEGetParamPtr (
   const AppleEvent *theAppleEvent,
   AEKeyword theAEKeyword,
   DescType desiredType,
   DescType *actualType,
   void *dataPtr,
   Size maximumSize,
   Size *actualSize
);
```

Parameters

theAppleEvent

A pointer to the Apple event to get the parameter data from.

theAEKeyword

The keyword that specifies the desired Apple event parameter. Some keyword constants are described in "Keyword Parameter Constants" (page 595).

desiredType

The desired descriptor type for the copied data. For a list of AppleScript's predefined descriptor types, see "Descriptor Type Constants" (page 581).

If the descriptor specified by the `theAEKeyword` parameter is not of the desired type, `AEGetParamPtr` attempts to coerce the data to this type. However, if the desired type is `typeWildCard`, no coercion is performed.

On return, you can determine the actual descriptor type by examining the `typeCode` parameter.

typeCode

A pointer to a descriptor type. On return, specifies the descriptor type of the data pointed to by `dataPtr`. The returned type is either the same as the type specified by the `desiredType` parameter or, if the desired type was type wildcard, the true type of the descriptor. Specify `NULL` if you do not care about this return value. For a list of AppleScript's predefined descriptor types, see "Descriptor Type Constants" (page 581).

dataPtr

A pointer to a buffer, local variable, or other storage location created and disposed of by your application. The size in bytes must be at least as large as the value you pass in the `maximumSize` parameter. On return, contains the parameter data. Specify `NULL` if you do not care about this return value.

maximumSize

The maximum length, in bytes, of the expected Apple event parameter data. The `AEGetParamPtr` function will not return more data than you specify in this parameter.

actualSize

A pointer to a variable of type `Size`. On return, the length, in bytes, of the data for the specified Apple event parameter. If this value is larger than the value you passed in the `maximumSize` parameter, the buffer pointed to by `dataPtr` was not large enough to contain all of the data for the parameter, though `AEGetParamPtr` does not write beyond the end of the buffer. If the buffer was too small, you can resize it and call `AEGetParamPtr` again. Specify `NULL` if you do not care about this return value.

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
You should use this function only to extract data from value descriptors such as `typeUTF8Text`.

Because this function allows you to specify a desired type, it can result in coercion. When used correctly, this has the positive effect of returning the data in the desired format. However, it can have side effects you may not be expecting, such as the overhead of calls to coercion handlers. See also the Version Notes section below for possible problems with coercion.

To get Apple event parameter data for your application to use directly, call `AEGetParamPtr`. To get a descriptor for an Apple event parameter to pass on to another Apple Event Manager routine, call `AEGetParamDesc` (page 443).

Before calling `AEGetParamPtr`, you can call the `AESizeOfParam` (page 485) function to determine a size for the `dataPtr` buffer. However, unless you specify `typeWildCard` for the `desiredType` parameter, `AEGetParamPtr` may coerce the data, which may cause the size of the data to change.

In some cases, you may get improved efficiency extracting information from an Apple event with the `AEGetDescDataRange` (page 433) function.

Version Notes
Thread safe starting in Mac OS X v10.2.

If the actual parameter you are getting with `AEGetParamPtr` is a record, `AEGetParamPtr` will erroneously allow you to get the parameter as any type at all, when it really should allow only `typeAERecord`, `typeAEList`, or `typeWildcard`. For other types, it will place raw record data into the designated buffer. With AppleScript 1.1.2, it would then return `errAECoercionFail`, as expected. With AppleScript 1.3 and later, however, it returns `noErr`.

You can work around this problem by checking the returned parameter from any call to `AEGetParamPtr`. If the source type is `typeAERecord` and the type you asked for was anything other than `typeAERecord`, `typeAEList`, or `typeWildcard`, you should assume the coercion failed.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

AEGetRegisteredMachPort

Returns the Mach port (in the form of a `mach_port_t`) that was registered with the bootstrap server for this process.

```
mach_port_t AEGetRegisteredMachPort (
   void
);
```

Return Value
Returns a Mach message port header.

Discussion
Apple events on Mac OS X are implemented in terms of Mach messages. If your application links with the Carbon umbrella framework, it includes the HIToolbox framework, which initializes a Mach port and registers it with the run loop for the application. That port is considered public, and is used for sending and receiving Apple events.

Linking with the HIToolbox also requires that the application have a connection to the window server. To facilitate writing server processes that can send and receive Apple events, the Apple Event Manager provides the following functions (on Mac OS X only): `AEGetRegisteredMachPort`, `AEDecodeMessage` (page 421), `AESendMessage` (page 478), and `AEProcessMessage` (page 458). Daemons and other processes with no user interface can take advantage of these functions, while typical high-level applications will have no need for them.

If your code doesn't link with the HIToolbox or doesn't have a run loop, it can call `AEGetRegisteredMachPort` to register a port directly, then listen on that port for Apple events. It can use the other low-level functions to process incoming Apple events on the port and to send Apple events through it.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEMach.h`

AEGetSpecialHandler

Gets a specified handler from a special handler dispatch table.

```
OSErr AEGetSpecialHandler (
   AEKeyword functionClass,
   AEEventHandlerUPP *handler,
   Boolean isSysHandler
);
```

Parameters

`functionClass`

The keyword for the special handler to get. You can specify any of the constants described in "Special Handler Callback Constants" (page 603). See `AEKeyword` (page 556).

`handler`

A universal procedure pointer. On return, a pointer to the specified special handler, if one exists that matches the value supplied in the `functionClass` parameter. See `AEEventHandlerUPP` (page 555).

`isSysHandler`

Specifies the special handler dispatch table to get the handler from. Pass `TRUE` to get the handler from the system special handler dispatch table or `FALSE` to get the handler from your application's special handler dispatch table. Use of the system special handler dispatch table is not recommended.

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
See also `AEInstallSpecialHandler` (page 452) and `AERemoveSpecialHandler` (page 471).

Version Notes
Thread safe starting in Mac OS X v10.2.

In Mac OS X, you should generally install all handlers in the application dispatch table. For Carbon applications running in Mac OS 8 or Mac OS 9, a special handler in the system dispatch table could reside in the system heap, where it would be available to other applications. However, this won't work in Mac OS X.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AppleEvents.h`

AEGetTheCurrentEvent

Gets the Apple event that is currently being handled.

```
OSErr AEGetTheCurrentEvent (
   AppleEvent *theAppleEvent
);
```

Parameters

`theAppleEvent`

A pointer to an Apple event. On return, the Apple event that is currently being handled. If no Apple event is currently being handled, `AEGetTheCurrentEvent` supplies a descriptor of descriptor type `typeNull`, which does not contain any data. See `AppleEvent` (page 559).

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
In many applications, the handling of an Apple event involves one or more long chains of calls to internal functions. The `AEGetTheCurrentEvent` function makes it unnecessary for these calls to include the current Apple event as a parameter; the functions can simply call `AEGetTheCurrentEvent` to get the current Apple event when it is needed.

You can also use the `AEGetTheCurrentEvent` function to make sure that no Apple event is currently being handled. For example, suppose your application always uses an application-defined function to delete a file. That function can first call `AEGetTheCurrentEvent` and delete the file only if `AEGetTheCurrentEvent` returns a null descriptor (that is, only if no Apple event is currently being handled).

Special Considerations

This function is not thread-safe and should only be called on the main thread.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEInteraction.h`

AEInitializeDesc

Initializes a new descriptor.

```
void AEInitializeDesc (
   AEDesc *desc
);
```

Parameters

desc

A pointer to a new descriptor. See AEDesc (page 546).

Discussion

The function sets the type of the descriptor to typeNull and sets the data handle to NULL. If you need to initialize a descriptor that already has some data in it, use AEDisposeDesc (page 424) to deallocate the memory and initialize the descriptor.

Version Notes

Thread safe starting in Mac OS X v10.2.

Availability

Available in Mac OS X v10.0 and later.

Declared In

AEDataModel.h

AEInstallCoercionHandler

Installs a coercion handler in either the application or system coercion handler dispatch table.

```
OSErr AEInstallCoercionHandler (
   DescType fromType,
   DescType toType,
   AECoercionHandlerUPP handler,
   SRefCon handlerRefcon,
   Boolean fromTypeIsDesc,
   Boolean isSysHandler
);
```

Parameters

fromType

The descriptor type of the data coerced by the handler. For a list of AppleScript's predefined descriptor types, see "Descriptor Type Constants" (page 581). See DescType (page 560).

toType

The descriptor type of the resulting data. For a list of AppleScript's predefined descriptor types, see "Descriptor Type Constants" (page 581).

If there was already an entry in the specified coercion handler table for the same source descriptor type and result descriptor type, the existing entry is replaced. See DescType (page 560).

handler

A universal procedure pointer to the coercion handler function to install. See AECoercionHandlerUPP (page 552).

handlerRefcon

A reference constant. The Apple Event Manager passes this value to the handler each time it calls it. If your handler doesn't require a reference constant, pass 0 for this parameter.

fromTypeIsDesc

Specifies the form of the data to coerce. Pass `TRUE` if the coercion handler expects the data as a descriptor or `FALSE` if the coercion handler expects a pointer to the data. The Apple Event Manager can provide a pointer to data more efficiently than it can provide a descriptor, so all coercion functions should accept a pointer to data if possible.

isSysHandler

Specifies the coercion table to add the handler to. Pass `TRUE` to add the handler to the system coercion table or `FALSE` to add the handler to your application's coercion table. Use of the system coercion table is not recommended.

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
Before using `AEInstallCoercionHandler` to install a handler for a particular descriptor type, you can use the `AEGetCoercionHandler` (page 431) function to determine whether the table already contains a coercion handler for that type.

Version Notes
See the Version Notes section for the `AECoercePtr` (page 414) function for information on when to use descriptor-based versus pointer-based coercion handlers starting in Mac OS X version 10.2.

Thread safe starting in Mac OS X v10.2.

Your application should not install a coercion handler in a system coercion handler dispatch table with the goal that the handler will get called when other applications perform coercions—this won't work in Mac OS X. For more information, see "Writing and Installing Coercion Handlers" in Apple Events Programming Guide.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

AEInstallEventHandler

Adds an entry for an event handler to an Apple event dispatch table.

```
OSErr AEInstallEventHandler (
   AEEventClass theAEEventClass,
   AEEventID theAEEventID,
   AEEventHandlerUPP handler,
   SRefCon handlerRefcon,
   Boolean isSysHandler
);
```

Parameters

theAEEventClass

The event class for the Apple event or events to dispatch to this event handler. The Discussion section describes interactions between this parameter and the `theAEEventID` parameter. See `AEEventClass` (page 555).

theAEEventID

The event ID for the Apple event or events to dispatch to this event handler. The Discussion section describes interactions between this parameter and the `theAEEventClass` parameter. See `AEEventID` (page 556).

handler

A universal procedure pointer to the Apple event handler function to install. See `AEEventHandlerUPP` (page 555).

handlerRefcon

A reference constant. The Apple Event Manager passes this value to the handler each time it calls it. If your handler doesn't require a reference constant, pass 0 for this parameter.

isSysHandler

Specifies the Apple event dispatch table to add the handler to. Pass `TRUE` to add the handler to the system dispatch table or `FALSE` to add the handler to your application's dispatch table. See Version Notes for related information.

Return Value

A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion

The parameters `theAEEventClass` and `theAEEventID` specify the event class and event ID of the Apple events handled by the handler for this dispatch table entry. If there is already an entry in the specified dispatch table for the same event class and event ID, it is replaced. For these parameters, you must provide one of the following combinations:

- the event class and event ID of a single Apple event to dispatch to the handler (for example, an event class of `kAECoreSuite` and an event ID of `kAEDelete` so that a specific kind of `delete` event is dispatched to the handler)
- the `typeWildCard` constant for `theAEEventClass` and an event ID for `theAEEventID`, which indicates that Apple events from all event classes whose event IDs match `theAEEventID` should be dispatched to the handler (for example, an event class of `typeWildCard` and an event ID of `kAEDelete` so that for all event classes, the `delete` event is dispatched to the handler)
- an event class for `theAEEventClass` and the `typeWildCard` constant for `theAEEventID`, which indicates that all events from the specified event class should be dispatched to the handler (for example, an event class of `kAECoreSuite` and an event ID of `typeWildCard` so that all events for the core suite are dispatched to the handler)
- the `typeWildCard` constant for both the `theAEEventClass` and `theAEEventID` parameters, which indicates that all Apple events should be dispatched to the handler

If you use the `typeWildCard` constant for either the `theAEEventClass` or the `theAEEventID` parameter (or for both parameters), the corresponding handler must return the error `errAEEventNotHandled` if it does not handle a particular event.

If an Apple event dispatch table contains one entry for an event class and a specific event ID, and also contains another entry that is identical except that it specifies a wildcard value for either the event class or the event ID, the Apple Event Manager dispatches the more specific entry. For example, if an Apple event dispatch table includes one entry that specifies the event class as `kAECoreSuite` and the event ID as `kAEDelete`, and another entry that specifies the event class as `kAECoreSuite` and the event ID as `typeWildCard`, the Apple Event Manager dispatches the Apple event handler associated with the entry that specifies the event ID as `kAEDelete`.

In addition to the Apple event handler dispatch tables, applications can add entries to special handler dispatch tables, as described in "Managing Special Handler Dispatch Tables" (page 404).

Version Notes
Thread safe starting in Mac OS X v10.2.

Your application should not install a handler in a system dispatch table with the goal that the handler will get called when other applications receive events—this won't work in Mac OS X. For more information, see "The System Dispatch Table" in "Apple Event Dispatching" in Apple Events Programming Guide.

Availability
Available in Mac OS X v10.0 and later.

`AppleEvents.h`

AEInstallObjectAccessor

Adds or replaces an entry for an object accessor function to an object accessor dispatch table.

```
OSErr AEInstallObjectAccessor (
   DescType desiredClass,
   DescType containerType,
   OSLAccessorUPP theAccessor,
   SRefCon accessorRefcon,
   Boolean isSysHandler
);
```

Parameters

desiredClass
The object type of the Apple event objects located by this accessor. See `DescType` (page 560).

containerType
The type of the token whose objects are accessed by this accessor. (Token is defined in `AEDisposeToken` (page 425).) The accessor function finds objects in containers specified by tokens of this type. See `DescType` (page 560).

theAccessor
A universal procedure pointer to the object accessor function to install. See `OSLAccessorUPP` (page 560).

accessorRefcon
A reference constant the Apple Event Manager passes to the object accessor function whenever it calls the function. If your object accessor function doesn't require a reference constant, pass 0 for this parameter. To change the value of the reference constant, you must call `AEInstallObjectAccessor` again.

isSysHandler
Specifies the object accessor dispatch table to add the entry to. Pass `TRUE` to add the entry to the system object accessor dispatch table or `FALSE` to add the entry to your application's object accessor dispatch table. Use of the system object accessor dispatch table is not recommended.

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
The `AEInstallObjectAccessor` function adds or replaces an entry to either the application or system object accessor dispatch table.

Version Notes
In Mac OS X, your application can not make an object callback function available to other applications by installing it in a system object accessor dispatch table.

If your Carbon application running in Mac OS 8 or OS 9 installs a system object accessor function in its application heap, rather than in the system heap, you must call `AERemoveObjectAccessor` (page 470) to remove the function before your application terminates.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEObjects.h`

AEInstallSpecialHandler

Installs a callback function in a special handler dispatch table.

```
OSErr AEInstallSpecialHandler (
   AEKeyword functionClass,
   AEEventHandlerUPP handler,
   Boolean isSysHandler
);
```

Parameters

functionClass

A value that specifies the type of handler to install. You can use any of the constants defined in "Special Handler Callback Constants" (page 603).

If there is already an entry in the specified special handler dispatch table for the value you specify in this parameter, it is replaced.

See `AEKeyword` (page 556).

handler

A universal procedure pointer to the special handler to install. See `AEEventHandlerUPP` (page 555).

isSysHandler

Specifies the special handler dispatch table to add the handler to. Pass `TRUE` to add the handler to the system special handler dispatch table or `FALSE` to add the handler to your application's special handler dispatch table. Use of the system special handler dispatch table is not recommended.

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
An Apple event special handler dispatch table contains entries with a function class keyword, the address of the handler function that handles the Apple events indicated by the keyword, and a reference constant. Depending on which handlers you choose to install, a special handler dispatch table can have entries for any of the following:

- a predispatch handler (an Apple event handler that the Apple Event Manager calls immediately before it dispatches an Apple event)
- up to one each of the callback functions described in "Object Callback Functions" (page 524) these functions, such as an object comparison function and an object-counting function, can be installed with `AEInstallSpecialHandler` or with the `AEInstallObjectAccessor` (page 451) function

See also `AEGetSpecialHandler` (page 446) and `AERemoveSpecialHandler` (page 471).

Version Notes
Thread safe starting in Mac OS X v10.2.

For Carbon applications running in Mac OS 8 or Mac OS 9, a handler in the system special handler dispatch table should reside in the system heap, where it may be available to other applications. If you put your system handler code in your application heap, be sure to use `AERemoveSpecialHandler` to remove the handler when your application quits. Otherwise, your handler will still have an entry in the system dispatch table with a pointer a handler that no longer exists. Another application may dispatch an Apple event that attempts to call your handler, leading to a system crash.

Your application should not install a handler in a system dispatch table with the goal that the handler will get called when other applications receive events—this won't work in Mac OS X.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AppleEvents.h`

AEInteractWithUser

Initiates interaction with the user when your application is a server application responding to an Apple event.

```
OSErr AEInteractWithUser (
   SInt32 timeOutInTicks,
   NMRecPtr nmReqPtr,
   AEIdleUPP idleProc
);
```

Parameters

timeOutInTicks
The amount of time (in ticks) that your handler is willing to wait for a response from the user. You can specify a number of ticks or use one of the constants defined in "Timeout Constants" (page 605).

nmReqPtr
A pointer to a Notification Manager record provided by your application. You can specify `NULL` for this parameter to get the default notification handling provided by the Apple Event Manager. See the Notification Manager documentation for a description of the `NMRecPtr` data type.

idleProc
A universal procedure pointer to your application's idle function, which handles events while waiting for the Apple Event Manager to return control. See `AEIdleUPP` (page 556).

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636). The `AEInteractWithUser` function returns the `errAENoUserInteraction` result code if the user interaction preferences don't allow user interaction. If `AEInteractWithUser` returns the `noErr` result code, then your application is in the foreground and is free to interact with the user.

Discussion
Your application should call the `AEInteractWithUser` function before displaying a dialog box or alert box or otherwise interacting with the user in response to an Apple event. The `AEInteractWithUser` function checks whether the client application set the `kAENeverInteract` flag for the current Apple event, if any, and if so, returns an error. If not, then `AEInteractWithUser` checks the server application's preference set by the `AESetInteractionAllowed` (page 479) function and compares it against the source of the Apple event—that is, whether it came from the same application, another process on the same computer, or a process running on another computer.

If the user interaction preference settings permit the application to come to the foreground, this function brings your application to the front, either directly or by posting a notification request.

Your application should normally pass a notification record in the `nmReqPtr` parameter rather than specifying `NULL` for default notification handling. If you specify `NULL`, the Apple Event Manager looks for an application icon with the ID specified by the application's bundle (`'BNDL'`) resource and the application's file reference (`'FREF'`) resource. The Apple Event Manager first looks for an `'SICN'` resource with the specified ID if it can't find an `'SICN'` resource, it looks for the `'ICN#'` resource and compresses the icon to fit in the menu bar. The Apple Event Manager won't look for any members of an icon family other than the icon specified in the `'ICN#'` resource.

If the application doesn't have `'SICN'` or `'ICN#'` resources, or if it doesn't have a file reference resource, the Apple Event Manager passes no icon to the Notification Manager, and no icon appears in the upper-right corner of the screen. Therefore, if you want to display any icon other than those of type `'SICN'` or `'ICN#'`, you must specify a notification record as the second parameter to the AEInteractWithUser function.

If you want the Notification Manager to use a color icon when it posts a notification request, you should provide a Notification Manager record that specifies a `'cicn'` resource.

For additional information on interaction level, see `AESend` (page 476) and "`AESendMode`" (page 566).

See also `AESetInteractionAllowed` (page 479) and `AEGetInteractionAllowed` (page 436).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEInteraction.h`

AEManagerInfo

Provides information about the version of the Apple Event Manager currently available or the number of processes that are currently recording Apple events.

```
OSErr AEManagerInfo (
   AEKeyword keyWord,
   long *result
);
```

Parameters

keyWord

A value that determines the kind of information the function supplies in the `result` parameter.

Pass the value `keyAERecorderCount` to obtain the number of processes that are currently recording Apple events.

Pass the value `keyAEVersion` to obtain version information for the Apple Event Manager, in `NumVersion` format.

Some keyword constants are defined in "Keyword Parameter Constants" (page 595).

See `AEKeyword` (page 556).

result

A pointer to a long value. On return, provides information that depends on what you pass in the `keyword` parameter.

If you pass `keyAERecorderCount`, `result` specifies the number of processes that are currently recording Apple events.

If you pass `keyAEVersion`, `result` supplies version information for the Apple Event Manager, in a format that matches the `'vers'` resource.

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
For recordable applications, the information provided by `AEManagerInfo` may be useful when the application is responding to Apple events that it sends to itself.

For information on determining whether the Apple Event Manager is available, see the Apple Event Manager Gestalt Selector, described in *Inside Mac OS X: Gestalt Manager Reference*.

Version Notes
Thread safe starting in Mac OS X v10.2.

The `AEManagerInfo` function is available only in version 1.01 and later of the Apple Event Manager.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AppleEvents.h`

AEObjectInit

Initializes the Object Support Library.

```
OSErr AEObjectInit (
   void
);
```

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
You must call this function before calling any of the Apple Event Manager functions that describe or manipulate Apple event objects.

You should call the `AEObjectInit` function to initialize the Apple Event Manager functions that handle object specifiers and Apple event objects.

Version Notes
To make these functions available to your application with version 1.01 and earlier versions of the Apple Event Manager, you must also link the Apple Event Object Support Library with your application when you build it. For more information, see the Version Notes section for the AppleScript Gestalt Selector described in *Inside Mac OS X: Gestalt Manager Reference* and the function `AERemoveSpecialHandler` (page 471).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEObjects.h`

AEPrintDescToHandle

Provides a pretty printer facility for displaying the contents of Apple event descriptors.

```
OSStatus AEPrintDescToHandle (
   const AEDesc *desc,
   Handle *result
);
```

Parameters

desc

A pointer to a descriptor containing the information to be printed. See `AEDesc` (page 546).

result

A pointer to a location for a new `Handle` data type. On return, contains a new handle allocated by the Memory Manager.

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
The data handle returned in the *result* parameter contains a text string formatted using the "AEBuild" syntax. This string is useful for looking at the contents of Apple events sent by other applications and for debugging your own descriptors.

`AEPrintDescToHandle` prints the contents of `AEDesc`, `AERecord`, and `AEDescList` descriptors in a format that is suitable for input to `AEBuildDesc` (page 410). `AEPrintDescToHandle` also attempts display coerced Apple event records as the coerced record type instead of as the original type. Any data structures that cannot be identified are displayed as hexadecimal data.

`AEPrintDescToHandle` prints the contents of Apple events in a slightly different format. For these events, the event class and event ID appear at the beginning of the output string, followed by the contents of the event enclosed in curly braces. In addition, each attribute is printed with its four-character identifier and preceded by an ampersand character. You cannot use the output string to recreate the Apple event from `AEBuildAppleEvent` (page 408).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEHelpers.h`

AEProcessAppleEvent

Calls the handler, if one exists, for a specified Apple event.

```
OSErr AEProcessAppleEvent (
   const EventRecord *theEventRecord
);
```

Parameters

`theEventRecord`

A pointer to the event record for the Apple event to process. See the Event Manager documentation for a description of the `EventRecord` data type.

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636). This is the error result from the Apple event handler (or `errAEHandlerNotFound`). In most cases your application should ignore this error because it will be seen by the Apple event sender as the `keyErrorNumber` parameter in the reply.

Discussion
After receiving a high-level event (and optionally determining whether it is a type of high-level event other than an Apple event that your application might support), your application typically calls the `AEProcessAppleEvent` function to determine the type of Apple event received and call the corresponding handler. Your application should always handle high-level events immediately, or the Apple Event Manager may return the event to the sending application with the `errAEEventNotHandled` result code.

The `AEProcessAppleEvent` function looks first in the application's special handler dispatch table for an entry that was installed by the `AEInstallSpecialHandler` (page 452) function with the constant `keyPreDispatch`. If the application's special handler dispatch table does not include such a handler or if the handler returns `errAEEventNotHandled`, `AEProcessAppleEvent` looks in the application's Apple event dispatch table for an entry that matches the event class and event ID of the specified Apple event. You install handlers in the application's dispatch table with the `AEInstallEventHandler` (page 449) function.

If the application's Apple event dispatch table does not include such a handler or if the handler returns `errAEEventNotHandled`, the `AEProcessAppleEvent` function looks in the system special handler dispatch table for an entry that was installed with the constant `keyPreDispatch`. If the system special handler dispatch table does not include such a handler or if the handler returns `errAEEventNotHandled`, `AEProcessAppleEvent` looks in the system Apple event dispatch table for an entry that matches the event class and event ID of the specified Apple event.

If the system Apple event dispatch table does not include such a handler, the Apple Event Manager returns the result code `errAEEventNotHandled` to the server (or target) application and, if the client application is waiting for a reply, to the client application.

If AEProcessAppleEvent finds an entry in one of the dispatch tables that matches the event class and event ID of the specified Apple event, it calls the corresponding handler.

If an Apple event dispatch table contains one entry for an event class and a specific event ID, and also contains another entry that specifies a wildcard value for either the event class or the event ID, the Apple Event Manager uses the more specific entry. For example, if one entry specifies an event class of kAECoreSuite and an event ID of kAEDelete and another entry specifies an event class of kAECoreSuite and an event ID of typeWildCard, the Apple Event Manager will dispatch an Apple event with an event ID of kAEDelete to the handler from the entry that specifies the event ID as kAEDelete.

Version Notes
Your application should not install a handler in a system dispatch table with the goal that the handler will get called when other applications receive events—this won't work in Mac OS X. For more information, see "The System Dispatch Table" in "Apple Event Dispatching" in Apple Events Programming Guide.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
Simple DrawSprocket

Declared In
AEInteraction.h

AEProcessMessage

Decodes and dispatches a low level Mach message event to an event handler, including packaging and returning the reply to the sender.

```
OSStatus AEProcessMessage (
   mach_msg_header_t *header
);
```

Parameters

header

A pointer to the received Mach message that should be processed. The contents of the message header are invalid after calling this method.

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
The Apple Event Manager provides the following functions (on Mac OS X only) for working with Apple events at a lower level: AEGetRegisteredMachPort (page 445), AEDecodeMessage (page 421), AESendMessage (page 478), and AEProcessMessage. See the descriptions for those functions for more information on when you might use them.

If your daemon or other code has initialized a Mach port and is listening on it for Apple events and other messages, it can call AEProcessMessage to handle any incoming events it identifies as Apple events, while handling other types of events itself. AEProcessMessage will dispatch the event to an event handler (by calling AEDecodeMessage for you) and package and return the reply to the sender, simplifying handling for your code.

The Apple Event Manager reserves Mach message IDs in the range 0 to 999 for its own use. AEProcessMessage returns a paramErr result code if the Mach message did not contain an Apple event.

Availability
Available in Mac OS X v10.0 and later.

Declared In
AEMach.h

AEPutArray

Inserts the data for an Apple event array into a descriptor list, replacing any previous descriptors in the list.

```
OSErr AEPutArray (
   AEDescList *theAEDescList,
   AEArrayType arrayType,
   const AEArrayData *arrayPtr,
   DescType itemType,
   Size itemSize,
   long itemCount
);
```

Parameters

theAEDescList

A pointer to the descriptor list to put the Apple event array into. If there are any descriptors already in the descriptor list, they are replaced. If the array type is kAEKeyDescArray, theAEDescList must point to an Apple event record; otherwise, it can point to either a descriptor list or an Apple event record.

If you pass a pointer to a factored descriptor list, created by calling the AECreateList (page 419) function, each array item in the array pointed to by the arrayPtr parameter must include the data that is common to all the descriptors in the list. The Apple Event Manager automatically isolates the common data you specified in the call to AECreateList. A factored descriptor list is described in the Discussion section.

See AEDescList (page 553).

arrayType

The Apple event array type to create. Pass a value specified by one of the constants described in "Data Array Constants" (page 580). See AEArrayType (page 552).

arrayPtr

A pointer to a buffer, local variable, or other storage location, created and disposed of by your application, that contains the array to put into the descriptor list. See AEArrayData (page 545).

itemType

For arrays of type kAEDataArray, kAEPackedArray, or kAEHandleArray, the descriptor type of the array items to create. Use one of the constants described in "Descriptor Type Constants" (page 581), such as typeLongInteger. You don't need to specify an item type for arrays of type kAEDescArray or kAEKeyDescArray because the data is already stored in descriptors which contain a descriptor type. See DescType (page 560).

itemSize

For arrays of type kAEDataArray or kAEPackedArray, the size (in bytes) of the array items to create. You don't need to specify an item size for arrays of type kAEDescArray, kAEKeyDescArray, or kAEHandleArray because their descriptors (though not the data they point to) have a known size.

itemCount

The number of elements in the array.

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
A factored descriptor list is one in which the Apple Event Manager automatically isolates the data that is common to all the elements of the list so that the common data only appears in the list once. To create a factored descriptor list, you call the `AECreateList` (page 419) function and specify the data that is common to all elements in the descriptor array.

Version Notes
Thread safe starting in Mac OS X v10.2.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

AEPutAttributeDesc

Adds a descriptor and a keyword to an Apple event as an attribute.

```
OSErr AEPutAttributeDesc (
   AppleEvent *theAppleEvent,
   AEKeyword theAEKeyword,
   const AEDesc *theAEDesc
);
```

Parameters

theAppleEvent
A pointer to the Apple event to add an attribute to. See the `AppleEvent` (page 559) data type.

theAEKeyword
The keyword for the attribute to add. If the Apple event already includes an attribute with this keyword, the attribute is replaced.

Some keyword constants are described in "Keyword Attribute Constants" (page 593).

See `AEKeyword` (page 556).

theAEDesc
A pointer to the descriptor to assign to the attribute. The descriptor type of the specified descriptor should match the defined descriptor type for that attribute. See `AEDesc` (page 546).

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
The `AEPutAttributeDesc` function takes a descriptor and a keyword and adds them to an Apple event as an attribute. If the descriptor type required for the attribute is different from the descriptor type of the descriptor, the Apple Event Manager attempts to coerce the descriptor into the required type, with one exception: the Apple Event Manager does not attempt to coerce the data for an address attribute, thereby allowing applications to use their own address types.

Version Notes
Thread safe starting in Mac OS X v10.2.

Availability
Available in Mac OS X v10.0 and later.

Declared In
AEDataModel.h

AEPutAttributePtr

Adds a pointer to data, a descriptor type, and a keyword to an Apple event as an attribute.

```
OSErr AEPutAttributePtr (
   AppleEvent *theAppleEvent,
   AEKeyword theAEKeyword,
   DescType typeCode,
   const void *dataPtr,
   Size dataSize
);
```

Parameters

theAppleEvent
A pointer to the Apple event to add an attribute to. See the `AppleEvent` (page 559) data type.

theAEKeyword
The keyword for the attribute to add. If the Apple event already includes an attribute with this keyword, the attribute is replaced.

Some keyword constants are described in "Keyword Attribute Constants" (page 593).

See `AEKeyword` (page 556).

typeCode
The descriptor type for the attribute to add. For a list of AppleScript's predefined descriptor types, see "Descriptor Type Constants" (page 581). See `DescType` (page 560).

dataPtr
A pointer to the data for the attribute to add.

dataSize
The length, in bytes, of the data for the attribute to add.

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Version Notes
Thread safe starting in Mac OS X v10.2.

Availability
Available in Mac OS X v10.0 and later.

Declared In
AEDataModel.h

AEPutDesc

Adds a descriptor to any descriptor list, possibly replacing an existing descriptor in the list.

```
OSErr AEPutDesc (
   AEDescList *theAEDescList,
   long index,
   const AEDesc *theAEDesc
);
```

Parameters

theAEDescList

A pointer to the descriptor list to add a descriptor to. See `AEDescList` (page 553).

index

A one-based positive integer indicating the position to insert the descriptor at. If there is already a descriptor in the specified position, it is replaced.

You can pass a value of zero or count + 1 to add the descriptor at the end of the list. `AEPutDesc` returns an error (`AEIllegalIndex`) if you pass a negative number or a value that is out of range.

theAEDesc

A pointer to the descriptor to add to the list. See `AEDesc` (page 546).

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Version Notes
Thread safe starting in Mac OS X v10.2.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

AEPutKeyDesc

Inserts a descriptor and a keyword into an Apple event record as an Apple event parameter.

```
OSErr AEPutKeyDesc (
    AERecord *theAERecord,
    AEKeyword theAEKeyword,
    const AEDesc *theAEDesc
);
```

Parameters

theAERecord

A pointer to the Apple event record to add a parameter to.

theAEKeyword

The keyword specifying the parameter to add. If the Apple event record already has a parameter with this keyword, the parameter is replaced.

Some keyword constants are described in "Keyword Parameter Constants" (page 595).

See `AEKeyword` (page 556).

theAEDesc

A pointer to the descriptor for the parameter to add. See `AEDesc` (page 546).

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
This function is declared as a macro that invokes `AEPutParamDesc` (page 464), which can operate on an Apple event or an Apple event record. See the Discussion for that function for more information.

Version Notes
See `AEPutParamDesc` (page 464).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

AEPutKeyPtr

Inserts data, a descriptor type, and a keyword into an Apple event record as an Apple event parameter.

```
OSErr AEPutKeyPtr (
    AERecord *theAERecord,
    AEKeyword theAEKeyword,
    DescType typeCode,
    const void *dataPtr,
    Size dataSize
);
```

Parameters

theAERecord
A pointer to the Apple event record to add a parameter to.

theAEKeyword
The keyword for the parameter to add. If the Apple event record already includes a parameter with this keyword, the parameter is replaced.

Some keyword constants are described in "Keyword Parameter Constants" (page 595).

See `AEKeyword` (page 556).

typeCode
The descriptor type for the parameter to add. For a list of AppleScript's predefined descriptor types, see "Descriptor Type Constants" (page 581). See `DescType` (page 560).

dataPtr
A pointer to the data for the parameter to add.

dataSize
The length, in bytes, of the data for the parameter to add.

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
This function is declared as a macro that invokes `AEPutParamPtr` (page 464), which can operate on an Apple event or an Apple event record. See the Discussion for that function for more information.

Version Notes
See `AEPutParamPtr` (page 464).

Availability
Available in Mac OS X v10.0 and later.

Declared In
AEDataModel.h

AEPutParamDesc

Inserts a descriptor and a keyword into an Apple event or Apple event record as an Apple event parameter.

```
OSErr AEPutParamDesc (
   AppleEvent *theAppleEvent,
   AEKeyword theAEKeyword,
   const AEDesc *theAEDesc
);
```

Parameters

theAppleEvent
A pointer to the Apple event to add a parameter to. See the AppleEvent (page 559) data type.

theAEKeyword
The keyword specifying the parameter to add. If the Apple event already has a parameter with this keyword, the parameter is replaced.

Some keyword constants are described in "Keyword Parameter Constants" (page 595).

See AEKeyword (page 556).

theAEDesc
A pointer to the descriptor for the parameter to add. See AEDesc (page 546).

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Version Notes
Thread safe starting in Mac OS X v10.2.

Availability
Available in Mac OS X v10.0 and later.

Declared In
AEDataModel.h

AEPutParamPtr

Inserts data, a descriptor type, and a keyword into an Apple event or Apple event record as an Apple event parameter.

```
OSErr AEPutParamPtr (
   AppleEvent *theAppleEvent,
   AEKeyword theAEKeyword,
   DescType typeCode,
   const void *dataPtr,
   Size dataSize
);
```

Parameters

theAppleEvent
A pointer to the Apple event to add a parameter to. See the AppleEvent (page 559) data type.

theAEKeyword

The keyword for the parameter to add. If the Apple event already includes an parameter with this keyword, the parameter is replaced.

Some keyword constants are described in "Keyword Parameter Constants" (page 595).

See `AEKeyword` (page 556).

typeCode

The descriptor type for the parameter to add. For a list of AppleScript's predefined descriptor types, see "Descriptor Type Constants" (page 581). See `DescType` (page 560).

dataPtr

A pointer to the data for the parameter to add.

dataSize

The length, in bytes, of the data for the parameter to add.

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Version Notes
Thread safe starting in Mac OS X v10.2.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

AEPutPtr

Inserts data specified in a buffer into a descriptor list as a descriptor, possibly replacing an existing descriptor in the list.

```
OSErr AEPutPtr (
   AEDescList *theAEDescList,
   long index,
   DescType typeCode,
   const void *dataPtr,
   Size dataSize
);
```

Parameters

theAEDescList

A pointer to the descriptor list to add a descriptor to. See `AEDescList` (page 553).

index

A one-based positive integer indicating the position to insert the descriptor at. If there is already a descriptor in the specified position, it is replaced.

You can pass a value of zero or count + 1 to add the descriptor at the end of the list. `AEPutPtr` returns an error (`AEIllegalIndex`) if you pass a negative number or a value that is out of range.

typeCode

The descriptor type for the descriptor to be put into the list. For a list of AppleScript's predefined descriptor types, see "Descriptor Type Constants" (page 581). See `DescType` (page 560).

dataPtr
A pointer to the data for the descriptor to add.

dataSize
The length, in bytes, of the data for the descriptor to add.

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Version Notes
Thread safe starting in Mac OS X v10.2.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

AERemoteProcessResolverGetProcesses

Returns an array of objects containing information about processes running on a remote machine.

```
CFArrayRef AERemoteProcessResolverGetProcesses (
   AERemoteProcessResolverRef ref,
   CFStreamError *outError
);
```

Parameters

ref
The `AERemoteProcessResolverRef` (page 557) to query. Acquired from a previous call to `AECreateRemoteProcessResolver` (page 420).

outError
If the function result is `NULL`, `outError` contains information about the failure. See the Core Foundation Reference Documentation for a description of the `CFStreamError` data type.

Return Value
In the case of an error, returns `NULL`, in which case the `outError` parameter provides error information. If successful, returns a `CFArrayRef` of `CFDictionaryRef` objects containing information about the discovered remote processes. Each dictionary contains the URL of a remote application and its human readable name; it may also contain a `CFNumberRef` specifying a user ID for the application, if it has one; and it may also contain a `CFNumberRef` specifying the process ID for the process. The array is owned by the resolver, so you must retain it before disposing of the resolver object itself. For information on the keys for getting information from the dictionary, see "Remote Process Dictionary Keys" (page 602).

Discussion
You first call `AECreateRemoteProcessResolver` (page 420) to obtain a reference to a resolver object you can use to obtain a list of processes running on a specified remote machine. See the description for that function for additional information. You then pass that reference to `AERemoteProcessResolverGetProcesses` to get an array of objects containing information about the discovered remote processes.

If the resolver was not previously scheduled for execution (by a call to the `AERemoteProcessResolverScheduleWithRunLoop` (page 467) function), `AERemoteProcessResolverGetProcesses` will block until the resulting array is available or an error occurs. If the resolver was previously scheduled but had not yet completed fetching the array, this call will block until the resolver does complete.

Version Notes
Thread safe starting in Mac OS X v10.3.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`AppleEvents.h`

AERemoteProcessResolverScheduleWithRunLoop

Schedules a resolver for execution on a given run loop in a given mode.

```
void AERemoteProcessResolverScheduleWithRunLoop (
   AERemoteProcessResolverRef ref,
   CFRunLoopRef runLoop,
   CFStringRef runLoopMode,
   AERemoteProcessResolverCallback callback,
   const AERemoteProcessResolverContext *ctx
);
```

Parameters

ref

The `AERemoteProcessResolverRef` (page 557) to query. Acquired from a previous call to `AECreateRemoteProcessResolver` (page 420).

runLoop

The run loop on which to schedule resolution of remote processes. For information on run loops, see Introduction to Run Loops. See the Core Foundation Reference Documentation for a description of the `CFRunLoop` data type.

runLoopMode

Specifies the run loop mode. See Input Modes for information on available modes. See the Core Foundation Reference Documentation for a description of the `CFStringRef` data type.

callback

A callback function to be executed when the resolver completes. See `AERemoteProcessResolverCallback` (page 532) for information on the callback definition.

ctx

Optionally supplies information of use while resolving remote processes. If this parameter is not `NULL`, the info field of this structure is passed to the callback function (otherwise, the info parameter to the `callback` function will explicitly be `NULL`). See `AERemoteProcessResolverContext` (page 547) for a description of this data type.

Discussion
Schedules a resolver for execution on a given run loop in a given mode. The resolver will move through various internal states as long as the specified run loop is run. When the resolver completes, either with success or with an error condition, the callback is executed. There is no explicit unschedule of the resolver; you must dispose of it to remove it from the run loop.

Version Notes
Thread safe starting in Mac OS X v10.3.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`AppleEvents.h`

AERemoveCoercionHandler

Removes a coercion handler from a coercion handler dispatch table.

```
OSErr AERemoveCoercionHandler (
   DescType fromType,
   DescType toType,
   AECoercionHandlerUPP handler,
   Boolean isSysHandler
);
```

Parameters

fromType

The descriptor type of the data coerced by the handler. For a list of AppleScript's predefined descriptor types, see "Descriptor Type Constants" (page 581). See `DescType` (page 560).

toType

The descriptor type of the resulting data. For a list of AppleScript's predefined descriptor types, see "Descriptor Type Constants" (page 581). See `DescType` (page 560).

handler

A universal procedure pointer to the coercion handler to remove. Although the parameters `fromType` and `toType` are sufficient to identify the handler, you can identify the handler explicitly as a safeguard. If you pass `NULL` for this parameter, the Apple Event Manager relies solely on the event class and event ID to identify the handler. See `AECoercionHandlerUPP` (page 552).

isSysHandler

Specifies the coercion table to remove the handler from. Pass `TRUE` to remove the handler from the system coercion table or `FALSE` to remove the handler from your application's coercion table. Use of the system coercion table is not recommended.

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Version Notes
Thread safe starting in Mac OS X v10.2.

Use of system coercion tables is not recommended. For more information, see "Writing and Installing Coercion Handlers" in Apple Events Programming Guide.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

AERemoveEventHandler

Removes an event handler entry from an Apple event dispatch table.

```
OSErr AERemoveEventHandler (
   AEEventClass theAEEventClass,
   AEEventID theAEEventID,
   AEEventHandlerUPP handler,
   Boolean isSysHandler
);
```

Parameters

theAEEventClass

The event class for the handler to remove. See `AEEventClass` (page 555).

theAEEventID

The event ID for the handler to remove. See `AEEventID` (page 556).

handler

A universal procedure pointer to the handler to remove. Although the parameters `theAEEventClass` and `theAEEventID` are sufficient to identify the handler, you can identify the handler explicitly as a safeguard. If you pass `NULL` for this parameter, the Apple Event Manager relies solely on the event class and event ID to identify the handler.

If you use the `typeWildCard` constant for either or both of the event class and event ID parameters, `AERemoveEventHandler` will return an error unless an entry exists that specifies `typeWildCard` in exactly the same way. For example, if you specify `typeWildCard` in both the `theAEEventClass` parameter and the `theAEEventID` parameter, `AERemoveEventHandler` will not remove the first handler for any event class and event ID in the dispatch table; instead, it will only remove a handler if an entry exists that specifies type `typeWildCard` for both the event class and the event ID.

For an explanation of wildcard values, see the Discussion section for `AEInstallEventHandler` (page 449).

See `AEEventHandlerUPP` (page 555).

isSysHandler

Specifies the Apple event dispatch table to remove the handler from. Pass `TRUE` to remove the handler from the system dispatch table or `FALSE` to remove the handler from your application's dispatch table. See Version Notes for related information.

Return Value

A result code. See "Apple Event Manager Result Codes" (page 636).

Version Notes

Thread safe starting in Mac OS X v10.2.

Your application should not install a handler in a system dispatch table with the goal that the handler will get called when other applications receive events—this won't work in Mac OS X. For more information, see "The System Dispatch Table" in "Apple Event Dispatching" in Apple Events Programming Guide.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`AppleEvents.h`

AERemoveObjectAccessor

Removes an object accessor function from an object accessor dispatch table.

```
OSErr AERemoveObjectAccessor (
   DescType desiredClass,
   DescType containerType,
   OSLAccessorUPP theAccessor,
   Boolean isSysHandler
);
```

Parameters

desiredClass

The object class of the Apple event objects located by the object accessor function to remove. Pass the value `typeWildCard` to remove an object accessor function whose entry in an object accessor dispatch table specifies `typeWildCard` as the object class. Pass the value `cProperty` to remove an object accessor function whose entry in an object accessor dispatch table specifies `cProperty` (a constant used to specify a property of any object class). Some other possible values are defined in "Object Class ID Constants" (page 599). See `DescType` (page 560).

containerType

The descriptor type of the token that identifies the container for the objects located by the object accessor function to remove. (Token is defined in `AEDisposeToken` (page 425).) Pass the value `typeWildCard` to remove an object accessor function whose entry in an object accessor dispatch table specifies `typeWildCard` as the descriptor type of the token used to specify the container type. See `DescType` (page 560).

theAccessor

A universal procedure pointer to the special handler to remove. Although the `functionClass` parameter is sufficient to identify the handler to remove, you can identify the handler explicitly as a safeguard. If you pass `NULL` for this parameter, the Apple Event Manager relies solely on the function class to identify the handler. A universal procedure pointer (UPP) to the object accessor function to remove. Although the parameters `desiredClass` and `containerType` are sufficient to identify the function to remove, you can identify the function explicitly by providing a UPP in this parameter. If you pass `NULL` for this parameter, the Apple Event Manager relies solely on the desired class and container type. See `OSLAccessorUPP` (page 560).

isSysHandler

Specifies the object accessor dispatch table to remove the object accessor function from. Pass `TRUE` to remove the object accessor function from the system object accessor dispatch table or `FALSE` to remove the object accessor function from your application's object accessor dispatch table. Use of the system object accessor dispatch table is not recommended.

Return Value

A result code. See "Apple Event Manager Result Codes" (page 636).

Version Notes

In Mac OS X, your application can not make an object callback function available to other applications by installing it in a system object accessor dispatch table.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`AEObjects.h`

AERemoveSpecialHandler

Removes a handler from a special handler dispatch table.

```
OSErr AERemoveSpecialHandler (
   AEKeyword functionClass,
   AEEventHandlerUPP handler,
   Boolean isSysHandler
);
```

Parameters

functionClass

The keyword for the special handler to remove. Pass one of the constants described in "Special Handler Callback Constants" (page 603). See `AEKeyword` (page 556).

handler

A universal procedure pointer to the special handler to remove. Although the `functionClass` parameter is sufficient to identify the handler to remove, you can identify the handler explicitly as a safeguard. If you pass `NULL` for this parameter, the Apple Event Manager relies solely on the function class to identify the handler. See `AEEventHandlerUPP` (page 555).

isSysHandler

Specifies the special handler dispatch table to remove the handler from. Pass `TRUE` to remove the handler from the system special handler dispatch table or `FALSE` to remove the handler from your application's special handler dispatch table. Use of the system special handler dispatch table is not recommended.

Return Value

A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion

See also `AEInstallSpecialHandler` (page 452) and `AEGetSpecialHandler` (page 446).

Version Notes

Thread safe starting in Mac OS X v10.2.

Your application should not install a special handler in a system dispatch table with the goal that the handler will get called when other applications receive events—this won't work in Mac OS X.

In some previous versions of the Mac OS, applications might have reason to disable, within the application only, all Apple Event Manager functions that support Apple event objects—that is, all the functions available to an application as a result of linking the Object Support Library (OSL) and calling the `AEObjectInit` (page 455) function.

To disable the OSL, you should pass the keyword `keySelectProc` in the `functionClass` parameter, `NULL` in the `handler` parameter, and `FALSE` in the `isSysHandler` parameter. An application that expects its copy of the OSL to move after it is installed—for example, an application that keeps it in a stand-alone code resource—would need to disable the OSL. When an application calls `AEObjectInit` to initialize the OSL, the OSL installs the addresses of its functions as extensions to the pack. If those functions move, the addresses become invalid.

Once you have called the `AERemoveSpecialHandler` function to disable the OSL, subsequent calls by your application to any of the Apple Event Manager functions that support Apple event objects will return errors. To initialize the OSL after disabling it with the `AERemoveSpecialHandler` function, your application must call `AEObjectInit` again.

If you expect to initialize the OSL and disable it several times, you should call `AERemoveObjectAccessor` to remove your application's object accessor functions from your application's object accessor dispatch table before you call `AERemoveSpecialHandler`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AppleEvents.h`

AEReplaceDescData

Copies the specified data into the specified descriptor, replacing any previous data.

```
OSErr AEReplaceDescData (
   DescType typeCode,
   const void *dataPtr,
   Size dataSize,
   AEDesc *theAEDesc
);
```

Parameters

typeCode
Specifies the descriptor type of the data pointed to by `dataPtr`. For a list of AppleScript's predefined descriptor types, see "Descriptor Type Constants" (page 581). See `DescType` (page 560).

dataPtr
A pointer to the data to store in the specified descriptor.

dataSize
The size, in bytes, of the data pointed to by the `dataSize` parameter.

theAEDesc
A pointer to a descriptor. On return, contains the copied data. See `AEDesc` (page 546).

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Version Notes
Thread safe starting in Mac OS X v10.2.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

AEResetTimer

Resets the timeout value for an Apple event to its starting value.

```
OSErr AEResetTimer (
   const AppleEvent *reply
);
```

Parameters

reply

A pointer to the default reply for an Apple event, provided by the Apple Event Manager. See `AppleEvent` (page 559).

Return Value

A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion

The `AEResetTimer` function resets the timeout value for an Apple event to its starting value. A server application can call this function when it knows it cannot fulfill a client application's request (either by returning a result or by sending back a reply Apple event) before the client application is due to time out.

When your application calls `AEResetTimer`, the Apple Event Manager for the server application uses the default reply to send a Reset Timer event to the client application the Apple Event Manager for the client application's computer intercepts this Apple event and resets the client application's timer for the Apple event. (The Reset Timer event is never dispatched to a handler, so the client application does not need a handler for it.)

Version Notes

Prior to Mac OS X version 10.3, calling `AEResetTimer` did not reset the timeout value.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`AEInteraction.h`

AEResolve

Resolves an object specifier.

```
OSErr AEResolve (
   const AEDesc *objectSpecifier,
   short callbackFlags,
   AEDesc *theToken
);
```

Parameters

objectSpecifier

A pointer to the object specifier to resolve. See `AEDesc` (page 546).

callbackFlags

A value that determines what additional assistance, if any, your application can give the Apple Event Manager when it parses the object specifier. The value is specified by adding the desired constants described in "Callback Constants for the AEResolve Function" (page 571). Most applications use `kAEIDoMinimum`.

theToken

A pointer to a descriptor. On return, a token that identifies the Apple event objects specified by the `objectSpecifier` parameter. (Token is defined in `AEDisposeToken` (page 425).)

Your object accessor functions may need to create many tokens to resolve a single object specifier; this parameter contains only the final token that identifies the requested Apple event object.

Whenever the `AEResolve` function returns final token to your event handler as the result of the resolving an object specifier passed to `AEResolve`, your application must deallocate the memory used by the token. If your application uses complex tokens, it must dispose of the token by calling `AEDisposeToken` (page 425). If your application uses simple tokens, you can use either `AEDisposeToken` (page 425) or `AEDisposeDesc` (page 424). See `AEDesc` (page 546).

Return Value

A result code. See "Apple Event Manager Result Codes" (page 636). The `AEResolve` function returns any result code returned by one of your application's object accessor functions or object callback functions. For example, an object accessor function can return `errAENoSuchObject` (–1728) when it can't find an Apple event object, or it can return more specific result codes. If any object accessor function or object callback function returns a result code other than `noErr` or `errAEEventNotHandled`, `AEResolve` immediately disposes of any existing tokens and returns. The result code it returns in this case is the result code returned by the object accessor function or the object callback function.

Discussion

If an Apple event parameter consists of an object specifier, your handler for the event typically calls the `AEResolve` function to begin the process of resolving the object specifier.

The `AEResolve` function resolves the object specifier passed in the `objectSpecifier` parameter with the help of your object accessor functions, described in "Object Accessor Callbacks" (page 523), and the object callback functions, described in "Object Callback Functions" (page 524).

For information on how to receive error information from the `AEResolve` function, see `OSLGetErrDescProcPtr` (page 541).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`AEObjects.h`

AEResumeTheCurrentEvent

Informs the Apple Event Manager that your application wants to resume the handling of a previously suspended Apple event or that it has completed the handling of the Apple event.

```
OSErr AEResumeTheCurrentEvent (
   const AppleEvent *theAppleEvent,
   const AppleEvent *reply,
   AEEventHandlerUPP dispatcher,
   SRefCon handlerRefcon
);
```

Parameters

theAppleEvent

A pointer to the Apple event to resume handling for. See `AppleEvent` (page 559).

reply

A pointer to the default reply provided by the Apple Event Manager for the Apple event. See `AppleEvent` (page 559).

dispatcher

One of the following:

- a universal procedural pointer to a function that the Apple Event Manager calls to handle the resumed event, or
- the constant `kAEUseStandardDispatch`, which tells the Apple Event Manager to handle the resumed event with its standard dispatching mechanism, or
- the constant `kAENoDispatch`, which tells the Apple Event Manager the Apple event has been completely processed and doesn't need to be dispatched.

See the `handlerRefcon` parameter for more information.

The dispatch constants are described in "Resume Event Dispatch Constants" (page 603).

See `AEEventHandlerUPP` (page 555).

handlerRefcon

If the `dispatcher` parameter specifies a universal procedure pointer to your routine, the reference constant is passed to your handler. If you pass the value `kAEUseStandardDispatch` or `kAENoDispatch` for the `dispatcher` parameter, you must pass 0 for the `handlerRefcon` parameter.

If the value of `dispatcher` is `kAEUseStandardDispatch`, the Apple Event Manager ignores the `handlerRefcon` parameter and instead passes the reference constant stored in the Apple event dispatch table entry for the resumed Apple event.

If the value of `dispatcher` is any other value then it is a universal procedure pointer to an event handler, and the Apple Event Manager passes the value from the `handlerRefcon` parameter as the reference constant when it calls the handler.

Return Value

A result code. See "Apple Event Manager Result Codes" (page 636). This is the error result from the Apple event handler (or `errAEHandlerNotFound`). In most cases your application should ignore this error because it will be seen by the Apple event sender as the `keyErrorNumber` parameter in the reply.

Discussion

Applications call `AESuspendTheCurrentEvent` (page 497) to suspend handling of an Apple event and `AEResumeTheCurrentEvent` to resume it again. You typically call the `AESuspendTheCurrentEvent` function when your application needs to do some lengthy processing before responding to the event.

When your application calls the `AEResumeTheCurrentEvent` function, the Apple Event Manager resumes handling the specified Apple event using the handler specified in the `dispatcher` parameter, if any. If `kAENoDispatch` is specified in the `dispatcher` parameter, `AEResumeTheCurrentEvent` simply informs the Apple Event Manager that the specified event has been handled.

Special Considerations

This function is not thread-safe and, along with `AESuspendTheCurrentEvent`, should be called only on the main thread.

When your application suspends an Apple event, it does not need to dispose of the Apple event or the reply Apple event passed to the handler that suspends the event, whether or not the application eventually resumes the event. However, if the application will later resume the event, the handler that suspends the event should save a copy of the underlying data storage for the Apple event and the reply event. When resuming the event, you pass those copies to `AEResumeTheCurrentEvent`, which uses the information they contain to identify the original event and reply. For related information, see `AESuspendTheCurrentEvent` (page 497).

Make sure all processing involving the event or the reply has been completed before your application calls `AEResumeTheCurrentEvent`. Do not call `AEResumeTheCurrentEvent` for an event that was not suspended.

An Apple event handler that suspends an event should not immediately call `AEResumeTheCurrentEvent`, because the handler will generate an error. Instead, the handler should just return after suspending the event.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEInteraction.h`

AESend

Sends the specified Apple event.

```
OSErr AESend (
   const AppleEvent *theAppleEvent,
   AppleEvent *reply,
   AESendMode sendMode,
   AESendPriority sendPriority,
   SInt32 timeOutInTicks,
   AEIdleUPP idleProc,
   AEFilterUPP filterProc
);
```

Parameters

theAppleEvent
A pointer to the Apple event to send. See `AppleEvent` (page 559).

reply
A pointer to a reply Apple event. On return, contains the reply Apple event from the server application, if you specified the `kAEWaitReply` flag in the `sendMode` parameter. If you specify the `kAEQueueReply` flag in the `sendMode` parameter, you receive the reply Apple event in your event queue. If you specify `kAENoReply` flag, the reply Apple event is a null descriptor (one with descriptor type `typeNull`). If you specify `kAEWaitReply` in the `sendMode` parameter, and if the function returns successfully (see function result below), your application is responsible for using the `AEDisposeDesc` (page 424) function to dispose of the descriptor returned in the `reply` parameter.

sendMode
Specifies various options for how the server application should handle the Apple event. To obtain a value for this parameter, you add together constants to set bits that specify the reply mode, the interaction level, the application switch mode, the reconnection mode, and the return receipt mode. For more information, see "`AESendMode`" (page 566).

sendPriority
See the Version Notes section below for important information. A value that specifies the priority for processing the Apple event. You can specify normal or high priority, using the constants described in "`AESendMode`" (page 566). See `AESendPriority` (page 558).

timeOutInTicks

If the reply mode specified in the `sendMode` parameter is `kAEWaitReply`, or if a return receipt is requested, this parameter specifies the length of time (in ticks) that the client application is willing to wait for the reply or return receipt from the server application before timing out. Most applications should use the `kAEDefaultTimeout` constant, which tells the Apple Event Manager to provide an appropriate timeout duration. If the value of this parameter is `kNoTimeOut`, the Apple event never times out. These constants are described in "Timeout Constants" (page 605).

idleProc

A universal procedure pointer to a function that handles events (such as update, operating-system, activate, and null events) that your application receives while waiting for a reply. Your idle function can also perform other tasks (such as displaying a wristwatch or spinning beach ball cursor) while waiting for a reply or a return receipt.

If your application specifies the `kAEWaitReply` flag in the `sendMode` parameter and you wish your application to get periodic time while waiting for the reply to return, you must provide an idle function. Otherwise, you can pass a value of `NULL` for this parameter. For more information on the idle function, see `AEIdleProcPtr` (page 531).

filterProc

A universal procedure pointer to a function that determines which incoming Apple events should be received while the handler waits for a reply or a return receipt. If your application doesn't need to filter Apple events, you can pass a value of `NULL` for this parameter. If you do so, no application-oriented Apple events are processed while waiting. For more information on the filter function, see `AEFilterProcPtr` (page 530).

Return Value

A result code. See "Apple Event Manager Result Codes" (page 636). The `AESend` function returns `noErr` if the Event Manager successfully sends the Apple event—this value does not indicate that the Apple event was handled successfully. If the handler returns a result code other than `noErr`, and if the client is waiting for a reply, `AESend` returns the result code in the `keyErrorNumber` parameter of the reply Apple event. For a result code other than `noErr`, you should not call the `AEDisposeDesc` (page 424) function to dispose of the descriptor returned in the `reply` parameter, because the descriptor is invalid.

Discussion

You typically create an Apple event to send with the `AECreateAppleEvent` (page 416) function and add information to it with the functions described in "Adding Parameters and Attributes to Apple Events and Apple Event Records" (page 398).

If the Apple Event Manager cannot find a handler for the Apple event in the server application's dispatch table or in the system dispatch table, it returns the result code `errAEEventNotHandled` to the server application (as the result of the `AEProcessAppleEvent` (page 457) function). If the client application is waiting for a reply, the Apple Event Manager also returns this result code to the client in the `keyErrorNumber` parameter of the reply event.

In addition to specifying the wait duration for replies, the `timeOutInTicks` parameter is used as a wait value when queuing events for other applications. The Apple Event Manager waits for the specified duration as it attempts to queue the event. If you specify `kAEWaitReply` and the target application quits or crashes after the event is queued but before the reply is returned, the Apple Event Manager returns a `sessionClosedErr` result code.

In some situations, there are advantages to sending Apple events with the `AESendMessage` (page 478) function. That function requires less overhead than `AESend` and it allows you to send Apple events without linking to the entire Carbon framework (and window server), as required by `AESend`. For more information on sending Apple events, see "Sending an Apple Event" in Apple Events Programming Guide.

Version Notes
In Mac OS 9 and earlier, you use the `sendMode` parameter to specify how the server should handle the Apple event. "`AESendMode`" (page 566) provides a complete description of the constants you use with this parameter. The `sendPriority` parameter is deprecated in Mac OS X and later.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEInteraction.h`

AESendMessage

Sends an AppleEvent to a target process without some of the overhead required by `AESend`.

```
OSStatus AESendMessage (
   const AppleEvent *event,
   AppleEvent *reply,
   AESendMode sendMode,
   long timeOutInTicks
);
```

Parameters

event

A pointer to the Apple event to send.

reply

A pointer to a reply Apple event. On return, contains the reply Apple event from the server application, if you specified the `kAEWaitReply` flag in the `sendMode` parameter. If you specify the `kAEQueueReply` flag in the `sendMode` parameter, you receive the reply Apple event in your event queue. If you specify `kAENoReply` flag, the reply Apple event is a null descriptor (one with descriptor type `typeNull`). If you specify `kAEWaitReply` in the `sendMode` parameter, and if the function returns successfully (see function result below), your application is responsible for using the `AEDisposeDesc` (page 424) function to dispose of the descriptor returned in the `reply` parameter.

sendMode

Specifies various options for how the server application should handle the Apple event. To obtain a value for this parameter, you add together constants to set bits that specify the reply mode, the interaction level, the application switch mode, the reconnection mode, and the return receipt mode. For more information, see "`AESendMode`" (page 566).

timeOutInTicks

If the reply mode specified in the `sendMode` parameter is `kAEWaitReply`, or if a return receipt is requested, this parameter specifies the length of time (in ticks) that the client application is willing to wait for the reply or return receipt from the server application before timing out. Most applications should use the `kAEDefaultTimeout` constant, which tells the Apple Event Manager to provide an appropriate timeout duration. If the value of this parameter is `kNoTimeOut`, the Apple event never times out. These constants are described in "Timeout Constants" (page 605).

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
The `AESendMessage` function allows you to send Apple events without linking to the entire Carbon framework, as required by `AESend` (page 476). Linking with Carbon brings in the HIToolbox framework, which requires that your application have a connection to the window server. Daemons and other applications that have

no interface but wish to send and receive Apple events can use the following functions for working with Apple events at a lower level: `AESendMessage`, `AEGetRegisteredMachPort` (page 445), `AEDecodeMessage` (page 421), and `AEProcessMessage` (page 458). See the descriptions for those functions for more information on when you might use them.

If the target of an event sent with `AESendMessage` is the current process (as specified by using `typeProcessSerialNumber` of `{ 0, kCurrentProcess }` in the Apple event being sent), the Apple event is dispatched directly to the appropriate event handler in your process and not serialized.

Special Considerations

The `AESendMessage` function is both asynchronous and thread-safe, so you could, for example, set up a thread to send an Apple event and wait for a reply. If you use threads, you must add a `typeReplyPortAttr` attribute to your event that identifies the Mach port on which to receive the reply.

However, due to a bug that was present prior to Mac OS X version 10.5, you could not safely dispose of a Mach port you created to use as the reply port. Disposing of the port could, rarely, lead to a crash, while failing to dispose of if leaked resources. The sample code project *AESendThreadSafe* shows how to safely work around the bug in earlier Mac OS versions.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEMach.h`

AESetInteractionAllowed

Specifies user interaction preferences for responding to an Apple event when your application is the server application.

```
OSErr AESetInteractionAllowed (
   AEInteractAllowed level
);
```

Parameters

level

The desired user interaction level. Pass one of the values described in "User Interaction Level Constants" (page 605).

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
If you don't set the user interaction level by calling `AESetInteractionAllowed`, the default level is `kAEInteractWithLocal` (which indicates that your server application may interact with the user in response to an Apple event only if the client application is on the same computer as the server application).

For additional information on interaction level, see `AESend` (page 476) and "`AESendMode`" (page 566).

See also `AESetInteractionAllowed` (page 479) and `AEInteractWithUser` (page 453).

Availability
Available in Mac OS X v10.0 and later.

Declared In
AEInteraction.h

AESetObjectCallbacks

Specifies the object callback functions for your application.

```
OSErr AESetObjectCallbacks (
   OSLCompareUPP myCompareProc,
   OSLCountUPP myCountProc,
   OSLDisposeTokenUPP myDisposeTokenProc,
   OSLGetMarkTokenUPP myGetMarkTokenProc,
   OSLMarkUPP myMarkProc,
   OSLAdjustMarksUPP myAdjustMarksProc,
   OSLGetErrDescUPP myGetErrDescProcPtr
);
```

Parameters

myCompareProc
Either a universal procedure pointer to the object comparison function provided by your application or NULL if no function is provided. See OSLCompareUPP (page 561).

myCountProc
Either a universal procedure pointer to the object-counting function provided by your application or NULL if no function is provided. See OSLCountUPP (page 561).

myDisposeTokenProc
Either a universal procedure pointer to the token disposal function provided by your application or NULL if no function is provided. (Token is defined in AEDisposeToken (page 425). See OSLDisposeTokenUPP (page 561).

myGetMarkTokenProc
Either a universal procedure pointer to the function for returning a mark token provided by your application or NULL if no function is provided. See OSLGetMarkTokenUPP (page 562).

myMarkProc
Either a universal procedure pointer to the object-marking function provided by your application or NULL if no function is provided. See OSLMarkUPP (page 562).

myAdjustMarksProc
Either a universal procedure pointer to the mark-adjusting function provided by your application or NULL if no function is provided. See OSLAdjustMarksUPP (page 561).

myGetErrDescProcPtr
Either a universal procedure pointer to the error callback function provided by your application or NULL if no function is provided. See OSLGetErrDescUPP (page 562).

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
This function is just a convenient wrapper for AEInstallSpecialHandler (page 452). You can manipulate the special handler table with more control using the routines described in "Managing Special Handler Dispatch Tables" (page 404).

Your application can provide only one each of the object callback functions specified by AESetObjectCallbacks—one object comparison function, one object-counting function, and so on. As a result, each of these callback functions must perform the requested task (comparing, counting, and so on)

for all the object classes that your application supports. In contrast, your application may provide many different object accessor functions if necessary, depending on the object classes and token types your application supports. You install object accessor functions with `AEInstallObjectAccessor` (page 451).

To replace object callback functions that have been previously installed, you can call `AESetObjectCallbacks` again. Each additional call to `AESetObjectCallbacks` replaces any object callback functions installed by previous calls. Only those functions you specify are replaced; to avoid replacing existing callback functions, specify a value of `NULL` for the functions you don't want to replace.

You cannot use `AESetObjectCallbacks` to replace system object callback functions or object accessor functions. To install system object callback functions, use the function `AEInstallSpecialHandler` (page 452).

Version Notes
In Mac OS X, your application can not make an object callback function available to other applications by installing it in a system object accessor dispatch table.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEObjects.h`

AESetTheCurrentEvent

Specifies a current Apple event to take the place of the one your application has suspended.

```
OSErr AESetTheCurrentEvent (
   const AppleEvent *theAppleEvent
);
```

Parameters

theAppleEvent
A pointer to the Apple event to handle as the current event. See `AppleEvent` (page 559).

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
There is usually no reason for your application to use the `AESetTheCurrentEvent` function. Instead of calling this function, your application should let the Apple Event Manager set the current Apple event through its standard dispatch mechanism.

If you need to avoid the dispatch mechanism, you must use the `AESetTheCurrentEvent` function only in the following way:

1. Your application suspends handling of an Apple event by calling the `AESuspendTheCurrentEvent` (page 497) function.

2. Your application calls the `AESetTheCurrentEvent` function. This informs the Apple Event Manager that your application is handling the suspended Apple event. In this way, any functions that call the `AEGetTheCurrentEvent` (page 447) function can ascertain which event is currently being handled.

3. When your application finishes handling the Apple event, it calls the `AEResumeTheCurrentEvent` (page 474) function with the value `kAENoDispatch` to tell the Apple Event Manager that the event has been processed and need not be dispatched.

Special Considerations

This function is not thread-safe and should only be called on the main thread.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEInteraction.h`

AESizeOfAttribute

Gets the size and descriptor type of an Apple event attribute from a descriptor of type `AppleEvent`.

```
OSErr AESizeOfAttribute (
   const AppleEvent *theAppleEvent,
   AEKeyword theAEKeyword,
   DescType *typeCode,
   Size *dataSize
);
```

Parameters

theAppleEvent
A pointer to the Apple event to get the attribute data from. See `AppleEvent` (page 559).

theAEKeyword
The keyword that specifies the attribute. Some keyword constants are described in "Keyword Attribute Constants" (page 593). See `AEKeyword` (page 556).

typeCode
A pointer to a descriptor type. On return, specifies the descriptor type of the attribute. For a list of AppleScript's predefined descriptor types, see "Descriptor Type Constants" (page 581). Can be `NULL`. See `DescType` (page 560).

dataSize
A pointer to a size variable. On return, the length, in bytes, of the data in the attribute. Can be `NULL`.

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Version Notes
Thread safe starting in Mac OS X v10.2.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

AESizeOfFlattenedDesc

Returns the amount of buffer space needed to store the descriptor after flattening it.

```
Size AESizeOfFlattenedDesc (
   const AEDesc *theAEDesc
);
```

Parameters

theAEDesc

A pointer to the descriptor to be flattened. See `AEDesc` (page 546).

Return Value

The size, in bytes, required to store the flattened descriptor.

Discussion

You call this function before calling `AEFlattenDesc` (page 426) to determine the required size of the buffer for the flatten operation.

Version Notes

Thread safe starting in Mac OS X v10.2.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`AEDataModel.h`

AESizeOfKeyDesc

Gets the size and descriptor type of an Apple event parameter from a descriptor of type `AERecord`.

```
OSErr AESizeOfKeyDesc (
    const AppleEvent *theAERecord,
    AEKeyword theAEKeyword,
    DescType *typeCode,
    Size *dataSize
);
```

Parameters

theAERecord

A pointer to the Apple event record to get the parameter data from.

theAEKeyword

The keyword that specifies the desired parameter. Some keyword parameter constants are described in "Keyword Parameter Constants" (page 595). See `AEKeyword` (page 556).

typeCode

A pointer to a descriptor type. On return, specifies the descriptor type of the Apple event parameter. For a list of AppleScript's predefined descriptor types, see "Descriptor Type Constants" (page 581). See `DescType` (page 560).

dataSize

A pointer to a size variable. On return, the length, in bytes, of the data in the Apple event parameter.

Return Value

A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
This function is declared as a macro that invokes `AESizeOfParam` (page 485), which can operate on an Apple event or an Apple event record. See the Discussion for that function for more information.

Version Notes
See `AESizeOfParam` (page 485).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

AESizeOfNthItem

Gets the data size and descriptor type of the descriptor at a specified position in a descriptor list.

```
OSErr AESizeOfNthItem (
   const AEDescList *theAEDescList,
   long index,
   DescType *typeCode,
   Size *dataSize
);
```

Parameters

theAEDescList
A pointer to the descriptor list containing the descriptor. See `AEDescList` (page 553).

index
A one-based positive integer indicating the position of the descriptor to get the data size for. `AESizeOfNthItem` returns an error if you pass zero, a negative number, or a value that is out of range.

typeCode
A pointer to a descriptor type. On return, specifies the descriptor type of the descriptor. For a list of AppleScript's predefined descriptor types, see "Descriptor Type Constants" (page 581). See `DescType` (page 560).

dataSize
A pointer to a size variable. On return, the length (in bytes) of the data in the descriptor.

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Version Notes
Thread safe starting in Mac OS X v10.2.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

AESizeOfParam

Gets the size and descriptor type of an Apple event parameter from a descriptor of type `AERecord` or `AppleEvent`.

```
OSErr AESizeOfParam (
   const AppleEvent *theAppleEvent,
   AEKeyword theAEKeyword,
   DescType *typeCode,
   Size *dataSize
);
```

Parameters

theAppleEvent

A pointer to the Apple event to get the parameter data from. See `AppleEvent` (page 559).

theAEKeyword

The keyword that specifies the desired parameter. Some keyword parameter constants are described in "Keyword Parameter Constants" (page 595). See `AEKeyword` (page 556).

typeCode

A pointer to a descriptor type. On return, specifies the descriptor type of the Apple event parameter. For a list of AppleScript's predefined descriptor types, see "Descriptor Type Constants" (page 581). See `DescType` (page 560).

dataSize

A pointer to a size variable. On return, the length, in bytes, of the data in the Apple event parameter.

Return Value

A result code. See "Apple Event Manager Result Codes" (page 636).

Version Notes

Thread safe starting in Mac OS X v10.2.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`AEDataModel.h`

AEStreamClose

Closes and deallocates an `AEStreamRef`.

```
OSStatus AEStreamClose (
   AEStreamRef ref,
   AEDesc *desc
);
```

Parameters

ref

An `AEStreamRef` (page 558)containing the stream data.

desc

A pointer to a descriptor for receiving a the stream data, or `NULL` if you want to discard the data. See `AEDesc` (page 546).

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
Use this function to dispose of an `AEStreamRef` you created using `AEStreamCreateEvent` (page 487), `AEStreamOpen` (page 489), or `AEStreamOpenEvent` (page 490). To retrieve the resulting descriptor from the stream prior to disposal, pass in a pointer to an `AEDesc` structure in the *`desc`* parameter. If this parameter exists, `AEStreamClose` fills in the descriptor with the stream data. If the stream contains invalid information, possibly due to improperly balanced calls to "AEStream" functions, the returned descriptor type is set to `typeNull`.

Regardless of any errors returned by this function, it is always safe to call `AEDisposeDesc` (page 424) on the returned descriptor.

Specifying `NULL` for the *`desc`* parameter causes `AEStreamClose` to discard the stream data and dispose of the `AEStreamRef`. When you call `AEStreamClose` in this way, you do not need to worry about balancing nested calls to "AEStream" functions. This technique is particularly useful during error-handling situations where you need to dispose of a stream but do not know its exact state.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEHelpers.h`

AEStreamCloseDesc

Marks the end of a descriptor in an `AEStreamRef`.

```
OSStatus AEStreamCloseDesc (
   AEStreamRef ref
);
```

Parameters

`ref`
An `AEStreamRef` (page 558)containing the stream data.

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
Call this function to balance a preceding call to `AEStreamOpenDesc` (page 489) or `AEStreamOpenKeyDesc` (page 490). This function completes the definition of the `AEDesc`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEHelpers.h`

AEStreamCloseList

Marks the end of a list of descriptors in an `AEStreamRef`.

```
OSStatus AEStreamCloseList (
   AEStreamRef ref
);
```

Parameters

ref

An `AEStreamRef` (page 558)containing the stream data.

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
Call this function to balance a preceding call to `AEStreamOpenList` (page 491). This function completes the definition of the `AEDescList`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEHelpers.h`

AEStreamCloseRecord

Marks the end of a record in an `AEStreamRef`.

```
OSStatus AEStreamCloseRecord (
   AEStreamRef ref
);
```

Parameters

ref

An `AEStreamRef` (page 558)containing the stream data.

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
Call this function to balance a preceding call to `AEStreamOpenRecord` (page 491). This function completes the definition of the Apple event record.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEHelpers.h`

AEStreamCreateEvent

Creates a new Apple event and opens a stream for writing data to it.

```
AEStreamRef AEStreamCreateEvent (
   AEEventClass clazz,
   AEEventID id,
   DescType targetType,
   const void *targetData,
   Size targetLength,
   SInt16 returnID,
   SInt32 transactionID
);
```

Parameters

clazz

The event class of the Apple event. See `AEEventClass` (page 555).

id

The event ID of the Apple event. See `AEEventID` (page 556).

targetType

The address type for the addressing information in the next two parameters. Usually contains one of the following values: `typeApplSignature`. `typeKernelProcessID`, or `typeProcessSerialNumber`. See `DescType` (page 560).

targetData

A pointer to the address information. The data in this pointer must match the data associated with the specified *targetType*.

targetLength

The number of bytes pointed to by the `targetData` parameter.

returnID

The return ID for the created Apple event. If you pass a value of `kAutoGenerateReturnID`, the Apple Event Manager assigns the created Apple event a return ID that is unique to the current session. If you pass any other value, the Apple Event Manager assigns that value for the ID. The return ID constant is described in "ID Constants for the AECreateAppleEvent Function" (page 589). See `AEReturnID` (page 558).

transactionID

The transaction ID for this Apple event. A transaction is a sequence of Apple events that are sent back and forth between the client and server applications, beginning with the client's initial request for a service. All Apple events that are part of a transaction must have the same transaction ID. You can specify the `kAnyTransactionID` constant if the Apple event is not one of a series of interdependent Apple events. This transaction ID constant is described in "ID Constants for the AECreateAppleEvent Function" (page 589). See `AETransactionID` (page 559).

Return Value

An `AEStreamRef` (page 558) associated with the new event.

Discussion

This routine effectively combines a call to `AECreateAppleEvent` (page 416) followed by a call to `AEStreamOpenEvent` (page 490) to create a new Apple event in the stream. You can use the returned `AEStreamRef` to add parameters to the new Apple event.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`AEHelpers.h`

AEStreamOpen

Opens a new `AEStreamRef` for use in building a descriptor.

```
AEStreamRef AEStreamOpen (
   void
);
```

Return Value
A new `AEStreamRef` (page 558) or `NULL` if the stream data structures cannot be allocated.

Discussion
This function creates a new stream for use in describing the contents of a descriptor, descriptor list, or Apple event record (`AEDesc`, `AEDescList`, or `AERecord`).

You can use the returned `AEStreamRef` with other "AEStream" routines to build the contents of a descriptor. When you are done building the descriptor, use `AEStreamClose` (page 485) to close the stream.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEHelpers.h`

AEStreamOpenDesc

Marks the beginning of a descriptor in an `AEStreamRef`.

```
OSStatus AEStreamOpenDesc (
   AEStreamRef ref,
   DescType newType
);
```

Parameters

ref
An `AEStreamRef` (page 558) containing the stream data.

newType
A type code for the new `AEDesc` being added to the stream. See `DescType` (page 560).

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
Use this routine to mark the beginning of a descriptor definition in an `AEDesc`. After calling this routine, you should call `AEStreamWriteData` (page 494) one or more times to write the descriptor data to the stream. When you are done writing data, you must call `AEStreamCloseDesc` (page 486) to complete the descriptor definition.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEHelpers.h`

AEStreamOpenEvent

Opens a stream for an existing Apple event.

```
AEStreamRef AEStreamOpenEvent (
   AppleEvent *event
);
```

Parameters

event

An existing Apple event. See `AppleEvent` (page 559).

Return Value

An `AEStreamRef` (page 558) for the Apple event or `NULL` if the stream data structures could not be allocated.

Discussion

Use this function to open a stream and add parameters to an existing Apple event. This function copies any parameters already in the Apple event to the stream prior to returning the `AEStreamRef`. When you are done adding parameters, use `AEStreamClose` (page 485) to save them to the Apple event and close the stream.

If there is not enough available storage to complete the operation, `AEStreamOpenEvent` returns `NULL` and leaves the Apple event unchanged.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`AEHelpers.h`

AEStreamOpenKeyDesc

Marks the beginning of a key descriptor in an `AEStreamRef`.

```
OSStatus AEStreamOpenKeyDesc (
   AEStreamRef ref,
   AEKeyword key,
   DescType newType
);
```

Parameters

ref

An `AEStreamRef` (page 558) containing the stream data.

key

The `AEKeyword` associated with the new descriptor being added to the stream. See `AEKeyword` (page 556).

newType

A type code for the new `AEDesc` being added to the stream. See `DescType` (page 560).

Return Value

A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
Use this routine to mark the beginning of a keyword/descriptor definition in an Apple event record. After calling this routine, you should call `AEStreamWriteData` (page 494) one or more times to write the record data to the stream. When you are done writing data, you must call `AEStreamCloseDesc` (page 486) to complete the record definition.

This routine must be called only as part of an Apple event record definition. You cannot use this routine to write keyword/descriptor definitions to other descriptor types, such as an `AEDesc` or `AEDescList`, even if those types are nested inside an Apple event record. In situations where you need to create nested records, this routine opens a new keyword/descriptor definition in the Apple event record associated with the most recent call to `AEStreamOpenRecord` (page 491).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEHelpers.h`

AEStreamOpenList

Marks the beginning of a descriptor list in an `AEStreamRef`.

```
OSStatus AEStreamOpenList (
   AEStreamRef ref
);
```

Parameters
ref
An `AEStreamRef` (page 558) containing the stream data.

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
This routine marks the beginning of a sequence of zero or more descriptor definitions that you use to build an `AEDescList` structure. After calling this routine, you can write any number of `AEDesc`, `AEDescList`, or `AERecord` structures to the stream as elements of the list. When you are done, you must call `AEStreamCloseList` (page 486) to complete the `AEDescList` definition.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEHelpers.h`

AEStreamOpenRecord

Marks the beginning of an Apple event record in an `AEStreamRef`.

```
OSStatus AEStreamOpenRecord (
   AEStreamRef ref,
   DescType newType
);
```

Parameters

ref

An `AEStreamRef` (page 558) containing the stream data.

newType

A type code for the new record you are adding to the stream. This value can be `typeAERecord` or any other appropriate value. See `DescType` (page 560).

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
This routine marks the beginning of a sequence of zero or more keyword/descriptor definitions that you use to build an `AERecord` structure. You must balance each call to this method with a corresponding call to `AEStreamCloseRecord` (page 487).

For information on adding keyword/descriptor data to the record, see the `AEStreamOpenKeyDesc` (page 490), `AEStreamWriteKey` (page 495), and `AEStreamWriteKeyDesc` (page 496) routines.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEHelpers.h`

AEStreamOptionalParam

Designates a parameter in an Apple event as optional.

```
OSStatus AEStreamOptionalParam (
   AEStreamRef ref,
   AEKeyword key
);
```

Parameters

ref

An `AEStreamRef` (page 558) containing the stream data.

key

The `AEKeyword` associated with any keyword/descriptor pair in an Apple event. See `AEKeyword` (page 556).

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
Calls to this routine must be preceded by a call to either `AEStreamCreateEvent` (page 487) or `AEStreamOpenEvent` (page 490).

The descriptor associated with the specified *key* does not need to exist before you call this routine.

Availability
Available in Mac OS X v10.0 and later.

Declared In
AEHelpers.h

AEStreamSetRecordType

Sets the type of the most recently created record in an AEStreamRef.

```
OSStatus AEStreamSetRecordType (
   AEStreamRef ref,
   DescType newType
);
```

Parameters

ref
An AEStreamRef (page 558) containing the stream data.

newType
The new type code for the AERecord being added to the stream. See DescType (page 560).

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
Use this routine to change the type of a record after it has been opened. You must call this routine between calls to AEStreamOpenRecord (page 491) and AEStreamCloseRecord (page 487). The type you specify in the *newType* parameter replaces the previous type specified by AEStreamOpenRecord (page 491).

Availability
Available in Mac OS X v10.0 and later.

Declared In
AEHelpers.h

AEStreamWriteAEDesc

Copies an existing descriptor into an AEStreamRef.

```
OSStatus AEStreamWriteAEDesc (
   AEStreamRef ref,
   const AEDesc *desc
);
```

Parameters

ref
An AEStreamRef (page 558) containing the stream data.

desc
A pointer to the descriptor you want to copy into the stream. See AEDesc (page 546).

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
You can use this routine to incorporate an existing descriptor into the stream. For example, you could use this routine if you had a complex descriptor you wanted to add to multiple streams, but which would be costly to create each time.

Do not use `AEStreamOpenDesc` (page 489) and `AEStreamCloseDesc` (page 486) with this routine to open and close the descriptor.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEHelpers.h`

AEStreamWriteData

Appends data to the current descriptor in an `AEStreamRef`.

```
OSStatus AEStreamWriteData (
   AEStreamRef ref,
   const void *data,
   Size length
);
```

Parameters

ref
An `AEStreamRef` (page 558) containing the stream data.

data
A pointer to the block of memory containing the descriptor data. This routine copies the memory block immediately, so you do not need to retain it for the benefit of this routine.

length
The number of bytes pointed to by the *data* parameter.

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
You can call this routine any number of times to build up the data contents of the descriptor incrementally. You must precede calls to this routine by a call to either `AEStreamOpenDesc` (page 489) or `AEStreamOpenKeyDesc` (page 490). When you are done adding data to the descriptor, call `AEStreamCloseDesc` (page 486) to complete the descriptor definition.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEHelpers.h`

AEStreamWriteDesc

Appends the data for a complete descriptor to an `AEStreamRef`.

```
OSStatus AEStreamWriteDesc (
   AEStreamRef ref,
   DescType newType,
   const void *data,
   Size length
);
```

Parameters

ref

An `AEStreamRef` (page 558) containing the stream data.

newType

A type code for the new `AEDesc` being added to the stream. See `DescType` (page 560).

data

A pointer to the block of memory containing the descriptor data. This routine copies the memory block immediately, so you do not need to retain it for the benefit of this routine.

length

The number of bytes pointed to by the *data* parameter.

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
Use this routine to write the data for a descriptor to the stream. When using this routine, you must supply all of the descriptor data at once.

Do not use `AEStreamOpenDesc` (page 489) and `AEStreamCloseDesc` (page 486) with this routine to open and close the descriptor.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEHelpers.h`

AEStreamWriteKey

Marks the beginning of a keyword/descriptor pair for a descriptor in an `AEStreamRef`.

```
OSStatus AEStreamWriteKey (
   AEStreamRef ref,
   AEKeyword key
);
```

Parameters

ref

An `AEStreamRef` (page 558) containing the stream data.

key

The `AEKeyword` associated with the new descriptor being added to the stream. See `AEKeyword` (page 556).

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
You must follow this call with a sequence of "AEStream" calls to specify exactly one descriptor that goes with the keyword. The descriptor you create can be of type `AEDesc`, `AEDescList`, or `AERecord`.

If you are creating nested descriptors, this routine begins a new keyword/descriptor pair for the descriptor most recently opened by a call to `AEStreamWriteKey` (page 495) or `AEStreamOpenEvent` (page 490). You cannot use this routine to write parameters to any other types of descriptors, even if they are nested inside of an `AERecord`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEHelpers.h`

AEStreamWriteKeyDesc

Writes a complete keyword/descriptor pair to an `AEStreamRef`.

```
OSStatus AEStreamWriteKeyDesc (
   AEStreamRef ref,
   AEKeyword key,
   DescType newType,
   const void *data,
   Size length
);
```

Parameters

ref
An `AEStreamRef` (page 558) containing the stream data.

key
The `AEKeyword` associated with the new descriptor being added to the stream. See `AEKeyword` (page 556).

newType
A type code for the new `AEDesc` being added to the stream. See `DescType` (page 560).

data
A pointer to the block of memory containing the descriptor data. This routine copies the memory block immediately, so you do not need to retain it for the benefit of this routine.

length
The number of bytes pointed to by the *data* parameter.

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
Use this routine to add a descriptor to the currently open `AERecord` inside a stream. You cannot use this routine to write parameters to any other types of descriptors, even if they are nested inside of an `AERecord`. This routine can only be called in between calls to `AEStreamOpenRecord` (page 491) and `AEStreamCloseRecord` (page 487).

This method is analogous to the Apple Event Manager routine `AEPutParamPtr` (page 464), except it is for use with streams.

Availability
Available in Mac OS X v10.0 and later.

Declared In
AEHelpers.h

AESuspendTheCurrentEvent

Suspends the processing of the Apple event that is currently being handled.

```
OSErr AESuspendTheCurrentEvent (
   const AppleEvent *theAppleEvent
);
```

Parameters

theAppleEvent

A pointer to the Apple event to suspend handling for. If the pointed-to Apple event is not the current event, AESuspendTheCurrentEvent does nothing and returns noErr. See AppleEvent (page 559).

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
You typically call the AESuspendTheCurrentEvent function from an Apple event handler function, such as when your application needs to do some lengthy processing before responding to the event. After a successful call to this function, you are not required to return a result or a reply for the Apple event that was being handled. You can, however, return a result if you later call the AEResumeTheCurrentEvent (page 474) function to resume event processing.

Whether you will resume the suspended Apple event or not, you do not need to dispose of the Apple event or the reply Apple event passed to your handler. However, if your handler will later resume the event, you must save a copy of the underlying data storage for the Apple event and the reply event. When resuming the event, you pass those copies to AEResumeTheCurrentEvent (page 474), which uses the information they contain to identify the original event and reply.

You cannot merely save the pointers that are passed to your handler because they do not persist after your handler returns (although the underlying Apple events do persist). Use a function such as AEDuplicateDesc (page 426) to obtain copies of the Apple event and reply event. Later, after calling AEResumeTheCurrentEvent to resume the event, call AEDisposeDesc (page 424) to dispose of the copies.

Special Considerations

This function is not thread-safe and, along with AEResumeTheCurrentEvent, should be called only on the main thread.

If your application suspends handling of an Apple event it sends to itself, the Apple Event Manager immediately returns from the AESend (page 476) call with the error code errAETimeout, regardless of the parameters specified in the call to AESend. The function calling AESend should take the timeout error as confirmation that the event was sent.

As with other calls to AESend that return a timeout error, the handler continues to process the event nevertheless. The handler's reply, if any, is provided in the reply event when the handling is completed. The Apple Event Manager provides no notification that the reply is ready. If no data has yet been placed in the reply event, the Apple Event Manager returns errAEReplyNotArrived when your application attempts to extract data from the reply.

Availability
Available in Mac OS X v10.0 and later.

Declared In
AEInteraction.h

AEUnflattenDesc

Unflattens the data in the passed buffer and creates a descriptor from it.

```
OSStatus AEUnflattenDesc (
   const void *buffer,
   AEDesc *result
);
```

Parameters

buffer

A pointer to memory, allocated by the application, that contains flattened data produced by a previous call to AEFlattenDesc (page 426).

result

A null descriptor. On successful completion, points to a descriptor created from the flattened data. The caller is responsible for disposing of the descriptor.

Return Value
A result code. Returns paramErr if the flattened data in buffer is found to be invalid. See "Apple Event Manager Result Codes" (page 636) for other possible values.

Discussion
This function assumes the passed buffer contains valid flattened data, produced by a previous call to AEFlattenDesc (page 426). See that function for a description of when you might want to flatten and unflatten descriptors, and of possible limitations.

Flattening and unflattening works across OS versions, including between Mac OS 9 and Mac OS X.

Flattening is endian-neutral. That is, you can save flattened data on a machine that is either big-endian or little-endian, then retrieve and unflatten the data on either type of machine, without any special steps by your application.

Version Notes
Thread safe starting in Mac OS X v10.2.

Availability
Available in Mac OS X v10.0 and later.

Declared In
AEDataModel.h

CreateCompDescriptor

Creates a comparison descriptor that specifies how to compare one or more Apple event objects with either another Apple event object or a descriptor.

```
OSErr CreateCompDescriptor (
   DescType comparisonOperator,
   AEDesc *operand1,
   AEDesc *operand2,
   Boolean disposeInputs,
   AEDesc *theDescriptor
);
```

Parameters

comparisonOperator

The comparison operator for comparing the descriptors in the `operand1` and `operand2` parameters. The standard comparison operators are defined in "Comparison Operator Constants" (page 574).

The actual comparison of the two operands is performed by the object comparison function provided by the client application. The way a comparison operator is interpreted is up to each application.

See `DescType` (page 560).

operand1

A pointer to an object specifier. See `AEDesc` (page 546).

operand2

A pointer to a descriptor (which can be an object specifier or any other descriptor) whose value is compared to the value of `operand1`. See `AEDesc` (page 546).

disposeInputs

A Boolean value. Pass `TRUE` if the function should automatically dispose of any descriptors you have provided in the `operand1` and `operand2` parameters to the function. Pass `FALSE` if your application will dispose of the descriptors itself. A value of `FALSE` may be more efficient for some applications because it allows them to reuse descriptors.

theDescriptor

A pointer to a descriptor. On successful return, the comparison descriptor created by `CreateCompDescriptor`. Your application must dispose of this descriptor after it has finished using it. See `AEDesc` (page 546).

Return Value

A result code. See "Apple Event Manager Result Codes" (page 636).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`AEPackObject.h`

CreateLogicalDescriptor

Creates a logical descriptor that specifies a logical operator and one or more logical terms for the Apple Event Manager to evaluate.

```
OSErr CreateLogicalDescriptor (
   AEDescList *theLogicalTerms,
   DescType theLogicOperator,
   Boolean disposeInputs,
   AEDesc *theDescriptor
);
```

Parameters

theLogicalTerms

A pointer to a list containing comparison descriptors (typeLogicalDescriptor), logical descriptors (typeCompDescriptor), or both. If the value of the parameter theLogicOperator is kAEAND or kAEOR, the list can contain any number of descriptors. If the value of the parameter theLogicOperator is kAENOT, logically this list should contain a single descriptor. However, the function will not return an error if the list contains more than one descriptor for a logical operator of kAENOT. See AEDescList (page 553).

theLogicOperator

A logical operator represented by one of the constants described in "Constants for Object Specifiers, Positions, and Logical and Comparison Operations" (page 575). What you pass for this parameter helps determine what you pass for the theLogicalTerms parameter. See DescType (page 560).

disposeInputs

A Boolean value. Pass TRUE if the function should automatically dispose of the descriptors you have provided in the theLogicalTerms parameter or (FALSE) if your application will. A value of FALSE may be more efficient for some applications because it allows them to reuse descriptors.

theDescriptor

A pointer to a descriptor. On successful return, the logical descriptor created by CreateLogicalDescriptor. Your application must dispose of this descriptor after it has finished using it. See AEDesc (page 546).

Return Value

A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion

The CreateLogicalDescriptor function creates a logical descriptor, which specifies a logical operator and one or more logical terms for the Apple Event Manager to evaluate.

Availability

Available in Mac OS X v10.0 and later.

Declared In

AEPackObject.h

CreateObjSpecifier

Assembles an object specifier that identifies one or more Apple event objects, from other descriptors.

```
OSErr CreateObjSpecifier (
   DescType desiredClass,
   AEDesc *theContainer,
   DescType keyForm,
   AEDesc *keyData,
   Boolean disposeInputs,
   AEDesc *objSpecifier
);
```

Parameters

desiredClass

The object class of the desired Apple event objects. See `DescType` (page 560).

theContainer

A pointer to a descriptor that describes the container for the requested object, usually in the form of another object specifier. See `AEDesc` (page 546).

keyForm

The key form for the object specifier.

keyData

A pointer to a descriptor that supplies the key data for the object specifier.

disposeInputs

A Boolean value. Pass (`TRUE`) if the function should dispose of the descriptors for the `theContainer` and `keyData` parameters or (`FALSE`) if your application will. A value of `FALSE` may be more efficient for some applications because it allows them to reuse descriptors.

objSpecifier

On successful return, a pointer to the object specifier created by the `CreateObjSpecifier` function. If the function returns successfully, your application should call the `AEDisposeDesc` (page 424) function to dispose of this descriptor after it has finished using it.

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEPackObject.h`

CreateOffsetDescriptor

Creates an offset descriptor that specifies the position of an element in relation to the beginning or end of its container.

```
OSErr CreateOffsetDescriptor (
   long theOffset,
   AEDesc *theDescriptor
);
```

Parameters

theOffset

A positive integer that specifies the offset from the beginning of the container (the first element has an offset of 1), or a negative integer that specifies the offset from the end (the last element has an offset of –1).

theDescriptor

A pointer to a descriptor. On successful return, the offset descriptor created by `CreateOffsetDescriptor`. On error, returns a null descriptor. Your application must dispose of the descriptor after it has finished using it. See `AEDesc` (page 546).

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEPackObject.h`

CreateRangeDescriptor

Creates a range descriptor that specifies a series of consecutive elements in the same container.

```
OSErr CreateRangeDescriptor (
   AEDesc *rangeStart,
   AEDesc *rangeStop,
   Boolean disposeInputs,
   AEDesc *theDescriptor
);
```

Parameters

rangeStart

A pointer to an object specifier that identifies the first Apple event object in the range. See `AEDesc` (page 546).

rangeStop

A pointer to an object specifier that identifies the last Apple event object in the range. See `AEDesc` (page 546).

disposeInputs

A Boolean value. Pass (`TRUE`) if the function should dispose of the descriptors for the `rangeStart` and `rangeStop` parameters and set them to the null descriptor or (`FALSE`) if your application will. A value of `FALSE` may be more efficient for some applications because it allows them to reuse descriptors.

theDescriptor

A pointer to a descriptor. On successful return, the range descriptor created by `CreateRangeDescriptor`. Your application must dispose of this descriptor after it has finished using it. See `AEDesc` (page 546).

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
Although the `rangeStart` and `rangeStop` parameters can be any object specifiers—including object specifiers that specify more than one Apple event object—most applications expect these parameters to specify single Apple event objects.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEPackObject.h`

DisposeAECoerceDescUPP

Disposes of a universal procedure pointer to a function that coerces data stored in a descriptor.

```
void DisposeAECoerceDescUPP (
   AECoerceDescUPP userUPP
);
```

Discussion
See the `AECoerceDescProcPtr` (page 524) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

DisposeAECoercePtrUPP

Disposes of a universal procedure pointer to a function that coerces data stored in a buffer.

```
void DisposeAECoercePtrUPP (
   AECoercePtrUPP userUPP
);
```

Discussion
See the `AECoercePtrProcPtr` (page 525) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

DisposeAEDisposeExternalUPP

Disposes of a universal procedure pointer to a function that disposes of data supplied to the `AECreateDescFromExternalPtr` function.

```
void DisposeAEDisposeExternalUPP (
   AEDisposeExternalUPP userUPP
);
```

Parameters
userUPP
The universal procedure pointer to be disposed of. See `AEDisposeExternalUPP` (page 555).

Discussion
See the `AECreateDescFromExternalPtr` (page 418) function.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`AEDataModel.h`

DisposeAEEventHandlerUPP

Disposes of a universal procedure pointer to an event handler function.

```
void DisposeAEEventHandlerUPP (
   AEEventHandlerUPP userUPP
);
```

Discussion
See the `AEEventHandlerProcPtr` (page 528) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

DisposeAEFilterUPP

Disposes of a universal procedure pointer to an Apple event filter function.

```
void DisposeAEFilterUPP (
   AEFilterUPP userUPP
);
```

Discussion
See the `AEFilterProcPtr` (page 530) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEInteraction.h`

DisposeAEIdleUPP

Disposes of a universal procedure pointer to an Apple event idle function.

```
void DisposeAEIdleUPP (
   AEIdleUPP userUPP
);
```

Discussion
See the `AEIdleProcPtr` (page 531) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEInteraction.h`

DisposeOSLAccessorUPP

Disposes of a universal procedure pointer to an object accessor function.

```
void DisposeOSLAccessorUPP (
   OSLAccessorUPP userUPP
);
```

Discussion
See the `OSLAccessorProcPtr` (page 533) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEObjects.h`

DisposeOSLAdjustMarksUPP

Disposes of a universal procedure pointer to an object callback adjust marks function.

```
void DisposeOSLAdjustMarksUPP (
   OSLAdjustMarksUPP userUPP
);
```

Discussion
See the `OSLAdjustMarksProcPtr` (page 535) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEObjects.h`

DisposeOSLCompareUPP

Disposes of a universal procedure pointer to an object callback comparison function.

```
void DisposeOSLCompareUPP (
   OSLCompareUPP userUPP
);
```

Discussion
See the `OSLCompareProcPtr` (page 536) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEObjects.h`

DisposeOSLCountUPP

Disposes of a universal procedure pointer to an object callback count function.

```
void DisposeOSLCountUPP (
   OSLCountUPP userUPP
);
```

Discussion
See the `OSLCountProcPtr` (page 538) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEObjects.h`

DisposeOSLDisposeTokenUPP

Disposes of a universal procedure pointer to an object callback dispose token function.

```
void DisposeOSLDisposeTokenUPP (
   OSLDisposeTokenUPP userUPP
);
```

Discussion
See the `OSLDisposeTokenProcPtr` (page 539) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEObjects.h`

DisposeOSLGetErrDescUPP

Disposes of a universal procedure pointer to an object callback get error descriptor function.

```
void DisposeOSLGetErrDescUPP (
   OSLGetErrDescUPP userUPP
);
```

Discussion
See the `OSLGetErrDescProcPtr` (page 541) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEObjects.h`

DisposeOSLGetMarkTokenUPP

Disposes of a universal procedure pointer to an object callback get mark function.

```
void DisposeOSLGetMarkTokenUPP (
   OSLGetMarkTokenUPP userUPP
);
```

Discussion
See the `OSLGetMarkTokenProcPtr` (page 542) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEObjects.h`

DisposeOSLMarkUPP

Disposes of a universal procedure pointer to an object callback mark function.

```
void DisposeOSLMarkUPP (
   OSLMarkUPP userUPP
);
```

Discussion
See the `OSLMarkProcPtr` (page 544) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEObjects.h`

InvokeAECoerceDescUPP

Calls a universal procedure pointer to a function that coerces data stored in a descriptor.

```
OSErr InvokeAECoerceDescUPP (
   const AEDesc *fromDesc,
   DescType toType,
   SRefCon handlerRefcon,
   AEDesc *toDesc,
   AECoerceDescUPP userUPP
);
```

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
See the `AECoerceDescProcPtr` (page 524) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

InvokeAECoercePtrUPP

Calls a universal procedure pointer to a function that coerces data stored in a buffer.

```
OSErr InvokeAECoercePtrUPP (
   DescType typeCode,
   const void *dataPtr,
   Size dataSize,
   DescType toType,
   SRefCon handlerRefcon,
   AEDesc *result,
   AECoercePtrUPP userUPP
);
```

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
See the `AECoercePtrProcPtr` (page 525) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

InvokeAEDisposeExternalUPP

Calls a dispose external universal procedure pointer.

```
void InvokeAEDisposeExternalUPP (
   const void *dataPtr,
   Size dataLength,
   SRefCon refcon,
   AEDisposeExternalUPP userUPP
);
```

Parameters

dataPtr
A pointer to the data to be disposed of. The data must be immutable and must not be freed until this UPP is called.

dataLength
The length, in bytes, of the data to be disposed of.

refcon
A reference constant, supplied by your application, that you can use in your dispose function.

Discussion
See the `AEDisposeExternalProcPtr` (page 527) function.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`AEDataModel.h`

InvokeAEEventHandlerUPP

Calls an event handler universal procedure pointer.

```
OSErr InvokeAEEventHandlerUPP (
   const AppleEvent *theAppleEvent,
   AppleEvent *reply,
   SRefCon handlerRefcon,
   AEEventHandlerUPP userUPP
);
```

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
See the `AEEventHandlerProcPtr` (page 528) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

InvokeAEFilterUPP

Calls an Apple event filter universal procedure pointer.

```
Boolean InvokeAEFilterUPP (
   EventRecord *theEvent,
   SInt32 returnID,
   AETransactionID transactionID,
   const AEAddressDesc *sender,
   AEFilterUPP userUPP
);
```

Return Value
The return value of the callback function. The filter routine returns `TRUE` to accept the Apple event or `FALSE` to filter it out.

Discussion
See the `AEFilterProcPtr` (page 530) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEInteraction.h`

InvokeAEIdleUPP

Calls an Apple event idle universal procedure pointer.

```
Boolean InvokeAEIdleUPP (
   EventRecord *theEvent,
   SInt32 *sleepTime,
   RgnHandle *mouseRgn,
   AEIdleUPP userUPP
);
```

Return Value
The return value of the callback function. The filter routine returns `TRUE` if your application is no longer willing to wait for a reply from the server or for the user to bring the application to the front. It returns `FALSE` if your application is still willing to wait.

Discussion
See the `AEIdleProcPtr` (page 531) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEInteraction.h`

InvokeOSLAccessorUPP

Calls an object accessor universal procedure pointer.

```
OSErr InvokeOSLAccessorUPP (
   DescType desiredClass,
   const AEDesc *container,
   DescType containerClass,
   DescType form,
   const AEDesc *selectionData,
   AEDesc *value,
   SRefCon accessorRefcon,
   OSLAccessorUPP userUPP
);
```

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
See the `OSLAccessorProcPtr` (page 533) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEObjects.h`

InvokeOSLAdjustMarksUPP

Calls an object callback adjust marks universal procedure pointer.

```
OSErr InvokeOSLAdjustMarksUPP (
   long newStart,
   long newStop,
   const AEDesc *markToken,
   OSLAdjustMarksUPP userUPP
);
```

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
See the `OSLAdjustMarksProcPtr` (page 535) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEObjects.h`

InvokeOSLCompareUPP

Calls an object callback comparison universal procedure pointer.

```
OSErr InvokeOSLCompareUPP (
   DescType oper,
   const AEDesc *obj1,
   const AEDesc *obj2,
   Boolean *result,
   OSLCompareUPP userUPP
);
```

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
See the `OSLCompareProcPtr` (page 536) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEObjects.h`

InvokeOSLCountUPP

Calls an object callback count universal procedure pointer.

```
OSErr InvokeOSLCountUPP (
   DescType desiredType,
   DescType containerClass,
   const AEDesc *container,
   long *result,
   OSLCountUPP userUPP
);
```

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
See the `OSLCountProcPtr` (page 538) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEObjects.h`

InvokeOSLDisposeTokenUPP

Calls an object callback dispose token universal procedure pointer.

```
OSErr InvokeOSLDisposeTokenUPP (
   AEDesc *unneededToken,
   OSLDisposeTokenUPP userUPP
);
```

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
See the `OSLDisposeTokenProcPtr` (page 539) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEObjects.h`

InvokeOSLGetErrDescUPP

Calls an object callback get error descriptor universal procedure pointer.

```
OSErr InvokeOSLGetErrDescUPP (
   AEDesc **appDescPtr,
   OSLGetErrDescUPP userUPP
);
```

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
See the `OSLGetErrDescProcPtr` (page 541) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
AEObjects.h

InvokeOSLGetMarkTokenUPP

Calls an object callback get mark universal procedure pointer.

```
OSErr InvokeOSLGetMarkTokenUPP (
   const AEDesc *dContainerToken,
   DescType containerClass,
   AEDesc *result,
   OSLGetMarkTokenUPP userUPP
);
```

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
See the `OSLGetMarkTokenProcPtr` (page 542) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
AEObjects.h

InvokeOSLMarkUPP

Calls an object callback mark universal procedure pointer.

```
OSErr InvokeOSLMarkUPP (
   const AEDesc *dToken,
   const AEDesc *markToken,
   long index,
   OSLMarkUPP userUPP
);
```

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
See the `OSLMarkProcPtr` (page 544) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
AEObjects.h

NewAECoerceDescUPP

Creates a new universal procedure pointer to a function that coerces data stored in a descriptor.

```
AECoerceDescUPP NewAECoerceDescUPP (
   AECoerceDescProcPtr userRoutine
);
```

Return Value
See `AECoerceDescUPP` (page 552).

Discussion
See the `AECoerceDescProcPtr` (page 524) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

NewAECoercePtrUPP

Creates a new universal procedure pointer to a function that coerces data stored in a buffer.

```
AECoercePtrUPP NewAECoercePtrUPP (
   AECoercePtrProcPtr userRoutine
);
```

Return Value
See `AECoercePtrUPP` (page 552).

Discussion
See the `AECoercePtrProcPtr` (page 525) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

NewAEDisposeExternalUPP

Creates a new universal procedure pointer to a function that disposes of data stored in a buffer.

```
AEDisposeExternalUPP NewAEDisposeExternalUPP (
   AEDisposeExternalProcPtr userRoutine
);
```

Return Value
See `AEDisposeExternalUPP` (page 555).

Discussion
See the `AEDisposeExternalProcPtr` (page 527) callback function.

Availability
Available in Mac OS X v10.2 and later.

Declared In
AEDataModel.h

NewAEEventHandlerUPP

Creates a new universal procedure pointer to an event handler function.

```
AEEventHandlerUPP NewAEEventHandlerUPP (
   AEEventHandlerProcPtr userRoutine
);
```

Return Value
See AEEventHandlerUPP (page 555).

Discussion
See the AEEventHandlerProcPtr (page 528) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
AEDataModel.h

NewAEFilterUPP

Creates a new universal procedure pointer to an Apple event filter function.

```
AEFilterUPP NewAEFilterUPP (
   AEFilterProcPtr userRoutine
);
```

Return Value
See AEFilterUPP (page 556).

Discussion
See the AEFilterProcPtr (page 530) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
AEInteraction.h

NewAEIdleUPP

Creates a new universal procedure pointer to an Apple event idle function.

```
AEIdleUPP NewAEIdleUPP (
   AEIdleProcPtr userRoutine
);
```

Return Value
See `AEIdleUPP` (page 556).

Discussion
See the `AEIdleProcPtr` (page 531) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEInteraction.h`

NewOSLAccessorUPP

Creates a new universal procedure pointer to an object accessor function.

```
OSLAccessorUPP NewOSLAccessorUPP (
   OSLAccessorProcPtr userRoutine
);
```

Return Value
See `OSLAccessorUPP` (page 560).

Discussion
See the `OSLAccessorProcPtr` (page 533) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEObjects.h`

NewOSLAdjustMarksUPP

Creates a new universal procedure pointer to an object callback adjust marks function.

```
OSLAdjustMarksUPP NewOSLAdjustMarksUPP (
   OSLAdjustMarksProcPtr userRoutine
);
```

Return Value
See `OSLAdjustMarksUPP` (page 561).

Discussion
See the `OSLAdjustMarksProcPtr` (page 535) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEObjects.h`

NewOSLCompareUPP

Creates a new universal procedure pointer to an object callback comparison function.

```
OSLCompareUPP NewOSLCompareUPP (
   OSLCompareProcPtr userRoutine
);
```

Return Value
See `OSLCompareUPP` (page 561).

Discussion
See the `OSLCompareProcPtr` (page 536) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEObjects.h`

NewOSLCountUPP

Creates a new universal procedure pointer to an object callback count function.

```
OSLCountUPP NewOSLCountUPP (
   OSLCountProcPtr userRoutine
);
```

Return Value
See `OSLCountUPP` (page 561).

Discussion
See the `OSLCountProcPtr` (page 538) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEObjects.h`

NewOSLDisposeTokenUPP

Creates a new universal procedure pointer to an object callback dispose token function.

```
OSLDisposeTokenUPP NewOSLDisposeTokenUPP (
   OSLDisposeTokenProcPtr userRoutine
);
```

Return Value
See `OSLDisposeTokenUPP` (page 561).

Discussion
See the `OSLDisposeTokenProcPtr` (page 539) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
AEObjects.h

NewOSLGetErrDescUPP

Creates a new universal procedure pointer to an object callback get error descriptor function.

```
OSLGetErrDescUPP NewOSLGetErrDescUPP (
   OSLGetErrDescProcPtr userRoutine
);
```

Return Value
See OSLGetErrDescUPP (page 562).

Discussion
See the OSLGetErrDescProcPtr (page 541) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
AEObjects.h

NewOSLGetMarkTokenUPP

Creates a new universal procedure pointer to an object callback get mark function.

```
OSLGetMarkTokenUPP NewOSLGetMarkTokenUPP (
   OSLGetMarkTokenProcPtr userRoutine
);
```

Return Value
See OSLGetMarkTokenUPP (page 562).

Discussion
See the OSLGetMarkTokenProcPtr (page 542) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
AEObjects.h

NewOSLMarkUPP

Creates a new universal procedure pointer to an object callback mark function.

```
OSLMarkUPP NewOSLMarkUPP (
   OSLMarkProcPtr userRoutine
);
```

Return Value
See `OSLMarkUPP` (page 562).

Discussion
See the `OSLMarkProcPtr` (page 544) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEObjects.h`

vAEBuildAppleEvent

Allows you to encapsulate calls to `AEBuildAppleEvent` in a wrapper routine.

```
OSStatus vAEBuildAppleEvent (
   AEEventClass theClass,
   AEEventID theID,
   DescType addressType,
   const void *addressData,
   Size addressLength,
   SInt16 returnID,
   SInt32 transactionID,
   AppleEvent *resultEvt,
   AEBuildError *error,
   const char *paramsFmt,
   va_list args
);
```

Parameters

`theClass`
The event class for the resulting Apple event. See `AEEventClass` (page 555).

`theID`
The event id for the resulting Apple event. See `AEEventID` (page 556).

`addressType`
The address type for the addressing information described in the next two parameters: usually one of `typeApplSignature`, `typeProcessSerialNumber`, or `typeKernelProcessID`. See `DescType` (page 560).

`addressData`
A pointer to the address information.

`addressLength`
The number of bytes pointed to by the `addressData` parameter.

`returnID`
The return ID for the created Apple event. If you pass a value of `kAutoGenerateReturnID`, the Apple Event Manager assigns the created Apple event a return ID that is unique to the current session. If you pass any other value, the Apple Event Manager assigns that value for the ID.

transactionID

The transaction ID for this Apple event. A transaction is a sequence of Apple events that are sent back and forth between the client and server applications, beginning with the client's initial request for a service. All Apple events that are part of a transaction must have the same transaction ID. You can specify the `kAnyTransactionID` constant if the Apple event is not one of a series of interdependent Apple events.

result

A pointer to a descriptor where the resulting descriptor should be stored. See `AppleEvent` (page 559) for a description of the data type.

error

A pointer to an `AEBuildError` structure where additional information about any errors that occur will be saved. This is an optional parameter and you can pass `NULL` if this information is not required. See "AEBuild Error Codes" (page 563) for the syntax error codes that can be returned in this structure.

paramsFmt

An AEBuild format string describing the AppleEvent record to be created. The format of these strings is described in Technical Note TN2106, AEBuild*, AEPrint*, and Friends.

args

A variable array of arguments to be substituted into the `paramsFmt` format string. See the ANSI C Interfaces documentation for a description of the `va_list` data type.

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
Passing an argument list to `vAEBuildAppleEvent` corresponds to passing a series of individual parameters to the `AEBuildAppleEvent` (page 408) function.

This function and related "AEBuild" routines provide a very simple translation service for converting specially formatted strings into complex Apple event descriptors. Normally, creating complex Apple event descriptors requires a large number of calls to Apple event Manager routines to build up the descriptor piece by piece. The `vAEBuildAppleEvent` function and related routines allow you to consolidate all of the calls required to construct a complex Apple event descriptor into a single system call that creates the desired structure as directed by a format string that you provide.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEHelpers.h`

vAEBuildDesc

Allows you to encapsulate calls to `AEBuildDesc` in your own wrapper routines.

```
OSStatus vAEBuildDesc (
   AEDesc *dst,
   AEBuildError *error,
   const char *src,
   va_list args
);
```

Parameters

dst

A pointer to a descriptor where the resulting descriptor should be stored. See `AEDesc` (page 546).

error

A pointer to an `AEBuildError` structure where additional information about any errors that occur will be saved. This is an optional parameter and you can pass `NULL` if this information is not required. See `AEBuildError` (page 546).

src

An *`AEBuild`* format string describing the descriptor to be created.

args

A reference to a previously defined, variable argument parameter list to use with the descriptor-string. The file `<stdarg.h>` defines macros for declaring and using the `va_list` data type.

Return Value

A numeric result code indicating the success of the call. A value of `AEBuildSyntaxNoErr` (zero) means the call succeeded. You can use the `error` parameter to discover information about other errors. See "Apple Event Manager Result Codes" (page 636).

Discussion

Passing an argument list to `vAEBuildDesc` corresponds to passing a series of individual parameters to the `AEBuildDesc` (page 410) function.

This function and related "AEBuild" routines provide a very simple translation service for converting specially formatted strings into complex Apple event descriptors. Normally, creating complex Apple event descriptors requires a large number of calls to Apple Event Manager routines to build up the descriptor piece by piece. The `vAEBuildDesc` function and related routines allow you to consolidate all of the calls required to construct a complex Apple event descriptor into a single system call that creates the desired structure as directed by a format string that you provide.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`AEHelpers.h`

vAEBuildParameters

Allows you to encapsulate calls to `AEBuildParameters` in your own `stdarg`-style wrapper routines, using techniques similar to those allowed by vsprintf.

```
OSStatus vAEBuildParameters (
   AppleEvent *event,
   AEBuildError *error,
   const char *format,
   va_list args
);
```

Parameters

event

The Apple event to which you are adding parameters. See `AppleEvent` (page 559).

error

A pointer to an `AEBuildError` structure where additional information about any errors that occur will be saved. This is an optional parameter and you can pass `NULL` if this information is not required. See `AEBuildError` (page 546).

format

An *`AEBuild`* format string describing the `AEDesc` parameters to be created.

args

A reference to a previously defined, variable argument parameter list to use with the descriptor-string. The file `<stdarg.h>` defines macros for declaring and using the `va_list` data type.

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636).

Discussion
Passing an argument list to `vAEBuildParameters` corresponds to passing a series of individual parameters to the `AEBuildParameters` (page 411) function.

This function and related "AEBuild" routines provide a very simple translation service for converting specially formatted strings into complex Apple event descriptors. Normally, creating complex Apple event descriptors requires a large number of calls to Apple event Manager routines to build up the descriptor piece by piece. The `vAEBuildParameters` function and related routines allow you to consolidate all of the calls required to construct a complex Apple event descriptor into a single system call that creates the desired structure as directed by a format string that you provide.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEHelpers.h`

Callbacks by Task

Callbacks When Resolving Remote Processes

`AERemoteProcessResolverCallback` (page 532)

Defines a pointer to a function the Apple Event Manager calls when the asynchronous execution of a remote process resolver completes, either due to success or failure, after a call to the `AERemoteProcessResolverScheduleWithRunLoop` function. Your callback function can use the reference passed to it to get the remote process information.

Callbacks When Creating Apple Events

`AEDisposeExternalProcPtr` (page 527)
Defines a pointer to a function the Apple Event Manager calls to dispose of a descriptor created by the `AECreateDescFromExternalPtr` function. Your callback function disposes of the buffer you originally passed to that function.

Callbacks When Sending Apple Events

`AEFilterProcPtr` (page 530)
Defines a pointer to a function the Apple Event Manager calls while your application waits for a reply to an Apple event. Your filter function determines which high-level events your application is willing to handle.

`AEIdleProcPtr` (page 531)
Defines a pointer to a function the Apple Event Manager calls while your application waits for a reply to an Apple event. Your idle function must handle update, null, operating-system, and activate events.

Coercing Apple Event Data Callbacks

`AECoerceDescProcPtr` (page 524)
Defines a pointer to a function that coerces data stored in a descriptor. Your descriptor coercion callback function coerces the data from the passed descriptor to the specified type, returning the coerced data in a second descriptor.

`AECoercePtrProcPtr` (page 525)
Defines a pointer to a function that coerces data stored in a buffer. Your pointer coercion callback routine coerces the data from the passed buffer to the specified type, returning the coerced data in a descriptor.

Handling Apple Events Callbacks

`AEEventHandlerProcPtr` (page 528)
Defines a pointer to a function that handles one or more Apple events. Your Apple event handler function performs any action requested by the Apple event, adds parameters to the reply Apple event if appropriate (possibly including error information), and returns a result code.

Object Accessor Callbacks

`OSLAccessorProcPtr` (page 533)
Your object accessor function either finds elements or properties of an Apple event object.

Object Callback Functions

`OSLAdjustMarksProcPtr` (page 535)
: Defines a pointer to an adjust marks callback function. Your adjust marks function unmarks objects previously marked by a call to your marking function.

`OSLCompareProcPtr` (page 536)
: Defines a pointer to an object comparison callback function. Your object comparison function compares one Apple event object to another or to the data for a descriptor.

`OSLCountProcPtr` (page 538)
: Defines a pointer to an object counting callback function. Your object counting function counts the number of Apple event objects of a specified class in a specified container object.

`OSLDisposeTokenProcPtr` (page 539)
: Defines a pointer to a dispose token callback function. Your dispose token function, required only if you use a complex token format, disposes of the specified token.

`OSLGetErrDescProcPtr` (page 541)
: Defines a pointer to an error descriptor callback function. Your error descriptor callback function supplies a pointer to an address where the Apple Event Manager can store the current descriptor if an error occurs during a call to the `AEResolve` function.

`OSLGetMarkTokenProcPtr` (page 542)
: Defines a pointer to a mark token callback function. Your mark token function returns a mark token.

`OSLMarkProcPtr` (page 544)
: Defines a pointer to an object marking callback function. Your object-marking function marks a specific Apple event object.

Callbacks

AECoerceDescProcPtr

Defines a pointer to a function that coerces data stored in a descriptor. Your descriptor coercion callback function coerces the data from the passed descriptor to the specified type, returning the coerced data in a second descriptor.

```
typedef OSErr (*AECoerceDescProcPtr)
(
    const AEDesc * fromDesc,
    DescType toType,
    long handlerRefcon,
    AEDesc * toDesc
);
```

If you name your function `MyAECoerceDescCallback`, you would declare it like this:

```
OSErr MyAECoerceDescCallback (
    const AEDesc * fromDesc,
    DescType toType,
    long handlerRefcon,
    AEDesc * toDesc
);
```

Parameters

fromDesc

A pointer to the descriptor that contains the data to coerce. See AEDesc (page 546).

toType

The desired descriptor type for the resulting descriptor. For a list of AppleScript's predefined descriptor types, see "Descriptor Type Constants" (page 581). See DescType (page 560).

handlerRefcon

A reference constant that is stored in the coercion dispatch table entry for the handler. The Apple Event Manager passes this value to the handler each time it calls it. The reference constant may have a value of 0.

toDesc

A pointer to a descriptor where your coercion routine must store the descriptor that contains the coerced data. See AEDesc (page 546).

Return Value

A result code. See "Apple Event Manager Result Codes" (page 636). Your handler should return noErr if it successfully handled the coercion, errAECoercionFailed if it can't handle the coercion and it wants the Apple Event Manager to continue dispatching to other coercion handlers, or a nonzero result code otherwise.

Discussion

Your coercion handler should coerce the data to the desired descriptor type and return the resulting data in the descriptor specified by the result parameter.

To provide a pointer to your descriptor coercion callback function, you create a universal procedure pointer (UPP) of type AECoerceDescUPP (page 552), using the function NewAECoerceDescUPP (page 514). You can do so with code like the following:

```
AECoerceDescUPP MyCoerceDescUPP;
MyCoerceDescUPP = NewAECoerceDescUPP (&MyCoerceDescCallback)
```

You can then pass the UPP MyCoerceDescUPP as a parameter to any function that installs or removes a coercion handler, such as AEInstallCoercionHandler (page 448). If your application installs the same coercion handler to coerce more than one type of data, you can use the same UPP to install the handler multiple times.

If you wish to call your descriptor coercion callback function directly, you can use the InvokeAECoerceDescUPP (page 507) function.

After you are finished with a descriptor coercion callback function, and have removed it with the AERemoveCoercionHandler (page 468) function, you can dispose of the UPP with the DisposeAECoerceDescUPP (page 503) function. However, don't dispose of the UPP if any remaining coercion handler uses it or if you plan to install the coercion handler again.

Availability

Available in Mac OS X v10.0 and later.

Declared In

AEDataModel.h

AECoercePtrProcPtr

Defines a pointer to a function that coerces data stored in a buffer. Your pointer coercion callback routine coerces the data from the passed buffer to the specified type, returning the coerced data in a descriptor.

```
typedef OSErr (*AECoercePtrProcPtr) (
    DescType typeCode,
    const void * dataPtr,
    Size dataSize,
    DescType toType,
    long handlerRefcon,
    AEDesc * result
);
```

If you name your function `MyAECoercePtrCallback`, you would declare it like this:

```
OSErr MyAECoercePtrCallback (
    DescType typeCode,
    const void * dataPtr,
    Size dataSize,
    DescType toType,
    long handlerRefcon,
    AEDesc * result
);
```

Parameters

typeCode

The descriptor type of the original data. For a list of AppleScript's predefined descriptor types, see "Descriptor Type Constants" (page 581). See `DescType` (page 560).

dataPtr

A pointer to the data to coerce.

dataSize

The length, in bytes, of the data to coerce.

toType

The desired descriptor type for the resulting descriptor. For a list of AppleScript's predefined descriptor types, see "Descriptor Type Constants" (page 581). See `DescType` (page 560).

handlerRefcon

A reference constant that is stored in the coercion dispatch table entry for the handler. The Apple Event Manager passes this value to the handler each time it calls it. The reference constant may have a value of `NULL`.

result

A pointer to a descriptor where your coercion routine must store the descriptor that contains the coerced data. If your routine cannot coerce the data, return a null descriptor. See `AEDesc` (page 546).

Return Value

A result code. See "Apple Event Manager Result Codes" (page 636). Your handler should return `noErr` if it successfully handled the coercion, `errAECoercionFailed` if it can't handle the coercion and it wants the Apple Event Manager to continue dispatching to other coercion handlers, or a nonzero result code otherwise.

Discussion

To provide a pointer to your coercion callback function, you create a universal procedure pointer (UPP) of type `AECoercePtrUPP` (page 552), using the function `NewAECoercePtrUPP` (page 514). You can do so with code like the following:

```
AECoercePtrUPP MyCoercePtrUPP;
MyCoercePtrUPP = NewAECoercePtrUPP (&MyCoercePtrCallback)
```

You can then pass the UPP `MyCoercePtrUPP` as a parameter to any function that installs or removes a coercion handler, such as `AEInstallCoercionHandler` (page 448). If your application installs the same coercion handler to coerce more than one type of data, you can use the same UPP to install the handler multiple times.

If you wish to call your coercion callback function directly, you can use the `InvokeAECoercePtrUPP` (page 508) function.

After you are finished with a coercion callback function, and have removed it with the `AERemoveCoercionHandler` (page 468) function, you can dispose of the UPP with the `DisposeAECoercePtrUPP` (page 503) function. However, don't dispose of the UPP if any remaining coercion handler uses it or if you plan to install the coercion handler again.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

AEDisposeExternalProcPtr

Defines a pointer to a function the Apple Event Manager calls to dispose of a descriptor created by the `AECreateDescFromExternalPtr` function. Your callback function disposes of the buffer you originally passed to that function.

```
typedef (void, AEDisposeExternalProcPtr)(
                const void *dataPtr,
                Size dataLength,
                long refcon);
```

If you name your function `MyAEDisposeExternalCallback`, you would declare it like this:

```
void MyAEDisposeExternalCallback (
            const void *dataPtr,
            Size dataLength,
            long refcon);
```

Parameters

dataPtr

A pointer to the data to be disposed of. The data must be immutable and must not be freed until this callback function is called.

dataLength

The length, in bytes, of the data in the *dataPtr* parameter.

refcon

A reference constant, supplied by your application in its original call to `AECreateDescFromExternalPtr` (page 418). The Apple Event Manager passes this value to your dispose function each time it calls it. The reference constant may have a value of 0.

Return Value
Your callback routine should not return a value.

Discussion
Your application must provide a universal procedure pointer to a dispose function as a parameter to the `AECreateDescFromExternalPtr` (page 418) function.

To provide a pointer to your dispose callback function, you create a universal procedure pointer (UPP) of type `AEDisposeExternalProcPtr`, using the function `NewAEDisposeExternalUPP` (page 514). You can do so with code like the following:

```
AEDisposeExternalProcPtr MyDisposeCallbackUPP;
MyDisposeCallbackUPP = NewAEDisposeExternalUPP (&MyAEDisposeExternalCallback);
```

You can then pass the UPP `MyDisposeCallbackUPP` as a parameter to the `AECreateDescFromExternalPtr` function.

If you wish to call your dispose callback function directly, you can use the `InvokeAEDisposeExternalUPP` (page 508) function.

After you are finished with your dispose callback function, you can dispose of the UPP with the `DisposeAEDisposeExternalUPP` (page 503) function. However, if you will use the same dispose function in subsequent calls to `AECreateDescFromExternalPtr`, you can reuse the same UPP, rather than dispose of it and later create a new UPP.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`AEDataModel.h`

AEEventHandlerProcPtr

Defines a pointer to a function that handles one or more Apple events. Your Apple event handler function performs any action requested by the Apple event, adds parameters to the reply Apple event if appropriate (possibly including error information), and returns a result code.

```
typedef OSErr (*AEEventHandlerProcPtr)
(
    const AppleEvent * theAppleEvent,
    AppleEvent * reply,
    long handlerRefcon
);
```

If you name your function `MyAEEventHandlerCallback`, you would declare it like this:

```
OSErr MyAEEventHandlerCallback (
    const AppleEvent * theAppleEvent,
    AppleEvent * reply,
    long handlerRefcon
);
```

Parameters

`theAppleEvent`
A pointer to the Apple event to handle. See `AppleEvent` (page 559).

reply

A pointer to the default reply Apple event provided by the Apple Event Manager. See `AppleEvent` (page 559). If no reply is expected, `reply` has descriptor type `typeNull`.

handlerRefcon

The reference constant stored in the Apple event dispatch table when you install the handler function for the Apple event. You can store any 32-bit value in the dispatch table and use it any way you want when the handler is called. The reference constant may have a value of `NULL`.

Return Value

A result code. See "Apple Event Manager Result Codes" (page 636). Your handler should always return `noErr` if it successfully handled the Apple event. If an error occurs, your handler should return either `errAEEventNotHandled` or some other nonzero result code. For more information, see the Discussion section.

Discussion

An Apple event handler should extract any parameters and attributes from the Apple event, perform the requested action, and add parameters to the reply Apple event if appropriate. You must provide an Apple event handler for each Apple event your application supports. The `AEProcessAppleEvent` (page 457) function calls one of your Apple event handlers when it processes an Apple event.

If an error occurs because your application cannot understand the event, return `errAEEventNotHandled`, so that the Apple Event Manager may be able to find another handler to handle the event. If the error occurs because the event is impossible to handle as specified, return the result code returned by whatever function caused the failure, or whatever other result code is appropriate.

For example, suppose your application receives a `kAEGetData` event that requests the name of the current printer, and your application cannot handle such an event. In this situation, you should return `errAEEventNotHandled` so that another handler available to the Apple Event Manager can have a chance to handle the event. This strategy allows users to take advantage of system capabilities from within your application via system handlers.

If your Apple event handler calls the `AEResolve` (page 473) function and `AEResolve` calls an object accessor function in the system object accessor dispatch table, your Apple event handler may not recognize the descriptor type of the token returned by the function. In this case, your handler should return the result code `errAEUnknownObjectType`. When your handler returns this result code, the Apple Event Manager attempts to locate a system Apple event handler that can recognize the token.

For additional information on dealing with error conditions, see `OSLGetErrDescProcPtr` (page 541).

To provide a pointer to your event handler callback function, you create a universal procedure pointer (UPP) of type `AEEventHandlerUPP` (page 555), using the function `NewAEEventHandlerUPP` (page 515). You can do so with code like the following:

```
AEEventHandlerUPP MyEventHandlerUPP;
MyEventHandlerUPP = NewAEEventHandlerUPP (&MyEventHandlerCallback)
```

You can then pass the UPP `MyEventHandlerUPP` as a parameter to any function that installs or removes a handler, such as `AEInstallEventHandler` (page 449). If your application installs the same event handler to handle more than one kind of event (more than one pair of event class and event ID), you can use the same UPP to install the handler multiple times.

If you wish to call your event handler callback function directly, you can use the `InvokeAEEventHandlerUPP` (page 509) function.

After you are finished with an event handler callback function, and have removed it with the `AERemoveEventHandler` (page 469) function, you can dispose of the UPP with the `DisposeAEEventHandlerUPP` (page 504) function. However, don't dispose of the UPP if any remaining handler uses it or if you plan to install the handler again.

Version Notes
Your application should not install a handler in a system dispatch table with the goal that the handler will get called when other applications receive an Apple event—this won't work in Mac OS X. For more information, see "The System Dispatch Table" in "Apple Event Dispatching" in Apple Events Programming Guide.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

AEFilterProcPtr

Defines a pointer to a function the Apple Event Manager calls while your application waits for a reply to an Apple event. Your filter function determines which high-level events your application is willing to handle.

```
typedef Boolean (*AEFilterProcPtr) (
    EventRecord * theEvent,
    long returnID,
    long transactionID,
    const AEAddressDesc * sender
);
```

If you name your function `MyAEFilterCallback`, you would declare it like this:

```
Boolean MyAEFilterCallback (
    EventRecord * theEvent,
    long returnID,
    long transactionID,
    const AEAddressDesc * sender
);
```

Parameters

`theEvent`
A pointer to the event record for a high-level event. The next three parameters contain valid information only if the event is an Apple event. See the Event Manager documentation for a description of the `EventRecord` data type.

`returnID`
Return ID for the Apple event.

`transactionID`
Transaction ID for the Apple event.

`sender`
A pointer to the address of the process that sent the Apple event. See `AEAddressDesc` (page 551).

Return Value
Your filter routine returns `TRUE` to accept the Apple event or `FALSE` to filter it out.

Discussion
If your application provides a universal procedure pointer to a reply filter function as a parameter to the `AESend` (page 476) function, the reply filter function can indicate any high-level events that it is willing to handle while your application is waiting for a reply.

If your filter function returns `true`, the Apple Event Manager will dispatch the event through the standard dispatch mechanism (equivalent to calling `AEProcessAppleEvent` (page 457)).

To provide a pointer to your reply filter callback function, you create a universal procedure pointer (UPP) of type `AEFilterUPP` (page 556), using the function `NewAEFilterUPP` (page 515). You can do so with code like the following:

```
AEFilterUPP MyReplyFilterUPP;
MyReplyFilterUPP = NewAEFilterUPP (&MyReplyFilterCallback)
```

You can then pass the UPP `MyReplyFilterUPP` as a parameter to the `AESend` function.

If you wish to call your filter callback function directly, you can use the `InvokeAEFilterUPP` (page 509) function.

After you are finished with your filter callback function, you can dispose of the UPP with the `DisposeAEFilterUPP` (page 504) function. However, if you will use the same filter function in subsequent calls to `AESend`, you can reuse the same UPP, rather than dispose of it and later create a new UPP.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEInteraction.h`

AEIdleProcPtr

Defines a pointer to a function the Apple Event Manager calls while your application waits for a reply to an Apple event. Your idle function must handle update, null, operating-system, and activate events.

```
typedef Boolean (*AEIdleProcPtr) (
    EventRecord * theEvent,
    long * sleepTime,
    RgnHandle * mouseRgn
);
```

If you name your function `MyAEIdleCallback`, you would declare it like this:

```
Boolean MyAEIdleCallback (
    EventRecord * theEvent,
    long * sleepTime,
    RgnHandle * mouseRgn
);
```

Parameters

`theEvent`

A pointer to the event record of the event to process. See the Event Manager documentation for a description of the `EventRecord` data type.

sleepTime

A pointer to a value that specifies the amount of time (in ticks) your application is willing to relinquish the processor if no events are pending.

mouseRgn

A pointer to a value that specifies a screen region that determines the conditions under which your application is to receive notice of mouse-moved events. See the QuickDraw Manager documentation for a description of the `RgnHandle` data type.

Return Value
Your idle routine returns `TRUE` if your application is no longer willing to wait for a reply from the server or for the user to bring the application to the front. It returns `FALSE` if your application is still willing to wait.

Discussion
If your application provides a pointer to an idle function as a parameter to the `AESend` (page 476) function or the `AEInteractWithUser` (page 453) function, the Apple Event Manager will call the idle function to handle any update event, null event, operating-system event, or activate event received for your application while it is waiting for a reply.

To provide a pointer to your idle callback function, you create a universal procedure pointer (UPP) of type `AEIdleUPP` (page 556), using the function `NewAEIdleUPP` (page 515). You can do so with code like the following:

```
AEIdleUPP MyIdleUPP;
MyIdleUPP = NewAEIdleUPP (&MyIdleCallback)
```

You can then pass the UPP `MyIdleUPP` as a parameter to either the `AESend` function or the `AEInteractWithUser` function.

If you wish to call your idle callback function directly, you can use the `InvokeAEIdleUPP` (page 509) function.

After you are finished with your idle callback function, you can dispose of the UPP with the `DisposeAEIdleUPP` (page 504) function. However, if you will use the same idle function in subsequent calls to `AESend` or `AEInteractWithUser`, you can reuse the same UPP, rather than dispose of it and later create a new UPP.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEInteraction.h`

AERemoteProcessResolverCallback

Defines a pointer to a function the Apple Event Manager calls when the asynchronous execution of a remote process resolver completes, either due to success or failure, after a call to the `AERemoteProcessResolverScheduleWithRunLoop` function. Your callback function can use the reference passed to it to get the remote process information.

```
typedef (void, AERemoteProcessResolverCallback)(
                AERemoteProcessResolverRef ref,
                void *info);
```

If you name your function `MyAERemoteProcessCallback`, you would declare it like this:

```
void MyAERemoteProcessCallback (
```

```
            AERemoteProcessResolverRef ref,
            void *info);
```

Parameters

ref

A reference of type `AERemoteProcessResolverRef` (page 557) you can query to obtain the remote process information. Acquired from a previous call to `AECreateRemoteProcessResolver` (page 420).

info

An untyped pointer your application can use to pass information it needs when resolving remote processes. The application originally supplies this pointer in the `AERemoteProcessResolverContext` (page 547) structure in the `ctx` parameter) when it calls the `AERemoteProcessResolverScheduleWithRunLoop` function.

Return Value
Your callback routine should not return a value.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`AppleEvents.h`

OSLAccessorProcPtr

Your object accessor function either finds elements or properties of an Apple event object.

```
typedef OSErr (*OSLAccessorProcPtr) (
    DescType desiredClass,
    const AEDesc * container,
    DescType containerClass,
    DescType form,
    const AEDesc * selectionData,
    AEDesc * value,
    long accessorRefcon
);
```

If you name your function `MyObjectAccessorCallback`, you would declare it like this:

```
OSErr MyObjectAccessorCallback (
    DescType desiredClass,
    const AEDesc * container,
    DescType containerClass,
    DescType form,
    const AEDesc * selectionData,
    AEDesc * value,
    long accessorRefcon
);
```

Parameters

desiredClass

The object class of the desired Apple event object or objects. Constants for object class IDs are described in "Object Class ID Constants" (page 599). See `DescType` (page 560).

container
A pointer to a descriptor that specifies the container of the desired Apple event object or objects. See `AEDesc` (page 546).

containerClass
The object class of the container. Constants for object class IDs are described in "Object Class ID Constants" (page 599). See `DescType` (page 560).

form
The key form specified by the object specifier being resolved. Constants for key form are described in "Key Form and Descriptor Type Object Specifier Constants" (page 590). See `DescType` (page 560).

selectionData
A pointer to a descriptor containing the key data specified by the object specifier being resolved. See `AEDesc` (page 546).

value
A pointer to a descriptor where your object accessor routine stores a descriptor that identifies the found object. See `AEDesc` (page 546).

accessorRefcon
A reference constant. The Apple Event Manager passes this value to your object accessor function each time it calls it. The reference constant may have a value of 0.

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636). Your object accessor function should return `noErr` if it successfully located the requested object and `errAEEventNotHandled` if it could not locate the object. When the Apple Event Manager receives the result code `errAEEventNotHandled` after calling an object accessor function, it attempts to use other methods of locating the requested objects, such as calling an equivalent system object accessor function.

Discussion
To resolve an object specifier, your application calls the `AEResolve` (page 473) function. `AEResolve` in turn calls application-defined object accessor functions to locate specific Apple event objects and properties in the application's data structures. Your application provides one or more object accessor functions that can locate all the element classes and properties it supports.

Each object accessor function provided by your application should either find elements or properties of an Apple event object. The `AEResolve` function uses the object class ID of the specified Apple event object and the descriptor type of the token that identifies the object's container to determine which object accessor function to call. To install an object accessor function, use the `AEInstallObjectAccessor` (page 451) function.

To provide a pointer to your object accessor callback function, you create a universal procedure pointer (UPP) of type `OSLAccessorUPP` (page 560), using the function `NewOSLAccessorUPP` (page 516). You can do so with code like the following:

```
AEObjectAccessorUPP MyObjectAccessorUPP;
MyObjectAccessorUPP = NewAEObjectAccessorUPP (&MyObjectAccessorCallback)
```

You can then pass the UPP `MyObjectAccessorUPP` as a parameter to any function that installs or removes an object accessor, such as `AEInstallObjectAccessor` (page 451). If your application installs the same object accessor to handle more than one kind of object class or property of an Apple event, you can use the same UPP to install the accessor multiple times.

If you wish to call your object accessor callback function directly, you can use the `InvokeOSLAccessorUPP` (page 510) function.

After you are finished with an object accessor callback function, and have removed it with the `AERemoveObjectAccessor` (page 470) function, you can dispose of the UPP with the `DisposeOSLAccessorUPP` (page 504) function. However, don't dispose of the UPP if any remaining accessor function uses it or if you plan to install the accessor function again.

Version Notes
In Mac OS X, your application can not make an object callback function available to other applications by installing it in a system object accessor dispatch table.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEObjects.h`

OSLAdjustMarksProcPtr

Defines a pointer to an adjust marks callback function. Your adjust marks function unmarks objects previously marked by a call to your marking function.

```
typedef OSErr (*OSLAdjustMarksProcPtr)
(
    long newStart,
    long newStop,
    const AEDesc * markToken
);
```

If you name your function `MyAdjustMarksCallback`, you would declare it like this:

```
OSErr MyAdjustMarksCallback (
    long newStart,
    long newStop,
    const AEDesc * markToken
);
```

Parameters

newStart
The mark count value (provided when the `MyAdjustMarksCallback` callback function was called to mark the object) for the first object in the new set of marked objects.

newStop
The mark count value (provided when the `MyAdjustMarksCallback` callback function was called to mark the object) for the last object in the new set of marked objects.

markToken
A pointer to the mark token for the marked objects. (Token is defined in `AEDisposeToken` (page 425). See `AEDesc` (page 546).

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636). Your adjust marks function should return `noErr` if it successfully adjusted the marks and `errAEEventNotHandled` if it could not locate the object. When the Apple Event Manager gets an error result of `errAEEventNotHandled`, it attempts to adjust the marks by calling the equivalent system mark-adjusting function.

Discussion
When the Apple Event Manager needs to identify either a range of elements or the absolute position of an element in a group of Apple event objects that pass a test, it can use your application's mark-adjusting function to unmark objects previously marked by a call to your marking function.

For example, suppose an object specifier specifies `any row in the table "MyCustomers" for which the City column is "San Francisco"`. The Apple Event Manager first uses the appropriate object accessor function to locate all the rows in the table for which the City column is `"San Francisco"` and calls the application's marking function repeatedly to mark them. It then generates a random number between 1 and the number of rows it found that passed the test and calls the application's mark-adjusting function to unmark all the rows whose mark count does not match the randomly generated number. If the randomly chosen row has a mark count value of 5, the Apple Event Manager passes the value 5 to the mark-adjusting function in both the `newStart` parameter and the `newStop` parameter, and passes the current mark token in the `markToken` parameter.

When the Apple Event Manager calls your `MyAdjustMarksCallback` function, your application must dispose of any data structures that it created to mark the previously marked objects.

To provide a pointer to your adjust marks callback function, you create a universal procedure pointer (UPP) of type `OSLAdjustMarksUPP` (page 561), using the function `NewOSLAdjustMarksUPP` (page 516). You can do so with code like the following:

```
OSLAdjustMarksUPP MyAdjustMarksUPP;
MyAdjustMarksUPP = NewOSLAdjustMarksUPP (&MyAdjustMarksCallback)
```

You can then pass the UPP `MyAdjustMarksUPP` as a parameter to the `AESetObjectCallbacks` (page 480) function or the `AEInstallSpecialHandler` (page 452) function.

If you wish to call your adjust marks callback function directly, you can use the `InvokeOSLAdjustMarksUPP` (page 510) function.

After you are finished with your adjust marks callback function, you can dispose of the UPP with the `DisposeOSLAdjustMarksUPP` (page 505) function. However, if you will use the same adjust marks function in subsequent calls to the function `AESetObjectCallbacks` or the function `AEInstallSpecialHandler`, you can reuse the same UPP, rather than dispose of it and later create a new UPP.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEObjects.h`

OSLCompareProcPtr

Defines a pointer to an object comparison callback function. Your object comparison function compares one Apple event object to another or to the data for a descriptor.

```
typedef OSErr (*OSLCompareProcPtr) (
    DescType oper,
    const AEDesc * obj1,
    const AEDesc * obj2,
    Boolean * result
);
```

If you name your function `MyCompareObjectsCallback`, you would declare it like this:

```
OSErr MyCompareObjectsCallback (
    DescType oper,
    const AEDesc * obj1,
    const AEDesc * obj2,
    Boolean * result
);
```

Parameters

oper

A comparison operator that specifies the type of comparison to perform. The available comparison operators are described in "Comparison Operator Constants" (page 574). For related information, see the function `CreateCompDescriptor` (page 498). See `DescType` (page 560).

obj1

A pointer to a token describing the first Apple event object to compare. (Token is defined in `AEDisposeToken` (page 425). See `AEDesc` (page 546).

obj2

A pointer to a token or some other descriptor that specifies either an Apple event object or a value to compare to the Apple event object specified by the `obj1` parameter. See `AEDesc` (page 546).

result

A pointer to a Boolean value where your object comparison function stores a value indicating the result of the comparison operation. You store `TRUE` if the values of the `obj1` and `obj2` parameters have the relationship specified by the `comparisonOperator` parameter; otherwise, you store `FALSE`.

Return Value

A result code. See "Apple Event Manager Result Codes" (page 636). Your object comparison function should return `noErr` if it successfully compared the objects and `errAEEventNotHandled` if it can't compare the objects. When the Apple Event Manager gets an error result of `errAEEventNotHandled`, it attempts to use other methods of comparing the specified objects, such as calling an equivalent system object comparison function.

Discussion

The Apple Event Manager calls your object comparison function when, in the course of resolving an object specifier, the manager needs to compare an Apple event object with another object or with a value in a descriptor.

If you want the Apple Event Manager to help your application resolve object specifiers of key form `formTest` (and if your application doesn't specify `kAEIDoWhose` as described in "Callback Constants for the AEResolve Function" (page 571)), you should provide an object-counting function, as described in `OSLCountProcPtr` (page 538), and an object comparison function.

It is up to your application to interpret the comparison operators it receives. The meaning of comparison operators differs according to the Apple event objects being compared, and not all comparison operators apply to all object classes. The available comparison operators are described in "Comparison Operator Constants" (page 574).

To provide a pointer to your object comparison callback function, you create a universal procedure pointer (UPP) of type `OSLCompareUPP` (page 561), using the function `NewOSLCompareUPP` (page 517). You can do so with code like the following:

```
OSLCompareObjectsUPP MyCompareObjectsUPP;
MyCompareObjectsUPP = NewOSLCompareObjectsUPP(&MyCompareObjectsCallback)
```

You can then pass the UPP `MyCompareObjectsUPP` as a parameter to the `AESetObjectCallbacks` (page 480) function or the `AEInstallSpecialHandler` (page 452) function.

If you wish to call your object comparison callback function directly, you can use the `InvokeOSLCompareUPP` (page 511) function.

After you are finished with your object comparison callback function, you can dispose of the UPP with the `DisposeOSLCompareUPP` (page 505) function. However, if you will use the same object comparison function in subsequent calls to the function `AESetObjectCallbacks` or the function `AEInstallSpecialHandler`, you can reuse the same UPP, rather than dispose of it and later create a new UPP.

Version Notes
In Mac OS X, your application can not make an object callback function available to other applications by installing it in a system object accessor dispatch table.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEObjects.h`

OSLCountProcPtr

Defines a pointer to an object counting callback function. Your object counting function counts the number of Apple event objects of a specified class in a specified container object.

```
typedef OSErr (*OSLCountProcPtr) (
    DescType desiredType,
    DescType containerClass,
    const AEDesc * container,
    long * result
);
```

If you name your function `MyCountObjectsCallback`, you would declare it like this:

```
OSErr MyCountObjectsCallback (
    DescType desiredType,
    DescType containerClass,
    const AEDesc * container,
    long * result
);
```

Parameters

desiredType
The object class of the Apple event objects to be counted. See `DescType` (page 560).

containerClass
The object class of the container for the Apple event objects to be counted. See `DescType` (page 560).

container
A pointer to a token that identifies the container for the Apple event objects to be counted. (Token is defined in `AEDisposeToken` (page 425). See `AEDesc` (page 546).

result

A pointer to a variable where your object-counting function stores the number of Apple objects of the specified class in the specified container.

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636). Your object counting function should return `noErr` if it successfully counted the objects and `errAEEventNotHandled` if it can't count the objects. When the Apple Event Manager receives the result code `errAEEventNotHandled` after calling an object counting function, it attempts to use other methods of counting the specified objects, such as calling an equivalent system object counting function.

Discussion
If you want the Apple Event Manager to help your application resolve object specifiers of key form `formTest` (and if your application doesn't specify `kAEIDoWhose` as described in "Callback Constants for the AEResolve Function" (page 571)), you should provide an object comparison function, as described in `OSLCompareProcPtr` (page 536), and an object-counting function.

The Apple Event Manager calls your object-counting function when, in the course of resolving an object specifier, the manager requires a count of the number of Apple event objects of a given class in a given container.

To provide a pointer to your object counting callback function, you create a universal procedure pointer (UPP) of type `OSLCountUPP` (page 561), using the function `NewOSLCountUPP` (page 517). You can do so with code like the following:

```
OSLCountObjectsUPP MyCountObjectsUPP;
MyCountObjectsUPP = NewOSLCountObjectsUPP (&MyCountObjectsCallback)
```

You can then pass the UPP `MyCountObjectsUPP` as a parameter to the `AESetObjectCallbacks` (page 480) function or the `AEInstallSpecialHandler` (page 452) function.

If you wish to call your object counting callback function directly, you can use the `InvokeOSLCountUPP` (page 511) function.

After you are finished with your object counting callback function, you can dispose of the UPP with the `DisposeOSLCountUPP` (page 505) function. However, if you will use the same object counting function in subsequent calls to the function `AESetObjectCallbacks` or the function `AEInstallSpecialHandler`, you can reuse the same UPP, rather than dispose of it and later create a new UPP.

Version Notes
In Mac OS X, your application can not make an object callback function available to other applications by installing it in a system object accessor dispatch table.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEObjects.h`

OSLDisposeTokenProcPtr

Defines a pointer to a dispose token callback function. Your dispose token function, required only if you use a complex token format, disposes of the specified token.

```
typedef OSErr (*OSLDisposeTokenProcPtr)
(
    AEDesc * unneededToken
);
```

If you name your function `MyDisposeTokenCallback`, you would declare it like this:

```
OSErr MyDisposeTokenCallback (
    AEDesc * unneededToken
);
```

Parameters

unneededToken

A pointer to the token to dispose of. (Token is defined in `AEDisposeToken` (page 425).) On successful return, your function must set this to the null descriptor. See `AEDesc` (page 546).

Return Value

A result code. See "Apple Event Manager Result Codes" (page 636). Your token disposal function should return `noErr` if it successfully disposed of the token and `errAEEventNotHandled` if it can't dispose of the token. When the Apple Event Manager receives the result code `errAEEventNotHandled` after calling a token disposal function, it attempts to use other methods of disposing of the specified token, such as calling an equivalent system token disposal function if one is available or, if that fails, by calling `AEDisposeDesc` (page 424).

Discussion

The Apple Event Manager calls your token disposal function whenever it needs to dispose of a token. It also calls your disposal function when your application calls the `AEDisposeToken` (page 425) function. If your application does not provide a token disposal function, the Apple Event Manager calls `AEDisposeDesc` (page 424) instead.

Your token disposal function must be able to dispose of all of the token types used by your application.

If your application supports marking, a call to `MyDisposeTokenCallback` to dispose of a mark token lets your application know that it can unmark the objects marked with that mark token, as described in the Discussion section for `OSLGetMarkTokenProcPtr` (page 542).

To provide a pointer to your token disposal callback function, you create a universal procedure pointer (UPP) of type `OSLDisposeTokenUPP` (page 561), using the function `NewOSLDisposeTokenUPP` (page 517). You can do so with code like the following:

```
OSLDisposeTokenUPP MyDisposeTokenUPP;
MyDisposeTokenUPP = NewOSLDisposeTokenUPP (&MyDisposeTokenCallback)
```

You can then pass the UPP `MyDisposeTokenUPP` as a parameter to the `AESetObjectCallbacks` (page 480) function or the `AEInstallSpecialHandler` (page 452) function.

If you wish to call your token disposal callback function directly, you can use the `InvokeOSLDisposeTokenUPP` (page 512) function.

After you are finished with your token disposal callback function, you can dispose of the UPP with the `DisposeOSLDisposeTokenUPP` (page 506) function. However, if you will use the same token disposal function in subsequent calls to the function `AESetObjectCallbacks` or the function `AEInstallSpecialHandler`, you can reuse the same UPP, rather than dispose of it and later create a new UPP.

Version Notes
In Mac OS X, your application can not make an object callback function available to other applications by installing it in a system object accessor dispatch table.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEObjects.h`

OSLGetErrDescProcPtr

Defines a pointer to an error descriptor callback function. Your error descriptor callback function supplies a pointer to an address where the Apple Event Manager can store the current descriptor if an error occurs during a call to the `AEResolve` function.

```
typedef OSErr (*OSLGetErrDescProcPtr)
(
    AEDesc ** appDescPtr
);
```

If you name your function `MyGetErrorDescCallback`, you would declare it like this:

```
OSErr MyGetErrorDescCallback (
    AEDesc ** appDescPtr
);
```

Parameters

appDescPtr

A pointer to a pointer to a descriptor address. Your error descriptor callback function supplies a pointer to an address of a descriptor where the Apple Event Manager can store the current descriptor if an error occurs. See `AEDesc` (page 546).

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636). Your error descriptor function should return `noErr` if it completes successfully and a nonzero error value if it is unsuccessful. If it returns a nonzero value, the Apple Event Manager continues to resolve the object specifier as if it had never called the error callback function.

Discussion
Your get error descriptor callback function simply supplies a pointer to an address. Shortly after your application calls the `AEResolve` (page 473) function, the Apple Event Manager calls your get error descriptor callback function and writes a null descriptor to the address supplied by your callback, overwriting whatever was there previously.

If an error occurs during the resolution of the object specifier, the Apple Event Manager calls your get error descriptor callback function again and writes the descriptor it is currently working with—often an object specifier—to the address supplied by your callback. If `AEResolve` returns an error during the resolution of an object specifier, this address contains the descriptor responsible for the error.

You should always write a null descriptor at the address provided by your get error descriptor callback function before calling `AEResolve`. When recovering from an error, the Apple Event Manager, never writes to the address you provide unless it already contains a null descriptor. You may wish to maintain a single global variable of type `AEDesc` and have your get error descriptor callback function always provide the address of that variable.

After `AEResolve` returns, if your error descriptor is not the null descriptor, you are responsible for disposing of it.

To provide a pointer to your get error descriptor callback function, you create a universal procedure pointer (UPP) of type `OSLGetErrDescUPP` (page 562), using the function `NewOSLGetErrDescUPP` (page 518). You can do so with code like the following:

```
OSLGetErrorDescUPP MyGetErrorDescUPP;
MyGetErrorDescUPP = NewOSLGetErrorDescUPP (&MyGetErrorDescCallback)
```

You can then pass the UPP `MyGetErrorDescUPP` as a parameter to the `AESetObjectCallbacks` (page 480) function or the `AEInstallSpecialHandler` (page 452) function.

If you wish to call your get error descriptor callback function directly, you can use the `InvokeOSLGetErrDescUPP` (page 512) function.

After you are finished with your get error descriptor callback function, you can dispose of the UPP with the `DisposeOSLGetErrDescUPP` (page 506) function. However, if you will use the same get error descriptor callback function in subsequent calls to the function `AESetObjectCallbacks` or the function `AEInstallSpecialHandler`, you can reuse the same UPP, rather than dispose of it and later create a new UPP.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEObjects.h`

OSLGetMarkTokenProcPtr

Defines a pointer to a mark token callback function. Your mark token function returns a mark token.

```
typedef OSErr (*OSLGetMarkTokenProcPtr)
(
    const AEDesc * dContainerToken,
    DescType containerClass,
    AEDesc * result
);
```

If you name your function `MyGetMarkTokenCallback`, you would declare it like this:

```
OSErr MyGetMarkTokenCallback (
    const AEDesc * dContainerToken,
    DescType containerClass,
    AEDesc * result
);
```

Parameters

dContainerToken

A pointer to the Apple event object that contains the elements to be marked with the mark token. (Token is defined in AEDisposeToken (page 425). See AEDesc (page 546).

containerClass

The object class of the container that contains the objects to be marked. See DescType (page 560).

result

A pointer to a descriptor where your mark token function should return a mark token. If your function can't return a mark token, it should return a null descriptor. See AEDesc (page 546).

Return Value

A result code. See "Apple Event Manager Result Codes" (page 636). Your mark token function should return noErr if it successfully supplies a mark token and errAEEventNotHandled if it fails to supply a mark token. When the Apple Event Manager gets an error result of errAEEventNotHandled after calling a mark token function, it attempts to get a mark token by calling the equivalent system marking callback function.

Discussion

To get a mark token, the Apple Event Manager calls your mark token function. Like other tokens, the mark token returned can be a descriptor of any type; however, unlike other tokens, a mark token identifies the way your application will mark Apple event objects during the current session while resolving a single object specifier that specifies the key form formTest.

A mark token is valid until the Apple Event Manager either disposes of it by calling AEDisposeToken (page 425) or returns it as the result of the AEResolve (page 473) function. If the final result of a call to AEResolve is a mark token, the Apple event objects currently marked for that mark token are those specified by the object specifier passed to AEResolve, and your application can proceed to do whatever the Apple event has requested. Note that your application is responsible for disposing of a final mark token with a call to AEDisposeToken, just as for any other final token.

If your application supports marking, it should also provide a token disposal function modeled after the token disposal function described in OSLDisposeTokenProcPtr (page 539). When the Apple Event Manager calls AEDisposeToken to dispose of a mark token that is not the final result of a call to AEResolve, the subsequent call to your token disposal function lets you know that you can unmark the Apple event objects marked with that mark token. A call to AEDisposeDesc to dispose of a mark token (which would occur if you did not provide a token disposal function) would go unnoticed.

To provide a pointer to your mark token callback function, you create a universal procedure pointer (UPP) of type OSLGetMarkTokenUPP (page 562), using the function NewOSLGetMarkTokenUPP (page 518). You can do so with code like the following:

```
OSLGetMarkTokenUPP MyGetMarkTokenUPP;
MyGetMarkTokenUPP = NewOSLGetMarkTokenUPP (&MyGetMarkTokenCallback)
```

You can then pass the UPP MyGetMarkTokenUPP as a parameter to the AESetObjectCallbacks (page 480) function or the AEInstallSpecialHandler (page 452) function.

If you wish to call your mark token callback function directly, you can use the InvokeOSLGetMarkTokenUPP (page 513) function.

After you are finished with your mark token callback function, you can dispose of the UPP with the DisposeOSLGetMarkTokenUPP (page 506) function. However, if you will use the same mark token function in subsequent calls to the function AESetObjectCallbacks or the function AEInstallSpecialHandler, you can reuse the same UPP, rather than dispose of it and later create a new UPP.

Availability
Available in Mac OS X v10.0 and later.

Declared In
AEObjects.h

OSLMarkProcPtr

Defines a pointer to an object marking callback function. Your object-marking function marks a specific Apple event object.

```
typedef OSErr (*OSLMarkProcPtr) (
    const AEDesc * dToken,
    const AEDesc * markToken,
    long index
);
```

If you name your function MyMarkCallback, you would declare it like this:

```
OSErr MyMarkCallback (
    const AEDesc * dToken,
    const AEDesc * markToken,
    long index
);
```

Parameters

dToken

A pointer to the token for the Apple event object to be marked. (Token is defined in AEDisposeToken (page 425). See AEDesc (page 546).

markToken

A pointer to the mark token used to mark the Apple event object. See AEDesc (page 546).

index

The number of times your MyMarkCallback function has been called for the current mark token (that is, the number of Apple event objects that have so far passed the test, including the element to be marked).

Return Value
A result code. See "Apple Event Manager Result Codes" (page 636). Your object marking function should return noErr if it successfully marks the Apple event object and errAEEventNotHandled if it fails to mark the object. When the Apple Event Manager gets an error result of errAEEventNotHandled after calling an object marking function, it attempts to get mark the object by calling the equivalent system object marking function.

Discussion
To mark an Apple event object using the current mark token, the Apple Event Manager calls the object-marking function provided by your application. In addition to marking the specified object, your MyMarkCallback function should record the mark count for each object that it marks. The mark count recorded for each marked object allows your application to determine which of a set of marked tokens pass a test, as described in the Discussion section for the OSLAdjustMarksProcPtr (page 535) function.

To provide a pointer to your mark callback function, you create a universal procedure pointer (UPP) of type OSLMarkUPP (page 562), using the function NewOSLMarkUPP (page 518). You can do so with code like the following:

```
OSLMarkUPP MyMarkUPP;
MyMarkUPP = NewOSLMarkUPP (&MyMarkCallback)
```

You can then pass the UPP `MyMarkUPP` as a parameter to the `AESetObjectCallbacks` (page 480) function or the `AEInstallSpecialHandler` (page 452) function.

If you wish to call your mark callback function directly, you can use the `InvokeOSLMarkUPP` (page 513) function.

After you are finished with your mark callback function, you can dispose of the UPP with the `DisposeOSLMarkUPP` (page 507) function. However, if you will use the same mark function in subsequent calls to the function `AESetObjectCallbacks` or the function `AEInstallSpecialHandler`, you can reuse the same UPP, rather than dispose of it and later create a new UPP.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEObjects.h`

Data Types

AEArrayData

Stores array information to be put into a descriptor list with the `AEPutArray` function or extracted from a descriptor list with the `AEGetArray` function.

```
union AEArrayData {
    short kAEDataArray[1];
    char kAEPackedArray[1];
    Handle kAEHandleArray[1];
    AEDesc kAEDescArray[1];
    AEKeyDesc kAEKeyDescArray[1];
};
typedef union AEArrayData AEArrayData;
```

Discussion
When your application calls the `AEPutArray` (page 459) function to put information into a descriptor list or the `AEGetArray` (page 428) function to get information from a descriptor list, it uses an to store the information. The type of array depends on the data for the array, as specified by one of the constants described in "Data Array Constants" (page 580).

Array items in Apple event arrays of type `kAEDataArray`, `kAEPackedArray`, or `kAEHandleArray` must be factored—that is, contained in a factored descriptor list. Before adding array items to a factored descriptor list, you should provide both a pointer to the data that is common to all array items and the size of that common data when you first call `AECreateList` (page 419) to create a factored descriptor list. When you call `AEPutArray` to add the array data to such a descriptor list, the Apple Event Manager automatically isolates the common data you specified in the call to `AECreateList`.

When you call `AEGetArray` or `AEPutArray`, you specify a pointer of data type `AEArrayDataPointer` that points to a buffer containing the data for the array.

Availability
Available in Mac OS X v10.0 and later.

Declared In
AEDataModel.h

AEBuildError

Defines a structure for storing additional error code information for "AEBuild" routines.

```
struct AEBuildError {
    AEBuildErrorCode fError;
    UInt32 fErrorPos;
};
typedef struct AEBuildError AEBuildError;
```

Fields

`fError`
The error code. See "AEBuild Error Codes" (page 563) for a list of errors.

`fErrorPos`
The character position where the parser detected the error.

Availability
Available in Mac OS X v10.0 and later.

Declared In
AEHelpers.h

AEDesc

Stores data and an accompanying descriptor type to form the basic building block of all Apple Events.

```
struct AEDesc {
    DescType descriptorType;
    AEDataStorage dataHandle;
};
typedef struct AEDesc AEDesc;
```

Fields

`descriptorType`
A four-character code of type `DescType` (page 560) that indicates the type of data in the structure. See `DescType` (page 560).

`dataHandle`
An opaque storage type that points to the storage for the descriptor data. Your application doesn't access this data directly—rather, it calls one of the functions `AEGetDescDataSize` (page 434), `AEGetDescData` (page 432), or `AEReplaceDescData` (page 472). See `AEDataStorage` (page 553).

Discussion
The Apple Event Manager uses one or more descriptors to construct Apple event attributes and parameters, object specifiers, tokens, and many other types of data it works with. (Token is defined in `AEDisposeToken` (page 425).) A descriptor consists of an opaque data storage container and a descriptor type that identifies the type of the data stored in the descriptor.

The descriptor type is a structure of type `DescType`, which in turn is of data type `ResType`—that is, a four-character code. "Descriptor Type Constants" (page 581) lists the constants for the basic descriptor types used by the Apple Event Manager. For information about descriptor types used with object specifiers, see "Key Form and Descriptor Type Object Specifier Constants" (page 590).

Version Notes
Prior to Carbon, the `AEDataStorage` (page 553) data type was defined as follows:

```
typedef Handle AEDataStorage;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

AEKeyDesc

Associates a keyword with a descriptor to form a keyword-specified descriptor.

```
struct AEKeyDesc {
    AEKeyword descKey;
    AEDesc descContent;
};
typedef struct AEKeyDesc AEKeyDesc;
```

Fields

`descKey`
A four-character code of type `AEKeyword` (page 556) that uniquely identifies the key that is associated with the data in the structure. Some keyword constants are described in "Keyword Attribute Constants" (page 593) and "Keyword Parameter Constants" (page 595). See `AEKeyword` (page 556).

`descContent`
A descriptor of type `AEDesc` (page 546) that stores the keyword descriptor data. See `AEDesc` (page 546).

Discussion
The Apple Event Manager uniquely identifies the various parts of an Apple event by means of keywords associated with corresponding descriptors. A keyword is an arbitrary constant of type `AEKeyword` (page 556) that represents a four-character code.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

AERemoteProcessResolverContext

Supplied as a parameter when performing asynchronous resolution of remote processes.

```
struct AERemoteProcessResolverContext {
    CFIndex version;
    void * info;
    CFAllocatorRetainCallBack retain;
    CFAllocatorReleaseCallBack release;
    CFAllocatorCopyDescriptionCallBack copyDescription;
};
typedef struct AERemoteProcessResolverContext AERemoteProcessResolverContext;
```

Fields

`version`
: This should be set to zero (0).

`info`
: A pointer to arbitrary information. The pointer is retained and passed to the callback, allowing you to provide information to that routine.

`retain`
: A prototype for a function callback that retains the specified data. Called on the info pointer. This field may be `NULL`.

`release`
: A prototype for a function callback that releases the specified data. Called on the info pointer. This field may be `NULL`.

`copyDescription`
: A prototype for a function callback that provides a description of the specified data. Called on the info pointer. This field may be `NULL`.

Discussion

When you call `AERemoteProcessResolverScheduleWithRunLoop` (page 467) for asynchronous resolution, you supply a reference to a structure of this type, along with a reference to a callback routine, defined by `AERemoteProcessResolverCallback` (page 532). The context is copied and the info pointer retained. When the callback is made, the info pointer is passed to the callback.

Availability

Available in Mac OS X v10.3 and later.

Declared In

`AppleEvents.h`

ccntTokenRecord

Stores token information used by the AEResolve function while locating a range of objects.

```
struct ccntTokenRecord {
    DescType tokenClass;
    AEDesc token;
};
typedef struct ccntTokenRecord ccntTokenRecord;
```

Fields

`tokenClass`
: The class ID of the container represented by the `token` parameter. See `DescType` (page 560).

`token`
: A token for the current container. (Token is defined in `AEDisposeToken` (page 425). See `AEDesc` (page 546).

Discussion
When the `AEResolve` (page 473) function calls an object accessor function to locate a range of objects, the Apple Event Manager replaces the descriptor of type `typeCurrentContainer` with a token for the container of each boundary object. When using `AEResolve` to resolve the object specifier, your application doesn't need to examine the contents of this token, because the Apple Event Manager keeps track of it.

If your application attempts to resolve some or all of the object specifier without calling `AEResolve`, the application may need to examine the token before it can locate the boundary objects. The token provided by the Apple Event Manager for a boundary object's container is a descriptor of type `typeToken` whose data storage pointer refers to a structure of type `ccntTokenRecord`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEObjects.h`

IntlText

International text consists of an ordered series of bytes, beginning with a 4-byte language code and a 4-byte script code that together determine the format of the bytes that follow. (**Deprecated.** Use Unicode text instead.)

```
struct IntlText {
    ScriptCode theScriptCode;
    LangCode theLangCode;
    char theText[1];
};
typedef struct IntlText IntlText;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AERegistry.h`

OffsetArray

Specifies offsets of ranges of text. Not typically used by developers.

```
struct OffsetArray {
    sort fNumOfOffsets;
    long fOffset[1];
};
typedef struct OffsetArray OffsetArray;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AERegistry.h`

TextRange

Specifies a range of text. Not typically used by developers.

```
struct TextRange {
    long fStart;
    long fEnd;
    short fHiliteStyle;
};
typedef struct TextRange TextRange;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
AERegistry.h

TextRangeArray

Specifies an array of text ranges. Not typically used by developers.

```
struct TextRangeArray {
    short fNumOfRanges;
    TextRange fRange[1];
};
typedef struct TextRangeArray TextRangeArray;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
AERegistry.h

TScriptingSizeResource

Defines a data type to store stack and heap information. Not typically used by developers.

```
struct TScriptingSizeResource {
    short scriptingSizeFlags;
    unsigned long minStackSize;
    unsigned long preferredStackSize;
    unsigned long maxStackSize;
    unsigned long minHeapSize;
    unsigned long preferredHeapSize;
    unsigned long maxHeapSize;
};
typedef struct TScriptingSizeResource TScriptingSizeResource;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
AEUserTermTypes.h

WritingCode

```
struct WritingCode {
    ScriptCode theScriptCode;
    LangCode theLangCode;
};
typedef struct WritingCode WritingCode;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
AERegistry.h

AEAddressDesc

A descriptor that contains the address of an application. Typically used to describe the target application for an Apple event.

```
typedef AEDesc AEAddressDesc;
```

Discussion
An address descriptor is identical to a descriptor of data type AEDesc (page 546); however, the data for an address descriptor must always consist of the address of an application.

Every Apple event includes an attribute specifying the address of the target application. The address in an address descriptor can be specified as one of these types (or as any other descriptor type you define that can be coerced to one of these types): typeApplSignature, typeSessionID, or typeProcessSerialNumber. These constants are described in "Descriptor Type Constants" (page 581). You can also use "typeApplicationBundleID" (page 628).

If your application sends Apple events to itself using a typeProcessSerialNumber address descriptor with the lowLongOfPSN field set to kCurrentProcess (and the highLongOfPSN field set to 0), the Apple Event Manager jumps directly to the appropriate Apple event handler without going through the normal event-processing sequence.

Availability
Available in Mac OS X v10.0 and later.

Declared In
AEDataModel.h

AEArrayDataPointer

A pointer to a union of type AEArrayData.

```
typedef AEArrayData * AEArrayDataPointer
```

Discussion
This data type merely defines a pointer to an AEArrayData (page 545) union.

AEArrayType

Stores a value that specifies an array type.

```
typedef SInt8 AEArrayType;
```

Discussion
You use this data type with the `AEGetArray` (page 428) function and the `AEPutArray` (page 459) function to specify an array type, using one of the constants from "Data Array Constants" (page 580).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

AECoerceDescUPP

Defines a data type for the universal procedure pointer for the `AECoerceDescProcPtr` callback function pointer.

```
typedef AECoerceDescProcPtr AECoerceDescUPP;
```

Discussion
For a description of a coerce descriptor callback function, see `AECoerceDescProcPtr` (page 524).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

AECoercePtrUPP

Defines a data type for the universal procedure pointer for the `AECoercePtrProcPtr` callback function pointer.

```
typedef AECoercePtrProcPtr AECoercePtrUPP;
```

Discussion
For a description of a coerce pointer callback function, see `AECoercePtrProcPtr` (page 525).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

AECoercionHandlerUPP

Defines a data type for the universal procedure pointer for the `AECoercionHandlerUPP` callback function pointer.

```
typedef AECoerceDescUPP AECoercionHandlerUPP;
```

Discussion
For a description of a coercion handler callback function, see `AECoercePtrProcPtr` (page 525).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

AEDataStorage

A pointer to an opaque data type that provides storage for an `AEDesc` descriptor.

```
typedef AEStorageDataType * AEDataStorage;
```

Discussion
The Apple Event Manager defines the `AEDataStorage` data type to serve as a data storage field in the `AEDesc` (page 546) structure. Your application doesn't access the data pointed to by a data storage pointer directly. Rather, you work with the following functions:

- `AEGetDescDataSize` (page 434)
- `AEGetDescData` (page 432)
- `AEGetDescDataRange` (page 433)
- `AEReplaceDescData` (page 472)

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

AEDataStorageType

An opaque data type used to store data in Apple event descriptors.

```
typedef struct OpaqueAEDataStorageType * AEDataStorageType;
```

Discussion
See `AEDesc` (page 546) for related information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

AEDescList

A descriptor whose data consists of a list of one or more descriptors.

```
typedef AEDesc AEDescList;
```

Discussion
A descriptor list is identical to a descriptor of data type `AEDesc` (page 546) —the only difference is that the data in a descriptor list must always consist of a list of other descriptors.

Descriptor lists are a key building block of Apple events. Many Apple Event Manager functions take or return lists of descriptors in descriptor lists. For example, see the functions described in "Counting the Items in Descriptor Lists" (page 398) and "Getting Items From Descriptor Lists" (page 403).

The format of the data in the `dataHandle` of the descriptor is private. You can only operate on the contained elements with Apple Event Manager functions, including those described in "Counting the Items in Descriptor Lists" (page 398) and "Getting Items From Descriptor Lists" (page 403).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

AEEventSource

A data type for values that specify how an Apple event was delivered.

```
typedef SInt8 AEEventSource;
```

Discussion
"Event Source Constants" (page 588) lists the valid constant values for a variable or parameter of type `AEEventSource`.

You might use a variable of this type, for example, to get the source type of an Apple event by calling the function `AEGetAttributePtr` (page 430). You pass the `keyEventSourceAttr` constant as the value for the `theAEKeyWord` parameter and you pass a pointer to a variable of type `AEEventSource` for the `dataPtr` parameter. On return, the variable will contain one of the event source constant values described in "Event Source Constants" (page 588). The complete call looks like the following:

```
AppleEvent       theAppleEvent; // previously obtained Apple event
DescType         returnedType;
AEEventSource    sourceOfAE;
Size             actualSize;
OSErr            myErr;
myErr = AEGetAttributePtr(theAppleEvent,
                          keyEventSourceAttr,
                          typeShortInteger,
                          &returnedType,
                          (void *) &sourceOfAE,
                          sizeof (sourceOfAE),
                          &actualSize);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AppleEvents.h`

AEDisposeExternalUPP

Defines a universal procedure pointer to a function the Apple Event Manager calls to dispose of a descriptor created by the `AECreateDescFromExternalPtr` function.

```
typedef AEDisposeExternalProcPtr AEDisposeExternalUPP;
```

Discussion
See the `AEDisposeExternalProcPtr` (page 527) callback function.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`AEDataModel.h`

AEEventClass

Specifies the event class of an Apple event.

```
typedef FourCharCode AEEventClass;
```

Discussion
Apple events are identified by their event class and event ID attributes. The event class is the attribute that identifies a group of related Apple events. When you call the `AEProcessAppleEvent` (page 457) function, the Apple Event Manager uses these attributes to identify a handler for a specific Apple event.

For more information on Apple event classes, see "Event Class Constants" (page 585).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

AEEventHandlerUPP

Defines a data type for the universal procedure pointer for the `AEEventHandlerUPP` callback function pointer.

```
typedef AEEventHandlerProcPtr AEEventHandlerUPP;
```

Discussion
For a description of an event handler callback function, see `AEEventHandlerProcPtr` (page 528).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

AEEventID

Specifies the event ID of an Apple event.

```
typedef FourCharCode AEEventID;
```

Discussion
Apple events are identified by their event class and event ID attributes. The event ID is the attribute that identifies a particular Apple event within its event class. In conjunction with the event class, the event ID uniquely identifies the Apple event and communicates what action the Apple event should perform.

For more information on Apple event IDs, see "Event ID Constants" (page 586).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

AEFilterUPP

Defines a data type for the universal procedure pointer for the `AEFilterProcPtr` callback function pointer.

```
typedef AEFilterProcPtr AEFilterUPP;
```

Discussion
For a description of a filter callback function, see `AEFilterProcPtr` (page 530).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEInteraction.h`

AEIdleUPP

Defines a data type for the universal procedure pointer for the `AEIdleProcPtr` callback function pointer.

```
typedef AEIdleProcPtr AEIdleUPP;
```

Discussion
For a description of an idle callback function, see `AEIdleProcPtr` (page 531).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEInteraction.h`

AEKeyword

A four-character code that uniquely identifies a descriptor in an Apple event record or an Apple event.

```
typedef FourCharCode AEKeyword;
```

Discussion
The Apple Event Manager uniquely identifies the various parts of an Apple event by means of keywords associated with corresponding descriptors. Keywords are arbitrary names, stored as four-character codes of type `AEKeyword`. A keyword combined with a descriptor forms a keyword-specified descriptor, which is defined by a data structure of type `AERemoteProcessResolverContext` (page 547).

The Apple Event Manager also uses keywords for Apple event attributes. Keyword constants used by the Apple Event Manager are defined in "Keyword Attribute Constants" (page 593) and "Keyword Parameter Constants" (page 595).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

AERecord

A descriptor whose data is a list of keyword-specified descriptors.

```
typedef AEDescList AERecord;
```

Discussion
The Apple Event Manager provides routines that allow your application to create Apple event records and extract data from them when creating or responding to Apple events. You also work with Apple event records if your application resolves or creates object specifiers. Functions that use Apple event records are described in "Getting Data or Descriptors From Apple Events and Apple Event Records" (page 402) and "Adding Parameters and Attributes to Apple Events and Apple Event Records" (page 398).

The descriptor list of keyword-specified descriptors in an Apple event record must specify Apple event parameters—they cannot specify Apple event attributes. Only descriptor lists of type Apple event can contain both attributes and parameters.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

AERemoteProcessResolverRef

An opaque reference to an object that encapsulates the mechanism for obtaining a list of processes running on a remote machine.

```
typedef AERemoteProcessResolver * AERemoteProcessResolverRef;
```

Discussion
You create an instance of `AERemoteProcessResolverRef` by calling `AECreateRemoteProcessResolver` (page 420), and you must disposed of it by calling `AEDisposeRemoteProcessResolver` (page 424). An instance of this type is not a CFType (the base type used by all Core Foundation derived opaque types). For more information, see Core Foundation Reference Documentation.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`AppleEvents.h`

AEReturnID

Specifies a return ID for a created Apple event.

```
typedef SInt16 AEReturnID;
```

Discussion
When you call the `AECreateAppleEvent` (page 416) function, you pass a value of type `AEReturnID` for the `returnID` parameter. "ID Constants for the AECreateAppleEvent Function" (page 589) lists the valid constant values for a variable or parameter of this type.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

AESendOptions

This data type is not available. (**Deprecated.** Not available in Apple Event Manager API.)

```
typedef OptionBits AESendOptions;
```

AESendPriority

Specifies the processing priority for a sent Apple event.

```
typedef SInt16 AESendPriority;
```

Discussion
When you call the `AESend` (page 476) function, you pass a value of type `AESendPriority` for the `sendPriority` parameter. "Priority Constants for the AESend Function (Deprecated in Mac OS X)" (page 601) lists the valid constant values for a variable or parameter of this type.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

AEStreamRef

An opaque data structure for storing stream-based descriptor data.

```
typedef struct OpaqueAEStreamRef * AEStreamRef;
```

Discussion
You create `AEStreamRef` objects and manipulate their contents using the "AEStream" routines found in the section "Creating Apple Event Structures Using Streams" (page 406)

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEHelpers.h`

AETransactionID

Specifies a transaction ID.

```
typedef SInt32 AETransactionID;
```

Discussion
A transaction is a sequence of Apple events that are sent back and forth between the client and server applications, beginning with the client's initial request for a service. When you call the `AECreateAppleEvent` (page 416) function, you pass a value of type `AETransactionID` for the `transactionID` parameter. "ID Constants for the AECreateAppleEvent Function" (page 589) lists the valid constant values for a variable or parameter of this type.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

AppleEvent

A descriptor whose data is a list of descriptors containing both attributes and parameters that make up an Apple event.

```
typedef AERecord AppleEvent;
```

Discussion
The Apple event data type describes a full-fledged Apple event. Like the data for an Apple event record (data type `AERecord` (page 557)), the data for an Apple event consists of a list of keyword-specified descriptors. Unlike an Apple event record, the data for an Apple event is conceptually divided into two parts, one for attributes and one for parameters. This division within the Apple event allows the Apple Event Manager to distinguish between an event's attributes and its parameters.

For additional information on the structure of an Apple event and on how to build one, see "Building an Apple Event" in Apple Events Programming Guide.

Many functions work with Apple events, including the functions described in "Getting Data or Descriptors From Apple Events and Apple Event Records" (page 402), "Adding Parameters and Attributes to Apple Events and Apple Event Records" (page 398), "Creating an Apple Event" (page 399), and "Sending an Apple Event" (page 405).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

DescType

Specifies the type of the data stored in an `AEDesc` descriptor.

```
typedef ResType DescType;
```

Discussion
A `DescType` data type is a four-character code that stores a value that identifies the data in an `AEDesc` (page 546) descriptor, the basic building block for all Apple events.

The descriptor type constants used by the Apple Event Manager are described in "Descriptor Type Constants" (page 581) and "Key Form and Descriptor Type Object Specifier Constants" (page 590).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEDataModel.h`

OffsetArrayHandle

Defines a data type that points to an `OffsetArray`. Not typically used by developers.

```
typedef OffsetArrayPtr * OffsetArrayHandle;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AERegistry.h`

OSLAccessorUPP

Defines a data type for the universal procedure pointer for the `OSLAccessorProcPtr` callback function pointer.

```
typedef OSLAccessorProcPtr OSLAccessorUPP;
```

Discussion
For a description of an object accessor callback function, see `OSLAccessorProcPtr` (page 533).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEObjects.h`

OSLAdjustMarksUPP

Defines a data type for the universal procedure pointer for the `OSLAdjustMarksProcPtr` callback function pointer.

```
typedef OSLAdjustMarksProcPtr OSLAdjustMarksUPP;
```

Discussion
For a description of an adjust marks callback function, see `OSLAdjustMarksProcPtr` (page 535).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEObjects.h`

OSLCompareUPP

Defines a data type for the universal procedure pointer for the `OSLCompareProcPtr` callback function pointer.

```
typedef OSLCompareProcPtr OSLCompareUPP;
```

Discussion
For a description of a compare callback function, see `OSLCompareProcPtr` (page 536).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEObjects.h`

OSLCountUPP

Defines a data type for the universal procedure pointer for the `OSLCountProcPtr` callback function pointer.

```
typedef OSLCountProcPtr OSLCountUPP;
```

Discussion
For a description of a count callback function, see `OSLCountProcPtr` (page 538).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEObjects.h`

OSLDisposeTokenUPP

Defines a data type for the universal procedure pointer for the `OSLDisposeTokenProcPtr` callback function pointer.

```
typedef OSLDisposeTokenProcPtr OSLDisposeTokenUPP;
```

Discussion
For a description of a dispose token callback function, see `OSLDisposeTokenProcPtr` (page 539).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEObjects.h`

OSLGetErrDescUPP

Defines a data type for the universal procedure pointer for the `OSLGetErrDescProcPtr` callback function pointer.

```
typedef OSLGetErrDescProcPtr OSLGetErrDescUPP;
```

Discussion
For a description of a get error descriptor callback function, see `OSLGetErrDescProcPtr` (page 541).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEObjects.h`

OSLGetMarkTokenUPP

Defines a data type for the universal procedure pointer for the `OSLGetMarkTokenProcPtr` callback function pointer.

```
typedef OSLGetMarkTokenProcPtr OSLGetMarkTokenUPP;
```

Discussion
For a description of a mark token callback function, see `OSLGetMarkTokenProcPtr` (page 542).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEObjects.h`

OSLMarkUPP

Defines a data type for the universal procedure pointer for the `OSLMarkProcPtr` callback function pointer.

```
typedef OSLMarkProcPtr OSLMarkUPP;
```

Discussion
For a description of a mark callback function, see `OSLMarkProcPtr` (page 544).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEObjects.h`

AEInteractAllowed

Specifies an interaction level.

```
typedef SInt8 AEInteractAllowed;
```

Discussion
When you call the `AEGetInteractionAllowed` (page 436) function or the `AESetInteractionAllowed` (page 479) function, you receive or pass a value of type `AEInteractAllowed` for the `level` parameter. Interaction levels are described and the valid interaction level constants are listed in "User Interaction Level Constants" (page 605).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AEInteraction.h`

Constants

AEBuild Error Codes

Represents syntax errors found by an "AEBuild" routine.

```
typedef UInt32 AEBuildErrorCode;
enum {
aeBuildSyntaxNoErr = 0,
aeBuildSyntaxBadToken = 1,
aeBuildSyntaxBadEOF = 2,
aeBuildSyntaxNoEOF = 3,
aeBuildSyntaxBadNegative = 4,
aeBuildSyntaxMissingQuote = 5,
aeBuildSyntaxBadHex = 6,
aeBuildSyntaxOddHex = 7,
aeBuildSyntaxNoCloseHex = 8,
aeBuildSyntaxUncoercedHex = 9,
aeBuildSyntaxNoCloseString = 10,
aeBuildSyntaxBadDesc = 11,
aeBuildSyntaxBadData = 12,
aeBuildSyntaxNoCloseParen = 13,
aeBuildSyntaxNoCloseBracket = 14,
aeBuildSyntaxNoCloseBrace = 15,
aeBuildSyntaxNoKey = 16,
aeBuildSyntaxNoColon = 17,
aeBuildSyntaxCoercedList = 18,
aeBuildSyntaxUncoercedDoubleAt = 19
};
```

Constants

`aeBuildSyntaxNoErr`
No error.

Available in Mac OS X v10.0 and later.

Declared in `AEHelpers.h`.

`aeBuildSyntaxBadToken`
An illegal character was specified.

Available in Mac OS X v10.0 and later.

Declared in `AEHelpers.h`.

`aeBuildSyntaxBadEOF`
An unexpected end of format string was encountered.

Available in Mac OS X v10.0 and later.

Declared in `AEHelpers.h`.

`aeBuildSyntaxNoEOF`
There were unexpected characters beyond the end of the format string.

Available in Mac OS X v10.0 and later.

Declared in `AEHelpers.h`.

`aeBuildSyntaxBadNegative`
A minus sign “-” was not followed by digits.

Available in Mac OS X v10.0 and later.

Declared in `AEHelpers.h`.

`aeBuildSyntaxMissingQuote`
A string was not terminated by a closing quotation mark.

Available in Mac OS X v10.0 and later.

Declared in `AEHelpers.h`.

`aeBuildSyntaxBadHex`
A hex string contained characters other than hexadecimal digits.
Available in Mac OS X v10.0 and later.
Declared in `AEHelpers.h`.

`aeBuildSyntaxOddHex`
A hex string contained an odd number of digits.
Available in Mac OS X v10.0 and later.
Declared in `AEHelpers.h`.

`aeBuildSyntaxNoCloseHex`
A hex string was missing a "$" or "»" character.
Available in Mac OS X v10.0 and later.
Declared in `AEHelpers.h`.

`aeBuildSyntaxUncoercedHex`
A hex string must be coerced to a type.
Available in Mac OS X v10.0 and later.
Declared in `AEHelpers.h`.

`aeBuildSyntaxNoCloseString`
A string was missing a closing quote.
Available in Mac OS X v10.0 and later.
Declared in `AEHelpers.h`.

`aeBuildSyntaxBadDesc`
An illegal descriptor was specified.
Available in Mac OS X v10.0 and later.
Declared in `AEHelpers.h`.

`aeBuildSyntaxBadData`
Bad data was found inside a variable argument list.
Available in Mac OS X v10.0 and later.
Declared in `AEHelpers.h`.

`aeBuildSyntaxNoCloseParen`
A data value was missing a closing parenthesis.
Available in Mac OS X v10.0 and later.
Declared in `AEHelpers.h`.

`aeBuildSyntaxNoCloseBracket`
A comma or closing bracket "]" was expected.
Available in Mac OS X v10.0 and later.
Declared in `AEHelpers.h`.

`aeBuildSyntaxNoCloseBrace`
A comma or closing brace "}" was expected.
Available in Mac OS X v10.0 and later.
Declared in `AEHelpers.h`.

`aeBuildSyntaxNoKey`
A keyword was missing from a descriptor.

Available in Mac OS X v10.0 and later.

Declared in `AEHelpers.h`.

`aeBuildSyntaxNoColon`
In a descriptor, one of the keywords was not followed by a colon.

Available in Mac OS X v10.0 and later.

Declared in `AEHelpers.h`.

`aeBuildSyntaxCoercedList`
Cannot coerce a list.

Available in Mac OS X v10.0 and later.

Declared in `AEHelpers.h`.

`aeBuildSyntaxUncoercedDoubleAt`
You must coerce a "@@" substitution.

Available in Mac OS X v10.0 and later.

Declared in `AEHelpers.h`.

AESendMode

Specify send preferences to the `AESend` function.

```
typedef SInt32 AESendMode;
enum {
    kAENoReply = 0x00000001,
    kAEQueueReply = 0x00000002,
    kAEWaitReply = 0x00000003,
    kAEDontReconnect = 0x00000080,
    kAEWantReceipt = 0x00000200,
    kAENeverInteract = 0x00000010,
    kAECanInteract = 0x00000020,
    kAEAlwaysInteract = 0x00000030,
    kAECanSwitchLayer = 0x00000040,
    kAEDontRecord = 0x00001000,
    kAEDontExecute = 0x00002000,
    kAEProcessNonReplyEvents = 0x00008000
};
```

Constants

`kAENoReply`
The reply preference—your application does not want a reply Apple event. If you set the bit specified by this constant, the server processes the Apple event as soon as it has the opportunity.

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

`kAEQueueReply`

The reply preference—your application wants a reply Apple event. If you set the bit specified by this constant, the reply appears in your event queue as soon as the server has the opportunity to process and respond to your Apple event.

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

`kAEWaitReply`

The reply preference—your application wants a reply Apple event and is willing to give up the processor while waiting for the reply. For example, if the server application is on the same computer as your application, your application yields the processor to allow the server to respond to your Apple event.

If you set the bit specified by this constant, you must provide an idle function. This function should process any update events, null events, operating-system events, or activate events that occur while your application is waiting for a reply. For more information on idle routines, see `AEInteractWithUser` (page 453).

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

`kAEDontReconnect`

Deprecated and unsupported in Mac OS X. The reconnection preference—the Apple Event Manager must not automatically try to reconnect if it receives a `sessClosedErr` result code from the PPC Toolbox. If you don't set this flag, the Apple Event Manager automatically attempts to reconnect and reestablish the session.

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

`kAEWantReceipt`

Deprecated and unsupported in Mac OS X. The return receipt preference—the sender wants to receive a return receipt for this Apple event from the Event Manager. (A return receipt means only that the receiving application accepted the Apple event the Apple event may or may not be handled successfully after it is accepted.) If the receiving application does not send a return receipt before the request times out, `AESend` returns `errAETimeout` as its function result.

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

`kAENeverInteract`

The user interaction preference—the server application should never interact with the user in response to the Apple event. If you set the bit specified by this constant, the `AEInteractWithUser` (page 453) function (when called by the server) returns the `errAENoUserInteraction` result code. When you send an Apple event to a remote application, the default is to set this bit.

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

`kAECanInteract`

The user interaction preference—the server application can interact with the user in response to the Apple event. By convention, you set the bit specified by this constant if the user needs to supply information to the server. If you set the bit and the server allows interaction, the `AEInteractWithUser` (page 453) function either brings the server application to the foreground or posts a notification request. When you send an Apple event to a local application, the default is to set this bit.

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

`kAEAlwaysInteract`

The user interaction preference—the server application should always interact with the user in response to the Apple event. By convention, you set the bit specified by this constant whenever the server application normally asks a user to confirm a decision or interact in any other way, even if no additional information is needed from the user. If you set the bit specified by this constant, the `AEInteractWithUser` (page 453) function either brings the server application to the foreground or posts a notification request.

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

`kAECanSwitchLayer`

The application switch preference—if both the client and server allow interaction, and if the client application is the active application on the local computer and is waiting for a reply (that is, it has set the `kAEWaitReply` flag), `AEInteractWithUser` brings the server directly to the foreground. Otherwise, `AEInteractWithUser` uses the Notification Manager to request that the user bring the server application to the foreground.

You should specify the `kAECanSwitchLayer` flag only when the client and server applications reside on the same computer. In general, you should not set this flag if it would be confusing or inconvenient to the user for the server application to come to the front unexpectedly. This flag is ignored if you are sending an Apple event to a remote computer.

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

`kAEDontRecord`

The recording preference—your application is sending an event to itself but does not want the event recorded. When Apple event recording is on, the Apple Event Manager records a copy of every event your application sends to itself except for those events for which this flag is set.

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

`kAEDontExecute`

The execution preference—your application is sending an Apple event to itself for recording purposes only—that is, you want the Apple Event Manager to send a copy of the event to the recording process but you do not want your application actually to receive the event.

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

`kAEProcessNonReplyEvents`

Allow processing of non-reply Apple events while awaiting a synchronous Apple event reply (you specified `kAEWaitReply` for the reply preference).

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

Discussion
You use these constants with the `sendMode` parameter to the `AESend` (page 476) function to specify how the server application should handle the reply mode, the interaction level, the application switch mode, the reconnection mode, the return receipt mode, the recording mode, and whether to process non-reply Apple events. To obtain a value for this parameter, you add together constants to set the appropriate bits for the Apple event you are about to send. The following paragraphs provide additional information about how you use these constants.

You can set only one flag reply preference (`kAENoReply`, `kAEQueueReply`, or `kAEWaitReply`), one user interaction preference (`kAENeverInteract`, `kAECanInteract`, or `kAEAlwaysInteract`), and one recording and execution preference (`kAEDontRecord` or `kAEDontExecute`).

Before the Apple Event Manager sends a reply event back to the client application, the `keyAddressAttr` attribute contains the address of the client application. After the client receives the reply event, the `keyAddressAttr` attribute contains the address of the server application.

If you specify `kAEWaitReply`, the Apple Event Manager uses the Event Manager to send the event. The Apple Event Manager then calls the `WaitNextEvent` function on behalf of your application, causing your application to yield the processor and giving the server application a chance to receive and handle the Apple event. Your application continues to yield the processor until the server handles the Apple event or the request times out.

Specify the `kAEWantReceipt` flag if your application wants notification that the server application has accepted the Apple event. If you specify this flag, your application receives a return receipt as a high-level event.

If you specify the `kAEWantReceipt` flag and the server application does not accept the Apple event within the time specified by the `timeOutInTicks` parameter to `AESend`, the `AESend` function returns a timeout error. Note that `AESend` also returns a timeout error if your application sets the `kAEWaitReply` flag and does not receive the reply Apple event within the time specified by the `timeOutInTicks` parameter.

You use one of the three flags—`kAENeverInteract`, `kAECanInteract`, and `kAEAlwaysInteract`—to specify whether the server should interact with the user when handling the Apple event. Specify `kAENeverInteract` if the server should not interact with the user when handling the Apple event. You might specify this constant if you don't want the user to be interrupted while the server is handling the Apple event.

Use the `kAECanInteract` flag if the server should interact with the user when the user needs to supply information to the server. Use the `kAEAlwaysInteract` flag if the server should interact with the user whenever the server normally asks a user to confirm a decision or interact in any other way, even if no additional information is needed from the user. Note that it is the responsibility of the server and client applications to agree on how to interpret the `kAEAlwaysInteract` flag.

If the client application does not set any one of the user interaction flags, the Apple Event Manager sets a default, depending on the location of the target of the Apple event. If the server application is on a remote computer, the Apple Event Manager sets the `kAENeverInteract` flag as the default. If the target of the Apple event is on the local computer, the Apple Event Manager sets the `kAECanInteract` flag as the default.

The server application should call `AEInteractWithUser` if it needs to interact with the user. If both the client and the server allow user interaction, the Apple Event Manager attempts to bring the server to the foreground if it is not already the foreground process. If both the `kAECanSwitchLayer` and the `kAEWaitReply` flags are set, and if the client application is the active application on the local computer, the Apple Event Manager brings the server application directly to the front. Otherwise, the Apple Event Manager

posts a notification request asking the user to bring the server application to the front, regardless of whether the `kAECanSwitchLayer` flag is set. This ensures that the user will not be interrupted by an unexpected application switch.

Specify the `kAEDontRecord` flag if your application is sending an Apple event to itself that you don't want to be recorded. When Apple event recording has been turned on, every event that your application sends to itself will be automatically recorded by the Apple Event Manager except those sent with the `kAEDontRecord` flag set.

Specify the `kAEDontExecute` flag if your application is sending an Apple event to itself for recording purposes only—that is, if you want the Apple Event Manager to send a copy of the event to the recording process but you do not want your application actually to receive the event.

See also "Requesting User Interaction" (page 405).

Version Notes
The `kAEDontReconnect` and `kAEWantReceipt` constants are deprecated and unsupported in Mac OS X.

Declared In
`AEDataModel.h`

Apple Event Recording Event ID Constants

Specify event IDs for events that deal with Apple event recording.

```
enum {
    kAEStartRecording = 'reca',
    kAEStopRecording = 'recc',
    kAENotifyStartRecording = 'rec1',
    kAENotifyStopRecording = 'rec0',
    kAENotifyRecording = 'recr'
};
```

Constants

`kAEStartRecording`

Event ID for an event by a scripting component to the recording process (or to any running process on the local computer), but handled by the Apple Event Manager. The Apple Event Manager responds by turning on recording and sending a `recording on` event to all running processes on the local computer.

If sent by process serial number (PSN), this event must be addressed using a real PSN; it should never be sent to an address specified as `kCurrentProcess`.

Available in Mac OS X v10.0 and later.

Declared in `AppleEvents.h`.

`kAEStopRecording`

Event ID for an event sent by a scripting component to the recording process (or to any running process on the local computer), but handled by the Apple Event Manager. The Apple Event Manager responds by sending a `recording off` event to all running processes on the local computer.

If sent by a PSN, this event must be addressed using a real PSN; it should never be sent to an address specified as `kCurrentProcess`.

Available in Mac OS X v10.0 and later.

Declared in `AppleEvents.h`.

`kAENotifyStartRecording`
: An event that notifies an application that recording has been turned on.

  Available in Mac OS X v10.0 and later.

  Declared in `AppleEvents.h`.

`kAENotifyStopRecording`
: An event that notifies an application that recording has been turned off.

  Available in Mac OS X v10.0 and later.

  Declared in `AppleEvents.h`.

`kAENotifyRecording`
: Wildcard event class and event ID handled by a recording process in order to receive and record copies of recordable events sent to it by the Apple Event Manager. Scripting components install a handler for this event on behalf of a recording process when recording is turned on and remove the handler when recording is turned off.

  Available in Mac OS X v10.0 and later.

  Declared in `AppleEvents.h`.

Version Notes
These constants are available only in version 1.0.1 and later of the Apple Event Manager.

cAEList

```
enum {
    cAEList = 'list',
    cApplication = 'capp',
    cArc = 'carc',
    cBoolean = 'bool',
    cCell = 'ccel',
    cChar = 'cha ',
    cColorTable = 'clrt',
    cColumn = 'ccol',
    cDocument = 'docu',
    cDrawingArea = 'cdrw',
    cEnumeration = 'enum',
    cFile = 'file',
    cFixed = 'fixd',
    cFixedPoint = 'fpnt',
    cFixedRectangle = 'frct',
    cGraphicLine = 'glin',
    cGraphicObject = 'cgob',
    cGraphicShape = 'cgsh',
    cGraphicText = 'cgtx',
    cGroupedGraphic = 'cpic'
};
```

Callback Constants for the AEResolve Function

Specify supported callback features to the `AEResolve` function.

```
enum {
    kAEIDoMinimum = 0x0000,
    kAEIDoWhose = 0x0001,
    kAEIDoMarking = 0x0004,
    kAEPassSubDescs = 0x0008,
    kAEResolveNestedLists = 0x0010,
    kAEHandleSimpleRanges = 0x0020,
    kAEUseRelativeIterators = 0x0040
};
```

Constants

`kAEIDoMinimum`

The application does not handle whose tests or provide marking callbacks.

Available in Mac OS X v10.0 and later.

Declared in `AEObjects.h`.

`kAEIDoWhose`

The application supports whose tests (supports key form `formWhose`).

Available in Mac OS X v10.0 and later.

Declared in `AEObjects.h`.

`kAEIDoMarking`

The application provides marking callback functions. Marking callback functions are described in "Object Callback Functions" (page 524).

Available in Mac OS X v10.0 and later.

Declared in `AEObjects.h`.

Discussion

You use these constants to supply a value for the `callbackFlags` parameter to the `AEResolve` (page 473) function. This value specifies whether your application supports whose descriptors or provides marking callback functions. To obtain a value for this parameter, you can add together constants to set the appropriate bits, as shown in the following example (for an application that supports both whose tests and marking):

```
    AEDesc objectSpecifier; // Previously obtained object specifier.     AEDesc
  resultToken;
    OSErr myErr;

    myErr = AEResolve (&objectSpecifier,
                       kAEIDoWhose + kAEIDoMarking, &resultToken)
```

AppleScript generates whose clauses from script statements such as the following:

```
tell application "Finder"
    every file in control panels folder whose file type is "APPL"
end tell
```

cInsertionLoc

```
enum {
    cInsertionLoc = 'insl',
    cInsertionPoint = 'cins',
    cIntlText = 'itxt',
    cIntlWritingCode = 'intl',
    cItem = 'citm',
    cLine = 'clin',
    cLongDateTime = 'ldt ',
    cLongFixed = 'lfxd',
    cLongFixedPoint = 'lfpt',
    cLongFixedRectangle = 'lfrc',
    cLongInteger = 'long',
    cLongPoint = 'lpnt',
    cLongRectangle = 'lrct',
    cMachineLoc = 'mLoc',
    cMenu = 'cmnu',
    cMenuItem = 'cmen',
    cObject = 'cobj',
    cObjectSpecifier = 'obj ',
    cOpenableObject = 'coob',
    cOval = 'covl'
};
```

cKeystroke

```
enum {
    cKeystroke = 'kprs',
    pKeystrokeKey = 'kMsg',
    pModifiers = 'kMod',
    pKeyKind = 'kknd',
    eModifiers = 'eMds',
    eOptionDown = 'Kopt',
   eCommandDown = 'Kcmd',
    eControlDown = 'Kctl',
    eShiftDown = 'Ksft',
    eCapsLockDown = 'Kclk',
    eKeyKind = 'ekst',
    eEscapeKey = 0x6B733500,
    eDeleteKey = 0x6B733300,
    eTabKey = 0x6B733000,
    eReturnKey = 0x6B732400,
    eClearKey = 0x6B734700,
    eEnterKey = 0x6B734C00,
    eUpArrowKey = 0x6B737E00,
    eDownArrowKey = 0x6B737D00,
    eLeftArrowKey = 0x6B737B00,
    eRightArrowKey = 0x6B737C00,
    eHelpKey = 0x6B737200,
    eHomeKey = 0x6B737300,
    ePageUpKey = 0x6B737400,
    ePageDownKey = 0x6B737900,
    eForwardDelKey = 0x6B737500,
    eEndKey = 0x6B737700,
    eF1Key = 0x6B737A00,
```

```
    eF2Key = 0x6B737800,
    eF3Key = 0x6B736300,
    eF4Key = 0x6B737600,
    eF5Key = 0x6B736000,
    eF6Key = 0x6B736100,
    eF7Key = 0x6B736200,
    eF8Key = 0x6B736400,
    eF9Key = 0x6B736500,
    eF10Key = 0x6B736D00,
    eF11Key = 0x6B736700,
    eF12Key = 0x6B736F00,
    eF13Key = 0x6B736900,
    eF14Key = 0x6B736B00,
    eF15Key = 0x6B737100
};
```

Comparison Operator Constants

Specify a comparison operation to perform on two operands.

```
enum {
    kAEAsk = 'ask ',
    kAEBefore = 'befo',
    kAEBeginning = 'bgng',
    kAEBeginsWith = 'bgwt',
    kAEBeginTransaction = 'begi',
    kAEBold = 'bold',
    kAECaseSensEquals = 'cseq',
    kAECentered = 'cent',
    kAEChangeView = 'view',
    kAEClone = 'clon',
    kAEClose = 'clos',
    kAECondensed = 'cond',
    kAEContains = 'cont',
    kAECopy = 'copy',
    kAECoreSuite = 'core',
    kAECountElements = 'cnte',
    kAECreateElement = 'crel',
    kAECreatePublisher = 'cpub',
    kAECut = 'cut ',
    kAEDelete = 'delo'
};
```

Constants

`kAEBeginsWith`

The value of `operand1` begins with the value of `operand2` (for example, the string `"operand"` begins with the string `"opera"`).

Available in Mac OS X v10.0 and later.

Declared in `AERegistry.h`.

`kAEContains`

The value of `operand1` contains the value of `operand2` (for example, the string `"operand"` contains the string `"era"`).

Available in Mac OS X v10.0 and later.

Declared in `AERegistry.h`.

`kAECoreSuite`
: An Apple event in the Standard Suite.

  Available in Mac OS X v10.0 and later.

  Declared in `AERegistry.h`.

Discussion
When you call the `CreateCompDescriptor` (page 498) function, you pass one of these comparison operators in the `comparisonOperator` parameter. The `CreateCompDescriptor` function creates a comparison descriptor that specifies how to compare one or more Apple event objects with either another Apple event object or a descriptor.

The actual comparison of the two operands is performed by the object comparison function provided by the client application—see `OSLCompareProcPtr` (page 536). The way a comparison operator is interpreted is up to each application.

For related information, see "Constants for Object Specifiers, Positions, and Logical and Comparison Operations" (page 575).

Constants for Object Specifiers, Positions, and Logical and Comparison Operations

Specify the types of the four keyword-specified descriptors that make up the data in an object specifier, as well as constants for position, logical operations, and comparison operations.

```
enum {
    kAEAND = 'AND ',
    kAEOR = 'OR  ',
    kAENOT = 'NOT ',
    kAEFirst = 'firs',
    kAELast = 'last',
    kAEMiddle = 'midd',
    kAEAny = 'any ',
    kAEAll = 'all ',
    kAENext = 'next',
    kAEPrevious = 'prev',
    keyAECompOperator = 'relo',
    keyAELogicalTerms = 'term',
    keyAELogicalOperator = 'logc',
    keyAEObject1 = 'obj1',
    keyAEObject2 = 'obj2',
    keyAEDesiredClass = 'want',
    keyAEContainer = 'from',
    keyAEKeyForm = 'form',
    keyAEKeyData = 'seld'
};
```

Constants
`kAEAND`
: Specifies a logical `AND` operation.

  Available in Mac OS X v10.0 and later.

  Declared in `AEObjects.h`.

`kAEOR`
Specifies a logical `OR` operation.
Available in Mac OS X v10.0 and later.
Declared in `AEObjects.h`.

`kAENOT`
Specifies a logical `NOT` operation.
Available in Mac OS X v10.0 and later.
Declared in `AEObjects.h`.

`kAEFirst`
The first element in the specified container.
Available in Mac OS X v10.0 and later.
Declared in `AEObjects.h`.

`kAELast`
Specifies the last element in the container.
Available in Mac OS X v10.0 and later.
Declared in `AEObjects.h`.

`kAEMiddle`
Specifies the middle element in the container. If an object specifier specifies `kAEMiddle` and the number of elements in the container is even, the Apple Event Manager rounds down. For example, in a range of four words the second word is the "middle" word.
Available in Mac OS X v10.0 and later.
Declared in `AEObjects.h`.

`kAEAny`
Specifies a single element chosen at random from the container.
Available in Mac OS X v10.0 and later.
Declared in `AEObjects.h`.

`kAEAll`
Specifies all the elements in the container.
Available in Mac OS X v10.0 and later.
Declared in `AEObjects.h`.

`kAENext`
Specifies the Apple event object after the container.
Available in Mac OS X v10.0 and later.
Declared in `AEObjects.h`.

`kAEPrevious`
Specifies the Apple event object before the container.
Available in Mac OS X v10.0 and later.
Declared in `AEObjects.h`.

`keyAECompOperator`
Specifies a descriptor of `typeType`, whose data consists of one of the constant values described in "Key Form and Descriptor Type Object Specifier Constants" (page 590).
Available in Mac OS X v10.0 and later.
Declared in `AEObjects.h`.

`keyAELogicalTerms`
Specifies a descriptor of type `typeAEList` containing one or more comparison or logical descriptors.

Available in Mac OS X v10.0 and later.

Declared in `AEObjects.h`.

`keyAELogicalOperator`
Specifies a descriptor of type `typeEnumerated` whose data is one of the logical operators (such as `kAEAND`) defined in "Key Form and Descriptor Type Object Specifier Constants" (page 590).

Available in Mac OS X v10.0 and later.

Declared in `AEObjects.h`.

`keyAEObject1`
Identifies a descriptor for the element that is currently being compared to the object or data specified by the descriptor for the keyword `keyAEObject2`. Either object can be described by a descriptor of type `typeObjectSpecifier` or `typeObjectBeingExamined`.

A descriptor of `typeObjectBeingExamined` acts as a placeholder for each of the successive elements in a container when the Apple Event Manager tests those elements one at a time.

Available in Mac OS X v10.0 and later.

Declared in `AEObjects.h`.

`keyAEObject2`
Identifies a descriptor for the element that is currently being compared to the object or data specified by the descriptor for the keyword `keyAEObject1`.

The keyword `keyAEObject2` can also be used with a descriptor of any other descriptor type whose data is to be compared to each element in a container.

Available in Mac OS X v10.0 and later.

Declared in `AEObjects.h`.

`keyAEDesiredClass`
A four-character code that identifies the object class of the specified object or objects.

Constants for object class IDs are described in "Key Form and Descriptor Type Object Specifier Constants" (page 590).

Available in Mac OS X v10.0 and later.

Declared in `AEObjects.h`.

`keyAEContainer`
Specifies the container for the requested object or objects. The data is an object specifier (or in some cases a null descriptor).

Available in Mac OS X v10.0 and later.

Declared in `AEObjects.h`.

`keyAEKeyForm`
A four-character code that identifies the key form for the specified object or objects.

The constants for specifying the key form are described in "Key Form and Descriptor Type Object Specifier Constants" (page 590).

Available in Mac OS X v10.0 and later.

Declared in `AEObjects.h`.

`keyAEKeyData`

Data or nested descriptors that specify a property, name, position, range, or test, depending on the key form.

The descriptor types used in object specifiers are described in "Key Form and Descriptor Type Object Specifier Constants" (page 590).

Available in Mac OS X v10.0 and later.

Declared in `AEObjects.h`.

Discussion

When you call the `CreateLogicalDescriptor` (page 499) function to create a logical descriptor, you pass one of the logical operators `kAEAND`, `kAEOR`, or `kAENOT` in the `theLogicOperator` parameter. The `CreateLogicalDescriptor` function creates a logical descriptor that specifies a logical operation to perform on one or more operands.

The constants `kAEFirst`, `kAELast`, `kAEMiddle`, `kAEAny`, and `kAEAll` provide the key data for a keyword-specified descriptor of key form `formAbsolutePosition` and descriptor type `typeAbsoluteOrdinal`.

The constants `kAENext`, and `kAEPrevious` provide the key data for a keyword-specified descriptor of key form `formRelativePosition`.

Key form constants and descriptor type constants for object specifiers are defined in "Key Form and Descriptor Type Object Specifier Constants" (page 590).

The constants `keyAELogicalTerms` and `keyAELogicalOperator` define the keyword descriptors for a logical descriptor. A logical descriptor is a coerced Apple event record of type `typeLogicalDescriptor` that specifies a logical expression—that is, an expression that the Apple Event Manager evaluates to either `TRUE` or `FALSE`. You can create a logical descriptor with the `CreateLogicalDescriptor` (page 499) function.

The data for a logical descriptor consists of two keyword-specified descriptors: the first with descriptor type `keyAELogicalOperator`, descriptor type `typeEnumerated`, and one of the logical operators defined in "Constants for Object Specifiers, Positions, and Logical and Comparison Operations" (page 575) for its data; and the second with descriptor type `keyAELogicalTerms`, descriptor type `typeEnumerated`, and one or more comparison or logical descriptors for its data. Comparison constants are described in "Comparison Operator Constants" (page 574).

The logical expression is constructed from a logical operator (one of the Boolean operators `AND`, `OR`, or `NOT`) and a list of logical terms to which the operator is applied (where `NOT` can only be used where the list of terms is a single-item list). Each logical term in the list can be either another logical descriptor or a comparison descriptor (described in "Constants for Object Specifiers, Positions, and Logical and Comparison Operations" (page 575)).

The Apple Event Manager short-circuits its evaluation of a logical expression as soon as one part of the expression fails a test. For example, if while testing a logical expression such as A `AND` B `AND` C the Apple Event Manager discovers that A `AND` B is not true, it will evaluate the expression to `FALSE` without testing C.

The constants `keyAECompOperator`, `keyAEObject1`, and `keyAEObject2` define the keyword descriptors for a comparison descriptor. A comparison descriptor is a coerced Apple event record of type `typeCompDescriptor` that specifies an Apple event object and either another Apple event object or data for the Apple Event Manager to compare to the first object. You can create a logical descriptor with the `CreateCompDescriptor` (page 498) function.

The Apple Event Manager can also use the information in a comparison descriptor to compare elements in a container, one at a time, either to an Apple event object or to data. The data for a comparison descriptor consists of three keyword-specified descriptors:

- A descriptor with keyword `keyAECompOperator`, descriptor type `typeType`, and one of the logical operators defined in "Comparison Operator Constants" (page 574) for its data.
- A descriptor with keyword `keyAEObject1` and either
- descriptor type `typeObjectSpecifier` and object specifier data to compare, or
- descriptor type `typeObjectBeingExamined` and a data storage pointer of `NULL`.
- A descriptor with keyword `keyAEObject2` and either
- descriptor type `typeObjectSpecifier` and object specifier data to compare, or
- descriptor type `typeObjectBeingExamined` and a data storage pointer of `NULL`, or
- any other descriptor type and the data to be compared for that descriptor type.

You don't have to support all the available comparison operators for all Apple event objects for example, the `begins with` operator probably doesn't make sense for objects of type `cRectangle`. It is up to you to decide which comparison operators are appropriate for your application to support, and how to interpret them. If necessary, you can define your own custom comparison operators. If you think you need to do this, check the Apple Events and Scripting header files to see if existing definitions of comparison operators can be adapted to the needs of your application.

An object specifier is a coerced Apple event record of descriptor type `typeObjectSpecifier` whose data contains consists of four keyword-specified descriptors. The constants `keyAEDesiredClass`, `keyAEContainer`, `keyAEKeyForm`, and `keyAEKeyData` specify the keywords for the four descriptor types that together identify the specified object or objects.

cURL

```
enum {
    cURL = 'url ',
    cInternetAddress = 'IPAD',
    cHTML = 'html',
    cFTPItem = 'ftp '
};
```

Constants

`cURL`

Specifies a Uniform Resource Locator or Uniform Resource ID (URI).

Available in Mac OS X v10.0 and later.

Declared in `AERegistry.h`.

`cInternetAddress`

Specifies an Internet or Intranet address for the TCP/IP protocol.

Available in Mac OS X v10.0 and later.

Declared in `AERegistry.h`.

`cHTML`
Specifies HTML (HyperText Markup Language) format.

Available in Mac OS X v10.0 and later.

Declared in `AERegistry.h`.

`cFTPItem`
Specifies FTP (File Transfer Protocol) protocol.

Available in Mac OS X v10.0 and later.

Declared in `AERegistry.h`.

cVersion

```
enum {
    cVersion = 'vers',
    cWindow = 'cwin',
    cWord = 'cwor',
    enumArrows = 'arro',
    enumJustification = 'just',
    enumKeyForm = 'kfrm',
    enumPosition = 'posi',
    enumProtection = 'prtn',
    enumQuality = 'qual',
    enumSaveOptions = 'savo',
    enumStyle = 'styl',
    enumTransferMode = 'tran',
    formUniqueID = 'ID  ',
    kAEAbout = 'abou',
    kAEAfter = 'afte',
    kAEAliasSelection = 'sali',
    kAEAllCaps = 'alcp',
    kAEArrowAtEnd = 'aren',
    kAEArrowAtStart = 'arst',
    kAEArrowBothEnds = 'arbo'
};
```

Constants

`formUniqueID`
Specifies a value that uniquely identifies an object within its container or across an application.

Available in Mac OS X v10.0 and later.

Declared in `AEObjects.h`.

Data Array Constants

Specify an array type for storing or extracting descriptor lists with the `AEPutArray` and `AEGetArray` functions.

```
enum {
    kAEDataArray = 0,
    kAEPackedArray = 1,
    kAEDescArray = 3,
    kAEKeyDescArray = 4
};
```

Constants

`kAEDataArray`

Array items consist of data of the same size and same type, and are aligned on word boundaries.

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

`kAEPackedArray`

Array items consist of data of the same size and same type, and are packed without regard for word boundaries.

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

`kAEDescArray`

Array items consist of descriptors of different descriptor types with data of variable size.

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

`kAEKeyDescArray`

Array items consist of keyword-specified descriptors with different keywords, different descriptor types, and data of variable size.

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

Discussion

When your application calls the `AEPutArray` (page 459) function to put information into a descriptor list or the `AEGetArray` (page 428) function to get information from a descriptor list, it uses an array to store the information. The type of array depends on the data for the array, as specified by one of these constants.

Array items in Apple event arrays of type `kAEDataArray`, `kAEPackedArray`, or `kAEHandleArray` must be factored—that is, contained in a factored descriptor list. For more information, see `AEPutArray` (page 459).

Descriptor Type Constants

Specify types for descriptors.

```
enum {
    typeAEList = 'list',
    typeAERecord = 'reco',
    typeAppleEvent = 'aevt',
    typeEventRecord = 'evrc',
    typeTrue = 'true',
    typeFalse = 'fals',
    typeAlias = 'alis',
    typeEnumerated = 'enum',
    typeType = 'type',
    typeAppParameters = 'appa',
    typeProperty = 'prop',
    typeFSS = 'fss ',
    typeFSRef = 'fsrf',
    typeFileURL = 'furl',
    typeKeyword = 'keyw',
    typeSectionH = 'sect',
    typeWildCard = '****',
    typeApplSignature = 'sign',
    typeQDRectangle = 'qdrt',
    typeFixed = 'fixd',
    typeProcessSerialNumber = 'psn ',
    typeApplicationURL = 'aprl',
    typeNull = 'null'
};
```

Constants

`typeAEList`
List of descriptors.
Available in Mac OS X v10.0 and later.
Declared in `AEDataModel.h`.

`typeAERecord`
List of keyword-specified descriptors.
Available in Mac OS X v10.0 and later.
Declared in `AEDataModel.h`.

`typeAppleEvent`
Apple event.
Available in Mac OS X v10.0 and later.
Declared in `AEDataModel.h`.

`typeTrue`
`TRUE` Boolean value.
Available in Mac OS X v10.0 and later.
Declared in `AEDataModel.h`.

`typeFalse`
`FALSE` Boolean value.
Available in Mac OS X v10.0 and later.
Declared in `AEDataModel.h`.

`typeAlias`
Alias.

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

`typeEnumerated`
Enumerated data.

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

`typeType`
Four-character code for event class or event ID

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

`typeAppParameters`
Process Manager launch parameters.

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

`typeProperty`
Apple event object property.

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

`typeFSS`
File system specification. Deprecated in Mac OS X. Use file system references (`typeFSRef`) instead.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `AEDataModel.h`.

`typeFSRef`
File system reference. Use in preference to file system specifications (`typeFSS`).

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

`typeFileURL`
A file URL. That is, the associated data consists of the bytes of a UTF-8 encoded URL with a scheme of "file". This type is appropriate for describing a file that may not yet exist—see Technical Note 2022 for more information.

You can translate between a descriptor of this type and an instance of `CFURL` by calling `CFURLCreateWithBytes` and specifying `kCFStringEncodingUTF8` for the encoding. Or, if you have a `CFURLRef`, you can call `CFURLCreateData` to get the data as an instance of `CFData` (again specifying an encoding of `kCFStringEncodingUTF8`), and`CFDataGetBytes` to get the actual bytes to insert into a descriptor of this type.

Available in Mac OS X v10.1 and later.

Declared in `AEDataModel.h`.

`typeKeyword`
Apple event keyword.

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

`typeSectionH`
: Handle to a section record. (Deprecated.)

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

`typeWildCard`
: Matches any type.

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

`typeApplSignature`
: Application signature.

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

`typeProcessSerialNumber`
: A process serial number. See also `AEAddressDesc` (page 551).

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

`typeApplicationURL`
: For specifying an application by URL. See Discussion section below for important information.

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

`typeNull`
: A null data storage pointer. When resolving an object specifier, an object with a null storage pointer specifies the default container at the top of the container hierarchy.

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

Discussion
The constants described here specify the data type for a descriptor and show the kind of data stored in a descriptor with that type.

Descriptors are the building blocks used by the Apple Event Manager to construct Apple event attributes and parameters. A descriptor is a data structure of type `AEDesc` (page 546), which consists of data storage and a descriptor type that identifies the type of the data. A descriptor type is defined by the data type `DescType` (page 560). AppleScript defines descriptor type constants for a wide variety of common data types. For additional types, see "Numeric Descriptor Type Constants" (page 597) and "Other Descriptor Type Constants" (page 601). For a complete listing, including data types such as units of length, weight, and volume, see the Apple Event Manager and Open Scripting Architecture header files.

For the constant `typeApplicationURL`, the data that specifies the application URL takes the following format:

```
eppc://[username[:password]@]host/AppName[[?uid=#]&[pid=#]]
```

As indicated by this format:

- `username` is optional. If present, an `'@'` must appear before the host name. `password` is optional. If present, `username` is not optional, and the password must be separated from the username by a `':'` and must precede the `'@'`. `AppName` is not optional; if it contains non-UTF-8 characters or white space, it must be URL-encoded (for example, `My%20Application`).

- `uid` and `pid` are optional. If `pid` is present, `uid` and `AppName` are ignored and the event is delivered only to applications with the given process id. If `uid` is present, events are directed to the application name owned by the given user id.

The following are examples of valid URLs:

```
eppc://Steve%20Zellers:wombat@grrr.apple.com/Microsoft%20Word
eppc://Steve%20Zellers:wombat@grrr.apple.com/Microsoft%20Word?pid=1284
```

The availability of user identifiers provides enhanced Apple event support for Fast User Switching. Such identifiers make it possible to send Apple events to applications running in any session, if the uids of the processes match. `'root'` (or `uid 0`) processes are allowed to send Apple events to any process in any session. Non-root processes can only target applications that match their uid.

eScheme

```
enum {
    eScheme = 'esch',
    eurlHTTP = 'http',
    eurlHTTPS = 'htps',
    eurlFTP = 'ftp ',
    eurlMail = 'mail',
    eurlFile = 'file',
    eurlGopher = 'gphr',
    eurlTelnet = 'tlnt',
    eurlNews = 'news',
    eurlSNews = 'snws',
    eurlNNTP = 'nntp',
    eurlMessage = 'mess',
    eurlMailbox = 'mbox',
    eurlMulti = 'mult',
    eurlLaunch = 'laun',
    eurlAFP = 'afp ',
    eurlAT = 'at  ',
    eurlEPPC = 'eppc',
    eurlRTSP = 'rtsp',
    eurlIMAP = 'imap',
    eurlNFS = 'unfs',
    eurlPOP = 'upop',
    eurlLDAP = 'uldp',
    eurlUnknown = 'url?'
};
```

Event Class Constants

Specify the event class for an Apple event.

```
enum {
    kCoreEventClass = 'aevt'
};
```

Constants

`kCoreEventClass`

An Apple event sent by the Mac OS; applications that present a graphical interface to the user should be able to any events sent by the Mac OS that apply to the application.

Available in Mac OS X v10.0 and later.

Declared in `AppleEvents.h`.

Discussion

Apple events are identified by their event class and event ID attributes, each of which specifies an arbitrary four-character code. The event class appears in the `message` field of the event record for an Apple event. For example, certain Apple events that are sent by the Mac OS have the value `'aevt'` in the `message` fields of their event records. This value can be represented with the constant `kCoreEventClass`.

Groups of related Apple events are known as suites. For example, the common events that most applications support are grouped in the Standard Suite. The Standard Suite includes the events of the Core suite (`open application`, `reopen`, `open contents`, `open documents`, `print documents`, and `quit`), as well as such events as `count`, `delete`, and `make`. Suites may use a common event class, but doing so is not required, and does not result in any special treatment by AppleScript or the Apple Event Manager.

AppleScript defines suites that provide terminology for Text, Database, Macintosh Connectivity, and other types of related operations. The terms defined in the AppleScript suite itself make up the largest suite. These terms are global to AppleScript, and are available to your application, even if your `'aete'` resource doesn't explicitly include them.

Event Handler Flags

```
enum {
    kAEDoNotIgnoreHandler = 0x00000000,
    kAEIgnoreAppPhacHandler = 0x00000001,
    kAEIgnoreAppEventHandler = 0x00000002,
    kAEIgnoreSysPhacHandler = 0x00000004,
    kAEIgnoreSysEventHandler = 0x00000008,
    kAEIngoreBuiltInEventHandler = 0x00000010,
    kAEDontDisposeOnResume = 0x80000000
};
```

Event ID Constants

Specify the event ID for an Apple event.

```
enum {
    kAEOpenApplication          = 'oapp',
    kAEReopenApplication        = 'rapp',
    kAEOpenDocuments            = 'odoc',
    kAEPrintDocuments           = 'pdoc',
    kAEOpenContents             = 'ocon',
    kAEQuitApplication          = 'quit',
    kAEAnswer                   = 'ansr',
    kAEApplicationDied          = 'obit',
    kAEShowPreferences          = 'pref'
};
```

Constants

`kAEOpenApplication`

Event that launches an application.

Available in Mac OS X v10.0 and later.

Declared in `AppleEvents.h`.

`kAEReopenApplication`

Event that reopens an application. Sent, for example, when your application is running and a user clicks your application icon in the Dock.

Available in Mac OS X v10.0 and later.

Declared in `AERegistry.h`.

`kAEOpenDocuments`

Event that provides an application with a list of documents to open. Sent, for example, when a selects one or more documents for your application in the Finder and double-clicks them.

See also the constant `keyAESearchText` in the enum "keyAEPropData" (page 619).

Available in Mac OS X v10.0 and later.

Declared in `AppleEvents.h`.

`kAEPrintDocuments`

Event that provides an application with a list of documents to print.

Available in Mac OS X v10.0 and later.

Declared in `AppleEvents.h`.

`kAEOpenContents`

Event that provides an application with dragged content, such as text or an image. Sent, for example, when a user drags an image file onto your application's icon in the Dock. The application can use the content as desired—for example, if no document is currently open, it might open a new document and insert the provided text or image.

For more information, see "Handling Apple Events Sent by the Mac OS" in "Responding to Apple Events" in Apple Events Programming Guide.

Available in Mac OS X v10.4 and later.

Declared in `AppleEvents.h`.

`kAEQuitApplication`

Event that causes the application to quit.

Available in Mac OS X v10.0 and later.

Declared in `AppleEvents.h`.

`kAEAnswer`
: Event that is a reply Apple event.

  Available in Mac OS X v10.0 and later.

  Declared in `AppleEvents.h`.

`kAEApplicationDied`
: Event sent by the Process Manager to an application that launched another application when the launched application quits or terminates.

  Available in Mac OS X v10.0 and later.

  Declared in `AppleEvents.h`.

`kAEShowPreferences`
: Event sent by the Mac OS X to a process when the user chooses the Preferences item for that process.

  Carbon applications that handle the Preferences command can install an Apple event handler for this event, but they more commonly install a Carbon event handler for `kEventCommandProcess` and check for the `kHICommandPreferences` command ID.

  Available in Mac OS X v10.0 and later.

  Declared in `AppleEvents.h`.

Discussion
Apple events are identified by their event class and event ID attributes. The event ID is the attribute that identifies the particular Apple event within its event class. In conjunction with the event class, the event ID uniquely identifies the Apple event and communicates what action the Apple event should perform. The event ID appears in the `where` field of the event record for an Apple event. For example, an event with ID `kAEOpenApplication` and class `kCoreEventClass` is an event sent by the Mac OS that launches an application.

Only a small number of event IDs are shown here. For a more complete listing, see the Apple Event Manager and Open Scripting Architecture header files.

Event Source Constants

Identify how an Apple event was delivered.

```
enum {
    kAEUnknownSource = 0,
    kAEDirectCall = 1,
    kAESameProcess = 2,
    kAELocalProcess = 3,
    kAERemoteProcess = 4
};
```

Constants
`kAEUnknownSource`
: The source of the Apple event is unknown.

  Available in Mac OS X v10.0 and later.

  Declared in `AppleEvents.h`.

`kAEDirectCall`
: The source of the Apple event is a direct call that bypassed the PPC Toolbox.

  Available in Mac OS X v10.0 and later.

  Declared in `AppleEvents.h`.

`kAESameProcess`
: The source of the Apple event is the same application that received the event (the target application and the source application are the same).

  Available in Mac OS X v10.0 and later.

  Declared in `AppleEvents.h`.

`kAELocalProcess`
: The source application is another process on the same computer as the target application.

  Available in Mac OS X v10.0 and later.

  Declared in `AppleEvents.h`.

`kAERemoteProcess`
: The source application is a process on a remote computer on the network.

  Available in Mac OS X v10.0 and later.

  Declared in `AppleEvents.h`.

Discussion
For an example of how you might use these constants with the `AEGetAttributePtr` (page 430) function, see the data type `AEEventSource` (page 554).

Declared In
`AppleEvents.h`

Factoring Constants

```
enum {
    kAEDescListFactorNone = 0,
    kAEDescListFactorType = 4,
    kAEDescListFactorTypeAndSize = 8
};
```

Discussion
These constants have no effect in Mac OS X v10.2 and later.

ID Constants for the AECreateAppleEvent Function

Specify values for the ID parameters of the `AECreateAppleEvent` function.

```
enum {
    kAutoGenerateReturnID = -1,
    kAnyTransactionID = 0
};
```

Constants
`kAutoGenerateReturnID`
: If you pass this value for the `returnID` parameter of the `AECreateAppleEvent` (page 416) function, the Apple Event Manager assigns to the created Apple event a return ID that is unique to the current session.

  Available in Mac OS X v10.0 and later.

  Declared in `AEDataModel.h`.

`kAnyTransactionID`

You pass this value for the `transactionID` parameter of the `AECreateAppleEvent` (page 416) function if the Apple event is not one of a series of interdependent Apple events.

A transaction is a sequence of Apple events that are sent back and forth between the client and server applications, beginning with the client's initial request for a service. All Apple events that are part of a transaction must have the same transaction ID.

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

Discussion
You use these constants with the `AECreateAppleEvent` (page 416) function.

Key Form and Descriptor Type Object Specifier Constants

Specify possible values for the `keyAEKeyForm` field of an object specifier, as well as descriptor types used in resolving object specifiers.

```
enum {
    formAbsolutePosition = 'indx',
    formRelativePosition = 'rele',
    formTest = 'test',
    formRange = 'rang',
    formPropertyID = 'prop',
    formName = 'name',
    typeObjectSpecifier = 'obj ',
    typeObjectBeingExamined = 'exmn',
    typeCurrentContainer = 'ccnt',
    typeToken = 'toke',
    typeRelativeDescriptor = 'rel ',
    typeAbsoluteOrdinal = 'abso',
    typeIndexDescriptor = 'inde',
    typeRangeDescriptor = 'rang',
    typeLogicalDescriptor = 'logi',
    typeCompDescriptor = 'cmpd',
    typeOSLTokenList = 'ostl'
};
```

Constants
`formAbsolutePosition`

An integer or other constant indicating the position of one or more elements in relation to the beginning or end of their container. The key data consists of an integer that specifies either an offset or an ordinal position.

For descriptor type `typeAbsoluteOrdinal`, the data consists of one of the constants `kAEFirst`, `kAEMiddle`, `kAELast`, `kAEAny`, or `kAEAll`, which are described in `AEDisposeToken` (page 425).

For other descriptor types, the data can be coerced to either a positive integer, indicating the offset of the requested element from the beginning of the container, or a negative integer, indicating its offset from the end of the container.

Available in Mac OS X v10.0 and later.

Declared in `AEObjects.h`.

`formRelativePosition`

Specifies an element position either immediately before or immediately after a container, not inside it. The key data is specified by a descriptor of type `typeEnumerated` whose data consists of one of the constants `kAENext` and `kAEPrevious`, which are described in `AEDisposeToken` (page 425).

Available in Mac OS X v10.0 and later.

Declared in `AEObjects.h`.

`formTest`

Specifies a test. The key data is specified by either a comparison descriptor or a logical descriptor.

The Apple Event Manager internally translates object specifiers of key form `formTest` into object specifiers of key form `formWhose` to optimize resolution of object specifiers. This involves collapsing the key form and key data from two object specifiers in a container hierarchy into one object specifier with the key form `formWhose`.

See also `AEDisposeToken` (page 425), "Constants for Object Specifiers, Positions, and Logical and Comparison Operations" (page 575), `CreateCompDescriptor` (page 498), and `CreateLogicalDescriptor` (page 499).

Available in Mac OS X v10.0 and later.

Declared in `AEObjects.h`.

`formRange`

Specifies a group of elements between two other elements. The key data is specified by a range descriptor, which is a coerced Apple event record of type `typeRangeDescriptor` that identifies two Apple event objects marking the beginning and end of a range of elements.

The data for a range descriptor consists of two keyword-specified descriptors with the keywords `keyAERangeStart` and `keyAERangeStop`.

Available in Mac OS X v10.0 and later.

Declared in `AEObjects.h`.

`formPropertyID`

Specifies the property ID for an element's property.

Available in Mac OS X v10.0 and later.

Declared in `AEObjects.h`.

`formName`

Specifies the Apple event object by name.

Available in Mac OS X v10.0 and later.

Declared in `AEObjects.h`.

`typeObjectSpecifier`

Specifies a descriptor used with the `keyAEContainer` keyword in a keyword-specified descriptor. The key data for the descriptor is an object specifier.

Available in Mac OS X v10.0 and later.

Declared in `AEObjects.h`.

`typeObjectBeingExamined`

Specifies a descriptor that acts as a placeholder for each of the successive elements in a container when the Apple Event Manager tests those elements one at a time. The descriptor has a null data storage pointer. This descriptor type is used only with `formTest`.

Available in Mac OS X v10.0 and later.

Declared in `AEObjects.h`.

`typeCurrentContainer`
Specifies a container for an element that demarcates one boundary in a range. The descriptor has a null data storage pointer. This descriptor type is used only with `formRange`.

Available in Mac OS X v10.0 and later.

Declared in `AEObjects.h`.

`typeToken`
Specifies a descriptor whose data storage pointer refers to a structure of type `AEDisposeToken` (page 425).

Available in Mac OS X v10.0 and later.

Declared in `AEObjects.h`.

`typeRelativeDescriptor`
Specifies a descriptor whose data consists of one of the constants `kAENext` or `kAEPrevious`, which are described in `AEDisposeToken` (page 425). Used with `formRelativePosition`.

Available in Mac OS X v10.0 and later.

Declared in `AEObjects.h`.

`typeAbsoluteOrdinal`
Specifies a descriptor whose data consists of one of the constants `kAEFirst`, `kAEMiddle`, `kAELast`, `kAEAny`, or `kAEAll`, which are described in `AEDisposeToken` (page 425). Used with `formAbsolutePosition`.

Available in Mac OS X v10.0 and later.

Declared in `AEObjects.h`.

`typeIndexDescriptor`
Specifies a descriptor whose data indicates an indexed position within a range of values.

Available in Mac OS X v10.0 and later.

Declared in `AEObjects.h`.

`typeRangeDescriptor`
Specifies a range descriptor that identifies two Apple event objects marking the beginning and end of a range of elements. The data for a range descriptor consists of two keyword-specified descriptors with the keywords `keyAERangeStart` and `keyAERangeStop`, respectively, which specify the first Apple event object in the desired range and the last Apple event object in the desired range.

Available in Mac OS X v10.0 and later.

Declared in `AEObjects.h`.

`typeLogicalDescriptor`
Specifies a logical descriptor. Data is one of the constants described in `AEDisposeToken` (page 425).

Available in Mac OS X v10.0 and later.

Declared in `AEObjects.h`.

`typeCompDescriptor`
Specifies a comparison descriptor. Data is one of the constants described in `AEDisposeToken` (page 425).

Available in Mac OS X v10.0 and later.

Declared in `AEObjects.h`.

`typeOSLTokenList`
Specifies a descriptor whose data consists of a list of tokens. (Token is defined in `AEDisposeToken` (page 425).)

Available in Mac OS X v10.0 and later.

Declared in `AEObjects.h`.

Discussion
The constants in this enum that begin with "form" specify the key form for an object specifier. The key form indicates how key data should be interpreted. Key form is one of the keyword-specified descriptors described in "Constants for Object Specifiers, Positions, and Logical and Comparison Operations" (page 575).

The constants in this enum that begin with "type" specify descriptor types used in resolving object specifiers. An object specifier is a coerced Apple event record of descriptor type `typeObjectSpecifier` whose data consists of the four keyword-specified descriptors described in "Constants for Object Specifiers, Positions, and Logical and Comparison Operations" (page 575). One of those four keyword-specified descriptors has the type `keyAEKeyData`. This descriptor can contain data or nested descriptors specified by any of the descriptor type constants defined here (or by types defined by your application).

Keyword Attribute Constants

Specify keyword values for Apple event attributes.

```
enum {
    keyTransactionIDAttr = 'tran',
    keyReturnIDAttr = 'rtid',
    keyEventClassAttr = 'evcl',
    keyEventIDAttr = 'evid',
    keyAddressAttr = 'addr',
    keyOptionalKeywordAttr = 'optk',
    keyTimeoutAttr = 'timo',
    keyInteractLevelAttr = 'inte',
    keyEventSourceAttr = 'esrc',
    keyMissedKeywordAttr = 'miss',
    keyOriginalAddressAttr = 'from',
    keyAcceptTimeoutAttr = 'actm',
    keyReplyRequestedAttr = 'repq'
};
```

Constants
`keyTransactionIDAttr`
Transaction ID identifying a series of Apple events that are part of one transaction.

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

`keyReturnIDAttr`
Return ID for a reply Apple event.

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

`keyEventClassAttr`
Event class of an Apple event. See `AEAddressDesc` (page 551).

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

`keyEventIDAttr`
Event ID of an Apple event. See `AEAddressDesc` (page 551).

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

`keyAddressAttr`
Address of a target or client application. See also `AEAddressDesc` (page 551).

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

`keyOptionalKeywordAttr`
List of keywords for parameters of an Apple event that should be treated as optional by the target application.

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

`keyTimeoutAttr`
Length of time, in ticks, that the client will wait for a reply or a result from the server.

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

`keyInteractLevelAttr`
Settings for when to allow the Apple Event Manager to bring a server application to the foreground, if necessary, to interact with the user. See `AEAddressDesc` (page 551). (Read only.)

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

`keyEventSourceAttr`
Nature of the source application. (Read only.)

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

`keyMissedKeywordAttr`
Keyword for first required parameter remaining in an Apple event. (Read only.)

After extracting all known Apple event parameters from an event, your handler should check whether the `keyMissedKeywordAttr` attribute exists. If so, your handler has not retrieved all the parameters that the source application considered to be required, and it should return an error.

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

`keyOriginalAddressAttr`
Address of original source of Apple event if the event has been forwarded (available only in version 1.01 or later versions of the Apple Event Manager). See also `AEAddressDesc` (page 551).

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

`keyReplyRequestedAttr`
A Boolean value indicating whether the Apple event expects to be replied to.

Available in Mac OS X v10.3 and later.

Declared in `AEDataModel.h`.

Discussion
These constants are keyword constants for Apple event attributes. An Apple event consists of attributes (which identify the Apple event and denote its task) and, often, parameters (which contain information to be used by the target application). An Apple event attribute is a descriptor that identifies the event class, event ID, target application, or some other characteristic of the Apple event. Taken together, the attributes of an Apple event denote the task to be performed on any data specified in the Apple event's parameters.

Keywords are arbitrary names used by the Apple Event Manager to keep track of various descriptors. Your application cannot examine the contents of an Apple event directly. Instead, you call Apple Event Manager routines such as those described in "Getting Data or Descriptors From Apple Events and Apple Event Records" (page 402) to request attributes and parameters by keyword.

See also "Keyword Parameter Constants" (page 595).

Version Notes
The constant `keyReplyRequestedAttr` was added in Mac OS X version 10.3.

Keyword Parameter Constants

Specify keyword values for Apple event parameters, as well as information for the `AEManagerInfo` function to retrieve. Some common key word values are shown here.

```
enum {
    keyDirectObject = '----',
    keyErrorNumber = 'errn',
    keyErrorString = 'errs',
    keyProcessSerialNumber = 'psn ',
    keyPreDispatch = 'phac',
    keySelectProc = 'selh',
    keyAERecorderCount = 'recr',
    keyAEVersion = 'vers'
};
```

Constants

`keyDirectObject`
Direct parameter. Usually specifies the data to be acted upon by the target application.
Available in Mac OS X v10.0 and later.
Declared in `AppleEvents.h`.

`keyErrorNumber`
Error number. Often used to extract error information from a reply Apple event.
Available in Mac OS X v10.0 and later.
Declared in `AppleEvents.h`.

`keyErrorString`
Error string. Often used to extract error information from a reply Apple event to display to the user.
Available in Mac OS X v10.0 and later.
Declared in `AppleEvents.h`.

`keyProcessSerialNumber`
Process serial number. See also `AEManagerInfo` (page 454).
Available in Mac OS X v10.0 and later.
Declared in `AppleEvents.h`.

`keyPreDispatch`
: A predispatch handler (an Apple event handler that the Apple Event Manager calls immediately before it dispatches an Apple event). See also "Managing Special Handler Dispatch Tables" (page 404).

  Available in Mac OS X v10.0 and later.

  Declared in `AppleEvents.h`.

`keySelectProc`
: You pass this value in the `functionClass` parameter of the `AEManagerInfo` (page 454) function to disable the Object Support Library. Disabling the Object Support Library is not recommended.

  Available in Mac OS X v10.0 and later.

  Declared in `AppleEvents.h`.

`keyAERecorderCount`
: Used with the `keyword` parameter of the `AEManagerInfo` (page 454) function. If you pass this value, on return, the `result` parameter supplies the number of processes that are currently recording Apple events.

  Available in Mac OS X v10.0 and later.

  Declared in `AppleEvents.h`.

`keyAEVersion`
: Used with the `keyword` parameter of the `AEManagerInfo` (page 454) function. If you pass this value, on return, the `result` parameter supplies version information for the Apple Event Manager, in NumVersion format.

  Available in Mac OS X v10.0 and later.

  Declared in `AppleEvents.h`.

Discussion
These constants are keyword constants for Apple event parameters. An Apple event consists of attributes (which identify the Apple event and denote its task) and, often, parameters (which contain information to be used by the target application). Taken together, the attributes of an Apple event denote the task to be performed on any data specified in the Apple event's parameters.

Keywords are arbitrary names used by the Apple Event Manager to keep track of various descriptors. Your application cannot examine the contents of an Apple event directly. Instead, you call Apple Event Manager routines such as those described in "Getting Data or Descriptors From Apple Events and Apple Event Records" (page 402) to request attributes and parameters by keyword.

See also "Keyword Attribute Constants" (page 593).

Launch Apple Event Constants

In a `kAEOpenApplication` event, specify information about how the receiving application was launched.

```
enum {
    keyAELaunchedAsLogInItem = 'lgit',
    keyAELaunchedAsServiceItem = 'svit'
};
```

Constants

`keyAELaunchedAsLogInItem`

If present in a `kAEOpenApplication` event, the receiving application was launched as a login item and should only perform actions suitable to that environment—for example, it probably shouldn't open an untitled document.

Available in Mac OS X v10.5 and later.

Declared in `AERegistry.h`.

`keyAELaunchedAsServiceItem`

If present in a `kAEOpenApplication` event, the receiving application was launched as a service item and should only perform actions suitable to that environment—for example, it probably shouldn't open an untitled document.

Available in Mac OS X v10.5 and later.

Declared in `AERegistry.h`.

Special Considerations

Although these constants were not publicly defined in Mac OS X version 10.4, corresponding information was provided in `kAEOpenApplication` Apple events sent by that version of the OS. Therefore your application, running on Mac OS X version 10.4 or later, can examine the open application Apple event to determine if the application was launched as a login item or a service item. However, for version 10.4, you will have to define these constants in your own code file.

You check for a `keyAEPropData` parameter of the `kAEOpenApplication` Apple event, with a data value that matches `keyAELaunchedAsLogInItem` or `keyAELaunchedAsServiceItem`.

Declared In

`AERegistry.h`

Numeric Descriptor Type Constants

Specify types for numeric descriptors.

```
enum {
    typeSInt16 = 'shor',
    typeUInt16 = 'ushr',
    typeSInt32 = 'long',
    typeUInt32 = 'magn',
    typeSInt64 = 'comp',
    typeUInt64 = 'ucom',
    typeIEEE32BitFloatingPoint = 'sing',
    typeIEEE64BitFloatingPoint = 'doub',
    type128BitFloatingPoint = 'ldbl',
    typeDecimalStruct = 'decm'
};
```

Constants

`typeSInt16`
16-bit signed integer.
Available in Mac OS X v10.0 and later.
Declared in `AEDataModel.h`.

`typeUInt16`
16-bit unsigned integer.
Available in Mac OS X v10.5 and later.
Declared in `AEDataModel.h`.

`typeSInt32`
32-bit signed integer.
Available in Mac OS X v10.0 and later.
Declared in `AEDataModel.h`.

`typeUInt32`
32-bit unsigned integer.
Available in Mac OS X v10.0 and later.
Declared in `AEDataModel.h`.

`typeSInt64`
64-bit signed integer.
Available in Mac OS X v10.0 and later.
Declared in `AEDataModel.h`.

`typeUInt64`
64-bit unsigned integer.
Available in Mac OS X v10.5 and later.
Declared in `AEDataModel.h`.

`typeIEEE32BitFloatingPoint`
32-bit floating point value.
Available in Mac OS X v10.0 and later.
Declared in `AEDataModel.h`.

`typeIEEE64BitFloatingPoint`
64-bit floating point value.
Available in Mac OS X v10.0 and later.
Declared in `AEDataModel.h`.

`type128BitFloatingPoint`
128-bit floating point value.

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

`typeDecimalStruct`
Decimal.

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

Discussion
The constants described here specify the data type for a descriptor and show the kind of numeric data stored in a descriptor with that type. These constants are preferred over their older equivalents described in "typeSMInt" (page 632).

Descriptors are the building blocks used by the Apple Event Manager to construct Apple event attributes and parameters. A descriptor is a data structure of type `AEDesc` (page 546), which consists of data storage and a descriptor type that identifies the type of the data. A descriptor type is defined by the data type `DescType` (page 560).

AppleScript defines descriptor type constants for a wide variety of common data types. For additional types, see "Descriptor Type Constants" (page 581) and "Other Descriptor Type Constants" (page 601). For a complete listing, including data types such as units of length, weight, and volume, see the Apple Event Manager and Open Scripting Architecture header files.

Declared In
`AEDataModel.h`

Object Class ID Constants

Specify the object class for an Apple event object.

```
enum {
    cParagraph = 'cpar',
    cPICT = 'PICT',
    cPixel = 'cpxl',
    cPixelMap = 'cpix',
    cPolygon = 'cpgn',
    cProperty = 'prop',
    cQDPoint = 'QDpt',
    cQDRectangle = 'qdrt',
    cRectangle = 'crec',
    cRGBColor = 'cRGB',
    cRotation = 'trot',
    cRoundedRectangle = 'crrc',
    cRow = 'crow',
    cSelection = 'csel',
    cShortInteger = 'shor',
    cTable = 'ctbl',
    cText = 'ctxt',
    cTextFlow = 'cflo',
    cTextStyles = 'tsty',
    cType = 'type'
};
```

Constants

`cParagraph`

A paragraph of text.

Available in Mac OS X v10.0 and later.

Declared in `AERegistry.h`.

`cPICT`

A PICT format figure.

Available in Mac OS X v10.0 and later.

Declared in `AERegistry.h`.

`cProperty`

A property of any object class.

Available in Mac OS X v10.0 and later.

Declared in `AERegistry.h`.

`cRGBColor`

An RGB color value.

Available in Mac OS X v10.0 and later.

Declared in `AERegistry.h`.

Discussion

The object class of an Apple event object is identified by an object class ID. For example, the object class for an object specifier that specifies an RGB color value is the four-character code `'cRGB'`, which can be represented by the constant `cRGBColor`.

AppleScript defines constants for a wide variety of common object classes, though only a small number are shown here. For a more complete listing, see the Apple Event Manager and Open Scripting Architecture header files.

Other Descriptor Type Constants

Specify types for Boolean and character descriptors.

```
enum {
    typeBoolean = 'bool',
    typeChar = 'TEXT'
};
```

Constants

`typeBoolean`

Boolean value—single byte with value 0 or 1.

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

`typeChar`

Unterminated string of system script characters.

See the Version Notes section below for important information.

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

Discussion

The constants described here specify the data type for a descriptor and show the kind of data stored in a descriptor with that type.

Descriptors are the building blocks used by the Apple Event Manager to construct Apple event attributes and parameters. A descriptor is a data structure of type `AEDesc` (page 546), which consists of data storage and a descriptor type that identifies the type of the data. A descriptor type is defined by the data type `DescType` (page 560).

AppleScript defines descriptor type constants for a wide variety of common data types. For additional types, see "Descriptor Type Constants" (page 581) and "Numeric Descriptor Type Constants" (page 597). For a complete listing, including data types such as units of length, weight, and volume, see the Apple Event Manager and Open Scripting Architecture header files.

Version Notes

On Mac OS X `typeChar` type is deprecated in favor of `typeUTF8Text` or `typeUTF16ExternalRepresentation`. For more information, see `typeUTF16ExternalRepresentation` (page 635).

Priority Constants for the AESend Function (Deprecated in Mac OS X)

Specify a value for the `sendPriority` parameter of the `AESend` function. (**Deprecated.** Not used in Mac OS X.)

```
enum {
    kAENormalPriority = 0x00000000,
    kAEHighPriority = 0x00000001
};
```

Constants

`kAENormalPriority`

The Apple Event Manager posts the event at the end of the event queue of the server process and the server processes the Apple event as soon as it has the opportunity.

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

`kAEHighPriority`

The Apple Event Manager posts the event at the beginning of the event queue of the server process.

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

Discussion

For related information, see the `AESend` (page 476) function and "AESendMode" (page 566).

Version Notes

The `sendPriority` parameter of the `AESend` function is deprecated in Mac OS X.

Remote Process Dictionary Keys

Used to extract information from dictionaries with entries that describe remote processes.

```
extern const CFStringRef kAERemoteProcessURLKey;
extern const CFStringRef kAERemoteProcessNameKey;
extern const CFStringRef kAERemoteProcessUserIDKey;
extern const CFStringRef kAERemoteProcessProcessIDKey;
```

Constants

`kAERemoteProcessURLKey`

Use this key to obtain the full URL to the remote process, as a `CFURLRef`.

Available in Mac OS X v10.3 and later.

Declared in `AppleEvents.h`.

`kAERemoteProcessNameKey`

Use this key to obtain the visible name of the remote process, in the localization supplied by the server, as a `CFStringRef`.

Available in Mac OS X v10.3 and later.

Declared in `AppleEvents.h`.

`kAERemoteProcessUserIDKey`

Use this key to obtain the user ID of the remote process, if available; if so, returned as a `CFNumberRef`.

Available in Mac OS X v10.3 and later.

Declared in `AppleEvents.h`.

`kAERemoteProcessProcessIDKey`
Use this key to obtain the process ID of the remote process, if available; if so, returned as a `CFNumberRef`.

Available in Mac OS X v10.3 and later.

Declared in `AppleEvents.h`.

Declared In
`AppleEvents.h`

Resume Event Dispatch Constants

Specify event dispatching information to the `AEResumeTheCurrentEvent` function.

```
enum {
    kAENoDispatch = 0,
    kAEUseStandardDispatch = 0xFFFFFFFF
};
```

Constants
`kAENoDispatch`
Tells the Apple Event Manager that the Apple event has been completely processed and need not be dispatched.

Available in Mac OS X v10.0 and later.

Declared in `AEInteraction.h`.

`kAEUseStandardDispatch`
Tells the Apple Event Manager to dispatch the resumed event using the standard dispatching scheme it uses for other Apple events.

Available in Mac OS X v10.0 and later.

Declared in `AEInteraction.h`.

Discussion
You call the `AEResumeTheCurrentEvent` (page 474) function to inform the Apple Event Manager that your application wants to resume the handling of a previously suspended Apple event or that it has completed the handling of the Apple event. You pass one of the constants described here in the `dispatcher` parameter to provide dispatching information to the Apple Event Manager. You can also pass a handler universal procedure pointer.

Special Handler Callback Constants

Specify an object callback function to install, get, or remove from the special handler dispatch table.

```
enum {
    keyAERangeStart = 'star',
    keyAERangeStop = 'stop',
    keyDisposeTokenProc = 'xtok',
    keyAECompareProc = 'cmpr',
    keyAECountProc = 'cont',
    keyAEMarkTokenProc = 'mkid',
    keyAEMarkProc = 'mark',
    keyAEAdjustMarksProc = 'adjm',
    keyAEGetErrDescProc = 'indc'
};
```

Constants

`keyAERangeStart`
Specifies the first Apple event object in a desired range.
Available in Mac OS X v10.0 and later.
Declared in `AEObjects.h`.

`keyAERangeStop`
Specifies the last Apple event object in the desired range.
Available in Mac OS X v10.0 and later.
Declared in `AEObjects.h`.

`keyDisposeTokenProc`
Token disposal function. See `OSLDisposeTokenProcPtr` (page 539).
Available in Mac OS X v10.0 and later.
Declared in `AEObjects.h`.

`keyAECompareProc`
Object-comparison function. See `OSLCompareProcPtr` (page 536).
Available in Mac OS X v10.0 and later.
Declared in `AEObjects.h`.

`keyAECountProc`
Object-counting function. See `OSLCountProcPtr` (page 538).
Available in Mac OS X v10.0 and later.
Declared in `AEObjects.h`.

`keyAEMarkTokenProc`
Mark token function. See `OSLGetMarkTokenProcPtr` (page 542).
Available in Mac OS X v10.0 and later.
Declared in `AEObjects.h`.

`keyAEMarkProc`
Object-marking function. See `OSLMarkProcPtr` (page 544).
Available in Mac OS X v10.0 and later.
Declared in `AEObjects.h`.

`keyAEAdjustMarksProc`
Mark-adjusting function. See `OSLAdjustMarksProcPtr` (page 535).
Available in Mac OS X v10.0 and later.
Declared in `AEObjects.h`.

`keyAEGetErrDescProc`
: Get error descriptor callback function. See `OSLGetErrDescProcPtr` (page 541).

  Available in Mac OS X v10.0 and later.

  Declared in `AEObjects.h`.

Discussion
You use these constants with the `AEInstallSpecialHandler` (page 452), `AEGetSpecialHandler` (page 446), or `AERemoveSpecialHandler` (page 471) functions.

Timeout Constants

Specify a timeout value.

```
enum {
    kAEDefaultTimeout = -1,
    kNoTimeOut = -2
};
```

Constants
`kAEDefaultTimeout`
: The timeout value is determined by the Apple Event Manager. The default timeout value is about one minute.

  Available in Mac OS X v10.0 and later.

  Declared in `AEDataModel.h`.

`kNoTimeOut`
: Your application is willing to wait indefinitely. Most commonly, you instead provide a timeout value (in ticks) that will provide a reasonable amount of time for the current operation.

  Available in Mac OS X v10.0 and later.

  Declared in `AEDataModel.h`.

Discussion
Your application can use these constants when it calls the `AEInteractWithUser` (page 453) function, or it can supply the specific amount of time (in ticks) that your handler is willing to wait for a response from the user. You can also use the constants with the `AESend` (page 476) function.

User Interaction Level Constants

Specify to the `AESetInteractionAllowed` function the conditions under which your application is willing to interact with the user.

```
enum {
    kAEInteractWithSelf = 0,
    kAEInteractWithLocal = 1,
    kAEInteractWithAll = 2
};
```

Constants

`kAEInteractWithSelf`

Indicates that the server application may interact with the user in response to an Apple event only when the client application and server application are the same—that is, only when your application is sending the Apple event to itself.

Available in Mac OS X v10.0 and later.

Declared in `AEInteraction.h`.

`kAEInteractWithLocal`

Indicates that your server application may interact with the user in response to an Apple event only if the client application is on the same computer as the server application. This is the default value if your application has not called the `AESetInteractionAllowed` (page 479) function to set the interaction level explicitly.

Available in Mac OS X v10.0 and later.

Declared in `AEInteraction.h`.

`kAEInteractWithAll`

Indicates that your server application may interact with the user in response to an Apple event sent from any client application on any computer.

Available in Mac OS X v10.0 and later.

Declared in `AEInteraction.h`.

Discussion

If your application does not set the user interaction level by calling the `AESetInteractionAllowed` (page 479) function, the Apple Event Manager uses `kAEInteractWithLocal` as the default value.

Declared In

`AERegistry.h`

Whose Test Constants

```
enum {
    typeWhoseDescriptor = 'whos',
    formWhose = 'whos',
    typeWhoseRange = 'wrng',
    keyAEWhoseRangeStart = 'wstr',
    keyAEWhoseRangeStop = 'wstp',
    keyAEIndex = 'kidx',
    keyAETest = 'ktst'
};
```

Constants

`formWhose`

Specifies a container of one or more objects and a test to perform on the objects.

The key data for `formWhose` is specified by a whose descriptor, which is a coerced Apple event record of descriptor type `typeWhoseDescriptor`. The data for a whose descriptor consists of two keyword-specified descriptors with the keywords `keyAEIndex` and `keyAETest`.

See also the description for `formTest`.

Available in Mac OS X v10.0 and later.

Declared in `AEObjects.h`.

kAEDoObjectsExist

```
enum {
    kAEDoObjectsExist = 'doex',
    kAEDoScript = 'dosc',
    kAEDrag = 'drag',
    kAEDuplicateSelection = 'sdup',
    kAEEditGraphic = 'edit',
    kAEEmptyTrash = 'empt',
    kAEEnd = 'end ',
    kAEEndsWith = 'ends',
    kAEEndTransaction = 'endt',
    kAEEquals = '=   ',
    kAEExpanded = 'pexp',
    kAEFast = 'fast',
    kAEFinderEvents = 'FNDR',
    kAEFormulaProtect = 'fpro',
    kAEFullyJustified = 'full',
    kAEGetClassInfo = 'qobj',
    kAEGetData = 'getd',
    kAEGetDataSize = 'dsiz',
    kAEGetEventInfo = 'gtei',
    kAEGetInfoSelection = 'sinf'
};
```

Constants

`kAEEndsWith`

The value of `operand1` ends with the value of `operand2` (for example, the string `"operand"` ends with the string `"and"`).

Available in Mac OS X v10.0 and later.

Declared in `AERegistry.h`.

`kAEEquals`
The value of `operand1` is equal to the value of `operand2`

Available in Mac OS X v10.0 and later.

Declared in `AERegistry.h`.

`kAEFinderEvents`
An event that the Finder accepts.

Available in Mac OS X v10.0 and later.

Declared in `AERegistry.h`.

kAEDebugPOSTHeader

```
enum {
    kAEDebugPOSTHeader = 0x01,
    kAEDebugReplyHeader = 0x02,
    kAEDebugXMLRequest = 0x04,
    kAEDebugXMLResponse = 0x08,
    kAEDebugXMLDebugAll = 0xFFFFFFFF
};
```

kAEGetPrivilegeSelection

```
enum {
    kAEGetPrivilegeSelection = 'sprv',
    kAEGetSuiteInfo = 'gtsi',
    kAEGreaterThan = '>   ',
    kAEGreaterThanEquals = '>=  ',
    kAEGrow = 'grow',
    kAEHidden = 'hidn',
    kAEHiQuality = 'hiqu',
    kAEImageGraphic = 'imgr',
    kAEIsUniform = 'isun',
    kAEItalic = 'ital',
    kAELeftJustified = 'left',
    kAELessThan = '<   ',
    kAELessThanEquals = '<=  ',
    kAELowercase = 'lowc',
    kAEMakeObjectsVisible = 'mvis',
    kAEMiscStandards = 'misc',
    kAEModifiable = 'modf',
    kAEMove = 'move',
    kAENo = 'no  ',
    kAENoArrow = 'arno'
};
```

Constants

`kAEGreaterThan`
The value of `operand1` is greater than the value of `operand2`.

Available in Mac OS X v10.0 and later.

Declared in `AERegistry.h`.

`kAEGreaterThanEquals`
The value of `operand1` is greater than or equal to the value of `operand2`.

Available in Mac OS X v10.0 and later.

Declared in `AERegistry.h`.

`kAELessThanEquals`
The value of `operand1` is less than or equal to the value of `operand2`.

Available in Mac OS X v10.0 and later.

Declared in `AERegistry.h`.

kAEHandleArray

```
enum {
    kAEHandleArray = 2
};
```

Constants

`kAEHandleArray`
Array items consist of handles to data of the same type and possibly variable size.

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

kAEInfo

```
enum {
    kAEInfo = 11,
    kAEMain = 0,
    kAESharing = 13
};
```

kAEInternetSuite

```
enum {
    kAEInternetSuite = 'gurl',
    kAEISWebStarSuite = 'WWW'
};
```

kAEISGetURL

```
enum {
    kAEISGetURL = 'gurl',
    KAEISHandleCGI = 'sdoc'
};
```

kAEISHTTPSearchArgs

```
enum {
    kAEISHTTPSearchArgs = 'kfor',
    kAEISPostArgs = 'post',

    kAEUndo = 'undo',
    kAEWholeWordEquals = 'wweq',
    kAEYes = 'yes ',
    kAEZoom = 'zoom'
};
```

kAESocks4Protocol

```
enum {
    kAESocks4Protocol = 4,
    kAESocks5Protocol = 5
};
```

kAEUseHTTPProxyAttr

Web Services Proxy support—these constants should be added as attributes of the event that is being sent (not as part of the direct object).

```
enum {
    kAEUseHTTPProxyAttr = 'xupr',
    kAEHTTPProxyPortAttr = 'xhtp',
    kAEHTTPProxyHostAttr = 'xhth'
};
```

Constants

`kAEUseHTTPProxyAttr`

A value of type `typeBoolean`. Specifies whether to manually specify the proxy host and port. Defaults to `true`.

Available in Mac OS X v10.2 and later.

Declared in `AEDataModel.h`.

`kAEHTTPProxyPortAttr`

A value of type `typeSInt32`.

Available in Mac OS X v10.2 and later.

Declared in `AEDataModel.h`.

`kAEHTTPProxyHostAttr`

A value of type `typeChar` or `typeUTF8Text`.

Available in Mac OS X v10.2 and later.

Declared in `AEDataModel.h`.

kAEUserTerminology

```
enum {
    kAEUserTerminology = 'aeut',
    kAETerminologyExtension = 'aete',
    kAEScriptingSizeResource = 'scsz',
    kAEOSAXSizeResource = 'osiz'
};
```

kAEUseSocksAttr

```
enum {
    kAEUseSocksAttr = 'xscs',
    kAESocksProxyAttr = 'xsok',
    kAESocksHostAttr = 'xshs',
    kAESocksPortAttr = 'xshp',
    kAESocksUserAttr = 'xshu',
    kAESocksPasswordAttr = 'xshw'
};
```

kAEUTHasReturningParam

```
enum {
    kAEUTHasReturningParam = 31,
    kAEUTOptional = 15,
    kAEUTlistOfItems = 14,
    kAEUTEnumerated = 13,
    kAEUTReadWrite = 12,
    kAEUTChangesState = 12,
    kAEUTTightBindingFunction = 12,
    kAEUTEnumsAreTypes = 11,
    kAEUTEnumListIsExclusive = 10,
    kAEUTReplyIsReference = 9,
    kAEUTDirectParamIsReference = 9,
    kAEUTParamIsReference = 9,
    kAEUTPropertyIsReference = 9,
    kAEUTNotDirectParamIsTarget = 8,
    kAEUTParamIsTarget = 8,
    kAEUTApostrophe = 3,
    kAEUTFeminine = 2,
    kAEUTMasculine = 1,
    kAEUTPlural = 0
};
```

kAEZoomIn

```
enum {
    kAEZoomIn = 7,
    kAEZoomOut = 8
};
```

kBySmallIcon

```
enum {
    kBySmallIcon = 0,
    kByIconView = 1,
    kByNameView = 2,
    kByDateView = 3,
    kBySizeView = 4,
    kByKindView = 5,
    kByCommentView = 6,
    kByLabelView = 7,
    kByVersionView = 8
};
```

kCaretPosition

```
enum {
    kCaretPosition = 1,
    kRawText = 2,
    kSelectedRawText = 3,
    kConvertedText = 4,
    kSelectedConvertedText = 5,
    kBlockFillText = 6,
    kOutlineText = 7,
    kSelectedText = 8
};
```

Version Notes
Starting in Mac OS X v10.4, use the constants defined in "kTSMHiliteCaretPosition" (page 624) in place of these constants.

kConnSuite

```

    keyAERotPoint = 'krtp',
    keyAERowList = 'krls',
    keyAESaveOptions = 'savo',
    keyAEScale = 'pscl',
    keyAEScriptTag = 'psct',
    keyAESearchText = 'stxt',
    keyAEShowWhere = 'show',
    keyAEStartAngle = 'pang',
    keyAEStartPoint = 'pstp',
    keyAEStyles = 'ksty'
};
```

Constants

`keyAESearchText`

Identifies an optional parameter to the `open documents` Apple event, described in "Event ID Constants" (page 586). The parameter contains the search text from the Spotlight search that identified the documents to be opened. The application should make a reasonable effort to display an occurrence of the search text in each opened document—for example by scrolling the text into view.

For more information, see "Handling Apple Events Sent by the Mac OS" in "Responding to Apple Events" in Apple Events Programming Guide.

Available in Mac OS X v10.4 and later.

Declared in `AERegistry.h`.

Version Notes

The constant `keyAESearchText` is available starting in Mac OS X v10.4.

keyAESuiteID

```
enum {
    keyAESuiteID = 'suit',
    keyAEText = 'ktxt',
    keyAETextColor = 'ptxc',
    keyAETextFont = 'ptxf',
    keyAETextPointSize = 'ptps',
    keyAETextStyles = 'txst',

    typeTextRangeArray = 'tray',
    typeLowLevelEventRecord = 'evtr',
    typeGlyphInfoArray = 'glia',
    typeEventRef = 'evrf',
    typeText = 'TEXT'
};
```

kTSMHiliteCaretPosition

Specify text highlighting information.

```
enum {
    kTSMHiliteCaretPosition = 1,
    kTSMHiliteRawText = 2,
    kTSMHiliteSelectedRawText = 3,
    kTSMHiliteConvertedText = 4,
    kTSMHiliteSelectedConvertedText = 5,
    kTSMHiliteBlockFillText = 6,
    kTSMHiliteOutlineText = 7,
    kTSMHiliteSelectedText = 8,
    kTSMHiliteNoHilite = 9
};
```

Constants

`kTSMHiliteCaretPosition`

Specifies caret position.

Available in Mac OS X v10.4 and later.

Declared in `AERegistry.h`.

`kTSMHiliteRawText`
Specifies range of raw text.
Available in Mac OS X v10.4 and later.
Declared in `AERegistry.h`.

`kTSMHiliteSelectedRawText`
Specifies range of selected raw text.
Available in Mac OS X v10.4 and later.
Declared in `AERegistry.h`.

`kTSMHiliteConvertedText`
Specifies range of converted text.
Available in Mac OS X v10.4 and later.
Declared in `AERegistry.h`.

`kTSMHiliteSelectedConvertedText`
Specifies range of selected converted text.
Available in Mac OS X v10.4 and later.
Declared in `AERegistry.h`.

`kTSMHiliteBlockFillText`
Specifies block fill highlight style.
Available in Mac OS X v10.4 and later.
Declared in `AERegistry.h`.

`kTSMHiliteOutlineText`
Specifies outline highlight style.
Available in Mac OS X v10.4 and later.
Declared in `AERegistry.h`.

`kTSMHiliteSelectedText`
Specifies selected highlight style.
Available in Mac OS X v10.4 and later.
Declared in `AERegistry.h`.

`kTSMHiliteNoHilite`
Specifies range of non-highlighted text.
Available in Mac OS X v10.4 and later.
Declared in `AERegistry.h`.

Version Notes
This enumeration is available starting in Mac OS X v10.4. Use these constants in place of the constants defined in "kCaretPosition" (page 615).

kTSMOutsideOfBody

```
enum {
    kTSMOutsideOfBody = 1,
    kTSMInsideOfBody = 2,
    kTSMInsideOfActiveInputArea = 3
};
```

pArcAngle

```
enum {
    pArcAngle = 'parc',
    pBackgroundColor = 'pbcl',
    pBackgroundPattern = 'pbpt',
    pBestType = 'pbst',
    pBounds = 'pbnd',
    pClass = 'pcls',
    pClipboard = 'pcli',
    pColor = 'colr',
    pColorTable = 'cltb',
    pContents = 'pcnt',
    pCornerCurveHeight = 'pchd',
    pCornerCurveWidth = 'pcwd',
    pDashStyle = 'pdst',
    pDefaultType = 'deft',

    pEnabled = 'enbl',
    pEndPoint = 'pend',
    pFillColor = 'flcl',
    pFillPattern = 'flpt',
    pFont = 'font'
};
```

pFormula

```
enum {
    pFormula = 'pfor',
    pGraphicObjects = 'gobs',
    pHasCloseBox = 'hclb',
    pHasTitleBar = 'ptit',
    pID = 'ID  ',
    pIndex = 'pidx',
    pInsertionLoc = 'pins',
    pIsFloating = 'isfl',
    pIsFrontProcess = 'pisf',
    pIsModal = 'pmod',
    pIsModified = 'imod',
    pIsResizable = 'prsz',
    pIsStationeryPad = 'pspd',
    pIsZoomable = 'iszm',
    pIsZoomed = 'pzum',
    pItemNumber = 'itmn',
    pJustification = 'pjst',
    pLineArrow = 'arro',
    pMenuID = 'mnid',
```

```
    pName = 'pnam'
};
```

pNewElementLoc

```
enum {
    pNewElementLoc = 'pnel',
    pPenColor = 'ppcl',
    pPenPattern = 'pppa',
    pPenWidth = 'ppwd',
    pPixelDepth = 'pdpt',
    pPointList = 'ptlt',
    pPointSize = 'ptsz',
    pProtection = 'ppro',
    pRotation = 'prot',
    pScale = 'pscl',
    pScript = 'scpt',
    pScriptTag = 'psct',
    pSelected = 'selc',
    pSelection = 'sele',
    pStartAngle = 'pang',
    pStartPoint = 'pstp',
    pTextColor = 'ptxc',
    pTextFont = 'ptxf',
    pTextItemDelimiters = 'txdl',
    pTextPointSize = 'ptps'
};
```

pScheme

```
enum {
    pScheme = 'pusc',
    pHost = 'HOST',
    pPath = 'FTPc',
    pUserName = 'RAun',
    pUserPassword = 'RApw',
    pDNSForm = 'pDNS',
    pURL = 'pURL',
    pTextEncoding = 'ptxe',
    pFTPKind = 'kind'
};
```

pTextStyles

```
enum {
    pTextStyles = 'txst',
    pTransferMode = 'pptm',
    pTranslation = 'ptrs',
    pUniformStyles = 'ustl',
    pUpdateOn = 'pupd',
    pUserSelection = 'pusl',
    pVersion = 'vers',
    pVisible = 'pvis'
```

```
};
```

typeAEText

```
enum {
    typeAEText = 'tTXT',
    typeArc = 'carc',
    typeBest = 'best',
    typeCell = 'ccel',
    typeClassInfo = 'gcli',
    typeColorTable = 'clrt',
    typeColumn = 'ccol',
    typeDashStyle = 'tdas',
    typeData = 'tdta',
    typeDrawingArea = 'cdrw',
    typeElemInfo = 'elin',
    typeEnumeration = 'enum',
    typeEPS = 'EPS ',
    typeEventInfo = 'evin'
};
```

typeApplicationBundleID

For specifying a target application by bundle ID.

```
enum {
    typeApplicationBundleID = 'bund'
};
```

Constants

`typeApplicationBundleID`

Indicates a descriptor containing UTF-8 characters that specify the bundle ID of an application. Bundle IDs should be constructed similarly to `"com.company.directorylocation.ApplicationName"`.

Available in Mac OS X v10.3 and later.

Declared in `AEDataModel.h`.

Discussion

This address mode is preferred for targeting specific applications. For example, you should target the Finder by sending an event whose target address descriptor uses the bundle ID `"com.apple.finder"` rather than the application signature `'MACS'`.

typeFinderWindow

```
enum {
    typeFinderWindow = 'fwin',
    typeFixedPoint = 'fpnt',
    typeFixedRectangle = 'frct',
    typeGraphicLine = 'glin',
    typeGraphicText = 'cgtx',
    typeGroupedGraphic = 'cpic',
    typeInsertionLoc = 'insl',
    typeIntlText = 'itxt',
    typeIntlWritingCode = 'intl',
    typeLongDateTime = 'ldt ',
    typeISO8601DateTime = 'isot',
    typeLongFixed = 'lfxd',
    typeLongFixedPoint = 'lfpt',
    typeLongFixedRectangle = 'lfrc',
    typeLongPoint = 'lpnt',
    typeLongRectangle = 'lrct',
    typeMachineLoc = 'mLoc',
    typeOval = 'covl',
    typeParamInfo = 'pmin',
    typePict = 'PICT'
};
```

Constants

`typeIntlText`

For important information, see the Version Notes section of the "`typeUnicodeText`" (page 635) enum.

Available in Mac OS X v10.0 and later.

Declared in `AERegistry.h`.

typeHIMenu

```
enum {
    typeHIMenu = 'mobj',
    typeHIWindow = 'wobj'
};
```

typeKernelProcessID

For specifying an application by UNIX process ID.

```
enum {
    typeKernelProcessID = 'kpid'
};
```

Constants

`typeKernelProcessID`

Indicates a descriptor containing a UNIX process ID. A process ID is similar to a PSN (processor serial number) but does not require a Process Manager connection. It is analogous to a 32-bit unsigned integer.

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

Discussion

You might use this constant in a situation where you have access to the PID for a process but don't have a Process Manager connection. Your code for creating the descriptor might look like the following:

```
pid_t pid = findTheAppPid(); // User supplied routine to get PID. // Now create
 a descriptor with it: AECreateDesc(typeKernelProcessID, &pid, sizeof(pid),
&desc);
```

typeMachPort

For specifying a Mach port.

```
enum {
    typeMachPort = 'port'
};
```

Constants

`typeMachPort`

Indicates a descriptor that specifies a Mach port.

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

Discussion

You might use this constant as part of sending an Apple event to an arbitrary Mach port. Your code for creating the descriptor might look like the following:

```
mach_port_t port = lookupPortForTarget(); // User routine to get  port.
// Now create a descriptor with it:
AECreateDesc(typeMachPort, &port, sizeof(port), &desc);
```

Actually sending an Apple event to a Mach port is an advanced technique and is not documented here.

typeMeters

```
enum {
    typeMeters = 'metr',
    typeInches = 'inch',
    typeFeet = 'feet',
    typeYards = 'yard',
    typeMiles = 'mile',
    typeKilometers = 'kmtr',
    typeCentimeters = 'cmtr',
    typeSquareMeters = 'sqrm',
    typeSquareFeet = 'sqft',
    typeSquareYards = 'sqyd',
    typeSquareMiles = 'sqmi',
    typeSquareKilometers = 'sqkm',
    typeLiters = 'litr',
    typeQuarts = 'qrts',
    typeGallons = 'galn',
    typeCubicMeters = 'cmet',
    typeCubicFeet = 'cfet',
    typeCubicInches = 'cuin',
    typeCubicCentimeter = 'ccmt',
    typeCubicYards = 'cyrd',
    typeKilograms = 'kgrm',
    typeGrams = 'gram',
    typeOunces = 'ozs ',
    typePounds = 'lbs ',
    typeDegreesC = 'degc',
    typeDegreesF = 'degf',
    typeDegreesK = 'degk'
};
```

typePixelMap

```
enum {
    typePixelMap = 'cpix',
    typePixMapMinus = 'tpmm',
    typePolygon = 'cpgn',
    typePropInfo = 'pinf',
    typePtr = 'ptr ',
    typeQDPoint = 'QDpt',
    typeQDRegion = 'Qrgn',
    typeRectangle = 'crec',
    typeRGB16 = 'tr16',
    typeRGB96 = 'tr96',
    typeRGBColor = 'cRGB',
    typeRotation = 'trot',
    typeRoundedRectangle = 'crrc',
    typeRow = 'crow',
    typeScrapStyles = 'styl',
    typeScript = 'scpt',
    typeStyledText = 'STXT',
    typeSuiteInfo = 'suin',
    typeTable = 'ctbl',
    typeTextStyles = 'tsty'
};
```

Constants

`typeStyledText`

Text that includes style information.

Styled text is stored as a record, in which the styles have the key `'ksty'` and the plain text is has the key `'ktxt'`. You can use this information to extract plain text from styled text without coercion.

However, getting rid of the style information, with or without coercion, may corrupt the text, since the styles imply what encoding to use. In fact, use of `typeText` and `typeStyledText` are not recommended, starting with Mac OS X, because they are not safe with international characters—you should use one of the Unicode text types instead.

For important information, see the Version Notes section of the "`typeUnicodeText`" (page 635) enum.

Available in Mac OS X v10.0 and later.

Declared in `AERegistry.h`.

typeReplyPortAttr

```
enum {
    typeReplyPortAttr = 'repp'
};
```

typeSessionID

```
enum {
    typeSessionID = 'ssid',
    typeTargetID = 'targ',
    typeDispatcherID = 'dspt'
};
```

Constants

`typeSessionID`

Session reference number.

`typeTargetID`

Target ID descriptor. Target IDs are not supported in Mac OS X.

typeSMInt

Where possible, you should use the constants defined in "Numeric Descriptor Type Constants" (page 597), rather than those defined here.

```
enum {
    typeSMInt = 'shor',
    typeShortInteger = 'shor',
    typeInteger = 'long',
    typeLongInteger = 'long',
    typeMagnitude = 'magn',
    typeComp = 'comp',
    typeSMFloat = 'sing',
    typeShortFloat = 'sing',
    typeFloat = 'doub',
    typeLongFloat = 'doub',
    typeExtended = 'exte'
};
```

Constants

`typeSMInt`
16-bit integer.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `AEDataModel.h`.

`typeShortInteger`
16-bit integer.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `AEDataModel.h`.

`typeInteger`
32-bit integer.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `AEDataModel.h`.

`typeLongInteger`
32-bit integer.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `AEDataModel.h`.

`typeMagnitude`
Unsigned 32-bit integer.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `AEDataModel.h`.

`typeComp`
Standard Apple Numerics Environment (SANE) comparison operator.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `AEDataModel.h`.

`typeSMFloat`
SANE single.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `AEDataModel.h`.

`typeShortFloat`
SANE single.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `AEDataModel.h`.

`typeFloat`
SANE double.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `AEDataModel.h`.

`typeLongFloat`
SANE double.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `AEDataModel.h`.

`typeExtended`
SANE extended.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `AEDataModel.h`.

typeTIFF

```
enum {
    typeTIFF = 'TIFF',
    typeVersion = 'vers'
};
```

typeUnicodeText

```
enum {
    typeUTF16ExternalRepresentation = 'ut16',
    typeUnicodeText = 'utxt',
    typeStyledUnicodeText = 'sutx',
    typeUTF8Text = 'utf8',
    typeEncodedString = 'encs',
    typeCString = 'cstr',
    typePString = 'pstr'
};
```

Constants

`typeUTF16ExternalRepresentation`
Unicode text in 16-bit external representation with byte-order-mark (BOM).
Guarantees that either there is a BOM or the data is in UTF-16BE.
Available in Mac OS X v10.4 and later.
Declared in `AEDataModel.h`.

`typeUnicodeText`
Unicode text. Native byte ordering, optional BOM.
Available in Mac OS X v10.0 and later.
Declared in `AEDataModel.h`.

`typeStyledUnicodeText`
Styled Unicode text. Not implemented.
Available in Mac OS X v10.0 and later.
Declared in `AEDataModel.h`.

`typeUTF8Text`
8-bit Unicode (UTF-8 encoding).
Available in Mac OS X v10.2 and later.
Declared in `AEDataModel.h`.

`typeEncodedString`
Styled Unicode text. Not implemented.
Available in Mac OS X v10.0 and later.
Declared in `AEDataModel.h`.

`typeCString`
C string—Mac OS Roman characters followed by a NULL byte. Deprecated.
Available in Mac OS X v10.0 and later.
Declared in `AEDataModel.h`.

`typePString`

Pascal string—unsigned length byte followed by Mac OS Roman characters. Deprecated.

Available in Mac OS X v10.0 and later.

Declared in `AEDataModel.h`.

Version Notes
In Mac OS X version 10.4, you should use `typeUTF16ExternalRepresentation` or `typeUTF8Text` to represent text. In earlier versions of Mac OS X, the recommended text type is `typeUnicodeText`. All of the other constants in this enum are deprecated due to their lack of explicit encoding or byte order definition.

The implicitly encoded text types, `typeText`, `typeCString`, and `typePString`, are all deprecated in Mac OS X, because they are incapable of representing international characters and may be reinterpreted in unpredictable ways. Additionally, `typeCString` and `typePString` do not support the full range of text coercions, and will be removed entirely in a future release. `typeStyledText` and `typeIntlText`, while they have explicit encodings, are not recommended, since they are incapable of representing Unicode-only characters, such as Hungarian, Arabic, or Thai.

Result Codes

Because the Apple Event Manager uses the services of the Event Manager, the functions described in this document may return Event Manager result codes in addition to the Apple Event Manager result codes listed here. Less commonly, an Apple Event Manager function may return other result codes, including some of those found in the CarbonCore header file `MacErrors.h`.

For result codes for the AEBuild-related functions, see "AEBuild Error Codes" (page 563).

Result Code	Value	Description
`noPortErr`	-903	Client hasn't set `'SIZE'` resource to indicate awareness of high-level events Available in Mac OS X v10.0 and later.
`destPortErr`	-906	Server hasn't set `'SIZE'` resource to indicate awareness of high-level events, or else is not present Available in Mac OS X v10.0 and later.
`sessClosedErr`	-917	The `kAEDontReconnect` flag in the `sendMode` parameter was set and the server quit, then restarted Available in Mac OS X v10.0 and later.
`errAECoercionFail`	-1700	Data could not be coerced to the requested descriptor type Available in Mac OS X v10.0 and later.
`errAEDescNotFound`	-1701	Descriptor was not found Available in Mac OS X v10.0 and later.
`errAECorruptData`	-1702	Data in an Apple event could not be read Available in Mac OS X v10.0 and later.

Result Code	Value	Description
errAEWrongDataType	-1703	Wrong descriptor type Available in Mac OS X v10.0 and later.
errAENotAEDesc	-1704	Not a valid descriptor Available in Mac OS X v10.0 and later.
errAEBadListItem	-1705	Operation involving a list item failed Available in Mac OS X v10.0 and later.
errAENewerVersion	-1706	Need a newer version of the Apple Event Manager Available in Mac OS X v10.0 and later.
errAENotAppleEvent	-1707	The event is not in AppleEvent format. Available in Mac OS X v10.0 and later.
errAEEventNotHandled	-1708	Event wasn't handled by an Apple event handler Available in Mac OS X v10.0 and later.
errAEReplyNotValid	-1709	AEResetTimer was passed an invalid reply Available in Mac OS X v10.0 and later.
errAEUnknownSendMode	-1710	Invalid sending mode was passed Available in Mac OS X v10.0 and later.
errAEWaitCanceled	-1711	User canceled out of wait loop for reply or receipt Available in Mac OS X v10.0 and later.
errAETimeout	-1712	Apple event timed out Available in Mac OS X v10.0 and later.
errAENoUserInteraction	-1713	No user interaction allowed Available in Mac OS X v10.0 and later.
errAENotASpecialFunction	-1714	Wrong keyword for a special function Available in Mac OS X v10.0 and later.
errAEParamMissed	-1715	A required parameter was not accessed. Available in Mac OS X v10.0 and later.
errAEUnknownAddressType	-1716	Unknown Apple event address type Available in Mac OS X v10.0 and later.
errAEHandlerNotFound	-1717	No handler found for an Apple event Available in Mac OS X v10.0 and later.

Result Code	Value	Description
errAEReplyNotArrived	-1718	Reply has not yet arrived Available in Mac OS X v10.0 and later.
errAEIllegalIndex	-1719	Not a valid list index Available in Mac OS X v10.0 and later.
errAEImpossibleRange	-1720	The range is not valid because it is impossible for a range to include the first and last objects that were specified; an example is a range in which the offset of the first object is greater than the offset of the last object Available in Mac OS X v10.0 and later.
errAEWrongNumberArgs	-1721	The number of operands provided for the kAENOT logical operator is not 1 Available in Mac OS X v10.0 and later.
errAEAccessorNotFound	-1723	There is no object accessor function for the specified object class and container type Available in Mac OS X v10.0 and later.
errAENoSuchLogical	-1725	The logical operator in a logical descriptor is not kAEAND, kAEOR, or kAENOT Available in Mac OS X v10.0 and later.
errAEBadTestKey	-1726	The descriptor in a test key is neither a comparison descriptor nor a logical descriptor Available in Mac OS X v10.0 and later.
errAENotAnObjectSpec	–1727	The objSpecifier parameter of AEResolve is not an object specifier
errAENoSuchObject	-1728	Runtime resolution of an object failed. Available in Mac OS X v10.0 and later.
errAENegativeCount	-1729	An object-counting function returned a negative result Available in Mac OS X v10.0 and later.
errAEEmptyListContainer	-1730	The container for an Apple event object is specified by an empty list Available in Mac OS X v10.0 and later.
errAEUnknownObjectType	-1731	The object type isn't recognized Available in Mac OS X v10.0 and later.
errAERecordingIsAlreadyOn	-1732	Recording is already on Available in Mac OS X v10.0 and later.

Result Code	Value	Description
errAEReceiveTerminate	-1733	Break out of all levels of AEReceive to the topmost (1.1 or greater) Available in Mac OS X v10.0 and later.
errAEReceiveEscapeCurrent	-1734	Break out of lowest level only of AEReceive (1.1 or greater) Available in Mac OS X v10.0 and later.
errAEEventFiltered	-1735	Event has been filtered and should not be propagated (1.1 or greater) Available in Mac OS X v10.0 and later.
errAEDuplicateHandler	-1736	Attempt to install handler in table for identical class and ID (1.1 or greater) Available in Mac OS X v10.0 and later.
errAEStreamBadNesting	-1737	Nesting violation while streaming Available in Mac OS X v10.0 and later.
errAEStreamAlreadyConverted	-1738	Attempt to convert a stream that has already been converted Available in Mac OS X v10.0 and later.
errAEDescIsNull	-1739	Attempt to perform an invalid operation on a null descriptor Available in Mac OS X v10.0 and later.
errAEBuildSyntaxError	-1740	AEBuildDesc and related functions detected a syntax error Available in Mac OS X v10.0 and later.
errAEBufferTooSmall	-1741	Buffer for AEFlattenDesc too small Available in Mac OS X v10.0 and later.
errASCantConsiderAndIgnore	-2720	Can't both consider and ignore <attribute>. Available in Mac OS X v10.0 and later.
errASCantCompareMoreThan32k	-2721	Can't perform operation on text longer than 32K bytes. Available in Mac OS X v10.0 and later.
errASTerminologyNestingTooDeep	-2760	Tell statements are nested too deeply. Available in Mac OS X v10.0 and later.
errASIllegalFormalParameter	-2761	<name> is illegal as a formal parameter. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
errASParameterNotForEvent	-2762	<name> is not a parameter name for the event <event>. Available in Mac OS X v10.0 and later.
errASNoResultReturned	-2763	No result was returned for some argument of this expression. Available in Mac OS X v10.0 and later.
errAEEventFailed	-10000	Apple event handler failed. Available in Mac OS X v10.0 and later.
errAETypeError	-10001	A descriptor type mismatch occurred. Available in Mac OS X v10.0 and later.
errAEBadKeyForm	-10002	Invalid key form. Available in Mac OS X v10.0 and later.
errAENotModifiable	-10003	Can't set <object or data> to <object or data>. Access not allowed. Available in Mac OS X v10.0 and later.
errAEPrivilegeError	-10004	A privilege violation occurred. Available in Mac OS X v10.0 and later.
errAEReadDenied	-10005	The read operation was not allowed. Available in Mac OS X v10.0 and later.
errAEWriteDenied	-10006	Can't set <object or data> to <object or data>. Available in Mac OS X v10.0 and later.
errAEIndexTooLarge	-10007	The index of the event is too large to be valid. Available in Mac OS X v10.0 and later.
errAENotAnElement	-10008	The specified object is a property, not an element. Available in Mac OS X v10.0 and later.
errAECantSupplyType	-10009	Can’t supply the requested descriptor type for the data. Available in Mac OS X v10.0 and later.
errAECantHandleClass	-10010	The Apple event handler can’t handle objects of this class. Available in Mac OS X v10.0 and later.
errAEInTransaction	-10011	Couldn’t handle this command because it wasn’t part of the current transaction. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
`errAENoSuchTransaction`	-10012	The transaction to which this command belonged isn't a valid transaction. Available in Mac OS X v10.0 and later.
`errAENoUserSelection`	-10013	There is no user selection. Available in Mac OS X v10.0 and later.
`errAENotASingleObject`	-10014	Handler only handles single objects. Available in Mac OS X v10.0 and later.
`errAECantUndo`	-10015	Can't undo the previous Apple event or user action. Available in Mac OS X v10.0 and later.
`errAENotAnEnumMember`	-10023	Enumerated value in `SetData` is not allowed for this property Available in Mac OS X v10.0 and later.
`errAECantPutThatThere`	-10024	In make new, duplicate, etc. class can't be an element of container Available in Mac OS X v10.0 and later.
`errAEPropertiesClash`	-10025	Illegal combination of properties settings for SetData, make new, or duplicate Available in Mac OS X v10.0 and later.

Gestalt Constants

You can check for version and feature availability information by using the Apple Event Manager selectors defined in the Gestalt Manager. For more information see *Inside Mac OS X: Gestalt Manager Reference*.

Apple Type Services for Fonts Reference

Framework: ApplicationServices/ApplicationServices.h

Declared in ATSTypes.h
ATSFont.h

Overview

Apple Type Services for Fonts is a collection of functions and data types that you can use to access and manage font data in Mac OS X. It is designed to handle a wide range of font technologies and data formats. The programming interface is designed with performance, scalability, and consistency in mind, and is available to Cocoa and Carbon applications through the Apple Type Services (ATS) and QuickDraw frameworks in Mac OS X.

Carbon supports the Apple Type Services for Fonts.

Functions by Task

Activating and Deactivating Fonts

`ATSFontActivateFromFileReference` (page 647)
Activates one or more fonts from a file reference.

`ATSFontActivateFromMemory` (page 649)
Activates one or more fonts at the specified location in memory.

`ATSFontDeactivate` (page 651)
Deactivates one or more fonts.

`ATSGetGeneration` (page 678)
Obtains the generation of the font database.

`ATSFontSetGlobalAutoActivationSetting` (page 678)
Sets the user's global auto-activation setting.

`ATSFontGetGlobalAutoActivationSetting` (page 666)
Gets the user's global auto-activation setting.

`ATSFontSetAutoActivationSettingForApplication` (page 677)
Sets the auto-activation setting for the specified application bundle.

`ATSFontGetAutoActivationSettingForApplication` (page 661)
Gets the activation setting for the specified application.

ATSFontActivateFromFileSpecification (page 648) Deprecated in Mac OS X v10.5
Activates one or more fonts from a file specification. (Deprecated. Instead use ATSFontActivateFromFileReference (page 647).)

Working With Font Families

ATSFontFamilyApplyFunction (page 652)
Applies your callback to a font family iteration.

ATSFontFamilyIteratorCreate (page 655)
Creates a font family iterator that your application can use to access font family objects.

ATSFontFamilyIteratorRelease (page 658)
Releases the memory associated with a font family iterator.

ATSFontFamilyIteratorReset (page 658)
Resets a font family iterator to the beginning of the iteration.

ATSFontFamilyIteratorNext (page 657)
Obtains the next font family reference.

ATSFontFamilyFindFromName (page 652)
Returns the font family reference associated with a font family name.

ATSFontFamilyFindFromQuickDrawName (page 653)
Returns the font family reference associated with a standard QuickDraw font name.

ATSFontFamilyGetGeneration (page 654)
Returns the generation count of a font family.

ATSFontFamilyGetName (page 654)
Obtains the font family name associated with a font family reference.

ATSFontFamilyGetQuickDrawName (page 655)
Obtains the standard QuickDraw font name associated with a font family reference.

ATSFontFamilyGetEncoding (page 653)
Returns the text encoding used by a font family.

Working With Fonts

ATSFontApplyFunction (page 650)
Applies your callback to a font iteration.

ATSFontIteratorCreate (page 671)
Creates a font iterator.

ATSFontIteratorRelease (page 673)
Releases a font iterator.

ATSFontIteratorReset (page 674)
Resets a font iterator to the beginning of the iteration.

ATSFontIteratorNext (page 672)
Obtains the next font reference.

ATSFontFindFromName (page 660)
Returns the font reference associated with a font name.

`ATSFontFindFromPostScriptName` (page 661)
Returns the font reference associated with a PostScript font name.

`ATSFontFindFromContainer` (page 659)
Obtains the font references contained in a font container.

`ATSFontGetGeneration` (page 665)
Returns the generation count for a font.

`ATSFontGetContainerFromFileReference` (page 662)
Gets the font container reference associated with an activated file reference.

`ATSFontGetContainer` (page 662)
Gets the font container reference for a font.

`ATSFontGetName` (page 666)
Obtains the name of a font associated with a font reference.

`ATSFontGetPostScriptName` (page 667)
Obtains the PostScript name from a font reference.

`ATSFontGetTableDirectory` (page 669)
Obtains the table directory for a font.

`ATSFontGetTable` (page 668)
Obtains a font table.

`ATSFontGetHorizontalMetrics` (page 666)
Obtains the horizontal metrics for a font.

`ATSFontGetVerticalMetrics` (page 670)
Obtains the vertical metrics for a font.

`ATSFontGetFileReference` (page 663)
Obtains the file reference for a font.

`ATSFontGetFontFamilyResource` (page 664)
Obtains the font family resource for a font.

`ATSFontSetEnabled` (page 678)
Sets a font state to enabled or disabled.

`ATSFontIsEnabled` (page 671)
Returns `true` if the font is enabled.

`ATSFontGetFileSpecification` (page 663) Deprecated in Mac OS X v10.5
Obtains the file specification for a font. (Deprecated. Instead use `ATSFontGetFileReference` (page 663).)

Setting Up Notifications and Queries

`ATSFontNotify` (page 676)
Notifies Apple Type Services of an action taken by your application.

`ATSFontNotificationSubscribe` (page 675)
Signs up your application to receive notification of changes to fonts and font directories.

`ATSFontNotificationUnsubscribe` (page 676)
Unsubscribes your application from receiving notifications of changes to fonts and font directories.

`ATSCreateFontQueryRunLoopSource` (page 646)
Sets up your application to handle font queries.

Creating, Calling, and Deleting Universal Procedure Pointers

`NewFMFontCallbackFilterUPP` (page 680)
Creates a new universal procedure pointer (UPP) to a filter callback function that uses your criteria for filtering fonts.

`DisposeFMFontCallbackFilterUPP` (page 679)
Disposes of a universal procedure pointer to a customized filter function used for fonts.

`InvokeFMFontCallbackFilterUPP` (page 680)
Calls a customized filter function used for fonts.

`NewFMFontFamilyCallbackFilterUPP` (page 681)
Creates a new universal procedure pointer (UPP) to a filter callback function that uses your criteria for filtering font families.

`DisposeFMFontFamilyCallbackFilterUPP` (page 679)
Disposes of a universal procedure pointer to a customized filter function used for font families.

`InvokeFMFontFamilyCallbackFilterUPP` (page 680)
Calls a customized filter function used for font families.

Functions

ATSCreateFontQueryRunLoopSource

Sets up your application to handle font queries.

```
CFRunLoopSourceRef ATSCreateFontQueryRunLoopSource (
   CFIndex queryOrder,
   CFIndex sourceOrder,
   ATSFontQueryCallback callout,
   const ATSFontQuerySourceContext *context
);
```

Parameters

queryOrder
A `CFIndex` value that specifies the priority of the query relative to other queries. ATS sends font queries to each run loop in priority order, from highest to lowest, with normal priority equal to `0`.

sourceOrder
A `CFIndex` value that specifies the order of the run loop source.

callout
A pointer to your callback for processing a font query. See `ATSFontQueryCallback` (page 683) for more information on the callback you can supply.

context
A pointer to font query source context that ATS passes to your callback function. You can pass `NULL` if your callback function does not need any data passed to it.

Return Value
A `CFRunLoopSourceRef`. When you want to stop receiving queries, you must invalidate this reference.

Discussion
When an application needs a font, ATS sends a query to those font utility applications who have signed up to handle queries by calling the function `ATSCreateFontQueryRunLoopSource`. When a font utility application receives a query, it iterates through its available fonts to look for the requested font. If the font utility application finds the font, it obtains the file specification for the font and sends the file specification to ATS. ATS activates the font and sends notification of the activation to each application who subscribes to notifications.

The function `ATSCreateFontQueryRunLoopSource` creates a Core Foundation run loop source reference (`CFRunLoopSourceRef`) to convey font queries from ATS to your font utility application. If your application does not have a `CFRunLoop` (for example, a faceless server application), you must explicitly set up a `CFRunLoop` before you can receive queries.

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X 10.2 and later.

Declared In
`ATSFont.h`

ATSFontActivateFromFileReference

Activates one or more fonts from a file reference.

```
OSStatus ATSFontActivateFromFileReference (
   const FSRef *iFile,
   ATSFontContext iContext,
   ATSFontFormat iFormat,
   void *iRefCon,
   ATSOptionFlags iOptions,
   ATSFontContainerRef *oContainer
);
```

Parameters

iFile

A pointer to the file reference that specifies the name and location of a file or directory that contains the font data you want to activate.

iContext

A value that specifies the context of the activated font. If you want the activated font to be accessible only from your application use the `kATSFontContextLocal` constant. If you want the activated font to be accessible to all applications use the constant `kATSFontContextGlobal`. See "Context Options" (page 703) for more information.

iFormat

A value that represents the format identifier of the font. Pass `kATSFontFormatUnspecified` as the system automatically determines the format of the font. For more information on this constant, see "Font Formats" (page 706).

iRefCon

This parameter is currently reserved for future use, so you should pass `NULL`.

iOptions

An options flag. Pass `kATSOptionFlagsDefault` unless the font's data fork contains resource-fork information, you need to activate a directory of font directories, or you plan to call this function a number of time. If the font's data fork contains resource-fork information, pass the option `kATSOptionFlagsUseDataForkAsResourceFork`. If the you want to activate a font directory that contains font directories, you must pass the option `kATSOptionFlagsProcessSubdirectories`. If you plan to call this function a number of times, you can set the `iOptions` parameter to `kATSOptionFlagsDoNotNotify` set. When you are done activating fonts you can call the function `ATSFontNotify` (page 676) with the `action` parameter set to `kATSFontNotifyActionFontsChanged`. Then ATS notifies all applications who subscribe to notifications of the changes you made.

oContainer

On output, a reference to the font container that is activated from the file reference. You need this reference when you deactivate the font by calling the function `ATSFontDeactivate` (page 651).

Return Value
If activated successfully, `noErr`.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`ATSFont.h`

ATSFontActivateFromFileSpecification

Activates one or more fonts from a file specification. (Deprecated in Mac OS X v10.5. Instead use `ATSFontActivateFromFileReference` (page 647).)

```
OSStatus ATSFontActivateFromFileSpecification (
   const FSSpec *iFile,
   ATSFontContext iContext,
   ATSFontFormat iFormat,
   void *iReserved,
   ATSOptionFlags iOptions,
   ATSFontContainerRef *oContainer
);
```

Parameters

iFile

A pointer to the file specification that specifies the name and location of a file or directory that contains the font data you want to activate.

iContext

A value that specifies the context of the activated font. If you want the activated font to be accessible only from your application use the `kATSFontContextLocal` constant. If you want the activated font to be accessible to all applications use the constant `kATSFontContextGlobal`. See "Context Options" (page 703) for more information.

iFormat

A value that represents the format identifier of the font. Pass `kATSFontFormatUnspecified` as the system automatically determines the format of the font. For more information on this constant, see "Font Formats" (page 706).

iReserved

An arbitrary 32-bit value. This parameter is currently reserved for future use, so you should pass `NULL`.

iOptions

An options flag. Pass `kATSOptionFlagsDefault` unless the font's data fork contains resource-fork information, you need to activate a directory of font directories, or you plan to call this function a number of time. If the font's data fork contains resource-fork information, pass the option `kATSOptionFlagsUseDataForkAsResourceFork`. If the you want to activate a font directory that contains font directories, you must pass the option `kATSOptionFlagsProcessSubdirectories`. If you plan to call this function a number of times, you can set the `iOptions` parameter to `kATSOptionFlagsDoNotNotify` set. When you are done activating fonts you can call the function `ATSFontNotify` (page 676) with the `action` parameter set to `kATSFontNotifyActionFontsChanged`. Then ATS notifies all applications who subscribe to notifications of the changes you made.

oContainer

On output, a reference to the font container that is activated from the file specification. You need this reference when you deactivate the font by calling the function `ATSFontDeactivate` (page 651).

Return Value
A result code. See "Apple Type Services for Fonts Result Codes" (page 715).

Discussion
You can use the function `ATSFontActivateFromFileSpecification` to activate one font or more fonts. Activating a font makes that font available for use either locally (available only to your application) or globally (available to all applications on the system). A font's availability—local or global—is referred to as its context.

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`ATSFont.h`

ATSFontActivateFromMemory

Activates one or more fonts at the specified location in memory.

```
OSStatus ATSFontActivateFromMemory (
   LogicalAddress iData,
   ByteCount iLength,
   ATSFontContext iContext,
   ATSFontFormat iFormat,
   void *iReserved,
   ATSOptionFlags iOptions,
   ATSFontContainerRef *oContainer
);
```

Parameters

iData

The logical address of the font you want to activate.

iLength
The length (in bytes) of the font data.

iContext
A value that specifies the context of the activated font. If you want the activated font to be accessible only from your application use the `kATSFontContextLocal` constant. If you want the activated font to be accessible to all applications use the constant `kATSFontContextGlobal`. See "Context Options" (page 703) for more information.

iFormat
A value that represents the format identifier of the font. There is only one font format constant available for you to pass—`kATSFontFormatUnspecified`. This constant specifies the default behavior, which is to handle the data as raw TrueType font data. This is equivalent to the contents of an `'sfnt'` font resource or the data fork of a Windows TrueType `.ttf` or `.ttc` file. You can also activate the contents of an OpenType TrueType `.OTF` file. See "Font Formats" (page 706) for more information.

iReserved
An arbitrary 32-bit value. This parameter is currently reserved for future use, so you should pass `NULL`.

iOptions
An `ATSOptionFlags` value. This parameter is currently reserved for future use, so you should pass `kATSOptionFlagsDefault`.

oContainer
On output, a pointer to a font container reference that refers to the file that contains the activated font data.

Return Value
A result code. See "Apple Type Services for Fonts Result Codes" (page 715).

Discussion
You use this function to activate a streamed font, such as a font contained in a PDF file. Your application must first map the streamed font data to memory and then pass the address of the font data in memory to the function `ATSFontActivateFromMemory`.

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X 10.0 and later.

Declared In
`ATSFont.h`

ATSFontApplyFunction

Applies your callback to a font iteration.

```
OSStatus ATSFontApplyFunction (
   ATSFontApplierFunction iFunction,
   void *iRefCon
);
```

Parameters

iFunction
The callback function you want applied to a font iteration. See `ATSFontApplierFunction` (page 682) for more information on the callback you need to supply.

iRefCon

An arbitrary 32-bit value specified by your application. This is passed to your callback.

Return Value
A result code. See "Apple Type Services for Fonts Result Codes" (page 715).

Discussion
The function `ATSFontApplyFunction` iterates through the default fonts, which include globally activated fonts and fonts activated locally to your application. Calling this function is similar to creating an iterator that operates on a local context with an unrestricted scope.

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X 10.0 and later.

Declared In
`ATSFont.h`

ATSFontDeactivate

Deactivates one or more fonts.

```
OSStatus ATSFontDeactivate (
   ATSFontContainerRef iContainer,
   void *iRefCon,
   ATSOptionFlags iOptions
);
```

Parameters

iContainer

A font container reference that refers to the file containing the activated font data. You obtain a font container reference when you activate a font by calling the functions `ATSFontActivateFromFileSpecification` (page 648) or `ATSFontActivateFromMemory` (page 649).

iRefCon

An arbitrary 32-bit value specified. This parameter is currently reserved for future use, so you should pass `NULL`.

iOptions

An `ATSOptionFlags` value. You should pass `kATSOptionFlagsDefault` unless to plan to call this function a number of times to deactivate many fonts. If you plan to call this function a number of times, you can set the `iOptions` parameter to `kATSOptionFlagsDoNotNotify` set. When you are done deactivating fonts you can call the function `ATSFontNotify` (page 676) with the `action` parameter set to `kATSFontNotifyActionFontsChanged`. ATS notifies all applications who subscribe to notifications of the changes you made.

Return Value
A result code. See "Apple Type Services for Fonts Result Codes" (page 715).

Discussion
When you deactivate a font, you must supply the font container reference you obtained when you activated the font. You can't deactivate a font that you did not activate by calling the functions `ATSFontActivateFromFileSpecification` (page 648) or `ATSFontActivateFromMemory` (page 649).

You should use caution if you deactivate a font that is available globally, as its deactivation impacts any application that uses that font.

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X 10.0 and later.

Declared In
`ATSFont.h`

ATSFontFamilyApplyFunction

Applies your callback to a font family iteration.

```
OSStatus ATSFontFamilyApplyFunction (
   ATSFontFamilyApplierFunction iFunction,
   void *iRefCon
);
```

Parameters

`iFunction`
The callback function you want applied to a font family iteration. See `ATSFontApplierFunction` (page 682) for more information on the callback you need to supply.

`iRefCon`
An arbitrary 32-bit value specified by your application. This value is passed to your callback.

Return Value
A result code. See "Apple Type Services for Fonts Result Codes" (page 715).

Discussion
The function `ATSFontFamilyApplyFunction` iterates through the default font families, which include globally activated font families and font families activated locally to your application. Calling this function is similar to creating an iterator that operates on a local context with an unrestricted scope.

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X 10.0 and later.

Declared In
`ATSFont.h`

ATSFontFamilyFindFromName

Returns the font family reference associated with a font family name.

```
ATSFontFamilyRef ATSFontFamilyFindFromName (
   CFStringRef iName,
   ATSOptionFlags iOptions
);
```

Parameters

`iName`
A reference to a font family name, formatted as a `CFString`.

iOptions
An `ATSOptionFlags` value. This parameter is currently reserved for future use, so you should pass `kATSOptionFlagsDefault`.

Return Value
A reference to the font family specified by the `iName` parameter. See the description of the `ATSFontFamilyRef` data type.

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X 10.0 and later.

Declared In
`ATSFont.h`

ATSFontFamilyFindFromQuickDrawName

Returns the font family reference associated with a standard QuickDraw font name.

```
ATSFontFamilyRef ATSFontFamilyFindFromQuickDrawName (
   ConstStr255Param iName
);
```

Parameters

iName
A QuickDraw font name.

Return Value
A reference to the font family associated with the font name specified by the `iName` parameter. See the description of the `ATSFontFamilyRef` data type.

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X 10.0 and later.

Declared In
`ATSFont.h`

ATSFontFamilyGetEncoding

Returns the text encoding used by a font family.

```
TextEncoding ATSFontFamilyGetEncoding (
   ATSFontFamilyRef iFamily
);
```

Parameters

iFamily
A font family reference.

Return Value
On output, a pointer to the text encoding used by the font family associated with the font family reference. See the Text Encoding Conversion Manager documentation for a description of the `TextEncoding` data type.

Discussion
Once you have obtained the text encoding, you can use Text Encoding Converter Manager function `RevertTextEncodingToScriptInfo` to extract the script as follows:

```
status = ATSFontFamilyGetEncoding (myFontFamily, &myTextEncoding)

status = RevertTextEncodingToScriptInfo (myTextEncoding, &myScriptCode);
```

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X 10.0 and later.

Declared In
`ATSFont.h`

ATSFontFamilyGetGeneration

Returns the generation count of a font family.

```
ATSGeneration ATSFontFamilyGetGeneration (
   ATSFontFamilyRef iFamily
);
```

Parameters

iFamily
A font family reference.

Return Value
On output, the generation count for the font family associated with the font family reference. See the description of the `ATSGeneration` data type.

Discussion
The generation of a font family changes any time part of a font family is removed or added.

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X 10.0 and later.

Declared In
`ATSFont.h`

ATSFontFamilyGetName

Obtains the font family name associated with a font family reference.

```
OSStatus ATSFontFamilyGetName (
   ATSFontFamilyRef iFamily,
   ATSOptionFlags iOptions,
   CFStringRef *oName
);
```

Parameters

iFamily
A font family reference.

iOptions

An `ATSOptionFlags` value. This parameter is currently reserved for future use, so you should pass `kATSOptionFlagsDefault`.

oName

On output, a reference to the name associated with the font family reference, formatted as a `CFString`. You are responsible for releasing the `CFStringRef`.

Return Value
A result code. See "Apple Type Services for Fonts Result Codes" (page 715).

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X 10.0 and later.

Declared In
`ATSFont.h`

ATSFontFamilyGetQuickDrawName

Obtains the standard QuickDraw font name associated with a font family reference.

```
OSStatus ATSFontFamilyGetQuickDrawName (
   ATSFontFamilyRef iFamily,
   Str255 oName
);
```

Parameters

iName

A reference to the font family name whose QuickDraw name you want to obtain.

oName

On input, a `Str255` value allocated by your application. On output, the QuickDraw name associated with the font family reference.

Return Value
A result code. See "Apple Type Services for Fonts Result Codes" (page 715).

Discussion
All font families are assigned a QuickDraw name by the system. The QuickDraw name is almost identical to the font family name.

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X 10.0 and later.

Declared In
`ATSFont.h`

ATSFontFamilyIteratorCreate

Creates a font family iterator that your application can use to access font family objects.

```
OSStatus ATSFontFamilyIteratorCreate (
   ATSFontContext iContext,
   const ATSFontFilter *iFilter,
   void *iRefCon,
   ATSOptionFlags iOptions,
   ATSFontFamilyIterator *ioIterator
);
```

Parameters

iContext

A value that specifies the context of the iterator. If you want to apply the font family iterator only to the fonts accessible from your application use the `kATSFontContextLocal` constant. If you want the to apply the font family iterator to all fonts registered with the system use the constant `kATSFontContextGlobal`. See "Context Options" (page 703) for more information on the constants you can supply. See the Discussion for information on the interaction between the `iContext` and `iOptions` parameters.

iFilter

A pointer to a filter specification. Pass `NULL` if you do not want to apply a filter to this iteration. Otherwise, you can use this parameter to restrict the iteration to the font families that match a generation count or criteria you specify in a custom filter function. Pass the filter selector constant `kATSFontFilterSelectorGeneration` to select a generation filter or the constant `kATSFontFilterSelectorFontApplierFunction` to select a custom filter. See "Font Filter Selectors" (page 705) for more information on the constants you can supply.

iRefCon

An arbitrary 32-bit value specified by your application. If you are using a custom filter function, you can use this parameter to pass data to the custom filter function. Otherwise, pass `NULL`.

iOptions

A value that specifies the scope of the iterator. If you want to iterate through font families that can be used only by your application, pass the constant `kATSOptionFlagsRestrictedScope`. If you want to iterate through font families that can be used by all applications pass the constant `kATSOptionFlagsUnRestrictedScope`. See "Scoping Options" (page 710) for more information on the constants you can supply. See the Discussion for information on the interaction between the `iContext` and `iOptions` parameters.

ioIterator

A pointer to a font family iterator. On output, points to an opaque font family iterator ready for you to use. When you no longer need the font family iterator, you should call the function `ATSFontFamilyIteratorRelease` (page 658) to release the auxiliary data and memory allocated by the system.

Return Value

A result code. See "Apple Type Services for Fonts Result Codes" (page 715).

Discussion

Your application can use a font family iterator to access font family objects. A font family iterator is an opaque data structure used by ATS for Fonts to keep track of an iteration over currently active font families. When the font family iterator is initialized, it does not yet reference a font family.

The context and scope you specify for the font family iterator interact as shown in Table 31-1 (page 657).

Table 31-1 The interaction of context and scope in a font family enumeration

	Local context	Global context
Restricted scope	Font families activated locally to your application	Only globally activated font families
Unrestricted scope	Defaults font families, which include globally activated font families and font families activated locally to your application	All font families, which include globally activated font families and all other font families activated locally for an application.

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X 10.0 and later.

Declared In
`ATSFont.h`

ATSFontFamilyIteratorNext

Obtains the next font family reference.

```
OSStatus ATSFontFamilyIteratorNext (
   ATSFontFamilyIterator iIterator,
   ATSFontFamilyRef *oFamily
);
```

Parameters

iIterator
A pointer to a font family iterator you created with the function `ATSFontFamilyIteratorCreate` (page 655).

oFamily
A pointer to a font family reference. On output, points to the font family reference obtained by the iterator. You are responsible for allocating memory for the font family reference.

Return Value
A result code. See "Apple Type Services for Fonts Result Codes" (page 715).

Discussion
If any changes are made to the font database while you are using the font family iterator, the iterator is invalidated and the function `ATSFontFamilyIteratorNext` returns the error `kATSIterationScopeModified`. To remedy this error, your application must either restart or cancel the enumeration by calling the `ATSFontFamilyIteratorReset` (page 658) or the `ATSFontFamilyIteratorRelease` (page 658) functions.

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X 10.0 and later.

Declared In
`ATSFont.h`

ATSFontFamilyIteratorRelease

Releases the memory associated with a font family iterator.

```
OSStatus ATSFontFamilyIteratorRelease (
   ATSFontFamilyIterator *ioIterator
);
```

Parameters

ioIterator

A pointer to a font family iterator you created with the function `ATSFontFamilyIteratorCreate` (page 655). If you try to use the font family iterator after disposing of its contents through this function, ATS for Fonts returns an error code to your application.

Return Value

A result code. See "Apple Type Services for Fonts Result Codes" (page 715).

Discussion

If you plan to use the font family iterator again, you should consider calling the function `ATSFontFamilyIteratorReset` rather than releasing the font family iterator and then creating it again.

Availability

Not available in CarbonLib 1.x.

Available in Mac OS X 10.0 and later.

Declared In

`ATSFont.h`

ATSFontFamilyIteratorReset

Resets a font family iterator to the beginning of the iteration.

```
OSStatus ATSFontFamilyIteratorReset (
   ATSFontContext iContext,
   const ATSFontFilter *iFilter,
   void *iRefCon,
   ATSOptionFlags iOptions,
   ATSFontFamilyIterator *ioIterator
);
```

Parameters

iContext

A value that specifies the context of the iterator. If you want to apply the font family iterator only to the fonts accessible from your application use the `kATSFontContextLocal` constant. If you want the to apply the font family iterator to all fonts registered with the system use the constant `kATSFontContextGlobal`. See "Context Options" (page 703) for more information.

iFilter

A pointer to a filter specification. Pass `NULL` if you do not want to apply a filter to this iteration. Otherwise, you can use this parameter to restrict the iteration to the font families that match a generation count or criteria you specify in a custom filter function. Pass the filter selector constant `kATSFontFilterSelectorGeneration` to select a generation filter or the constant `kATSFontFilterSelectorFontApplierFunction` to select a custom filter. See "Font Filter Selectors" (page 705) for more information on these constants.

iRefCon

An arbitrary 32-bit value specified by your application. If you are using a custom filter function, you can use this parameter to pass data to the custom filter function. If you are not using a custom filter function, pass `NULL`.

iOptions

An value that specifies the scope of the iterator. If you want to iterate through font families that can be used only by your application, pass the constant `kATSOptionFlagsRestrictedScope`. If you want to iterate through font families that can be used by all applications pass the constant `kATSOptionFlagsUnRestrictedScope`.

ioIterator

A pointer to a font family iterator you created with the function `ATSFontFamilyIteratorCreate` (page 655). On output, the font family iterator is reset to the beginning of the iteration.

Return Value
A result code. See "Apple Type Services for Fonts Result Codes" (page 715).

Discussion
Once you have created a font family iterator, you can reuse it by calling the function `ATSFontFamilyIteratorReset`. This function sets the parameters to the new values you specify, and repositions the iterator so it is ready to get the first font family reference when you call the function `ATSFontFamilyIteratorNext` (page 657).

During an iteration, if you obtain the result code `kATSIterationScopeModified` from the function `ATSFontFamilyIteratorNext` (page 657), you can reset the iteration by calling the function `ATSFontFamilyIteratorReset`. This assures that you obtain the most up-to-date information from the iteration.

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X 10.0 and later.

Declared In
`ATSFont.h`

ATSFontFindFromContainer

Obtains the font references contained in a font container.

```
OSStatus ATSFontFindFromContainer (
   ATSFontContainerRef iContainer,
   ATSOptionFlags iOptions,
   ItemCount iCount,
   ATSFontRef ioArray[],
   ItemCount *oCount
);
```

Parameters

iContainer

A reference to the font container whose fonts you want to obtain. You obtain a font container reference when you activate a font by calling the functions `ATSFontActivateFromFileSpecification` (page 648) or `ATSFontActivateFromMemory` (page 649).

iOptions
An ATSOptionFlags value. This parameter is currently reserved for future use, so you should pass kATSOptionFlagsDefault.

iCount
The number of items in the ioArray array. If you are uncertain of how many items are in this array, see the Discussion.

ioArray
A pointer to memory you have allocated for an array of font references. On return, the array contains the font references in the font container specified by the iContainer parameter. If you are uncertain of how much memory to allocate for this array, see the Discussion.

oCount
A pointer to an ItemCount value. On output, the value specifies the actual number of ATSFontRef values in the font container.

Return Value
A result code. See "Apple Type Services for Fonts Result Codes" (page 715).

Discussion
The function ATSFontFindFromContainer operates on font containers that reference font files. It does not work on font containers that reference font directories.

Typically you use the function ATSFindFontFromContainer by calling it twice, as follows:

1. Pass a reference to the font container to examine in the iContainer parameter, a valid pointer to an ItemCount value in the *oCount* parameter, NULL for the ioArray parameter, and 0 for the *iCount* parameter. ATSFindFontFromContainer returns the size of the array in the oCount parameter.

2. Allocate enough space for an array of the returned size, then call the ATSFindFontFromContainer function again, passing a valid pointer in the ioArray parameter and the number of items in the array in the *iCount* parameter. On return, the pointer refers to an array of the font references contained in the font container.

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X 10.0 and later.

Declared In
ATSFont.h

ATSFontFindFromName

Returns the font reference associated with a font name.

```
ATSFontRef ATSFontFindFromName (
   CFStringRef iName,
   ATSOptionFlags iOptions
);
```

Parameters

iName
A reference to a font name formatted as a CFString.

iOptions
An `ATSOptionFlags` value. This parameter is currently reserved for future use, so you should pass `kATSOptionFlagsDefault`.

Return Value
A reference to the font specified by the `iName` parameter. See the description of the `ATSFontRef` data type.

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X 10.0 and later.

Declared In
`ATSFont.h`

ATSFontFindFromPostScriptName

Returns the font reference associated with a PostScript font name.

```
ATSFontRef ATSFontFindFromPostScriptName (
   CFStringRef iName,
   ATSOptionFlags iOptions
);
```

Parameters
iName
A reference to the PostScript name for a font, formatted as a `CFString`.

iOptions
An `ATSOptionFlags` value. This parameter is currently reserved for future use, so you should pass `kATSOptionFlagsDefault`.

Return Value
A reference to the font specified by the `iName` parameter. See the description of the `ATSFontRef` data type.

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X 10.0 and later.

Declared In
`ATSFont.h`

ATSFontGetAutoActivationSettingForApplication

Gets the activation setting for the specified application.

```
ATSFontAutoActivationSetting ATSFontGetAutoActivationSettingForApplication (
   CFURLRef iApplicationFileURL
);
```

Parameters
iApplicationFileURL
A valid file URL for an application. Pass `NULL` to specify the current process.

Return Value
The activation setting for the specified application.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`ATSFont.h`

ATSFontGetContainer

Gets the font container reference for a font.

```
OSStatus ATSFontGetContainer (
   ATSFontRef iFont,
   ATSOptionFlags iOptions,
   ATSFontContainerRef *oContainer
);
```

Parameters

iFont
The font reference.

iOptions
An options flag.

oContainer
On output, a reference to the font container that was used to activate the font reference. On error ATS sets this to `kATSFontContainerRefUnspecified`.

Return Value
If successful, `noErr`; if the container is invalid, `kATSInvalidFontContainerAccess`.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`ATSFont.h`

ATSFontGetContainerFromFileReference

Gets the font container reference associated with an activated file reference.

```
OSStatus ATSFontGetContainerFromFileReference (
   const FSRef *iFile,
   ATSFontContext iContext,
   ATSOptionFlags iOptions,
   ATSFontContainerRef *oContainer
);
```

Parameters

iFile
A pointer to the valid file reference that specifies the activated font file for which to get the container.

iContext

The context that the font file is accessible to. If you want the activated font to be accessible only from your application pass `kATSFontContextDefault` or `kATSFontContextLocal`. If you want the activated font to be accessible to all applications use the constant `kATSFontContextGlobal`. See "Context Options" (page 703) for more information.

iOptions

An options flag.

oContainer

On output, a reference to the font container representing the file reference activated in the specified context. On error or for a file that is not activated, ATS sets this to `kATSFontContainerRefUnspecified`.

Return Value
`noErr` or `paramErr` if one or more parameters are invalid.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`ATSFont.h`

ATSFontGetFileReference

Obtains the file reference for a font.

```
OSStatus ATSFontGetFileReference (
   ATSFontRef iFont,
   FSRef *oFile
);
```

Parameters

iFont

A reference to the font whose file reference you want to obtain.

oFile

On output, points to the file reference that specifies the name and location of a file or directory that contains the font data specified by the `iFont` parameter.

Return Value
If successful, `noErr`.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`ATSFont.h`

ATSFontGetFileSpecification

Obtains the file specification for a font. (Deprecated in Mac OS X v10.5. Instead use `ATSFontGetFileReference` (page 663).)

```
OSStatus ATSFontGetFileSpecification (
   ATSFontRef iFont,
   ATSFSSpec *oFile
);
```

Parameters

iFont

A reference to the font whose file specification you want to obtain.

oFile

On output, points to the file specification that specifies the name and location of a file or directory that contains the font data specified by the `iFont` parameter.

Return Value

A result code. See "Apple Type Services for Fonts Result Codes" (page 715).

Discussion

The function `ATSFontGetFileSpecification` obtains the file specification for a font, not the font container. You must call the functions `ATSFontActivateFromFileSpecification` (page 648) or `ATSFontActivateFromMemory` (page 649) to obtain a font container reference.

Availability

Not available in CarbonLib 1.x.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`ATSFont.h`

ATSFontGetFontFamilyResource

Obtains the font family resource for a font.

```
OSStatus ATSFontGetFontFamilyResource (
   ATSFontRef iFont,
   ByteCount iBufferSize,
   void *ioBuffer,
   ByteCount *oSize
);
```

Parameters

iFont

A font reference.

iBufferSize

The size of the buffer pointed to by the `ioBuffer` parameter. See the Discussion if you are unsure of the size of this buffer.

ioBuffer

On input, a pointer to memory you allocated for the font family resource. On output, points to the `FOND` resource for the font. Note that the `FOND` resource data is in big endian format, regardless of the native endian format of the Macintosh computer on which you make the function call. If you are uncertain of how much memory to allocate for this array, see the Discussion.

oSize
On output, the actual size of the buffer.

Return Value
A result code. See "Apple Type Services for Fonts Result Codes" (page 715).

Discussion
The function `ATSFontGetFontFamilyResource` provides a compatibility path for font families that use resources. Beginning with Mac OS X version 10.2, ATS for Fonts synthesizes `FOND` resources for OpenType fonts.

Typically you use the function `ATSFontGetFontFamilyResource` by calling it twice, as follows:

1. Pass a reference to the font to examine in the `iFont` parameter, a valid pointer in the *oSize* parameter, `NULL` for the `ioBuffer` parameter, and 0 for the *iBufferSize* parameter. `ATSFontGetFontFamilyResource` returns the size of the buffer in the `oSize` parameter.

2. Allocate enough space for an array of the returned size, then call the `ATSFontGetFontFamilyResource` function again, passing a valid pointer in the `ioBuffer` parameter, the size of the buffer in the *iBufferSize* parameter, and the appropriate values in the other parameters. On return, the pointer refers to an array of the font references contained in the font container.

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X 10.0 and later.

Declared In
`ATSFont.h`

ATSFontGetGeneration

Returns the generation count for a font.

```
ATSGeneration ATSFontGetGeneration (
   ATSFontRef iFont
);
```

Parameters
iFont
A font reference.

Return Value
A generation count. See the description of the `ATSGeneration` data type.

Discussion
ATS for Fonts increments the generation count for any changes to a font, including when the system synthesizes data for the font.

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X 10.0 and later.

Declared In
`ATSFont.h`

ATSFontGetGlobalAutoActivationSetting

Gets the user's global auto-activation setting.

```
ATSFontAutoActivationSetting ATSFontGetGlobalAutoActivationSetting (
   void
);
```

Return Value
The user's global auto-activation setting.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`ATSFont.h`

ATSFontGetHorizontalMetrics

Obtains the horizontal metrics for a font.

```
OSStatus ATSFontGetHorizontalMetrics (
   ATSFontRef iFont,
   ATSOptionFlags iOptions,
   ATSFontMetrics *oMetrics
);
```

Parameters

iFont

A reference to the font whose horizontal metrics you want to obtain.

iOptions

An options flag. This parameter is currently reserved for future use, so you should pass `kATSOptionFlagsDefault`.

oMetrics

On input, a valid pointer to an `ATSFontMetrics` (page 689) data structure. On output, the structure contains the font's horizontal metrics. If one or more measurements are not available for a font, then the appropriate fields in the `ATSFontMetrics` data structure are set to `0`.

Return Value
A result code. See "Apple Type Services for Fonts Result Codes" (page 715).

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X 10.0 and later.

Declared In
`ATSFont.h`

ATSFontGetName

Obtains the name of a font associated with a font reference.

```
OSStatus ATSFontGetName (
   ATSFontRef iFont,
   ATSOptionFlags iOptions,
   CFStringRef *oName
);
```

Parameters

iFont

A font reference.

iOptions

An `ATSOptionFlags` value. This parameter is currently reserved for future use, so you should pass `kATSOptionFlagsDefault`.

oName

On output, a reference to the font name associated with the specified font reference, formatted as a `CFString`. You are responsible for releasing the `CFStringRef`.

Return Value
A result code. See "Apple Type Services for Fonts Result Codes" (page 715).

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X 10.0 and later.

Declared In
`ATSFont.h`

ATSFontGetPostScriptName

Obtains the PostScript name from a font reference.

```
OSStatus ATSFontGetPostScriptName (
   ATSFontRef iFont,
   ATSOptionFlags iOptions,
   CFStringRef *oName
);
```

Parameters

iFont

A font reference.

iOptions

An `ATSOptionFlags` value. This parameter is currently reserved for future use, so you should pass `kATSOptionFlagsDefault`.

oName

On output, a reference to the PostScript name for the font, formatted as a `CFString`. You are responsible for releasing the `CFStringRef`.

Return Value
A result code. See "Apple Type Services for Fonts Result Codes" (page 715).

Discussion
The system automatically detects whether or not the font is composed PostScript. If the font is, ATS for Fonts appends the CMAP name.

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X 10.0 and later.

Declared In
`ATSFont.h`

ATSFontGetTable

Obtains a font table.

```
OSStatus ATSFontGetTable (
   ATSFontRef iFont,
   FourCharCode iTag,
   ByteOffset iOffset,
   ByteCount iBufferSize,
   void *ioBuffer,
   ByteCount *oSize
);
```

Parameters

iFont
A reference to the font whose table you want to obtain.

iTag
A four-character code that specifies the font table you want to obtain.

iOffset
The offset to a font table. If you want to obtain all the font tables associated with a font, pass `0`.

iBufferSize
The size of the buffer pointed to by the `ioBuffer` parameter. The size should be the actual size of the buffer (`oSize`) minus the offset to the font table (`iOffset`) you want to obtain. See the Discussion if you are unsure of value to supply.

ioBuffer
On input, a valid pointer. On output, a pointer to the font table. Note that the data returned in the font table is in big endian format, regardless of the native endian format of the Macintosh computer on which you make the function call. See the Discussion for information on allocating this buffer.

oSize
On output, the actual size of the buffer returned in the `ioBuffer` parameter.

Return Value
A result code. See "Apple Type Services for Fonts Result Codes" (page 715).

Discussion
Synthetic font tables (entries with offset of 0) can only be accessed by calling the function `ATSFontGetTable`.

Typically you use the function `ATSFontGetTable` by calling it twice, as follows:

1. Pass a reference to the font whose table you want obtain in the `iFont` parameter, a four-character code that specifies the font table you want to obtain in the `iTag` parameter, the appropriate offset to the font table in the *`iOffset`* parameter, `0` for the *`iBufferSize`* parameter, `NULL` for the `ioBuffer` parameter, and a valid pointer to a `ByteCount` value in the *`oSize`* parameter. `ATSUFontGetTable` returns the size of the table in the `oSize` parameter.

2. Allocate enough space for a buffer of the returned size, then call the `ATSFontGetTable` function again, passing a valid pointer in the `ioBuffer` parameter, the size of the buffer in the *`iBufferSize`* parameter, and the appropriate values in the other parameters. On return, the pointer refers to the table for the font specified by the `iFont` parameter and the table specified by the `iTag` parameter.

You should use the function `ATSFontGetTable` when you need to obtain an entire font table. For performance reasons, avoid using the function to check a single value in the table.

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X 10.0 and later.

Declared In
`ATSFont.h`

ATSFontGetTableDirectory

Obtains the table directory for a font.

```
OSStatus ATSFontGetTableDirectory (
   ATSFontRef iFont,
   ByteCount iBufferSize,
   void *ioBuffer,
   ByteCount *oSize
);
```

Parameters

`iFont`
The font reference whose table directory you want to obtain.

`iBufferSize`
The size of the buffer pointed to by the `ioBuffer` parameter. See the Discussion if you are unsure of the size of this buffer.

`ioBuffer`
On input, a valid pointer. On output, points to the table directory for the font specified by the `iFont` parameter. Note that the data returned in the table directory is in big endian format, regardless of the native endian format of the Macintosh computer on which you make the function call. See the Discussion for information on allocating this buffer.

`oSize`
On output, the actual size of the buffer returned in the `ioBuffer` parameter.

Return Value
A result code. See "Apple Type Services for Fonts Result Codes" (page 715).

Discussion
If necessary, ATS for Fonts synthesizes font tables or data, replacing existing tables or data. ATS for Fonts synthesizes data on an as needed basis; if data is synthesized, the generation count of the font increases.

Typically you use the function `ATSFontGetTableDirectory` by calling it twice, as follows:

1. Pass a reference to the font whose table directory you want obtain in the `iFont` parameter, `0` for the *`iBufferSize`* parameter, `NULL` for the `ioBuffer` parameter, and a valid pointer to a `ByteCount` value in the *`oSize`* parameter. `ATSFontGetTableDirectory` returns the size of the table directory in the `oSize` parameter.

2. Allocate enough space for a buffer of the returned size, then call the `ATSFontGetTableDirectory` function again, passing a valid pointer in the `ioBuffer` parameter, and the size of the buffer in the *`iBufferSize`* parameter. On return, the pointer refers to the table directory for the font specified by the `iFont` parameter.

If you want to obtain a font table, call the function `ATSFontGetTable` (page 668).

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X 10.0 and later.

Declared In
`ATSFont.h`

ATSFontGetVerticalMetrics

Obtains the vertical metrics for a font.

```
OSStatus ATSFontGetVerticalMetrics (
   ATSFontRef iFont,
   ATSOptionFlags iOptions,
   ATSFontMetrics *oMetrics
);
```

Parameters

`iFont`
A reference to the font whose vertical metrics you want to obtain.

`iOptions`
An options flag. This parameter is currently reserved for future use, so you should pass `kATSOptionFlagsDefault`.

`oMetrics`
On input, a valid pointer to an `ATSFontMetrics` (page 689) data structure. On output, the structure contains the font's vertical metrics. If one or more measurements are not available for a font, then the appropriate fields in the `ATSFontMetrics` data structure are set to `0`.

Return Value
A result code. See "Apple Type Services for Fonts Result Codes" (page 715).

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X 10.0 and later.

Declared In
`ATSFont.h`

ATSFontIsEnabled

Returns `true` if the font is enabled.

```
Boolean ATSFontIsEnabled (
   ATSFontRef iFont
);
```

Parameters

iFont

The font reference.

Return Value

`true` if the font is enabled.

Availability

Available in Mac OS X v10.5 and later.

Declared In

`ATSFont.h`

ATSFontIteratorCreate

Creates a font iterator.

```
OSStatus ATSFontIteratorCreate (
   ATSFontContext iContext,
   const ATSFontFilter *iFilter,
   void *iRefCon,
   ATSOptionFlags iOptions,
   ATSFontIterator *ioIterator
);
```

Parameters

iContext

A value that specifies the context of the iterator. If you want to apply the font iterator only to the fonts accessible from your application use the `kATSFontContextLocal` constant. If you want the to apply the font iterator to all fonts registered with the system use the constant `kATSFontContextGlobal`. See "Context Options" (page 703) for more information on the constants you can supply. See the Discussion for information on the interaction between the `iContext` and `iOptions` parameters.

iFilter

A pointer to a filter specification. Pass `NULL` if you do not want to apply a filter to this iteration. Otherwise, you can use this parameter to restrict the iteration to the fonts that match a generation count or criteria you specify in a custom filter function. Pass the filter selector constant `kATSFontFilterSelectorGeneration` to select a generation filter or the constant `kATSFontFilterSelectorFontApplierFunction` to select a custom filter. See "Font Filter Selectors" (page 705) for more information on these constants.

iRefCon

An arbitrary 32-bit value specified by your application. If you are using a custom filter function, you can use this parameter to pass data to the custom filter function. Otherwise, pass `NULL`.

iOptions

A value that specifies the scope of the iterator. If you want to iterate through fonts that can be used only by your application, pass the constant `kATSOptionFlagsRestrictedScope`. If you want to iterate through fonts that can be used by all applications pass the constant `kATSOptionFlagsUnRestrictedScope`. See "Scoping Options" (page 710) for more information on the constants you can supply. See the Discussion for information on the interaction between the `iContext` and `iOptions` parameters.

ioIterator

A pointer to a font iterator. On input, pass a pointer to an uninitialized iterator. On output, the iterator's contents may have been changed and may include references to data structures allocated by the system to maintain the iterator's state. When you no longer need the font iterator, you should call the function `ATSFontIteratorRelease` (page 673) to release the auxiliary data and memory allocated by the system.

Return Value
A result code. See "Apple Type Services for Fonts Result Codes" (page 715).

Discussion
Your application can use a font iterator to access font data. A font iterator is an opaque data structure used by ATS for Fonts to keep track of an iteration over currently active fonts. When the font iterator is initialized, it does not yet reference a font.

The context and scope you specify for the font iterator interact as shown in Table 31-2 (page 672).

Table 31-2 The interaction of context and scope in a font enumeration

	Local context	Global context
Restricted scope	Fonts activated locally to your application	Only globally activated fonts
Unrestricted scope	Defaults fonts, which include globally activated fonts and fonts activated locally to your application	All fonts, which include globally activated fonts and all other fonts activated locally for an application.

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X 10.0 and later.

Declared In
`ATSFont.h`

ATSFontIteratorNext

Obtains the next font reference.

```
OSStatus ATSFontIteratorNext (
   ATSFontIterator iIterator,
   ATSFontRef *oFont
);
```

Parameters

iIterator

A pointer to a font iterator you created with the function `ATSFontIteratorCreate` (page 671). If you try to use the font iterator after disposing of its contents through this function, ATS for Fonts returns an error code to your application.

oFont

A pointer to a font reference. On output, points to the font reference obtained by the iterator. You are responsible for allocating memory for the font reference.

Return Value

A result code. See "Apple Type Services for Fonts Result Codes" (page 715).

Discussion

If any changes are made to the font database while you are using the font iterator, the iterator is invalidated and the function `ATSFontFamilyIteratorNext` returns the error `kATSIterationScopeModified`. To remedy this error, your application must either restart or cancel the enumeration by calling the `ATSFontFamilyIteratorReset` (page 658) or the `ATSFontIteratorRelease` (page 673) functions.

Availability

Not available in CarbonLib 1.x.

Available in Mac OS X 10.0 and later.

Declared In

`ATSFont.h`

ATSFontIteratorRelease

Releases a font iterator.

```
OSStatus ATSFontIteratorRelease (
   ATSFontIterator *ioIterator
);
```

Parameters

ioIterator

A pointer to a font iterator you created with the function `ATSFontIteratorCreate` (page 671). If you try to use the font iterator after disposing of its contents through this function, ATS for Fonts returns an error code to your application.

Return Value

A result code. See "Apple Type Services for Fonts Result Codes" (page 715).

Discussion

If you plan to use the font iterator again, you should consider calling the function `ATSFontIteratorReset` rather than releasing the font iterator and then creating it again.

Availability

Not available in CarbonLib 1.x.

Available in Mac OS X 10.0 and later.

Declared In
ATSFont.h

ATSFontIteratorReset

Resets a font iterator to the beginning of the iteration.

```
OSStatus ATSFontIteratorReset (
   ATSFontContext iContext,
   const ATSFontFilter *iFilter,
   void *iRefCon,
   ATSOptionFlags iOptions,
   ATSFontIterator *ioIterator
);
```

Parameters

iContext

A value that specifies the context of the iterator. If you want to apply the font iterator only to the fonts accessible from your application use the kATSFontContextLocal constant. If you want the to apply the font iterator to all fonts registered with the system use the constant kATSFontContextGlobal. See "Context Options" (page 703) for more information.

iFilter

A pointer to a filter specification. Pass NULL if you do not want to apply a filter to this iteration. Otherwise, you can use this parameter to restrict the iteration to the fonts that match a generation count or criteria you specify in a custom filter function. Pass the filter selector constant kATSFontFilterSelectorGeneration to select a generation filter or the constant kATSFontFilterSelectorFontApplierFunction to select a custom filter. See "Font Filter Selectors" (page 705) for more information on these constants.

iRefCon

An arbitrary 32-bit value specified by your application. If you are using a custom filter function, you can use this parameter to pass data to the custom filter function. Otherwise, pass NULL.

iOptions

A value that specifies the scope of the iterator. If you want to iterate through fonts that can be used only by your application, pass the constant kATSOptionFlagsRestrictedScope. If you want to iterate through fonts that can be used by all applications pass the constant kATSOptionFlagsUnRestrictedScope.

ioIterator

A pointer to a font iterator you created with the function ATSFontIteratorCreate (page 671). If you try to use the font iterator after disposing of its contents through this function, ATS for Fonts returns an error code to your application.

Return Value
A result code. See "Apple Type Services for Fonts Result Codes" (page 715).

Discussion
Once you have created a font iterator, you can reuse it by calling the function ATSFontIteratorReset. This function sets the parameters to the new values you specify, and repositions the iterator so it is ready to get the first font reference when you call the function ATSFontIteratorNext (page 672).

During an iteration, if you obtain the result code kATSIterationScopeModified from the function ATSFontIteratorNext (page 672), you can reset the iteration by calling the function ATSFontIteratorReset. This assures that you obtain the most up-to-date information from the iteration.

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X 10.0 and later.

Declared In
`ATSFont.h`

ATSFontNotificationSubscribe

Signs up your application to receive notification of changes to fonts and font directories.

```
OSStatus ATSFontNotificationSubscribe (
   ATSNotificationCallback callback,
   ATSFontNotifyOption options,
   void *iRefcon,
   ATSFontNotificationRef *oNotificationRef
);
```

Parameters

callback

The callback function you want ATS to invoke whenever the notification action specified in the `options` parameter occurs. See `ATSNotificationCallback` (page 684) for more information on the callback you can supply.

options

A notification option that specifies when you want ATS to respond to notification actions. If you want to receive notifications when your application is in the foreground, pass the constant `kATSFontNotifyOptionDefault`. If your application is a server process or a tool that performs font management functions and requires immediate notification when fonts change, pass the constant `kATSFontNotifyOptionReceiveWhileSuspended`. See "Notification Options" (page 709) for more information.

iRefCon

An arbitrary 32-bit value specified by your application and which you want passed to your callback function. You can pass `NULL` if your callback does not need any data.

oNotificationRef

On output, a notification reference. You need this reference when you call the function `ATSFontNotificationUnsubscribe` (page 676). You can pass `NULL` if you do not want to obtain the reference.

Return Value
A result code. See "Apple Type Services for Fonts Result Codes" (page 715). This function returns `paramErr` the `callback` parameter is `NULL` and `memFullErr` if the function cannot allocate enough memory for internal data structures.

Discussion
If your application uses Carbon events or the Application Kit, you can call the function `ATSFontNotificationSubscribe` to receive notifications of changes to fonts and font directories. However, if your application is of a type that does not use a `CFRunLoop`, it can't receive notifications unless you explicitly set up a run loop. For more information on run loops, see *Overview of Programming Topic: Run Loops* on the Cocoa Developer Documentation website.

If you want to stop receiving notifications, call the function `ATSFontNotificationUnsubscribe` (page 676).

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X 10.2 and later.

Declared In
`ATSFont.h`

ATSFontNotificationUnsubscribe

Unsubscribes your application from receiving notifications of changes to fonts and font directories.

```
OSStatus ATSFontNotificationUnsubscribe (
   ATSFontNotificationRef notificationRef
);
```

Parameters

oNotificationRef

On input, the notification reference you obtained when you called the function `ATSFontNotificationSubscribe` (page 675). On output, `NULL`.

Return Value
A result code. See "Apple Type Services for Fonts Result Codes" (page 715). Returns `paramErr` if you pass a `NULL` or invalid notification reference in the `oNotificationRef` parameter.

Discussion
The function `ATSFontNotificationUnsubscribe` unsubscribes your application from receiving the notification associated with the notification reference you pass to the function. You must call `ATSFontNotificationUnsubscribe` for each notification for which you want to unsubscribe.

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X 10.2 and later.

Declared In
`ATSFont.h`

ATSFontNotify

Notifies Apple Type Services of an action taken by your application.

```
OSStatus ATSFontNotify (
   ATSFontNotifyAction action,
   void *info
);
```

Parameters

action

A notification action that specifies the action taken by your application. If your application activates or deactivates fonts, you should pass `kATSFontNotifyActionFontsChanged`. If your application makes changes to any of the font directories (System, local, user, or the Classic System folder), you should pass the constant `kATSFontNotifyActionDirectoriesChanged`. See "Notification Actions" (page 708) for more information on the constants you can supply.

info

A pointer to the data you want ATS for Fonts to pass to the clients who subscribe to notifications. You can pass `NULL` if there is no data associated with this action.

Return Value
A result code. See "Apple Type Services for Fonts Result Codes" (page 715). Returns `paramErr` if you pass an invalid notification action in the `action` parameter.

Discussion
A notification is a mechanism by which your application can inform ATS for Fonts that you have changed a font or font directory. Other applications can sign up to receive notifications of these changes by calling the function `ATSFontNotificationSubscribe` (page 675). When you call the function `ATSFontNotify`, the system passes the notification along with any data you provide to every client who is signed up to receive notifications.

You can call the function `ATSFontNotify` after your application makes a batch of changes. For example, if your application calls the functions `ATSFontActivateFromFileSpecification` (page 648) or `ATSFontDeactivate` (page 651) multiple times to activate and deactivate fonts, you can set the `iOptions` parameter in these functions to `kATSOptionFlagsDoNotNotify` set. When you are done activating and deactivating fonts you can call the function `ATSFontNotify` with the `action` parameter set to `kATSFontNotifyActionFontsChanged`. Then ATS notifies all applications who subscribe to notifications of the changes you made.

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X 10.2 and later.

Declared In
`ATSFont.h`

ATSFontSetAutoActivationSettingForApplication

Sets the auto-activation setting for the specified application bundle.

```
OSStatus ATSFontSetAutoActivationSettingForApplication (
   ATSFontAutoActivationSetting iSetting,
   CFURLRef iApplicationFileURL
);
```

Parameters

iSetting

A font auto-activation setting. See "Automatic Activation Settings" (page 703).

iApplicationFileURL

A valid file URL for an application. Pass `NULL` to specify the current process.

Return Value
Returns `noErr` on success, and `paramErr` for any invalid input. May return `memFullErr` if unable to allocate temporary structures.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`ATSFont.h`

ATSFontSetEnabled

Sets a font state to enabled or disabled.

```
OSStatus ATSFontSetEnabled (
   ATSFontRef iFont,
   ATSOptionFlags iOptions,
   Boolean iEnabled
);
```

Parameters

iFont

The font reference.

iOptions

An options flag.

iEnabled

The state to set the font to. `True` for enabled, `false` for disabled.

Return Value

`kATSInvalidFontAccess` if the font reference is invalid in the current application context.

Availability

Available in Mac OS X v10.5 and later.

Declared In

`ATSFont.h`

ATSFontSetGlobalAutoActivationSetting

Sets the user's global auto-activation setting.

```
OSStatus ATSFontSetGlobalAutoActivationSetting (
   ATSFontAutoActivationSetting iSetting
);
```

Parameters

iSetting

A font auto-activation setting. See "Automatic Activation Settings" (page 703).

Return Value

If successful, `noErr`; if invalid input, `paramErr`.

Availability

Available in Mac OS X v10.5 and later.

Declared In

`ATSFont.h`

ATSGetGeneration

Obtains the generation of the font database.

```
ATSGeneration ATSGetGeneration (
   void
);
```

Return Value
A value that specifies the generation count of the font database. See the description of the `ATSGeneration` data type.

Discussion
Any operation that adds, deletes, or modifies one or more font families or fonts triggers an update of the font database generation count. If you want to obtain the generation of a font family, call the function `ATSFontFamilyGetGeneration` (page 654). If you want to obtain the generation of a font, call the function `ATSFontGetGeneration` (page 665).

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X 10.0 and later.

Declared In
`ATSFont.h`

DisposeFMFontCallbackFilterUPP

Disposes of a universal procedure pointer to a customized filter function used for fonts.

```
void DisposeFMFontCallbackFilterUPP (
   FMFontCallbackFilterUPP userUPP
);
```

Discussion
See the callback `FMFontCallbackFilterProcPtr` (page 685) for more information.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.

Declared In
`ATSTypes.h`

DisposeFMFontFamilyCallbackFilterUPP

Disposes of a universal procedure pointer to a customized filter function used for font families.

```
void DisposeFMFontFamilyCallbackFilterUPP (
   FMFontFamilyCallbackFilterUPP userUPP
);
```

Discussion
See the callback `FMFontFamilyCallbackFilterProcPtr` (page 686) for more information.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.

Declared In
ATSTypes.h

InvokeFMFontCallbackFilterUPP

Calls a customized filter function used for fonts.

```
OSStatus InvokeFMFontCallbackFilterUPP (
   FMFont iFont,
   void *iRefCon,
   FMFontCallbackFilterUPP userUPP
);
```

Return Value
A result code. See "Apple Type Services for Fonts Result Codes" (page 715).

Discussion
This function is not recommended nor needed, as the system invokes your filter for you.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.

Declared In
ATSTypes.h

InvokeFMFontFamilyCallbackFilterUPP

Calls a customized filter function used for font families.

```
OSStatus InvokeFMFontFamilyCallbackFilterUPP (
   FMFontFamily iFontFamily,
   void *iRefCon,
   FMFontFamilyCallbackFilterUPP userUPP
);
```

Return Value
A result code. See "Apple Type Services for Fonts Result Codes" (page 715).

Discussion
This function is not recommended nor needed, as the system invokes your filter for you.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.

Declared In
ATSTypes.h

NewFMFontCallbackFilterUPP

Creates a new universal procedure pointer (UPP) to a filter callback function that uses your criteria for filtering fonts.

```
FMFontCallbackFilterUPP NewFMFontCallbackFilterUPP (
   FMFontCallbackFilterProcPtr userRoutine
);
```

Return Value
See the description of the `FMFontCallbackFilterUPP` data type.

Discussion
See the callback `FMFontCallbackFilterProcPtr` (page 685) for more information.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.

Declared In
`ATSTypes.h`

NewFMFontFamilyCallbackFilterUPP

Creates a new universal procedure pointer (UPP) to a filter callback function that uses your criteria for filtering font families.

```
FMFontFamilyCallbackFilterUPP NewFMFontFamilyCallbackFilterUPP (
   FMFontFamilyCallbackFilterProcPtr userRoutine
);
```

Return Value
See the description of the `FMFontFamilyCallbackFilterUPP` data type.

Discussion
See the callback `FMFontFamilyCallbackFilterProcPtr` (page 686) for more information.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.

Declared In
`ATSTypes.h`

Callbacks by Task

ATS Callbacks

The callbacks in this section are used by ATS for Fonts.

`ATSFontApplierFunction` (page 682)
Defines a pointer to a customized function to be applied to a font iteration.

`ATSFontFamilyApplierFunction` (page 683)
Defines a pointer to a customized function to be applied to a font family iteration.

`ATSFontQueryCallback` (page 683)
Defines a pointer to a customized function that handles font queries.

`ATSNotificationCallback` (page 684)
Defines a pointer to a customized function that handles notifications.

FM Callbacks

The callbacks in this section are used by the Font Manager.

`FMFontCallbackFilterProcPtr` (page 685)
Defines a pointer to a customized filter function to be used with a font iterator.

`FMFontFamilyCallbackFilterProcPtr` (page 686)
Defines a pointer to a customized filter function to be used with a font family iterator.

Callbacks

ATSFontApplierFunction

Defines a pointer to a customized function to be applied to a font iteration.

```
typedef OSStatus (*ATSFontApplierFunction) (
    ATSFontRef iFont,
    void * iRefCon
);
```

If you name your function `MyATSFontApplierFunction`, you would declare it like this:

```
OSStatus MyATSFontApplierFunction (
    ATSFontRef iFont,
    void * iRefCon
);
```

Parameters

iFont
A font reference. This is the font on which your callback operates.

iRefCon
An arbitrary 32-bit value specified by your application and that is passed to your callback.

Return Value

A result code. See "Apple Type Services for Fonts Result Codes" (page 715).

Discussion

You provide a pointer to an `ATSFontApplierFunction` callback as a parameter to the function `ATSFontApplyFunction` (page 650). You can also provide a pointer to an `ATSFontApplierFunction` callback in the `ATSFontFilter` (page 688) data structure. This structure can be passed as a parameter to the functions `ATSFontIteratorCreate` (page 671) and `ATSFontIteratorReset` (page 674).

Availability

Available in Mac OS X v10.0 and later.

Declared In
ATSFont.h

ATSFontFamilyApplierFunction

Defines a pointer to a customized function to be applied to a font family iteration.

```
typedef OSStatus (*ATSFontFamilyApplierFunction) (
    ATSFontFamilyRef iFamily,
    void * iRefCon
);
```

If you name your function `MyATSFontFamilyApplierFunction`, you would declare it like this:

```
OSStatus MyATSFontFamilyApplierFunction (
    ATSFontFamilyRef iFamily,
    void * iRefCon
);
```

Parameters

iFamily
A font family reference. This is the font family on which your callback operates.

iRefCon
An arbitrary 32-bit value specified by your application and that is passed to your callback.

Return Value
A result code. See "Apple Type Services for Fonts Result Codes" (page 715).

Discussion
You provide a pointer to an `ATSFontFamilyApplierFunction` callback as a parameter to the function `ATSFontFamilyApplyFunction` (page 652). You can also provide a pointer to an `ATSFontApplierFunction` callback in the `ATSFontFilter` (page 688) data structure. This structure can be passed as a parameter to the functions `ATSFontFamilyIteratorCreate` (page 655) and `ATSFontFamilyIteratorReset` (page 658).

Availability
Available in Mac OS X v10.0 and later.

Declared In
ATSFont.h

ATSFontQueryCallback

Defines a pointer to a customized function that handles font queries.

```
typedef CFPropertyListRef (*ATSFontQueryCallback) (
    ATSFontQueryMessageID msgid,
     CFPropertyListRef data
       void * iRefCon
);
```

If you name your function `MyATSFontQueryCallback`, you would declare it like this:

```
CFPropertyListRef MyATSFontQueryCallback (
    ATSFontQueryMessageID msgid,
     CFPropertyListRef data
       void * iRefCon
);
```

Parameters

msgid

An `ATSFontQueryMessageID` value that identifies the message type your application receives from ATS. See "Font Query Message ID" (page 708) for the constants you can supply.

data

A `CFPropertyListRef` that represents the font query. The content of the `CFPropertyList` is specific to the message type. The property list should contain data that specifies the font for which the query is sent.

iRefCon

An arbitrary 32-bit value specified by your application and that is passed to your callback.

Return Value

A `CFPropertyListRef` that represents your application's response to the query. The content of the `CFPropertyList` is specific to the message type, and it may be `NULL`.

Discussion

ATS for Fonts calls your customized function each time ATS receives a font query from another application. You provide a pointer to an `ATSFontQueryCallback` as a parameter to the function `ATSCreateFontQueryRunLoopSource` (page 646).

Availability

Available in Mac OS X v10.2 and later.

Declared In

`ATSFont.h`

ATSNotificationCallback

Defines a pointer to a customized function that handles notifications.

```
typedef void (*ATSNotificationCallback) (
   ATSFontNotificationInfoRef info,
      void * iRefCon
);
```

If you name your function `MyATSNotificationCallback`, you would declare it like this:

```
void MyATSNotificationCallback (
   ATSFontNotificationInfoRef info,
      void * iRefCon
);
```

Parameters

info

Reserved for future use. Currently, your callback is passed `NULL`.

iRefCon
An arbitrary 32-bit value specified by your application and that is passed to your callback.

Discussion
ATS for Fonts calls your customized function each time ATS receives a font notification from another application. You provide a pointer to an `ATSNotificationCallback` callback function as a parameter to the function `ATSFontNotificationSubscribe` (page 675).

Availability
Available in Mac OS X v10.2 and later.

Declared In
`ATSFont.h`

FMFontCallbackFilterProcPtr

Defines a pointer to a customized filter function to be used with a font iterator.

```
typedef OSStatus (*FMFontCallbackFilterProcPtr) (
    FMFont iFont,
    void * iRefCon
);
```

If you name your function `MyFMFontCallbackFilterProc`, you would declare it like this:

```
OSStatus MyFMFontCallbackFilterProcPtr (
    FMFont iFont,
    void * iRefCon
);
```

Parameters

iFont
A font reference. This is the font on which your callback operates.

iRefCon
A pointer to arbitrary data that defines your custom filter.

Return Value
A result code. See "Apple Type Services for Fonts Result Codes" (page 715).

Discussion
The Font Manager calls your customized function each time it obtains a font in a font iteration. You can use a custom filter function in any Font Manager function that has a parameter of type `FMFilter`. You provide a universal procedure pointer to your filter callback function in the `FMFilter` data structure. First, you must use the `NewFMFontCallbackFilterUPP` (page 680) function to create a universal procedure pointer (UPP) of type `FMFontCallbackFilterUPP`. You can do so with code similar to the following:

```
FMFontCallbackFilterUPP MyFMFontFilterUPPMyFMFontFilterUPP =
NewFMFontCallbackFilterUPP (&MyFMFontCallbackFilterCallback)
```

Your application must specify the result code that should be returned by the Font Manager. Any value other than `noErr` will cause the iterator to ignore a font.

When you are finished with your filter callback function, you should use the `DisposeFMFontCallbackFilterUPP` (page 679) function to dispose of the UPP associated with it. However, if you plan to use the same filter callback function in subsequent calls, you can reuse the same UPP, rather than dispose of it and later create a new UPP.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSTypes.h`

FMFontFamilyCallbackFilterProcPtr

Defines a pointer to a customized filter function to be used with a font family iterator.

```
typedef OSStatus (*FMFontFamilyCallbackFilterProcPtr) (
    FMFontFamily iFontFamily,
    void * iRefCon
);
```

If you name your function `MyFMFontFamilyCallbackFilterProc`, you would declare it like this:

```
OSStatus MyFMFontFamilyCallbackFilterProcPtr (
    FMFontFamily iFontFamily,
    void * iRefCon
);
```

Parameters

iFontFamily
A font family reference. This is the font family on which your callback operates.

iRefCon
A pointer to arbitrary data that defines your custom filter.

Return Value
A result code. See "Apple Type Services for Fonts Result Codes" (page 715).

Discussion
The Font Manager calls your customized function each time it obtains a font family in a font family iteration. You can use a custom filter function in any Font Manager function that has a parameter of type `FMFilter`. You provide a universal procedure pointer to your filter callback function in the `FMFilter` data structure. First, you must use the function `NewFMFontFamilyCallbackFilterUPP` (page 681) to create a universal procedure pointer (UPP) of type `FMFontFamilyCallbackFilterUPP`. You can do so with code similar to the following:

```
FMFontFamilyCallbackFilterUPP MyFMFontFamilyFilterUPPMyFMFontFamilyFilterUPP =
NewFMFontFamilyCallbackFilterUPP (&MyFMFontFamilyCallbackFilterCallback)
```

Your application must specify the result code that should be returned by the Font Manager. Any value other than `noErr` will cause the iterator to ignore a font family.

When you are finished with your filter callback function, you should use the `DisposeFMFontFamilyCallbackFilterUPP` (page 679) function to dispose of the UPP associated with it. However, if you plan to use the same filter callback function in subsequent calls, you can reuse the same UPP, rather than dispose of it and later create a new UPP.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSTypes.h`

Data Types

ATS Data Types

The data types in this section are used by ATS for Fonts.

ATSFontContainerRef

An opaque data type that represents a reference to a font file or folder.

```
typedef UInt32 ATSFontContainerRef;
```

Discussion
A font container reference is an opaque type used as a parameter in the functions `ATSFontActivateFromFileSpecification` (page 648) and `ATSFontActivateFromMemory` (page 649).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSTypes.h`

ATSFontFamilyIterator

An opaque data type that represents a font family iterator.

```
typedef struct ATSFontFamilyIterator_ * ATSFontFamilyIterator;
```

Discussion
You initialize a structure of type `ATSFontFamilyIterator` by calling the function `ATSFontFamilyIteratorCreate` (page 655). You should not attempt to modify the contents of a font family iterator.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSFont.h`

ATSFontFamilyRef

An opaque data type that represents a font family reference.

```
typedef UInt32 ATSFontFamilyRef;
```

Discussion
Unlike font family and font names which are part of a font's data, data types, such as `ATSFontFamily` represent values that are arbitrarily assigned by ATS at system startup. These values can change when the system is restarted.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSTypes.h`

ATSFontFilter

Contains font filter information.

```
struct ATSFontFilter {
    UInt32 version
    ATSFontFilterSelector filterSelector
    union {
        ATSGeneration generationFilter;
        ATSFontFamilyRef fontFamilyFilter;
        ATSFontFamilyApplierFunction fontFamilyApplierFunctionFilter;
        ATSFontApplierFunction fontApplierFunctionFilter;
    } filter;
};
typedef struct ATSFontFilter ATSFontFilter;
```

Fields

`version`
The version of the filter.

`filterSelector`
A font filter selector. See "Font Filter Selectors" (page 705)for a list of the filter selectors you can specify.

`filter`
A union whose contents are specified by the `filterSelector` field.

`generationFilter`
An `ATSGeneration` value that specifies the generation to which you want to restrict an operation.

`fontFamilyFilter`
A font family reference that specifies the font family to which you want to restrict an operation.

`fontFamilyApplierFunctionFilter`
A pointer the callback you want applied to a font family iteration. See `ATSFontFamilyApplierFunction` (page 683) for more information on the callback you can supply.

`fontApplierFunctionFilter`
A pointer the callback you want applied to a font iteration. See `ATSFontApplierFunction` (page 682) for more information on the callback you can supply.

Discussion
You can pass an `ATSFontFilter` structure to the functions `ATSFontFamilyIteratorCreate` (page 655), `ATSFontFamilyIteratorReset` (page 658), `ATSFontIteratorCreate` (page 671), and `ATSFontIteratorReset` (page 674).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSFont.h`

ATSFontIterator

An opaque data type that represents a font iterator.

```
typedef struct ATSFontIterator_ * ATSFontIterator;
```

Discussion
You initialize a structure of type `ATSFontIterator` by calling the function `ATSFontIteratorCreate` (page 671). You should not attempt to modify the contents of a font iterator.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSFont.h`

ATSFontMetrics

Contains metrics for a font.

```
struct ATSFontMetrics {
    UInt32 version;
    Float32 ascent;
    Float32 descent;
    Float32 leading;
    Float32 avgAdvanceWidth;
    Float32 maxAdvanceWidth;
    Float32 minLeftSideBearing;
    Float32 minRightSideBearing;
    Float32 stemWidth;
    Float32 stemHeight;
    Float32 capHeight;
    Float32 xHeight;
    Float32 italicAngle;
    Float32 underlinePosition;
    Float32 underlineThickness;
};
typedef struct ATSFontMetrics ATSFontMetrics;
```

Fields

`version`
The version of the font metrics structure.

`ascent`
The maximum height from the baseline to the ascent line of the glyphs in the font. For vertical text, the maximum distance from the center line to the ascent line of the glyphs in the font.

`descent`
: The maximum distance from the baseline to the descent line of the the glyphs in the font. For vertical text, the maximum distance from center line to the descent line of the glyphs in the font.

`leading`
: The spacing from the descent line to the ascent line below it. This defines the spacing between lines of text

`avgAdvanceWidth`
: The average advance width of the glyph in the font.

`maxAdvanceWidth`
: The maximum advance width of the glyphs in the font.

`minLeftSideBearing`
: The minimum left-side bearing value of the glyphs in the font. For vertical text, the minimum top-side bearing value of the glyphs in the font.

`minRightSideBearing`
: The minimum right-side bearing value of the glyphs in the font. For vertical text, the minimum bottom side bearing of a glyphs in the font.

`stemWidth`
: The width of the dominant vertical stems of the glyphs in the font.

`stemHeight`
: The vertical width of the dominant horizontal stems of glyphs in the font.

`capHeight`
: The height of a capital letter in the font from the baseline to the top of the letter.

`xHeight`
: The height of lowercase characters in the font, specifically the letter x, excluding ascenders and descenders.

`italicAngle`
: The angle (in degrees counterclockwise) at which glyphs in the font slant when italicized.

`underlinePosition`
: The position at which an underline stroke should be placed for the font.

`underlineThickness`
: The thickness, in pixels, of the underscore character used to underline the glyphs in the font.

Discussion
This structure is passed as a parameter to the functions `ATSFontGetHorizontalMetrics` (page 666) and `ATSFontGetVerticalMetrics` (page 670).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSTypes.h`

ATSFontNotificationInfoRef

An opaque data type that represents a font notification information structure.

```
typedef struct ATSFontNotificationInfoRef_ * ATSFontNotificationInfoRef;
```

Discussion
This data type is used in the `ATSNotificationCallback` (page 684) callback function.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`ATSFont.h`

ATSFontNotificationRef

An opaque data type that represents a font notification structure.

```
typedef struct ATSFontNotificationRef_ * ATSFontNotificationRef;
```

Discussion
The `ATSFontNotificationRef` data type is returned by the function `ATSFontNotificationSubscribe` (page 675) and passed as a parameter to the function `ATSFontNotificationUnsubscribe` (page 676).

Availability
Available in Mac OS X v10.2 and later.

Declared In
`ATSFont.h`

ATSFontQuerySourceContext

Contains font query information that is passed back to a font query callback.

```
struct ATSFontQuerySourceContext {
    UInt32 version;
    void * refCon;
    CFAllocatorRetainCallBack retain;
    CFAllocatorReleaseCallBack release;
};
typedef struct ATSFontQuerySourceContext ATSFontQuerySourceContext;
```

Fields

`version`
A 32-bit unsigned integer that indicates the version of this data structure. You can set this value to `0`.

`refCon`
An arbitrary 32-bit value specified in your font query callback function.

`retain`
A callback you supply for increasing the retention count associated with the `refCon` value. The `CFAllocatorRetainCallBack` is defined in the header file `CFBase.h`. For more information on Core Foundation allocators, see the *Core Foundation Base Services Reference*.

`release`
A callback you supply for decreasing the retention count associated with the `refCon` value. The `CFAllocatorReleaseCallBack` is defined in the header file `CFBase.h`.

Discussion
You pass a `ATSFontQuerySourceContext` data structure to the function `ATSCreateFontQueryRunLoopSource` (page 646).

Availability
Available in Mac OS X v10.2 and later.

Declared In
`ATSFont.h`

ATSFontRef

An opaque data type that represents a font reference.

```
typedef UInt32 ATSFontRef;
```

Discussion
Unlike font names which are part of a font's data, data types, such as `ATSFontRef` represent values that are arbitrarily assigned by ATS at system startup. These values can change when the system is restarted.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSTypes.h`

ATSFontSize

Represents a font size.

```
typedef Float32 ATSFontSize;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSTypes.h`

ATSGeneration

Represents a generation count.

```
typedef UInt32 ATSGeneration;
```

Discussion
The generation count data type is used by ATS for Fonts to keep track of the generation of the font database, each font family, and each font. You can obtain a generation count from the functions `ATSGetGeneration` (page 678), `ATSFontFamilyGetGeneration` (page 654), and `ATSFontGetGeneration` (page 665).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSTypes.h`

ATSOptionFlags

Represents options you can pass to various ATS functions.

```
typedef OptionBits ATSOptionFlags;
```

Discussion
There are a variety of options associated with this data type. See "Assorted Options" (page 702), "Scoping Options" (page 710), and "Iteration Precedence Options" (page 708).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSTypes.h`

FM Data types

The data types in this section are used by the Font Manager.

FMFilter

Contains a filter format, a selector and filter information.

```
struct FMFilter {
    UInt32 format
    FMFilterSelector selector
    union {
        FourCharCode fontTechnologyFilter;
        FSSpec fontContainerFilter;
        FMGeneration generationFilter;
        FMFontFamilyCallbackFilterUPP fontFamilyCallbackFilter;
        FMFontCallbackFilterUPP fontCallbackFilter;
        FMFontDirectoryFilter fontDirectoryFilter;
    } filter;
};
typedef struct FMFilter FMFilter;
```

Fields

`format`
A filter format. For possible values, see FM Filter Format (page 711).

`selector`
A filter selector. The selector indicates the data contained in the union. For possible values, see "FM Filter Selectors" (page 711).

`filter`
: The filter you want to use to restrict an operation. The filter must correspond to the `selector` parameter. If you are using a custom filter, you should provide a universal procedure pointer that is either of type `FMFontFamilyCallbackFilterUPP` or `FMFontCallBackFilterUPP`.

`fontTechnologyFilter`
: A `FourCharCode` value that specifies the font technology to which you want to restrict an operation. See "FM Font Technologies" (page 712) for constants you can supply.

`fontContainerFilter`
: A pointer to the file specification that specifies the name and location of a file or directory to which you want to restrict an operation.

`generationFilter`
: The generation count to which you want to restrict an operation.

`fontFamilyCallbackFilter`
: The font family callback that you want to use to restrict an operation.

`fontCallbackFilter`
: The font callback that you want to use to restrict an operation.

`fontDirectoryFilter`
: The font directory filter that you want to use to restrict an operation.

Discussion
You use the `FMFilter` (page 693) data structure when you want to restrict the enumeration and activation functions to the criteria specified by a filter.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSTypes.h`

FMFont

An opaque data type that specifies a font registered with the font database.

```
typedef UInt32 FMFont;
```

Discussion
You should not modify this value.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSTypes.h`

FMFontCallbackFilterUPP

Defines a universal procedure pointer to a font filter callback.

```
typedef FMFontCallbackFilterProcPtr FMFontCallbackFilter;
```

Discussion
For more information, see the description of the `FMFontCallbackFilterProcPtr` (page 685) callback function.

FMFontDirectoryFilter

Contains font directory information used to restrict a font iteration.

```
struct FMFontDirectoryFilter {
    SInt16 fontFolderDomain;
    UInt32 reserved[2];
};
typedef struct FMFontDirectoryFilter FMFontDirectoryFilter;
```

Fields
`fontFolderDomain`
A signed 16-bit integer that specifies the directory to which you want to restrict the font iteration.
`reserved`
Reserved for future use.

Discussion
You supply the `FMFontDirectoryFilter` data structure as part of the `FMFilter` (page 693) data structure when you want to restrict a font iteration to a font directory.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSTypes.h`

FMFontFamily

A reference to a collection of fonts with the same design characteristics.

```
typedef SInt16 FMFontFamily;
```

Discussion
The font family reference replaces the QuickDraw font ID and can be used with all QuickDraw functions including `GetFontName` and `TextFont`. Unlike the QuickDraw font identifier, the font family reference cannot be passed to the Resource Manager to access information from a `'FOND'` resource. A font family reference does not imply a script system, nor is the character encoding of a font family determined by an arithmetic mapping of the font family reference.

The fonts associated with a font family consist of individual outline fonts that may be used with the font access functions of the Font Manager and ATSUI.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSTypes.h`

FMFontFamilyCallbackFilterUPP

Defines a universal procedure pointer to a font family filter callback.

```
typedef FMFontFamilyCallbackFilterProcPtr FMFontFamilyCallbackFilter;
```

Discussion
For more information, see the description of the `FMFontFamilyCallbackFilterProcPtr` (page 686) callback function.

FMFontFamilyInstance

Contains a font family reference and a QuickDraw style.

```
struct FMFontFamilyInstance {
    FMFontFamily fontFamily;
    FMFontStyle fontStyle;
};
typedef struct FMFontFamilyInstance FMFontFamilyInstance;
```

Fields
`fontFamily`
A font family reference.
`fontStyle`
A QuickDraw font style.

Discussion
Each font object can map to one or more font family instance. This mapping is equivalent to the information stored in the font association table of the `'FOND'` resource, except the font family instance does not contain a point size descriptor. Since a font object represents the entire array of point sizes for a given font, only the font family reference and style are required to specify fully any given font object.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSTypes.h`

FMFontFamilyInstanceIterator

An opaque structure used to enumerate font family instances.

```
struct FMFontFamilyInstanceIterator {
    UInt32 reserved[16];
};
typedef struct FMFontFamilyInstanceIterator FMFontFamilyInstanceIterator;
```

Fields
`reserved`
Reserved for Apple's use.

Discussion
You initialize a structure of type `FMFontFamilyInstanceIterator` by calling the function `FMCreateFontFamilyInstanceIterator`. You should not attempt to modify the contents of a font family instance iterator.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSTypes.h`

FMFontFamilyIterator

An opaque structure used to enumerate font families.

```
struct FMFontFamilyIterator {
    UInt32 reserved[16];
};
typedef struct FMFontFamilyIterator FMFontFamilyIterator;
```

Fields
`reserved`
Reserved for Apple's use.

Discussion
You initialize a structure of type `FMFontFamilyIterator` by calling the function `FMCreateFontFamilyIterator`. You should not attempt to modify the contents of a font family iterator.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSTypes.h`

FMFontIterator

An opaque structure used to enumerate fonts.

```
struct FMFontIterator {
    UInt32 reserved[16];
};
typedef struct FMFontIterator FMFontIterator;
```

Fields
`reserved`
Reserved for Apple's use.

Discussion
You initialize a structure of type `FMFontIterator` by calling the function `FMCreateFontIterator`. You should not attempt to modify the contents of a font iterator.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSTypes.h`

FMFontSize

Represents a font size.

```
typedef SInt16 FMFontSize;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSTypes.h`

FMFontStyle

Represents a font style.

```
typedef SInt16 FMFontStyle;
```

Discussion
The low 8 bits of a Font Manager font style correspond to a QuickDraw style.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSTypes.h`

FMGeneration

Keeps track of any operation that adds, deletes, or modifies one or more fonts or font family objects.

```
typedef UInt32 FMGeneration;
```

Discussion
Any operation that adds, deletes, or modifies one or more fonts or font family objects triggers an update of a global generation seed value. Each font and font family modified during a transaction is tagged with a copy of the generation seed.

You can use the function `FMGetGeneration` to get the current value of the generation seed. Then you can use this information in conjunction with the functions `FMGetFontGeneration` and `FMGetFontFamilyGeneration` to identify any changes in the font database.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSTypes.h`

ATSUI Data Types

The data types in this section are used by Apple Type Services for Unicode Imaging (ATSUI).

ATSGlyph

Represents a glyph code.

```
typedef UInt16 ATSGlyph;
```

ATSGlyphIdealMetrics

Contains ideal (resolution-independent) metrics for a glyph.

```
struct ATSGlyphIdealMetrics {
    Float32Point advance;
    Float32Point sideBearing;
    Float32Point otherSideBearing;
};
typedef struct ATSGlyphIdealMetrics ATSGlyphIdealMetrics;
```

Fields

`advance`
The amount by which the pen is advanced after drawing the glyph.

`sideBearing`
The offset from the glyph origin to the beginning of the glyph image.

`otherSideBearing`
The offset from the end of the glyph image to the end of the glyph advance.

Discussion
This data structure is passed as a parameter to the ATSUI function `ATSUGlyphGetIdealMetrics`. For more information, see *Inside Mac OS X: ATSUI Reference*.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSTypes.h`

ATSGlyphRef

Represents a glyph reference.

```
typedef UInt16 ATSGlyphRef;
```

Discussion
This data type is used in the ATSUI data structure `ATSLayoutRecord`. For information, see *Inside Mac OS X: ATSUI Reference*.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSTypes.h`

ATSGlyphScreenMetrics

Contains device-adjusted font metric information for glyphs in a font.

```
struct ATSGlyphScreenMetrics {
    Float32Point deviceAdvance;
    Float32Point topLeft;
    UInt32 height;
    UInt32 width;
    Float32Point sideBearing;
    Float32Point otherSideBearing;
};
typedef struct ATSGlyphScreenMetrics ATSGlyphScreenMetrics;
```

Fields

`deviceAdvance`
The number of pixels of the advance for the glyph as actually drawn on the screen.

`topLeft`
The top-left point of the glyph in device coordinates.

`height`
The height of the glyph, in pixels. The glyph specified by this value may overlap with other glyphs when drawn.

`width`
The width of the glyph, in pixels. The glyph specified by this value may overlap with other glyphs when drawn.

`sideBearing`
The origin-side bearing, in pixels.

`otherSideBearinge`
The trailing-side bearing, in pixels.

Discussion

The `ATSGlyphScreenMetrics` data structure contains metrics for where glyphs should be drawn on the screen. The metrics include any adjustments needed to display the glyphs properly on the current screen. The structure is returned by the ATSUI function `ATSUGlyphGetScreenMetrics`. Many of the metrics in this structure are `Float32Point` data types so the metrics can integrate with Quartz functions, which all require `Float32Point` data types.

For information on the ATSUI function `ATSUGlyphGetScreenMetrics`, see *Inside Mac OS X: ATSUI Reference*.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`ATSTypes.h`

ATSUCurvePath

Contains curve information for a glyph path.

```
struct ATSUCurvePath {
    UInt32 vectors;
    UInt32 controlBits[1];
    Float32Point vector[1];
};
typedef struct ATSUCurvePath ATSUCurvePath;
```

Fields

`vectors`
: The number of values in each of the `controlBits` and `vector` arrays.

`controlBits`
: An array of control bit values that, together with the values in the `vector` array, define one cubic curve in a glyph.

`vector`
: An array of vector values that, together with the values in the `controlBits` array, define one cubic curve in a glyph.

Discussion

This data structure is used in the `ATSUCurvePaths` (page 701) data structure. The `ATSUCurvePaths` data structure is passed as a parameter to the ATSUI function `ATSUGlyphGetCurvePaths`. For more information, see *Inside Mac OS X: ATSUI Reference*.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`ATSTypes.h`

ATSUCurvePaths

Contains curve information for an array of glyph paths.

```
struct ATSUCurvePaths {
    UInt32 contours;
    ATSUCurvePath contour[1];
};
typedef struct ATSUCurvePaths ATSUCurvePaths;
```

Fields

`contours`
: The number of cubic curves contained in the `contour` array.

`contour`
: An array of cubic curves that define the outline of a glyph.

Discussion

The `ATSUCurvePaths` data structure is passed as a parameter to the ATSUI function `ATSUGlyphGetCurvePaths`. For more information, see *Inside Mac OS X: ATSUI Reference*.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`ATSTypes.h`

GlyphID

Represents a reference to a glyph.

```
typedef ATSGlyphRef GlyphID;
```

Discussion
The `GlyphID` data type is used by ATSUI. For more information, see *Inside Mac OS X: ATSUI Reference*.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ATSTypes.h`

Constants

ATS Constants

Assorted Options

Specify assorted options.

```
enum {
    kATSOptionFlagsDefault = kNilOptions,
    kATSOptionFlagsComposeFontPostScriptName = 1 << 0,
    kATSOptionFlagsUseDataForkAsResourceFork = 1 << 8,
    kATSOptionFlagsUseResourceFork = 2 << 8,
    kATSOptionFlagsUseDataFork = 3 << 8
};
```

Constants

`kATSOptionFlagsDefault`
Specifies to use the default setting.
Available in Mac OS X v10.0 and later.
Declared in `ATSFont.h`.

`kATSOptionFlagsComposeFontPostScriptName`
Specifies the composed PostScript name of a font.
Available in Mac OS X v10.0 and later.
Declared in `ATSFont.h`.

`kATSOptionFlagsUseDataForkAsResourceFork`
Specifies to use the data fork of a font as a resource fork. You can pass this option in the `iOptions` parameter for the function `ATSFontActivateFromFileSpecification` (page 648).
Available in Mac OS X v10.0 and later.
Declared in `ATSFont.h`.

`kATSOptionFlagsUseResourceFork`
Specifies to use the resource fork of a font.

Available in Mac OS X v10.0 and later.

Declared in `ATSFont.h`.

`kATSOptionFlagsUseDataFork`
Specifies to use the data fork of a font.

Available in Mac OS X v10.0 and later.

Declared in `ATSFont.h`.

Automatic Activation Settings

Values for automatic activation settings.

```
enum {
  kATSFontAutoActivationDefault = 0,
  kATSFontAutoActivationDisabled = 1,
  kATSFontAutoActivationEnabled = 2,
  kATSFontAutoActivationAsk     = 4
}
typedef UInt32  ATSFontAutoActivationSetting;
```

Constants

`kATSFontAutoActivationDefault`
Resets the setting the the default state. For application settings this clears the setting. For the global setting, it reverts to the initial system setting, `kATSFontAutoActivationEnabled`.

Available in Mac OS X v10.5 and later.

Declared in `ATSFont.h`.

`kATSFontAutoActivationAsk`
Asks the user before automatically activating fonts requested by the application.

Available in Mac OS X v10.5 and later.

Declared in `ATSFont.h`.

`kATSFontAutoActivationEnabled`
Enables automatic activation of fonts.

Available in Mac OS X v10.5 and later.

Declared in `ATSFont.h`.

`kATSFontAutoActivationDisabled`
Disables automatic activation of fonts.

Available in Mac OS X v10.5 and later.

Declared in `ATSFont.h`.

Declared In

`ATSFont.h`

Context Options

Specify a context to use when enumerating, activating, or deactivating fonts and font families.

```
typedef UInt32 ATSFontContext;
enum {
    kATSFontContextUnspecified = 0,
    kATSFontContextGlobal = 1,
    kATSFontContextLocal = 2
};
```

Constants

`kATSFontContextUnspecified`
Indicates a context is not specified. This option has the same result as providing the option `kATSFontContextLocal`.

Available in Mac OS X v10.0 and later.

Declared in `ATSFont.h`.

`kATSFontContextGlobal`
Specifies to use a global context. Fonts with a global context are available to all applications on the system.

Available in Mac OS X v10.0 and later.

Declared in `ATSFont.h`.

`kATSFontContextLocal`
Specifies to use a local context. Fonts with a local context are available to your application.

Available in Mac OS X v10.1 and later.

Declared in `ATSFont.h`.

Discussion

Context refers to the font's availability and can be local or global. You provide a context as an option to such functions as `ATSFontActivateFromFileSpecification` (page 648), `ATSFontActivateFromMemory` (page 649), `ATSFontFamilyIteratorCreate` (page 655), `ATSFontFamilyIteratorReset` (page 658). `ATSFontIteratorCreate` (page 671), and `ATSFontIteratorReset` (page 674).

Data Not Specified Constants

Indicate data that is not specified.

```
enum {
    kATSGenerationUnspecified = 0,
    kATSFontContainerRefUnspecified = 0,
    kATSFontFamilyRefUnspecified = 0,
    kATSFontRefUnspecified = 0
};
```

Constants

`kATSGenerationUnspecified`
Indicates the generation is not specified.

Available in Mac OS X v10.0 and later.

Declared in `ATSTypes.h`.

`kATSFontContainerRefUnspecified`
Indicates the font container reference is not specified.

Available in Mac OS X v10.0 and later.

Declared in `ATSTypes.h`.

`kATSFontFamilyRefUnspecified`
Indicates the font family reference is not specified.

Available in Mac OS X v10.0 and later.

Declared in `ATSTypes.h`.

`kATSFontRefUnspecified`
Indicates the font reference is not specified.

Available in Mac OS X v10.0 and later.

Declared in `ATSTypes.h`.

Discussion
You can pass these constants to functions when you either don't know the appropriate value or do not care to obtain the associated information. These constants can also be returned to you to indicate an error.

Font Filter Selectors

Specify the type of criteria to use when limiting an iteration.

```
enum ATSFontFilterSelector {
    kATSFontFilterSelectorUnspecified = 0,
    kATSFontFilterSelectorGeneration = 3,
    kATSFontFilterSelectorFontFamily = 7,
    kATSFontFilterSelectorFontFamilyApplierFunction = 8,
    kATSFontFilterSelectorFontApplierFunction = 9
};
typedef enum ATSFontFilterSelector ATSFontFilterSelector;
```

Constants
`kATSFontFilterSelectorUnspecified`
Specifies to limit an iteration based on unspecified criteria. In this case, the default is used, which is to iterate using a local context with an unrestricted scope.

Available in Mac OS X v10.0 and later.

Declared in `ATSFont.h`.

`kATSFontFilterSelectorGeneration`
Specifies to limit an iteration based on generation criteria.

Available in Mac OS X v10.0 and later.

Declared in `ATSFont.h`.

`kATSFontFilterSelectorFontFamily`
Specifies to limit an iteration based on font family criteria.

Available in Mac OS X v10.0 and later.

Declared in `ATSFont.h`.

`kATSFontFilterSelectorFontFamilyApplierFunction`
Specifies to limit an iteration based on criteria defined by a font family applier function.

Available in Mac OS X v10.0 and later.

Declared in `ATSFont.h`.

`kATSFontFilterSelectorFontApplierFunction`
Specifies to limit an iteration based on criteria defined by a font applier function.

Available in Mac OS X v10.0 and later.

Declared in `ATSFont.h`.

Discussion
You use these constants in the data structure `ATSFontFilter` (page 688) to specify the type of data in the `filter` union.

Font Filter Versions

Specify the version of a font filter.

```
typedef UInt32 ATSFontFormat;
enum {
    kATSFontFilterCurrentVersion = 0
};
```

Constants
`kATSFontFilterCurrentVersion`
Specifies to use the current version of a font filter.

Available in Mac OS X v10.0 and later.

Declared in `ATSFont.h`.

Discussion
There is currently only one constant in this enumeration. You can assign this constant to the `version` field in the `ATSFontFilter` (page 688) data structure.

Font Formats

Specify a font format.

```
enum {
    kATSFontFormatUnspecified = 0
};
```

Constants
`kATSFontFormatUnspecified`
Indicates the font format is not specified. You can pass this in the `iFormat` parameter of the function `ATSFontActivateFromFileSpecification` (page 648).

Available in Mac OS X v10.0 and later.

Declared in `ATSTypes.h`.

Discussion
There are no other font formats currently defined for this enumeration.

Font Request Query Keys

Represent keys in a font request query dictionary.

```
#define kATSQueryClientPID                                              CFSTR("ATS
 client
pid")
#define kATSQueryQDFamilyName               CFSTR("font family
name")
#define kATSQueryFontName                CFSTR("font name")
#define kATSQueryFontPostScriptName      CFSTR("font PS name")
#define kATSQueryFontNameTableEntries    CFSTR("font name table
entries")
#define kATSFontNameTableCode            CFSTR("font name code")
#define kATSFontNameTablePlatform        CFSTR("font platform
code")
#define kATSFontNameTableScript          CFSTR("font script
code")
#define kATSFontNameTableLanguage        CFSTR("font language
code")
#define kATSFontNameTableBytes
CFSTR("font
name table bytes")
```

Constants

`kATSQueryClientPID`
Specifies a process ID. The value associated with this key is a `CFNumberRef` value that refers to a the process ID (`pid_t`) of the application making the query.

`kATSQueryQDFamilyName`
Specifies a QuickDraw family name. The value associated with this key is a `CFStringRef` value that refers to the QuickDraw family name of the requested font. For example, the name passed to the function `GetFNum`.

`kATSQueryFontName`
Specifies a font name. The value associated with this key is a `CFStringRef` value that refers to the full name of the requested font. You can use this font name as an argument to the function `ATSFontFindFromName` (page 660).

`kATSQueryFontPostScriptName`
Specifies the PostScript name of a font. The value associated with this key is a `CFStringRef` value that refers to either the PostScript name derived from the font's `FOND` resource or from the font's `'sfnt'` name table, with preference given to the `FOND` PostScript name. You can use this font name as an argument to the function `ATSFontFindFromPostScriptName` (page 661).

`kATSQueryFontNameTableEntries`
Specifies the descriptor for `'sfnt'` name table entries. The value associated with this key an array (`CFArrayRef`) of `CFDictionaryRef` values that describe entries in a name table. A font must have all of the specified entries to be considered a match.

`kATSFontNameTableCode`
Specifies the font name's name code. The value associated with this key is a `CFNumberRef`. If no value is specified, the value `kFontNoNameCode` is used.

`kATSFontNameTablePlatform`
Specifies the font name's platform code. The value associated with this key is a `CFNumberRef`. If no value is specified, the value `kFontNoPlatformCode` is used.

`kATSFontNameTableScript`
Specifies the font name's script code. The value associated with this key is a `CFNumberRef`. If no value is specified, the value `kFontNoScriptCode` is used.

`kATSFontNameTableLanguage`
: Specifies the font name's language code. The value associated with this key is a `CFNumberRef`. If no value is specified, the value `kFontNoLanguageCode` is used.

`kATSFontNameTableBytes`
: Specifies the raw bytes of the font name. The value associated with this key is a `CFDataRef` value that refers to the raw name bytes for the font.

Discussion
Font request query keys appear in the dictionary passed to, and returned by, your `ATSFontQueryCallback` (page 683) callback function. The keys comprise a property list (`CFPropertyList`) that defines the query sent to your callback. On return, you supply a property list that specifies your response to the query.

Font Query Message ID

Specifies a message ID for a font request query.

```
enum ATSFontQueryMessageID {
    kATSQueryActivateFontMessage = 'atsa'
};
typedef enum ATSFontQueryMessageID ATSFontQueryMessageID;
```

Constants
`kATSQueryActivateFontMessage`
: Specifies to activate a font message. The data associated with this message ID is a flattened `CFDictionaryRef`. The `CFDictionary` contains on or more of the keys described in "Font Request Query Keys" (page 706).

Available in Mac OS X v10.2 and later.

Declared in `ATSFont.h`.

Discussion
There is currently only one constant in this enumeration. You use a constant of this type when you create an `ATSFontQueryCallback` (page 683) callback function.

Iteration Precedence Options

Specify the order of an iteration.

```
enum {
    kATSOptionFlagsIterateByPrecedenceMask = 0x00000001 <<  5
};
```

Constants
`kATSOptionFlagsIterateByPrecedenceMask`
: Specifies to iterate fonts in the order dictated by a precedence mask.

Available in Mac OS X v10.1 and later.

Declared in `ATSFont.h`.

Notification Actions

Specify a notification action.

```
enum ATSFontNotifyAction {
    kATSFontNotifyActionFontsChanged = 1,
    kATSFontNotifyActionDirectoriesChanged = 2
};
typedef enum ATSFontNotifyAction ATSFontNotifyAction;
```

Constants

`kATSFontNotifyActionFontsChanged`

Specifies that your application has activated or deactivated fonts. Typically you call the functions `ATSFontActivateFromFileSpecification` (page 648) or `ATSFontDeactivate` (page 651) multiple times to activate and deactivate fonts. In each call, you set the `iOptions` parameter to `kATSOptionFlagsDoNotNotify` set. When you are done activating and deactivating fonts you can call the function `ATSFontNotify` (page 676) with the `action` parameter set to `kATSFontNotifyActionFontsChanged`. Then ATS notifies all applications who subscribe to notifications of the changes you made.

Available in Mac OS X v10.2 and later.

Declared in `ATSFont.h`.

`kATSFontNotifyActionDirectoriesChanged`

Specifies that your application has made changes to one or more of the font directories. When you are making changes to font directories, you can call the function `ATSFontNotify` (page 676) with the `action` parameter set to `kATSFontNotifyActionDirectoriesChanged`. Then ATS scans these directories and notifies all applications who subscribe to notifications of the changes you made.

Available in Mac OS X v10.2 and later.

Declared in `ATSFont.h`.

Discussion

You can use these options with the function `ATSFontNotify` (page 676).

Notification Options

Specify when ATS should notify your application of changes in the font database.

```
enum ATSFontNotifyOption {
    kATSFontNotifyOptionDefault = 0,
    kATSFontNotifyOptionReceiveWhileSuspended = 1L << 0
};
typedef enum ATSFontNotifyOption ATSFontNotifyOption;
```

Constants

`kATSFontNotifyOptionDefault`

Specifies to use the default behavior of the function `ATSFontNotificationSubscribe` (page 675).

Available in Mac OS X v10.2 and later.

Declared in `ATSFont.h`.

`kATSFontNotifyOptionReceiveWhileSuspended`

Specifies to receive notifications even if the application is in the background. Setting this option can degrade performance; you should set this option if your application is a faceless process or a tool that performs font management functions and requires immediate notification when fonts change.

Available in Mac OS X v10.2 and later.

Declared in `ATSFont.h`.

Discussion
You use notification options when you call the function `ATSFontNotificationSubscribe` (page 675). The default behavior is for applications to receive ATS notifications only when the application runs in the foreground. By default, if the application is suspended, the notification is delivered when the application comes to the foreground.

Scoping Options

Specify the scope to which an operation should apply or a notification schedule.

```
enum {
    kATSOptionFlagsDoNotNotify = 0x00000001 << 8,
    kATSOptionFlagsIterationScopeMask = 0x00000007 << 12,
    kATSOptionFlagsDefaultScope = 0x00000000 << 12,
    kATSOptionFlagsUnRestrictedScope = 0x00000001 << 12,
    kATSOptionFlagsRestrictedScope = 0x00000002 << 12,
    kATSOptionFlagsProcessSubdirectories = 0x00000001 << 6
};
```

Constants

`kATSOptionFlagsDoNotNotify`
Specifies not to send a notification after a font is activated or deactivated globally. You can set the `iOptions` parameter of the functions `ATSFontActivateFromFileSpecification` (page 648) or `ATSFontDeactivate` (page 651) to this constant. When you are done activating and deactivating fonts you can call the function `ATSFontNotify` (page 676) with the `action` parameter set to `kATSFontNotifyActionFontsChanged`. Then ATS notifies all applications who subscribe to notifications of the changes you made.

Available in Mac OS X v10.2 and later.

Declared in `ATSFont.h`.

`kATSOptionFlagsIterationScopeMask`
Specifies mask option bits 12-14 for iteration scopes.

Available in Mac OS X v10.1 and later.

Declared in `ATSFont.h`.

`kATSOptionFlagsDefaultScope`
Specifies to use the default scope, which is equivalent to `kATSOptionFlagsUnRestrictedScope`. You can pass this as a parameter to the functions `ATSFontFamilyIteratorCreate` (page 655), `ATSFontFamilyIteratorReset` (page 658), `ATSFontIteratorCreate` (page 671) and `ATSFontIteratorReset` (page 674).

Available in Mac OS X v10.1 and later.

Declared in `ATSFont.h`.

`kATSOptionFlagsUnRestrictedScope`
Specifies to use an unrestricted scope. You can pass this as a parameter to the functions `ATSFontFamilyIteratorCreate` (page 655), `ATSFontFamilyIteratorReset` (page 658), `ATSFontIteratorCreate` (page 671) and `ATSFontIteratorReset` (page 674).

Available in Mac OS X v10.1 and later.

Declared in `ATSFont.h`.

`kATSOptionFlagsRestrictedScope`
: Specifies to use a restricted scope. You can pass this as a parameter to the functions `ATSFontFamilyIteratorCreate` (page 655), `ATSFontFamilyIteratorReset` (page 658), `ATSFontIteratorCreate` (page 671) and `ATSFontIteratorReset` (page 674).

Available in Mac OS X v10.1 and later.

Declared in `ATSFont.h`.

`kATSOptionFlagsProcessSubdirectories`
: Specifies to process the font directories within a font directory. You can pass this as a parameter to the function `ATSFontActivateFromFileSpecification` (page 648).

Available in Mac OS X v10.2 and later.

Declared in `ATSFont.h`.

Discussion
Scope refers to whether a font's use is restricted or unrestricted. Fonts with a restricted scope can be used only by your application whereas fonts with an unrestricted scope cay be used by all applications.

Font Manager Constants

FM Filter Format

Specifies a filter format.

```
enum {
    kFMCurrentFilterFormat = 0
};
```

Constants
`kFMCurrentFilterFormat`
: Specifies the current filter format. You can use this to set the format field when you initialize the `FMFilter` data type for use in creating an iterator object with the functions `FMCreateFontFamilyIterator` or `FMCreateFontIterator`. Currently, this is the only format you can specify.

Available in Mac OS X v10.0 and later.

Declared in `ATSTypes.h`.

FM Filter Selectors

Specifies a filter type.

```
typedef UInt32 FMFilterSelector;
enum {
    kFMFontTechnologyFilterSelector = 1,
    kFMFontContainerFilterSelector = 2,
    kFMGenerationFilterSelector = 3,
    kFMFontFamilyCallbackFilterSelector = 4,
    kFMFontCallbackFilterSelector = 5,
    kFMFontDirectoryFilterSelector = 6
};
```

Constants

`kFMFontTechnologyFilterSelector`
Selects font technology filter. You can use this filter only with a font iterator.
Available in Mac OS X v10.0 and later.
Declared in `ATSTypes.h`.

`kFMFontContainerFilterSelector`
Selects font container filter. You can use this filter only with a font iterator.
Available in Mac OS X v10.0 and later.
Declared in `ATSTypes.h`.

`kFMGenerationFilterSelector`
Selects generation filter. You can use this filter only with a font family iterator.
Available in Mac OS X v10.0 and later.
Declared in `ATSTypes.h`.

`kFMFontFamilyCallbackFilterSelector`
Indicates a custom filter to be used only with a font family iterator.
Available in Mac OS X v10.0 and later.
Declared in `ATSTypes.h`.

`kFMFontCallbackFilterSelector`
Indicates a custom filter to be used only with a font iterator.
Available in Mac OS X v10.0 and later.
Declared in `ATSTypes.h`.

Discussion

You use these constants to specify a filter type in the `FMFilter` (page 693) data structure used by many Font Manager functions.

FM Font Technologies

Specify a font technology.

```
enum {
    kFMTrueTypeFontTechnology = 'true',
    kFMPostScriptFontTechnology = 'typ1'
};
```

Constants

`kFMTrueTypeFontTechnology`
Indicates True Type font technology.
Available in Mac OS X v10.0 and later.
Declared in `ATSTypes.h`.

`kFMPostScriptFontTechnology`
Indicates Post Script font technology.
Available in Mac OS X v10.0 and later.
Declared in `ATSTypes.h`.

Invalid Values

Specify an invalid value.

```
enum {
    kInvalidGeneration = 0,
    kInvalidFontFamily = -1,
    kInvalidFont = 0
};
```

Constants

`kInvalidGeneration`
Indicates an invalid generation value.
Available in Mac OS X v10.0 and later.
Declared in `ATSTypes.h`.

`kInvalidFontFamily`
Indicates the font family reference is invalid.
Available in Mac OS X v10.0 and later.
Declared in `ATSTypes.h`.

`kInvalidFont`
Indicates the font reference is invalid.
Available in Mac OS X v10.0 and later.
Declared in `ATSTypes.h`.

Discussion

The `kInvalidGeneration`, `kInvalidFontFamily`, and `kInvalidFont` constants may be used to indicate invalid values for generation count, font family, and font data types.

ATSUI Constants

Convenience Constants

Represent numerical values that are commonly used in font calculations.

```
enum {
    kATSItalicQDSkew = (1 << 16) / 4,
    kATSBoldQDStretch = (1 << 16) * 3 / 2,
    kATSRadiansFactor = 1144
};
```

Constants

`kATSItalicQDSkew`
A `Fixed` value of `0.25` that represents the skew used by QuickDraw to draw italicized glyphs.

Available in Mac OS X v10.0 and later.

Declared in `ATSTypes.h`.

`kATSBoldQDStretch`
A `Fixed` value that represents the stretch-factor used by QuickDraw to draw bold-faced glyphs.

Available in Mac OS X v10.0 and later.

Declared in `ATSTypes.h`.

`kATSRadiansFactor`
A `Fixed` value of approximately `pi/180(0.0174560546875)` that represents an angle of 1 radian. This is a convenience constant you can use when you draw rotated text.

Available in Mac OS X v10.0 and later.

Declared in `ATSTypes.h`.

Discussion

These constants are provided for convenience. Your application can use them when it needs to perform font calculations.

Version Notes

Available beginning with ATSUI 1.0.

Curve Types

Specify a curve type used to draw a font.

```
typedef UInt16 ATSCurveType;
enum {
    kATSCubicCurveType = 0x0001,
    kATSQuadCurveType = 0x0002,
    kATSOtherCurveType = 0x0003
};
```

Constants

`kATSCubicCurveType`
Specifies a cubic curve.
Available in Mac OS X v10.0 and later.
Declared in `ATSTypes.h`.

`kATSQuadCurveType`
Specifies a quadratic curve.
Available in Mac OS X v10.0 and later.
Declared in `ATSTypes.h`.

`kATSOtherCurveType`
Specifies a curve other than cubic or quadratic.
Available in Mac OS X v10.0 and later.
Declared in `ATSTypes.h`.

Discussion

These are used in the ATSUI function `ATSUGetNativeCurveType`. See *Inside Mac OS X: ATSUI Reference* for more information.

Deleted Glyph Code

Specifies that a glyph is deleted.

```
enum {
    kATSDeletedGlyphcode = 0xFFFF
};
```

Constants

`kATSDeletedGlyphcode`
Indicates that a glyph is deleted. That is, the glyph is set to no longer appear in a text layout.
Available in Mac OS X v10.2 and later.
Declared in `ATSTypes.h`.

Discussion

This constant is used by ATSUI. When a glyph is deleted, ATSUI sets the corresponding `ATSGlyphRef` (page 699) to `kATSDeletedGlyphcode`. For more information, see *Inside Mac OS X: ATSUI Reference*.

Result Codes

The most common result codes returned by Apple Type Services for Fonts are listed below.

Result Code	Value	Description
kATSIterationCompleted	-980L	The iteration is complete. Available in Mac OS X v10.0 and later.
kATSInvalidFontFamilyAccess	-981L	Your application tried to access an invalid font family. Available in Mac OS X v10.0 and later.
kATSInvalidFontAccess	-982L	Your application tried to access an invalid font. Available in Mac OS X v10.0 and later.
kATSIterationScopeModified	-983L	The font database changed during an iteration. Available in Mac OS X v10.0 and later.
kATSInvalidFontTableAccess	-984L	Your application tried to access an invalid font table. Available in Mac OS X v10.0 and later.
kATSInvalidFontContainerAccess	-985L	Your application tried to access an invalid font container. Available in Mac OS X v10.0 and later.

ColorSync Manager Reference

Framework: ApplicationServices/ApplicationServices.h, Carbon/Carbon.h

Declared in CMApplication.h
CMMComponent.h
CMTypes.h
CMCalibrator.h
CMScriptingPlugin.h
CMDeviceIntegration.h

Overview

The ColorSync Manager is the API for ColorSync, a platform-independent color management system from Apple. ColorSync provides essential services for fast, consistent, and accurate color calibration, proofing, and reproduction using input, output, and display devices. ColorSync also provides an interface to system-wide color management settings that allows users to save color settings for specific jobs and switch between settings.

You need this reference if your software product performs color drawing, printing, or calculation, or if your peripheral device supports color. You also need this reference if you are creating a color management module (CMM)—a component that implements color-matching, color-conversion, and gamut-checking services.

The Color Picker Manager, documented separately, provides a standard user interface for soliciting color choices.

Carbon supports the majority of the ColorSync Manager programming interface. However, ColorSync 1.0 compatibility calls such as `CWNewColorWorld`, `GetProfile`, and `SetProfile` are not supported.

Nor does Carbon support ColorSync functions used for color management modules (CMMs). These functions aren't supported because Mac OS X uses Bundle Services to implement CMMs.

Some applications use the Component Manager to determine what CMMs are available. You cannot use the Component Manager for this purpose in Mac OS X. Apple has, however, provided a the function `CMIterateCMMInfo` to query for available CMMs.

Functions by Task

Accessing Profiles

`CMOpenProfile` (page 790)
Opens the specified profile and returns a reference to the profile.

`CMValidateProfile` (page 818)
Indicates whether the specified profile contains the minimum set of elements required by the current color management module (CMM) for color matching or color checking.

`CMCloseProfile` (page 728)
Decrements the reference count for the specified profile reference and, if the reference count reaches 0, frees all private memory and other resources associated with the profile.

`CMUpdateProfile` (page 816)
Saves modifications to the specified profile.

`CMCopyProfile` (page 740)
Duplicates the specified existing profile.

`CMProfileModified` (page 795)
Indicates whether the specified profile has been modified since it was created or last updated.

`CMGetProfileMD5` (page 771)
Gets the MD5 checksum from the profile header (message digest)

`CMGetProfileHeader` (page 769)
Obtains the profile header for the specified profile.

`CMSetProfileHeader` (page 813)
Sets the header for the specified profile.

`NCMGetProfileLocation` (page 841)
Obtains either a profile location structure for a specified profile or the size of the location structure for the profile.

`CMCloneProfileRef` (page 727)
Increments the reference count for the specified profile reference.

`CMGetProfileRefCount` (page 772)
Obtains the current reference count for the specified profile.

`CMFlattenProfile` (page 748) Deprecated in Mac OS X v10.5
Transfers a profile stored in an independent disk file to an external profile format that can be embedded in a graphics document.

`CMGetProfileLocation` (page 770) Deprecated in Mac OS X v10.5
Obtains the location of a profile based on the specified profile reference.

`NCMUnflattenProfile` (page 843) Deprecated in Mac OS X v10.5
Unflattens a previouslyflattened profile.

Iterating Installed Profiles

`CMIterateColorSyncFolder` (page 780)
Iterates over the available profiles.

`CMGetColorSyncFolderSpec` (page 749) Deprecated in Mac OS X v10.5
Obtains the volume reference number and the directory ID for a ColorSync Profiles folder.

Creating Profiles

`CMNewProfile` (page 788)
Creates a new profile and associated backing copy.

`NCWNewLinkProfile` (page 848)
Obtains a profile reference for the specified by the profile location.

`CMMakeProfile` (page 784)
Makes a display or abstract profile by modifying an existing one.

`CWNewLinkProfile` (page 830) Deprecated in Mac OS X v10.5
Creates a device link profile based on the specified set of profiles.

Accessing Special Profiles

`CMGetSystemProfile` (page 778)
Obtains a reference to the current system profile.

`CMGetDefaultProfileBySpace` (page 752)
Gets the default profile for the specified color space.

`CMGetDefaultProfileByUse` (page 753)
Obtains the users' preferred device profile setting.

`CMGetProfileByAVID` (page 767)
Gets the current profile for a monitor.

`CMSetProfileByAVID` (page 808)
Sets the profile for the specified monitor, optionally setting video card gamma.

`CMSetDefaultProfileBySpace` (page 801) Deprecated in Mac OS X v10.5
Sets the default profile for the specified color space.

`CMSetDefaultProfileByUse` (page 801) Deprecated in Mac OS X v10.5
Sets values for device profile settings.

`CMSetSystemProfile` (page 814) Deprecated in Mac OS X v10.5
Sets the current system profile.

`NCMSetSystemProfile` (page 842) Deprecated in Mac OS X v10.5
Sets the location of a color profile.

Accessing Profile Elements

`CMCountProfileElements` (page 744)
Counts the number of elements in the specified profile.

`CMProfileElementExists` (page 792)
Tests whether the specified profile contains a specific element based on the element's tag signature.

`CMGetProfileElement` (page 768)
Obtains element data from the specified profile based on the specified element tag signature.

`CMSetProfileElement` (page 810)
Sets or replaces the element data for a specific tag in the specified profile.

`CMSetProfileElementSize` (page 812)
Reserves the element data size for a specific tag in the specified profile before setting the element data.

`CMGetPartialProfileElement` (page 765)
Obtains a portion of the element data from the specified profile based on the specified element tag signature.

`CMSetPartialProfileElement` (page 807)
Sets part of the element data for a specific tag in the specified profile.

`CMGetIndProfileElementInfo` (page 761)
Obtains the element tag and data size of an element by index from the specified profile.

`CMGetIndProfileElement` (page 760)
Obtains the element data corresponding to a particular index from the specified profile.

`CMSetProfileElementReference` (page 811)
Adds a tag to the specified profile to refer to data corresponding to a previously set element.

`CMRemoveProfileElement` (page 797)
Removes an element corresponding to a specific tag from the specified profile.

Accessing Profile Descriptions

`CMCopyProfileDescriptionString` (page 742)
Returns the name of a profile as a CFString.

`CMCopyProfileLocalizedString` (page 742)
Gets one specific string out of a profile

`CMCopyProfileLocalizedStringDictionary` (page 743)
Obtains a CFDictionary which contains the language locale and string for multiple localizations from a given tag.

`CMSetProfileLocalizedStringDictionary` (page 813)
Writes a dictionary of localized strings to a given tag in a profile.

`CMGetProfileDescriptions` (page 767)
Obtains the description tag data for a specified profile.

`CMSetProfileDescriptions` (page 809)
Sets the description tag data for a specified profile.

`CMGetScriptProfileDescription` (page 777) Deprecated in Mac OS X v10.5
Obtains the internal name (or description) of a profile and the script code identifying the language in which the profile name is specified from the specified profile.

Accessing Name-Class Profiles

`CMGetNamedColorInfo` (page 763)
Obtains information about a named color space from its profile reference.

`CMGetNamedColorValue` (page 764)
Obtains device and PCS color values for a specific color name from a named color space profile.

`CMGetIndNamedColorValue` (page 759)
Obtains device and PCS color values for a specific named color index from a named color space profile.

`CMGetNamedColorIndex` (page 762)
Obtains a named color index for a specific color name from a named color space profile.

`CMGetNamedColorName` (page 763)
Obtains a named color name for a specific named color index from a named color space profile.

Working With ColorWorlds

`NCWNewColorWorld` (page 846)
Creates a color world for color matching based on the specified source and destination profiles.

`CWConcatColorWorld` (page 823)
Sets up a color world that includes a set of profiles for various color transformations among devices in a sequence.

`NCWConcatColorWorld` (page 845)
Defines a color world for color transformations among a series of concatenated profiles.

`CWDisposeColorWorld` (page 825)
Releases the private storage associated with a color world when your application has finished using the color world.

`CWMatchColors` (page 828)
Matches colors in a color list, using the specified color world.

`CWCheckColors` (page 821)
Tests a list of colors using a specified color world to see if they fall within the gamut of a destination device.

`CWMatchBitmap` (page 826)
Matches the colors of a bitmap to the gamut of a destination device using the profiles specified by a color world.

`CWCheckBitmap` (page 819)
Tests the colors of the pixel data of a bitmap to determine whether the colors map to the gamut of the destination device.

`CWFillLookupTexture` (page 826)
Fills a 3-D lookup texture from a color world.

`CMGetCWInfo` (page 751) Deprecated in Mac OS X v10.5
Obtains information about the color management modules (CMMs) used for a specific color world.

Converting Colors

`CMConvertFixedXYZToXYZ` (page 730) Deprecated in Mac OS X v10.5
Converts colors specified in XYZ color space whose components are expressed as Fixed XYZ 32-bit signed values of type `CMFixedXYZColor` to equivalent colors expressed as XYZ 16-bit unsigned values of type `CMXYZColor`.

`CMConvertHLSToRGB` (page 730) Deprecated in Mac OS X v10.5
Converts colors specified in the HLS color space to equivalent colors defined in the RGB color space.

`CMConvertHSVToRGB` (page 731) Deprecated in Mac OS X v10.5
Converts colors specified in the HSV color space to equivalent colors defined in the RGB color space.

`CMConvertLabToXYZ` (page 732) Deprecated in Mac OS X v10.5
Converts colors specified in the L*a*b* color space to the XYZ color space.

`CMConvertLuvToXYZ` (page 733) Deprecated in Mac OS X v10.5
Converts colors specified in the L*u*v* color space to the XYZ color space.

`CMConvertRGBToGray` (page 733) Deprecated in Mac OS X v10.5
Converts colors specified in the RGB color space to equivalent colors defined in the Gray color space.

CMConvertRGBToHLS (page 734) Deprecated in Mac OS X v10.5
Converts colors specified in the RGB color space to equivalent colors defined in the HLS color space.

CMConvertRGBToHSV (page 735) Deprecated in Mac OS X v10.5
Converts colors specified in the RGB color space to equivalent colors defined in the HSV color space when the device types are the same.

CMConvertXYZToFixedXYZ (page 736) Deprecated in Mac OS X v10.5
Converts colors specified in the XYZ color space whose components are expressed as XYZ 16-bit unsigned values of type CMXYZColor to equivalent colors expressed as 32-bit signed values of type CMFixedXYZColor.

CMConvertXYZToLab (page 736) Deprecated in Mac OS X v10.5
Converts colors specified in the XYZ color space to the L*a*b* color space.

CMConvertXYZToLuv (page 737) Deprecated in Mac OS X v10.5
Converts colors specified in the XYZ color space to the L*u*v* color space.

CMConvertXYZToXYZ (page 738) Deprecated in Mac OS X v10.5
Converts a source color to a destination color using the specified chromatic adaptation method.

CMConvertXYZToYxy (page 739) Deprecated in Mac OS X v10.5
Converts colors specified in the XYZ color space to the Yxy color space.

CMConvertYxyToXYZ (page 739) Deprecated in Mac OS X v10.5
Converts colors specified in the Yxy color space to the XYZ color space.

Working With CMMs

CMIterateCMMInfo (page 779)
Iterates through the color management modules installed on the system.

CMGetPreferredCMM (page 766) Deprecated in Mac OS X v10.5
Identifies the preferred CMM specified by the ColorSync control panel.

Working With PostScript

CMGetPS2ColorSpace (page 776)
Obtains color space element data in text format usable as the parameter to the PostScript setColorSpace operator, which characterizes the color space of subsequent graphics data.

CMGetPS2ColorRenderingIntent (page 774)
Obtains the rendering intent element data in text format usable as the parameter to the PostScript findRenderingIntent operator, which specifies the color-matching option for subsequent graphics data.

CMGetPS2ColorRendering (page 773)
Obtains the color rendering dictionary (CRD) element data usable as the parameter to the PostScript setColorRendering operator, which specifies the PostScript color rendering dictionary to use for the following graphics data.

CMGetPS2ColorRenderingVMSize (page 775)
Determines the virtual memory size of the color rendering dictionary (CRD) for a printer profile before your application or driver obtains the CRD and sends it to the printer.

Working With QuickDraw

`CMEnableMatchingComment` (page 746) Deprecated in Mac OS X v10.4
Inserts a comment into the currently open picture to turn matching on or off.

`CMEndMatching` (page 747) Deprecated in Mac OS X v10.4
Concludes a QuickDraw-specific ColorSync matching session initiated by a previous call to the `NCMBeginMatching` function.

`CWCheckPixMap` (page 822) Deprecated in Mac OS X v10.4
Checks the colors of a pixel map using the profiles of a specified color world to determine whether the colors are in the gamut of the destination device.

`CWMatchPixMap` (page 829) Deprecated in Mac OS X v10.4
Matches a pixel map in place based on a specified color world.

`NCMBeginMatching` (page 838) Deprecated in Mac OS X v10.4
Sets up a QuickDraw-specific ColorSync matching session, using the specified source and destination profiles.

`NCMDrawMatchedPicture` (page 840) Deprecated in Mac OS X v10.4
Matches a picture's colors to a destination device's color gamut, as the picture is drawn, using the specified destination profile.

`NCMUseProfileComment` (page 843) Deprecated in Mac OS X v10.4
Automatically embeds a profile or a profile identifier into an open picture.

Registering Devices

`CMRegisterColorDevice` (page 797)
Registers a device with ColorSync.

`CMUnregisterColorDevice` (page 815)
Unregisters a device.

Accessing Default Devices

`CMGetDefaultDevice` (page 752)
Gets the default device.

`CMSetDefaultDevice` (page 800)
Sets the default device.

Accessing Devices Profiles

`CMGetDeviceFactoryProfiles` (page 754)
Retrieves the original profiles for a given device.

`CMSetDeviceFactoryProfiles` (page 803)
Establishes the profiles used by a given device.

`CMGetDeviceDefaultProfileID` (page 754)
Gets the default profile ID for a given device.

`CMSetDeviceDefaultProfileID` (page 802)
Sets the default profile ID for a given device.

`CMSetDeviceProfile` (page 803)
Change the profile used by a given device.

`CMGetDeviceProfile` (page 756)
Gets a profile used by a given device.

`CMGetDeviceProfiles` (page 756) Deprecated in Mac OS X v10.5
Gets the profiles used by a given device.

`CMSetDeviceProfiles` (page 804) Deprecated in Mac OS X v10.5
Changes the profiles used by a given device.

Accessing Device State and Information

`CMGetDeviceState` (page 757)
Gets the state of a device.

`CMSetDeviceState` (page 805)
Sets the state of a device.

`CMGetDeviceInfo` (page 755)
Gets information about a specified device.

Iterating Over Devices and Device Profiles

`CMIterateColorDevices` (page 780)
Iterates through the color devices available on the system, returning device information to a callback you supply.

`CMIterateDeviceProfiles` (page 782)
Iterates through the device profiles available on the system and returns information about profiles of the devices to a callback you supply.

Working With Image Files

`CMCountImageProfiles` (page 743) Deprecated in Mac OS X v10.5
Obtains a count of the number of embeded profiles for a given image.

`CMEmbedImage` (page 746) Deprecated in Mac OS X v10.5
Embeds an image with an ICC profile.

`CMGetImageSpace` (page 758) Deprecated in Mac OS X v10.5
Returns the signature of the data color space in which the color values of colors in an image are expressed.

`CMGetIndImageProfile` (page 758) Deprecated in Mac OS X v10.5
Obtains a specific embeded profile for a given image.

`CMLinkImage` (page 783) Deprecated in Mac OS X v10.5
Matches an image file with a device link profile.

`CMMatchImage` (page 787) Deprecated in Mac OS X v10.5
Color matches an image file.

`CMProofImage` (page 796) Deprecated in Mac OS X v10.5
Proofs an image.

`CMSetIndImageProfile` (page 807) Deprecated in Mac OS X v10.5
Sets a specific embeded profile for a given image.

`CMUnembedImage` (page 814) Deprecated in Mac OS X v10.5
Removes any ICC profiles embeded in an image.

`CMValidImage` (page 819) Deprecated in Mac OS X v10.5
Validates the specified image file.

Working With Video Card Lookup Tables

`CMGetGammaByAVID` (page 757)
Obtains the gamma value for the specified display device.

`CMSetGammaByAVID` (page 806)
Sets the gamma for the specified display device.

Miscellaneous

`CMGetColorSyncVersion` (page 750)
Gets ColorSync version information.

`CMLaunchControlPanel` (page 783)
Launches the ColorSync preferences pane.

`CMCalibrateDisplay` (page 727)
Calibrates a display.

Working With Universal Procedure Pointers

`DisposeCMBitmapCallBackUPP` (page 832) Deprecated in Mac OS X v10.5
Disposes of a universal procedure pointer (UPP) to a bitmap callback.

`DisposeCMConcatCallBackUPP` (page 832) Deprecated in Mac OS X v10.5
Disposes of a universal procedure pointer (UPP) to a progress-monitoring callback.

`DisposeCMFlattenUPP` (page 833) Deprecated in Mac OS X v10.5
Disposes of a universal procedure pointer (UPP) to a data-flattening callback.

`DisposeCMMIterateUPP` (page 833) Deprecated in Mac OS X v10.5
Disposes of a universal procedure pointer (UPP) to a progress-monitoring callback for the `CMIterateCMMInfo` function.

`DisposeCMProfileAccessUPP` (page 834) Deprecated in Mac OS X v10.5
Disposes of a universal procedure pointer (UPP) to a profile-access callback.

`DisposeCMProfileFilterUPP` (page 834) Deprecated in Mac OS X v10.5
Disposes of a universal procedure pointer (UPP) to a profile-filter callback.

`DisposeCMProfileIterateUPP` (page 834) Deprecated in Mac OS X v10.5
Disposes of a universal procedure pointer (UPP) to a profile-iteration callback.

`InvokeCMBitmapCallBackUPP` (page 835) Deprecated in Mac OS X v10.5
Invokes a universal procedure pointer (UPP) to a bitmap callback.

`InvokeCMConcatCallBackUPP` (page 835) Deprecated in Mac OS X v10.5
Invokes a universal procedure pointer (UPP) to a progress-monitoring callback.

`InvokeCMFlattenUPP` (page 836) Deprecated in Mac OS X v10.5
Invokes a universal procedure pointer (UPP) to a data-flattening callback.

`InvokeCMMIterateUPP` (page 836) Deprecated in Mac OS X v10.5
Invokes a universal procedure pointer (UPP) to a a progress-monitoring callback for the `CMIterateCMMInfo` function.

`InvokeCMProfileAccessUPP` (page 837) Deprecated in Mac OS X v10.5
Invokes a universal procedure pointer (UPP) to a profile-access callback.

`InvokeCMProfileFilterUPP` (page 837) Deprecated in Mac OS X v10.5
Invokes a universal procedure pointer (UPP) to a profile-filter callback.

`InvokeCMProfileIterateUPP` (page 837) Deprecated in Mac OS X v10.5
Invokes a universal procedure pointer (UPP) to a profile-iteration callback.

`NewCMBitmapCallBackUPP` (page 848) Deprecated in Mac OS X v10.5
Creates a new universal procedure pointer (UPP) to a bitmap callback.

`NewCMConcatCallBackUPP` (page 849) Deprecated in Mac OS X v10.5
Creates a new universal procedure pointer (UPP) to a progress-monitoring callback.

`NewCMFlattenUPP` (page 849) Deprecated in Mac OS X v10.5
Creates a new universal procedure pointer (UPP) to a data-flattening callback.

`NewCMMIterateUPP` (page 850) Deprecated in Mac OS X v10.5
Creates a new universal procedure pointer (UPP) to a progress-monitoring callback for the `CMIterateCMMInfo` function.

`NewCMProfileAccessUPP` (page 850) Deprecated in Mac OS X v10.5
Creates a new universal procedure pointer (UPP) to a profile-access callback.

`NewCMProfileFilterUPP` (page 851) Deprecated in Mac OS X v10.5
Creates a new universal procedure pointer (UPP) to a profile-filter callback.

`NewCMProfileIterateUPP` (page 851) Deprecated in Mac OS X v10.5
Creates a new universal procedure pointer (UPP) to a profile-iteration callback.

Not Recommended

`CMCreateProfileIdentifier` (page 745) Deprecated in Mac OS X v10.5
Creates a profile identifier for a specified profile.

`CMDisposeProfileSearch` (page 745) Deprecated in Mac OS X v10.5
Frees the private memory allocated for a profile search after your application has completed the search.

`CMNewProfileSearch` (page 789) Deprecated in Mac OS X v10.5
Searches the ColorSync Profiles folder and returns a list of 2.x profiles that match the search specification.

`CMProfileIdentifierFolderSearch` (page 792) Deprecated in Mac OS X v10.5
: Searches the ColorSync Profiles folder and returns a list of profile references, one for each profile that matches the specified profile identifier.

`CMProfileIdentifierListSearch` (page 793) Deprecated in Mac OS X v10.5
: Searches a list of profile references and returns a list of all references that match a specified profile identifier.

`CMSearchGetIndProfile` (page 798) Deprecated in Mac OS X v10.5
: Opens the profile corresponding to a specific index into a specific search result list and obtains a reference to that profile.

`CMSearchGetIndProfileFileSpec` (page 799) Deprecated in Mac OS X v10.5
: Obtains the file specification for the profile at a specific index into a search result.

`CMUpdateProfileSearch` (page 817) Deprecated in Mac OS X v10.5
: Searches the ColorSync Profiles folder and updates an existing search result obtained originally from the `CMNewProfileSearch` function.

Functions

CMCalibrateDisplay

Calibrates a display.

```
OSErr CMCalibrateDisplay (
   CalibratorInfo *theInfo
);
```

Parameters

theInfo
: A pointer to a calibrator info data structure that contains the necessary data for calibrating a display.

Return Value

An `OSErr` value.

Availability

Not available in CarbonLib.

Available in Mac OS X 10.0 and later.

Declared In

`CMCalibrator.h`

CMCloneProfileRef

Increments the reference count for the specified profile reference.

```
CMError CMCloneProfileRef (
   CMProfileRef prof
);
```

Parameters

prof

A profile reference of type `CMProfileRef` (page 925) to the profile whose reference count is incremented.

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion

The ColorSync Manager keeps an internal reference count for each profile reference returned from a call to the `CMOpenProfile`, `CMNewProfile`, or `CMCopyProfile` functions. Calling the `CMCloneProfileRef` function increments the count; calling the function `CMCloseProfile` (page 728) decrements it. The profile remains open as long as the reference count is greater than 0, indicating that at least one routine retains a reference to the profile. When the count reaches 0, the ColorSync Manager releases all private memory, files, or resources allocated in association with that profile.

When your application creates a copy of an entire profile with `CMCopyProfile`, the copy has its own reference count. The `CMCloseProfile` routine should be called for the copied profile, just as for the original. When the reference count reaches 0, private resources associated with the copied profile are freed.

When your application merely duplicates a profile reference, as it may do to pass a profile reference to a synchronous or an asynchronous task, it should call `CMCloneProfileRef` to increment the reference count. Both the called task and the caller should call `CMCloseProfile` when finished with the profile reference.

In your application, you must make sure that `CMCloseProfile` is called once for each time a profile reference is created or cloned. Otherwise, the memory and resources associated with the profile reference may not be properly freed, or an application may attempt to use a profile reference that is no longer valid.

Availability

Available in CarbonLib 1.0 and later when ColorSync 2.1 or later is present.

Available in Mac OS X 10.0 and later.

Related Sample Code

CarbonSketch

Declared In

`CMApplication.h`

CMCloseProfile

Decrements the reference count for the specified profile reference and, if the reference count reaches 0, frees all private memory and other resources associated with the profile.

```
CMError CMCloseProfile (
   CMProfileRef prof
);
```

Parameters

prof

A profile reference of type `CMProfileRef` (page 925) that identifies the profile that may need to be closed.

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion

The ColorSync Manager keeps an internal reference count for each profile reference returned from a call to the `CMOpenProfile` (page 790), `CMNewProfile` (page 788), `CMCopyProfile` (page 740), or `CWNewLinkProfile` (page 830) functions. Calling the function `CMCloneProfileRef` (page 727) increments the count; calling the `CMCloseProfile` function decrements it. The profile remains open as long as the reference count is greater than 0, indicating there is at least one remaining reference to the profile. When the count reaches 0, the ColorSync Manager releases all private memory, files, or resources allocated in association with that profile.

When the ColorSync Manager releases all private memory and resources associated with a profile, any temporary changes your application made to the profile are not saved unless you first call the `CMUpdateProfile` function to update the profile.

When your application passes a copy of a profile reference to an independent task, whether synchronous or asynchronous, it should call the function `CMCloneProfileRef` (page 727) to increment the reference count. Both the called task and the caller should call `CMCloseProfile` when finished with the profile reference.

You call `CMCloneProfileRef` after copying a profile reference, but not after duplicating an entire profile (as with the `CMCopyProfile` function).

When your application passes a copy of a profile reference internally, it may not need to call `CMCloneProfileRef`, as long as the application calls `CMCloseProfile` once for the profile.

In your application, make sure that `CMCloseProfile` is called once for each time a profile reference is created or cloned. Otherwise, the private memory and resources associated with the profile reference may not be properly freed, or an application may attempt to use a profile reference that is no longer valid.

If you create a new profile by calling the `CMNewProfile` function, the profile is saved to disk when you call the `CMCloseProfile` function unless you specified `NULL` as the profile location when you created the profile.

To save changes to a profile before closing it, use the function `CMUpdateProfile` (page 816).

Availability

Available in CarbonLib 1.0 and later when ColorSync 2.0 or later is present.

Available in Mac OS X 10.0 and later.

Related Sample Code

CarbonSketch

Declared In

`CMApplication.h`

CMConvertFixedXYZToXYZ

Converts colors specified in XYZ color space whose components are expressed as Fixed XYZ 32-bit signed values of type `CMFixedXYZColor` to equivalent colors expressed as XYZ 16-bit unsigned values of type `CMXYZColor`. (Deprecated in Mac OS X v10.5.)

```
CMError CMConvertFixedXYZToXYZ (
   const CMFixedXYZColor *src,
   CMXYZColor *dst,
   size_t count
);
```

Parameters

src

A pointer to an array containing the list of Fixed XYZ colors to convert to XYZ colors.

dst

A pointer to an array containing the list of colors resulting from the conversion specified as XYZ colors.

count

The number of colors to convert.

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion

The `CMConvertFixedXYZToXYZ` function converts one or more colors defined in the Fixed XYZ color space to equivalent colors defined in the XYZ color space. The XYZ color space is device independent.

If your application does not require that you preserve the source color list, you can pass the pointer to the same color list array as the `src` and `dst` parameters and allow the `CMConvertFixedXYZToXYZ` function to overwrite the source colors with the resulting converted color specifications.

Availability

Available in CarbonLib 1.0 and later when ColorSync 2.1 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`CMApplication.h`

CMConvertHLSToRGB

Converts colors specified in the HLS color space to equivalent colors defined in the RGB color space. (Deprecated in Mac OS X v10.5.)

```
CMError CMConvertHLSToRGB (
   const CMColor *src,
   CMColor *dst,
   size_t count
);
```

Parameters

src

A pointer to an array containing the list of HLS colors to convert to RGB colors.

dst

A pointer to an array containing the list of colors, resulting from the conversion, as specified in the RGB color space.

count

The number of colors to convert.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
The `CMConvertHLSToRGB` function converts one or more colors defined in the HLS color space to equivalent colors defined in the RGB color space. Both color spaces are device dependent.

If your application does not require that you preserve the source color list, you can pass the pointer to the same color list array as the `src` and `dst` parameters and allow the `CMConvertHLSToRGB` function to overwrite the source colors with the resulting converted color specifications.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.1 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

`CMApplication.h`

CMConvertHSVToRGB

Converts colors specified in the HSV color space to equivalent colors defined in the RGB color space. (Deprecated in Mac OS X v10.5.)

```
CMError CMConvertHSVToRGB (
   const CMColor *src,
   CMColor *dst,
   size_t count
);
```

Parameters

src

A pointer to an array containing the list of HSV colors to convert to RGB colors.

dst

A pointer to an array containing the list of colors, resulting from the conversion, as specified in the RGB color space.

count

The number of colors to convert.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
The `CMConvertHSVToRGB` function converts one or more colors defined in the HSV color space to equivalent colors defined in the RGB color space. Both color spaces are device dependent.

If your application does not require that you preserve the source color list, you can pass the pointer to the same color list array as the `src` and `dst` parameters and allow the `CMConvertHSVToRGB` function to overwrite the source colors with the resulting converted color specifications.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.1 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`CMApplication.h`

CMConvertLabToXYZ

Converts colors specified in the L*a*b* color space to the XYZ color space. (Deprecated in Mac OS X v10.5.)

```
CMError CMConvertLabToXYZ (
   const CMColor *src,
   const CMXYZColor *white,
   CMColor *dst,
   size_t count
);
```

Parameters

src
A pointer to a buffer containing the list of L*a*b* colors to convert to XYZ colors.

white
A pointer to a reference white point.

dst
A pointer to a buffer containing the list of colors as specified in the XYZ color space resulting from the conversion.

count
The number of colors to convert.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
The `CMConvertLabToXYZ` function converts one or more colors defined in the L*a*b color space to equivalent colors defined in the XYZ color space. Both color spaces are device independent.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.1 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`CMApplication.h`

CMConvertLuvToXYZ

Converts colors specified in the L*u*v* color space to the XYZ color space. (Deprecated in Mac OS X v10.5.)

```
CMError CMConvertLuvToXYZ (
   const CMColor *src,
   const CMXYZColor *white,
   CMColor *dst,
   size_t count
);
```

Parameters

src

A pointer to an array containing the list of L*u*v* colors to convert.

white

A pointer to a reference white point.

dst

A pointer to an array containing the list of colors, resulting from the conversion, as specified in the XYZ color space.

count

The number of colors to convert.

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion

The `CMConvertLuvToXYZ` function converts one or more colors defined in the L*u*v color space to equivalent colors defined in the XYZ color space. Both color spaces are device independent.

Availability

Available in CarbonLib 1.0 and later when ColorSync 2.1 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`CMApplication.h`

CMConvertRGBToGray

Converts colors specified in the RGB color space to equivalent colors defined in the Gray color space. (Deprecated in Mac OS X v10.5.)

```
CMError CMConvertRGBToGray (
   const CMColor *src,
   CMColor *dst,
   size_t count
);
```

Parameters

src

A pointer to an array containing the list of colors specified in RGB space to convert to colors specified in Gray space.

dst

A pointer to an array containing the list of colors, resulting from the conversion, as specified in the Gray color space.

count

The number of colors to convert.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
The `CMConvertRGBToGray` function converts one or more colors defined in the RGB color space to equivalent colors defined in the Gray color space. Both color spaces are device dependent.

If your application does not require that you preserve the source color list, you can pass the pointer to the same color list array as the `src` and `dst` parameters and allow the `CMConvertRGBToGray` function to overwrite the source colors with the resulting converted color specifications.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.1 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`CMApplication.h`

CMConvertRGBToHLS

Converts colors specified in the RGB color space to equivalent colors defined in the HLS color space. (Deprecated in Mac OS X v10.5.)

```
CMError CMConvertRGBToHLS (
   const CMColor *src,
   CMColor *dst,
   size_t count
);
```

Parameters

src

A pointer to an array containing the list of RGB colors to convert to HLS colors.

dst

A pointer to an array containing the list of colors, resulting from the conversion, as specified in the HLS color space.

count

The number of colors to convert.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
The `CMConvertRGBToHLS` function converts one or more colors defined in the RGB color space to equivalent colors defined in the HLS color space. Both color spaces are device dependent.

If your application does not require that you preserve the source color list, you can pass the pointer to the same color list array as the `src` and `dst` parameters and allow the `CMConvertRGBToHLS` function to overwrite the source colors with the resulting converted color specifications.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.1 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`CMApplication.h`

CMConvertRGBToHSV

Converts colors specified in the RGB color space to equivalent colors defined in the HSV color space when the device types are the same. (Deprecated in Mac OS X v10.5.)

```
CMError CMConvertRGBToHSV (
   const CMColor *src,
   CMColor *dst,
   size_t count
);
```

Parameters

src
A pointer to an array containing the list of RGB colors to convert to HSV colors.

dst
A pointer to an array containing the list of colors, resulting from the conversion, as specified in the HSV color space.

count
The number of colors to convert.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
The `CMConvertRGBToHSV` function converts one or more colors defined in the RGB color space to equivalent colors defined in the HSV color space. Both color spaces are device dependent.

If your application does not require that you preserve the source color list, you can pass the pointer to the same color list array as the `src` and `dst` parameters and allow the `CMConvertRGBToHSV` function to overwrite the source colors with the resulting converted color specifications.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.1 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`CMApplication.h`

CMConvertXYZToFixedXYZ

Converts colors specified in the XYZ color space whose components are expressed as XYZ 16-bit unsigned values of type `CMXYZColor` to equivalent colors expressed as 32-bit signed values of type `CMFixedXYZColor`. (Deprecated in Mac OS X v10.5.)

```
CMError CMConvertXYZToFixedXYZ (
   const CMXYZColor *src,
   CMFixedXYZColor *dst,
   size_t count
);
```

Parameters

src

A pointer to an array containing the list of XYZ colors to convert to Fixed XYZ colors.

dst

A pointer to an array containing the list of colors resulting from the conversion in which the colors are specified as Fixed XYZ colors.

count

The number of colors to convert.

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion

The `CMConvertXYZToFixedXYZ` function converts one or more colors whose components are defined as XYZ colors to equivalent colors whose components are defined as Fixed XYZ colors. Fixed XYZ colors allow for 32-bit precision. The XYZ color space is device independent.

Availability

Available in CarbonLib 1.0 and later when ColorSync 2.1 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`CMApplication.h`

CMConvertXYZToLab

Converts colors specified in the XYZ color space to the L*a*b* color space. (Deprecated in Mac OS X v10.5.)

```
CMError CMConvertXYZToLab (
   const CMColor *src,
   const CMXYZColor *white,
   CMColor *dst,
   size_t count
);
```

Parameters

src

A pointer to an array containing the list of XYZ colors to convert to L*a*b* colors.

white
A pointer to a reference white point.

dst
A pointer to an array containing the list of L*a*b* colors resulting from the conversion.

count
The number of colors to convert.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
The `CMConvertXYZToLab` function converts one or more colors defined in the XYZ color space to equivalent colors defined in the L*a*b* color space. Both color spaces are device independent.

If your application does not require that you preserve the source color list, you can pass the pointer to the same color list array as the `src` and `dst` parameters and allow the `CMConvertXYZToLab` function to overwrite the source colors with the resulting converted color specifications.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.1 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`CMApplication.h`

CMConvertXYZToLuv

Converts colors specified in the XYZ color space to the L*u*v* color space. (Deprecated in Mac OS X v10.5.)

```
CMError CMConvertXYZToLuv (
   const CMColor *src,
   const CMXYZColor *white,
   CMColor *dst,
   size_t count
);
```

Parameters

src
A pointer to an array containing the list of XYZ colors to convert to L*u*v* colors.

white
A pointer to a reference white point.

dst
A pointer to an array containing the list of colors represented in L*u*v* color space resulting from the conversion.

count
The number of colors to convert.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
The `CMConvertXYZToLuv` function converts one or more colors defined in the XYZ color space to equivalent colors defined in the L*u*v* color space. Both color spaces are device independent.

If your application does not require that you preserve the source color list, you can pass the pointer to the same color list array as the `src` and `dst` parameters and allow the `CMConvertXYZToLuv` function to overwrite the source colors with the resulting converted color specifications.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.1 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`CMApplication.h`

CMConvertXYZToXYZ

Converts a source color to a destination color using the specified chromatic adaptation method. (Deprecated in Mac OS X v10.5.)

```
CMError CMConvertXYZToXYZ (
   const CMColor *src,
   const CMXYZColor *srcIlluminant,
   CMColor *dst,
   const CMXYZColor *dstIlluminant,
   CMChromaticAdaptation method,
   size_t count
);
```

Parameters
src
srcIlluminant
dst
dstIlluminant
method
count

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.1 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`CMApplication.h`

CMConvertXYZToYxy

Converts colors specified in the XYZ color space to the Yxy color space. (Deprecated in Mac OS X v10.5.)

```
CMError CMConvertXYZToYxy (
   const CMColor *src,
   CMColor *dst,
   size_t count
);
```

Parameters

src

A pointer to an array containing the list of XYZ colors to convert to Yxy colors.

dst

A pointer to an array containing the list of colors resulting from the conversion represented in the Yxy color space.

count

The number of colors to convert.

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion

The `CMConvertXYZToYxy` function converts one or more colors defined in the XYZ color space to equivalent colors defined in the Yxy color space. Both color spaces are device independent.

If your application does not require that you preserve the source color list, you can pass the pointer to the same color list array as the `src` and `dst` parameters and allow the `CMConvertXYZToYxy` function to overwrite the source colors with the resulting converted color specifications.

Availability

Available in CarbonLib 1.0 and later when ColorSync 2.1 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`CMApplication.h`

CMConvertYxyToXYZ

Converts colors specified in the Yxy color space to the XYZ color space. (Deprecated in Mac OS X v10.5.)

```
CMError CMConvertYxyToXYZ (
   const CMColor *src,
   CMColor *dst,
   size_t count
);
```

Parameters

src

A pointer to an array containing the list of Yxy colors to convert.

dst

A pointer to an array containing the list of colors, resulting from the conversion, as specified in the XYZ color space.

count

The number of colors to convert.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
The `CMConvertYxyToXYZ` function converts one or more colors defined in the Yxy color space to equivalent colors defined in the XYZ color space. Both color spaces are device independent.

If your application does not require that you preserve the source color list, you can pass the pointer to the same color list array as the `src` and `dst` parameters and allow the `CMConvertYxyToXYZ` function to overwrite the source colors with the resulting converted color specifications.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.1 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`CMApplication.h`

CMCopyProfile

Duplicates the specified existing profile.

```
CMError CMCopyProfile (
   CMProfileRef *targetProf,
   const CMProfileLocation *targetLocation,
   CMProfileRef srcProf
);
```

Parameters

targetProf

A pointer to a profile reference of type `CMProfileRef` (page 925). On return, points to the profile copy that was created.

targetLocation

A pointer to a location specification that indicates the location, such as in memory or on disk, where the ColorSync Manager is to create the copy of the profile. A profile is commonly disk-file based. However, to accommodate special requirements, you can create a handle- or pointer-based profile, you can create a profile that is accessed through a procedure provided by your application, or you can create a temporary profile that is not saved after you call the `CMCloseProfile` function. To create a temporary profile, you either specify `cmNoProfileBase` as the kind of profile in the profile location structure or specify `NULL` for this parameter. To specify the location, you use the data type `CMProfileLocation` (page 924).

srcProf

A profile reference to the profile to duplicate.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
The `CMCopyProfile` function duplicates an entire open profile whose reference you specify. If you have made temporary changes to the profile, which you have not saved by calling `CMUpdateProfile`, those changes are included in the duplicated profile. They are not saved to the original profile unless you call `CMUpdateProfile` for that profile.

The ColorSync Manager maintains a modified flag to track whether a profile has been modified. After copying a profile, the `CMCopyProfile` function sets the value of the modified flag for that profile to `false`.

Unless you are copying a profile that you created, you should not infringe on copyright protection specified by the profile creator. To obtain the copyright information, you call the function `CMGetProfileElement` (page 768), specifying the `cmCopyrightTag` tag signature for the copyright element (defined in the `CMICCProfile.h` header file).

You should also check the `flags` field of the profile header structure `CM2Header` (page 875) for copyright information. You can test the `cmEmbeddedUseMask` bit of the flags field to determine whether the profile can be used independently. If the bit is set, you should use this profile as an embedded profile only and not copy the profile for your own purposes. The `cmEmbeddedUseMask` mask is described in "Flag Mask Definitions for Version 2.x Profiles" (page 983). The following code snippet shows how you might perform a test using the `cmEmbeddedUseMask` mask:

```
if (myCM2Header.flags & cmEmbeddedUseMask)
{
// profile should only be used as an embedded profile
}
else
{
// profile can be used independently
}
```

A calibration program, for example, might use the `CMCopyProfile` function to copy a device's original profile, then modify the copy to reflect the current state of the device. Or an application might want to copy a profile after unflattening it.

To copy a profile, you must obtain a reference to that profile by either opening the profile or creating it. To open a profile, use the function `CMOpenProfile` (page 790). To create a new profile, use the function `CMNewProfile` (page 788). As an alternative to using the `CMCopyProfile` function to duplicate an entire profile, you can use the same profile reference more than once. To do so, you call the function `CMCloneProfileRef` (page 727) to increment the reference count for the reference each time you reuse it. Calling the `CMCloneProfileRef` function increments the count; calling the function `CMCloseProfile` (page 728) decrements it. The profile remains open as long as the reference count is greater than 0, indicating at least one routine retains a reference to the profile.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`CMApplication.h`

CMCopyProfileDescriptionString

Returns the name of a profile as a CFString.

```
CMError CMCopyProfileDescriptionString (
   CMProfileRef prof,
   CFStringRef *str
);
```

Parameters

prof

The profile to query.

str

On ouput, the name of the profile as a CFString.

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion

If the profile is localized, ColorSync obtains the best localized name for the current process.

Availability

Available in Mac OS X v. 10.3 and later.

Declared In

`CMApplication.h`

CMCopyProfileLocalizedString

Gets one specific string out of a profile

```
CMError CMCopyProfileLocalizedString (
   CMProfileRef prof,
   OSType tag,
   CFStringRef reqLocale,
   CFStringRef *locale,
   CFStringRef *str
);
```

Parameters

prof

The profile to query.

tag

The tag type of profile to query.

reqLocale

The requested locale (optional).

locale

On ouput, points to the locale (optional).

str

On output, points to the dictionary string (optional).

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
For example, you pass in the optional tag 'dscm' plus "enUS" for the `reqLocale` parameter, to for a U.S. Enlish string. If a U.S. English string is not found, ColorSync falls back to a reasonable default:

```
err = CMCopyProfileLocalizedString (prof, 'dscm',
                CFSTR("enUS"), nil, &theStr);
```

Availability
Not available in CarbonLib.
Available in Mac OS X 10.1 and later.

Declared In
`CMApplication.h`

CMCopyProfileLocalizedStringDictionary

Obtains a CFDictionary which contains the language locale and string for multiple localizations from a given tag.

```
CMError CMCopyProfileLocalizedStringDictionary (
   CMProfileRef prof,
   OSType tag,
   CFDictionaryRef *theDict
);
```

Parameters

prof
The profile to query

tag
The tag type of profile to query

theDict
On output, points to the dictionary .See the CFDictionary documentation for a description of the `CFDictionaryRef` data type.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
This function allows you to get a CFDictionary which contains the language locale and string for multiple localizations from a given tag.

Availability
Not available in CarbonLib.
Available in Mac OS X 10.1 and later.

Declared In
`CMApplication.h`

CMCountImageProfiles

Obtains a count of the number of embeded profiles for a given image. (Deprecated in Mac OS X v10.5.)

```
CMError CMCountImageProfiles (
   const FSSpec *spec,
   UInt32 *count
);
```

Parameters

spec

A file specification for the image file. See the File Manager documentation for a description of the `FSSpec` data type.

count

On output, a count of the embeded profiles for the image

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Availability

Available in CarbonLib 1.0 and later when ColorSync 2.6 or later is present.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`CMScriptingPlugin.h`

CMCountProfileElements

Counts the number of elements in the specified profile.

```
CMError CMCountProfileElements (
   CMProfileRef prof,
   UInt32 *elementCount
);
```

Parameters

prof

A profile reference of type `CMProfileRef` (page 925) to the profile to examine.

elementCount

A pointer to an element count. On return, a one-based count of the number of elements.

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion

Every element in the profile outside the header is counted. A profile may contain tags that are references to other elements. These tags are included in the count.

Availability

Available in CarbonLib 1.0 and later when ColorSync 2.0 or later is present.

Available in Mac OS X 10.0 and later.

Declared In

`CMApplication.h`

CMCreateProfileIdentifier

Creates a profile identifier for a specified profile. (Deprecated in Mac OS X v10.5.)

```
CMError CMCreateProfileIdentifier (
   CMProfileRef prof,
   CMProfileIdentifierPtr ident,
   UInt32 *size
);
```

Parameters

prof

ident

size

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Availability

Available in CarbonLib 1.0 and later when ColorSync 2.1 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`CMApplication.h`

CMDisposeProfileSearch

Frees the private memory allocated for a profile search after your application has completed the search. (Deprecated in Mac OS X v10.5.)

```
void CMDisposeProfileSearch (
   CMProfileSearchRef search
);
```

Parameters

search

A reference to the profile search result list whose private memory is to be released. For a description of the `CMProfileSearchRef` private data type, see `CMProfileSearchRef` (page 927). See the QuickDraw Reference for a description of the PixMap data type.

Discussion

To set up a search, use the function `CMNewProfileSearch` (page 789). To obtain a reference to a profile corresponding to a specific index in the list, use the function `CMSearchGetIndProfile` (page 798). To obtain the file specification for a profile corresponding to a specific index in the list, use the function `CMSearchGetIndProfileFileSpec` (page 799). To update the search result list, use the function `CMUpdateProfileSearch` (page 817).

Version Notes

This function is not recommended for use in ColorSync 2.5.

Starting with version 2.5, you should use the function `CMIterateColorSyncFolder` (page 780) for profile searching.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`CMApplication.h`

CMEmbedImage

Embeds an image with an ICC profile. (Deprecated in Mac OS X v10.5.)

```
CMError CMEmbedImage (
   const FSSpec *specFrom,
   const FSSpec *specInto,
   Boolean repl,
   CMProfileRef embProf
);
```

Parameters

specFrom
A file specification for the image file. See the File Manager documentation for a description of the `FSSpec` data type.

specInto
If this parameter is a file, it specifies the resulting image. If this parameter is a folder, it specifies the location of the resulting image which will have the same name as the original file. If this parameter is not provided, the original file is modified. See the File Manager documentation for a description of the `FSSpec` data type.

repl
A Boolean value. If a file with the same name already exists, it will be replaced if this parameter is set to true.

embProf
The profile to embed in the image.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.6 or later is present.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`CMScriptingPlugin.h`

CMEnableMatchingComment

Inserts a comment into the currently open picture to turn matching on or off. (Deprecated in Mac OS X v10.4.)

```
void CMEnableMatchingComment (
   Boolean enableIt
);
```

Parameters

enableIt

A flag that directs the ColorSync Manager to generate a `cmEnableMatchingPicComment` comment if `true`, or a `cmDisbleMatchingPicComment` comment if `false`.

Discussion

If you call this function when no picture is open, it will have no effect.

Availability

Available in CarbonLib 1.0 and later when ColorSync 2.0 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

CMEndMatching

Concludes a QuickDraw-specific ColorSync matching session initiated by a previous call to the `NCMBeginMatching` function. (Deprecated in Mac OS X v10.4.)

```
void CMEndMatching (
   CMMatchRef myRef
);
```

Parameters

myRef

A reference to the matching session to end. This reference was previously created and returned by a call to `NCMBeginMatching` function. See the QuickDraw Reference for a description of the PixMap data type.

Discussion

The `CMEndMatching` function releases private memory allocated for the QuickDraw-specific matching session.

After you call the `NCMBeginMatching` function and before you call `CMEndMatching` to end the matching session, embedded color-matching picture comments, such as `cmEnableMatching` and `cmDisableMatching`, are not acknowledged.

Availability

Available in CarbonLib 1.0 and later when ColorSync 2.0 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`QuickdrawAPI.h`

CMFlattenProfile

Transfers a profile stored in an independent disk file to an external profile format that can be embedded in a graphics document. (Deprecated in Mac OS X v10.5.)

```
CMError CMFlattenProfile (
   CMProfileRef prof,
   UInt32 flags,
   CMFlattenUPP proc,
   void *refCon,
   Boolean *preferredCMMnotfound
);
```

Parameters

prof

A profile reference of type `CMProfileRef` (page 925) to the profile to flatten.

flags

Reserved for future use.

proc

A pointer to a function that you provide to perform the low-level data transfer. For more information, see the function `CMFlattenProcPtr` (page 855).

refCon

A pointer to a reference constant for application data which the color management module (CMM) passes to the `CMFlattenProcPtr` function each time it calls the function. For example, the reference constant may point to a data structure that holds information required by the `CMFlattenProcPtr` function to perform the data transfer, such as the reference number to a disk file in which the flattened profile is to be stored.

Starting with ColorSync version 2.5, the ColorSync Manager calls your transfer function directly, without going through the preferred, or any, CMM.

preferredCMMnotfound

A pointer to a flag for whether the preferred CMM was found. On return, has the value `true` if the CMM specified by the profile was not available to perform flattening or does not support this function and the default CMM was used. Has the value `false` if the profile's preferred CMM is able to perform flattening.

Starting with ColorSync 2.5, the ColorSync Manager calls your transfer function directly, without going through the preferred, or any, CMM. On return, the value of `preferredCMMnotfound` is guaranteed to be `false`.

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion

The ColorSync Manager passes to the CMM the pointer to your profile-flattening function. The CMM calls your function `CMFlattenProcPtr` (page 855) to perform the actual data transfer.

To unflatten a profile embedded in a graphics document to an independent disk file, use the function "Accessing Profile Elements".

Version Notes

Prior to version 2.5, the ColorSync Manager dispatches the `CMFlattenProfile` function to the CMM specified by the profile whose reference you provide. If the preferred CMM is unavailable or it does not support this function, then the default CMM is used.

Starting with ColorSync version 2.5, the ColorSync Manager calls your transfer function directly, without going through the preferred, or any, CMM. As a result, the value returned in the `preferredCMMnotfound` parameter is guaranteed to be `false`.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`CMApplication.h`

CMGetColorSyncFolderSpec

Obtains the volume reference number and the directory ID for a ColorSync Profiles folder. (Deprecated in Mac OS X v10.5.)

```
CMError CMGetColorSyncFolderSpec (
   short vRefNum,
   Boolean createFolder,
   short *foundVRefNum,
   long *foundDirID
);
```

Parameters

`vRefNum`

The location of the ColorSync profiles folder. In Mac OS X, pass a constant that specifies one of the four possible locations for ColorSync profiles. Pass `kSystemDomain` for profiles located in:

`/System/Library/ColorSync/Profiles`

Pass `kLocalDomain` for profiles located in:

`/Library/ColorSync/Profiles`

Pass `kNetworkDomain` for profiles located in:

`/Network/Library/ColorSync/Profiles`

Pass `kUserDomain` for profiles located in:

`~/Library/ColorSync/Profiles`

In Mac OS 9, pass the reference number of the volume to examine. The volume must be mounted. The constant `kOnSystemDisk` defined in the Folders header file (`Folders.h`) specifies the active system volume.

`createFolder`

A flag you set to `true` to direct the ColorSync Manager to create the ColorSync Profiles folder, if it does not exist. You can use the constants `kCreateFolder` and `kDontCreateFolder`, defined in the `Folders.h` header file, to assign a value to the flag.

`foundVRefNum`

A pointer to a volume reference number. On return, the volume reference number for the volume on which the ColorSync Profiles folder resides.

foundDirID
A pointer to a directory ID. On return, the directory ID for the volume on which the ColorSync Profiles folder resides.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
If the ColorSync Profiles folder does not already exist, you can use this function to create it.

Version Notes
Starting with version 2.5, the name and location of the profile folder changed.

Your application should use the function `CMIterateColorSyncFolder` (page 780), available starting in ColorSync version 2.5, or one of the search functions described in "Searching for Profiles Prior to ColorSync 2.5", to search for a profile file, even if it is only looking for one file. Do not search for a profile file by obtaining the location of the profiles folder and searching for the file directly.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`CMApplication.h`

CMGetColorSyncVersion

Gets ColorSync version information.

```
CMError CMGetColorSyncVersion (
   UInt32 *version
);
```

Parameters

version
On output, points to the version of ColorSync installed on the system.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
`CMGetColorSyncVersion` relieves you from having to call `Gestalt` to find out the version of ColorSync installed on the system.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.6 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`CMApplication.h`

CMGetCWInfo

Obtains information about the color management modules (CMMs) used for a specific color world. (Deprecated in Mac OS X v10.5.)

```
CMError CMGetCWInfo (
   CMWorldRef cw,
   CMCWInfoRecord *info
);
```

Parameters

cw

A reference to the color world of type `CMWorldRef` (page 942) about which you want information.

The functions `NCWNewColorWorld` (page 846) and `CWConcatColorWorld` (page 823) both allocate color world references of type `CMWorldRef` (page 942).

info

A pointer to a color world information record of type `CMCWInfoRecord` (page 888) that your application supplies. On return, the ColorSync Manager returns information in this structure describing the number of CMMs involved in the matching session and the CMM type and version of each CMM used.

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion

This discussion is accurate for versions of ColorSync prior to 2.5. See the version notes below for changes starting with version 2.5.

To learn whether one or two CMMs are used for color matching and color checking in a given color world and to obtain the CMM type and version number of each CMM used, your application must first obtain a reference to the color world. To obtain a reference to a ColorSync color world, you (or some other process) must have created the color world using the function `NCWNewColorWorld` (page 846) or the function `CWConcatColorWorld` (page 823).

The source and destination profiles you specify when you create a color world identify their preferred CMMs, and you explicitly identify the profile whose CMM is used for a device link profile or a concatenated color world. However, you cannot be certain if the specified CMM will actually be used until the ColorSync Manager determines internally if the CMM is available and able to perform the requested function. For example, when the specified CMM is not available, the default CMM is used.

The `CMGetCWInfo` function identifies the CMM or CMMs to use. Your application must allocate a data structure of type `CMCWInfoRecord` and pass a pointer to it in the `info` parameter. The `CMGetCWInfo` function returns the color world information in this structure. The structure includes a `cmmCount` field identifying the number of CMMs that will be used and an array of two members containing structures of type `CMMInfoRecord` (page 909). The `CMGetCWInfo` function returns information in one or both of the CMM information records depending on whether one or two CMMs are used.

Version Notes

Starting with ColorSync 2.5, a user can select a preferred CMM with the ColorSync control panel. If the user has selected a preferred CMM, and if it is available, then it will be used for all color conversion and matching operations.

Availability

Available in CarbonLib 1.0 and later when ColorSync 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In
`CMApplication.h`

CMGetDefaultDevice

Gets the default device.

```
CMError CMGetDefaultDevice (
   CMDeviceClass deviceClass,
   CMDeviceID *deviceID
);
```

Parameters

deviceClass

The device class whose default device you want to get. See "Device Classes" (page 979) for a list of the constants you can supply.

deviceID

On return, points to the device ID for the default device.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
For each class of device, a device management layer may establish which of the registered devices is the default. This helps keep color management choices to a minimum and allows for some automatic features to be enabled, such as the "Default printer" as an output profile selection.

Availability
Not available in CarbonLib.
Available in Mac OS X 10.1 and later.

Declared In
`CMDeviceIntegration.h`

CMGetDefaultProfileBySpace

Gets the default profile for the specified color space.

```
CMError CMGetDefaultProfileBySpace (
   OSType dataColorSpace,
   CMProfileRef *prof
);
```

Parameters

dataColorSpace

A four-character identifier of type `OSType`. You pass a color space signature that identifies the color space you wish to get the default profile for. The currently-supported values are `cmRGBData`, `cmCMYKData`, `cmLabData`, and `cmXYZData`. These constants are a subset of the constants described in "Color Space Signatures" (page 969). If you supply a value that is not supported, the `CMGetDefaultProfileBySpace` function returns an error value of `paramErr`.

prof

A pointer to a profile reference. On return, the reference specifies the current profile for the color space specified by `dataColorSpace`. `CMGetDefaultProfileBySpace` currently supports only file-based profiles.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
The `CMGetDefaultProfileBySpace` function currently supports the RGB, CMYK, Lab, and XYZ color spaces. The signature constants for these color spaces (shown above with the `dataColorSpace` parameter description) are described in "Color Space Signatures" (page 969). Support for additional color spaces may be provided in the future. `CMGetDefaultProfileBySpace` returns an error value of `paramErr` if you pass a color space constant it does not currently support.

The `CMGetDefaultProfileBySpace` function always attempts to return a file-based profile for a supported color space. For example, if the user has not specified a default profile in the ColorSync control panel for the specified color space, or if the profile is not found (the user may have deleted the profiles in the ColorSync Profiles folder or even the folder itself), `CMGetDefaultProfileBySpace` creates a profile, stores it on disk, and returns a reference to that profile. However, you should always check for an error return—for example, a user may have booted from a CD, so that `CMGetDefaultProfileBySpace` cannot save a profile file to disk.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.5 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`CMApplication.h`

CMGetDefaultProfileByUse

Obtains the users' preferred device profile setting.

```
CMError CMGetDefaultProfileByUse (
   OSType use,
   CMProfileRef *prof
);
```

Parameters

use

A value that specifies the device type for which to obtain the profile.

prof

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Availability
Available in CarbonLib 1.0 and later when ColorSync 3.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`CMApplication.h`

CMGetDeviceDefaultProfileID

Gets the default profile ID for a given device.

```
CMError CMGetDeviceDefaultProfileID (
   CMDeviceClass deviceClass,
   CMDeviceID deviceID,
   CMDeviceProfileID *defaultProfID
);
```

Parameters

deviceClass

The device class to query. See "Device Classes" (page 979) for a list of the constants you can supply.

deviceID

The device ID to query.

defaultID

On output, points to the id of the default profile for this device.

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion

Device drivers and host software can set the default profile for a given device using the function `CMSetDeviceDefaultProfileID`.

Availability

Not available in CarbonLib.

Available in Mac OS X 10.1 and later.

Declared In

`CMDeviceIntegration.h`

CMGetDeviceFactoryProfiles

Retrieves the original profiles for a given device.

```
CMError CMGetDeviceFactoryProfiles (
   CMDeviceClass deviceClass,
   CMDeviceID deviceID,
   CMDeviceProfileID *defaultProfID,
   UInt32 *arraySize,
   CMDeviceProfileArray *deviceProfiles
);
```

Parameters

deviceClass

The device class to query. See "Device Classes" (page 979) for a list of the constants you can supply.

deviceID

The device ID to query.

defaultProfID

A pointer to the default profile for this device.

arraySize

A pointer to the size of the array to be returned. You can first call this routine to get the size returned, then call it again with the size of the buffer to receive the array.

deviceProfiles

On output, points to the profile array. You can first pass `NULL` in this parameter to receive the size of the array in the `arraySize` parameter. Then, once the appropriate amount of storage has been allocated, a pointer to it can be passed in this parameter to have the array copied to that storage.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
This function allows you to retrieve the original profiles for a given device. These may differ from the actual profiles in use for that device, in the case where any factory profiles have been replaced (updated). To get the actual profiles in use, call `CMGetDeviceProfiles`.

Availability
Not available in CarbonLib.
Available in Mac OS X 10.1 and later.

Declared In
`CMDeviceIntegration.h`

CMGetDeviceInfo

Gets information about a specified device.

```
CMError CMGetDeviceInfo (
   CMDeviceClass deviceClass,
   CMDeviceID deviceID,
   CMDeviceInfo *deviceInfo
);
```

Parameters

deviceClass

A device class to query. See "Device Classes" (page 979) for a list of the constants you can supply.

deviceID

A device ID to query. You can pass `cmDefaultDeviceID`.

deviceInfo

On input, points to a device information dictionary On output, the dictionary is filled with device information. If, on input, `deviceInfo->deviceName` is `nil` then the name is not returned. If you wants the device name dictionary returned, you should provide in `deviceInfo->deviceName` the address where this routine should store the CFDictionaryRef. The caller is responsible for disposing of the name dictionary.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.1 and later.

Declared In
CMDeviceIntegration.h

CMGetDeviceProfile

Gets a profile used by a given device.

```
CMError CMGetDeviceProfile (
   CMDeviceClass deviceClass,
   CMDeviceID deviceID,
   CMDeviceProfileID profileID,
   CMProfileLocation *profileLoc
);
```

Parameters

deviceClass
The device class for the device whose profile you want to get. See "Device Classes" (page 979) for a list of the constants you can supply.

deviceID
The device ID for the device whose profile you want to get.

defaultID
The ID of the default profile for this device.

deviceProfLoc
On return, the location of the profile.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.1 and later.

Declared In
CMDeviceIntegration.h

CMGetDeviceProfiles

Gets the profiles used by a given device. (Deprecated in Mac OS X v10.5.)

```
CMError CMGetDeviceProfiles (
   CMDeviceClass deviceClass,
   CMDeviceID deviceID,
   UInt32 *arraySize,
   CMDeviceProfileArray *deviceProfiles
);
```

Parameters

deviceClass
The device class for the device whose profiles you want to get. See "Device Classes" (page 979) for a list of the constants you can supply.

deviceID
The device ID for the device whose profiles you want to get.

arraySize
A pointer to the size of the array to be returned. You can first call this routine to get the size returned, then call it again with the size of the buffer to receive the array.

deviceProfiles
On output, an array of profiles used by the device. You can first pass `NULL` in this parameter to receive the size of the array in the `arraySize` parameter. Then, once the appropriate amount of storage has been allocated, a pointer to it can be passed in this parameter to have the array copied to that storage.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.1 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`CMDeviceIntegration.h`

CMGetDeviceState

Gets the state of a device.

```
CMError CMGetDeviceState (
   CMDeviceClass deviceClass,
   CMDeviceID deviceID,
   CMDeviceState *deviceState
);
```

Parameters
deviceClass
A device class to query. See "Device Classes" (page 979) for a list of the constants you can supply.

deviceID
A device ID to query. You can pass `cmDefaultDeviceID`.

deviceState
On output, points to the device state. See "Device States" (page 980) for the values that can be returned.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.1 and later.

Declared In
`CMDeviceIntegration.h`

CMGetGammaByAVID

Obtains the gamma value for the specified display device.

```
CMError CMGetGammaByAVID (
   CMDisplayIDType theID,
   CMVideoCardGamma *gamma,
   UInt32 *size
);
```

Parameters

theID

A Display Manager ID value. You pass the ID value for the display device for which to set the gamma.

gamma

size

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Availability

Available in CarbonLib 1.0 and later when ColorSync 3.0 or later is present.

Available in Mac OS X 10.0 and later.

Declared In

`CMApplication.h`

CMGetImageSpace

Returns the signature of the data color space in which the color values of colors in an image are expressed. (Deprecated in Mac OS X v10.5.)

```
CMError CMGetImageSpace (
   const FSSpec *spec,
   OSType *space
);
```

Parameters

spec

A file specification for the image file. See the File Manager documentation for a description of the `FSSpec` data type.

space

The signature of the data color space of the color values of colors for the image file is returned here.

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Availability

Available in CarbonLib 1.0 and later when ColorSync 2.6 or later is present.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`CMScriptingPlugin.h`

CMGetIndImageProfile

Obtains a specific embeded profile for a given image. (Deprecated in Mac OS X v10.5.)

```
CMError CMGetIndImageProfile (
   const FSSpec *spec,
   UInt32 index,
   CMProfileRef *prof
);
```

Parameters

spec

A file specification for the image file. See the File Manager documentation for a description of the `FSSpec` data type.

index

The numeric index of the profile to return.

prof

On output, points to the profile.

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Availability

Available in CarbonLib 1.0 and later when ColorSync 2.6 or later is present.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`CMScriptingPlugin.h`

CMGetIndNamedColorValue

Obtains device and PCS color values for a specific named color index from a named color space profile.

```
CMError CMGetIndNamedColorValue (
   CMProfileRef prof,
   UInt32 index,
   CMColor *deviceColor,
   CMColor *PCSColor
);
```

Parameters

prof

A profile reference of type `CMProfileRef` (page 925) to a named color space profile to obtain color values from.

index

A one-based index value for a named color.

deviceColor

A pointer to a device color. On return, a device color value in `CMColor` union format. If the profile does not contain device values, `deviceColor` is undefined.

PCSColor

A pointer to a profile connection space color. On return, an interchange color value in `CMColor` union format.

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
Based on the passed named color index, the `CMGetIndNamedColorValue` function does a lookup into the named color tag and returns device and PCS values. If the index is greater than the number of named colors, `CMGetIndNamedColorValue` returns an error code.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.1 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`CMApplication.h`

CMGetIndProfileElement

Obtains the element data corresponding to a particular index from the specified profile.

```
CMError CMGetIndProfileElement (
   CMProfileRef prof,
   UInt32 index,
   UInt32 *elementSize,
   void *elementData
);
```

Parameters

prof

A profile reference of type `CMProfileRef` (page 925) to the profile containing the element.

index

The index of the element whose data you want to obtain. This is a one-based element index within the range returned as the `elementCount` parameter of the `CMCountProfileElements` function.

elementSize

A pointer to an element data size. On input, specify the size of the element data to copy (except when `elementData` is set to `NULL`). Specify `NULL` to copy the entire element data. To obtain a portion of the element data, specify the number of bytes to be copy.

On return, the size of the element data actually copied.

elementData

A pointer to memory for element data. On input, you allocate memory. On return, this buffer holds the element data.

To obtain the element size in the `elementSize` parameter without copying the element data to this buffer, specify `NULL` for this parameter.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
Before you call the `CMGetIndProfileElement` function to obtain the element data for an element at a specific index, you first determine the size in bytes of the element data. To determine the data size, you can

- call the function `CMGetIndProfileElementInfo` (page 761), passing the element's index
- call the `CMGetIndProfileElement` function itself, specifying a pointer to an unsigned long data type in the `elementSize` field and a `NULL` value in the `elementData` field

Once you have determined the size of the element data, you allocate a buffer to hold as much of the data as you need. If you want all of the element data, you specify `NULL` in the `elementSize` parameter. If you want only a portion of the element data, you specify the number of bytes you want in the `elementSize` parameter. You supply a pointer to the data buffer in the `elementData` parameter. After calling `CMGetIndProfileElement`, the `elementSize` parameter contains the size in bytes of the element data actually copied.

Before calling this function, you should call the function `CMCountProfileElements` (page 744). It returns the profile's total element count in the `elementCount` parameter.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`CMApplication.h`

CMGetIndProfileElementInfo

Obtains the element tag and data size of an element by index from the specified profile.

```
CMError CMGetIndProfileElementInfo (
   CMProfileRef prof,
   UInt32 index,
   OSType *tag,
   UInt32 *elementSize,
   Boolean *refs
);
```

Parameters

prof
A profile reference of type `CMProfileRef` (page 925) to the profile containing the element.

index
A one-based element index within the range returned by the `elementCount` parameter of the `CMCountProfileElements` function.

tag
A pointer to an element signature. On return, the tag signature of the element corresponding to the index.

elementSize
A pointer to an element size. On return, the size in bytes of the element data corresponding to the tag.

refs
A pointer to a reference count flag. On return, set to `true` if more than one tag in the profile refers to element data associated with the tag corresponding to the index.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
The index order of elements is determined internally by the ColorSync Manager and is not publicly defined.

Before calling the `CMGetIndProfileElementInfo` function, you should call the function `CMCountProfileElements` (page 744), which returns the total number of elements in the profile in the `elementCount` parameter. The number you specify for the `index` parameter when calling `CMGetIndProfileElementInfo` should be in the range of 1 to `elementCount`; otherwise the function will return a result code of `cmIndexRangeErr`.

You might want to call this function, for example, to print out the contents of a profile.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`CMApplication.h`

CMGetNamedColorIndex

Obtains a named color index for a specific color name from a named color space profile.

```
CMError CMGetNamedColorIndex (
   CMProfileRef prof,
   StringPtr name,
   UInt32 *index
);
```

Parameters

prof

A profile reference of type `CMProfileRef` (page 925) to a named color space profile to obtain a named color index from.

name

A pointer to a Pascal string. You supply a color name string value for the color to obtain the color index for.

index

A pointer to an index value. On return, an index value for a named color.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
Based on the passed color name, the `CMGetNamedColorIndex` function does a lookup into the named color tag and, if the name is found in the tag, returns the index. Otherwise, `CMGetNamedColorIndex` returns an error code.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.1 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`CMApplication.h`

CMGetNamedColorInfo

Obtains information about a named color space from its profile reference.

```
CMError CMGetNamedColorInfo (
   CMProfileRef prof,
   UInt32 *deviceChannels,
   OSType *deviceColorSpace,
   OSType *PCSColorSpace,
   UInt32 *count,
   StringPtr prefix,
   StringPtr suffix
);
```

Parameters

prof

A profile reference of type `CMProfileRef` (page 925) to a named color space profile to obtain named color information from.

deviceChannels

A pointer to a count value. On return, the number of device channels in the color space for the profile. It should agree with the "data color space" field in the profile header. For example, Pantone maps to CMYK, a four-channel color space. A value of 0 indicates no device channels were available.

deviceColorSpace

A pointer to a device color space. On return, a device color space, such as CMYK.

PCSColorSpace

A pointer to a profile connection space color space. On return, an interchange color space, such as Lab.

count

A pointer to a count value. On return, the number of named colors in the profile.

prefix

A pointer to a Pascal string. On return, the string contains a prefix, such as "Pantone", for each color name. The prefix identifies the named color system described by the profile.

suffix

A pointer to a Pascal string. On return, the string contains a suffix for each color name, such as "CVC".

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion

The `CMGetNamedColorInfo` function returns information about the named color space referred to by the passed profile reference.

Availability

Available in CarbonLib 1.0 and later when ColorSync 2.1 or later is present.

Available in Mac OS X 10.0 and later.

Declared In

`CMApplication.h`

CMGetNamedColorName

Obtains a named color name for a specific named color index from a named color space profile.

```
CMError CMGetNamedColorName (
   CMProfileRef prof,
   UInt32 index,
   StringPtr name
);
```

Parameters

prof

A profile reference of type `CMProfileRef` (page 925) to a named color space profile to obtain a named color name from.

index

An index value for a named color to obtain the color name for.

name

A pointer to a Pascal string. On return, a color name string.

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion

Based on the passed color name index, the `CMGetNamedColorName` function does a lookup into the named color tag and returns the name. If the index is greater than the number of named colors, `CMGetNamedColorName` returns an error code.

Availability

Available in CarbonLib 1.0 and later when ColorSync 2.1 or later is present.

Available in Mac OS X 10.0 and later.

Declared In

`CMApplication.h`

CMGetNamedColorValue

Obtains device and PCS color values for a specific color name from a named color space profile.

```
CMError CMGetNamedColorValue (
   CMProfileRef prof,
   StringPtr name,
   CMColor *deviceColor,
   CMColor *PCSColor
);
```

Parameters

prof

A profile reference of type `CMProfileRef` (page 925) to a named color space profile to obtain color values from.

name

A pointer to a Pascal string. You supply a color name string for the color to get information for.

deviceColor

A pointer to a device color. On return, a device color value in `CMColor` union format. If the profile does not contain device values, `deviceColor` is undefined.

PCSColor

A pointer to a profile connection space color. On return, an interchange color value in `CMColor` union format.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
Based on the passed color name, the `CMGetNamedColorValue` function does a lookup into the named color tag and, if the name is found in the tag, returns device and color PCS values. Otherwise, `CMGetNamedColorValue` returns an error code.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.1 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`CMApplication.h`

CMGetPartialProfileElement

Obtains a portion of the element data from the specified profile based on the specified element tag signature.

```
CMError CMGetPartialProfileElement (
   CMProfileRef prof,
   OSType tag,
   UInt32 offset,
   UInt32 *byteCount,
   void *elementData
);
```

Parameters

prof

A profile reference of type `CMProfileRef` (page 925) to the profile containing the target element.

tag

The tag signature for the element in question. For a complete list of the tag signatures a profile may contain, including a description of each tag, refer to the International Color Consortium Profile Format Specification. The signatures for profile tags are defined in the `CMICCProfile.h` header file.

offset

Beginning from the first byte of the element data, the offset from which to begin copying the element data.

byteCount

A pointer to a data byte count. On input, the number of bytes of element data to copy, beginning from the offset specified by the `offset` parameter. On return, the number of bytes actually copied.

elementData

A pointer to memory for element data. On input, you pass a pointer to allocated memory. On return, this buffer holds the element data.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
The `CMGetPartialProfileElement` function allows you to copy any portion of the element data beginning from any offset into the data. For the `CMGetPartialProfileElement` function to copy the element data and return it to you, your application must allocate a buffer in memory to hold the data.

You cannot use this function to obtain a portion of the `CM2Header` profile header. Instead, you must call the function `CMGetProfileHeader` (page 769) to get the entire profile header and read its contents.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`CMApplication.h`

CMGetPreferredCMM

Identifies the preferred CMM specified by the ColorSync control panel. (Deprecated in Mac OS X v10.5.)

```
CMError CMGetPreferredCMM (
   OSType *cmmType,
   Boolean *prefCMMnotfound
);
```

Parameters

cmmType
A pointer to an `OSType`. On return, the component subtype for the preferred CMM. For example, the subtype for ColorSync's default CMM is `'appl'` and the subtype for the Kodak CMM is `'KCMS'`. A return value of `NULL` indicates the preferred CMM in the ColorSync control panel is set to Automatic.

preferredCMMnotfound
A pointer to a Boolean flag for whether the preferred CMM was not found. On return, has the value `true` if the CMM was not found, `false` if it was found.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
The `CMGetPreferredCMM` function returns in the `cmmType` parameter a value that identifies the preferred CMM the user last specified in the ColorSync control panel. `CMGetPreferredCMM` returns `false` in the `preferredCMMnotfound` parameter if the preferred CMM is currently available and `true` if it is not. The preferred CMM may not be available, for example, because a user specifies a preferred CMM in the ColorSync control panel, then reboots with extensions off. ColorSync does not change the preferred CMM setting when the preferred CMM is not available.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.5 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`CMApplication.h`

CMGetProfileByAVID

Gets the current profile for a monitor.

```
CMError CMGetProfileByAVID (
   CMDisplayIDType theID,
   CMProfileRef *prof
);
```

Parameters

theAVID

A Display Manager ID value. You pass the ID value for the monitor for which to get the profile.

prof

A pointer to a profile reference. On return, a reference to the current profile for the monitor specified by `theAVID`.

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion

If the Display Manager supports ColorSync, the `CMGetProfileByAVID` function calls on the Display Manager to get the profile for the specified display. This is the case if the version of the Display Manager is 2.2.5 or higher (if `gestaltDisplayMgrAttr` has the `gestaltDisplayMgrColorSyncAware` bit set).

Availability

Available in CarbonLib 1.0 and later when ColorSync 2.5 or later is present.

Available in Mac OS X 10.0 and later.

Declared In

`CMApplication.h`

CMGetProfileDescriptions

Obtains the description tag data for a specified profile.

```
CMError CMGetProfileDescriptions (
   CMProfileRef prof,
   char *aName,
   UInt32 *aCount,
   Str255 mName,
   ScriptCode *mCode,
   UniChar *uName,
   UniCharCount *uCount
);
```

Parameters

prof

A reference to the profile from which to obtain the description info.

aName

On output, a pointer to the profile name as a 7-bit Roman ASCII string.

aCount

On output, a pointer to a count of the number of characters returned in the `aName` field.

mName

On output, a pointer to the localized profile name string in Mac script-code format.

mCode

On output, a pointer the script code corresponding to the name string returned in the `mName` parameter.

uName

On output, a pointer to localizedUnicode profile name string.

uCount

On output, a pointer to a count of the number of Unicode (2-byte) characters returned in the `uName` parameter.

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion

Use this function to get the description tag data for a given profile. The ICC Profile Format Specification (available at http://www.color.org) includes a description tag (`'desc'`), designed to provide more information about a profile than can be contained in a file name. This is especially critical on file systems with 8.3 names. The tag data can consist of up to three separate pieces (strings) of information for a profile. These different strings are designed to allow for display in different languages or on different computer systems. Applications typically use one of the strings to show profiles in a list or a pop-up menu.

Availability

Available in CarbonLib 1.0 and later when ColorSync 2.6 or later is present.

Available in Mac OS X 10.0 and later.

Declared In

`CMApplication.h`

CMGetProfileElement

Obtains element data from the specified profile based on the specified element tag signature.

```
CMError CMGetProfileElement (
   CMProfileRef prof,
   OSType tag,
   UInt32 *elementSize,
   void *elementData
);
```

Parameters

prof

A profile reference of type `CMProfileRef` (page 925) to the profile containing the target element.

tag

The tag signature (for example, 'A2B0', or constant `cmAToB0Tag`) for the element in question. The tag identifies the element. For a complete list of the public tag signatures a profile may contain, including a description of each tag, refer to the International Color Consortium Profile Format Specification. The signatures for profile tags are defined in the `CMICCProfile.h` header file.

elementSize

A pointer to a size value. On input, you specify the size of the element data to copy. Specify `NULL` to copy the entire element data. To obtain a portion of the element data, specify the number of bytes to copy.

On return, the size of the data returned.

elementData

A pointer to memory for element data. On input, you allocate memory. On return, this buffer holds the element data.

To obtain the element size in the `elementSize` parameter without copying the element data to this buffer, specify `NULL` for this parameter.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
Before you call the `CMGetProfileElement` function to obtain the element data for a specific element, you must know the size in bytes of the element data so you can allocate a buffer to hold the returned data.

The `CMGetProfileElement` function serves two purposes: to get an element's size and to obtain an element's data. In both instances, you provide a reference to the profile containing the element in the `prof` parameter and the tag signature of the element in the `tag` parameter.

To obtain the element data size, call the `CMGetProfileElement` function specifying a pointer to an unsigned long data type in the `elementSize` field and a `NULL` value in the `elementData` field.

After you obtain the element size, you should allocate a buffer large enough to hold the returned element data, then call the `CMGetProfileElement` function again, specifying `NULL` in the `elementSize` parameter to copy the entire element data and a pointer to the data buffer in the `elementData` parameter.

To copy only a portion of the element data beginning from the first byte, allocate a buffer the size of the number of bytes of element data you want to obtain and specify the number of bytes to copy in the `elementSize` parameter. In this case, On return the `elementSize` parameter contains the size in bytes of the element data actually returned.

You cannot use the `CMGetProfileElement` function to copy a portion of element data beginning from an offset into the data. To copy a portion of the element data beginning from any offset, use the function `CMGetPartialProfileElement` (page 765).

You cannot use this function to obtain a portion of the `CM2Header` profile header. Instead, you must call the function `CMGetProfileHeader` (page 769) to copy the entire profile header and read its contents.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`CMApplication.h`

CMGetProfileHeader

Obtains the profile header for the specified profile.

```
CMError CMGetProfileHeader (
   CMProfileRef prof,
   CMAppleProfileHeader *header
);
```

Parameters

prof

A profile reference of type `CMProfileRef` (page 925) to the profile whose header is to be copied.

header

A pointer to a profile header. On input, depending on the profile version, you may allocate a ColorSync 2.x or 1.0 header. On return, contains the profile data. For information about the ColorSync 2.x profile header structure, see `CM2Header` (page 875). For information about the ColorSync 1.0 header, see `CMHeader` (page 898).

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion

The `CMGetProfileHeader` function returns the header for a ColorSync 2.x or ColorSync 1.0 profile. To return the header, the function uses a union of type `CMAppleProfileHeader` (page 881), with variants for version 1.0 and 2.x headers.

A 32-bit version value is located at the same offset in either header. For ColorSync 2.x profiles, this is the `profileVersion` field. For ColorSync 1.0 profiles, this is the `applProfileVersion` field. You can inspect the value at this offset to determine the profile version, and interpret the remaining header fields accordingly.

To copy a profile header to a profile after you modify the header's contents, use the function `CMSetProfileHeader` (page 813).

Availability

Available in CarbonLib 1.0 and later when ColorSync 2.0 or later is present.

Available in Mac OS X 10.0 and later.

Declared In

`CMApplication.h`

CMGetProfileLocation

Obtains the location of a profile based on the specified profile reference. (Deprecated in Mac OS X v10.5.)

```
CMError CMGetProfileLocation (
   CMProfileRef prof,
   CMProfileLocation *location
);
```

Parameters

prof

A profile reference of type `CMProfileRef` (page 925). Before calling `CMGetProfileLocation`, you set the reference to specify the profile you wish to obtain the location for.

theProfile

A pointer to a profile location structure of type `CMProfileLocation` (page 924). On return, specifies the location of the profile. Commonly, a profile is disk-file based, but it may instead be temporary, handle-based, pointer-based, or accessed through a procedure supplied by your application.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
When your application calls the `CMValidateProfile` function, the ColorSync Manager dispatches the function to the CMM specified by the `CMMType` header field of the profile whose reference you specify. The preferred CMM can support this function or not.

To open a profile and obtain a reference to it, use the function `CMOpenProfile` (page 790).

Version Notes
This function is not recommended for use in ColorSync 2.5.

Starting with ColorSync version 2.5, you should use the function `NCMGetProfileLocation` (page 841) instead of `CMGetProfileLocation`.

As of version 2.5, if you call `CMGetProfileLocation`, it will just call `NCMGetProfileLocation` in turn, passing the profile specified by `prof`, the profile location specified by `theProfile`, and a location size value of `cmOriginalProfileLocationSize`.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`CMApplication.h`

CMGetProfileMD5

Gets the MD5 checksum from the profile header (message digest)

```
CMError CMGetProfileMD5 (
   CMProfileRef prof,
   CMProfileMD5 digest
);
```

Parameters
prof
digest

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
You can call this function to determine if two profiles are identical, or if a profile has changed over time. You can access this new MD5 checksum directly in the profile header, or use the function `CMGetProfileMD5`. This function has the advantage that it works with both ICC 4 profiles and earlier profiles.

Availability
Not available in CarbonLib.
Available in Mac OS X 10.1 and later.

Declared In
CMApplication.h

CMGetProfileRefCount

Obtains the current reference count for the specified profile.

```
CMError CMGetProfileRefCount (
   CMProfileRef prof,
   long *count
);
```

Parameters

prof

A profile reference of type CMProfileRef (page 925) to the profile whose reference count is obtained.

count

A pointer to a reference count. On return, the reference count for the specified profile reference.

Return Value
A CMError value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
The ColorSync Manager keeps an internal reference count for each profile reference returned from calls such as CMOpenProfile (page 790) or CMNewProfile (page 788). Calling the function CMCloneProfileRef (page 727) increments the count; calling the function CMCloseProfile (page 728) decrements it. The profile remains open as long as the reference count is greater than 0, indicating at least one routine retains a reference to the profile. When the count reaches 0, the ColorSync Manager releases all memory, files, or resources allocated in association with that profile.

An application that manages profiles closely can call the CMGetProfileRefCount function to obtain the reference count for a profile reference, then perform special handling if necessary, based on the reference count.

To copy a profile with the function CMCopyProfile (page 740), you must obtain a reference to that profile by either opening the profile or creating it. To open a profile, use the function CMOpenProfile (page 790). To create a new profile, use the function CMNewProfile (page 788). As an alternative to using the CMCopyProfile function to duplicate an entire profile, you can use the same profile reference more than once. To do so, you call the function CMCloneProfileRef (page 727) to increment the reference count for the reference each time you reuse it. Calling the CMCloneProfileRef function increments the count; calling the function CMCloseProfile (page 728) decrements it. The profile remains open as long as the reference count is greater than 0, indicating at least one routine retains a reference to the profile.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.1 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
CMApplication.h

CMGetPS2ColorRendering

Obtains the color rendering dictionary (CRD) element data usable as the parameter to the PostScript `setColorRendering` operator, which specifies the PostScript color rendering dictionary to use for the following graphics data.

```
CMError CMGetPS2ColorRendering (
   CMProfileRef srcProf,
   CMProfileRef dstProf,
   UInt32 flags,
   CMFlattenUPP proc,
   void *refCon,
   Boolean *preferredCMMnotfound
);
```

Parameters

srcProf

A profile reference to a profile that supplies the rendering intent for the CRD.

dstProf

A profile reference to a profile from which to extract the CRD data.

flags

If the value of `flags` is equal to `cmPS8bit`, the generated PostScript will utilize 8-bit encoding whenever possible to achieve higher data compaction. If the value of `flags` is not equal to `cmPS8bit`, the generated data will be 7-bit safe, in either ASCII or ASCII base-85 encoding.

proc

A pointer to a callback flatten function to perform the data transfer. For information, see the function `CMFlattenProcPtr` (page 855).

refCon

An untyped pointer to arbitrary data supplied by your application. `CMGetPS2ColorSpace` passes this data in calls to your `CMFlattenProcPtr` (page 855) function.

preferredCMMnotfound

A pointer to a flag for whether the preferred CMM was found. On return, has the value `true` if the CMM corresponding to profile was not available or if it was unable to perform the function and the default CMM was used. Otherwise, has the value `false`.

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion

The `CMGetPS2ColorRendering` function obtains CRD data from the profile specified by the `dstProf` parameter. To be valid, the parameter must specify an output profile with at most four components. The CMM uses the rendering intent from the profile specified by the `srcProf` parameter to determine which of the PostScript tags (`ps2CR0Tag`, `ps2CR1Tag`, `ps2CR2Tag`, or `ps2CR3Tag`) to use in creating the CRD. If none of these tags exists in the profile, the CMM creates the CRD from one of the multidimensional table tags (`cmAToB0`, `cmAToB1`, or `cmAToB2`), again chosen according to the rendering intent of the profile specified by the `srcProf` parameter.

This function is dispatched to the CMM component specified by the destination profile. If the designated CMM is not available or the CMM does not implement this function, the ColorSync Manager dispatches this function to the default CMM.

The CMM obtains the PostScript data and passes it to your low-level data transfer procedure, specified by the `proc` parameter. The CMM converts the data into a PostScript stream and calls your procedure as many times as necessary to transfer the data to it. Typically, the low-level data transfer function returns this data to the calling application or device driver to pass to a PostScript printer.

Before your application or device driver sends the CRD to the printer, it can call the function `CMGetPS2ColorRenderingVMSize` (page 775) to determine the virtual memory size of the CRD.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`CMApplication.h`

CMGetPS2ColorRenderingIntent

Obtains the rendering intent element data in text format usable as the parameter to the PostScript `findRenderingIntent` operator, which specifies the color-matching option for subsequent graphics data.

```
CMError CMGetPS2ColorRenderingIntent (
   CMProfileRef srcProf,
   UInt32 flags,
   CMFlattenUPP proc,
   void *refCon,
   Boolean *preferredCMMnotfound
);
```

Parameters

srcProf
A profile reference to the source profile that defines the data color space and identifies the preferred CMM.

flags
If the value of `flags` is equal to `cmPS8bit`, the generated PostScript will utilize 8-bit encoding whenever possible to achieve higher data compaction. If the value of `flags` is not equal to `cmPS8bit`, the generated data will be 7-bit safe, in either ASCII or ASCII base-85 encoding.

proc
A low-level data transfer function supplied by the calling application to receive the PostScript data from the CMM. For more information, see the function `CMFlattenProcPtr` (page 855).

refCon
An untyped pointer to arbitrary data supplied by your application. `CMGetPS2ColorSpace` passes this data in calls to your `CMFlattenProcPtr` (page 855) function.

preferredCMMnotfound
A pointer to a flag for whether the preferred CMM was found. On return, has the value `true` if the CMM corresponding to profile was not available or if it was unable to perform the function and the default CMM was used. Otherwise, has the value `false`.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
The `CMGetPS2ColorRenderingIntent` function obtains PostScript rendering intent information from the header of the source profile. It returns data by calling your low-level data transfer procedure and passing the PostScript data to it. Typically, your low-level data transfer function returns this data to the calling application or device driver to pass to a PostScript printer.

The `CMGetPS2ColorRenderingIntent` function is dispatched to the CMM component specified by the source profile. If the designated CMM is not available or the CMM does not implement this function, then ColorSync dispatches the function to the default CMM.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`CMApplication.h`

CMGetPS2ColorRenderingVMSize

Determines the virtual memory size of the color rendering dictionary (CRD) for a printer profile before your application or driver obtains the CRD and sends it to the printer.

```
CMError CMGetPS2ColorRenderingVMSize (
   CMProfileRef srcProf,
   CMProfileRef dstProf,
   UInt32 *vmSize,
   Boolean *preferredCMMnotfound
);
```

Parameters

srcProf
A profile reference to a profile that supplies the rendering intent for the CRD.

dstProf
A profile reference to the destination printer profile.

vmSize
A pointer to a memory size. On return, the virtual memory size of the CRD.

preferredCMMnotfound
A pointer to a flag for whether the preferred CMM was found. On return, has the value `true` if the CMM corresponding to profile was not available or if it was unable to perform the function and the default CMM was used. Otherwise, has the value `false`.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
Your application or device driver can call this function to determine if the virtual memory size of the color rendering dictionary exceeds the printer's capacity before sending the CRD to the printer. If the printer's profile contains the Apple-defined optional tag `'psvm'` described in `CMConcatProfileSet` (page 887), then the default CMM will return the data supplied by this tag specifying the CRD virtual memory size for the rendering intent's CRD. If the printer's profile does not contain this tag, then the CMM uses an algorithm to assess the VM size of the CRD, in which case the assessment can be larger than the actual maximum VM size.

The CMM uses the profile specified by the `srcProf` parameter to determine the rendering intent to use.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`CMApplication.h`

CMGetPS2ColorSpace

Obtains color space element data in text format usable as the parameter to the PostScript `setColorSpace` operator, which characterizes the color space of subsequent graphics data.

```
CMError CMGetPS2ColorSpace (
   CMProfileRef srcProf,
   UInt32 flags,
   CMFlattenUPP proc,
   void *refCon,
   Boolean *preferredCMMnotfound
);
```

Parameters

srcProf
A profile reference to the source profile that defines the data color space and identifies the preferred CMM.

flags
If the value of `flags` is equal to `cmPS8bit`, the generated PostScript will utilize 8-bit encoding whenever possible to achieve higher data compaction. If the value of `flags` is not equal to `cmPS8bit`, the generated data will be 7-bit safe, in either ASCII or ASCII base-85 encoding.

proc
A pointer to a callback flatten function to receive the PostScript data from the CMM. For information, see the function `CMFlattenProcPtr` (page 855).

refCon
An untyped pointer to arbitrary data supplied by your application. `CMGetPS2ColorSpace` passes this data in calls to your `CMFlattenProcPtr` (page 855) function.

preferredCMMnotfound
A pointer to a flag for whether the preferred CMM was found. On return, has the value `true` if the CMM corresponding to profile was not available or if it was unable to perform the function and the default CMM was used. Otherwise, has the value `false`.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
The `CMGetPS2ColorSpace` function obtains PostScript color space data from the source profile. The valid profile classes for the `CMGetPS2ColorSpace` function are display, input, and output profiles with at most four components.

To determine which profile elements to use to generate the PostScript color space data, the CMM:

- uses the PostScript `cmPS2CSATag`, if it exists
- otherwise, uses the multidimensional table tag (`cmAToB0`, `cmAToB1`, or `cmAToB2`), if it exists, for the rendering intent currently specified by the profile

- otherwise, uses the multidimensional table tag `cmAToB0`, if it exists
- otherwise, for display profiles only, uses the tristimulus tags (`cmRedColorantTag`, `cmGreenColorantTag`, `cmBlueColorantTag`) and the tonal curve tags (`cmRedTRCTag`, `cmGreenTRCTag`, and `cmBlueTRCTag`)

The CMM obtains the PostScript data from the profile and calls your low-level data transfer procedure passing the PostScript data to it. The CMM converts the data into a PostScript stream and calls your procedure as many times as necessary to transfer the data to it.

Typically, the low-level data transfer function returns this data to the calling application or device driver to pass to a PostScript printer as an operand to the PostScript `setcolorspace` operator, which defines the color space of graphics data to follow.

The `CMGetPS2ColorSpace` function is dispatched to the CMM component specified by the source profile. If the designated CMM is not available or the CMM does not implement this function, then the ColorSync Manager dispatches the function to the default CMM.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`CMApplication.h`

CMGetScriptProfileDescription

Obtains the internal name (or description) of a profile and the script code identifying the language in which the profile name is specified from the specified profile. (Deprecated in Mac OS X v10.5.)

```
CMError CMGetScriptProfileDescription (
   CMProfileRef prof,
   Str255 name,
   ScriptCode *code
);
```

Parameters

prof
A profile reference of type `CMProfileRef` (page 925) to the profile whose profile name and script code are obtained.

name
A pointer to a name string. On return, the profile name.

code
A pointer to a script code. On return, the script code.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
The element data of the text description tag (which has the signature `'desc'` or constant `cmSigProfileDescriptionType`, defined in the `CMICCProfile.h` header file) specifies the profile name and script code. The `name` parameter returns the profile name as a Pascal string. Use this function so that your application does not need to obtain and parse the element data, which contains other information.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`CMApplication.h`

CMGetSystemProfile

Obtains a reference to the current system profile.

```
CMError CMGetSystemProfile (
   CMProfileRef *prof
);
```

Parameters

prof

A pointer to a profile reference of type `CMProfileRef` (page 925). On return, a reference to the current system profile.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
The following functions allow you to pass `NULL` as a parameter value to specify the system profile as a source or destination profile:

- `CMNewProfile` (page 788)
- `NCWNewColorWorld` (page 846)
- `NCMBeginMatching` (page 838)
- `NCMDrawMatchedPicture` (page 840)

Note that instead of passing `NULL`, you can pass a profile reference to a specific profile, including the system profile.

If you want to specify the system profile for any other function that requires a profile reference, such as `CWConcatColorWorld` (page 823) and `CWNewLinkProfile` (page 830), you must use an explicit reference. You can obtain such a reference with the `CMGetSystemProfile` function.

There are other reasons you might need to obtain a reference to the current system profile. For example, your application might need to display the name of the current system profile to a user.

To identify the location of the physical file, call the function `CMGetProfileLocation` (page 770).

When your application has finished using the current system profile, it must close the reference to the profile by calling the function `CMCloseProfile` (page 728).

Version Notes
Starting with version 2.5, use of the system profile has changed. So rather than call `CMGetSystemProfile` to obtain a reference to the system profile, you may be able to obtain a profile that is more appropriate for the current operation by calling `CMGetDefaultProfileBySpace` (page 752) to get the default profile for a color space or by calling `CMGetProfileByAVID` (page 767) to get the profile for a specific display.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`CMApplication.h`

CMIterateCMMInfo

Iterates through the color management modules installed on the system.

```
CMError CMIterateCMMInfo (
   CMMIterateUPP proc,
   UInt32 *count,
   void *refCon
);
```

Parameters

proc
A calling-program-supplied callback function that allows your application to monitor progress or abort the operation.

count
A pointer to the number of available CMMs.

refCon
A reference constant containing data specified by the calling application program.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
The `CMIterateCMMInfo` function returns information for all CMMs installed on the system. The caller can pass nil for the `CMMIterateUPP` param to simply get a count of CMMs. If a `CMMIterateUPP` proc is provided, it is called once for each CMM installed - with the `CMMInfo` structure filled accordingly. The caller can pass a data reference to `CMIterateCMMInfo` which will then be passed to the `CMMIterateUPP`. This might be used to allow some of the information in the `CMMInfo` data structure to be put into a menu, for example, by passing a menu reference as the refcon. Either the proc or the count parameter must be provided. The caller will get a `paramErr` if both are nil.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.6 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`CMApplication.h`

CMIterateColorDevices

Iterates through the color devices available on the system, returning device information to a callback you supply.

```
CMError CMIterateColorDevices (
   CMIterateDeviceInfoProcPtr proc,
   UInt32 *seed,
   UInt32 *count,
   void *refCon
);
```

Parameters

proc

A pointer to a function that iterates through device information available on the system. This is optional, but allows you to obtain device information. If provided, your callback is invoked once for each registered device.

seed

A pointer to a seed value. This is optional. If you pass a pointer to a seed value that is the same as the current seed value, then the callback function specified by the `proc` parameter is not invoked.

count

On output, the number of color devices available on the system.

refCon

An optional value that passed to your callback.

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion

This routine gets device information about all registered color devices. If provided, the supplied callback functions is called once for each registered device, passing in the device info and the supplied refcon.

Availability

Not available in CarbonLib.

Available in Mac OS X 10.1 and later.

Declared In

`CMDeviceIntegration.h`

CMIterateColorSyncFolder

Iterates over the available profiles.

```
CMError CMIterateColorSyncFolder (
   CMProfileIterateUPP proc,
   UInt32 *seed,
   UInt32 *count,
   void *refCon
);
```

Parameters

proc

A universal procedure pointer of type `CMProfileIterateUPP`, which is described in `CMProfileIterateData` (page 923). If you do not wish to receive callbacks, pass `NULL` for this parameter. Otherwise, pass a pointer to your callback routine.

seed

A pointer to a value of type `long`. The first time you call `CMIterateColorSyncFolder`, you typically set the value to 0. In subsequent calls, you set the value to the seed value obtained from the previous call. ColorSync uses the value in determining whether to call your callback routine, as described in the discussion for this function.

On return, the value is the current seed for the profile cache (unless you pass `NULL`, as described in the discussion).

count

A pointer to a value of type `long`. On return, the value is the number of available profiles. `CMIterateColorSyncFolder` provides the number of profiles even when no iteration occurs (unless you pass `NULL`, as described in the discussion below). To determine the count alone, without iteration, call `CMIterateColorSyncFolder` and pass a value of `NULL` for all parameters except `count`.

refCon

An untyped pointer to arbitrary data supplied by your application. `CMIterateColorSyncFolder` passes this data to your callback routine. If you pass `NULL` for the `refCon` parameter, `CMIterateColorSyncFolder` passes `NULL` to your callback routine.

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion

Starting with ColorSync version 2.5, when your application needs information about the profiles currently available in the ColorSync Profiles folder, it can call the `CMIterateColorSyncFolder` routine, which in turn calls your callback routine once for each profile.

Even though there may be many profiles available, `CMIterateColorSyncFolder` can take advantage of ColorSync's profile cache to return profile information quickly, and (if the cache is valid) without having to open any profiles. For each profile, `CMIterateColorSyncFolder` supplies your routine with the profile header, script code, name, and location, in a structure of type `CMProfileIterateData` (page 923). As a result, your routine may be able to perform its function, such as building a list of profiles to display in a pop-up menu, without further effort (such as opening each file-based profile).

Only 2.x profiles are included in the profile search result.

Before calling `CMIterateColorSyncFolder` for the first time, you typically set `seed` to 0. ColorSync compares 0 to its current seed for the profile cache. It is not likely they will match—the odds are roughly one in two billion against it. If the values do not match, the routine iterates through all the profiles in the cache, calling your callback routine once for each profile. `CMIterateColorSyncFolder` then returns the actual seed value in `seed` (unless you passed `NULL` for that parameter).

If you pass the returned seed value in a subsequent call, and if there has been no change in the available profiles, the passed seed will match the stored cache seed and no iteration will take place.

Note that you can pass a `NULL` pointer for the `seed` parameter without harm. The result is the same as if you passed a pointer to 0, in that the function iterates through the available profiles, calling your callback routine once for each profile. However, the function does not return a seed value, since you have not passed a valid pointer.

You can force ColorSync to call your callback routine (if any profiles are available) by passing a `NULL` pointer or by passing 0 for the seed value. But suppose you have an operation, such as building a pop-up menu, that you only want to perform if the available profiles have changed. In that case, you pass the seed value from a previous call to `CMIterateColorSyncFolder`. If the profile folder has not changed, ColorSync will not call your callback routine.

Note that if there are no profiles available, ColorSync does not call your callback routine.

You can safely pass `NULL` for any or all of the parameters to the `CMIterateColorSyncFolder` function. If you pass `NULL` for all of the parameters, calling the function merely forces rebuilding of the profile cache, if necessary.

Version Notes
Starting with version 2.5, the name and location of the profile folder changed. In addition, the folder can now contain profiles within nested folders, as well as aliases to profiles or aliases to folders containing profiles. There are limits on the nesting of folders and aliases.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.5 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`CMApplication.h`

CMIterateDeviceProfiles

Iterates through the device profiles available on the system and returns information about profiles of the devices to a callback you supply.

```
CMError CMIterateDeviceProfiles (
   CMIterateDeviceProfileProcPtr proc,
   UInt32 *seed,
   UInt32 *count,
   UInt32 flags,
   void *refCon
);
```

Parameters

proc

A pointer to a function that iterates through device information available on the system. This is optional, but allows you to obtain profile information for each device. If provided, your callback is invoked once for each registered device.

seed

A pointer to a seed value. This is optional. If you pass a pointer to a seed value that is the same as the current seed value, then the callback function specified by the `proc` parameter is not invoked.

count

On output, the number of color devices available on the system.

flags

A value that specifies which set of profiles you want to iterate through. It can have the following values: `cmIterateFactoryDeviceProfiles`, `cmIterateCustomDeviceProfiles`, `cmIterateCurrentDeviceProfiles`, `cmIterateAllDeviceProfiles` or `0`. Supplying `0` is the same as supplying `cmIterateCurrentDeviceProfiles`.

refCon

An optional value that passed to your callback.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.1 and later.

Declared In
`CMDeviceIntegration.h`

CMLaunchControlPanel

Launches the ColorSync preferences pane.

```
CMError CMLaunchControlPanel (
   UInt32 flags
);
```

Parameters

flags

A value that secifies how the preferences pane is launched. You currently must pass a vlaue of 0 for this parameter.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
When your application calls the function `CMLaunchControlPanel`, any changes made by the user will not be available (through calls such as `CMGetDefaultProfileBySpace`) until the user closes the ColorSync preferences pane. There is currently no ColorSync function that determines if the ColorSync preferences pane has been closed, but you can use the Process Manager API for this purpose.

Availability
Available in CarbonLib 1.0 and later when ColorSync 3.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`CMApplication.h`

CMLinkImage

Matches an image file with a device link profile. (Deprecated in Mac OS X v10.5.)

```
CMError CMLinkImage (
   const FSSpec *specFrom,
   const FSSpec *specInto,
   Boolean repl,
   UInt32 qual,
   CMProfileRef lnkProf,
   UInt32 lnkIntent
);
```

Parameters

specFrom

A file specification for the image file. See the File Manager documentation for a description of the `FSSpec` data type.

specInto

If this parameter is a file, it specifies the resulting image. If this parameter is a folder, it specifies the location of the resulting image which will have the same name as the original file. If this parameter is not provided, the original file is modified. See the File Manager documentation for a description of the `FSSpec` data type.

repl

If a file with the same name already exists, it will be replaced if this parameter is set to true.

qual

The optional quality for the match—normal, draft or best (`cmNormalMode`, `cmDraftMode`, or `cmBestMode`).

lnkProf

The device link profile for the match.

lnkIntent

The rendering intent for the match—perceptual intent, relative colorimetric intent, saturation i ntent , or absolute colorimetric intent (`cmPerceptual`, `cmRelativecolorimetric`, `cmSaturation`, or `cmAbsoluteColorimetric`).

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Availability

Available in CarbonLib 1.0 and later when ColorSync 2.6 or later is present.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`CMScriptingPlugin.h`

CMMakeProfile

Makes a display or abstract profile by modifying an existing one.

```
CMError CMMakeProfile (
   CMProfileRef prof,
   CFDictionaryRef spec
);
```

Parameters

prof

The profile to modify.

spec

A dictionary that specifies the modifications to make to the profile supplied in the `prof` parameter.

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion

The function `CMMakeProfile` adds appropriate tags to a profile to make a display or abstract profile based on a specification dictionary you supply.

One key in the specification dictionary must be `"profileType"` with a CFString value of either `"abstractLab"`, `"displayRGB"` or `"displayID"`.

The dictionary can optionally contain these keys-value pairs:

- `"description"`, with an associated CFString value
- `"copyright"`, with an associated CFString value

For a `profileType` key whose value is `"abstractLab"`, the dictionary can also contain the keys-value pairs listed in Table 32-1.

Table 32-1 Key-value pairs for "abstractLab"

Key	Value	Comment
`"gridPoints"`	A CFNumber (`SInt32`) that is an odd	Required
`"proc"`	A CFNumber (`SInt64`) coerced from a `LabToLabProcPtr` data type	Required
`"refcon"`	A CFNumber (`SInt64`) value coerced from a `void*` data type	Optional

For a `profileType` key whose value is `"displayRGB"`, the dictionary can also contain the keys-value pairs listed in Table 32-2.

Table 32-2 Key-value pairs for "displayRGB"

Key	Value	Comment
`"targetGamma"`	A CFNumber (`Float`), for example, 1.8	Optional
`"targetWhite"`	A CFNumber (`SInt32`), for example, 6500	Optional
`"gammaR`	A CFNumber (`Float`), for example, 2.5	Required
`"gammaG"`	A CFNumber (`Float`), for example, 2.5	Required

Key	Value	Comment
"gammaB"	A CFNumber (Float), for example, 2.5	Required
"tableChans"	A CFNumber (SInt32), for example, 1 or 3	Optional
"tableEntries"	A CFNumber (SInt32), for example, 16 or 255	Optional
"tableEntrySize"	A CFNumber (SInt32), for example,1 or 2	Optional
"tableData"	A CFData (lut in RRRGGGBBB order)	Optional
"phosphorRx"	A CFNumber (Float)	Only if not supplying the phospherSet key.
phosphorRy"	A CFNumber (Float)	Only if not supplying the phospherSet key.
phosphorGx"	A CFNumber (Float)	Only if not supplying the phospherSet key.
"phosphorGy"	A CFNumber (Float)	Only if not supplying the phospherSet key.
"phosphorBx"	A CFNumber (Float)	Only if not supplying the phospherSet key.
"phosphorBy"	A CFNumber (Float)	Only if not supplying the phospherSet key.
"phosphorSet"	A CFString: "WideRGB", "700/525/450nm", "P22-EBU", "HDTV", "CCIR709", "sRGB", "AdobeRGB98" or "Trinitron"	Only if not supplying the phospher R, G, B keys
"whitePointx"	A CFNumber (Float)	Only if not supplying a whiteTemp key
"whitePointy"	A CFNumber (Float)	Only if not supplying a whiteTemp key
"whiteTemp"	A CFNumber (SInt32), for example, 5000, 6500, or 9300	Only if not supplying whitePointx and whitePointy keys

For a profileType key whose value is "displayID", the dictionary can also contain the keys-value pairs in Table 32-3

Table 32-3 Key-value pairs for “displayID”

Key	Value	Comment
"targetGamma"	A CFNumber (Float), for example, 1.8	Optional
"targetWhite"	A CFNumber (SInt32), for example, 6500	Optional

Key	Value	Comment
"displayID"	A CFNumber (SInt32)	Required

Optionally, the keys-value pairs s for a profileType key whose value is "displayRGB" can be provided to override the values from the display.

Availability
Available in Mac OS X v. 10.3 and later.

Declared In
CMApplication.h

CMMatchImage

Color matches an image file. (Deprecated in Mac OS X v10.5.)

```
CMError CMMatchImage (
   const FSSpec *specFrom,
   const FSSpec *specInto,
   Boolean repl,
   UInt32 qual,
   CMProfileRef srcProf,
   UInt32 srcIntent,
   CMProfileRef dstProf
);
```

Parameters

specFrom
A file specification for the image file. See the File Manager documentation for a description of the FSSpec data type.

specInto
If this parameter is a file, it specifies the resulting image. If this parameter is a folder, it specifies the location of the resulting image which will have the same name as the original file. If this parameter is not provided, the original file is modified. See the File Manager documentation for a description of the FSSpec data type.

repl
A Boolean value. If a file with the same name already exists, it will be replaced if this parameter is set to true.

qual
The optional quality for the match—normal, draft or best (cmNormalMode, cmDraftMode, or cmBestMode).

srcProf
The optional source profile for the match.

srcIntent
The rendering intent for the match—perceptual intent, relative colorimetric intent, saturation i ntent , or absolute colorimetric intent (cmPerceptual, cmRelativecolorimetric, cmSaturation, or cmAbsoluteColorimetric).

dstProf
The destination profile for the match.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.6 or later is present.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`CMScriptingPlugin.h`

CMNewProfile

Creates a new profile and associated backing copy.

```
CMError CMNewProfile (
   CMProfileRef *prof,
   const CMProfileLocation *theProfile
);
```

Parameters

prof

A pointer to a profile reference of type `CMProfileRef` (page 925). On return, a reference to the new profile.

theProfile

A pointer of type `CMProfileLocation` (page 924) to the profile location where the new profile should be created. A profile is commonly disk-file based—the disk file type for a profile is `'prof'`. However, to accommodate special requirements, you can create a handle- or pointer-based profile, you can create a temporary profile that is not saved after you call the `CMCloseProfile` function, or you can create a profile that is accessed through a procedure provided by your application. To create a temporary profile, you either specify `cmNoProfileBase` as the kind of profile in the profile location structure or specify `NULL` for this parameter.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
The `CMNewProfile` function creates a new profile and backing copy in the location you specify. After you create the profile, you must fill in the profile header fields and populate the profile with tags and their element data, and then call the function `CMUpdateProfile` (page 816) to save the element data to the profile file. The default ColorSync profile contents include a profile header of type `CM2Header` (page 875) and an element table.

To set profile elements outside the header, you use the function `CMSetProfileElement` (page 810), the function `CMSetProfileElementSize` (page 812), and the function `CMSetPartialProfileElement` (page 807). You set these elements individually, identifying them by their tag names.

When you create a new profile, all fields of the `CM2Header` profile header are set to 0 except the `size` and `profileVersion` fields. To set the header elements, you call the function `CMGetProfileHeader` (page 769) to get a copy of the header, assign values to the header fields, then call the function `CMSetProfileHeader` (page 813) to write the new header to the profile.

For each profile class, such as a device profile, there is a specific set of elements and associated tags, defined by the ICC, that a profile must contain to meet the baseline requirements. The ICC also defines optional tags that a particular CMM might use to optimize or improve its processing. You can also define private tags, whose tag signatures you register with the ICC, to provide a CMM with greater capability to refine its processing.

After you fill in the profile with tags and their element data, you must call the `CMUpdateProfile` function to write the new profile elements to the profile file.

This function is most commonly used by profile developers who create profiles for device manufacturers and by calibration applications. In most cases, application developers use existing profiles.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`CMApplication.h`

CMNewProfileSearch

Searches the ColorSync Profiles folder and returns a list of 2.x profiles that match the search specification. (Deprecated in Mac OS X v10.5.)

```
CMError CMNewProfileSearch (
   CMSearchRecord *searchSpec,
   void *refCon,
   UInt32 *count,
   CMProfileSearchRef *searchResult
);
```

Parameters

searchSpec

A pointer to a search specification. For a description of the information you can provide in a search record of type `CMSearchRecord` to define the search, see `CMSearchRecord` (page 932). See the QuickDraw Reference for a description of the PixMap data type.

refCon

An untyped pointer to arbitrary data supplied by your application. `CMNewProfileSearch` passes this data to your filter routine. For a description of the filter routine, see the function `CMProfileFilterProcPtr` (page 864).

count

A pointer to a profile count. On return, a one-based count of profiles matching the search specification.

searchResult

A pointer to a search result reference. On return, a reference to the profile search result list. For a description of the `CMProfileSearchRef` private data type, see `CMProfileSearchRef` (page 927). See the QuickDraw Reference for a description of the PixMap data type.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
The `CMNewProfileSearch` function sets up and defines a new search identifying through the search record the elements that a profile must contain to qualify for inclusion in the search result list. The function searches the ColorSync profiles folder for version 2.x profiles that meet the criteria and returns a list of these profiles in an internal private data structure whose reference is returned to you in the `searchResult` parameter.

You must provide a search record of type `CMSearchRecord` identifying the search criteria. You specify which fields of the search record to use for any given search through a search bit mask whose value you set in the search record's `searchMask` field.

Among the information you can provide in the search record is a pointer to a filter function to use to eliminate profiles from the search based on additional criteria not defined by the search record. The search result reference is passed to the filter function after the search is performed. For a description of the filter function and its prototype, see the function `CMProfileFilterProcPtr` (page 864).

Your application cannot directly access the search result list. Instead, you pass the returned search result list reference to other search-related functions that allow you to use the result list.

When your application has completed its search, it should call the function `CMDisposeProfileSearch` (page 745) to free the private memory allocated for the search.

To obtain a reference to a profile corresponding to a specific index in the list, use the function `CMSearchGetIndProfile` (page 798). To obtain the file specification for a profile corresponding to a specific index in the list, use the function `CMSearchGetIndProfileFileSpec` (page 799). To update the search result list, use the function `CMUpdateProfileSearch` (page 817). To free the private memory allocated for a profile search after your application has completed the search, use the function `CMDisposeProfileSearch` (page 745).

Version Notes
The `CMNewProfileSearch` function does not take full advantage of the optimized profile searching available starting with ColorSync version 2.5. Use `CMIterateColorSyncFolder` (page 780) instead.

This function is not recommended for use in ColorSync 2.5.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`CMApplication.h`

CMOpenProfile

Opens the specified profile and returns a reference to the profile.

```
CMError CMOpenProfile (
   CMProfileRef *prof,
   const CMProfileLocation *theProfile
);
```

Parameters

prof

A pointer to a profile reference of type `CMProfileRef` (page 925). On return, the reference refers to the opened profile.

theProfile

A pointer to a profile location of type `CMProfileLocation` (page 924) for the profile to open. Commonly a profile is disk-file based, but it may instead be temporary, handle-based, pointer-based, or accessed through a procedure supplied by your application.

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion

If the `CMOpenProfile` function executes successfully, the profile reference refers to the opened profile. Your application uses this reference, for example, when it calls functions to color match, copy, and update a profile, and validate its contents.

The ColorSync Manager maintains private storage for each request to open a profile, allowing more than one application to use a profile concurrently.

When you create a new profile or modify the elements of an existing profile, the ColorSync Manager stores the new or modified elements in the private storage it maintains for your application. Any new or changed profile elements are not incorporated into the profile itself unless your application calls the function `CMUpdateProfile` (page 816) to update the profile. If you call the function `CMCopyProfile` (page 740) to create a copy of an existing profile under a new name, any changes you have made are incorporated in the profile duplicate but the original profile remains unchanged.

Before you call the `CMOpenProfile` function, you must set the `CMProfileLocation` data structure to identify the location of the profile to open. Most commonly, a profile is stored in a disk file. If the profile is in a disk file, use the profile location data type to provide its file specification. If the profile is in memory, use the profile location data type to specify a handle or pointer to the profile. If the profile is accessed through a procedure provided by your application, use the profile location data type to supply a universal procedure pointer to your procedure.

Your application must obtain a profile reference before you copy or validate a profile, and before you flatten the profile to embed it.

For example, your application can:

- open a profile
- call the `CMGetProfileHeader` function to obtain the profile's header to modify its values
- set new values
- call the `CMSetProfileHeader` function to replace the modified header
- pass the profile reference to a function such as `NCWNewColorWorld` (page 846) as the source or destination profile in a color world for a color-matching session
- When you close your reference to the profile by calling the function `CMCloseProfile` (page 728), your changes are discarded (unless you called the `CMUpdateProfile` function).

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Related Sample Code
CarbonSketch

Declared In
`CMApplication.h`

CMProfileElementExists

Tests whether the specified profile contains a specific element based on the element's tag signature.

```
CMError CMProfileElementExists (
   CMProfileRef prof,
   OSType tag,
   Boolean *found
);
```

Parameters

prof

A profile reference of type `CMProfileRef` (page 925) that specifies the profile to examine.

tag

The tag signature (for example, 'A2B0', or constant `cmAToB0Tag`) for the element in question. For a complete list of the tag signatures a profile may contain, including a description of each tag, refer to the International Color Consortium Profile Format Specification. The signatures for profile tags are defined in the `CMICCProfile.h` header file.

found

A pointer to a flag for whether the element was found. On return, the flag has the value `true` if the profile contains the element or `false` if it does not.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
You cannot use this function to test whether certain data in the `CM2Header` profile header exists. Instead, you must call the function `CMGetProfileHeader` (page 769) to copy the entire profile header and read its contents.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`CMApplication.h`

CMProfileIdentifierFolderSearch

Searches the ColorSync Profiles folder and returns a list of profile references, one for each profile that matches the specified profile identifier. (Deprecated in Mac OS X v10.5.)

```
CMError CMProfileIdentifierFolderSearch (
   CMProfileIdentifierPtr ident,
   UInt32 *matchedCount,
   CMProfileSearchRef *searchResult
);
```

Parameters

ident

A pointer to a profile identifier structure specifying the profile to search for.

matchedCount

A pointer to a value of type `unsigned long`. On return, the one-based count of profiles that match the specified profile identifier. The count is typically 0 or 1, but can be higher.

searchResult

A pointer to a search result reference of type `CMProfileSearchRef` (page 927). On return, a reference to the profile search result list. Only version 2.x profiles are included in the profile search result.

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020). It is not an error condition if this function finds no matching profiles. It returns an error only if a File Manager or other low-level system error occurs.

Discussion

When your application or device driver processes an image, it can keep a list of profile references for each profile it encounters in the image. Each time it encounters an embedded profile identifier, your application can call the function `CMProfileIdentifierListSearch` (page 793) to see if there is already a matching profile reference in its list. If not, it can call the `CMProfileIdentifierFolderSearch` function to see if the profile is located in the ColorSync Profiles folder.

Although there should typically be at most one profile in the ColorSync Profiles folder that matches the profile identifier, two or more profiles with different filenames may qualify.

Availability

Available in CarbonLib 1.0 and later when ColorSync 2.1 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`CMApplication.h`

CMProfileIdentifierListSearch

Searches a list of profile references and returns a list of all references that match a specified profile identifier. (Deprecated in Mac OS X v10.5.)

```
CMError CMProfileIdentifierListSearch (
   CMProfileIdentifierPtr ident,
   CMProfileRef *profileList,
   UInt32 listSize,
   UInt32 *matchedCount,
   CMProfileRef *matchedList
);
```

Parameters

ident

A pointer to a profile identifier. The function looks for profile references in `profileList` that match the profile described by this identifier. For information on how a profile identifier match is determined, see `CMProfileIdentifier` (page 921).

profileList

A pointer to a list of profile references to search.

listSize

The number of profile references in `profileList`.

matchedCount

A pointer to a count of matching profile references. If you set `matchedList` to `NULL`, On return `matchedCount` specifies the number of references in `profileList` that match `ident`. The count is typically 0 or 1, but can be higher.

If you do not set `matchedList` to `NULL`, on input you set `matchedCount` to the maximum number of matching references to be returned in `matchedList`. On return, the value of `matchedCount` specifies the actual number of matching references returned, which is always equal to or less than the number passed in.

matchedList

A pointer to a list of profile references. If you set `matchedList` to `NULL` on input, On return nothing is returned in the parameter, and the actual number of matching references is returned in `matchedCount`.

If you do not set `matchedList` to `NULL` on input, it is treated as a pointer to allocated memory. On return, the allocated memory will contain a list, in no particular order, of profile references that match `ident`. Only version 2.x profiles are included in the profile search result. The number of references in the list is equal to or less than the value you pass in the `matchedCount` parameter. You must allocate enough memory for `matchedList` to store the requested number of profile references.

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020). It is not an error condition if the `CMProfileIdentifierListSearch` function finds no matching profiles. The function returns an error only if a Memory Manager or other low-level system error occurs.

Discussion

When your application or device driver processes an image, it can keep a list of profile references for each unique profile or profile identifier it encounters in the image. Each time it encounters an embedded profile identifier, your application can call the `CMProfileIdentifierListSearch` function to see if there is already a matching profile reference in the list. Although your list of profile references would normally contain at most one reference that matches the profile identifier, it is possible to have two or more matches. For information on how a profile identifier match is determined, see `CMProfileIdentifier` (page 921).

If no matching profile is found in the list, your application can call the function `CMProfileIdentifierFolderSearch` (page 792) to see if a matching profile can be found in the ColorSync Profiles folder.

To determine the amount of memory needed for the list of profile references that match a profile identifier, your application may want to call `CMProfileIdentifierListSearch` twice. The first time, on input you set `matchedList` to `NULL` and ignore `matchedCount`. On return, `matchedCount` specifies the number of matching profiles. You then allocate enough memory to hold that many profile references (or a smaller number if you do not want all the references) and call `CMProfileIdentifierListSearch` again. This time you set `matchedList` to a pointer to the allocated memory and set `matchedCount` to the number of references you wish to obtain. To allocate memory, you use code such as the following:

```
myProfileRefListPtr = NewPtr(sizeof(CMProfileRef) * matchedCount);
```

If your application is interested in obtaining only the first profile that matches the specified profile, you need call `CMProfileIdentifierListSearch` only once. To do so, you just allocate enough memory to store one profile reference, set `matchedList` to point to that memory (or just set `matchedList` to point to a local variable), and set `matchedCount` to 1. On return, if `matchedCount` still has the value 1, then `CMProfileIdentifierListSearch` found a matching profile.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.1 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`CMApplication.h`

CMProfileModified

Indicates whether the specified profile has been modified since it was created or last updated.

```
CMError CMProfileModified (
   CMProfileRef prof,
   Boolean *modified
);
```

Parameters

prof
A profile reference of type `CMProfileRef` (page 925) to the profile to examine.

modified
A pointer to a Boolean variable. On return, the value of `modified` is set to `true` if the profile has been modified, `false` if it has not.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
When a profile is first opened, its modified flag is set to `false`. On calls that add to, delete from, or set the profile header or tags, the modified flag is set to `true`. After calling the function `CMUpdateProfile` (page 816), the modified flag is reset to `false`.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.1 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`CMApplication.h`

CMProofImage

Proofs an image. (Deprecated in Mac OS X v10.5.)

```
CMError CMProofImage (
   const FSSpec *specFrom,
   const FSSpec *specInto,
   Boolean repl,
   UInt32 qual,
   CMProfileRef srcProf,
   UInt32 srcIntent,
   CMProfileRef dstProf,
   CMProfileRef prfProf
);
```

Parameters

specFrom
The destination profile for the match. See the File Manager documentation for a description of the `FSSpec` data type.

specInto
If this parameter is a file, it specifies the resulting image. If this parameter is a folder, it specifies the location of the resulting image which will have the same name as the original file. If this parameter is not provided, the original file is modified. See the File Manager documentation for a description of the `FSSpec` data type.

repl
A Boolean value. If a file with the same name already exists, it will be replaced if this parameter is set to true.

qual
The optional quality for the match—normal, draft or best (`cmNormalMode`, `cmDraftMode`, or `cmBestMode`).

srcProf
The optional source profile for the match.

srcIntent
The rendering intent for the match—perceptual intent, relative colorimetric intent, saturation i ntent , or absolute colorimetric intent (`cmPerceptual`, `cmRelativecolorimetric`, `cmSaturation`, or `cmAbsoluteColorimetric`).

dstProf
The destination profile for the match.

prfProf
The proof profile for the match between the destination and proof profiles.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.6 or later is present.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`CMScriptingPlugin.h`

CMRegisterColorDevice

Registers a device with ColorSync.

```
CMError CMRegisterColorDevice (
   CMDeviceClass deviceClass,
   CMDeviceID deviceID,
   CFDictionaryRef deviceName,
   const CMDeviceScope *deviceScope
);
```

Parameters

deviceSpec
The class of the device (e.g., 'scnr' ,'cmra' ,'prtr' ,'mntr').

deviceScope
The unique identifier of the class (Class + ID uniquely id's device).

deviceName
Name of the device. See the CFDictionary documentation for a description of the `CFDictionaryRef` data type.

deviceScope
Structure defining the user and host scope this device pertains to.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
For a device to be recognized by ColorSync (and possibly other parts of Mac OS X) it needs to register itself using this function. If the device has ColorSync profiles associated with it, it should identify those u after registering with this function. Once a device is registered, it can appear as an input, output, or proofing device in ColorSync controls, as long as it has profiles associated with it. Registration need only happen once, when the device is installed. Device drivers need not register their device each time they are loaded.

Availability
Not available in CarbonLib.
Available in Mac OS X 10.1 and later.

Declared In
`CMDeviceIntegration.h`

CMRemoveProfileElement

Removes an element corresponding to a specific tag from the specified profile.

```
CMError CMRemoveProfileElement (
   CMProfileRef prof,
   OSType tag
);
```

Parameters

prof

A profile reference of type `CMProfileRef` (page 925) to the profile containing the tag remove.

tag

The tag signature for the element to remove.

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion

The `CMRemoveProfileElement` function deletes the tag as well as the element data from the profile.

Availability

Available in CarbonLib 1.0 and later when ColorSync 2.0 or later is present.

Available in Mac OS X 10.0 and later.

Declared In

`CMApplication.h`

CMSearchGetIndProfile

Opens the profile corresponding to a specific index into a specific search result list and obtains a reference to that profile. (Deprecated in Mac OS X v10.5.)

```
CMError CMSearchGetIndProfile (
   CMProfileSearchRef search,
   UInt32 index,
   CMProfileRef *prof
);
```

Parameters

search

A reference to the profile search result list containing the profile whose reference you want to obtain. For a description of the `CMProfileSearchRef` private data type, see `CMProfileSearchRef` (page 927). See the QuickDraw Reference for a description of the PixMap data type.

index

The position of the profile in the search result list. This value is specified as a one-based index into the set of profiles of the search result. The index must be less than or equal to the value returned as the `count` parameter of the `CMNewProfileSearch` function or the `CMUpdateProfileSearch` function; otherwise `CMSearchGetIndProfile` returns a result code of `cmIndexRangeErr`.

prof

A pointer to a profile reference of type `CMProfileRef` (page 925). On return, the reference refers to the profile associated with the specified index. See the QuickDraw Reference for a description of the PixMap data type.

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
Before your application can call the `CMSearchGetIndProfile` function, it must call the function `CMNewProfileSearch` (page 789) to perform a profile search and produce a search result list. The search result list is a private data structure maintained by the ColorSync Manager. After your application has finished using the profile reference, it must close the reference by calling the function `CMCloseProfile` (page 728).

Version Notes
This function is not recommended for use in ColorSync 2.5.

Starting with version 2.5, you should use the function `CMIterateColorSyncFolder` (page 780) for profile searching.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`CMApplication.h`

CMSearchGetIndProfileFileSpec

Obtains the file specification for the profile at a specific index into a search result. (Deprecated in Mac OS X v10.5.)

```
CMError CMSearchGetIndProfileFileSpec (
   CMProfileSearchRef search,
   UInt32 index,
   FSSpec *spec
);
```

Parameters

search
A reference to the profile search result containing the profile whose file specification you want to obtain. For a description of the `CMProfileSearchRef` private data type, see `CMProfileSearchRef` (page 927). See the QuickDraw Reference for a description of the PixMap data type.

index
The index of the profile whose file specification you want to obtain. This is a one-based index into a set of profiles in the search result list. The index must be less than or equal to the value returned as the `count` parameter of the `CMNewProfileSearch` function or the `CMUpdateProfileSearch` function; otherwise `CMSearchGetIndProfile` returns a result code of `cmIndexRangeErr`.

profileFile
A pointer to a file specification. On return, this parameter points to a file specification for the profile at the location specified by `index`. See the QuickDraw Reference for a description of the PixMap data type.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
Before your application can call the `CMSearchGetIndProfileFileSpec` function, it must call the function `CMNewProfileSearch` (page 789) to perform a profile search and produce a search result list. The search result list is a private data structure maintained by ColorSync.

The `CMSearchGetIndProfileFileSpec` function obtains the Macintosh file system file specification for a profile at a specific index in the search result list.

Version Notes
This function is not recommended for use in ColorSync 2.5.

Starting with version 2.5, you should use the function `CMIterateColorSyncFolder` (page 780) for profile searching.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`CMApplication.h`

CMSetDefaultDevice

Sets the default device.

```
CMError CMSetDefaultDevice (
   CMDeviceClass deviceClass,
   CMDeviceID deviceID
);
```

Parameters
deviceClass
The class of the device (e.g., 'scnr' ,'cmra' ,'prtr' ,'mntr').
deviceID
The unique identifier of the class (Class + ID uniquely id's device).

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
For each class of device, a device management layer may establish which of the registered devices is the default. This helps keep color management choices to a minimum and allows for some "automatic" features to be enabled, such as, "Default printer" as an output profile selection. If no such device (as specified by deviceClass and deviceID) has been registered, an error is returned.

Availability
Not available in CarbonLib.
Available in Mac OS X 10.1 and later.

Declared In
`CMDeviceIntegration.h`

CMSetDefaultProfileBySpace

Sets the default profile for the specified color space. (Deprecated in Mac OS X v10.5.)

```
CMError CMSetDefaultProfileBySpace (
   OSType dataColorSpace,
   CMProfileRef prof
);
```

Parameters

dataColorSpace

A four-character identifier of type `OSType`. You pass a color space signature that identifies the color space you wish to set the default profile for. The currently-supported values are `cmRGBData`, `cmCMYKData`, `cmLabData`, and `cmXYZData`. These constants are a subset of the constants described in "Color Space Signatures" (page 969). If you supply a value that is not supported, the `CMGetDefaultProfileBySpace` function returns an error value of `paramErr`.

prof

A profile reference. Before calling `CMSetDefaultProfileBySpace`, set the reference to specify the default profile for the color space. The profile must be file-based; otherwise, the function returns a `CMInvalidProfileLocation` error.

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion

The `CMSetDefaultProfileBySpace` function currently supports the RGB, CMYK, Lab, and XYZ color spaces. The signature constants for these color spaces (shown above with the `dataColorSpace` parameter description) are described in "Color Space Signatures" (page 969). Support for additional color spaces may be provided in the future. `CMSetDefaultProfileBySpace` returns a value of `paramErr` if you pass a color space constant it does not currently support.

Note that a user can also use the ColorSync control panel to specify a default profile for the RGB and CMYK color spaces.

Availability

Available in CarbonLib 1.0 and later when ColorSync 2.5 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`CMApplication.h`

CMSetDefaultProfileByUse

Sets values for device profile settings. (Deprecated in Mac OS X v10.5.)

```
CMError CMSetDefaultProfileByUse (
   OSType use,
   CMProfileRef prof
);
```

Parameters

use

A value that specifies the device type for which to set the profile.

prof

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Availability

Available in CarbonLib 1.0 and later when ColorSync 3.0 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`CMApplication.h`

CMSetDeviceDefaultProfileID

Sets the default profile ID for a given device.

```
CMError CMSetDeviceDefaultProfileID (
   CMDeviceClass deviceClass,
   CMDeviceID deviceID,
   CMDeviceProfileID defaultProfID
);
```

Parameters

deviceClass

The device class for the device whose default profile you want to set. See "Device Classes" (page 979) for a list of the constants you can supply.

deviceID

The device ID for the device whose default profile you want to set.

defaultID

The ID of profile you want to set as the default.

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion

The default profile ID for a given device is an important piece of information because of the function `CMGetProfileByUse`. The function `CMGetProfileByUse` returns the default profile for devices depending on the user's selection in the ColorSync preferences pane. Device drivers and host software can set the default profile for a given device using the function `CMSetDeviceDefaultProfileID`.

Availability

Not available in CarbonLib.

Available in Mac OS X 10.1 and later.

Declared In
CMDeviceIntegration.h

CMSetDeviceFactoryProfiles

Establishes the profiles used by a given device.

```
CMError CMSetDeviceFactoryProfiles (
   CMDeviceClass deviceClass,
   CMDeviceID deviceID,
   CMDeviceProfileID defaultProfID,
   const CMDeviceProfileArray *deviceProfiles
);
```

Parameters

deviceClass
The device class for the device whose factory profiles you want to establish. See "Device Classes" (page 979) for a list of the constants you can supply.

deviceID
The device ID for the device whose factory profiles you want to establish.

defaultProfID
The ID of the default profile for this device.

deviceProfiles
On output, points to array that contains the factory device profiles.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
This function establishes the profiles used by a given device. It should be called after device registration to notify ColorSync of the device's profiles. Note that factory device profiles and the current device profiles might not be the same, since the latter may contain modifications to the factory set.

Availability
Not available in CarbonLib.
Available in Mac OS X 10.1 and later.

Declared In
CMDeviceIntegration.h

CMSetDeviceProfile

Change the profile used by a given device.

```
CMError CMSetDeviceProfile (
   CMDeviceClass deviceClass,
   CMDeviceID deviceID,
   const CMDeviceProfileScope *profileScope,
   CMDeviceProfileID profileID,
   const CMProfileLocation *profileLoc
);
```

Parameters

deviceClass

The device class for the device whose profile you want to set. See "Device Classes" (page 979) for a list of the constants you can supply.

deviceID

The device ID for the device whose profile you want to set.

profileScope

A pointer to the structure defining the scope this profile pertains to.

profileID

The ID of the default profile for this device.

deviceProfLoc

A pointer to the `CMProfileLocation` of the profile. Since this structure is a fixed length structure, you can simply pass a pointer to a stack-based structure or memory allocated for it.

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion

This function provides a way to change a profile used by a given device by ID. It can be called after device registration by calibration applications to reset a device's profile from factory defaults to calibrated profiles. In order for this call to be made successfully, you must pass the `CMDeviceClass` and `CMDeviceID` of the device being calibrated along with the `CMDeviceProfileID` of the profile to set. (Device selection and identification can be facilitated using the function `CMIterateColorDevices`). If an invalid `CMDeviceClass` or `CMDeviceID` is passed, an error (`CMInvalidDeviceClass` or `CMInvalidDeviceID`) is returned.

Availability

Not available in CarbonLib.

Available in Mac OS X 10.1 and later.

Declared In

`CMDeviceIntegration.h`

CMSetDeviceProfiles

Changes the profiles used by a given device. (Deprecated in Mac OS X v10.5.)

```
CMError CMSetDeviceProfiles (
   CMDeviceClass deviceClass,
   CMDeviceID deviceID,
   const CMDeviceProfileScope *profileScope,
   const CMDeviceProfileArray *deviceProfiles
);
```

Parameters

deviceClass

The device class for the device whose profiles you want to set. See "Device Classes" (page 979) for a list of the constants you can supply.

deviceID

The device ID for the device whose profiles you want to set.

profileScope

A pointer to the structure defining the scope these profiles pertain to.

deviceProfiles

A pointer to the profile array that contains replacements for the factory profiles. You don't have to replace all the original profiles with this call. The array can contain as few as one profile or as many profiles as there are in the original factory array. You supply only those profiles you want to replace. Profiles are replaced by ID.

Return Value

A `CMError` value. If you pass a n invalid `CMDeviceClass` or `CMDeviceID`, the function returns `CMInvalidDeviceClass` or `CMInvalidDeviceID`. See "ColorSync Manager Result Codes" (page 1020).

Discussion

This function provides a way to change the profiles used by a given device. It can be called after device registration by calibration applications to reset a device's profiles from factory defaults to calibrated profiles. In order for this call to be made successfully, the caller must pass the `CMDeviceClass` and `CMDeviceID` device being calibrated. (You can call the function `CMIterateColorDevices` to find available device classes and IDs.).

Availability

Not available in CarbonLib.

Available in Mac OS X 10.1 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`CMDeviceIntegration.h`

CMSetDeviceState

Sets the state of a device.

```
CMError CMSetDeviceState (
   CMDeviceClass deviceClass,
   CMDeviceID deviceID,
   CMDeviceState deviceState
);
```

Parameters

deviceClass

The device class for the device whose state you want to set. See "Device Classes" (page 979) for a list of the constants you can supply.

deviceID

The device ID for the device whose state you want to set.

deviceState

The device state to set. See "Device States" (page 980) for the values you can supply.

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion

This routines provides access for the device management layer to update the state of a particular device. For example, a device can be offline, busy, or calibrated. The state data passed in replaces the old state data with the value you supply.

Availability

Not available in CarbonLib.

Available in Mac OS X 10.1 and later.

Declared In

`CMDeviceIntegration.h`

CMSetGammaByAVID

Sets the gamma for the specified display device.

```
CMError CMSetGammaByAVID (
   CMDisplayIDType theID,
   CMVideoCardGamma *gamma
);
```

Parameters

theID

A Display Manager ID value. You pass the ID value for the display device for which to set the gamma.

gamma

A pointer to the gamma value to which you want to set the display device.

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Availability

Available in CarbonLib 1.0 and later when ColorSync 3.0 or later is present.

Available in Mac OS X 10.0 and later.

Declared In

`CMApplication.h`

CMSetIndImageProfile

Sets a specific embeded profile for a given image. (Deprecated in Mac OS X v10.5.)

```
CMError CMSetIndImageProfile (
   const FSSpec *specFrom,
   const FSSpec *specInto,
   Boolean repl,
   UInt32 index,
   CMProfileRef prof
);
```

Parameters

specFrom

A file specification for the image file. See the File Manager documentation for a description of the `FSSpec` data type.

specInto

If this parameter is a file, it specifies the resulting image. If this parameter is a folder, it specifies the location of the resulting image which will have the same name as the original file. If this parameter is not provided, the original file is modified. See the File Manager documentation for a description of the `FSSpec` data type.

repl

A Boolean value. If a file with the same name already exists, it will be replaced if this parameter is set to true.

index

The numeric index of the profile to set.

prof

The profile to set at the index designated by the `index` parameter.

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Availability

Available in CarbonLib 1.0 and later when ColorSync 2.6 or later is present.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`CMScriptingPlugin.h`

CMSetPartialProfileElement

Sets part of the element data for a specific tag in the specified profile.

```
CMError CMSetPartialProfileElement (
   CMProfileRef prof,
   OSType tag,
   UInt32 offset,
   UInt32 byteCount,
   const void *elementData
);
```

Parameters

prof

A profile reference of type `CMProfileRef` (page 925) to the profile containing the tag for which the element data is set.

tag

The tag signature for the element whose data is set. The tag identifies the element. For a complete list of the tag signatures a profile may contain, including a description of each tag, refer to the International Color Consortium Profile Format Specification. The signatures for profile tags are defined in the `CMICCProfile.h` header file.

offset

The offset in the existing element data where data transfer should begin.

byteCount

The number of bytes of element data to transfer.

elementData

A pointer to the buffer containing the element data to transfer to the profile.

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion

You can use the `CMSetPartialProfileElement` function to set the data for an element when the amount of data is large and you need to copy it to the profile in segments.

After you set the element size, you can call this function repeatedly, as many times as necessary, each time appending a segment of data to the end of the data already copied until all the element data is copied.

If you know the size of the element data, you should call the function `CMSetProfileElementSize` (page 812) to reserve it before you call `CMSetPartialProfileElement` to set element data in segments. Setting the size first avoids the extensive overhead required to increase the size for the element data with each call to append another segment of data.

To copy the entire data for an element as a single operation, when the amount of data is small enough to allow this, call the function `CMSetProfileElement` (page 810).

Availability

Available in CarbonLib 1.0 and later when ColorSync 2.0 or later is present.

Available in Mac OS X 10.0 and later.

Declared In

`CMApplication.h`

CMSetProfileByAVID

Sets the profile for the specified monitor, optionally setting video card gamma.

```
CMError CMSetProfileByAVID (
   CMDisplayIDType theID,
   CMProfileRef prof
);
```

Parameters

theAVID

A Display Manager ID value. You pass the ID value for the monitor for which to set the profile.

prof

A profile reference. Before calling `CMSetProfileByAVID`, set the reference to identify the profile for the monitor specified by `theAVID`.

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion

If you specify a profile that contains the optional profile tag for video card gamma, `CMSetProfileByAVID` extracts the tag and sets the video card based on the tag data. This is the only ColorSync function that sets video card gamma. The tag constant `cmVideoCardGammaTag` is described in "Video Card Gamma Tags" (page 1019).

When a user sets a display profile using the Monitors & Sound control panel, the system profile is set to the same profile. When you call `CMSetProfileByAVID` to set a profile for a monitor, you may also wish to make that profile the system profile. If so, you must call `CMSetSystemProfile` (page 814) explicitly—calling `CMSetProfileByAVID` alone has no affect on the system profile.

Note that if the Display Manager supports ColorSync, the `CMSetProfileByAVID` function calls on the Display Manager to set the profile for the specified display. This is the case if the version of the Display Manager is 2.2.5 or higher (if `gestaltDisplayMgrAttr` has the `gestaltDisplayMgrColorSyncAware` bit set).

Availability

Available in CarbonLib 1.0 and later when ColorSync 2.5 or later is present.

Available in Mac OS X 10.0 and later.

Declared In

`CMApplication.h`

CMSetProfileDescriptions

Sets the description tag data for a specified profile.

```
CMError CMSetProfileDescriptions (
   CMProfileRef prof,
   const char *aName,
   UInt32 aCount,
   ConstStr255Param mName,
   ScriptCode mCode,
   const UniChar *uName,
   UniCharCount uCount
);
```

Parameters

prof

A reference to the profile into which to set the description tag data.

aName

A pointer to a 7-bit Roman ASCII profile name string to be set for the profile. This string must be null-terminated.

aCount

A count of the number of characters in the string specified in the `aName` parameter

mName

A pointer to the localized profile name string in Mac script-code format which is to be set for the profile. This string must be null-terminated.

mCode

The script code corresponding to the string specified by the `mName` parameter.

uName

A pointer to the localized Unicode profile name string which is to be set for the profile. This string must be null-terminated

uCount

A count of the number of Unicode characters in string specified by the `uName` parameter. Do not confuse this with a byte count, because each Unicode character requires two bytes.

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion

Use this function to set the description tag data for a given profile. The ICC Profile Format Specification (available at http://www.color.org) includes a description tag (`'desc'`), designed to provide more information about a profile than can be contained in a file name. This is especially critical on file systems with 8.3 names. The tag data can consist of up to three separate pieces (strings) of information for a profile. These different strings are designed to allow for display in different languages or on different computer systems. Applications typically use one of the strings to show profiles in a list or a pop-up menu.

Availability

Available in CarbonLib 1.0 and later when ColorSync 2.6 or later is present.

Available in Mac OS X 10.0 and later.

Declared In

`CMApplication.h`

CMSetProfileElement

Sets or replaces the element data for a specific tag in the specified profile.

```
CMError CMSetProfileElement (
   CMProfileRef prof,
   OSType tag,
   UInt32 elementSize,
   const void *elementData
);
```

Parameters

prof

A profile reference of type `CMProfileRef` (page 925) to the profile containing the tag for which the element data is set.

tag

The tag signature for the element whose data is set. For a complete list of the tag signatures a profile may contain, including a description of each tag, refer to the International Color Consortium Profile Format Specification. The signatures for profile tags are defined in the `CMICCProfile.h` header file.

elementSize

The size in bytes of the element data set.

elementData

A pointer to the buffer containing the element data to transfer to the profile.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
The `CMSetProfileElement` function replaces existing element data if an element with the specified tag is already present in the profile. Otherwise, it sets the element data for a new tag. Your application is responsible for allocating memory for the buffer to hold the data to transfer.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`CMApplication.h`

CMSetProfileElementReference

Adds a tag to the specified profile to refer to data corresponding to a previously set element.

```
CMError CMSetProfileElementReference (
   CMProfileRef prof,
   OSType elementTag,
   OSType referenceTag
);
```

Parameters

prof

A profile reference of type `CMProfileRef` (page 925) to the profile to add the tag to.

elementTag

The original element's signature tag corresponding to the element data to which the new tag will refer.

referenceTag

The new tag signature to add to the profile to refer to the element data corresponding to `elementTag`.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
After the `CMSetProfileElementReference` function executes successfully, the specified profile will contain more than one tag corresponding to a single piece of data. All of these tags are of equal importance. Your application can set a reference to an element that was originally a reference itself without circularity.

If you call the function `CMSetProfileElement` (page 810) subsequently for one of the tags acting as a reference to another tag's data, then the element data you provide is set for the tag and the tag is no longer considered a reference. Instead, the tag corresponds to its own element data and not that of another tag.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`CMApplication.h`

CMSetProfileElementSize

Reserves the element data size for a specific tag in the specified profile before setting the element data.

```
CMError CMSetProfileElementSize (
   CMProfileRef prof,
   OSType tag,
   UInt32 elementSize
);
```

Parameters

prof
A profile reference of type `CMProfileRef` (page 925) to the profile in which the element data size is reserved.

tag
The tag signature for the element whose size is reserved. The tag identifies the element. For a complete list of the tag signatures a profile may contain, including a description of each tag, refer to the International Color Consortium Profile Format Specification. The signatures for profile tags are defined in the `CMICCProfile.h` header file.

elementSize
The total size in bytes to reserve for the element data.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
Your application can use the `CMSetProfileElementSize` function to reserve the size of element data for a specific tag before you call the function `CMGetPartialProfileElement` (page 765) to set the element data. The most efficient way to set a large amount of element data when you know the size of the data is to first set the size, then call the `CMSetPartialProfileElement` function to set each of the data segments. Calling the `CMSetProfileElementSize` function first eliminates the need for the ColorSync Manager to repeatedly increase the size for the data each time you call the `CMSetPartialProfileElement` function.

In addition to reserving the element data size, the `CMSetProfileElementSize` function sets the element tag, if it does not already exist.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`CMApplication.h`

CMSetProfileHeader

Sets the header for the specified profile.

```
CMError CMSetProfileHeader (
   CMProfileRef prof,
   const CMAppleProfileHeader *header
);
```

Parameters

prof

A profile reference of type `CMProfileRef` (page 925) to the profile whose header is set.

header

A pointer to the new header to set for the profile.

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion

You can use the `CMSetProfileHeader` function to set a header for a version 1.0 or a version 2.x profile. Before you call this function, you must set the values for the header, depending on the version of the profile. For a version 2.x profile, you use a data structure of type `CM2Header` (page 875). For a version 1.0 profile, you use a data structure of type `CMHeader` (page 898). You pass the header you supply in the `CMAppleProfileHeader` union, described in `CMAppleProfileHeader` (page 881).

Availability

Available in CarbonLib 1.0 and later when ColorSync 2.0 or later is present.

Available in Mac OS X 10.0 and later.

Declared In

`CMApplication.h`

CMSetProfileLocalizedStringDictionary

Writes a dictionary of localized strings to a given tag in a profile.

```
CMError CMSetProfileLocalizedStringDictionary (
   CMProfileRef prof,
   OSType tag,
   CFDictionaryRef theDict
);
```

Parameters

prof

The profile to modify.

tag

The tag type of profile to modify.

theDict

The dictionary to modify. See the CFDictionary documentation for a description of the `CFDictionaryRef` data type.

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.1 and later.

Declared In
`CMApplication.h`

CMSetSystemProfile

Sets the current system profile. (Deprecated in Mac OS X v10.5.)

```
CMError CMSetSystemProfile (
   const FSSpec *profileFileSpec
);
```

Parameters

profileFileSpec

A pointer to a file specification structure. Before calling `CMSetSystemProfile`, set the structure to specify the desired system profile.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
By default, a standard RGB profile is configured as the system profile. By calling the `CMSetSystemProfile` function, your application can specify a new system profile. You can configure only a display device profile as the system profile.

Version Notes
Starting with version 2.5, use of the system profile has changed.

The function `CMSetSystemProfile` does not retrieve video card gamma data (introduced in ColorSync version 2.5) to set the video card; use the function `CMSetProfileByAVID` (page 808) instead.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`CMApplication.h`

CMUnembedImage

Removes any ICC profiles embeded in an image. (Deprecated in Mac OS X v10.5.)

```
CMError CMUnembedImage (
   const FSSpec *specFrom,
   const FSSpec *specInto,
   Boolean repl
);
```

Parameters

specFrom

A file specification for the image file. See the File Manager documentation for a description of the `FSSpec` data type.

specInto

If this parameter is a file, it specifies the resulting image. If this parameter is a folder, it specifies the location of the resulting image which will have the same name as the original file. If his parameter is not provided, the original file is modified. See the File Manager documentation for a description of the `FSSpec` data type.

repl

A Boolean value. If a file with the same name already exists, it will be replaced if this parameter is set to true.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.6 or later is present.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`CMScriptingPlugin.h`

CMUnregisterColorDevice

Unregisters a device.

```
CMError CMUnregisterColorDevice (
   CMDeviceClass deviceClass,
   CMDeviceID deviceID
);
```

Parameters

deviceClass

The device class of the device you want to unregister. See "Device Classes" (page 979) for a list of the constants you can supply.

deviceID

The device ID of the device you want to unregister.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
When a device is no longer to be used on a system (as opposed to being offline), it should be unregistered. If a device is temporarily shut down or disconnected, it does not to be unregistered unless either of the following is true:

- The device driver is being removed (uninstalled)
- The device driver can't access the device profiles without the device

Availability
Not available in CarbonLib.
Available in Mac OS X 10.1 and later.

Declared In
`CMDeviceIntegration.h`

CMUpdateProfile

Saves modifications to the specified profile.

```
CMError CMUpdateProfile (
   CMProfileRef prof
);
```

Parameters

prof

A profile reference of type `CMProfileRef` (page 925) to the profile to update.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
The `CMUpdateProfile` function makes permanent any changes or additions your application has made to the profile identified by the profile reference, if no other references to that profile exist.

The ColorSync Manager maintains a modified flag to track whether a profile has been modified. After updating a profile, the `CMUpdateProfile` function sets the value of the modified flag for that profile to `false`.

Each time an application calls the function `CMOpenProfile` (page 790), the function creates a unique reference to the profile. An application can also duplicate a profile reference by passing a copy to another task. You cannot use the `CMUpdateProfile` function to update a profile if more than one reference to the profile exists—attempting to do so will result in an error return. You can call the function `CMGetProfileRefCount` (page 772) to determine the reference count for a profile reference.

You cannot use the `CMUpdateProfile` function to update a ColorSync 1.0 profile.

After you fill in tags and their data elements for a new profile created by calling the function `CMNewProfile` (page 788), you must call the `CMUpdateProfile` function to write the element data to the new profile.

If you modify an open profile, you must call `CMUpdateProfile` to save the changes to the profile file before you call the function `CMCloseProfile` (page 728). Otherwise, the changes are discarded.

To modify a profile header, you use the function `CMGetProfileHeader` (page 769) and the function `CMSetProfileHeader` (page 813).

To set profile elements outside the header, you use the function `CMSetProfileElement` (page 810), the function `CMSetProfileElementSize` (page 812), and the function `CMSetPartialProfileElement` (page 807).

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
CMApplication.h

CMUpdateProfileSearch

Searches the ColorSync Profiles folder and updates an existing search result obtained originally from the CMNewProfileSearch function. (Deprecated in Mac OS X v10.5.)

```
CMError CMUpdateProfileSearch (
   CMProfileSearchRef search,
   void *refCon,
   UInt32 *count
);
```

Parameters

search

A reference to a search result list returned to your application when you called the CMNewProfileSearch function. For a description of the CMProfileSearchRef private data type, see CMProfileSearchRef (page 927). See the QuickDraw Reference for a description of the PixMap data type.

refCon

A pointer to a reference constant for application data passed as a parameter to calls to the filter function specified by the original search specification. For a description of the filter function, see the function CMProfileFilterProcPtr (page 864).

count

A pointer to a profile count. On return, if the function result is noErr, a one-based count of the number of profiles matching the original search specification passed to the CMNewProfileSearch function. Otherwise undefined.

Return Value
A CMError value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
After a profile search has been set up and performed through a call to the CMNewProfileSearch function, the CMUpdateProfileSearch function updates the existing search result. You must use this function if the contents of the ColorSync Profiles folder have changed since the original search result was created.

The search update uses the original search specification, including the filter function indicated by the search record. Data given in the CMUpdateProfileSearch function's refCon parameter is passed to the filter function each time it is called.

Sharing a disk over a network makes it possible for modification of the contents of the ColorSync Profiles folder to occur at any time.

For a description of the function you call to begin a new search, see the function CMNewProfileSearch (page 789). That function specifies the filter function referred to in the description of the refCon parameter.

Version Notes
Starting with version 2.5, you should use the function `CMIterateColorSyncFolder` (page 780) for profile searching.

This function is not recommended for use in ColorSync 2.5.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`CMApplication.h`

CMValidateProfile

Indicates whether the specified profile contains the minimum set of elements required by the current color management module (CMM) for color matching or color checking.

```
CMError CMValidateProfile (
   CMProfileRef prof,
   Boolean *valid,
   Boolean *preferredCMMnotfound
);
```

Parameters

prof
A profile reference of type `CMProfileRef` (page 925) to the profile to validate.

valid
A pointer to a valid profile flag. On return, has the value `true` if the profile contains the minimum set of elements to be valid and `false` if it does not.

preferredCMMnotfound
A pointer to a flag for whether the preferred CMM was found. On return, has the value `true` if the CMM specified by the profile was not available to perform validation or does not support this function and the default CMM was used. Has the value `false` if the profile's preferred CMM is able to perform validation.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
When your application calls the `CMValidateProfile` function, the ColorSync Manager dispatches the function to the CMM specified by the `CMMType` header field of the profile whose reference you specify. The preferred CMM can support this function or not.

If the preferred CMM supports this function, it determines if the profile contains the baseline elements for the profile class, which the CMM requires to perform color matching or gamut checking. For each profile class, such as a device profile, there is a specific set of required tagged elements defined by the ICC that the profile must include. The ICC also defines optional tags, which may be included in a profile. A CMM might use these optional elements to optimize or improve its processing. Additionally, a profile might include private tags defined to provide a CMM with processing capability particular to the needs of that CMM. The

profile developer can define these private tags, register the tag signatures with the ICC, and include the tags in a profile. The CMM checks only for the existence of profile elements it does not check the element's content and size.

If the preferred CMM does not support the `CMValidateProfile` function request, the ColorSync Manager calls the default CMM to handle the validation request.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`CMApplication.h`

CMValidImage

Validates the specified image file. (Deprecated in Mac OS X v10.5.)

```
CMError CMValidImage (
   const FSSpec *spec
);
```

Parameters

spec
A file specification for the image file you want to validate. See the File Manager documentation for a description of the `FSSpec` data type.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
This function validates the specified image file. ColorSync checks with any installed scripting plug-ins to see if they recognize the image's file format. If a scripting plug-in is found which recognizes the image's file format, `CMValidateImage` returns `noErr` . If the image's file format is not recognized, `CMValidateImage` returns the `cmInvalidImageFile` error.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.6 or later is present.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`CMScriptingPlugin.h`

CWCheckBitmap

Tests the colors of the pixel data of a bitmap to determine whether the colors map to the gamut of the destination device.

```
CMError CWCheckBitmap (
   CMWorldRef cw,
   const CMBitmap *bitmap,
   CMBitmapCallBackUPP progressProc,
   void *refCon,
   CMBitmap *resultBitmap
);
```

Parameters

cw

A reference to the color world of type `CMWorldRef` (page 942) to use for the color check.

The functions `NCWNewColorWorld` (page 846) and `CWConcatColorWorld` (page 823) both allocate color world references of type `CMWorldRef` (page 942).

bitmap

A pointer to a bitmap of type `CMBitmap` (page 882) whose colors are to be checked.

progressProc

A calling program–supplied callback function that allows your application to monitor progress or abort the operation as the bitmap's colors are checked against the gamut of the destination device. The default CMM calls your function approximately every half-second unless color checking occurs in less time this happens when there is a small amount of data to be checked. If the function returns a result of `true`, the operation is aborted. Specify `NULL` for this parameter if your application will not monitor the bitmap color checking. For information on the callback function and its type definition, see the function `CMBitmapCallBackProcPtr` (page 852).

refCon

A pointer to a reference constant for application data passed as a parameter to calls to `progressProc`.

resultBitmap

A pointer to a bitmap. On return, contains the results of the color check. The bitmap must have bounds equal to the parameter of the source bitmap pointed to by `bitMap`. You must allocate the pixel buffer pointed to by the `image` field of the structure `CMBitmap` (page 882) and initialize the buffer to zeroes. Pixels are set to 1 if the corresponding pixel of the source bitmap indicated by `bitMap` is out of gamut. You must set the `space` field of the `CMBitMap` structure to `cmGamutResult1Space` color space storage format, as described in "Abstract Color Space Constants" (page 946).

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion

When your application calls the `CWCheckBitMap` function, the ColorSync Manager dispatches the function to the preferred CMM. The ColorSync Manager determines the preferred CMM based on the color world configuration. If the color world you pass in was created by the `CWConcatColorWorld` function, then the `keyIndex` field of the `CMConcatProfileSet` data structure identifies the preferred CMM. If the preferred CMM is not available, the default CMM is used to perform the color matching.

For the `CWCheckBitMap` function to execute successfully, the source profile's `dataColorSpace` field value and the `space` field value of the source bitmap pointed to by the `bitMap` parameter must specify the same data color space. `CWCheckBitMap` is not supported if the color world was initialized with a named color space profile.

Availability

Available in CarbonLib 1.0 and later when ColorSync 2.0 or later is present.

Available in Mac OS X 10.0 and later.

Declared In
CMApplication.h

CWCheckColors

Tests a list of colors using a specified color world to see if they fall within the gamut of a destination device.

```
CMError CWCheckColors (
   CMWorldRef cw,
   CMColor *myColors,
   size_t count,
   UInt8 *result
);
```

Parameters

cw

A reference to the color world of type CMWorldRef (page 942) describing how the test is to occur.

The functions NCWNewColorWorld (page 846) and CWConcatColorWorld (page 823) both allocate color world references of type CMWorldRef (page 942).

myColors

A pointer to an array containing a list of colors of type CMColor (page 884) to be checked . This function assumes the color values are specified in the data color space of the source profile.

count

The number of colors in the array. This is a one-based count.

result

A pointer to a buffer of packed bits. On return, each bit value is interpreted as a bit field with each bit representing a color in the array pointed to by myColors. You allocate enough memory to allow for 1 bit to represent each color in the myColors array. Bits in the result field are set to 1 if the corresponding color is out of gamut for the destination device. Ensure that the buffer you allocate is zeroed out before you call this function.

To access the packed bit-array, use code similar to the following:

```
inline bool GetNthBit (UInt8* result, int n)
{
    return ( 0 != (result[n/8] & (128>>(n%8))) );
}
```

The result bit array indicates whether the colors in the list are in or out of gamut for the destination profile. If a bit is set, its corresponding color falls out of gamut for the destination device. The leftmost bit in the field corresponds to the first color in the list.

Return Value
A CMError value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
The color test provides a preview of color matching using the specified color world.

All CMMs must support the CWCheckColors function.

If you have set a profile's gamut-checking mask so that no gamut information is included—see "Flag Mask Definitions for Version 2.x Profiles" (page 983) — CWCheckColors returns the cmCantGamutCheckError error.

The CWCheckColors function supports matching sessions set up with one of the multichannel color data types. CWCheckColors is not supported if the color world was initialized with a named color space profile.

Availability
Available in CarbonLib 1.0 and later when ColorSync 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
CMApplication.h

CWCheckPixMap

Checks the colors of a pixel map using the profiles of a specified color world to determine whether the colors are in the gamut of the destination device. (Deprecated in Mac OS X v10.4.)

```
CMError CWCheckPixMap (
   CMWorldRef cw,
   PixMap *myPixMap,
   CMBitmapCallBackUPP progressProc,
   void *refCon,
   BitMap *resultBitMap
);
```

Parameters

cw

A reference to the color world of type CMWorldRef (page 942) in which color checking is to occur.

The functions NCWNewColorWorld (page 846) and CWConcatColorWorld (page 823) both return color world references of type CMWorldRef (page 942).

See the QuickDraw Reference for a description of the PixMap data type.

myPixMap

A pointer to the pixel map to check colors for. A pixel map is a QuickDraw structure describing pixel data. The pixel map must be nonrelocatable; to ensure this, you should lock the handle to the pixel map. See the QuickDraw Reference for a description of the PixMap data type.

progressProc

A calling program–supplied callback function that allows your application to monitor progress or abort the operation as the pixel map colors are checked against the gamut of the destination device.

The default CMM calls your function approximately every half-second unless color checking occurs in less time; this happens when there is a small amount of data to be checked. If the function returns a result of true, the operation is aborted. Specify NULL for this parameter if your application will not monitor the pixel map color checking. For information on the callback function and its type definition, see the function CMBitmapCallBackProcPtr (page 852).

See the QuickDraw Reference for a description of the PixMap data type.

refCon

A pointer to a reference constant for application data passed as a parameter to calls to your CMBitmapCallBack function pointed to by progressProc.

resultBitMap

A pointer to a QuickDraw bitmap. On return, bits are set to 1 if the corresponding pixel of the pixel map indicated by myPixMap is out of gamut. Boundaries of the bitmap indicated by resultBitMap must equal the parameter of the pixel map indicated by the myPixMap. See the QuickDraw Reference for a description of the PixMap data type.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
The `CWCheckPixMap` function performs a gamut test of the pixel data of the `myPixMap` pixel map to determine if its colors are within the gamut of the destination device as specified by the destination profile. The gamut test provides a preview of color matching using the specified color world.

The preferred CMM, as determined by the ColorSync Manager based on the profiles of the color world configuration, is called to perform the color matching.

If the preferred CMM is not available, then the ColorSync Manager calls the default CMM to perform the matching. If the preferred CMM is available but does not implement the `CMCheckPixmap` function, then the ColorSync Manager unpacks the colors in the pixel map to create a color list and calls the preferred CMM's `CMCheckColors` function, passing to this function the list of colors to match. Every CMM must support the `CMCheckColors` function.

For this function to execute successfully, the source and destination profiles' data color spaces (`dataColorSpace` field) must be RGB to match the data color space of the pixel map, which is implicitly RGB.

If you specify a pointer to a callback function in the `progressProc` parameter, the CMM performing the color checking calls your function to monitor progress of the session. Each time the CMM calls your function, it passes the function any data you specified in the `CWCheckPixMap` function's `refCon` parameter.

You can use the reference constant to pass in any kind of data your callback function requires. For example, if your application uses a dialog box with a progress bar to inform the user of the color-checking session's progress, you can use the reference constant to pass the dialog box's window reference to the callback routine. For information about the callback function, see the function `CMBitmapCallBackProcPtr` (page 852).

You should ensure that the buffer pointed to by the `baseAddr` field of the bitmap passed in the `resultBitMap` parameter is zeroed out.

Availability
Available in CarbonLib 1.0 and later when ColorSync 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

CWConcatColorWorld

Sets up a color world that includes a set of profiles for various color transformations among devices in a sequence.

```
CMError CWConcatColorWorld (
   CMWorldRef *cw,
   CMConcatProfileSet *profileSet
);
```

Parameters

cw

A pointer to a color world. On return, a reference to a color world of type `CMWorldRef` (page 942). You pass the returned reference to other functions that use the color world for color-matching and color-checking sessions.

profileSet

A pointer of type `CMConcatProfileSet` (page 887) to an array of profiles describing the processing to carry out. You create the array and initialize it in processing order—source through destination.

You set the `keyIndex` field of the `CMConcatProfileSet` data structure to specify the zero-based index of the profile within the profile array whose specified CMM should be used for the entire color-matching or color-checking session. The profile header's `CMMType` field specifies the CMM. This CMM will fetch the profile elements necessary for the session.

Note that starting with ColorSync 2.5, the user can set a preferred CMM with the ColorSync control panel. If that CMM is available, ColorSync will use that CMM for all color conversion and matching operations the CMM is capable of performing.

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion

The `CWConcatColorWorld` function sets up a session for color processing that includes a set of profiles. The array of profiles is in processing order—source through destination. Your application passes the function a pointer to a data structure of type `CMConcatProfileSet` to identify the profile array.

The quality flag setting—indicating normal mode, draft mode, or best mode—specified by the first profile prevails for the entire session the quality flags of following profiles in the sequence are ignored. The quality flag setting is stored in the `flags` field of the profile header. See `CM2Header` (page 875) and "Flag Mask Definitions for Version 2.x Profiles" (page 983) for more information on the use of flags.

The rendering intent specified by the first profile is used to color match to the second profile, the rendering intent for the second profile is used to color match to the third profile, and so on through the series of concatenated profiles.

The following rules govern the profiles you can specify in the profile array pointed to by the `profileSet` parameter for use with the `CWConcatColorWorld` function:

- In the profile array, you can pass in one or more profiles, but you must specify at least one profile. If you specify only one profile, it must be a device link profile. If you specify a device link profile, you cannot specify any other profiles in the profiles array; a device link profile must be used alone.
- In the profile array, you can specify an abstract profile anywhere in the sequence other than as the first or last profile.
- For the first and last profiles, you can specify device profiles or color space conversion profiles. However, when you set up a color-matching session with a named color space profile and other profiles, the named color profile must be first or the last profile in the color world—it cannot be in the middle.
- You cannot specify `NULL` to indicate the system profile. Note that starting with version 2.5, use of the system profile has changed.
- If you specify a color space profile in the middle of the profile sequence, it is ignored by the default CMM.

- If you specify a named color profile, it must be the first or the last profile. Otherwise, `CWConcatColorWorld` returns the value `cmCantConcatenateError`.

A after executing the `CWConcatColorWorld` function, you should call the function `CMCloseProfile` (page 728) for each profile to dispose of its reference.

Instead of passing in an array of profiles, you can specify a device link profile. For information on how to create a device link profile, see the `CWNewLinkProfile` function, which is described next.

Version Notes
The parameter description for `profileSet` includes changes in how this function is used starting with ColorSync version 2.5.

Note also that starting with version 2.5, use of the system profile has changed.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.0 or later is present.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`CMApplication.h`

CWDisposeColorWorld

Releases the private storage associated with a color world when your application has finished using the color world.

```
void CWDisposeColorWorld (
   CMWorldRef cw
);
```

Parameters

cw

A color world reference of type `CMWorldRef` (page 942).

The function `NCWNewColorWorld` (page 846) and the function `CWConcatColorWorld` (page 823) both allocate color world references of type `CMWorldRef` (page 942).

Discussion
The following functions use color worlds. If you create a color world to pass to one of these functions, you must dispose of the color world when your application is finished with it.

- `CWMatchColors` (page 828)
- `CWCheckColors` (page 821)
- `CWMatchBitmap` (page 826)
- `CWCheckBitmap` (page 819)
- `CWMatchPixMap` (page 829)
- `CWCheckPixMap` (page 822)

Availability
Available in CarbonLib 1.0 and later when ColorSync 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`CMApplication.h`

CWFillLookupTexture

Fills a 3-D lookup texture from a color world.

```
CMError CWFillLookupTexture (
   CMWorldRef cw,
   UInt32 gridPoints,
   UInt32 format,
   UInt32 dataSize,
   void *data
);
```

Parameters

cw
The color world to use.

gridPoints
The number of grid points per channel in the texture.

format
The format of pixels in texture; for example, `cmTextureRGBtoRGBX8`.

dataSize
The size in bytes of texture data to fill.

data
On output, points to the texture data to fill.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
You can use the resulting table in OpenGL to accelerate color management in hardware.

Availability
Available in Mac OS X v. 10.3 and later.

Declared In
`CMApplication.h`

CWMatchBitmap

Matches the colors of a bitmap to the gamut of a destination device using the profiles specified by a color world.

```
CMError CWMatchBitmap (
   CMWorldRef cw,
   CMBitmap *bitmap,
   CMBitmapCallBackUPP progressProc,
   void *refCon,
   CMBitmap *matchedBitmap
);
```

Parameters

cw

A reference to a color world of type `CMWorldRef` (page 942) in which matching is to occur.

The functions `NCWNewColorWorld` (page 846) and `CWConcatColorWorld` (page 823) both allocate color world references of type `CMWorldRef` (page 942).

bitmap

A pointer to a bitmap of type `CMBitmap` (page 882) whose colors are to be matched.

progressProc

A calling program–supplied universal procedure pointer to a callback function that allows your application to monitor progress or abort the operation as the bitmap colors are matched. The default CMM calls your function approximately every half-second unless color matching occurs in less time this happens when there is a small amount of data to be matched. If the function returns a result of `true`, the operation is aborted. To match colors without monitoring the process, specify `NULL` for this parameter. For a description of the function your application supplies, see the function `CMBitmapCallBackProcPtr` (page 852).

refCon

A pointer to a reference constant for application data passed through as a parameter to calls to the `progressProc` function.

matchedBitmap

A pointer to a bitmap. On return, contains the color-matched image. You must allocate the pixel buffer pointed to by the `image` field of the structure `CMBitmap` (page 882). If you specify `NULL` for `matchedBitMap`, then the source bitmap is matched in place.

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion

The `CWMatchBitmap` function matches a bitmap using the profiles specified by the given color world.

You should ensure that the buffer pointed to by the `image` field of the bitmap passed in the `bitMap` parameter is zeroed out before you call this function.

The ColorSync Manager does not explicitly support a CMY color space. However, for printers that have a CMY color space, you can use either of the following circumventions to make the adjustment:

- You can use a CMY profile, which the ColorSync Manager does support, with a CMYK color space. If you specify a CMYK color space in this case, the ColorSync Manager zeroes out the K channel to simulate a CMY color space.
- You can use an RGB color space and pass in the bitmap along with an RGB profile, then perform the conversion from RGB to CMY yourself.

For this function to execute successfully, the source profile's `dataColorSpace` field value and the `space` field value of the source bitmap pointed to by the `bitMap` parameter must specify the same data color space. Additionally, the destination profile's `dataColorSpace` field value and the `space` field value of the resulting bitmap pointed to by the `matchedBitMap` parameter must specify the same data color space, unless the destination profile is a named color space profile.

If you set `matchedBitMap` to `NULL` to specify in-place matching, you must be sure the space required by the destination bitmap is less than or equal to the size of the source bitmap.

Version Notes
The color spaces currently supported for the CWMatchBitmap function are defined in "Color Space Constants With Packing Formats" (page 962). Support for the following color space constants, was added with ColorSync version 2.5:

- `cmGray16Space`
- `cmGrayA32Space`
- `cmRGB48Space`.
- `cmCMYK64Space`
- `cmLAB48Space`

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`CMApplication.h`

CWMatchColors

Matches colors in a color list, using the specified color world.

```
CMError CWMatchColors (
   CMWorldRef cw,
   CMColor *myColors,
   size_t count
);
```

Parameters

cw

A reference to the color world of type `CMWorldRef` (page 942) that describes how matching is to occur in the color-matching session.

The functions `NCWNewColorWorld` (page 846) and `CWConcatColorWorld` (page 823) both allocate color world references of type `CMWorldRef` (page 942).

myColors

A pointer to an array containing a list of colors of type `CMColor` (page 884). On input, contains the list of colors to match. On return, contains the list of matched colors specified in the color data space of the color world's destination profile.

count

A one-based count of the number of colors in the color list of the `myColors` array.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
The `CWMatchColors` function matches colors according to the profiles corresponding to the specified color world. On input, the color values in the `myColors` array are assumed to be specified in the data color space of the source profile. On return, the color values in the `myColors` array are transformed to the data color space of the destination profile.

All color management modules (CMM)s must support this function.

This function supports color-matching sessions set up with one of the multichannel color data types.

Availability
Available in CarbonLib 1.0 and later when ColorSync 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`CMApplication.h`

CWMatchPixMap

Matches a pixel map in place based on a specified color world. (Deprecated in Mac OS X v10.4.)

```
CMError CWMatchPixMap (
   CMWorldRef cw,
   PixMap *myPixMap,
   CMBitmapCallBackUPP progressProc,
   void *refCon
);
```

Parameters

cw

A reference to the color world of type `CMWorldRef` (page 942) in which matching is to occur.

The functions `NCWNewColorWorld` (page 846) and `CWConcatColorWorld` (page 823) both allocate color world references of type `CMWorldRef` (page 942).

myPixMap

A pointer to the pixel map to match. A pixel map is a QuickDraw structure describing pixel data. The pixel map must be nonrelocatable; to ensure this, you should lock the handle to the pixel map before you call this function. See the QuickDraw Reference for a description of the `PixMap` data type.

progressProc

A function supplied by your application to monitor progress or abort the operation as the pixel map colors are matched. The default CMM calls your function approximately every half-second, unless matching is completed in less time.

If the function returns a result of `true`, the operation is aborted. You specify `NULL` for this parameter if your application will not monitor the pixel map color matching. For information on the callback function and its type definition, refer to the function `CMProfileFilterProcPtr` (page 864).

refCon

A pointer to a reference constant for application data that is passed as a parameter to calls to `progressProc`.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
The `CWMatchPixMap` function matches a pixel map in place using the profiles specified by the given color world. The preferred CMM, as determined by the ColorSync Manager based on the color world configuration, is called to perform the color matching.

If the preferred CMM is not available, then the ColorSync Manager calls the default CMM to perform the matching. If the preferred CMM is available but it does not implement the `CMMatchPixMap` function, then the ColorSync Manager unpacks the colors in the pixel map to create a color list and calls the preferred CMM's `CMMatchColors` function, passing to this function the list of colors to match. Every CMM must support the `CMMatchColors` function.

For this function to execute successfully, the source and destination profiles' data color spaces (`dataColorSpace` field) must be RGB to match the data color space of the pixel map, which is implicitly RGB. For color spaces other than RGB, you should use the function `CWMatchBitmap` (page 826).

If you specify a pointer to a callback function in the `progressProc` parameter, the CMM performing the color matching calls your function to monitor progress of the session. Each time the CMM calls your function, it passes the function any data you specified in the `CWMatchPixMap` function's `refCon` parameter. If the ColorSync Manager performs the color matching, it calls your callback monitoring function once every scan line during this process.

You can use the reference constant to pass in any kind of data your callback function requires. For example, if your application uses a dialog box with a progress bar to inform the user of the color-matching session's progress, you can use the reference constant to pass the dialog box's window reference to the callback routine. For information about the callback function, see the function `CMBitmapCallBackProcPtr` (page 852).

Applications do not interact directly with the function `CWMatchColors` (page 828).

Availability
Available in CarbonLib 1.0 and later when ColorSync 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

CWNewLinkProfile

Creates a device link profile based on the specified set of profiles. (Deprecated in Mac OS X v10.5.)

```
CMError CWNewLinkProfile (
   CMProfileRef *prof,
   const CMProfileLocation *targetLocation,
   CMConcatProfileSet *profileSet
);
```

Parameters

prof

A pointer to an uninitialized profile reference of type `CMProfileRef` (page 925). On return, points to the new device link profile reference.

targetLocation

On return, a pointer to a location specification for the resulting profile. A device link profile cannot be a temporary profile: that is, it cannot have a location type of `cmNoProfileBase`.

profileSet

On input, a pointer to an array of profiles describing the processing to carry out. The array is in processing order—source through destination. For a description of the `CMConcatProfileSet` (page 887) data type, see `CMHeader` (page 898).

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion

This discussion is accurate for versions of ColorSync prior to 2.5. See the version notes below for changes starting with version 2.5.

You can use this function to create a new single profile containing a set of profiles and pass the device link profile to the function `CWConcatColorWorld` (page 823) instead of specifying each profile in an array. A device link profile provides a means of storing in concatenated format a series of device profiles and non-device profiles that are used repeatedly in the same sequence.

The only way to use a device link profile is to pass it to the `CWConcatColorWorld` function as the sole profile specified by the array passed in the `profileSet` parameter.

The zero-based `keyIndex` field of the `CMConcatProfileSet` data structure specifies the index of the profile within the device link profile whose preferred CMM is used for the entire color-matching or color-checking session. The profile header's `CMMType` field specifies the preferred CMM for the specified profile. This CMM will fetch the profile elements necessary for the session.

The quality flag setting—indicating normal mode, draft mode, or best mode—specified by the first profile prevails for the entire session the quality flags of profiles that follow in the sequence are ignored. The quality flag setting is stored in the `flag` field of the profile header. See `CM2Header` (page 875) for more information on the use of flags.

The rendering intent specified by the first profile is used to color match to the second profile, the rendering intent specified by the second profile is used to color match to the third profile, and so on through the series of concatenated profiles.

The following rules govern the content and use of a device link profile:

- The first and last profiles you specify in the profiles array for a device link profile must be device profiles.
- You cannot specify a named color profile.
- You cannot include another device link profile in the series of profiles you specify in the profiles array.

- The only way to use a device link profile is to pass it to the `CWConcatColorWorld` function as the sole profile specified by the array passed in the `profileSet` parameter.
- You cannot embed a device link profile in an image.
- You cannot specify `NULL` to indicate the system profile.

This function privately maintains all the profile information required by the color world for color-matching and color-checking sessions. Therefore, after executing the `CWNewLinkProfile` function, you should call the `CMCloseProfile` (page 728) function for each profile used to build a device link profile (to dispose of each profile reference).

Version Notes
Note that starting with version 2.5, use of the system profile has changed.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

CMTypes.h

InvokeCMProfileFilterUPP

Invokes a universal procedure pointer (UPP) to a profile-filter callback. (Deprecated in Mac OS X v10.5.)

Discussion
In most cases, you do not need to call this function as ColorSync Manager invokes your callback for you. See the "CMProfileFilterProcPtr" (page 864) callback for more information and for a description of the parameters.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
CMTypes.h

InvokeCMProfileIterateUPP

Invokes a universal procedure pointer (UPP) to a profile-iteration callback. (Deprecated in Mac OS X v10.5.)

```
OSErr InvokeCMProfileIterateUPP (
   CMProfileIterateData *iterateData,
   void *refCon,
   CMProfileIterateUPP userUPP
);
```

Parameters

Return Value
A result code. See "ColorSync Manager Result Codes" (page 1020).

Discussion
In most cases, you do not need to call this function as ColorSync Manager invokes your callback for you. See the "CMProfileIterateProcPtr" (page 865) callback for more information and for a description of the parameters.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In
`CMApplication.h`

NCMBeginMatching

Sets up a QuickDraw-specific ColorSync matching session, using the specified source and destination profiles. (Deprecated in Mac OS X v10.4.)

```
CMError NCMBeginMatching (
   CMProfileRef src,
   CMProfileRef dst,
   CMMatchRef *myRef
);
```

Parameters

src

A profile reference of type `CMProfileRef` (page 925) that specifies the source profile for the matching session. Starting with ColorSync version 2.5, you can call `CMGetDefaultProfileBySpace` (page 752) to get the default profile for a specific color space or `CMGetProfileByAVID` (page 767) to get a profile for a specific display.

With any version of ColorSync, you can specify a `NULL` value to indicate the ColorSync system profile. Note, however, that starting with version 2.5, use of the system profile has changed.

See the QuickDraw Reference for a description of the PixMap data type.

dst

A profile reference of type `CMProfileRef` (page 925) that specifies the destination profile for the matching session. Starting with ColorSync version 2.5, you can call `CMGetDefaultProfileBySpace` (page 752) to get the default profile for a specific color space or `CMGetProfileByAVID` (page 767) to get a profile for a specific display.

With any version of ColorSync, you can specify a `NULL` value to indicate the ColorSync system profile. Note, however, that starting with version 2.5, use of the system profile has changed.See the QuickDraw Reference for a description of the PixMap data type.

myRef

A pointer to a matching session. On return, it specifies the QuickDraw-specific matching session that was set up. See the QuickDraw Reference for a description of the PixMap data type.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
The `NCMBeginMatching` function sets up a QuickDraw-specific matching session, telling the ColorSync Manager to match all colors drawn to the current graphics device using the specified source and destination profiles.

The `NCMBeginMatching` function returns a reference to the color-matching session. You must later pass this reference to the function `CMEndMatching` (page 747) to conclude the session.

The source and destination profiles define how the match is to occur. Passing `NULL` for either the source or destination profile is equivalent to passing the system profile. If the current device is a screen device, matching to all screen devices occurs.

The `NCMBeginMatching` and `CMEndMatching` functions can be nested. In such cases, the ColorSync Manager matches to the most recently added profiles first. Therefore, if you want to use the `NCMBeginMatching`–`CMEndMatching` pair to perform a page preview—which typically entails color matching from a source device (scanner) to a destination device (printer) to a preview device (display)— you first call `NCMBeginMatching` with the printer-to-display profiles, and then call `NCMBeginMatching` with the scanner-to-printer profiles. The ColorSync Manager then matches all drawing from the scanner to the printer and then back to the display. The print preview process entails multiprofile transformations. The ColorSync Manager general purpose functions (which include the use of concatenated profiles well suited to print-preview processing) offer an easier and faster way to do this. These functions are described in "Matching Colors Using General Purpose Functions".

If you call `NCMBeginMatching` before drawing to the screen's graphics device (as opposed to an offscreen device), you must call `CMEndMatching` to finish a matching session before calling `WaitNextEvent` or any other routine (such as Window Manager routines) that could draw to the screen. Failing to do so will cause unwanted matching to occur. Furthermore, if a device has color matching enabled, you cannot call the `CopyBits` procedure to copy from it to itself unless the source and destination rectangles are the same.

Even if you call the `NCMBeginMatching` function before calling the QuickDraw `DrawPicture` function, the ColorSync picture comments such as `cmEnableMatching` and `cmDisableMatching` are not acknowledged. For the ColorSync Manager to recognize these comments and allow their use, you must call the function `NCMUseProfileComment` (page 843) for color matching using picture comments.

This function causes matching for the specified devices rather than for the current color graphics port.

The `NCMBeginMatching` function uses QuickDraw and performs color matching in a manner acceptable to most applications. However, if your application needs a finer level of control over color matching, it can use the general purpose functions described in "Matching Colors Using General Purpose Functions".

Version Notes
The parameter descriptions for `src` and `dst` describe changes in how this function is used starting with ColorSync version 2.5.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

NCMDrawMatchedPicture

Matches a picture's colors to a destination device's color gamut, as the picture is drawn, using the specified destination profile. (Deprecated in Mac OS X v10.4.)

```
void NCMDrawMatchedPicture (
   PicHandle myPicture,
   CMProfileRef dst,
   Rect *myRect
);
```

Parameters

myPicture

The QuickDraw picture whose colors are to be matched. See the QuickDraw Reference for a description of the PixMap data type.

dst

A profile reference of type `CMProfileRef` (page 925) to the profile of the destination device. Starting with ColorSync version 2.5, if you know the destination display device, you can call `CMGetProfileByAVID` (page 767) to get the specific profile for the display, or you can call `CMGetDefaultProfileBySpace` (page 752) to get the default profile for the RGB color space,.

With any version of ColorSync, you can specify a `NULL` value to indicate the ColorSync system profile. Note, however, that starting with version 2.5, use of the system profile has changed.

See the QuickDraw Reference for a description of the PixMap data type.

myRect

A pointer to a destination rectangle for rendering the picture specified by `myPicture`.

Return Value
This function does not return an error value. Instead, after calling `NCMDrawMatchedPicture` you call the `QDError` routine to determine if an error has occurred.

Discussion
The `NCMDrawMatchedPicture` function operates in the context of the current color graphics port. This function sets up and takes down a color-matching session. It automatically matches all colors in a picture to the destination profile for a destination device as the picture is drawn. It uses the ColorSync system profile as the initial source profile and any embedded profiles as they are encountered thereafter. (Because color-matching picture comments embedded in the picture to be matched are recognized, embedded profiles are used.)

The ColorSync Manager defines five picture comment kinds, as described in "Picture Comment Kinds" (page 995). For embedding to work correctly, each embedded profile that is used for matching must be terminated by a picture comment of kind `cmEndProfile`. If a picture comment is not specified to end the profile after drawing operations using that profile are performed, the profile will remain in effect until another embedded profile is introduced that has a picture comment kind of `cmBeginProfile`. To avoid unexpected matching effects, always pair use of the `cmBeginProfile` and `cmEndProfile` picture comments. When the ColorSync Manager encounters a `cmEndProfile` picture comment, it restores use of the system profile for matching until it encounters another `cmBeginProfile` picture comment.

The picture is drawn with matched colors to all screen graphics devices. If the current graphics device is not a screen device, matching occurs for that graphics device only.

If the current port is not a color graphics port, then calling this function is equivalent to calling `DrawPicture`, in which case no color matching occurs.

Version Notes
The parameter description for `dst` describes changes in how this function is used starting with ColorSync version 2.5.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`QuickdrawAPI.h`

NCMGetProfileLocation

Obtains either a profile location structure for a specified profile or the size of the location structure for the profile.

```
CMError NCMGetProfileLocation (
   CMProfileRef prof,
   CMProfileLocation *theProfile,
   UInt32 *locationSize
);
```

Parameters

prof

A profile reference of type `CMProfileRef` (page 925). Before calling `NCMGetProfileLocation`, you set the reference to specify the profile for which you wish to obtain the location or location structure size.

theProfile

A pointer to a profile location structure, as described in `CMProfileLocation` (page 924). If you pass `NULL`, `NCMGetProfileLocation` returns the size of the profile location structure for the profile specified by `prof` in the `locationSize` parameter. If you instead pass a pointer to memory you have allocated for the structure, on return, the structure specifies the location of the profile specified by `prof`.

locationSize

A pointer to a value of type `long`. If you pass `NULL` for the `profLoc` parameter, on return, `locationSize` contains the size in bytes of the profile location structure for the profile specified by `prof`. If you pass a pointer to a profile location structure in `profLoc`, set `locationSize` to the size of the structure before calling `NCMGetProfileLocation`, using the constant `cmCurrentProfileLocationSize`.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
The `NCMGetProfileLocation` function is available starting with ColorSync version 2.5. It differs from its predecessor, `CMGetProfileLocation` (page 770), in that the newer version has a parameter for the size of the location structure for the specified profile.

You should use `NCMGetProfileLocation` rather than `CMGetProfileLocation` for the following reasons:

- Code using the older version (`CMGetProfileLocation`) may not be as easily ported to other platforms.
- Specifying the size of the profile location structure ensures that it can grow, if necessary, in the future.

The best way to use `NCMGetProfileLocation` is to call it twice:

1. Pass a reference to the profile to locate in the `prof` parameter and `NULL` for the `profLoc` parameter. `NCMGetProfileLocation` returns the size of the location structure in the `locationSize` parameter.
2. Allocate enough space for a structure of the returned size, then call the function again, passing a pointer in the `profLoc` parameter; on return, the structure specifies the location of the profile.

It is possible to call `NCMGetProfileLocation` just once, using the constant `cmCurrentProfileLocationSize` for the size of the allocated profile location structure and passing the same constant for the `locationSize` parameter. The constant `cmCurrentProfileLocationSize` may change in the future, but will be consistent within the set of headers you build your application with. However, if the size of the `CMProfileLocation` structure changes in a future version of ColorSync (and the value of `cmCurrentProfileLocationSize` as well) and you do not rebuild your application, `NCMGetProfileLocation` may return an error.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.5 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`CMApplication.h`

NCMSetSystemProfile

Sets the location of a color profile. (Deprecated in Mac OS X v10.5.)

```
CMError NCMSetSystemProfile (
   const CMProfileLocation *profLoc
);
```

Parameters

profLoc
The location of the profile. Commonly a profile is disk-file based. However, the profile may be a file-based profile, a handle-based profile, or a pointer-based profile.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
Prior to ColorSync 2.6, the function for setting the system profile supported only the `FSSpec` file specification type as a way of specifying a profile. This function allows for greater flexibility when specifying a system profile.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.6 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`CMApplication.h`

NCMUnflattenProfile

Unflattens a previouslyflattened profile. (Deprecated in Mac OS X v10.5.)

```
CMError NCMUnflattenProfile (
   CMProfileLocation *targetLocation,
   CMFlattenUPP proc,
   void *refCon,
   Boolean *preferredCMMnotfound
);
```

Parameters

targetLocation
The location of the profile you want to unflatten. Commonly a profile is disk-file based. However, the profile may be a file-based profile, a handle-based profile, or a pointer-based profile.

proc
A user-defined procedure which is called during the unflatten operation.

refCon
A reference constant containing data specified by the calling application program.

preferredCMMnotfound
A return value indicating whether or not the CMM specified in the profile was found.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.6 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`CMApplication.h`

NCMUseProfileComment

Automatically embeds a profile or a profile identifier into an open picture. (Deprecated in Mac OS X v10.4.)

```
CMError NCMUseProfileComment (
   CMProfileRef prof,
   UInt32 flags
);
```

Parameters

prof

A profile reference of type `CMProfileRef` (page 925) to the profile to embed. See the QuickDraw Reference for a description of the PixMap data type.

flags

A flag value in which individual bits determine settings. "Embedded Profile Identifiers" (page 982) describes constants for use with this parameter. For example, you pass `cmEmbedWholeProfile` to embed a whole profile or `cmEmbedProfileIdentifier` to embed a profile identifier. No other values are currently defined; all other bits are reserved for future use.

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion

The `NCMUseProfileComment` function automatically generates the picture comments required to embed the specified profile or profile identifier into the open picture.

To embed a profile, you use the constant `cmEmbedWholeProfile` to set the `flags` parameter before calling `NCMUseProfileComment`. The `NCMUseProfileComment` function calls the QuickDraw `PicComment` function with a picture comment `kind` value of `cmComment` and a 4-byte selector that describes the type of data in the picture comment: `cmBeginProfileSel` to begin the profile, `cmContinueProfileSel` to continue, and `cmEndProfileSel` to end the profile. These constants are described in "Picture Comment Selectors" (page 997).

If the size in bytes of the profile and the 4-byte selector together exceed 32 KB, this function segments the profile data and embeds the multiple segments in consecutive order using selector `cmContinueProfileSel` to embed each segment.

To embed a profile identifier of type `CMProfileIdentifier` (page 921) , you use the constant `cmEmbedProfileIdentifier` to set the `flags` parameter before calling `NCMUseProfileComment`. The function extracts the necessary information from the profile reference (`prof`) to embed a profile identifier for the profile. The profile reference can refer to a previously embedded profile, or to a profile on disk in the ColorSync Profiles folder.

You can use this function to embed most types of profiles in an image, including device link profiles, but not abstract profiles. You cannot use this function to embed ColorSync 1.0 profiles in an image.

The `NCMUseProfileComment` function precedes the profile it embeds with a picture comment of kind `cmBeginProfile`. For embedding to work correctly, the currently effective profile must be terminated by a picture comment of kind `cmEndProfile` after drawing operations using that profile are performed. You are responsible for adding the picture comment of kind `cmEndProfile`. If a picture comment was not specified to end the profile following the drawing operations to which the profile applies, the profile will remain in effect until the next embedded profile is introduced with a picture comment of kind `cmBeginProfile`. However, use of the next profile might not be the intended action. Always pair use of the `cmBeginProfile` and `cmEndProfile` picture comments. When the ColorSync Manager encounters a `cmEndProfile` picture comment, it restores use of the system profile for matching until it encounters another `cmBeginProfile` picture comment.

Version Notes

In ColorSync 2.0, the `flags` parameter was ignored and the routine always embedded the entire profile.

In ColorSync 2.0, if the `prof` parameter refers to a version 1.0 profile, the profile is not embedded into the picture correctly. In ColorSync versions starting with 2.1, this bug has been fixed. One possible workaround for this problem in ColorSync 2.0 is to call `CMCopyProfile` to copy the 1.0 profile reference into a handle. The handle can then be embedded into the picture using `CMUseProfileComment`.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

`QuickdrawAPI.h`

NCWConcatColorWorld

Defines a color world for color transformations among a series of concatenated profiles.

```
CMError NCWConcatColorWorld (
   CMWorldRef *cw,
   NCMConcatProfileSet *profileSet,
   CMConcatCallBackUPP proc,
   void *refCon
);
```

Parameters

cw
A reference to a color world that the ColorSync Manager returns if the function completes successfully. You pass this reference to other functions that use the color world for color-matching and color-checking sessions.

profileSet
An array of profiles describing the processing to be carried out. The array is in processing order source through destination.

proc
A calling-program-supplied callback function that allows your application to monitor progress or abort the operation.

refCon
A reference constant containing data specified by the calling application program.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
The caller can override the color management module (CMM) that would normally be selected by ColorSync by providing a CMM identifier in the `NCMConcatProfileSet` structure, or pass 0 to accept ColorSync's CMM selection (note that this could either be the user's preferred CMM selection or the CMM called for in the profile). The *flags* and k parameters are provided to allow easy customization of such attributes as quality and gamut-checking, while preserving the other settings. Each profile in the set can be customized by overriding the intent, and the selection of the transform tag. Together with other profiles, a custom-rendering environment can be set up to transform to or from device-dependent spaces with a minimum of gamut compression and/or unnecessary transformations to and from connection spaces. This flexibility comes at the price of specific knowledge of the profile contents and how device gamuts overlap.

Note that for standard input and output device profiles, A2B and B2A tags represent transforms from data space to connection space and from connection space to data space, respectively. Under these circumstances, the caller would not normally be able to use the same transform tags (e.g., `kUseAtoB`) consecutively, since a connection space would not be the same as the subsequent data space. If the spaces aren't the same, the caller will get `a cmCantConcatenateError` error returned. For profiles of type `cmLinkClass`, `cmAbstractClass`, `cmColorSpaceClass` , and `cmNamedColorClass` , these constants are not always meaningful, and the caller is encouraged to think in terms of the actual tags present in the profiles (e.g., A2B0 or B2A0). Under these conditions, it may well be appropriate to specify two transform tags of the same type consecutively, as long as the actual color spaces align in between tags. If this is not the case, a `cmCantConcatenateError` error is returned.

The callback proc is provided as protection against the appearance of a stalled machine during lengthy color world processing. If a CMM takes more than several seconds to process the information and create a color world, it will call the callback proc, if one is provided, and pass it the `refCon` provided. This is also true for `NCWNewLinkProfile`.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.6 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`CMApplication.h`

NCWNewColorWorld

Creates a color world for color matching based on the specified source and destination profiles.

```
CMError NCWNewColorWorld (
   CMWorldRef *cw,
   CMProfileRef src,
   CMProfileRef dst
);
```

Parameters

cw

A pointer to a color world. On return, a reference to a matching session color world of type `CMWorldRef` (page 942). You pass this reference to other functions that use the color world.

src

A profile reference of type `CMProfileRef` (page 925) that specifies the source profile for the color-matching world. This profile's `dataColorSpace` element corresponds to the source data type for subsequent calls to functions that use this color world.

Starting with ColorSync version 2.5, you can call `CMGetDefaultProfileBySpace` (page 752) to get the default profile for a specific color space or `CMGetProfileByAVID` (page 767) to get a profile for a specific display.

With any version of ColorSync, you can specify a `NULL` value to indicate the ColorSync system profile. Note, however, that starting with version 2.5, use of the system profile has changed.

dst

A profile reference of type `CMProfileRef` (page 925) that specifies the destination profile for the color-matching world. This profile's `dataColorSpace` element corresponds to the destination data type for subsequent calls to functions using this color world.

Starting with ColorSync version 2.5, you can call `CMGetDefaultProfileBySpace` (page 752) to get the default profile for a specific color space or `CMGetProfileByAVID` (page 767) to get a profile for a specific display.

With any version of ColorSync, you can specify a `NULL` value to indicate the ColorSync system profile. Note, however, that starting with version 2.5, use of the system profile has changed.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
You must set up a color world before your application can perform general purpose color-matching or color-checking operations. To set up a color world for these operations, your application can call `NCWNewColorWorld` after obtaining references to the profiles to use as the source and destination profiles for the color world. The following rules govern the types of profiles allowed:

- You can specify a device profile or a color space conversion profile for the source and destination profiles.
- You can not specify a device link profile or an abstract profile for either the source profile or the destination profile.
- Only one profile can be a named color profile.
- You can specify the system profile explicitly by reference or by giving `NULL` for either the source profile or the destination profile.

You should call the function `CMCloseProfile` (page 728) for both the source and destination profiles to dispose of their references after execution of the `NCWNewColorWorld` function.

The quality flag setting (indicating normal mode, draft mode, or best mode) specified by the source profile prevails for the entire session. The quality flag setting is stored in the `flags` field of the profile header. See `CM2Header` (page 875) and "Flag Mask Definitions for Version 2.x Profiles" (page 983) for more information on the use of flags. The rendering intent specified by the source profile also prevails for the entire session.

The function `CWConcatColorWorld` (page 823) also allocates a color world reference of type `CMWorldRef` (page 942).

Version Notes
The parameter descriptions for `src` and `dst` describe changes in how this functions is used starting with ColorSync version 2.5.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`CMApplication.h`

NCWNewLinkProfile

Obtains a profile reference for the specified by the profile location.

```
CMError NCWNewLinkProfile (
   CMProfileRef *prof,
   const CMProfileLocation *targetLocation,
   NCMConcatProfileSet *profileSet,
   CMConcatCallBackUPP proc,
   void *refCon
);
```

Parameters

prof
The returned profile reference.

targetLocation
The location of the profile. Commonly a profile is disk-file based. However, the profile may be a file-based profile, a handle-based profile, or a pointer-based profile.

profileSet
A pointer to the profile set structure.

proc
A calling-program-supplied callback function that allows your application to monitor progress or abort the operation.

refCon
A reference constant containing data specified by the calling application program.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Discussion
The same new flexibility in creating color worlds is extended to link profiles, which are not assumed to go from input device color space to output device color space. The returned profile is open, and should be closed when you are finished with it.

Availability
Available in CarbonLib 1.0 and later when ColorSync 2.6 or later is present.
Available in Mac OS X 10.0 and later.

`CMApplication.h`

NewCMBitmapCallBackUPP

Creates a new universal procedure pointer (UPP) to a bitmap callback. (Deprecated in Mac OS X v10.5.)

```
CMBitmapCallBackUPP NewCMBitmapCallBackUPP (
   CMBitmapCallBackProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your bitmap callback function.

Return Value
The universal procedure pointer.

Availability
Available in CarbonLib 1.0 and later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.5.

Declared In
`CMTypes.h`

NewCMConcatCallBackUPP

Creates a new universal procedure pointer (UPP) to a progress-monitoring callback. (Deprecated in Mac OS X v10.5.)

```
CMConcatCallBackUPP NewCMConcatCallBackUPP (
   CMConcatCallBackProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your progress-monitoring callback function.

Return Value
The universal procedure pointer.

Discussion
The callback protects against the appearance of a stalled machine during lengthy color world processing. If a CMM takes more than several seconds to process the information and create a color world, it will call the callback, if one is provided, and pass it the `refCon` provided. Passed to the functions `NCWNewLinkProfile` or `NCWConcatColorWorld` function .

Availability

   CMMIterateProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your progress-monitoring callback function.

Return Value

The universal procedure pointer.

Availability

Available in CarbonLib 1.0 and later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.5.

Declared In

`CMApplication.h`

NewCMProfileAccessUPP

Creates a new universal procedure pointer (UPP) to a profile-access callback. (Deprecated in Mac OS X v10.5.)

```
CMProfileAccessUPP NewCMProfileAccessUPP (
   CMProfileAccessProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your profile-access callback function.

Return Value
The universal procedure pointer.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`CMTypes.h`

NewCMProfileFilterUPP

Creates a new universal procedure pointer (UPP) to a profile-filter callback. (Deprecated in Mac OS X v10.5.)

```
CMProfileFilterUPP NewCMProfileFilterUPP (
   CMProfileFilterProcPtr userRoutine
);
```

Parameters
userRoutine
A pointer to your profile-filter callback function.

Return Value
The universal procedure pointer.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`CMTypes.h`

NewCMProfileIterateUPP

Creates a new universal procedure pointer (UPP) to a profile-iteration callback. (Deprecated in Mac OS X v10.5.)

```
CMProfileIterateUPP NewCMProfileIterateUPP (
   CMProfileIterateProcPtr userRoutine
);
```

Parameters
userRoutine
A pointer to your profile-iteration callback function.

Return Value
The universal procedure pointer.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In
`CMApplication.h`

Callbacks

CMBitmapCallBackProcPtr

Defines a pointer to a bitmap callback function that function reports on the progress of a color-matching or color-checking session being performed for a bitmap or a pixel map.

```
typedef Boolean (*MyCMBitmapCallBackProc)
(
    SInt16 progress,
    void * refCon
);
);
```

If you name your function `MyCMBitmapCallBackProc`, you would declare it like this:

```
Boolean MyCMBitmapCallBackProc (
    SInt16 progress,
    void * refCon
);
```

Parameters

progress

A byte count that begins at an arbitrary value when the function is first called. On each subsequent call, the value is decremented by an amount that can vary from call to call, but that reflects how much of the matching process has completed since the previous call. If the function is called at all, it will be called a final time with a byte count of 0 when the matching is complete.

refCon

The pointer to a reference constant passed to your `MyCMBitmapCallBack` function each time the color management module (CMM) calls your function.

Return Value
`False` indicates the color-matching or color-checking session should continue. `True` indicates the session should be aborted—for example, the user may be holding down the Command–period keys.

Discussion
Your `MyCMBitmapCallBack` function allows your application to monitor the progress of a color-matching or color-checking session for a bitmap or a pixel map. Your function can also terminate the matching or checking operation.

Your callback function is called by the CMM performing the matching or checking process if your application passes a pointer to your callback function in the `progressProc` parameter when it calls one of the following functions: `CWCheckBitmap` (page 819) , `CWMatchBitmap` (page 826) , `CWCheckPixMap` (page 822) , and `CWMatchPixMap` (page 829). Note that your callback function may not be called at all if the operation completes in a very short period.

The CMM used for the color-matching session calls your function at regular intervals. For example, the default CMM calls your function approximately every half-second unless the color matching or checking occurs in less time; this happens when there is a small amount of data to match or check.

Each time the ColorSync Manager calls your function, it passes to the function any data stored in the reference constant. This is the data that your application specified in the `refCon` parameter when it called one of the color-matching or checking functions.

For large bitmaps and pixel maps, your application can display a progress bar or other indicator to show how much of the operation has been completed. You might, for example, use the reference constant to pass to the callback function a window reference to a dialog box. You obtain information on how much of the operation has completed from the `progress` parameter. The first time your callback is called, this parameter contains an arbitrary byte count. On each subsequent call, the value is decremented by an amount that can vary from call to call, but that reflects how much of the matching process has completed since the previous call. Using the current value and the original value, you can determine the percentage that has completed. If the callback function is called at all, it will be called a final time with a byte count of 0 when the matching is complete.

To terminate the matching or checking operation, your function should return a value of `true`. Because pixel-map matching is done in place, an application that allows the user to terminate the process should revert to the prematched image to avoid partial mapping.

For bitmap matching, if the `matchedBitMap` parameter of the `CWMatchBitmap` function specifies `NULL`, to indicate that the source bitmap is to be matched in place, and the application allows the user to abort the process, you should also revert to the prematched bitmap if the user terminates the operation.

Each time the ColorSync Manager calls your progress function, it passes a byte count in the `progress` parameter. The last time the ColorSync Manager calls your progress function, it passes a byte count of 0 to indicate the completion of the matching or checking process. You should use the 0 byte count as a signal to perform any cleanup operations your function requires, such as filling the progress bar to completion to indicate to the user the end of the checking or matching session, and then removing the dialog box used for the display.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CMTypes.h`

CMConcatCallBackProcPtr

Defines a pointer to a progress-monitoring function that the ColorSync Manager calls during lengthy color world processing.

```
typedef Boolean (*CMConcatCallBackProcPtr)
(
    SInt32 progress,
    void *refCon
);
```

If you name your function `MyCMConcatCallBackProc`, you would declare it like this:

```
Boolean MyCMConcatCallBackProc (
    SInt32 progress,
    void *refCon
);
```

Parameters

progress

refCon

Discussion
If a CMM takes more than several seconds to process the information and create a color world, it will call the Callback proc, if one is provided, and pass it the refCon provided

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CMTypes.h`

CMCountImageProfilesProcPtr

Defines a pointer to a function that obtains a count of the number of embeded profiles for a given image..

```
typedef CMError (*CMCountImageProfilesProcPtr)
(
    const FSSpec * spec,
    UInt32 * count
);
```

If you name your function `MyCMCountImageProfilesProc`, you would declare it like this:

```
CMError MyCMCountImageProfilesProc (
    const FSSpec * spec,
    UInt32 * count
);
```

Parameters

spec

See the File Manager documentation for a description of the `FSSpec` data type.

count

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Availability
Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared In
`CMScriptingPlugin.h`

CMEmbedImageProcPtr

Defines a pointer to a function that embeds an image with an ICC profile..

```
typedef CMError (*CMEmbedImageProcPtr)
(
    const FSSpec * specFrom,
    const FSSpec * specInto,
    Boolean repl,
    CMProfileRef embProf
);
```

If you name your function `MyCMEmbedImageProc`, you would declare it like this:

```
CMError MyCMEmbedImageProc (
    const FSSpec * specFrom,
    const FSSpec * specInto,
    Boolean repl,
    CMProfileRef embProf
);
```

Parameters

specFrom
See the File Manager documentation for a description of the `FSSpec` data type.

specInto
See the File Manager documentation for a description of the `FSSpec` data type.

repl

embProf

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Availability
Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared In
`CMScriptingPlugin.h`

CMFlattenProcPtr

Defines a pointer to a data transfer callback function that transfers profile data from the format for embedded profiles to disk file format or vice versa.

```
typedef OSErr (*CMFlattenProcPtr) (
    SInt32 command,
    SInt32 *size,
    void *data,
    void *refCon
);
```

If you name your function `MyCMFlattenProc`, you would declare it like this:

```
OSErr MyCMFlattenProc (
    SInt32 command,
    SInt32 *size,
    void *data,
    void *refCon
);
```

Parameters

command

The command with which the `MyCMFlattenCallback` function is called. This command specifies the operation the function is to perform.

size

A pointer to a size value. On input, the size in bytes of the data to transfer. On return, the size of the data actually transferred.

data

A pointer to the buffer supplied by the ColorSync Manager to use for the data transfer.

refCon

A pointer to a reference constant that holds the application data passed in from the functions `CMFlattenProfile` (page 748), `NCMUnflattenProfile` (page 843), `CMGetPS2ColorRenderingVMSize` (page 775), `CMGetPS2ColorRenderingIntent` (page 774), or `CMFlattenProfile` (page 748). Each time the CMM calls your `MyCMFlattenCallback` function, it passes this data to the function.

Starting in ColorSync version 2.5, the ColorSync Manager calls your function directly, without going through the preferred, or any, CMM.

Return Value

A result code. See "ColorSync Manager Result Codes" (page 1020).

Discussion

IThis callback can be used, for example, by PostScript functions to transfer data from a profile to text format usable by a PostScript driver. Starting in ColorSync version 2.5, the ColorSync Manager calls your data transfer function directly, without going through the preferred, or any, CMM. So any references to the CMM in the discussion that follows are applicable only to versions of ColorSync prior to version 2.5. Where the discussion does not involve CMMs, it is applicable to all versions of ColorSync.

Your `MyCMFlattenCallback` function is called to flatten and unflatten profiles or to transfer PostScript-related data from a profile to the PostScript format to send to an application or device driver.

The ColorSync Manager and the CMM communicate with the `MyCMFlattenCallback` function using the command parameter to identify the operation to perform. To read and write profile data, your function must support the following commands: `cmOpenReadSpool`, `cmOpenWriteSpool`, `cmReadSpool`, `cmWriteSpool`, and `cmCloseSpool`.

You determine the behavior of your `MyCMFlattenCallback` function. The following sections describe how your function might handle the flattening and unflattening processes.

Flattening a Profile:

The ColorSync Manager calls the specified profile's preferred CMM when an application calls the `CMFlattenProfile` function to transfer profile data embedded in a graphics document.

The ColorSync Manager determines if the CMM supports the `CMFlattenProfile` function. If so, the ColorSync Manager dispatches the `CMFlattenProfile` function to the CMM. If not, ColorSync calls the default CMM, dispatching the `CMFlattenProfile` function to it.

The CMM communicates with the `MyCMFlattenCallback` function using a command parameter to identify the operation to perform. The CMM calls your function as often as necessary, passing to it on each call any data transferred to the CMM from the `CMFlattenProfile` function's `refCon` parameter.

The ColorSync Manager calls your function with the following sequence of commands: `cmOpenWriteSpool`, `cmWriteSpool`, and `cmCloseSpool`. Here is how you should handle these commands:

- When the CMM calls your function with the `cmOpenWriteSpool` command, you should perform any initialization required to write profile data you receive from the CMM to a buffer or file.
- The CMM will call your function with the `cmWriteSpool` command as many times as necessary to transfer all the profile data to you. Each time you are called, you should receive the data and write it to your buffer or file, returning in the `size` parameter the number of bytes of data you actually accepted.
- When the CMM calls your function with the `cmCloseSpool` command, you should perform any required cleanup processes.

As part of this process, your function can embed the profile data in a graphics document, for example, a PICT file or a TIFF file. For example, your `MyCMFlattenCallback` function can call the QuickDraw `PicComment` function to embed the flattened profile in a picture.

Unflattening a Profile:

When an application calls the `CMUnflattenProfile` function to transfer a profile that is embedded in a graphics document to an independent disk file, the ColorSync Manager calls your `MyCMFlattenCallback` function with the following sequence of commands: `cmOpenReadSpool`, `cmReadSpool`, `cmCloseSpool`. Here is how you should handle these commands:

- When the ColorSync Manager calls your function with the `cmOpenReadSpool` command, you should perform any initialization required to read from the embedded profile format.
- The ColorSync Manager calls your function with the `cmReadSpool` command as many times as necessary, directing your function to extract the profile data from the embedded format in the image file and return it to the ColorSync Manager in the `data` buffer. For each call, the ColorSync Manager specifies in the `size` parameter the number of bytes of data you should return. Each time your function is called it should read and return the requested data; it should also specify in the `size` parameter the actual number of bytes of data it returns.
- When the ColorSync Manager calls your function with the `cmCloseSpool` command, you should perform any required cleanup processes.

Version Notes
Starting in ColorSync version 2.5, the ColorSync Manager calls your function directly, without going through the preferred, or any, CMM.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CMTypes.h`

CMGetImageSpaceProcPtr

Defines a pointer to a function that obtains the signature of the data color space in which the color values of colors in an image are expressed.

```
typedef CMError (*CMGetImageSpaceProcPtr)
(
    const FSSpec * spec,
    OSType * space
);
```

If you name your function `MyCMGetImageSpaceProc`, you would declare it like this:

```
CMError MyCMGetImageSpaceProc (
    const FSSpec * spec,
    OSType * space
);
```

Parameters

spec

See the File Manager documentation for a description of the `FSSpec` data type.

space

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Availability
Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared In
`CMScriptingPlugin.h`

CMGetIndImageProfileProcPtr

Defines a pointer to a function that obtains a specific embeded profile for a given image.

```
typedef CMError (*CMGetIndImageProfileProcPtr)
(
    const FSSpec * spec,
    UInt32 index,
    CMProfileRef * prof
);
```

If you name your function `MyCMGetIndImageProfileProc`, you would declare it like this:

```
CMError MyCMGetIndImageProfileProc (
    const FSSpec * spec,
    UInt32 index,
```

```
    CMProfileRef * prof
);
```

Parameters

spec

See the File Manager documentation for a description of the `FSSpec` data type.

index

prof

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Availability
Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared In
`CMScriptingPlugin.h`

CMIterateDeviceInfoProcPtr

Defines a pointer to a function that iterates through device information available on the system.

```
typedef OSErr (*CMIterateDeviceInfoProcPtr)
(
    const CMDeviceInfo * deviceInfo,
    void * refCon
);
```

If you name your function `MyCMIterateDeviceInfoProc`, you would declare it like this:

```
OSErr MyCMIterateDeviceInfoProc (
    const CMDeviceInfo * deviceInfo,
    void * refCon
);
```

Parameters

deviceData

refCon

Return Value
An `OSErr` value.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CMDeviceIntegration.h`

CMIterateDeviceProfileProcPtr

Defines a pointer to a function that iterates through the device profiles available on the system.

```
typedef OSErr (*CMIterateDeviceProfileProcPtr)
(
    const CMDeviceInfo * deviceInfo,
    const NCMDeviceProfileInfo * profileInfo,
    void * refCon
);
```

If you name your function `MyCMIterateDeviceProfileProc`, you would declare it like this:

```
OSErr MyCMIterateDeviceProfileProc (
    const CMDeviceInfo * deviceInfo,
    const NCMDeviceProfileInfo * profileInfo,
    void * refCon
);
```

Parameters

deviceData

profileData

refCon

Return Value
An `OSErr` value.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CMDeviceIntegration.h`

CMLinkImageProcPtr

Defines a pointer to a function that matches an image file with a device link profile.

```
typedef CMError (*CMLinkImageProcPtr)
(
    const FSSpec * specFrom,
    const FSSpec * specInto,
    Boolean repl,
    UInt32 qual,
    CMProfileRef lnkProf,
    UInt32 lnkIntent
);
```

If you name your function `MyCMLinkImageProc`, you would declare it like this:

```
CMError MyCMLinkImageProc (
    const FSSpec * specFrom,
    const FSSpec * specInto,
    Boolean repl,
    UInt32 qual,
    CMProfileRef lnkProf,
    UInt32 lnkIntent
);
```

Parameters

specFrom

See the File Manager documentation for a description of the `FSSpec` data type.

specInto

See the File Manager documentation for a description of the `FSSpec` data type.

repl

qual

lnkProf

lnkIntent

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Availability

Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared In

`CMScriptingPlugin.h`

CMMatchImageProcPtr

Defines a pointer to a function that color matches an image file.

```
typedef CMError (*CMMatchImageProcPtr)
(
    const FSSpec * specFrom,
    const FSSpec * specInto,
    Boolean repl,
    UInt32 qual,
    CMProfileRef srcProf,
    UInt32 srcIntent,
    CMProfileRef dstProf
);
```

If you name your function `MyCMMatchImageProc`, you would declare it like this:

```
CMError MyCMMatchImageProc (
    const FSSpec * specFrom,
    const FSSpec * specInto,
    Boolean repl,
    UInt32 qual,
    CMProfileRef srcProf,
    UInt32 srcIntent,
    CMProfileRef dstProf
);
```

Parameters

specFrom

See the File Manager documentation for a description of the `FSSpec` data type.

specInto

See the File Manager documentation for a description of the `FSSpec` data type.

repl
qual
srcProf
srcIntent
dstProf

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Availability
Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared In
`CMScriptingPlugin.h`

CMMIterateProcPtr

Defines a pointer to a function that iterates through color management modules installed on the system.

```
typedef OSErr (*CMMIterateProcPtr) (
    CMMInfo * iterateData,
    void * refCon
);
```

If you name your function `MyCMMIterateProc`, you would declare it like this:

```
OSErr MyCMMIterateProc (
    CMMInfo * iterateData,
    void * refCon
);
```

Parameters
iterateData
refCon

Return Value
An `OSErr` value.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CMApplication.h`

CMProfileAccessProcPtr

Defines a pointer to a profile access callback function that provides procedure-based access to a profile.

```
typedef OSErr (*CMProfileAccessProcPtr)
(
    SInt32 command,
    SInt32 offset,
    SInt32 *size,
    void *data,
    void *refCon
);
```

If you name your function `MyCMProfileAccessProc`, you would declare it like this:

```
OSErr MyCMProfileAccessProc (
    SInt32 command,
    SInt32 offset,
    SInt32 *size,
    void *data,
    void *refCon
);
```

Parameters

command

A command value indicating the operation to perform. Operation constants are described in "Profile Access Procedures" (page 998).

offset

For read and write operations, the offset from the beginning of the profile at which to read or write data.

size

A pointer to a size value. On input, for the `cmReadAccess` and `cmWriteAccess` command constants, a pointer to a value indicating the number of bytes to read or write; for the `cmOpenWriteAccess` command, the total size of the profile. On return, after reading or writing, the actual number of bytes read or written.

data

A pointer to a buffer containing data to read or write. On return, for a read operation, contains the data that was read.

refCon

A reference constant pointer that can store private data for the `CMProfileAccessCallback` function.

Return Value

An `OSErr` value.

Discussion

When your application calls the `CMOpenProfile`, `CMNewProfile`, `CMCopyProfile`, or `CMNewLinkProfile` functions, it may supply the ColorSync Manager with a profile location structure of type `CMProfileLocation` (page 924) that specifies a procedure that provides access to a profile. In the structure, you provide a universal procedure pointer to a profile access procedure supplied by you and, optionally, a pointer to data your procedure can use. The ColorSync Manager calls your procedure when the profile is created, initialized, opened, read, updated, or closed.

When the ColorSync Manager calls your profile access procedure, it passes a constant indicating the operation to perform. The operations include creating a new profile, reading from the profile, writing the profile, and so on. Operation constants are described in "Profile Access Procedures" (page 998). Your procedure must be able to respond to each of these constants.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
CMTypes.h

CMProfileFilterProcPtr

Defines a pointer to a profile filter callback function that examines the profile whose reference you specify and determines whether to include it in the profile search result list.

```
typedef Boolean (*CMProfileFilterProcPtr)
(
    CMProfileRef prof,
    void * refCon
);
```

If you name your function MyCMProfileFilterProc, you would declare it like this:

```
Boolean MyCMProfileFilterProc (
    CMProfileRef prof,
    void * refCon
);
```

Parameters

prof

A profile reference of type CMProfileRef (page 925) to the profile to test.

refCon

A pointer to a reference constant that holds data passed through from the CMNewProfileSearch function or the CMUpdateProfileSearch function.

Return Value
A value of false indicates that the profile should be included; true indicates that the profile should be filtered out.

Discussion
Your MyCMProfileFilterCallback function is called after the CMNewProfileSearch function searches for profiles based on the search record's contents as specified by the search bitmask.

When your application calls CMNewProfileSearch, it passes a reference to a search specification record of type CMSearchRecord of type CMSearchRecord (page 932) that contains a filter field. If the filter field contains a pointer to your MyCMProfileFilterCallback function, then your function is called to determine whether to exclude a profile from the search result list. Your function should return true for a given profile to exclude that profile from the search result list. If you do not want to filter profiles beyond the criteria in the search record, specify a NULL value for the search record's filter field.

After a profile has been included in the profile search result based on criteria specified in the search record, your MyCMProfileFilterCallback function can further examine the profile. For example, you may wish to include or exclude the profile based on criteria such as an element or elements not included in the CMSearchRecord search record. Your MyCMProfileFilterCallback function can also perform searching using AND or OR logic.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
CMTypes.h

CMProfileIterateProcPtr

Defines a pointer to a profile iteration callback function that the ColorSync Manager calls for each found profile file as it iterates over the available profiles.

```
typedef OSErr (*CMProfileIterateProcPtr)
(
    CMProfileIterateData * iterateData,
    void * refCon
);
```

If you name your function `MyCMProfileIterateProc`, you would declare it like this:

```
OSErr MyCMProfileIterateProc (
    CMProfileIterateData * iterateData,
    void * refCon
);
```

Parameters

iterateData

A pointer to a structure of type `CMProfileIterateData` (page 923). When the function `CMIterateColorSyncFolder` (page 780) calls `MyProfileIterateCallback`, as it does once for each found profile, the structure contains key information about the profile.

refCon

An untyped pointer to arbitrary data your application previously passed to the function `CMIterateColorSyncFolder` (page 780).

Return Value
An `OSErr` value. If `MyCMProfileIterateCallback` returns an error, `CMIterateColorSyncFolder` stops iterating and returns the error value to its caller (presumably your code).

Discussion
When your application needs information about the profiles currently available in the profiles folder, it calls the function `CMIterateColorSyncFolder` (page 780) , which, depending on certain conditions, calls your callback routine once for each profile. See the description of `CMIterateColorSyncFolder` for information on when it calls the `MyCMProfileIterateCallback` function.

Your `MyCMProfileIterateCallback` function examines the structure pointed to by the `iterateData` parameter to obtain information about the profile it describes. The function determines whether to do anything with that profile, such as list its name in a pop-up menu of available profiles.

Availability
Available in Mac OS X v10.0 and later.

Declared In
CMApplication.h

CMProofImageProcPtr

Defines a pointer to a function that proofs an image.

```
typedef CMError (*CMProofImageProcPtr)
(
    const FSSpec * specFrom,
    const FSSpec * specInto,
    Boolean repl,
    UInt32 qual,
    CMProfileRef srcProf,
    UInt32 srcIntent,
    CMProfileRef dstProf,
    CMProfileRef prfProf
);
```

If you name your function `MyCMProofImageProc`, you would declare it like this:

```
CMError MyCMProofImageProc (
    const FSSpec * specFrom,
    const FSSpec * specInto,
    Boolean repl,
    UInt32 qual,
    CMProfileRef srcProf,
    UInt32 srcIntent,
    CMProfileRef dstProf,
    CMProfileRef prfProf
);
```

Parameters

specFrom
See the File Manager documentation for a description of the `FSSpec` data type.

specInto
See the File Manager documentation for a description of the `FSSpec` data type.

repl

qual

srcProf

srcIntent

dstProf

prfProf

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Availability

Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared In

`CMScriptingPlugin.h`

CMSetIndImageProfileProcPtr

Defines a pointer to a function that sets a specific embeded profile for a given image.

```
typedef CMError (*CMSetIndImageProfileProcPtr)
(
    const FSSpec * specFrom,
    const FSSpec * specInto,
    Boolean repl,
    UInt32 index,
    CMProfileRef prof
);
```

If you name your function `MyCMSetIndImageProfileProc`, you would declare it like this:

```
CMError MyCMSetIndImageProfileProc (
    const FSSpec * specFrom,
    const FSSpec * specInto,
    Boolean repl,
    UInt32 index,
    CMProfileRef prof
);
```

Parameters

specFrom

See the File Manager documentation for a description of the `FSSpec` data type.

specInto

See the File Manager documentation for a description of the `FSSpec` data type.

repl

index

prof

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Availability

Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared In

`CMScriptingPlugin.h`

CMUnembedImageProcPtr

Defines a pointer to a function that umembeds an ICC profile from an image.

```
typedef CMError (*CMUnembedImageProcPtr)
(
    const FSSpec * specFrom,
    const FSSpec * specInto,
    Boolean repl
);
```

If you name your function `MyCMUnembedImageProc`, you would declare it like this:

```
CMError MyCMUnembedImageProc (
    const FSSpec * specFrom,
    const FSSpec * specInto,
    Boolean repl
```

```
);
```

Parameters

specFrom

See the File Manager documentation for a description of the `FSSpec` data type.

specInto

See the File Manager documentation for a description of the `FSSpec` data type.

repl

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Availability
Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared In
`CMScriptingPlugin.h`

CMValidImageProcPtr

Defines a pointer to a function that validates a specified image file.

```
typedef CMError (*CMValidImageProcPtr)
(
    const FSSpec * spec
);
```

If you name your function `MyCMValidImageProc`, you would declare it like this:

```
CMError MyCMValidImageProc (
    const FSSpec * spec
);
```

Parameters

spec

See the File Manager documentation for a description of the `FSSpec` data type.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Availability
Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared In
`CMScriptingPlugin.h`

CountImageProfilesProcPtr

Defines a pointer to a function that counts the number of embeded profiles for a given image.

```
typedef CMError (*CountImageProfilesProcPtr)
(
    const FSSpec * spec,
    UInt32 * count
);
```

If you name your function `MyCountImageProfilesProc`, you would declare it like this:

```
CMError MyCountImageProfilesProc (
    const FSSpec * spec,
    UInt32 * count
);
```

Parameters

spec

See the File Manager documentation for a description of the `FSSpec` data type.

count

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Availability

Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared In

`CMScriptingPlugin.h`

EmbedImageProcPtr

Defines a pointer to an embed-image function.

```
typedef CMError (*EmbedImageProcPtr)
(
    const FSSpec * specFrom,
    const FSSpec * specInto,
    CMProfileRef embedProf,
    UInt32 embedFlags
);
```

If you name your function `MyEmbedImageProc`, you would declare it like this:

```
CMError MyEmbedImageProc (
    const FSSpec * specFrom,
    const FSSpec * specInto,
    CMProfileRef embedProf,
    UInt32 embedFlags
);
```

Parameters

specFrom

See the File Manager documentation for a description of the `FSSpec` data type.

specInto

See the File Manager documentation for a description of the `FSSpec` data type.

embedProf
embedFlags

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Availability
Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared In
`CMScriptingPlugin.h`

GetImageSpaceProcPtr

Defines a pointer to a get-image-space function.

```
typedef CMError (*GetImageSpaceProcPtr)
(
    const FSSpec * spec,
    OSType * space
);
```

If you name your function `MyGetImageSpaceProc`, you would declare it like this:

```
CMError MyGetImageSpaceProc (
    const FSSpec * spec,
    OSType * space
);
```

Parameters

spec
See the File Manager documentation for a description of the `FSSpec` data type.

space

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Availability
Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared In
`CMScriptingPlugin.h`

GetIndImageProfileProcPtr

Defines a pointer to a function that obtains a color profile for an individual image..

```
typedef CMError (*GetIndImageProfileProcPtr)
(
    const FSSpec * spec,
    UInt32 index,
    CMProfileRef * prof
);
```

If you name your function `MyGetIndImageProfileProc`, you would declare it like this:

```
CMError MyGetIndImageProfileProc (
    const FSSpec * spec,
    UInt32 index,
    CMProfileRef * prof
);
```

Parameters

spec

See the File Manager documentation for a description of the `FSSpec` data type.

index

prof

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Availability

Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared In

`CMScriptingPlugin.h`

MatchImageProcPtr

Defines a pointer to a match-image function.

```
typedef CMError (*MatchImageProcPtr)
(
    const FSSpec * specFrom,
    const FSSpec * specInto,
    UInt32 qual,
    UInt32 srcIntent,
    CMProfileRef srcProf,
    CMProfileRef dstProf,
    CMProfileRef prfProf,
    UInt32 matchFlags
);
```

If you name your function `MyMatchImageProc`, you would declare it like this:

```
CMError MyMatchImageProc (
    const FSSpec * specFrom,
    const FSSpec * specInto,
    UInt32 qual,
    UInt32 srcIntent,
    CMProfileRef srcProf,
    CMProfileRef dstProf,
```

```
    CMProfileRef prfProf,
    UInt32 matchFlags
);
```

Parameters

specFrom

See the File Manager documentation for a description of the `FSSpec` data type.

specInto

See the File Manager documentation for a description of the `FSSpec` data type.

qual

srcIntent

srcProf

dstProf

prfProf

matchFlags

Return Value

A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Availability

Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared In

`CMScriptingPlugin.h`

SetIndImageProfileProcPtr

Defines a pointer to a function that sets a color profile for an individual image.

```
typedef CMError (*SetIndImageProfileProcPtr)
(
    const FSSpec * specFrom,
    const FSSpec * specInto,
    UInt32 index,
    CMProfileRef prof,
    UInt32 embedFlags
);
```

If you name your function `MySetIndImageProfileProc`, you would declare it like this:

```
CMError MySetIndImageProfileProc (
    const FSSpec * specFrom,
    const FSSpec * specInto,
    UInt32 index,
    CMProfileRef prof,
    UInt32 embedFlags
);
```

Parameters

specFrom

See the File Manager documentation for a description of the `FSSpec` data type.

specInto
See the File Manager documentation for a description of the `FSSpec` data type.

index

prof

embedFlags

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Availability
Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared In
`CMScriptingPlugin.h`

UnembedImageProcPtr

Defines a pointer to an umembed-image function.

```
typedef CMError (*UnembedImageProcPtr)
(
    const FSSpec * specFrom,
    const FSSpec * specInto
);
```

If you name your function `MyUnembedImageProc`, you would declare it like this:

```
CMError MyUnembedImageProc (
    const FSSpec * specFrom,
    const FSSpec * specInto
);
```

Parameters

specFrom
See the File Manager documentation for a description of the `FSSpec` data type.

specInto
See the File Manager documentation for a description of the `FSSpec` data type.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Availability
Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared In
`CMScriptingPlugin.h`

ValidateImageProcPtr

Defines a pointer to a validate-image function.

```
typedef CMError (*ValidateImageProcPtr)
(
    const FSSpec * spec
);
```

If you name your function `MyValidateImageProc`, you would declare it like this:

```
CMError MyValidateImageProc (
    const FSSpec * spec
);
```

Parameters

spec

See the File Manager documentation for a description of the `FSSpec` data type.

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Availability
Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared In
`CMScriptingPlugin.h`

ValidateSpaceProcPtr

Defines a pointer to a validate-space function.

```
typedef CMError (*ValidateSpaceProcPtr)
(
    const FSSpec * spec,
    OSType * space
);
```

If you name your function `MyValidateSpaceProc`, you would declare it like this:

```
CMError MyValidateSpaceProc (
    const FSSpec * spec,
    OSType * space
);
```

Parameters

spec

See the File Manager documentation for a description of the `FSSpec` data type.

space

Return Value
A `CMError` value. See "ColorSync Manager Result Codes" (page 1020).

Availability
Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared In
`CMScriptingPlugin.h`

Data Types

CalibratorInfo

Contains data used to calibrate a display.

```
struct CalibratorInfo {
    UInt32 dataSize;
    CMDisplayIDType displayID;
    UInt32 profileLocationSize;
    CMProfileLocation * profileLocationPtr;
    CalibrateEventUPP eventProc;
    Boolean isGood;
};
typedef struct CalibratorInfo CalibratorInfo;
```

Fields

`dataSize`

`displayID`

`profileLocationSize`

`profileLocationPtr`

`eventProc`

`isGood`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CMCalibrator.h`

CM2Header

Contains information that supports the header format specified by the ICC format specification for version 2.x profiles.

```
struct CM2Header {
    UInt32 size;
    OSType CMMType;
    UInt32 profileVersion;
    OSType profileClass;
    OSType dataColorSpace;
    OSType profileConnectionSpace;
    CMDateTime dateTime;
    OSType CS2profileSignature;
    OSType platform;
    UInt32 flags;
    OSType deviceManufacturer;
    UInt32 deviceModel;
    UInt32 deviceAttributes[2];
    UInt32 renderingIntent;
    CMFixedXYZColor white;
    OSType creator;
    char reserved[44];
};
typedef struct CM2Header CM2Header;
```

Fields

`size`

The total size in bytes of the profile.

`CMMType`

The signature of the preferred CMM for color-matching and color-checking sessions for this profile. To avoid conflicts with other CMMs, this signature must be registered with the ICC. For the signature of the default CMM, see "Default CMM Signature" (page 977).

`profileVersion`

The version of the profile format. The first 8 bits indicate the major version number, followed by 8 bits indicating the minor version number. The following 2 bytes are reserved.

The profile version number is not tied to the version of the ColorSync Manager. Profile formats and their versions are defined by the ICC. For example, a major version change may indicate the addition of new required tags to the profile format; a minor version change may indicate the addition of new optional tags.

`profileClass`

One of the seven profile classes supported by the ICC: input, display, output, named color space, device link, color space conversion, or abstract. For the signatures representing profile classes, see "Profile Classes" (page 999).

`dataColorSpace`

The color space of the profile. Color values used to express colors of images using this profile are specified in this color space. For a list of the color space signatures, see "Color Space Signatures" (page 969).

`profileConnectionSpace`

The profile connection space, or PCS. The signatures for the two profile connection spaces supported by ColorSync, `cmXYZData` and `cmLabData`, are described in "Color Space Signatures" (page 969).

`dateTime`

The date and time when the profile was created. You can use this value to keep track of your own versions of this profile. For information on the date and time format, see `CMDateTime` (page 889).

`CS2profileSignature`

The `'acsp'` constant as required by the ICC format.

`platform`
: The signature of the primary platform on which this profile runs. For Apple Computer, this is `'APPL'`. For other platforms, refer to the International Color Consortium Profile Format Specification.

`flags`
: Flags that provide hints, such as preferred quality and speed options, to the preferred CMM. The `flags` field consists of an unsigned long data type. The 16 bits in the low word, 0-15, are reserved for use by the ICC. The 16 bits in the high word, 16-31, are available for use by color management systems. For information on how these bits are defined and how your application can set and test them, see "Flag Mask Definitions for Version 2.x Profiles" (page 983).

`deviceManufacturer`
: The signature of the manufacturer of the device to which this profile applies. This value is registered with the ICC.

`deviceModel`
: The model of this device, as registered with the ICC.

`deviceAttributes`
: Attributes that are unique to this particular device setup, such as media, paper, and ink types. The data type for this field is an array of two unsigned longs. The low word of `deviceAttributes[0]` is reserved by the ICC. The high word of `deviceAttributes[0]` and the entire word of `deviceAttributes[1]` are available for vendor use. For information on how the bits in `deviceAttributes` are defined and how your application can set and test them, see "Device Attribute Values for Version 2.x Profiles" (page 978).

`renderingIntent`
: The preferred rendering intent for the object or file tagged with this profile. Four types of rendering intent are defined: perceptual, relative colorimetric, saturation, and absolute colorimetric. The `renderingIntent` field consists of an unsigned long data type. The low word is reserved by the ICC and is used to set the rendering intent. The high word is available for use. For information on how the bits in `renderingIntent` are defined and how your application can set and test them, see "Rendering Intent Values for Version 2.x Profiles" (page 1012).

`white`
: The profile illuminant white reference point, expressed in the XYZ color space.

`creator`
: Signature identifying the profile creator.

`reserved`
: This field is reserved for future use.

Discussion

The ColorSync Manager defines the `CM2header` profile structure to support the header format specified by the ICC format specification for version 2.x profiles. For a description of `CMHeader`, the ColorSync 1.0 profile header, see `CMHeader` (page 898). To obtain a copy of the International Color Consortium Profile Format Specification, or to get other information about the ICC, visit the ICC Web site at http://www.color.org/.

Your application cannot obtain a discrete profile header value using the element tag scheme available for use with elements outside the header. Instead, to set or modify values of a profile header, your application must obtain the entire profile header using the function `CMGetProfileHeader` (page 769) and replace the header using the function `CMSetProfileHeader` (page 813).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CMICCProfile.h`

CM2Profile

```
struct CM2Profile {
    CM2Header header;
    CMTagElemTable tagTable;
    char elemData[1];
};
typedef struct CM2Profile CM2Profile;
typedef CM2Profile * CM2ProfilePtr;
```

Fields

`header`

`tagTable`

`elemData`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CMICCProfile.h`

    CMFixedXYZColor white;
    OSType creator;
    CMProfileMD5 digest;
    char reserved[28];
};
typedef struct CM4Header CM4Header;
```

Fields

`size`
`CMMType`
`profileVersion`
`profileClass`
`dataColorSpace`
`profileConnectionSpace`
`dateTime`
`CS2profileSignature`
`platform`
`flags`
`deviceManufacturer`
`deviceModel`
`deviceAttributes`
`renderingIntent`
`white`
`creator`
`digest`
`reserved`

Availability

Available in Mac OS X v10.1 and later.

Declared In

`CMICCProfile.h`

CMAccelerationCalcData

```
struct CMAccelerationCalcData {
    SInt32 pixelCount;
    Ptr inputData;
    Ptr outputData;
    UInt32 reserved1;
    UInt32 reserved2;
};
typedef struct CMAccelerationCalcData CMAccelerationCalcData;
```

Fields

CMAccelerationCalcDataPtr

```
typedef CMAccelerationCalcData* CMAccelerationCalcDataPtr;
```

CMAccelerationCalcDataHdl

```
typedef CMAccelerationCalcDataPtr* CMAccelerationCalcDataHdl;
```

CMAccelerationTableData

```
struct CMAccelerationTableData {
    SInt32 inputLutEntryCount;
    SInt32 inputLutWordSize;
    Handle inputLut;
    SInt32 outputLutEntryCount;

    Fixed adaptationMatrix[9];
};
typedef struct CMAdaptationMatrixType CMAdaptationMatrixType;
```

Fields

`typeDescriptor`

`reserved`

`adaptationMatrix`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CMICCProfile.h`

CMAppleProfileHeader

Defines a data structure to provide access to both version 2.x and version 1.0 profiles, as specified by the International Color Consortium.

```
union CMAppleProfileHeader {
    CMHeader cm1;
    CM2Header cm2;
    CM4Header cm4;
};
typedef union CMAppleProfileHeader CMAppleProfileHeader;
```

Fields

`cm1`

A version 1.0 profile header. For a description of the ColorSync version 1.0 profile header, see `CMHeader` (page 898).

`cm2`

A current profile header. For a description of the ColorSync profile header, see `CM2Header` (page 875).

`cm4`

Discussion
The ColorSync Manager defines the `CMAppleProfileHeader` structure to provide access to both version 2.x and version 1.0 profiles, as specified by the International Color Consortium. To obtain a copy of the International Color Consortium Profile Format Specification, or to get other information about the ICC, visit the ICC Web site at http://www.color.org/.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CMApplication.h`

CMBitmap

Contains information that describes color bitmap images.

```
struct CMBitmap {
    char * image;
    long width;
    long height;
    long rowBytes;
    long pixelSize;
    CMBitmapColorSpace space;
    long user1;
    long user2;
};
typedef struct CMBitmap CMBitmap;
```

Fields

`image`
A pointer to a bit image.

`width`
The width of the bit image, that is, the number of pixels in a row.

`height`
The height of the bit image, that is, the number of rows in the image.

`rowBytes`
The offset in bytes from one row of the image to the next.

`pixelSize`
The number of bits per pixel. The pixel size should correspond to the packing size specified in the `space` field. This requirement is not enforced as of ColorSync version 2.5, but it may be enforced in future versions.

`space`
The color space in which the colors of the bitmap image are specified. For a description of the possible color spaces for color bitmaps, see "Color Space Constants With Packing Formats" (page 962).

`user1`
Not used by ColorSync. It is recommended that you set this field to 0.

`user2`
Not used by ColorSync. It is recommended that you set this field to 0.

Discussion
The ColorSync Manager defines a bitmap structure of type `CMBitmap` to describe color bitmap images. When your application calls the function `CWMatchColors` (page 828) , you pass a pointer to a source bitmap of type `CMBitmap` containing the image whose colors are to be matched to the color gamut of the device specified by the destination profile of the given color world. If you do not want the image color matched in place, you can also pass a pointer to a resulting bitmap of type `CMBitmap` to define and hold the color-matched image.

For QuickDraw GX, an image can have an indexed bitmap to a list of colors. The ColorSync Manager does not support indexed bitmaps in the same way QuickDraw GX does. ColorSync supports indexed bitmaps only when the `cmNamedIndexed32Space` color space constant is used in conjunction with a named color space profile.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CMApplication.h`

CMBitmapCallBackProc

```
typedef CMBitmapCallBackProcPtr CMBitmapCallBackProc;
```

CMBitmapCallBackUPP

Defines a universal procedure pointer to a bitmap callback.

```
typedef CMBitmapCallBackProcPtr CMBitmapCallBackUPP;
```

Discussion
For more information, see the description of the `CMBitmapCallBackProcPtr` (page 852) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CMTypes.h`

CMBufferLocation

```
struct CMBufferLocation {
    void * buffer;
    UInt32 size;
};
typedef struct CMBufferLocation CMBufferLocation;
```

Fields
`buffer`
`size`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CMApplication.h`

CMCMYColor

Contains color values expressed in the CMY color space.

```
struct CMCMYColor {
    UInt16 cyan;
    UInt16 magenta;
    UInt16 yellow;
};
typedef struct CMCMYColor CMCMYColor;
```

Fields

`cyan`

`magenta`

`yellow`

Discussion

A color value expressed in the CMY color space is composed of `cyan`, `magenta`, and `yellow` component values. Each color component is expressed as a numeric value within the range of 0 to 65535 inclusive.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CMApplication.h`

CMCMYKColor

Contains color values expressed in the CMYK color space.

```
struct CMCMYKColor {
    UInt16 cyan;
    UInt16 magenta;
    UInt16 yellow;
    UInt16 black;
};
typedef struct CMCMYKColor CMCMYKColor;
```

Fields

`cyan`

`magenta`

`yellow`

`black`

Discussion

A color value expressed in the CMYK color space is composed of `cyan`, `magenta`, `yellow`, and `black` component values. Each color component is expressed as a numeric value within the range of 0 to 65535 inclusive.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CMApplication.h`

CMColor

Defines a union that can be used to specify a color value defined by one of the 15 data types supported by the union.

```
union CMColor {
    CMRGBColor rgb;
    CMHSVColor hsv;
    CMHLSColor hls;
    CMXYZColor XYZ;
    CMLabColor Lab;
    CMLuvColor Luv;
    CMYxyColor Yxy;
    CMCMYKColor cmyk;
    CMCMYColor cmy;
    CMGrayColor gray;
    CMMultichannel5Color mc5;
    CMMultichannel6Color mc6;
    CMMultichannel7Color mc7;
    CMMultichannel8Color mc8;
    CMNamedColor namedColor;
};
typedef union CMColor CMColor;
```

Fields

`rgb`
A color value expressed in the RGB color space as data of type `CMRGBColor` (page 930).

`hsv`
A color value expressed in the HSV color space as data of type `CMHSVColor` (page 901).

`hls`
A color value expressed in the HLS color space as data of type `CMHLSColor` (page 901).

`XYZ`
A color value expressed in the XYZ color space as data of type `CMXYZColor` (page 943).

`Lab`
A color value expressed in the L*a*b* color space as data of type `CMLabColor` (page 903).

`Luv`
A color value expressed in the L*u*v* color space as data of type `CMLuvColor` (page 905).

`Yxy`
A color value expressed in the Yxy color space as data of type `CMYxyColor` (page 944).

`cmyk`
A color value expressed in the CMYK color space as data of type `CMCMYKColor` (page 884).

`cmy`
A color value expressed in the CMY color space as data of type `CMCMYColor` (page 883).

`gray`
A color value expressed in the Gray color space as data of type `CMGrayColor` (page 897).

`mc5`
A color value expressed in the five-channel multichannel color space as data of type `CMMultichannel5Color`. See `CMMultichannel5Color` (page 910) for a description of the `CMMultichannel5Color` data type.

`mc6`
A color value expressed in the six-channel multichannel color space as data of type `CMMultichannel6Color`. See `CMMultichannel6Color` (page 911) for a description of the `CMMultichannel6Color` data type.

`mc7`
: A color value expressed in the seven-channel multichannel color space as data of type `CMMultichannel7Color`. See `CMMultichannel7Color` (page 911) for a description of the `CMMultichannel7Color` data type.

`mc8`
: A color value expressed in the eight-channel multichannel color space as data of type `CMMultichannel8Color`. See `CMMultichannel8Color` (page 911) for a description of the `CMMultichannel8Color` data type.

`namedColor`
: A color value expressed as an index into a named color space. See `CMNamedColor` (page 914) for a description of the `CMNamedColor` data type.

Discussion
A color union can contain one of the above fields.

Your application can use a union of type `CMColor` to specify a color value defined by one of the 15 data types supported by the union. Your application uses an array of color unions to specify a list of colors to match, check, or convert. The array is passed as a parameter to the general purpose color matching, color checking, or color conversion functions. The following functions use a color union:

- The function `CWMatchColors` (page 828) matches the colors in the color list array to the data color space of the destination profile specified by the color world.
- The function `CWCheckColors` (page 821) checks the colors in the color list array against the color gamut specified by the color world's destination profile.
- The color conversion functions, described in "Converting Between Color Spaces", take source and destination array parameters of type `CMColor` specifying lists of colors to convert from one color space to another.

You do not use a union of type `CMColor` to convert colors expressed in the XYZ color space as values of type `CMFixedXYZ` because the `CMColor` union does not support the `CMFixedXYZ` data type.

Availability
Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared In
`CMApplication.h`

CMConcatCallBackUPP

Defines a universal procedure pointer to a progress-monitoring function that the ColorSync Manager calls during lengthy color world processing.

```
typedef CMConcatCallBackProcPtr CMConcatCallBackUPP;
```

Discussion
For more information, see the description of the `CMConcatCallBackProcPtr` (page 853) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CMTypes.h`

CMConcatProfileSet

Contains profile and other information needed to set up a color world.

```
struct CMConcatProfileSet {
    UInt16 keyIndex;
    UInt16 count;
    CMProfileRef profileSet[1];
};
typedef struct CMConcatProfileSet CMConcatProfileSet;
```

Fields

`keyIndex`

A zero-based index into the array of profile references identifying the profile whose CMM is used for the entire session. The profile's `CMMType` field identifies the CMM.

`count`

The one-based count of profiles in the profile array. A minimum of one profile is required.

`profileSet`

A variable-length array of profile references. The references must be in processing order from source to destination. The rules governing the types of profiles you can specify in a profile array differ depending on whether you are creating a profile set for the function `CWConcatColorWorld` (page 823) or for the function `CWNewLinkProfile` (page 830). See the function descriptions for details.

Discussion

You can call the function `NCWNewColorWorld` (page 846) to create a color world for operations such as color matching and color conversion. A color world is normally based on two profiles—source and destination. But it can include a series of profiles that describe the processing for a work-flow sequence, such as scanning, printing, and previewing an image. To create a color world that includes a series of profiles, you use the function `CWConcatColorWorld` (page 823).

The array specified in the `profileSet` field identifies a concatenated profile set your application can use to establish a color world in which the sequential relationship among the profiles exists until your application disposes of the color world. Alternatively, you can create a device link profile composed of a series of linked profiles that remains intact and available for use again after your application disposes of the concatenated color world. In either case, you use a data structure of type `CMConcatProfileSet` to define the profile set.

A device link profile accommodates users who use a specific configuration requiring a combination of device profiles and possibly non-device profiles repeatedly over time.

To set up a color world that includes a concatenated set of profiles, your application uses the function `CWConcatColorWorld` (page 823) , passing it a structure of type `CMConcatProfileSet` . The array you pass may contain a set of profile references or it may contain only the profile reference of a device link profile. To create a device link profile, your application calls the function `CWNewLinkProfile` (page 830), passing a structure of type `CMConcatProfileSet`.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CMApplication.h`

CMCurveType

```
struct CMCurveType {
    OSType typeDescriptor;
    UInt32 reserved;
    UInt32 countValue;
    UInt16 data[1];
};
typedef struct CMCurveType CMCurveType;
```

Fields

`reserved`

`countValue`

`data`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CMICCProfile.h`

CMCWInfoRecord

Contains information about a given color world.

```
struct CMCWInfoRecord {
    UInt32 cmmCount;
    CMMInfoRecord cmmInfo[2];
};
typedef struct CMCWInfoRecord CMCWInfoRecord;
```

Fields

`cmmCount`

The number of CMMs involved in the color-matching session, either 1 or 2.

`cmmInfo`

An array containing two elements. Depending on the value that `cmmCount` returns, the `cmmInfo` array contains one or two records of type `CMMInfoRecord` (page 909) reporting the CMM type and version number.

If `cmmCount` is 1, the first element of the array (`cmmInfo[0]`) describes the CMM and the contents of the second element of the array (`cmmInfo[1]`) is undefined.

If `cmmCount` is 2, the first element of the array (`cmmInfo[0]`) describes the source CMM and the second element of the array (`cmmInfo[1]`) describes the destination CMM.

Discussion
Your application supplies a color world information record structure of type `CMCWInfoRecord` as a parameter to the `CMGetCWInfo` function to obtain information about a given color world. The ColorSync Manager uses this data structure to return information about the color world.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
CMApplication.h

CMDataType

```
struct CMDataType {
    OSType typeDescriptor;

    UInt32 dataFlag;
    char data[1];
};
typedef struct CMDataType CMDataType;
```

Fields
typeDescriptor
reserved
dataFlag
data

Availability
Available in Mac OS X v10.0 and later.

Declared In
CMICCProfile.h

CMDateTime

Contains data that specifies a date and time in year, month, day of the month, hours, minutes, and seconds

```
struct CMDateTime {
    UInt16 year;
    UInt16 month;
    UInt16 dayOfTheMonth;
    UInt16 hours;
    UInt16 minutes;
    UInt16 seconds;
};
typedef struct CMDateTime CMDateTime;
```

Fields
year
: The year. Note that to indicate the year 1984, this field would store the integer 1984, not just 84.

month
: The month of the year, where 1 represents January, and 12 represents December.

dayOfTheMonth
: The day of the month, ranging from 1 to 31.

hours
: The hour of the day, ranging from 0 to 23, where 0 represents midnight and 23 represents 11:00 P.M.

minutes
: The minutes of the hour, ranging from 0 to 59.

`seconds`
The seconds of the minute, ranging from 0 to 59.

Discussion
The ColorSync Manager defines the `CMDateTime` data structure to specify a date and time in year, month, day of the month, hours, minutes, and seconds. Other ColorSync structures use the `CMDateTime` structure to specify information such as the creation date or calibration date for a color space profile.

The `CMDateTime` structure is similar to the Macintosh Toolbox structure `DateTimeRec`, and like it, is intended to hold date and time values only for a Gregorian calendar.

The `CMDateTime` structure is platform independent. However, when used with Macintosh Toolbox routines such as `SecondsToDate` and `DateToSeconds`, which use seconds to designate years, the range of years that can be represented is limited.

Availability
Available in Mac OS X v10.0 and later.

CMDeviceProfileInfo

```
struct CMDeviceProfileInfo {
    UInt32 dataVersion;
    CMDeviceProfileID profileID;
    CMProfileLocation profileLoc;
    CFDictionaryRef profileName;
    UInt32 reserved;
};
typedef struct CMDeviceProfileInfo CMDeviceProfileInfo;
```

Fields

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CMDeviceIntegration.h`

CMDeviceProfileScope

```
typedef CMDeviceScope CMDeviceProfileScope;
```

Availability
Available in Mac OS X v10.1 and later.

Declared In
`CMDeviceIntegration.h`

CMDeviceScope

```
struct CMDeviceScope {
    CFStringRef deviceUser;
    CFStringRef deviceHost;
};
typedef struct CMDeviceScope CMDeviceScope;
typedef CMDeviceScope CMDeviceProfileScope;
```

Fields
`deviceUser`
`deviceHost`

Availability
Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared In
`CMDeviceIntegration.h`

CMDeviceSpec

```
struct CMDeviceSpec {
    UInt32 specVersion;
    CMDeviceClass deviceClass;
    CMDeviceID deviceID;
    CMDeviceName deviceName;
    UInt32 reserved;
};
typedef struct CMDeviceSpec CMDeviceSpec;
```

Fields

CMDeviceSpecPtr

```
typedef CMDeviceSpec* CMDeviceSpecPtr;
```

CMDeviceState

```
typedef UInt32 CMDeviceState;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
CMDeviceIntegration.h

CMDisplayIDType

Defines a data type for a display ID type.

```
typedef UInt32 CMDisplayIDType;
```

Discussion
This data type is passed as a parameter to the functions `CMGetProfileByAVID` (page 767) and `CMSetProfileByAVID` (page 808).

Availability
Available in Mac OS X v10.0 and later.

Declared In
CMTypes.h

CMError

Defines a data type for a ColorSync Manager result code.

```
typedef  CMError;
```

Discussion
For a list of possible resutlt codes, see "ColorSync Manager Result Codes" (page 1020).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CMTypes.h`

CMFileLocation

Contains a file specification for a profile stored in a disk file.

```
struct CMFileLocation {
    FSSpec spec;
};
typedef struct CMFileLocation CMFileLocation;
```

Fields

`spec`

A file system specification structure giving the location of the profile file. A file specification structure includes the volume reference number, the directory ID of the parent directory, and the filename or directory name. See the File Manager documentation for a description of the `FSSpec` data type.

Discussion
Your application uses the `CMFileLocation` structure to provide a file specification for a profile stored in a disk file. You provide a file specification structure in the `CMProfileLocation` structure's `u` field to specify the location of an existing profile or a profile to be created.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`CMApplication.h`

CMFixedXYColor

```
struct CMFixedXYColor {
    Fixed x;
    Fixed y;
};
typedef struct CMFixedXYColor CMFixedXYColor;
```

Fields

`x`

`y`

Availability
Available in Mac OS X v10.1 and later.

Declared In
`CMICCProfile.h`

CMFixedXYZColor

Contains data that specifies the profile illuminant in the profile header's `white` field and other profile element values.

```
struct CMFixedXYZColor {
    Fixed X;
    Fixed Y;
    Fixed Z;
};
typedef struct CMFixedXYZColor CMFixedXYZColor;
```

Fields

`X`

`Y`

`Z`

Discussion

ColorSync uses the `CMFixedXYZColor` data type to specify the profile illuminant in the profile header's `white` field and to specify other profile element values. Color component values defined by the `Fixed` type definition can be used to specify a color value in the XYZ color space with greater precision than a color whose components are expressed as `CMXYZComponent` data types. The `Fixed` data type is a signed 32-bit value. A color value expressed in the XYZ color space whose color components are of type `Fixed` is defined by the `CMFixedXYZColor` type definition.

Your application can convert colors defined in the XYZ color space between `CMXYZColor` data types (in which the color components are expressed as 16-bit unsigned values) and `CMFixedXYZColor` data types (in which the colors are expressed as 32-bit signed values). To convert color values, you use the functions `CMConvertFixedXYZToXYZ` (page 730) and `CMConvertXYZToFixedXYZ` (page 736).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CMICCProfile.h`

CMFlattenUPP

Defines a universal procedure pointer to a data-flattening callback.

```
typedef CMFlattenProcPtr CMFlattenUPP;
```

Discussion

For more information, see the description of the `CMFlattenProcPtr` (page 855) callback function.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CMTypes.h`

CMGrayColor

Contains a color value expressed in the gray color space.

```
struct CMGrayColor {
    UInt16 gray;
};
typedef struct CMGrayColor CMGrayColor;
```

Fields
`gray`

Discussion
A color value expressed in the Gray color space is composed of a single component, `gray`, represented as a numeric value within the range of 0 to 65535 inclusive.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CMApplication.h`

CMHandleLocation

Contains a handle specification for a profile stored in relocatable memory.

```
struct CMHandleLocation {
    Handle h;
};
typedef struct CMHandleLocation CMHandleLocation;
```

Fields
`h`
A data structure of type `Handle` containing a handle that indicates the location of a profile in memory.

Discussion
Your application uses the `CMHandleLocation` structure to provide a handle specification for a profile stored in relocatable memory. You provide the handle specification structure in the `CMProfileLocation` structure's `u` field to specify an existing profile or a profile to be created.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CMApplication.h`

CMHeader

Contains version 1.0 profile header data.

```
struct CMHeader {
    UInt32 size;
    OSType CMMType;
    UInt32 applProfileVersion;
    OSType dataType;
    OSType deviceType;
    OSType deviceManufacturer;
    UInt32 deviceModel;
    UInt32 deviceAttributes[2];
    UInt32 profileNameOffset;
    UInt32 customDataOffset;
    CMMatchFlag flags;
    CMMatchOption options;
    CMXYZColor white;
    CMXYZColor black;
};
typedef struct CMHeader CMHeader;
```

Fields

`size`
The total size in bytes of the profile, including any custom data.

`CMMType`
The signature of the preferred CMM for color-matching and color-checking sessions for this profile. To avoid conflicts with other CMMs, this signature must be registered with the ICC. For the signature of the default CMM, see "Default CMM Signature" (page 977).

`applProfileVersion`
The Apple profile version. Set this field to $0100 (defined as the constant `kCMApplProfileVersion`).

`dataType`
The kind of color data.

`deviceType`
The kind of device.

`deviceManufacturer`
A name supplied by the device manufacturer.

`deviceModel`
The device model specified by the manufacturer.

`deviceAttributes`
Private information such as paper surface and ink temperature.

`profileNameOffset`
The offset to the profile name from the top of data.

`customDataOffset`
The offset to any custom data from the top of data.

`flags`

A field used by drivers; it can hold one of the following flags:

`CMNativeMatchingPreferredCMTurnOffCache`

The `CMNativeMatchingPreferred` flag is available for developers of intelligent peripherals that can off-load color matching into the peripheral. Most drivers will not use this flag. (Its default setting is 0, meaning that the profile creator does not care whether matching occurs on the host or the device.)

Use the `CMTurnOffCache` flag for CMMs that will not benefit from a cache, such as those that can look up data from a table with less overhead, or that do not want to take the memory hit a cache entails, or that do their own caching and do not want the CMM to do it. (The default is 0, meaning turn on cache.

`options`

The `options` field specifies the preferred matching for this profile; the default is `CMPerceptualMatch`; other values are `CMColorimetricMatch` or `CMSaturationMatch`. The options are set by the image creator.

`white`

The profile illuminant white reference point, expressed in the XYZ color space.

`black`

The black reference point for this profile, expressed in the XYZ color space.

Discussion

ColorSync 1.0 defined a version 1.0 profile whose structure and format are different from that of the ICC version 2.x profile. The `CMHeader` data type represents the version 1.0 profile header. For more information on profile version numbers, see "ColorSync and ICC Profile Format Version Numbers". To obtain a copy of the International Color Consortium Profile Format Specification, or to get other information about the ICC, visit the ICC Web site at http://www.color.org/

Your application cannot use ColorSync Manager functions to update a version 1.0 profile or to search for version 1.0 profiles. However, your application can use other ColorSync Manager functions that operate on version 1.0 profiles. For example, your application can open a version 1.0 profile using the function `CMOpenProfile` (page 790), obtain the version 1.0 profile header using the function `CMGetProfileHeader` (page 769), and access version 1.0 profile elements using the function `CMGetProfileElement` (page 768).

To make it possible to operate on both version 1.0 profiles and version 2.x profiles, the ColorSync Manager defines the union `CMAppleProfileHeader` (page 881), which supports either profile -*header version. The `CMHeader` data type defines the version 1.0 profile header, while the `CM2Header` (page 875) data type defines the version 2.x profile header.

Version Notes

Use of the `CMHeader` type is not recommended for ColorSync versions starting with 2.0. Use `CM2Header` (page 875) instead.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`CMICCProfile.h`

CMHLSColor

Contains a color value expressed in the HLS color space.

```
struct CMHLSColor {
    UInt16 hue;
    UInt16 lightness;
    UInt16 saturation;
};
typedef struct CMHLSColor CMHLSColor;
```

Fields

`hue`
A hue value that represents a fraction of a circle in which red is positioned at 0. .

`lightness`
A lightness value.

`saturation`
A saturation value.

Discussion

A color value expressed in the HLS color space is composed of `hue`, `lightness`, and `saturation` component values. Each color component is expressed as a numeric value within the range of 0 to 65535 inclusive.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CMApplication.h`

CMHSVColor

Contains a color value expressed in the HSV color space.

```
struct CMHSVColor {
    UInt16 hue;
    UInt16 saturation;
    UInt16 value;
};
typedef struct CMHSVColor CMHSVColor;
```

Fields

`hue`

`saturation`

`value`

Discussion

A color value expressed in the HSV color space is composed of `hue`, `saturation`, and `value` component values. Each color component is expressed as a numeric value within the range of 0 to 65535 inclusive. The `hue` value represents a fraction of a circle in which red is positioned at 0.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CMApplication.h`

CMIntentCRDVMSize

Defines the rendering intent and its maximum VM size.

```
struct CMIntentCRDVMSize {
    long renderingIntent;
    UInt32 VMSize;
};
typedef struct CMIntentCRDVMSize CMIntentCRDVMSize;
```

Fields

`renderingIntent`
: The rendering intent whose CRD virtual memory size you want to obtain. The rendering intent values are described in "Rendering Intent Values for Version 2.x Profiles" (page 1012).

`VMSize`
: The virtual memory size of the CRD for the rendering intent specified for the `renderingIntent` field.

Discussion

To specify the maximum virtual memory (VM) size of the color rendering dictionary (CRD) for a specific rendering intent for a particular PostScript(TM) Level 2 printer type, a printer profile can include the optional Apple-defined `'psvm'` tag. The PostScript CRD virtual memory size tag structure's element data includes an array containing one entry for each rendering intent and its virtual memory size.

If a PostScript printer profile includes this tag, the default CMM uses the tag and returns the values specified by the tag when your application or device driver calls the function `CMGetPS2ColorRenderingVMSize` (page 775).

If a PostScript printer profile does not include this tag, the CMM uses an algorithm to determine the VM size of the CRD. This may result in a size that is greater than the actual VM size.

The `CMPS2CRDVMSizeType` data type for the tag includes an array containing one or more members of type `CMIntentCRDVMSize`.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CMICCProfile.h`

CMIString

Defines a profile name.

```
struct CMIString {
    ScriptCode theScript;
    Str63 theString;
};
typedef struct CMIString CMIString;
typedef CMIString IString;
```

Fields

`theScript`
: The script code for the `theString` parameter.

`theString`
: The profile name.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`CMICCProfile.h`

CMLabColor

Contains a color value expressed in the L*a*b* color space.

```
struct CMLabColor {
    UInt16 L;
    UInt16 a;
    UInt16 b;
};
typedef struct CMLabColor CMLabColor;
```

Fields

`L`

A numeric value within the range of 0 to 65535, which maps to 0 to 100 inclusive. Note that this encoding is slightly different from the 0 to 65280 encoding of the L channel defined in the ICC specification for PCS L*a*b values.

`a`

A value that ranges from 0 to 65535, and maps to –128 to 127.996 inclusive.

`b`

A value that ranges from 0 to 65535, and maps to –128 to 127.996 inclusive.

Discussion
A color expressed in the L*a*b* color space is composed of `L`, `a`, and `b` component values.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CMApplication.h`

CMLut16Type

```
struct CMLut16Type {
    OSType typeDescriptor;
    UInt32 reserved;
    UInt8 inputChannels;
    UInt8 outputChannels;
    UInt8 gridPoints;
    UInt8 reserved2;
    Fixed matrix[3][3];
    UInt16 inputTableEntries;
    UInt16 outputTableEntries;
    UInt16 inputTable[1];
};
typedef struct CMLut16Type CMLut16Type;
```

Fields

`typeDescriptor`

`reserved`

`inputChannels`

`outputChannels`

`gridPoints`

`reserved2`

`matrix`

`inputTableEntries`

`outputTableEntries`

`inputTable`

`CLUT`

`outputTable`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CMICCProfile.h`

CMLut8Type

```
struct CMLut8Type {
    OSType typeDescriptor;
    UInt32 reserved;
    UInt8 inputChannels;
    UInt8 outputChannels;
    UInt8 gridPoints;
    UInt8 reserved2;
    Fixed matrix[3][3];
    UInt8 inputTable[1];
};
typedef struct CMLut8Type CMLut8Type;
```

Fields

`typeDescriptor`
`reserved`
`inputChannels`
`outputChannels`
`gridPoints`
`reserved2`
`matrix`
`inputTable`
`CLUT`
`outputTable`
`aNet`
`aNode`
`aSocket`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CMICCProfile.h`

CMLuvColor

Contains a color value expressed in the L*u*v* color space.

```
struct CMLuvColor {
    UInt16 L;
    UInt16 u;
    UInt16 v;
};
typedef struct CMLuvColor CMLuvColor;
```

Fields

`L`
A numeric value within the range of 0 to 65535 that maps to 0 to 100 inclusive.

`u`
A numeric value within the range of 0 to 65535 that maps to –128 to 127.996 inclusive.

`v`
A numeric value within the range of 0 to 65535 that maps to –128 to 127.996 inclusive.

Discussion
A color value expressed in the L*u*v* color space is composed of `L`, `u`, and `v` component values.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CMApplication.h`

CMMakeAndModel

Contains make and model information fro a device.

```
struct CMMakeAndModel {
    OSType manufacturer;
    UInt32 model;
    UInt32 serialNumber;
    UInt32 manufactureDate;
    UInt32 reserved1;
    UInt32 reserved2;
    UInt32 reserved3;
    UInt32 reserved4;
};
typedef struct CMMakeAndModel CMMakeAndModel;
```

Fields
`manufacturer`
`model`
`serialNumber`
`manufactureDate`
`reserved1`
`reserved2`
`reserved3`
`reserved4`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CMICCProfile.h`

CMMakeAndModelType

Contains make and model information along with a type descriptor.

```
struct CMMakeAndModelType {
    OSType typeDescriptor;
    UInt32 reserved;
    CMMakeAndModel makeAndModel;
};
typedef struct CMMakeAndModelType CMMakeAndModelType;
```

Fields

`typeDescriptor`

`reserved`

`makeAndModel`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CMICCProfile.h`

CMMatchFlag

Defines a data type for match flags.

```
typedef  long CMMatchFlag;
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`CMICCProfile.h`

CMMatchOption

Defines a data type for match options.

```
typedef long CMMatchOption;
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`CMICCProfile.h`

CMMatchRef

Defines an abstract private data structure for the color-matching-session reference.

```
typedef struct OpaqueCMMatchRef * CMMatchRef;
```

Discussion
The ColorSync Manager defines an abstract private data structure of type `OpaqueCMMatchRef` for the color-matching-session reference. When your application calls the function `NCMBeginMatching` (page 838) to begin a QuickDraw-specific color-matching session, the ColorSync Manager returns a reference pointer to the color-matching session which you must later pass to the `CMEndMatching` function to conclude the session.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`CMTypes.h`

CMMeasurementType

Contains measurement type information.

```
struct CMMeasurementType {
    OSType typeDescriptor;
    UInt32 reserved;
    UInt32 standardObserver;
    CMFixedXYZColor backingXYZ;
    UInt32 geometry;
    UInt32 flare;
    UInt32 illuminant;
};
typedef struct CMMeasurementType CMMeasurementType;
```

Fields
`typeDescriptor`
`reserved`
`standardObserver`
`backingXYZ`
`geometry`
`flare`
`illuminant`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CMICCProfile.h`

CMMInfo

Contains information pertainting to a color management module.

```
struct CMMInfo {
    UInt32 dataSize;
    OSType CMMType;
    OSType CMMMfr;
    UInt32 CMMVersion;
    unsigned char ASCIIName[32];
    unsigned char ASCIIDesc[256];
    UniCharCount UniCodeNameCount;
    UniChar UniCodeName[32];
    UniCharCount UniCodeDescCount;
    UniChar UniCodeDesc[256];
};
typedef struct CMMInfo CMMInfo;
```

Fields

`dataSize`

`CMMType`

`CMMMfr`

`CMMVersion`

`ASCIIName`

`ASCIIDesc`

`UniCodeNameCount`

`UniCodeName`

`UniCodeDescCount`

`UniCodeDesc`

`TPLFMT_BKSZ`

`TPLFMT_NBLOCKS`

`TPLFMT_EDCLOC`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CMApplication.h`

CMMInfoRecord

Contains CMM type and version information.

```
struct CMMInfoRecord {
    OSType CMMType;
    long CMMVersion;
};
typedef struct CMMInfoRecord CMMInfoRecord;
```

Fields

`CMMType`

The signature of the CMM as specified in the profile header's `CMMType` field. The `CMGetCWInfo` function returns this value.

`CMMVersion`

The version of the CMM. The `CMGetCWInfo` function returns this value.

Discussion
Your application supplies an array containing two CMM information record structures of type `CMMInfoRecord` as a field of the `CMCWInfoRecord` structure. These structures allow the `CMGetCWInfo` function to return information about the one or two CMMs used in a given color world. Your application must allocate memory for the array. When your application calls the `CMGetCWInfo` function, it passes a pointer to the `CMCWInfoRecord` structure containing the array.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`CMApplication.h`

CMMIterateUPP

Defines a universal procedure pointer to a CMM interation callback.

```
typedef CMMIterateProcPtr CMMIterateUPP;
```

Discussion
For more information, see the description of the `CMMIterateProcPtr` (page 862) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CMApplication.h`

CMMultichannel5Color

Contains a color value expressed in the multichannel color space with 5 channels.

```
struct CMMultichannel5Color {
    UInt8 components[5];
};
typedef struct CMMultichannel5Color CMMultichannel5Color;
```

Fields
`components`

Discussion
A color expressed in the multichannel color space with 5 channels. The color value for each channel component is expressed as an unsigned byte of type `char`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CMApplication.h`

CMMultichannel6Color

Contains a color expressed in the multichannel color space with 6 channels.

```
struct CMMultichannel6Color {
    UInt8 components[6];
};
typedef struct CMMultichannel6Color CMMultichannel6Color;
```

Fields
`components`

Discussion
A color expressed in the multichannel color space with 6 channels. The color value for each channel component is expressed as an unsigned byte of type `char`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CMApplication.h`

CMMultichannel7Color

Contains a color value expressed in the multichannel color space with 7 channels.

```
struct CMMultichannel7Color {
    UInt8 components[7];
};
typedef struct CMMultichannel7Color CMMultichannel7Color;
```

Fields
`components`

Discussion
A color expressed in the multichannel color space with 7 channels. The color value for each channel component is expressed as an unsigned byte of type `char`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CMApplication.h`

CMMultichannel8Color

Contains a color value expressed in the multichannel color space with 8 channels

```
struct CMMultichannel8Color {
    UInt8 components[8];
};
typedef struct CMMultichannel8Color CMMultichannel8Color;
```

Fields
`components`

Discussion
A color expressed in the multichannel color space with 8 channels. The color value for each channel component is expressed as an unsigned byte of type `char`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CMApplication.h`

CMMultiFunctCLUTType

```
struct CMMultiFunctCLUTType {
    UInt8 gridPoints[16];
    UInt8 entrySize;
    UInt8 reserved[3];
    UInt8 data[1];
};
typedef struct CMMultiFunctCLUTType CMMultiFunctCLUTType;
```

Fields
`gridPoints`
`entrySize`
`reserved`
`data`

Availability
Available in Mac OS X v10.1 and later.

Declared In
`CMICCProfile.h`

CMMultiFunctLutA2BType

```
typedef CMMultiFunctLutType CMMultiFunctLutA2BType;
```

Availability
Available in Mac OS X v10.1 through Mac OS X v10.4.

Declared In
`CMICCProfile.h`

CMMultiFunctLutB2AType

```
typedef CMMultiFunctLutType CMMultiFunctLutB2AType;
```

Availability
Available in Mac OS X v10.1 and later.

Declared In
CMICCProfile.h

CMMultiFunctLutType

```
struct CMMultiFunctLutType {
    OSType typeDescriptor;
    UInt32 reserved;
    UInt8 inputChannels;
    UInt8 outputChannels;
    UInt16 reserved2;
    UInt32 offsetBcurves;
    UInt32 offsetMatrix;
    UInt32 offsetMcurves;
    UInt32 offsetCLUT;
    UInt32 offsetAcurves;
    UInt8 data[1];
};
typedef struct CMMultiFunctLutType CMMultiFunctLutType;
typedef CMMultiFunctLutType CMMultiFunctLutA2BType;
```

Fields
typeDescriptor
reserved
inputChannels
outputChannels
reserved2
offsetBcurves
offsetMatrix
offsetMcurves
offsetCLUT
offsetAcurves
data

Availability
Available in Mac OS X v10.1 through Mac OS X v10.4.

Declared In
CMICCProfile.h

CMMultiLocalizedUniCodeEntryRec

```
struct CMMultiLocalizedUniCodeEntryRec {
    char languageCode[2];
    char regionCode[2];
    UInt32 textLength;
    UInt32 textOffset;
};
typedef struct CMMultiLocalizedUniCodeEntryRec CMMultiLocalizedUniCodeEntryRec;
```

Fields

`languageCode`

`regionCode`

`textLength`

`textOffset`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CMICCProfile.h`

CMMultiLocalizedUniCodeType

```
struct CMMultiLocalizedUniCodeType {
    OSType typeDescriptor;
    UInt32 reserved;
    UInt32 entryCount;
    UInt32 entrySize;
};
typedef struct CMMultiLocalizedUniCodeType CMMultiLocalizedUniCodeType;
```

Fields

`typeDescriptor`

`reserved`

`entryCount`

`entrySize`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CMICCProfile.h`

CMNamedColor

Contains a color value expressed in a named color space.

```
struct CMNamedColor {
    UInt32 namedColorIndex;
};
typedef struct CMNamedColor CMNamedColor;
```

Fields
`namedColorIndex`

Discussion
A color value expressed in a named color space is composed of a single component, `namedColorIndex`, represented as a numeric value within the range of an unsigned long, or 1 to 232 – 1 inclusive.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CMApplication.h`

CMNamedColor2EntryType

```
struct CMNamedColor2EntryType {
    UInt8 rootName[32];
    UInt16 PCSColorCoords[3];
    UInt16 DeviceColorCoords[1];
};
typedef struct CMNamedColor2EntryType CMNamedColor2EntryType;
```

Fields
`rootName`
`PCSColorCoords`
`DeviceColorCoords`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CMICCProfile.h`

CMNamedColor2Type

```
struct CMNamedColor2Type {
    OSType typeDescriptor;
    UInt32 reserved;
    UInt32 vendorFlag;
    UInt32 count;
    UInt32 deviceChannelCount;
    UInt8 prefixName[32];
    UInt8 suffixName[32];
    char data[1];
};
typedef struct CMNamedColor2Type CMNamedColor2Type;
```

Fields

`typeDescriptor`

`reserved`

`vendorFlag`

`count`

`deviceChannelCount`

`prefixName`

`suffixName`

`data`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CMICCProfile.h`

CMNamedColorType

```
struct CMNamedColorType {
    OSType typeDescriptor;
    UInt32 reserved;
    UInt32 vendorFlag;
    UInt32 count;
    UInt8 prefixName[1];
};
typedef struct CMNamedColorType CMNamedColorType;
```

Fields

`typeDescriptor`

`reserved`

`vendorFlag`

`count`

`prefixName`

`suffixName`

`data`

Availability

Available in Mac OS X v10.0 and later.

Declared In
CMICCProfile.h

CMNativeDisplayInfo

Contains color information for a native display.

```
struct CMNativeDisplayInfo {
    UInt32 dataSize;
    CMFixedXYColor redPhosphor;
    CMFixedXYColor greenPhosphor;
    CMFixedXYColor bluePhosphor;
    CMFixedXYColor whitePoint;
    Fixed redGammaValue;
    Fixed greenGammaValue;
    Fixed blueGammaValue;
    UInt16 gammaChannels;
    UInt16 gammaEntryCount;
    UInt16 gammaEntrySize;
    char gammaData[1];
};
typedef struct CMNativeDisplayInfo CMNativeDisplayInfo;
```

Fields
dataSize
redPhosphor
greenPhosphor
bluePhosphor
whitePoint
redGammaValue
greenGammaValue
blueGammaValue
gammaChannels
gammaEntryCount
gammaEntrySize
gammaData

Availability
Available in Mac OS X v10.1 and later.

Declared In
CMICCProfile.h

CMNativeDisplayInfoType

Contins color information and a tpe descriptor for a native display.

```
struct CMNativeDisplayInfoType {
    OSType typeDescriptor;
    unsigned long reserved;
    CMNativeDisplayInfo nativeDisplayInfo;
};
typedef struct CMNativeDisplayInfoType CMNativeDisplayInfoType;
```

Fields

`typeDescriptor`

`reserved`

`nativeDisplayInfo`

Availability

Available in Mac OS X v10.1 and later.

Declared In

`CMICCProfile.h`

CMParametricCurveType

```
struct CMParametricCurveType {
    OSType typeDescriptor;
    UInt32 reserved;
    UInt16 functionType;
    UInt16 reserved2;
    Fixed value[1];
};
typedef struct CMParametricCurveType CMParametricCurveType;
```

Fields

`typeDescriptor`

`reserved`

`functionType`

`reserved2`

`value`

Availability

Available in Mac OS X v10.1 and later.

Declared In

`CMICCProfile.h`

CMPathLocation

Contains path information.

```
struct CMPathLocation {
    char path[256];
};
typedef struct CMPathLocation CMPathLocation;
```

Fields
`path`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CMApplication.h`

CMProcedureLocation

Contains a universal procedure pointer to a profile access procedure.

```
struct CMProcedureLocation {
    CMProfileAccessUPP proc;
    void * refCon;
};
typedef struct CMProcedureLocation CMProcedureLocation;
```

Fields
`proc`
A universal procedure pointer to a profile access procedure. For a description of the procedure, see the function `CMProfileAccessProcPtr` (page 862).

`refCon`
A pointer to the profile access procedure's private data, such as a file or resource name, a pointer to a current offset, and so on.

Discussion
Your application uses the `CMProcedureLocation` structure to provide a universal procedure pointer to a profile access procedure. You provide this structure in the `CMProfileLocation` structure's `u` field. The `CMProcedureLocation` structure also contains a pointer field to specify data associated with the profile access procedure.

The ColorSync Manager calls your profile access procedure when the profile is created, initialized, opened, read, updated, or closed.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`CMApplication.h`

CMProfile

```
struct CMProfile {
    CMHeader header;
    CMProfileChromaticities profile;
    CMProfileResponse response;
    CMIString profileName;
    char customData[1];
};
typedef struct CMProfile CMProfile;
typedef CMProfile * CMProfilePtr;
```

Fields

`header`

`profile`

`response`

`profileName`

`customData`

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`CMICCProfile.h`

CMProfileAccessUPP

Defines a universal procedure pointer to a profile access callback.

```
typedef CMProfileAccessProcPtr CMProfileAccessUPP;
```

Discussion

For more information, see the description of the `CMProfileAccessProcPtr` (page 862)) callback function.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`CMTypes.h`

CMProfileChromaticities

```
struct CMProfileChromaticities {
    CMXYZColor red;
    CMXYZColor green;
    CMXYZColor blue;
    CMXYZColor cyan;
    CMXYZColor magenta;
    CMXYZColor yellow;
};
typedef struct CMProfileChromaticities CMProfileChromaticities;
```

Fields

`red`

`green`

`blue`

`cyan`

`magenta`

`yellow`

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`CMICCProfile.h`

CMProfileFilterProc

```
typedef CMProfileFilterProcPtr CMProfileFilterProc;
```

CMProfileFilterUPP

Defines a universal procedure pointer to a profile filter callback.

```
typedef CMProfileFilterProcPtr CMProfileFilterUPP;
```

Discussion

For more information, see the description of the `CMProfileFilterProcPtr` (page 864) callback function.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`CMTypes.h`

CMProfileIdentifier

Contains data that can identify a profile but that takes up much less space than a large profile.

```
struct CMProfileIdentifier {
    CM2Header profileHeader;
    CMDateTime calibrationDate;
    UInt32 ASCIIProfileDescriptionLen;
    char ASCIIProfileDescription[1];
};
typedef struct CMProfileIdentifier CMProfileIdentifier;
typedef CMProfileIdentifier * CMProfileIdentifierPtr;
```

Fields

`profileHeader`

A version 2.x profile header structure. For more information, see `CM2Header` (page 875). In determining a profile match, all header fields are considered, except for primary platform, flags, and rendering intent.

`calibrationDate`

A structure of type `CMDateTime` (page 889), which specifies year, month, day of month, hours, minutes, and seconds. This field is optional—when set to 0, it is not considered in determining a profile match. When nonzero, it is compared to the `'calt'` tag data.

`ASCIIProfileDescriptionLen`

The length of the ASCII description string that follows.

`ASCIIProfileDescription`

The ASCII profile description string, as specified by the profile description tag.

Discussion

Embedding a profile in an image guarantees that the image can be rendered correctly on a different system. However, profiles can be large—as much as several hundred kilobytes. The ColorSync Manager defines a profile identifier structure, `CMProfileIdentifier`, that can identify a profile but that takes up much less space than a large profile.

The profile identifier structure contains a profile header, an optional calibration date, a profile description string length, and a variable-length profile description string. Your application might use an embedded profile identifier, for example, to change just the rendering intent or the flag values in an image without having to embed an entire copy of a profile. Rendering intent is described in "Rendering Intent Values for Version 2.x Profiles" (page 1012) and flag values are described in "Flag Mask Definitions for Version 2.x Profiles" (page 983).

A document containing an embedded profile identifier cannot necessarily be ported to different systems or platforms.

The ColorSync Manager provides the function routine `NCMUseProfileComment` (page 843) to embed profiles and profile identifiers in an open picture file. Your application can embed profile identifiers in place of entire profiles, or in addition to them. A profile identifier can refer to an embedded profile or to a profile on disk.

The ColorSync Manager provides two routines for finding a profile identifier:

- `CMProfileIdentifierListSearch` (page 793) for finding a profile identifier in a list of profile identifiers
- `CMProfileIdentifierFolderSearch` (page 792) for finding a profile identifier in the ColorSync Profiles folder.

The descriptions of those functions provide information on searching algorithms. See also `CMProfileSearchRef` (page 927)

The `CMProfileIdentifierPtr` type definition defines a pointer to a profile identifier structure.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`CMApplication.h`

CMProfileIterateData

Contains a callback routine with a description of a profile that is during an iteration through the available profiles.

```
struct CMProfileIterateData {
    UInt32 dataVersion;
    CM2Header header;
    ScriptCode code;
    Str255 name;
    CMProfileLocation location;
    UniCharCount uniCodeNameCount;
    UniChar * uniCodeName;
    unsigned char * asciiName;
    CMMakeAndModel * makeAndModel;
    CMProfileMD5 * digest;
};
typedef struct CMProfileIterateData CMProfileIterateData;
```

Fields

`dataVersion`
A value identifying the version of the structure. Currently set to `cmProfileIterateDataVersion1`.

`header`
A ColorSync version 2.x profile header structure of type `CM2Header` (page 875), containing information such as the profile size, type, version, and so on.

`code`
A script code identifying the script system used for the profile description. The `ScriptCode` data type is defined in the MacTypes.h header file.

`name`
The profile name, stored as a Pascal-type string (with length byte first) of up to 255 characters.

`location`
A structure specifying the profile location. With ColorSync 2.5, the location is always file-based, but that may not be true for future versions. Your code should always verify that the location structure contains a file specification before attempting to use it.

```
uniCodeNameCount
uniCodeName
asciiName
makeAndModel
digest
TPLDEV_TYPE_WPS_SPEED
deviceData
```

Discussion
The ColorSync Manager defines the `CMProfileIterateData` structure to provide your `CMProfileIterateProcPtr` (page 865) callback routine with a description of a profile during an iteration through the available profiles that takes place when you call `CMIterateColorSyncFolder` (page 780).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CMApplication.h`

CMProfileIterateUPP

Defines a universal procedure pointer to a profile iteration callback.

```
typedef CMProfileIterateProcPtr CMProfileIterateUPP;
```

Discussion
For more information, see the description of the `CMProfileIterateProcPtr` (page 865)) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CMApplication.h`

CMProfileLocation

Contains profile location information.

```
struct CMProfileLocation {
    short locType;
    CMProfLoc u;
};
typedef struct CMProfileLocation CMProfileLocation;
```

Fields
`locType`
The type of data structure that the `u` field's `CMProfLoc` union holds—a file specification, a handle, a pointer, or a universal procedure pointer. To specify the type, you use the constants defined in the enumeration described in "Profile Location Type" (page 1003).

`u`
A union of type `CMProfLoc` (page 928) identifying the profile location.

Discussion
Your application passes a profile location structure of type `CMProfileLocation` when it calls:

- the function `CMOpenProfile` (page 790), specifying the location of a profile to open
- the `CMNewProfile` (page 788), `CWNewLinkProfile` (page 830), or `CMCopyProfile` (page 740) functions, specifying the location of a profile to create or duplicate

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CMApplication.h`

CMProfileMD5

Defines a data type for an MD5 digest.

```
typedef  unsigned char CMProfileMD5[16];
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CMICCProfile.h`

CMProfileName

Contains profile name and length.

```
struct CMProfileName {
    UniCharCount profileNameLength;
    UniChar profileName[256];
};
typedef struct CMProfileName CMProfileName;
```

CMProfileNamePtr

Defines a poitner to a profile name data structure.

```
typedef CMProfileName* CMProfileNamePtr;
```

CMProfileRef

Defines a reference to an opaque data type that specifies profile information.

```
typedef struct OpaqueCMProfileRef * CMProfileRef;
```

Discussion
A profile reference is the means by which your application gains access to a profile. Several ColorSync Manager functions return a profile reference to your application. Your application then passes it as a parameter on subsequent calls to other ColorSync Manager functions that use profiles.

The ColorSync Manager returns a unique profile reference in response to each individual call to the `CMOpenProfile` (page 790), `CMCopyProfile` (page 740) , and `CMNewProfile` (page 788) functions. This allows multiple applications concurrent access to a profile. The ColorSync Manager defines an abstract private data structure of type `OpaqueCMProfileRef` for the profile reference.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CMTypes.h`

CMProfileResponse

```
struct CMProfileResponse {
    UInt16 counts[9];
    UInt16 data[1];
};
typedef struct CMProfileResponse CMProfileResponse;
```

Fields
`counts`
`data`

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`CMICCProfile.h`

CMProfileSearchRecord

```
struct CMProfileSearchRecord {
    CMHeader header;
    UInt32 fieldMask;
    UInt32 reserved[2];
};
typedef struct CMProfileSearchRecord CMProfileSearchRecord;
typedef CMProfileSearchRecord * CMProfileSearchRecordPtr;
```

Fields
`header`
`fieldMask`
`reserved`

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`CMApplication.h`

CMProfileSearchRef

Defines a reference to an opaque profile search object.

```
typedef struct OpaqueCMProfileSearchRef * CMProfileSearchRef;
```

Discussion
A search result consists of a list of profiles matching certain search criteria. When your application calls the function `CMNewProfileSearch` (page 789) to search in the ColorSync Profiles folder for profiles that meet certain criteria, the ColorSync Manager returns a reference to an internal private data structure containing the search result. Your application passes the search result reference to these ColorSync functions:

- `CMUpdateProfileSearch` (page 817) updates a search result list.
- `CMDisposeProfileSearch` (page 745) disposes of a search result list.
- `CMSearchGetIndProfile` (page 798) opens a reference to a profile at a specific position in a search result list.
- `CMSearchGetIndProfileFileSpec` (page 799) obtains the file specification for a profile in a search result list.

The ColorSync Manager uses an abstract private data structure of type `OpaqueCMProfileSearchRef` in defining the search result reference.

Version Notes
This type is not recommended for use in ColorSync 2.5.

This type does not take advantage of the profile cache added in ColorSync version 2.5. It is used with the searching described in "Searching for Profiles Prior to ColorSync 2.5". See `CMProfileIterateData` (page 923) for information on data structures used with searching in version 2.5.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`CMTypes.h`

CMProfileSequenceDescType

```
struct CMProfileSequenceDescType {
    OSType typeDescriptor;
    UInt32 reserved;
    UInt32 count;
    char data[1];
};
typedef struct CMProfileSequenceDescType CMProfileSequenceDescType;
```

Fields

`typeDescriptor`

`reserved`

`count`

`data`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CMICCProfile.h`

CMProfLoc

Defines a uniont that identifies the location of a profile.

```
union CMProfLoc {
    CMFileLocation fileLoc;
    CMHandleLocation handleLoc;
    CMPtrLocation ptrLoc;
    CMProcedureLocation procLoc;
    CMPathLocation pathLoc;
    CMBufferLocation bufferLoc;
};
typedef union CMProfLoc CMProfLoc;
```

Fields

`fileLoc`
A data structure containing a file system specification record specifying the location of a profile disk file.

`handleLoc`
A data structure containing a handle that indicates the location of a profile in relocatable memory.

`ptrLoc`
A data structure containing a pointer that points to a profile in nonrelocatable memory.

`procLoc`
A data structure containing a universal procedure pointer that points to a profile access procedure supplied by you. The ColorSync Manager calls your procedure when the profile is created, initialized, opened, read, updated, or closed.

`pathLoc`
`bufferLoc`

Discussion
You use a union of type `CMProfLoc` to identify the location of a profile. You specify the union in the `u` field of the data type `CMProfileLocation` (page 924). Your application passes a pointer to a `CMProfileLocation` structure when it calls the `CMOpenProfile` (page 790) function to identify the location of a profile or the `CMNewProfile` (page 788), `CMCopyProfile` (page 740) , or `CWNewLinkProfile` (page 830) functions to specify the location for a newly created profile.

You also pass a pointer to a `CMProfileLocation` structure to the `NCMGetProfileLocation` (page 841) and `CMGetProfileLocation` (page 770) functions to get the location of an existing profile. The `NCMGetProfileLocation` function is available starting with ColorSync version 2.5. It differs from its predecessor, `CMGetProfileLocation`, in that the newer version has a parameter for the size of the location structure for the specified profile.

Availability
Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared In
`CMApplication.h`

CMPS2CRDVMSizeType

Defines the Apple-defined `'psvm'` optional tag.

```
struct CMPS2CRDVMSizeType {
    OSType typeDescriptor;
    UInt32 reserved;
    UInt32 count;
    CMIntentCRDVMSize intentCRD[1];
};
typedef struct CMPS2CRDVMSizeType CMPS2CRDVMSizeType;
```

Fields
`typeDescriptor`
The `'psvm'` tag signature.
`reserved`
Reserved for future use.
`count`
The number of entries in the `intentCRD` array. You should specify at least four entries: 0, 1, 2, and 3.
`intentCRD`
A variable-sized array of four or more members defined by the `CMIntentCRDSize` data type.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CMICCProfile.h`

CMPtrLocation

Contains a pointer specification for a profile stored in nonrelocatable memory.

```
struct CMPtrLocation {
    Ptr p;
};
typedef struct CMPtrLocation CMPtrLocation;
```

Fields

`p`

A data structure of type `Ptr` holding a pointer that points to the location of a profile in memory.

Discussion

Your application uses the `CMPtrLocation` structure to provide a pointer specification for a profile stored in nonrelocatable memory. You provide the pointer specification structure in the `CMProfileLocation` structure's `u` field to point to an existing profile.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`CMApplication.h`

CMRGBColor

Contains a color value expressed in the RGB color space.

```
struct CMRGBColor {
    UInt16 red;
    UInt16 green;
    UInt16 blue;
};
typedef struct CMRGBColor CMRGBColor;
```

Fields

`red`

`green`

`blue`

Discussion

A color value expressed in the RGB color space is composed of `red`, `green`, and `blue` component values. Each color component is expressed as a numeric value within the range of 0 to 65535.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CMApplication.h`

CMS15Fixed16ArrayType

```
struct CMS15Fixed16ArrayType {
    OSType typeDescriptor;
    UInt32 reserved;
    Fixed value[1];
};
typedef struct CMS15Fixed16ArrayType CMS15Fixed16ArrayType;
```

Fields

`typeDescriptor`

`CMICCProfile.h`

CMScreeningChannelRec

```
struct CMScreeningChannelRec {
    Fixed frequency;
    Fixed angle;
    UInt32 spotFunction;
};
typedef struct CMScreeningChannelRec CMScreeningChannelRec;
```

Fields

`frequency`

`angle`

`spotFunction`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CMICCProfile.h`

CMScreeningType

```
struct CMScreeningType {
    OSType typeDescriptor;
    UInt32 reserved;
    UInt32 screeningFlag;
    UInt32 channelCount;
    CMScreeningChannelRec channelInfo[1];
};
typedef struct CMScreeningType CMScreeningType;
```

Fields

`typeDescriptor`

`reserved`

`screeningFlag`

`channelCount`

`data`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CMICCProfile.h`

CMSearchRecord

Contains information needed for a search.

```
struct CMSearchRecord {
    OSType CMMType;
    OSType profileClass;
    OSType dataColorSpace;
    OSType profileConnectionSpace;
    UInt32 deviceManufacturer;
    UInt32 deviceModel;
    UInt32 deviceAttributes[2];
    UInt32 profileFlags;
    UInt32 searchMask;
    CMProfileFilterUPP filter;
};
typedef struct CMSearchRecord CMSearchRecord;
```

Fields

`CMMType`

The signature of a CMM. The signature of the default CMM is specified by the `kDefaultCMMSignature` constant.

`profileClass`

The class signature identifying the type of profile to search for. For a list of profile class signatures, see "Profile Classes" (page 999).

`dataColorSpace`

A data color space. For a list of the color space signatures, see "Color Space Signatures" (page 969).

`profileConnectionSpace`

A profile connection color space. The signatures for the two profile connection spaces supported by ColorSync, `cmXYZData` and `cmLabData`, are described in "Color Space Signatures" (page 969).

`deviceManufacturer`
The signature of the manufacturer.

`deviceModel`
The model of a device.

`deviceAttributes`
Attributes for a particular device setup, such as media, paper, and ink types.

`profileFlags`
Flags that indicate hints for the preferred CMM, such as quality, speed, and memory options. In most cases, you will not want to search for profiles based on the flags settings.

`searchMask`
A bitmask that specifies the search record fields to use in the profile search.

`filter`
A pointer to an application-supplied function that determines whether to exclude a profile from the profile search result list. For more information, see the function `CMProfileFilterProcPtr` (page 864).

Discussion
Your application supplies a search record of type `CMSearchRecord` as the `searchSpec` parameter to the function `CMNewProfileSearch` (page 789). The search record structure provides the ColorSync Manager with search criteria to use in determining which version 2.x profiles to include in the result list and which to filter out.

Most of the fields in the `CMSearchRecord` structure are identical to corresponding fields in the `CM2Header` structure for version 2.x profiles. When you set a bit in the `searchMask` field of the `CMSearchRecord` structure, you cause the search criteria to include the data specified by that bit. For example, if you set the `cmMatchProfileCMMType` bit, the search result will not include a profile unless the data in the profile header's `CMMType` field matches the data you specify in the `CMSearchRecord` structure's `CMMType` field.

If you specify a bit in the `searchMask` field, you must supply information in the `CMSearchRecord` field that corresponds to that bit.

The ColorSync Manager preserves the search criteria internally along with the search result list until your application calls the `CMDisposeProfileSearch` function to release the memory. This allows your application to call the `CMUpdateProfileSearch` function to update the search result if the ColorSync Profiles folder contents change without needing to provide the search specification again.

Version Notes
This type is not recommended for use in ColorSync 2.5.

You cannot use the ColorSync Manager search functions to search for ColorSync 1.0 profiles.

This type does not take advantage of the profile cache added in ColorSync version 2.5. It is used with the searching described in "Searching for Profiles Prior to ColorSync 2.5". See `CMProfileIterateData` (page 923) for information on data structures used with searching in version 2.5.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`CMApplication.h`

CMVideoCardGamma

Contains video gamma data to store with a video gamma profile tag.

```
struct CMVideoCardGamma {
    UInt32 tagType
    union {
        CMVideoCardGammaTable table;
        CMVideoCardGammaFormula formula;
    } u;
};
typedef struct CMVideoCardGamma CMVideoCardGamma;
```

Fields

`tagType`

A "Video Card Gamma Storage Types" (page 1018) constant that specifies the format of the data currently stored in the union. To determine the type of structure present in a specific instance of the `CMVideoCardGamma` structure, you test this union tag. If you are setting up a `CMVideoCardGamma` structure to store video card gamma data, you set `tagType` to a constant value that identifies the structure type you are using. The possible constant values are described in "Video Card Gamma Storage Types" (page 1018).

`table`

A structure of type `CMVideoCardGammaTable`. If the `tagType` field has the value `cmVideoCardGammaTableType`, the `CMVideoCardGamma` structure's union field should be treated as a table, as described in `CMVideoCardGammaTable` (page 941).

`formula`

Discussion
The ColorSync Manager defines the `CMVideoCardGamma` data structure to specify the video gamma data to store with a video gamma profile tag. The structure is a union that can store data in either table or formula format.

Availability
Available in Mac OS X v10.0 and later.

Declared In
CMICCProfile.h

CMVideoCardGammaFormula

```
struct CMVideoCardGammaFormula {
    Fixed redGamma;
    Fixed redMin;
    Fixed redMax;
    Fixed greenGamma;
    Fixed greenMin;
    Fixed greenMax;
    Fixed blueGamma;
    Fixed blueMin;
    Fixed blueMax;
};
typedef struct CMVideoCardGammaFormula CMVideoCardGammaFormula;
```

Fields

`redGamma`
The gamma value for red. It must be greater than 0.0.

`redMin`
The minimum gamma value for red. It must be greater than 0.0 and less than 1.0.

`redMax`
The maximum gamma value for red. It must be greater than 0.0 and less than 1.0.

`greenGamma`
The gamma value for green. It must be greater than 0.0.

`greenMin`
The minimum gamma value for green. It must be greater than 0.0 and less than 1.0.

`greenMax`
The maximum gamma value for green. It must be greater than 0.0 and less than 1.0.

`blueGamma`
The gamma value for blue. It must be greater than 0.0.

`blueMin`
The minimum gamma value for blue. It must be greater than 0.0 and less than 1.0.

`blueMax`
The maximum gamma value for blue. It must be greater than 0.0 and less than 1.0.

Discussion
The ColorSync Manager defines the `CMVideoCardGammaFormula` data structure to specify video card gamma data by providing three values each for red, blue and green gamma. The values represent the actual gamma, the minimum gamma, and the maximum gamma for each color. Specifying video gamma information by formula takes less space than specifying it with a table, but the results may be less precise.

Availability
Available in Mac OS X v10.0 and later.

Declared In
CMICCProfile.h

CMVideoCardGammaTable

```
struct CMVideoCardGammaTable {
    UInt16 channels;
    UInt16 entryCount;
    UInt16 entrySize;
    char data[1];
};
typedef struct CMVideoCardGammaTable CMVideoCardGammaTable;
```

Fields

`channels`

Number of gamma channels (1 or 3). If `channels` is set to 1 then the red, green, and blue lookup tables (LUTs) of the video card will be loaded with the same data. If `channels` is set to 3, then if the video card supports separate red, green, and blue LUTs, then the video card LUTs will be loaded with the data for the three channels from the `data` array.

`entryCount`

Number of entries per channel (1-based). The number of entries must be greater than or equal to 2.

`entrySize`

Size in bytes of each entry.

`data`

Variable-sized array of data. The size of the data is equal to `channels*entryCount*entrySize`.

Discussion

The ColorSync Manager defines the `CMVideoCardGammaTable` data structure to specify video card gamma data in table format. You specify the number of channels, the number of entries per channel, and the size of each entry. The last field in the structure is an array of size one that serves as the start of the table data. The actual size of the array is equal to the number of channels times the number of entries times the size of each entry.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CMICCProfile.h`

CMVideoCardGammaType

Specifies a video card gamma profile tag.

```
struct CMVideoCardGammaType {
    OSType typeDescriptor;
    UInt32 reserved;
    CMVideoCardGamma gamma;
};
typedef struct CMVideoCardGammaType CMVideoCardGammaType;
```

Fields

`typeDescriptor`

The signature type for a video card gamma tag. There is currently only one type possible, `cmSigVideoCardGammaType`.

`reserved`

This field is reserved and must contain the value 0.

`gamma`

A structure that specifies the video card gamma data for the profile tag, as described in `CMVideoCardGamma` (page 939).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CMICCProfile.h`

CMViewingConditionsType

```
struct CMViewingConditionsType {
    OSType typeDescriptor;
    UInt32 reserved;
    CMFixedXYZColor illuminant;
    CMFixedXYZColor surround;
    UInt32 stdIlluminant;
};
typedef struct CMViewingConditionsType CMViewingConditionsType;
```

Fields
`typeDescriptor`
`reserved`
`illuminant`
`surround`
`stdIlluminant`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CMICCProfile.h`

CMWorldRef

Defines an opaque data type used for color-matching and color-checking sessions.

```
typedef struct OpaqueCMWorldRef * CMWorldRef;
```

Discussion
Your application passes a color world reference as a parameter on calls to functions to perform color-matching and color-checking sessions and to dispose of the color world. When your application calls the function `NCWNewColorWorld` (page 846) and the function `CWConcatColorWorld` (page 823) to allocate a color world for color-matching and color-checking sessions, the ColorSync Manager returns a reference to the color world. The ColorSync Manager defines an abstract private data structure of type `OpaqueCMWorldRef` for the color world reference.

The color world is affected by the rendering intent, lookup flag, gamut flag, and quality flag of the profiles that make up the color world. For more information, see "Rendering Intent Values for Version 2.x Profiles" (page 1012), "Flag Mask Definitions for Version 2.x Profiles" (page 983), and "Quality Flag Values for Version 2.x Profiles" (page 1011).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CMTypes.h`

CMXYZColor

Contains values for a color specified in XYZ color space.

```
struct CMXYZColor {
    CMXYZComponent X;
    CMXYZComponent Y;
    CMXYZComponent Z;
};
typedef struct CMXYZColor CMXYZColor;
typedef CMXYZColor XYZColor;
```

Fields
`X`
`Y`
`Z`

Discussion
Three color component values defined by the `CMXYZComponent` type definition combine to form a color value specified in the XYZ color space. The color value is defined by the `CMXYZColor` type definition.

Your application uses the `CMXYZColor` data structure to specify a color value in the `CMColor` union to use in general purpose color matching, color checking, or color conversion. You also use the `CMXYZColor` data structure to specify the XYZ white point reference used in the conversion of colors to or from the XYZ color space.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CMICCProfile.h`

CMXYZComponent

```
typedef UInt16 CMXYZComponent;
```

Discussion
Three components combine to express a color value defined by the `CMXYZColor` type definition in the XYZ color space. Each color component is described by a numeric value defined by the `CMXYZComponent` type definition. A component value of type `CMXYZComponent` is expressed as a 16-bit value. This is formatted as an unsigned value with 1 bit of integer portion and 15 bits of fractional portion.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CMICCProfile.h`

CMXYZType

```
struct CMXYZType {
    OSType typeDescriptor;
    UInt32 reserved;
    CMFixedXYZColor XYZ[1];
};
typedef struct CMXYZType CMXYZType;
```

Fields

`typeDescriptor`

`reserved`

`XYZ`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CMICCProfile.h`

CMYKColor

```
typedef CMCMYKColor CMYKColor;
```

CMYxyColor

Contains values for a color expresed in the Yxy color space.

```
struct CMYxyColor {
    UInt16 capY;
    UInt16 x;
    UInt16 y;
};
typedef struct CMYxyColor CMYxyColor;
```

Fields

`capY`

`x`

`y`

Discussion

A color value expressed in the Yxy color space is composed of `capY`, `x`, and `y` component values. Each color component is expressed as a numeric value within the range of 0 to 65535 which maps to 0 to 1.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CMApplication.h`

NCMConcatProfileSet

```
struct NCMConcatProfileSet {
    OSType cmm;
    UInt32 flags;
    UInt32 flagsMask;
    UInt32 profileCount;
    NCMConcatProfileSpec profileSpecs[1];
};
typedef struct NCMConcatProfileSet NCMConcatProfileSet;
```

Fields

`cmm`

`flags`

`flagsMask`

`profileCount`

`profileSpecs`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CMApplication.h`

NCMConcatProfileSpec

```
struct NCMConcatProfileSpec {
    UInt32 renderingIntent;
    UInt32 transformTag;
    CMProfileRef profile;
};
typedef struct NCMConcatProfileSpec NCMConcatProfileSpec;
```

Fields

`renderingIntent`

`transformTag`

`profile`

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CMApplication.h`

NCMDeviceProfileInfo

```
struct NCMDeviceProfileInfo {
    UInt32 dataVersion;
    CMDeviceProfileID profileID;
    CMProfileLocation profileLoc;
    CFDictionaryRef profileName;
    CMDeviceProfileScope profileScope;
    UInt32 reserved;
};
typedef struct NCMDeviceProfileInfo NCMDeviceProfileInfo;
```

Fields

`dataVersion`

`profileID`

`profileLoc`

`profileName`

`profileScope`

`reserved`

Availability

Available in Mac OS X v10.1 and later.

Declared In

`CMDeviceIntegration.h`

Constants

Abstract Color Space Constants

Specify values that represent general color spaces.

```
enum {
    cmNoSpace = 0x0000,
    cmRGBSpace = 0x0001,
    cmCMYKSpace = 0x0002,
    cmHSVSpace = 0x0003,
    cmHLSSpace = 0x0004,
    cmYXYSpace = 0x0005,
    cmXYZSpace = 0x0006,
    cmLUVSpace = 0x0007,
    cmLABSpace = 0x0008,
    cmReservedSpace1 = 0x0009,
    cmGraySpace = 0x000A,
    cmReservedSpace2 = 0x000B,
    cmGamutResultSpace = 0x000C,
    cmNamedIndexedSpace = 0x0010,
    cmMCFiveSpace = 0x0011,
    cmMCSixSpace = 0x0012,
    cmMCSevenSpace = 0x0013,
    cmMCEightSpace = 0x0014,
    cmAlphaPmulSpace = 0x0040,
    cmAlphaSpace = 0x0080,
    cmRGBASpace = cmRGBSpace + cmAlphaSpace,
    cmGrayASpace = cmGraySpace + cmAlphaSpace,
    cmRGBAPmulSpace = cmRGBASpace + cmAlphaPmulSpace,
    cmGrayAPmulSpace = cmGrayASpace + cmAlphaPmulSpace
};
```

Constants

`cmNoSpace`

The ColorSync Manager does not use this constant.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmRGBSpace`

An RGB color space composed of red, green, and blue components. A bitmap never uses this constant alone. Instead, this color space is always combined with a packing format describing the amount of storage per component.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmCMYKSpace`

A CMYK color space composed of cyan, magenta, yellow, and black. A bitmap never uses this constant alone. Instead, this color space is always combined with a packing format describing the amount of storage per component.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmHSVSpace`

An HSV color space composed of hue, saturation, and value components. A bitmap never uses this constant alone. Instead, this color space is always combined with a packing format describing the amount of storage per component.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmHLSSpace`
An HLS color space composed of hue, lightness, and saturation components. A bitmap never uses this constant alone. Instead, this color space is always combined with a packing format describing the amount of storage per component.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmYXYSpace`
A Yxy color space composed of Y, x, and y components. A bitmap never uses this constant alone. Instead, this color space is always combined with a packing format describing the amount of storage per component.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmXYZSpace`
An XYZ color space composed of X, Y, and Z components. A bitmap never uses this constant alone. Instead, this color space is always combined with a packing format describing the amount of storage per component.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmLUVSpace`
An L*u*v* color space composed of L*, u*, and v* components. A bitmap never uses this constant alone. Instead, this color space is always combined with a packing format describing the amount of storage per component.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmLABSpace`
An L*a*b* color space composed of L*, a*, b* components. A bitmap never uses this constant alone. Instead, this color space is always combined with a packing format describing the amount of storage per component.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmReservedSpace1`
This field is reserved for use by QuickDraw GX.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmGraySpace`
A luminance color space with a single component, gray.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmReservedSpace2`
This field is reserved for use by QuickDraw GX.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmGamutResultSpace`
A color space for the resulting bitmap pointed to by the `resultBitMap` field of the function `CWMatchColors` (page 828). A bitmap never uses this constant alone. Instead, it uses the constant `cmGamutResult1Space`, which combines `cmGamutResultSpace` and `cmOneBitDirectPacking` to define a bitmap that is 1 bit deep.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmNamedIndexedSpace`
A named indexed color space.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmMCFiveSpace`
A five-channel multichannel (HiFi) data color space.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmMCSixSpace`
A six-channel multichannel (HiFi) data color space.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmMCSevenSpace`
A seven-channel multichannel (HiFi) data color space.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmMCEightSpace`
An eight-channel multichannel (HiFi) data color space.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmAlphaPmulSpace`
A premultiplied alpha channel component is added to the color value.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmAlphaSpace`
An alpha channel component is added to the color value.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmRGBASpace`
An RGB color space composed of red, green, and blue color value components and an alpha channel component. ColorSync does not currently support bitmaps that use this constant alone. Instead, this constant indicates the presence of an alpha channel in combination with `cmLong8ColorPacking` to indicate 8-bit packing format and `cmAlphaFirstPacking` to indicate the position of the alpha channel as the first component.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmGrayASpace`
A luminance color space with two components, a gray component followed by an alpha channel component. Each component value is 16 bits.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmRGBAPmulSpace`
Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmGrayAPmulSpace`
Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

Discussion
The data type `CMBitmap` (page 882) defines a bitmap for an image whose colors can be matched with the function `CWMatchColors` (page 828) or color-checked with the function `CWCheckColors` (page 821).

The `space` field of the `CMBitmap` type definition identifies the color space in which the colors of the bitmap image are specified. A color space is characterized by a number of components or dimensions, with each component carrying a numeric value. These values together make up the color value. A color space also specifies the format in which the color value is stored. For bitmaps in which color values are packed, the `space` field of the `CMBitmap` data type holds a constant that defines the color space and the packing format.

For the `CWMatchBitmap` function to perform color matching successfully, the color space specified in the `CMBitmap` data type's `space` field must correspond to the color space specified in the profile's `dataColorSpace` field. The source bitmap and source profile values must match and the destination bitmap and destination profile values must match. For the `CWCheckBitMap` function to perform color checking successfully, the source profile's `dataColorSpace` field value and the `space` field value of the source bitmap must specify the same color space. These functions will execute successfully as long as the color spaces are the same without regard for the packing format specified by the bitmap.

This enumeration defines constants for abstract color spaces which, when combined with a packing format constant as described in "Color Packing for Color Spaces" (page 957), can be used in the `space` field of the `CMBitmap` structure. The combined constants are shown in "Color Space Constants With Packing Formats" (page 962).

Version Notes
The constants `cmRGBASpace` and `cmGrayASpace` were moved to this enum from "Color Space Constants With Packing Formats" (page 962) in ColorSync version 2.5.

Calibrator Name Prefix

Specify an interface for new ColorSync monitor calibrators (ColorSync 2.6 and greater)

```
enum {
    kCalibratorNamePrefix = 'cali'
};
```

Constants
`kCalibratorNamePrefix`
Available in Mac OS X v10.0 and later.

Declared in `CMCalibrator.h`.

Channel Encoding Format

Specify an encoding format for sRGB64.

```
enum {
    cmSRGB16ChannelEncoding = 0x00010000
};
```

Constants

`cmSRGB16ChannelEncoding`
Used for sRGB64 encoding (±3.12 format)
Available in Mac OS X v10.0 and later.
Declared in `CMApplication.h`.

Chromatic Adaptation Values

Specify a transformation to use for chromaric adaptation.

```
typedef UInt32 CMChromaticAdaptation;
enum {
    cmUseDefaultChromaticAdaptation = 0,
    cmLinearChromaticAdaptation = 1,
    cmVonKriesChromaticAdaptation = 2,
    cmBradfordChromaticAdaptation = 3
};
```

Constants

`cmUseDefaultChromaticAdaptation`
Available in Mac OS X v10.0 and later.
Declared in `CMTypes.h`.

`cmLinearChromaticAdaptation`
Available in Mac OS X v10.0 and later.
Declared in `CMTypes.h`.

`cmVonKriesChromaticAdaptation`
Available in Mac OS X v10.0 and later.
Declared in `CMTypes.h`.

`cmBradfordChromaticAdaptation`
Available in Mac OS X v10.0 and later.
Declared in `CMTypes.h`.

CMM Function Selectors

Define selectors used for component-based CMM functions.

```
enum {
    kCMMOpen = -1,
    kCMMClose = -2,
    kCMMGetInfo = -4,
    kNCMMInit = 6,
    kCMMMatchColors = 1,
    kCMMCheckColors = 2,
    kCMMValidateProfile = 8,
    kCMMMatchBitmap = 9,
    kCMMCheckBitmap = 10,
    kCMMConcatenateProfiles = 5,
    kCMMConcatInit = 7,
    kCMMNewLinkProfile = 16,
    kNCMMConcatInit = 18,
    kNCMMNewLinkProfile = 19,
    kCMMGetPS2ColorSpace = 11,
    kCMMGetPS2ColorRenderingIntent = 12,
    kCMMGetPS2ColorRendering = 13,
    kCMMGetPS2ColorRenderingVMSize = 17,
    kCMMFlattenProfile = 14,
    kCMMUnflattenProfile = 15,
    kCMMInit = 0,
    kCMMGetNamedColorInfo = 70,
    kCMMGetNamedColorValue = 71,
    kCMMGetIndNamedColorValue = 72,
    kCMMGetNamedColorIndex = 73,
    kCMMGetNamedColorName = 74,
    kCMMMatchPixMap = 3,
    kCMMCheckPixMap = 4
};
```

Constants

`kCMMOpen`

Required.

Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared in `CMMComponent.h`.

`kCMMClose`

Required.

Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared in `CMMComponent.h`.

`kCMMGetInfo`

Required.

Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared in `CMMComponent.h`.

`kNCMMInit`

In response to this request code, your CMM should initialize any private data it will need for the color session and for subsequent requests from the calling application or driver. Required.

Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared in `CMMComponent.h`.

`kCMMMatchColors`

In response to this request code, your CMM should match the colors in the `myColors` parameter to the color gamut of the destination profile and replace the color-list color values with the matched colors. Required.

Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared in `CMMComponent.h`.

`kCMMCheckColors`

In response to this request code, your CMM should test the given list of colors in the `myColors` parameter against the gamut specified by the destination profile and report if the colors fall within a destination device's color gamut. For more information, see the function `CWCheckColors` (page 821). Required.

Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared in `CMMComponent.h`.

`kCMMValidateProfile`

In response to this request code, your CMM should test the profile whose reference is passed in the `prof` parameter to determine if the profile contains the minimum set of elements required for a profile of its type. For more information, see the function `CMValidateProfile` (page 818).

Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared in `CMMComponent.h`.

`kCMMMatchBitmap`

In response to this request code, your CMM must match the colors of the source image bitmap pointed to by the `bitmap` parameter to the gamut of the destination device using the profiles specified by a previous `kNCMMInit`, `kCMMInit`, or `kCMMConcatInit` request to your CMM. For more information, see the function `CWMatchBitmap` (page 826).

Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared in `CMMComponent.h`.

`kCMMCheckBitmap`

In response to this request code, your CMM must check the colors of the source image bitmap pointed to by the `bitmap` parameter against the gamut of the destination device using the profiles specified by a previous `kNCMMInit`, `kCMMInit`, or `kCMMConcatInit` request to your CMM. For more information, see the function `CWCheckBitmap` (page 819).

Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared in `CMMComponent.h`.

`kCMMConcatenateProfiles`

This request code is for backward compatibility with ColorSync 1.0.

Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared in `CMMComponent.h`.

`kCMMConcatInit`

In response to this request code, your CMM should initialize any private data your CMM will need for a color session involving the set of profiles specified by the profile array pointed to by the `profileSet` parameter. Your function should also initialize any additional private data needed in handling subsequent calls pertaining to this component instance. For more information, see the function `CWConcatColorWorld` (page 823).

Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared in `CMMComponent.h`.

`kCMMNewLinkProfile`

In response to this request code, your CMM must create a single device link profile of type `DeviceLink` that includes the profiles passed to you in the array pointed to by the `profileSet` parameter. For more information, see the function `CWNewLinkProfile` (page 830).

Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared in `CMMComponent.h`.

`kNCMMConcatInit`

Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared in `CMMComponent.h`.

`kNCMMNewLinkProfile`

Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared in `CMMComponent.h`.

`kCMMGetPS2ColorSpace`

In response to this request code, your CMM must obtain or derive the color space element data from the source profile whose reference is passed to your function in the `srcProf` parameter and pass the data to a low-level data-transfer function supplied by the calling application or device driver. For more information, see the function `CMGetPS2ColorSpace` (page 776).

Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared in `CMMComponent.h`.

`kCMMGetPS2ColorRenderingIntent`

In response to this request code, your CMM must obtain the color-rendering intent from the header of the source profile whose reference is passed to your function in the `srcProf` parameter and then pass the data to a low-level data-transfer function supplied by the calling application or device driver. For more information, see the function `CMGetPS2ColorRenderingIntent` (page 774).

Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared in `CMMComponent.h`.

`kCMMGetPS2ColorRendering`

In response to this request code, your CMM must obtain the rendering intent from the source profile's header and generate the color rendering dictionary (CRD) data from the destination profile, and then pass the data to a low-level data-transfer function supplied by the calling application or device driver. For more information, see the function `CMGetPS2ColorRendering` (page 773).

Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared in `CMMComponent.h`.

`kCMMGetPS2ColorRenderingVMSize`

In response to this request code, your CMM must obtain or assess the maximum virtual memory (VM) size of the color rendering dictionary (CRD) specified by the destination profile. You must return the size of the CRD for the rendering intent specified by the source profile. For more information, see the function `CMGetPS2ColorRenderingVMSize` (page 775).

Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared in `CMMComponent.h`.

`kCMMFlattenProfile`

In response to this request code, your CMM must extract the profile data from the profile to flatten, identified by the `prof` parameter, and pass the profile data to the function specified in the `proc` parameter. For more information, see the function `CMFlattenProfile` (page 748).

Changed in ColorSync 2.5: Starting with ColorSync version 2.5, the ColorSync Manager calls the function provided by the calling program directly, without going through the preferred, or any, CMM. Your CMM only needs to handle this request code for versions of ColorSync prior to version 2.5.

Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared in `CMMComponent.h`.

`kCMMUnflattenProfile`

In response to this request code, your CMM must create a temporary file in which to store the profile data you receive from the low-level data-transfer function supplied by the calling application or driver. Your function must return the file specification.

Changed in ColorSync 2.5: Starting with ColorSync version 2.5, the ColorSync Manager calls the function provided by the calling program directly, without going through the preferred, or any, CMM. Your CMM only needs to handle this request code for versions of ColorSync prior to version 2.5.

Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared in `CMMComponent.h`.

`kCMMInit`

This request code is provided for backward compatibility with ColorSync 1.0. A CMM that supports ColorSync 1.0 profiles should respond to this request code by initializing any private data required for the color-matching or gamut-checking session to be held as indicated by subsequent request codes. If your CMM supports only ColorSync 1.0 profiles or both ColorSync 1.0 profiles and ColorSync Manager version 2.x profiles, you must support this request code. If you support only ColorSync Manager version 2.x profiles, you should return an unimplemented error in response to this request code.

Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared in `CMMComponent.h`.

`kCMMGetNamedColorInfo`

In response to this request code, your CMM extracts named color data from the profile whose reference is passed in the `srcProf` parameter. For more information, see the function `CMGetNamedColorInfo` (page 763).

Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared in `CMMComponent.h`.

`kCMMGetNamedColorValue`

In response to this request code, your CMM extracts device and profile connection space (PCS) color values for a specific color name from the profile whose reference is passed in the `prof` parameter. For more information, see the function `CMGetNamedColorValue` (page 764).

Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared in `CMMComponent.h`.

`kCMMGetIndNamedColorValue`

In response to this request code, your CMM extracts device and PCS color values for a specific named color index from the profile whose reference is passed in the `prof` parameter. For more information, see the function `CMGetIndNamedColorValue` (page 759).

Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared in `CMMComponent.h`.

`kCMMGetNamedColorIndex`
: In response to this request code, your CMM extracts a named color index for a specific color name from the profile whose reference is passed in the `prof` parameter. For more information, see the function `CMGetNamedColorIndex` (page 762).

  Available in Mac OS X v10.0 through Mac OS X v10.3.

  Declared in `CMMComponent.h`.

`kCMMGetNamedColorName`
: In response to this request code, your CMM extracts a named color name for a specific named color index from the profile whose reference is passed in the `prof` parameter. For more information, see the function `CMGetNamedColorName` (page 763).

  Available in Mac OS X v10.0 through Mac OS X v10.3.

  Declared in `CMMComponent.h`.

`kCMMMatchPixMap`
: In response to this request code, your CMM must match the colors of the pixel map image pointed to by the `myPixMap` parameter to the gamut of the destination device, replacing the original pixel colors with their corresponding colors as specified in the data color space of the destination device's color gamut. To perform the matching, you use the profiles specified by a previous `kNCMMInit`, `kCMMInit`, or `kCMMConcatInit` request to your CMM. For more information, see the function `CWMatchPixMap` (page 829).

  Available in Mac OS X v10.0 through Mac OS X v10.3.

  Declared in `CMMComponent.h`.

`kCMMCheckPixMap`
: In response to this request code, your CMM must check the colors of the pixel map image pointed to by the `myPixMap` parameter against the gamut of the destination device to determine if the pixel colors are within the gamut of the destination device and report the results. To perform the check, you use the profiles specified by a previous `kNCMMInit`, `kCMMInit`, or `kCMMConcatInit` request to your CMM. For more information, see the function `CWCheckPixMap` (page 822).

  Available in Mac OS X v10.0 through Mac OS X v10.3.

  Declared in `CMMComponent.h`.

Discussion
Your CMM must respond to the ColorSync Manager required request codes. When a CMM receives a required request code from the ColorSync Manager, the CMM must determine the nature of the request, perform the appropriate processing, set an error code if necessary, and return an appropriate function result to the Component Manager. The required request codes are:

- `kNCMMInit`
- `kCMMMatchColors`
- `kCMMCheckColors`
- `kCMMInit`

Your CMM should respond to the rest of the ColorSync Manager request codes defined by this enumeration, but it is not required to do so.

Color Management Module Component Interface

Specify a CMM interface version.

```
enum {
    CMMInterfaceVersion = 1
};
```

Constants

`CMMInterfaceVersion`

Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared in `CMMComponent.h`.

Discussion

If your CMM supports the ColorSync Manager version 2.x, it should return the constant defined by the following enumeration when the Component Manager calls your CMM with the `kComponentVersionSelect` request code.

In response to the `kComponentVersionSelect` request code, a CMM should set its entry point function's result to the CMM version number. The high-order 16 bits represent the major version and the low-order 16 bits represent the minor version. The `CMMInterfaceVersion` constant represents the major version number.

A CMM that only supports ColorSync 1.0 returns 0 for the major version in response to the version request.

The `kComponentVersionSelect` request code is one of four required Component Manager requests your CMM must handle.

Color Packing for Color Spaces

Specify how color values are stored.

```
enum {
    cmNoColorPacking = 0x0000,
    cmWord5ColorPacking = 0x0500,
    cmWord565ColorPacking = 0x0600,
    cmLong8ColorPacking = 0x0800,
    cmLong10ColorPacking = 0x0A00,
    cmAlphaFirstPacking = 0x1000,
    cmOneBitDirectPacking = 0x0B00,
    cmAlphaLastPacking = 0x0000,
    cm8_8ColorPacking = 0x2800,
    cm16_8ColorPacking = 0x2000,
    cm24_8ColorPacking = 0x2100,
    cm32_8ColorPacking = cmLong8ColorPacking,
    cm40_8ColorPacking = 0x2200,
    cm48_8ColorPacking = 0x2300,
    cm56_8ColorPacking = 0x2400,
    cm64_8ColorPacking = 0x2500,
    cm32_16ColorPacking = 0x2600,
    cm48_16ColorPacking = 0x2900,
    cm64_16ColorPacking = 0x2A00,
    cm32_32ColorPacking = 0x2700,
    cmLittleEndianPacking = 0x4000,
    cmReverseChannelPacking = 0x8000
};
```

Constants

`cmNoColorPacking`

This constant is not used for ColorSync bitmaps.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmWord5ColorPacking`

The color values for three 5-bit color channels are stored consecutively in 16-bits, with the highest order bit unused.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmWord565ColorPacking`

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmLong8ColorPacking`

The color values for three or four 8-bit color channels are stored consecutively in a 32-bit long. For three channels, this constant is combined with either `cmAlphaFirstPacking` or `cmAlphaLastPacking` to indicate whether the unused eight bits are located at the beginning or end.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmLong10ColorPacking`

The color values for three 10-bit color channels are stored consecutively in a 32-bit long, with the two highest order bits unused.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmAlphaFirstPacking`
An alpha channel is added to the color value as its first component.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmOneBitDirectPacking`
One bit is used as the pixel format. This storage format is used by the resulting bitmap pointed to by the `resultBitMap` field of the function `CWMatchColors` (page 828); the bitmap must be only 1 bit deep.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmAlphaLastPacking`
Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cm8_8ColorPacking`
Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cm16_8ColorPacking`
Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cm24_8ColorPacking`
The color values for three 8-bit color channels are stored in consecutive bytes, for a total of 24 bits.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cm32_8ColorPacking`
The color values for four 8-bit color channels are stored in consecutive bytes, for a total of 32 bits.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cm40_8ColorPacking`
The color values for five 8-bit color channels are stored in consecutive bytes, for a total of 40 bits.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cm48_8ColorPacking`
The color values for six 8-bit color channels are stored in consecutive bytes, for a total of 48 bits.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cm56_8ColorPacking`
The color values for seven 8-bit color channels are stored in consecutive bytes, for a total of 56 bits.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cm64_8ColorPacking`
The color values for eight 8-bit color channels are stored in consecutive bytes, for a total of 64 bits.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cm32_16ColorPacking`
The color values for two 16-bit color channels are stored in a 32-bit word.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cm48_16ColorPacking`
The color values for three 16-bit color channels are stored in 48 consecutive bits.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cm64_16ColorPacking`
The color values for four 16-bit color channels are stored in 64 consecutive bits.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cm32_32ColorPacking`
The color value for a 32-bit color channel is stored in a 32-bit word.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmLittleEndianPacking`
Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmReverseChannelPacking`
Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

Discussion
The ColorSync bitmap data type `CMBitmap` (page 882) includes a field that identifies the color space in which the color values of the bitmap image are expressed. This enumeration defines the types of packing for a color space's storage format. The enumeration also defines an alpha channel that can be added as a component of a color value to define the degree of opacity or transparency of a color. These constants are combined with the constants described in "Abstract Color Space Constants" (page 946) to create values that identify a bitmap's color space. Your application does not specify color packing constants directly, but rather uses the combined constants, which are described in "Color Space Constants With Packing Formats" (page 962).

Version Notes
The constants `cm48_16ColorPacking` and `cm64_16ColorPacking` were added in ColorSync version 2.5.

Color Responses

Specify responses for ColorSync 1.0 specifications.

```
enum {
    cmGrayResponse = 0,
    cmRedResponse = 1,
    cmGreenResponse = 2,
    cmBlueResponse = 3,
    cmCyanResponse = 4,
    cmMagentaResponse = 5,
    cmYellowResponse = 6,
    cmUcrResponse = 7,
    cmBgResponse = 8,
    cmOnePlusLastResponse = 9
};
```

Constants

`cmGrayResponse`
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CMICCProfile.h`.

`cmRedResponse`
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CMICCProfile.h`.

`cmGreenResponse`
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CMICCProfile.h`.

`cmBlueResponse`
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CMICCProfile.h`.

`cmCyanResponse`
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CMICCProfile.h`.

`cmMagentaResponse`
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CMICCProfile.h`.

`cmYellowResponse`
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CMICCProfile.h`.

`cmUcrResponse`
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CMICCProfile.h`.

`cmBgResponse`

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CMICCProfile.h`.

`cmOnePlusLastResponse`

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CMICCProfile.h`.

Color Space Constants With Packing Formats

Specifies bitmap spaces with a wide range of data formats appropriate for multiple platforms.

```
enum {
    cmGray8Space = cmGraySpace + cm8_8ColorPacking,
    cmGray16Space = cmGraySpace,
    cmGray16LSpace = cmGraySpace + cmLittleEndianPacking,
    cmGrayA16Space = cmGrayASpace + cm16_8ColorPacking,
    cmGrayA32Space = cmGrayASpace,
    cmGrayA32LSpace = cmGrayASpace + cmLittleEndianPacking,
    cmGrayA16PmulSpace = cmGrayAPmulSpace + cm16_8ColorPacking,
    cmGrayA32PmulSpace = cmGrayAPmulSpace,

    cmNamedIndexed32LSpace = cm32_32ColorPacking + cmNamedIndexedSpace
+ cmLittleEndianPacking,
    cmMCFive8Space = cm40_8ColorPacking + cmMCFiveSpace,
    cmMCSix8Space = cm48_8ColorPacking + cmMCSixSpace,
    cmMCSeven8Space = cm56_8ColorPacking + cmMCSevenSpace,
    cmMCEight8Space = cm64_8ColorPacking + cmMCEightSpace
};
```

```
typedef UInt32 CMBitmapColorSpace;
```

Constants

`cmGray8Space`
Available in Mac OS X v10.0 and later.
Declared in `CMApplication.h`.

`cmGray16Space`
A luminance color space with a single 16-bit component, gray.
Available in Mac OS X v10.0 and later.
Declared in `CMApplication.h`.

`cmGray16LSpace`
Available in Mac OS X v10.0 and later.
Declared in `CMApplication.h`.

`cmGrayA16Space`
Available in Mac OS X v10.0 and later.
Declared in `CMApplication.h`.

`cmGrayA32Space`
A luminance color space with two components, a gray component followed by an alpha channel component. Each component value is 16 bits.
Available in Mac OS X v10.0 and later.
Declared in `CMApplication.h`.

`cmGrayA32LSpace`
Available in Mac OS X v10.0 and later.
Declared in `CMApplication.h`.

`cmGrayA16PmulSpace`
Available in Mac OS X v10.0 and later.
Declared in `CMApplication.h`.

`cmGrayA32PmulSpace`
Available in Mac OS X v10.0 and later.
Declared in `CMApplication.h`.

`cmGrayA32LPmulSpace`
Available in Mac OS X v10.0 and later.
Declared in `CMApplication.h`.

`cmRGB16Space`
An RGB color space composed of red, green, and blue components whose values are packed with 5 bits of storage per component. The storage size for a color value expressed in this color space is 16 bits, with the high-order bit not used.
Available in Mac OS X v10.0 and later.
Declared in `CMApplication.h`.

`cmRGB16LSpace`
Available in Mac OS X v10.0 and later.
Declared in `CMApplication.h`.

`cmRGB565Space`
Available in Mac OS X v10.0 and later.
Declared in `CMApplication.h`.

`cmRGB565LSpace`

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmRGB24Space`

An RGB color space composed of red, green, and blue components whose values are packed with 8 bits of storage per component. The storage size for a color value expressed in this color space is 24 bits.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmRGB32Space`

An RGB color space composed of red, green, and blue components whose values are packed with 8 bits of storage per component. The storage size for a color value expressed in this color space is 32 bits, with bits 24-31 not used.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmRGB48Space`

An RGB color space composed of red, green, and blue components whose values are packed with 16 bits of storage per component. The storage size for a color value expressed in this color space is 48 bits.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmRGB48LSpace`

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmARGB32Space`

An RGB color space composed of red, green, and blue color value components preceded by an alpha channel component whose values are packed with 8 bits of storage per component. The storage size for a color value expressed in this color space is 32 bits.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmARGB64Space`

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmARGB64LSpace`

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmRGBA32Space`

An RGB color space composed of red, green, and blue color value components, followed by an alpha channel component. Values are packed with 8 bits of storage per component. The storage size for a color value expressed in this color space is 32 bits.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmRGBA64Space`

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmRGBA64LSpace`
Available in Mac OS X v10.0 and later.
Declared in `CMApplication.h`.

`cmARGB32PmulSpace`
Available in Mac OS X v10.0 and later.
Declared in `CMApplication.h`.

`cmARGB64PmulSpace`
Available in Mac OS X v10.0 and later.
Declared in `CMApplication.h`.

`cmARGB64LPmulSpace`
Available in Mac OS X v10.0 and later.
Declared in `CMApplication.h`.

`cmRGBA32PmulSpace`
Available in Mac OS X v10.0 and later.
Declared in `CMApplication.h`.

`cmRGBA64PmulSpace`
Available in Mac OS X v10.0 and later.
Declared in `CMApplication.h`.

`cmRGBA64LPmulSpace`
Available in Mac OS X v10.0 and later.
Declared in `CMApplication.h`.

`cmCMYK32Space`
A CMYK color space composed of cyan, magenta, yellow, and black components whose values are packed with 8 bits of storage per component. The storage size for a color value expressed in this color space is 32 bits.
Available in Mac OS X v10.0 and later.
Declared in `CMApplication.h`.

`cmCMYK64Space`
A CMYK color space composed of cyan, magenta, yellow, and black components whose values are packed with 16 bits of storage per component. The storage size for a color value expressed in this color space is 64 bits.
Available in Mac OS X v10.0 and later.
Declared in `CMApplication.h`.

`cmCMYK64LSpace`
Available in Mac OS X v10.0 and later.
Declared in `CMApplication.h`.

`cmHSV32Space`
An HSV color space composed of hue, saturation, and value components whose values are packed with 10 bits of storage per component. The storage size for a color value expressed in this color space is 32 bits, with the high-order 2 bits not used.
Available in Mac OS X v10.0 and later.
Declared in `CMApplication.h`.

`cmHLS32Space`

An HLS color space composed of hue, lightness, and saturation components whose values are packed with 10 bits of storage per component. The storage size for a color value expressed in this color space is 32 bits, with the high-order 2 bits not used.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmYXY32Space`

A Yxy color space composed of Y, x, and y components whose values are packed with 10 bits of storage per component. The storage size for a color value expressed in this color space is 32 bits, with the high-order 2 bits not used.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmXYZ24Space`

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmXYZ32Space`

An XYZ color space composed of X, Y, and Z components whose values are packed with 10 bits per component. The storage size for a color value expressed in this color space is 32 bits, with the high-order 2 bits not used.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmXYZ48Space`

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmXYZ48LSpace`

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmLUV32Space`

An L*u*v* color space composed of L*, u*, and v* components whose values are packed with 10 bits per component. The storage size for a color value expressed in this color space is 32 bits, with the high-order 2 bits not used.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmLAB24Space`

An L*a*b* color space composed of L*, a*, and b* components whose values are packed with 8 bits per component. The storage size for a color value expressed in this color space is 24 bits. The 8-bit unsigned a* and b* channels are interpreted numerically as ranging from -128.0 to approximately 128.0.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmLAB32Space`
An L*a*b* color space composed of L*, a*, and b* components whose values are packed with 10 bits per component. The storage size for a color value expressed in this color space is 32 bits, with the high-order 2 bits not used. The 10-bit unsigned a* and b* channels are interpreted numerically as ranging from -128.0 to approximately 128.0.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmLAB48Space`
An L*a*b* color space composed of L*, a*, and b* components whose values are packed with 16 bits per component. The storage size for a color value expressed in this color space is 48 bits. The 16-bit unsigned a* and b* channels are interpreted numerically as ranging from -128.0 to approximately 128.0.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmLAB48LSpace`
Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmGamutResult1Space`
A gamut result color space for the resulting bitmap pointed to by the `resultBitMap` field of the function `CWMatchColors` (page 828), with 1-bit direct packing. A pixel in the returned bitmap with value 1 (displayed as black) indicates an out-of-gamut color, while a pixel value of 0 (white) indicates a color that is in gamut.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmNamedIndexed32Space`
A color space where each color is stored as a single 32-bit value, specifying an index into a named color space. The storage size for a color value expressed in this color space is 32 bits.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmNamedIndexed32LSpace`
Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmMCFive8Space`
A five-channel multichannel (HiFi) data color space, whose values are packed with 8 bits per component. The storage size for a color value expressed in this color space is 40 bits.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmMCSix8Space`
A six-channel multichannel (HiFi) data color space, whose values are packed with 8 bits per component. The storage size for a color value expressed in this color space is 48 bits.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmMCSeven8Space`

A seven-channel multichannel (HiFi) data color space, whose values are packed with 8 bits per component. The storage size for a color value expressed in this color space is 56 bits.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmMCEight8Space`

A eight-channel multichannel (HiFi) data color space, whose values are packed with 8 bits per component. The storage size for a color value expressed in this color space is 64 bits.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

Discussion

This enumeration defines constants for color spaces which can specify color values for a bitmap image. As a rule, these constants include a packing format, defined in "Color Packing for Color Spaces" (page 957). You can use these constants to set the `space` field of the `CMBitmap` type definition identifies the color space in which the colors of the bitmap image are specified, as described in "Abstract Color Space Constants" (page 946).

Version Notes

The constants `cmRGBASpace` and `cmGrayASpace` were moved to "Abstract Color Space Constants" (page 946) in ColorSync version 2.5.

The constants `cmGray16Space`, `cmGrayA32Space`, `cmRGB48Space`, `cmCMYK64Space`, and `cmLAB48Space` were added in ColorSync version 2.5.

Color Space Signatures

Define four-character-sequences associated with color spaces.

```
enum {
    cmXYZData = 'XYZ ',
    cmLabData = 'Lab ',
    cmLuvData = 'Luv ',
    cmYCbCrData = 'YCbr',
    cmYxyData = 'Yxy ',
    cmRGBData = 'RGB ',
    cmSRGBData = 'sRGB',
    cmGrayData = 'GRAY',
    cmHSVData = 'HSV ',
    cmHLSData = 'HLS ',
    cmCMYKData = 'CMYK',
    cmCMYData = 'CMY ',
    cmMCH5Data = 'MCH5',
    cmMCH6Data = 'MCH6',
    cmMCH7Data = 'MCH7',
    cmMCH8Data = 'MCH8',
    cm3CLRData = '3CLR',
    cm4CLRData = '4CLR',
    cm5CLRData = '5CLR',
    cm6CLRData = '6CLR',
    cm7CLRData = '7CLR',
    cm8CLRData = '8CLR',
    cm9CLRData = '9CLR',
    cm10CLRData = 'ACLR',
    cm11CLRData = 'BCLR',
    cm12CLRData = 'CCLR',
    cm13CLRData = 'DCLR',
    cm14CLRData = 'ECLR',
    cm15CLRData = 'FCLR',
    cmNamedData = 'NAME'
};
```

Constants

`cmXYZData`
The XYZ data color space.
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmLabData`
The L*a*b* data color space.
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmLuvData`
The L*u*v* data color space.
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmYCbCrData`
Available in Mac OS X v10.1 and later.
Declared in `CMICCProfile.h`.

`cmYxyData`
The Yxy data color space.
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmRGBData`
The RGB data color space.
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmSRGBData`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmGrayData`
The Gray data color space.
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmHSVData`
The HSV data color space.
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmHLSData`
The HLS data color space.
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmCMYKData`
The CMYK data color space.
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmCMYData`
The CMY data color space.
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmMCH5Data`
The five-channel multichannel (HiFi) data color space.
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmMCH6Data`
The six-channel multichannel (HiFi) data color space.
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmMCH7Data`
The seven-channel multichannel (HiFi) data color space.
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmMCH8Data`
The eight-channel multichannel (HiFi) data color space.
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cm3CLRData`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cm4CLRData`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cm5CLRData`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cm6CLRData`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cm7CLRData`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cm8CLRData`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cm9CLRData`
Available in Mac OS X v10.1 and later.
Declared in `CMICCProfile.h`.

`cm10CLRData`
Available in Mac OS X v10.1 and later.
Declared in `CMICCProfile.h`.

`cm11CLRData`
Available in Mac OS X v10.1 and later.
Declared in `CMICCProfile.h`.

`cm12CLRData`
Available in Mac OS X v10.1 and later.
Declared in `CMICCProfile.h`.

`cm13CLRData`
Available in Mac OS X v10.1 and later.
Declared in `CMICCProfile.h`.

`cm14CLRData`
Available in Mac OS X v10.1 and later.
Declared in `CMICCProfile.h`.

`cm15CLRData`
Available in Mac OS X v10.1 and later.
Declared in `CMICCProfile.h`.

`cmNamedData`
Available in Mac OS X v10.0 and later.

Declared in `CMICCProfile.h`.

Discussion
A ColorSync profile header contains a `dataColorSpace` field that carries the signature of the data color space in which the color values in an image using the profile are expressed. This enumeration defines the signatures for the color spaces supported by ColorSync for version 2.x profiles.

Color Space Masks

Specify masks used for color spaces.

```
enum {
    cmColorSpaceSpaceMask = 0x0000003F,
    cmColorSpacePremulAlphaMask = 0x00000040,
    cmColorSpaceAlphaMask = 0x00000080,
    cmColorSpaceSpaceAndAlphaMask = 0x000000FF,
    cmColorSpacePackingMask = 0x0000FF00,
    cmColorSpaceEncodingMask = 0x000F0000,
    cmColorSpaceReservedMask = 0xFFF00000
};
```

Constants
`cmColorSpaceSpaceMask`
Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmColorSpacePremulAlphaMask`
Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmColorSpaceAlphaMask`
Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmColorSpaceSpaceAndAlphaMask`
Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmColorSpacePackingMask`
Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmColorSpaceEncodingMask`
Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmColorSpaceReservedMask`
Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

ColorSync Scripting AppleEvent Errorsl

Define ColorSync AppleEvent scripting errors.

```
enum {
    cmspInvalidImageFile = -4220,
    cmspInvalidImageSpace = -4221,
    cmspInvalidProfileEmbed = -4222,
    cmspInvalidProfileSource = -4223,
    cmspInvalidProfileDest = -4224,
    cmspInvalidProfileProof = -4225,
    cmspInvalidProfileLink = -4226
};
```

Constants

`cmspInvalidImageFile`
Plugin cannot handle this image file type

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CMScriptingPlugin.h`.

`cmspInvalidImageSpace`
Plugin cannot create an image file of this colorspace

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CMScriptingPlugin.h`.

`cmspInvalidProfileEmbed`
Specific invalid profile errors

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CMScriptingPlugin.h`.

`cmspInvalidProfileSource`
Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CMScriptingPlugin.h`.

`cmspInvalidProfileDest`
Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CMScriptingPlugin.h`.

`cmspInvalidProfileProof`
Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CMScriptingPlugin.h`.

`cmspInvalidProfileLink`
Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CMScriptingPlugin.h`.

Current Device Versions

Specify the current versions of the data structure containing information on registered devices.

```
enum {
    cmDeviceInfoVersion1 = 0x00010000,
    cmDeviceProfileInfoVersion1 = 0x00010000,
    cmDeviceProfileInfoVersion2 = 0x00020000
};
```

Constants

`cmDeviceInfoVersion1`
Available in Mac OS X v10.0 and later.
Declared in `CMDeviceIntegration.h`.

`cmDeviceProfileInfoVersion1`
Available in Mac OS X v10.0 and later.
Declared in `CMDeviceIntegration.h`.

`cmDeviceProfileInfoVersion2`
Available in Mac OS X v10.1 and later.
Declared in `CMDeviceIntegration.h`.

Current Info Versions

Specify current device and profile versions.

```
enum {
    cmCurrentDeviceInfoVersion = cmDeviceInfoVersion1,
    cmCurrentProfileInfoVersion = cmDeviceProfileInfoVersion1
};
```

Constants

`cmCurrentDeviceInfoVersion`
Available in Mac OS X v10.0 and later.
Declared in `CMDeviceIntegration.h`.

`cmCurrentProfileInfoVersion`
Available in Mac OS X v10.0 and later.
Declared in `CMDeviceIntegration.h`.

Current Major Version Mask

Specifies the current major version number.

```
enum {
    cmProfileMajorVersionMask = 0xFF000000,
    cmCurrentProfileMajorVersion = 0x02000000
};
```

Constants

`cmProfileMajorVersionMask`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmCurrentProfileMajorVersion`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

Data Transfer Commands

Specify commands for caller-supplied ColorSync data transfer functions.

```
enum {
    cmOpenReadSpool = 1,
    cmOpenWriteSpool = 2,
    cmReadSpool = 3,
    cmWriteSpool = 4,
    cmCloseSpool = 5
};
```

Constants

`cmOpenReadSpool`
Directs the function to begin the process of reading data.
Available in Mac OS X v10.0 and later.
Declared in `CMApplication.h`.

`cmOpenWriteSpool`
Directs the function to begin the process of writing data.
Available in Mac OS X v10.0 and later.
Declared in `CMApplication.h`.

`cmReadSpool`
Directs the function to read the number of bytes specified by the `CMFlattenProcPtr` function's `size` parameter.
Available in Mac OS X v10.0 and later.
Declared in `CMApplication.h`.

`cmWriteSpool`
Directs the function to write the number of bytes specified by the `CMFlattenProcPtr` function's `size` parameter.
Available in Mac OS X v10.0 and later.
Declared in `CMApplication.h`.

`cmCloseSpool`
Directs the function to complete the data transfer.
Available in Mac OS X v10.0 and later.
Declared in `CMApplication.h`.

Discussion
When your application calls the function `CMFlattenProfile` (page 748), any of the functions in the group "Accessing Profile Elements" (page 719), or the PostScript-related functions of type "Working With PostScript" (page 722), the selected CMM—or, for the `CMUnflattenProfile` function, the ColorSync Manager—calls the flatten function you supply to transform profile data. The call passes one of the command constants defined by this enumeration.

Your application provides a pointer to your ColorSync data transfer function as a parameter to the functions. The ColorSync Manager or the CMM calls your data transfer function, passing the command in the `command` parameter. For more information on the flatten function, see `CMFlattenProfile` (page 748).

Data Type Element Values

Specify a data type.

```
enum {
    cmAsciiData = 0,
    cmBinaryData = 1
};
```

Constants
`cmAsciiData`
ASCII data.
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmBinaryData`
Binary data.
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

Default CMM Signature

Specifies a signature for the default color management module supplied by Color Sync.

```
enum {
    kDefaultCMMSignature = 'appl'
};
```

Constants
`kDefaultCMMSignature`
Signature for the default CMM supplied with the ColorSync Manager.
Available in Mac OS X v10.0 and later.
Declared in `CMApplication.h`.

Discussion
A color management module (CMM) uses profiles to convert and match a color in a given color space on a given device to or from another color space or device.

To specify the default CMM, set the `CMMType` field of the profile header to the default signature defined by the following enumeration. You use a structure of type `CM2Header` (page 875) for a ColorSync 2.x profile and a structure of type `CMHeader` (page 898) for a 1.0 profile header.

Default IDs

Specify default values for device and profile IDs.

```
enum {
    cmDefaultDeviceID = 0,
    cmDefaultProfileID = 0
};
```

Constants

`cmDefaultDeviceID`

Available in Mac OS X v10.0 and later.

Declared in `CMDeviceIntegration.h`.

`cmDefaultProfileID`

Available in Mac OS X v10.0 and later.

Declared in `CMDeviceIntegration.h`.

Discussion

Certain routines require a device ID or profile ID. In some cases, a "default ID" can be used.

Device Attribute Values for Version 2.x Profiles

Define masks your application can use to set or test bits in the `deviceAttributes` field of the `CM2Header` structure.

```
enum {
    cmReflectiveTransparentMask = 0x00000001,
    cmGlossyMatteMask = 0x00000002
};
```

Constants

`cmReflectiveTransparentMask`

Bit 0 of `deviceAttributes[1]` specifies whether the media is transparent or reflective. If it has the value 0, the media is reflective; if it has the value 1, the media is transparent. Use the `cmReflectiveTransparentMask` mask to set the transparent/reflective bit in `deviceAttributes[1]` or to clear all bits except the transparent/reflective bit.

Available in Mac OS X v10.0 and later.

Declared in `CMICCProfile.h`.

`cmGlossyMatteMask`

Bit 1of `deviceAttributes[1]` specifies whether the media is glossy or matte. If it has the value 0, the media is glossy; if it has the value 1, the media is matte. Use the `cmGlossyMatteMask` mask to set the glossy/matte bit in `deviceAttributes[1]` or to clear all bits except the glossy/matte bit.

Available in Mac OS X v10.0 and later.

Declared in `CMICCProfile.h`.

Discussion

The ColorSync Manager defines the structure `CM2Header` (page 875) to represent the profile header for the version 2.x profile format defined by the ICC.The `deviceAttributes` field of the `CM2Header` structure is an array of two unsigned long values whose bits specify information about a profile. The ICC reserves the use of `deviceAttributes[1]` and has assigned values to bits 0 and 1. All the bits of `deviceAttributes[0]` are reserved for use by color management system (CMS) vendors.

Device Classes

Define constants to represent a variey of input and output devices.

```
enum {
    cmScannerDeviceClass = 'scnr',
    cmCameraDeviceClass = 'cmra',
    cmDisplayDeviceClass = 'mntr',
    cmPrinterDeviceClass = 'prtr',
    cmProofDeviceClass = 'pruf'
};
typedef OSType CMDeviceClass;
```

Constants

`cmScannerDeviceClass`
Available in Mac OS X v10.0 and later.
Declared in `CMDeviceIntegration.h`.

`cmCameraDeviceClass`
Available in Mac OS X v10.0 and later.
Declared in `CMDeviceIntegration.h`.

`cmDisplayDeviceClass`
Available in Mac OS X v10.0 and later.
Declared in `CMDeviceIntegration.h`.

`cmPrinterDeviceClass`
Available in Mac OS X v10.0 and later.
Declared in `CMDeviceIntegration.h`.

`cmProofDeviceClass`
Available in Mac OS X v10.0 and later.
Declared in `CMDeviceIntegration.h`.

Device and Media Attributes

Used to set or obtaind device or media attributes.

```
enum {
    cmReflective = 0,
    cmGlossy = 1
};
```

Constants

`cmReflective`
If the bit 0 of the associated mask is `0` then reflective media; if `1` then transparency media.
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmGlossy`
If the bit 1 of the associated mask is is `0` then glossy; if `1` then matte.
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

Device States

Specify device states.

```
enum {
    cmDeviceStateDefault = 0x00000000,
    cmDeviceStateOffline = 0x00000001,
    cmDeviceStateBusy = 0x00000002,
    cmDeviceStateForceNotify = 0x80000000,
    cmDeviceStateDeviceRsvdBits = 0x00FF0000,
    cmDeviceStateAppleRsvdBits = 0xFF00FFFF
};
```

Constants

`cmDeviceStateDefault`
Available in Mac OS X v10.0 and later.
Declared in `CMDeviceIntegration.h`.

`cmDeviceStateOffline`
Available in Mac OS X v10.0 and later.
Declared in `CMDeviceIntegration.h`.

`cmDeviceStateBusy`
Available in Mac OS X v10.0 and later.
Declared in `CMDeviceIntegration.h`.

`cmDeviceStateForceNotify`
Available in Mac OS X v10.0 and later.
Declared in `CMDeviceIntegration.h`.

`cmDeviceStateDeviceRsvdBits`
Available in Mac OS X v10.0 and later.
Declared in `CMDeviceIntegration.h`.

`cmDeviceStateAppleRsvdBits`
Available in Mac OS X v10.0 and later.
Declared in `CMDeviceIntegration.h`.

Discussion

Specify possible values for device states accessible by the functions `CMGetDeviceState` and `CMSetDeviceState`.

Device Types

Specify a device type.

```
enum {
    cmMonitorDevice = 'mntr',
    cmScannerDevice = 'scnr',
    cmPrinterDevice = 'prtr'
};
```

Constants

`cmMonitorDevice`

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CMICCProfile.h`.

`cmScannerDevice`

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CMICCProfile.h`.

`cmPrinterDevice`

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CMICCProfile.h`.

Element Tags and Signatures for Version 1.0 Profiles

Define tags and signatures used for version 1.0 profiles.

```
enum {
    cmCS1ChromTag = 'chrm',
    cmCS1TRCTag = 'trc ',
    cmCS1NameTag = 'name',
    cmCS1CustTag = 'cust'
};
```

Constants

`cmCS1ChromTag`

The tag signature for the profile chromaticities tag whose element data specifies the XYZ chromaticities for the six primary and secondary colors (red, green, blue, cyan, magenta, and yellow).

Available in Mac OS X v10.0 and later.

Declared in `CMICCProfile.h`.

`cmCS1TRCTag`

The tag signature for profile tonal response curve data for the associated device.

Available in Mac OS X v10.0 and later.

Declared in `CMICCProfile.h`.

`cmCS1NameTag`

The tag signature for the profile name string. This is an international string consisting of a Macintosh script code followed by a 63-byte text string identifying the profile.

Available in Mac OS X v10.0 and later.

Declared in `CMICCProfile.h`.

`cmCS1CustTag`
Private data for a custom CMM.

Available in Mac OS X v10.0 and later.

Declared in `CMICCProfile.h`.

Discussion
The ICC version 2.x profile format differs from the version 1.0 profile format, and ColorSync Manager routines for updating a profile and searching for profiles do not work with version 1.0 profiles. However, your application can use version 1.0 profiles with all other ColorSync routines. For example, you can open a version 1.0 profile using the function `CMOpenProfile` (page 790), obtain the version 1.0 profile header using the function `CMGetProfileHeader` (page 769), and access version 1.0 profile elements using the function `CMGetProfileElement` (page 768).

To make this possible, the ColorSync Manager includes support for the version 1.0 profile header structure and synthesizes tags to allow you to access four 1.0 elements outside the version 1.0 profile header. This enumeration defines these tags.

Embedded Profile Flags

Specify copyright-protection flag options,

```
enum {
    cmEmbeddedProfile = 0,
    cmEmbeddedUse = 1
};
```

Constants
`cmEmbeddedProfile`
0 is not embedded profile, 1 is embedded profile

Available in Mac OS X v10.0 and later.

Declared in `CMICCProfile.h`.

`cmEmbeddedUse`
0 is to use anywhere, 1 is to use as embedded profile only

Available in Mac OS X v10.0 and later.

Declared in `CMICCProfile.h`.

Embedded Profile Identifiers

Specify constants used when embedding picture comments.

```
enum {
    cmEmbedWholeProfile = 0x00000000,
    cmEmbedProfileIdentifier = 0x00000001
};
```

Constants

`cmEmbedWholeProfile`

When the `flags` parameter has the value `cmEmbedWholeProfile`, the `NCMUseProfileComment` function embeds the entire specified profile.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CMApplication.h`.

`cmEmbedProfileIdentifier`

When the `flags` parameter has the value `cmEmbedProfileIdentifier`, the `NCMUseProfileComment` function embeds a profile identifier for the specified profile.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CMApplication.h`.

Discussion

The ColorSync Manager provides these constant declarations to use with the function `NCMUseProfileComment` (page 843) for embedding picture comments. You use these constants to set the `flags` parameter to indicate whether to embed an entire profile or just a profile identifier.

Flag Mask Definitions for Version 2.x Profiles

Define masks your application can use to set or test various bits in the `flags` field of the `CM2Header` structure.

```
enum {
    cmICCReservedFlagsMask = 0x0000FFFF,
    cmEmbeddedMask = 0x00000001,
    cmEmbeddedUseMask = 0x00000002,
    cmCMSReservedFlagsMask = 0xFFFF0000,
    cmQualityMask = 0x00030000,
    cmInterpolationMask = 0x00040000,
    cmGamutCheckingMask = 0x00080000
};
```

Constants

`cmICCReservedFlagsMask`

This mask provides access to bits 0 through 15 of the `flags` field, which are defined and reserved by the ICC. For more information, see the International Color Consortium Profile Format Specification, and the next two mask definitions.

To obtain a copy of the ICC specification, or to get other information about the ICC, visit the ICC Web site at http://www.color.org/.

Available in Mac OS X v10.0 and later.

Declared in `CMICCProfile.h`.

`cmEmbeddedMask`

This mask provides access to bit 0 of the `flags` field, which specifies whether the profile is embedded. It has the value 1 if the profile is embedded, 0 if it is not.

Available in Mac OS X v10.0 and later.

Declared in `CMICCProfile.h`.

`cmEmbeddedUseMask`

This mask provides access to bit 1 of the `flags` field, which specifies whether the profile can be used independently or can only be used as an embedded profile. It has the value 0 if the profile can be used anywhere, 1 if it must be embedded.

You should interpret the setting of this bit as an indication of copyright protection. If the profile developer set this bit to 1, you should use this profile as an embedded profile only and not copy the profile for your own purposes. The profile developer also specifies explicit copyright intention using the `cmCopyrightTag` profile tag (defined in the `CMICCProfile.h` header file).

Available in Mac OS X v10.0 and later.

Declared in `CMICCProfile.h`.

`cmCMSReservedFlagsMask`

This mask provides access to bits 16 through 31 of the `flags` field, which are available for a color management system (CMS) vendor, such as ColorSync. ColorSync's default CMM uses bits 16 through 19 to provide hints for color matching, as described in the following three mask definitions. Other CMM vendors should follow the same conventions.

Available in Mac OS X v10.0 and later.

Declared in `CMICCProfile.h`.

`cmQualityMask`

This mask provides access to bits 16 and 17 of the `flags` field, which specify the preferred quality and speed preferences for color matching. In general, the higher the quality the slower the speed. For example, best quality is slowest, but produces the highest quality result.

Bits 16 and 17 have the value 0 for normal quality, 1 for draft quality, and 2 for best quality. "Quality Flag Values for Version 2.x Profiles" (page 1011) describes the constants ColorSync defines to test or set these bits.

This feature is provided by the ColorSync Manager; it is not defined by the ICC profile specification.

Available in Mac OS X v10.0 and later.

Declared in `CMICCProfile.h`.

`cmInterpolationMask`

This mask provides access to bit 18 of the `flags` field, which specifies whether to use interpolation in color matching. The value 0 specifies interpolation. The value 1 specifies table lookup without interpolation. Specifying lookup only improves speed but can reduce accuracy. You might use lookup only for a monitor profile, for example, when high resolution is not crucial.

This feature is provided by the ColorSync Manager; it is not defined by the ICC profile specification.

Available in Mac OS X v10.0 and later.

Declared in `CMICCProfile.h`.

`cmGamutCheckingMask`

This mask provides access to bit 19 of the `flags` field. When you use a profile to create a color world, bit 19 specifies whether the color world should include information for gamut checking. It has the value 0 if the color world should include a gamut-checking table, 1 if gamut-checking information is not required. ColorSync can create a color world without a gamut table more quickly and in less space.

Many applications do not perform gamut checking, so they should set this bit to 1. However, if you call a color checking function such as `CWCheckColors` (page 821), or `CWMatchColors` (page 828), after setting a profile's gamut-checking bit so that the color world does not contain gamut information, these routines return the `cmCantGamutCheckError` error.

This feature is provided by the ColorSync Manager; it is not defined by the ICC profile specification.

Available in Mac OS X v10.0 and later.

Declared in `CMICCProfile.h`.

Discussion

The `flags` field of the structure `CM2Header` (page 875) is an unsigned long value whose bits specify information about a profile. The ICC reserves the use of bits 0 to 15 and has assigned values to bits 0 and 1. Bits 16 to 31 are reserved for use by color management system (CMS) vendors. ColorSync has assigned values to bits 16 through 19.

ICC Profile Versions

Specify IDD profile version numbers.

```
enum {
    cmICCProfileVersion4 = 0x04000000,
    cmICCProfileVersion2 = 0x02000000,
    cmICCProfileVersion21 = 0x02100000,
    cmCS2ProfileVersion = cmICCProfileVersion2,
    cmCS1ProfileVersion = 0x00000100
};
```

Constants

`cmICCProfileVersion4`

Available in Mac OS X v10.1 and later.

Declared in `CMICCProfile.h`.

`cmICCProfileVersion2`

Available in Mac OS X v10.0 and later.

Declared in `CMICCProfile.h`.

`cmICCProfileVersion21`

Available in Mac OS X v10.0 and later.

Declared in `CMICCProfile.h`.

`cmCS2ProfileVersion`

Available in Mac OS X v10.0 and later.

Declared in `CMICCProfile.h`.

`cmCS1ProfileVersion`

Available in Mac OS X v10.0 and later.

Declared in `CMICCProfile.h`.

Illuminant Measurement Endocings

Specify standard illuminate measurement encodings.

```
enum {
    cmIlluminantUnknown = 0x00000000,
    cmIlluminantD50 = 0x00000001,
    cmIlluminantD65 = 0x00000002,
    cmIlluminantD93 = 0x00000003,
    cmIlluminantF2 = 0x00000004,
    cmIlluminantD55 = 0x00000005,
    cmIlluminantA = 0x00000006,
    cmIlluminantEquiPower = 0x00000007,
    cmIlluminantF8 = 0x00000008
};
```

Constants

`cmIlluminantUnknown`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmIlluminantD50`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmIlluminantD65`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmIlluminantD93`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmIlluminantF2`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmIlluminantD55`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmIlluminantA`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmIlluminantEquiPower`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmIlluminantF8`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

Macintosh 68K Trap Word

Specifies a 68K trap word for the Macintosh.

```
enum {
    cmTrap = 0xABEE
};
```

Constants

`cmTrap`

Available in Mac OS X v10.0 through Mac OS X v10.3.

Declared in `CMApplication.h`.

Magic Cookie Number

Specifies a magic cookie number for anonymous file ID.

```
enum {
    cmMagicNumber = 'acsp'
};
```

Constants

`cmMagicNumber`

Available in Mac OS X v10.0 and later.

Declared in `CMICCProfile.h`.

Match Flags Field

Specifies a profile to match.

```
enum {
    cmspFavorEmbeddedMask = 0x00000001
};
```

Constants

`cmspFavorEmbeddedMask`

If bit 0 is `0` then use `srcProf` profile; if `1` then use profile embedded in image if present.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CMScriptingPlugin.h`.

Match Profiles 2.0

Defines matching flags for version 2.0 of the `CMSearchRecord.searchMask`.

```
enum {
    cmMatchAnyProfile = 0x00000000,
    cmMatchProfileCMMType = 0x00000001,
    cmMatchProfileClass = 0x00000002,
    cmMatchDataColorSpace = 0x00000004,
    cmMatchProfileConnectionSpace = 0x00000008,
    cmMatchManufacturer = 0x00000010,
    cmMatchModel = 0x00000020,
    cmMatchAttributes = 0x00000040,
    cmMatchProfileFlags = 0x00000080
};
```

Constants

`cmMatchAnyProfile`
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CMApplication.h`.

`cmMatchProfileCMMType`
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CMApplication.h`.

`cmMatchProfileClass`
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CMApplication.h`.

`cmMatchDataColorSpace`
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CMApplication.h`.

`cmMatchProfileConnectionSpace`
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CMApplication.h`.

`cmMatchManufacturer`
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CMApplication.h`.

`cmMatchModel`
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CMApplication.h`.

`cmMatchAttributes`
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CMApplication.h`.

`cmMatchProfileFlags`

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CMApplication.h`.

Match Profiles 1.0

Defines matching flags for version 1.0 of the `CMSearchRecord.searchMask`.

```
enum {
    cmMatchCMMType = 0x00000001,
    cmMatchApplProfileVersion = 0x00000002,
    cmMatchDataType = 0x00000004,
    cmMatchDeviceType = 0x00000008,
    cmMatchDeviceManufacturer = 0x00000010,
    cmMatchDeviceModel = 0x00000020,
    cmMatchDeviceAttributes = 0x00000040,
    cmMatchFlags = 0x00000080,
    cmMatchOptions = 0x00000100,
    cmMatchWhite = 0x00000200,
    cmMatchBlack = 0x00000400
};
```

Constants

`cmMatchCMMType`

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CMApplication.h`.

`cmMatchApplProfileVersion`

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CMApplication.h`.

`cmMatchDataType`

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CMApplication.h`.

`cmMatchDeviceType`

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CMApplication.h`.

`cmMatchDeviceManufacturer`

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CMApplication.h`.

`cmMatchDeviceModel`
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CMApplication.h`.

`cmMatchDeviceAttributes`
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CMApplication.h`.

`cmMatchFlags`
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CMApplication.h`.

`cmMatchOptions`
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CMApplication.h`.

`cmMatchWhite`
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CMApplication.h`.

`cmMatchBlack`
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `CMApplication.h`.

Maximum Path Size

Specifies the maximum length for a path name.

```
enum {
    CS_MAX_PATH = 256
};
```

Constants

`CS_MAX_PATH`
Available in Mac OS X v10.0 and later.
Declared in `CMApplication.h`.

Measurement Flares

Specify measurement flare encodings.

```
enum {
    cmFlare0 = 0x00000000,
    cmFlare100 = 0x00000001
};
```

Constants

`cmFlare0`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmFlare100`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

Measurment Geometries

Specify measurement geometry encodings.

```
enum {
    cmGeometryUnknown = 0x00000000,
    cmGeometry045or450 = 0x00000001,
    cmGeometry0dord0 = 0x00000002
};
```

Constants

`cmGeometryUnknown`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmGeometry045or450`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmGeometry0dord0`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

Obsolete Color Response Values

Redefines obsolete color response values.

```
enum {
    grayResponse = cmGrayResponse,
    redResponse = cmRedResponse,
    greenResponse = cmGreenResponse,
    blueResponse = cmBlueResponse,
    cyanResponse = cmCyanResponse,
    magentaResponse = cmMagentaResponse,
    yellowResponse = cmYellowResponse,
    ucrResponse = cmUcrResponse,
    bgResponse = cmBgResponse,
    onePlusLastResponse = cmOnePlusLastResponse
};
```

Obsolete Color Space Signatures

Redefines obsolete color space signatures.

```
enum {
    rgbData = cmRGBData,
    cmykData = cmCMYKData,
    grayData = cmGrayData,
    xyzData = cmXYZData
};
```

Obsolete Device Type Names

Redefines obsolete device type names.

```
enum {
    monitorDevice = cmMonitorDevice,
    scannerDevice = cmScannerDevice,
    printerDevice = cmPrinterDevice
};
```

Parametric Types

Specify a parametric curve type enumeration,

```
enum {
    cmParametricType0 = 0,
    cmParametricType1 = 1,
    cmParametricType2 = 2,
    cmParametricType3 = 3,
    cmParametricType4 = 4
};
```

Constants

`cmParametricType0`

Y = X^gamma

Available in Mac OS X v10.1 and later.

Declared in `CMICCProfile.h`.

`cmParametricType1`
Y = (aX+b)^gamma [X>=-b/a], Y = 0 [X<-b/a]

Available in Mac OS X v10.1 and later.

Declared in `CMICCProfile.h`.

`cmParametricType2`
Y = (aX+b)^gamma + c [X>=-b/a], Y = c [X<-b/a]

Available in Mac OS X v10.1 and later.

Declared in `CMICCProfile.h`.

`cmParametricType3`
Y = (aX+b)^gamma [X>=d], Y = cX [X<d]

Available in Mac OS X v10.1 and later.

Declared in `CMICCProfile.h`.

`cmParametricType4`
Y = (aX+b)^gamma + e [X>=d], Y = cX+f [X<d]

Available in Mac OS X v10.2 and later.

Declared in `CMICCProfile.h`.

Platform Enumeration Values

Specify computer platforms.

```
enum {
    cmMacintosh = 'APPL',
    cmMicrosoft = 'MSFT',
    cmSolaris = 'SUNW',
    cmSiliconGraphics = 'SGI ',
    cmTaligent = 'TGNT'
};
```

Profile Iteration Values

Specify profiles to iterate.

```
enum {
    cmIterateFactoryDeviceProfiles = 0x00000001,
    cmIterateCustomDeviceProfiles = 0x00000002,
    cmIterateCurrentDeviceProfiles = 0x00000003,
    cmIterateAllDeviceProfiles = 0x00000004,
    cmIterateDeviceProfilesMask = 0x0000000F
};
```

Constants

`cmIterateFactoryDeviceProfiles`
Iterate profiles registered through the routine `CMSetDeviceFactoryProfiles`. To retrieve all factory profiles for all devices, use `cmIterateFactoryDeviceProfiles` as the flags value when calling `CMIterateDeviceProfiles`. I

Available in Mac OS X v10.0 and later.

Declared in `CMDeviceIntegration.h`.

`cmIterateCustomDeviceProfiles`
: Iterate profiles that are meant to take the place of the factory profiles, as a result of customization or calibration. To retrieve only custom profiles for all devices, use the `cmIterateCustomDeviceProfiles`, as the flags value when calling `CMIterateDeviceProfiles`.

  Available in Mac OS X v10.0 and later.

  Declared in `CMDeviceIntegration.h`.

`cmIterateCurrentDeviceProfiles`
: Iterate profiles registered through the routing `CMSetDeviceProfiles`. To get the profiles in use for all devices, use `cmIterateCurrentDeviceProfiles` as the flags value. This will replace the factory profiles with any overrides, yielding the currently used set.l

  Available in Mac OS X v10.0 and later.

  Declared in `CMDeviceIntegration.h`.

`cmIterateAllDeviceProfiles`
: Iterate all profiles, without replacement.

  Available in Mac OS X v10.1 and later.

  Declared in `CMDeviceIntegration.h`.

`cmIterateDeviceProfilesMask`
: Available in Mac OS X v10.0 and later.

  Declared in `CMDeviceIntegration.h`.

Discussion
These are possible values for flags passed to the function `CMIterateDeviceProfiles`.

Profile Location Sizes

Specify a location size.

```
enum {
    cmOriginalProfileLocationSize = 72,
    cmCurrentProfileLocationSize = 2 + CS_MAX_PATH
};
```

Constants
`cmOriginalProfileLocationSize`
: Available in Mac OS X v10.0 and later.

  Declared in `CMApplication.h`.

`cmCurrentProfileLocationSize`
: Available in Mac OS X v10.0 and later.

  Declared in `CMApplication.h`.

Profile Options

Specify a rendering intent.

```
enum {
    cmPerceptualMatch = 0x0000,
    cmColorimetricMatch = 0x0001,
    cmSaturationMatch = 0x0002
};
```

Constants

`cmPerceptualMatch`

Default. For photographic images

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CMICCProfile.h`.

`cmColorimetricMatch`

Exact matching when possible

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CMICCProfile.h`.

`cmSaturationMatch`

For solid colors

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CMICCProfile.h`.

PostScript Data Formats

Specify constants that indicate the format of PostScript data.

```
enum {
    cmPS7bit = 1,
    cmPS8bit = 2
};
```

Constants

`cmPS7bit`

The data is 7-bit safe—therefore the data could be in 7-bit ASCII encoding or in ASCII base-85 encoding.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmPS8bit`

The data is 8-bit safe—therefore the data could be in 7-bit or 8-bit ASCII encoding.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

Discussion

The ColorSync Manager provides these constant declarations to specify the format of PostScript data.

Picture Comment Kinds

Specify picture comment kinds for profiles and color matching.

```
enum {
    cmBeginProfile = 220,
    cmEndProfile = 221,
    cmEnableMatching = 222,
    cmDisableMatching = 223,
    cmComment = 224
};
```

Constants

`cmBeginProfile`

Indicates the beginning of a version 1.0 profile to embed. (To start a 2.x profile, you use `cmComment`.)

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CMApplication.h`.

`cmEndProfile`

Signals end of the use of an embedded version 2.x or 1.0 profile.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CMApplication.h`.

`cmEnableMatching`

Turns on color matching for the ColorSync Manager. Do not nest `cmEnableMatching` and `cmDisableMatching` pairs.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CMApplication.h`.

`cmDisableMatching`

Turns off color matching for the ColorSync Manager. Do not nest `cmEnableMatching` and `cmDisableMatching` pairs. After the ColorSync Manager encounters this comment, it ignores all ColorSync-related picture comments until it encounters the next `cmEnableMatching` picture comment. At that point, the most recently used profile is reinstated.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CMApplication.h`.

`cmComment`

Provides information about a 2.x embedded profile or embedded profile identifier reference. This picture comment is followed by a 4-byte selector identifying what follows. "Picture Comment Selectors" (page 997) describes the possible selectors.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CMApplication.h`.

Discussion

The ColorSync Manager defines five picture comment kinds. You use these comments to embed a profile identifier, begin or end use of an embedded profile, and enable or disable color matching within drawing code sent to an output device. The `PicComment` function's `kind` parameter specifies the kind of picture comment.

Use a picture comment of kind `cmEndProfile` to explicitly terminate use of the currently effective embedded profile and begin use of the system profile. Otherwise, the currently effective profile remains in effect, leading to unexpected results if another picture follows that is meant to use the system profile and so is not preceded by a profile.

Picture Comment Selectors

Specify selectors to use in piture comments.

```
enum {
    cmBeginProfileSel = 0,
    cmContinueProfileSel = 1,
    cmEndProfileSel = 2,
    cmProfileIdentifierSel = 3
};
```

Constants

`cmBeginProfileSel`

Identifies the beginning of version 2.x profile data. The amount of profile data you can specify is limited to 32K minus 4 bytes for the selector.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CMApplication.h`.

`cmContinueProfileSel`

Identifies the continuation of version 2.x profile data. The amount of profile data you can specify is limited to 32K minus 4 bytes for the selector. You can use this selector repeatedly until all the profile data is embedded.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CMApplication.h`.

`cmEndProfileSel`

Signals the end of version 2.x profile data—no more data follows. Even if the amount of profile data embedded does not exceed 32K minus 4 bytes for the selector and your application did not use `cmContinueProfileSel`, you must terminate the process with `cmEndProfileSel`. Note that this selector has a behavior that is different from the `cmEndProfile` picture comment described in "Picture Comment Kinds" (page 995).

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CMApplication.h`.

`cmProfileIdentifierSel`

Identifies the inclusion of profile identifier data. For information on embedding a profile identifier, see the function `NCMUseProfileComment` (page 843). For information on the format of profile identifier data, see `CMProfileIdentifier` (page 921).

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CMApplication.h`.

Discussion
To embed a version 2.x profile or profile identifier reference in a picture destined for display on another system or on a device such as a printer, your application uses the QuickDraw `PicComment` function. The ColorSync Manager provides the function `NCMUseProfileComment` (page 843) to embed picture comments. You specify a picture comment `kind` value of `cmComment` and a 4-byte selector describing the data in the picture comment.

Because a profile may exceed QuickDraw's 32 KB size limit for a picture comment, your application can use an ordered series of picture comments to embed a large profile.

You can also embed a profile identifier reference in a picture. The profile identifier may refer to a previously embedded profile, so that you do not have to embed the entire profile again, or it may refer to a profile stored on disk. When you embed a profile identifier, you can change certain values for the referred-to profile, including the quality flags and rendering intent. For more information on profile identifiers, see `CMProfileIdentifier` (page 921).

This enumeration defines the 4-byte selector values your application uses to identify the beginning and continuation of profile data and to signal the end of it.

Profile Access Procedures

Specify operations used to access profiles.

```
enum {
    cmOpenReadAccess = 1,
    cmOpenWriteAccess = 2,
    cmReadAccess = 3,
    cmWriteAccess = 4,
    cmCloseAccess = 5,
    cmCreateNewAccess = 6,
    cmAbortWriteAccess = 7,
    cmBeginAccess = 8,
    cmEndAccess = 9
};
```

Constants

`cmOpenReadAccess`
Available in Mac OS X v10.0 and later.
Declared in `CMApplication.h`.

`cmOpenWriteAccess`
Open the profile for writing. The total size of the profile is specified in the `size` parameter.
Available in Mac OS X v10.0 and later.
Declared in `CMApplication.h`.

`cmReadAccess`
Read the number of bytes specified by the `size` parameter.
Available in Mac OS X v10.0 and later.
Declared in `CMApplication.h`.

`cmWriteAccess`
Write the number of bytes specified by the `size` parameter.
Available in Mac OS X v10.0 and later.
Declared in `CMApplication.h`.

`cmCloseAccess`
: Close the profile for reading or writing.

  Available in Mac OS X v10.0 and later.

  Declared in `CMApplication.h`.

`cmCreateNewAccess`
: Create a new data stream for the profile.

  Available in Mac OS X v10.0 and later.

  Declared in `CMApplication.h`.

`cmAbortWriteAccess`
: Cancel the current write attempt.

  Available in Mac OS X v10.0 and later.

  Declared in `CMApplication.h`.

`cmBeginAccess`
: Begin the process of procedural access. This is always the first operation constant passed to the access procedure. If the call is successful, the `cmEndAccess` operation is guaranteed to be the last call to the procedure.

  Available in Mac OS X v10.0 and later.

  Declared in `CMApplication.h`.

`cmEndAccess`
: End the process of procedural access. This is always the last operation constant passed to the access procedure (unless the `cmBeginAccess` call failed).

  Available in Mac OS X v10.0 and later.

  Declared in `CMApplication.h`.

Discussion
When your application calls the `CMOpenProfile`, `CMNewProfile`, `CMCopyProfile`, or `CMNewLinkProfile` functions, it can supply the ColorSync Manager with a profile location structure of type `CMProcedureLocation` (page 919) to specify a procedure that provides access to a profile. The ColorSync Manager calls your procedure when the profile is created, initialized, opened, read, updated, or closed. The profile access procedure declaration is described in `CMProfileAccessProcPtr` (page 862).

When the ColorSync Manager calls your profile access procedure, it passes one of these constants in the `command` parameter to specify an operation. Your procedure must be able to respond to each of these constants.

Profile Classes

Specify profile class enumerations.

```
enum {
    cmInputClass = 'scnr',
    cmDisplayClass = 'mntr',
    cmOutputClass = 'prtr',
    cmLinkClass = 'link',
    cmAbstractClass = 'abst',
    cmColorSpaceClass = 'spac',
    cmNamedColorClass = 'nmcl'
};
```

Constants

`cmInputClass`
An input device profile defined for a scanner.
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmDisplayClass`
A display device profile defined for a monitor.
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmOutputClass`
An output device profile defined for a printer.
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmLinkClass`
A device link profile.
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmAbstractClass`
An abstract profile.
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmColorSpaceClass`
A color space profile.
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmNamedColorClass`
A named color space profile.
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

Discussion

The ColorSync Manager supports seven classes, or types, of profiles.

A profile creator specifies the profile class in the profile header's `profileClass` field. For a description of the profile header, see `CM2Header` (page 875). This enumeration defines the profile class signatures.

Profile Concatenation Values

Specify values to use when concatnating profiles.

```
enum {
    kNoTransform = 0,
    kUseAtoB = 1,
    kUseBtoA = 2,
    kUseBtoB = 3,
    kDeviceToPCS = kUseAtoB,
    kPCSToDevice = kUseBtoA,
    kPCSToPCS = kUseBtoB,
    kUseProfileIntent = 0xFFFFFFFF
};
```

Constants

`kNoTransform`
Not used.
Available in Mac OS X v10.0 and later.
Declared in `CMApplication.h`.

`kUseAtoB`
Use 'A2B*' tag from this profile or equivalent
Available in Mac OS X v10.0 and later.
Declared in `CMApplication.h`.

`kUseBtoA`
Use 'B2A*' tag from this profile or equivalent
Available in Mac OS X v10.0 and later.
Declared in `CMApplication.h`.

`kUseBtoB`
Use 'pre*' tag from this profile or equivalent
Available in Mac OS X v10.0 and later.
Declared in `CMApplication.h`.

`kDeviceToPCS`
Device Dependent to Device Independent
Available in Mac OS X v10.0 and later.
Declared in `CMApplication.h`.

`kPCSToDevice`
Device Independent to Device Dependent
Available in Mac OS X v10.0 and later.
Declared in `CMApplication.h`.

`kPCSToPCS`
Independent, through device's gamut
Available in Mac OS X v10.0 and later.
Declared in `CMApplication.h`.

`kUseProfileIntent`
For renderingIntent in NCMConcatProfileSpec

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

Profile Flags

Define flags that control native matchign and caching.

```
enum {
    cmNativeMatchingPreferred = 0x00000001,
    cmTurnOffCache = 0x00000002
};
```

Constants

`cmNativeMatchingPreferred`
Default to native not preferred

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CMICCProfile.h`.

`cmTurnOffCache`
Default to turn on CMM cache

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CMICCProfile.h`.

Profile Iteration Constants

Define an interation version.

```
enum {
    cmProfileIterateDataVersion1 = 0x00010000,
    cmProfileIterateDataVersion2 = 0x00020000,
    cmProfileIterateDataVersion3 = 0x00030000
};
```

Constants

`cmProfileIterateDataVersion1`
Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmProfileIterateDataVersion2`
Added makeAndModel

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmProfileIterateDataVersion3`
Added MD5 digest

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

Profile Location Type

Defines profile location kinds.

```
enum {
    cmNoProfileBase = 0,
    cmFileBasedProfile = 1,
    cmHandleBasedProfile = 2,
    cmPtrBasedProfile = 3,
    cmProcedureBasedProfile = 4,
    cmPathBasedProfile = 5,
    cmBufferBasedProfile = 6
};
```

Constants

`cmNoProfileBase`
The profile is temporary. It will not persist in memory after its use for a color session. You can specify this type of profile location with the `CMNewProfile` and the `CMCopyProfile` functions.

Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmFileBasedProfile`
The profile is stored in a disk-file and the `CMProfLoc` union of type `CMProfLoc` (page 928) holds a structure of type `CMFileLocation` (page 896) identifying the profile file. You can specify this type of profile location with the `CMOpenProfile`, `CMNewProfile`, `CMCopyProfile`, and `CMNewLinkProfile` functions.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CMApplication.h`.

`cmHandleBasedProfile`
The profile is stored in relocatable memory and the `CMProfLoc` union of type `CMProfLoc` (page 928) holds a handle to the profile in a structure of type `CMHandleLocation` (page 898). You can specify this type of profile location with the `CMOpenProfile`, `CMNewProfile`, and `CMCopyProfile` functions.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CMApplication.h`.

`cmPtrBasedProfile`
The profile is stored in nonrelocatable memory and the `CMProfLoc` union of type `CMProfLoc` (page 928) holds a pointer to the profile in a structure of type `CMPtrLocation` (page 929). You can specify this type of profile location with the `CMOpenProfile` function only.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CMApplication.h`.

`cmProcedureBasedProfile`
The profile is in an arbitrary location, accessed through a procedure supplied by you. The `CMProfLoc` union of type `CMProfLoc` (page 928) holds a universal procedure pointer to your profile access procedure in a structure of type `CMProcedureLocation` (page 919). You can specify this type of profile location with the `CMOpenProfile`, `CMNewProfile`, `CMCopyProfile`, and `CMNewLinkProfile` functions. For a description of an application-supplied profile access procedure, see `CMProfileAccessProcPtr` (page 862).

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CMApplication.h`.

`cmPathBasedProfile`
Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

`cmBufferBasedProfile`
Available in Mac OS X v10.0 and later.

Declared in `CMApplication.h`.

Discussion
Your application specifies the location for a profile using a profile location structure of type `CMProfileLocation` (page 924). A ColorSync profile that you open or create is typically stored in one of the following locations:

- In a disk file. The `u` field (a union) of the profile location data structure contains a file specification for a profile that is disk-file based. This is the most common way to store a ColorSync profile.
- In relocatable memory. The `u` field of the profile location data structure contains a handle specification for a profile that is stored in a handle.
- In nonrelocatable memory. The `u` field of the profile location data structure contains a pointer specification for a profile that is pointer based.
- In an arbitrary location, accessed by a procedure you provide. The `u` field of the profile location data structure contains a universal procedure pointer to your access procedure, as well as a pointer that may point to data associated with your procedure.

Additionally, your application can create a new or duplicate temporary profile. For example, you can use a temporary profile for a color-matching session and the profile is not saved after the session. For this case, the ColorSync Manager allows you to specify the profile location as having no specific location.

You use a pointer to a data structure of type `CMProfileLocation` to identify a profile's location when your application calls

- the `CMOpenProfile` function to obtain a reference to a profile
- the `CMNewProfile`, `CWNewLinkProfile`, or `CMCopyProfile` functions to create a new profile
- the `CMGetProfileLocation` function to get the location of an existing profile

Your application identifies the type of data the `CMProfileLocation u` field holds—a file specification, a handle, and so on—in the `CMProfileLocation` structure's `locType` field. You use the constants defined by this enumeration to identify the location type.

Public Tags

Specify tag values available for public use.

```
enum {
    cmAToB0Tag = 'A2B0',
    cmAToB1Tag = 'A2B1',
    cmAToB2Tag = 'A2B2',
    cmBlueColorantTag = 'bXYZ',
    cmBlueTRCTag = 'bTRC',
    cmBToA0Tag = 'B2A0',
    cmBToA1Tag = 'B2A1',
    cmBToA2Tag = 'B2A2',
    cmCalibrationDateTimeTag = 'calt',
    cmChromaticAdaptationTag = 'chad',
    cmCharTargetTag = 'targ',
    cmCopyrightTag = 'cprt',
    cmDeviceMfgDescTag = 'dmnd',
    cmDeviceModelDescTag = 'dmdd',
    cmGamutTag = 'gamt',
    cmGrayTRCTag = 'kTRC',
    cmGreenColorantTag = 'gXYZ',
    cmGreenTRCTag = 'gTRC',
    cmLuminanceTag = 'lumi',
    cmMeasurementTag = 'meas',
    cmMediaBlackPointTag = 'bkpt',
    cmMediaWhitePointTag = 'wtpt',
    cmNamedColorTag = 'ncol',
    cmNamedColor2Tag = 'ncl2',
    cmPreview0Tag = 'pre0',
    cmPreview1Tag = 'pre1',
    cmPreview2Tag = 'pre2',
    cmProfileDescriptionTag = 'desc',
    cmProfileSequenceDescTag = 'pseq',
    cmPS2CRD0Tag = 'psd0',
    cmPS2CRD1Tag = 'psd1',
    cmPS2CRD2Tag = 'psd2',
    cmPS2CRD3Tag = 'psd3',
    cmPS2CSATag = 'ps2s',
    cmPS2RenderingIntentTag = 'ps2i',
    cmRedColorantTag = 'rXYZ',
    cmRedTRCTag = 'rTRC',
    cmScreeningDescTag = 'scrd',
    cmScreeningTag = 'scrn',
    cmTechnologyTag = 'tech',
    cmUcrBgTag = 'bfd ',
    cmViewingConditionsDescTag = 'vued',
    cmViewingConditionsTag = 'view'
};
```

Constants

`cmAToB0Tag`

Available in Mac OS X v10.0 and later.

Declared in `CMICCProfile.h`.

`cmAToB1Tag`

Available in Mac OS X v10.0 and later.

Declared in `CMICCProfile.h`.

`cmAToB2Tag`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmBlueColorantTag`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmBlueTRCTag`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmBToA0Tag`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmBToA1Tag`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmBToA2Tag`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmCalibrationDateTimeTag`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmChromaticAdaptationTag`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmCharTargetTag`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmCopyrightTag`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmDeviceMfgDescTag`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmDeviceModelDescTag`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmGamutTag`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmGrayTRCTag`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmGreenColorantTag`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmGreenTRCTag`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmLuminanceTag`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmMeasurementTag`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmMediaBlackPointTag`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmMediaWhitePointTag`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmNamedColorTag`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmNamedColor2Tag`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmPreview0Tag`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmPreview1Tag`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmPreview2Tag`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmProfileDescriptionTag`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmProfileSequenceDescTag`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmPS2CRD0Tag`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmPS2CRD1Tag`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmPS2CRD2Tag`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmPS2CRD3Tag`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmPS2CSATag`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmPS2RenderingIntentTag`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmRedColorantTag`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmRedTRCTag`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmScreeningDescTag`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmScreeningTag`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmTechnologyTag`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmUcrBgTag`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmViewingConditionsDescTag`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmViewingConditionsTag`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

Public Type Signatures

Specify signatures for public types.

```
enum {
    cmSigCrdInfoType = 'crdi',
    cmSigCurveType = 'curv',
    cmSigDataType = 'data',
    cmSigDateTimeType = 'dtim',
    cmSigLut16Type = 'mft2',
    cmSigLut8Type = 'mft1',
    cmSigMeasurementType = 'meas',
    cmSigMultiFunctA2BType = 'mAB ',
    cmSigMultiFunctB2AType = 'mBA ',
    cmSigNamedColorType = 'ncol',
    cmSigNamedColor2Type = 'ncl2',
    cmSigParametricCurveType = 'para',
    cmSigProfileDescriptionType = 'desc',
    cmSigProfileSequenceDescType = 'pseq',
    cmSigScreeningType = 'scrn',
    cmSigS15Fixed16Type = 'sf32',
    cmSigSignatureType = 'sig ',
    cmSigTextType = 'text',
    cmSigU16Fixed16Type = 'uf32',
    cmSigU1Fixed15Type = 'uf16',
    cmSigUInt8Type = 'ui08',
    cmSigUInt16Type = 'ui16',
    cmSigUInt32Type = 'ui32',
    cmSigUInt64Type = 'ui64',
    cmSigUcrBgType = 'bfd ',
    cmSigUnicodeTextType = 'utxt',
    cmSigViewingConditionsType = 'view',
    cmSigXYZType = 'XYZ '
};
```

Constants

`cmSigCrdInfoType`
Available in Mac OS X v10.1 and later.
Declared in `CMICCProfile.h`.

`cmSigCurveType`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmSigDataType`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmSigDateTimeType`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmSigLut16Type`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmSigLut8Type`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmSigMeasurementType`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmSigMultiFunctA2BType`
Available in Mac OS X v10.1 and later.
Declared in `CMICCProfile.h`.

`cmSigMultiFunctB2AType`
Available in Mac OS X v10.1 and later.
Declared in `CMICCProfile.h`.

`cmSigNamedColorType`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmSigNamedColor2Type`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmSigParametricCurveType`
Available in Mac OS X v10.1 and later.
Declared in `CMICCProfile.h`.

`cmSigProfileDescriptionType`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmSigProfileSequenceDescType`
Available in Mac OS X v10.1 and later.
Declared in `CMICCProfile.h`.

`cmSigScreeningType`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmSigS15Fixed16Type`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmSigSignatureType`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmSigTextType`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmSigU16Fixed16Type`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmSigU1Fixed15Type`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmSigUInt8Type`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmSigUInt16Type`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmSigUInt32Type`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmSigUInt64Type`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmSigUcrBgType`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmSigUnicodeTextType`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmSigViewingConditionsType`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmSigXYZType`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

Quality Flag Values for Version 2.x Profiles

Define the possible values for the quality bits in the `flags` field of the `CM2Header` structure.

```
enum {
    cmNormalMode = 0,
    cmDraftMode = 1,
    cmBestMode = 2
};
```

Constants

`cmNormalMode`
This is the default setting. Normal mode indicates that the CMM should use its default method to compromise between performance and resource requirements.
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmDraftMode`

Draft mode indicates that the CMM should sacrifice quality, if necessary, to minimize resource requirements. Note that the default CMM currently produces the same results for both normal and draft mode.

Available in Mac OS X v10.0 and later.

Declared in `CMICCProfile.h`.

`cmBestMode`

Best mode indicates that the CMM should maximize resource usage to ensure the highest possible quality.

Available in Mac OS X v10.0 and later.

Declared in `CMICCProfile.h`.

Discussion

To determine the value of the quality flag, you mask the `flags` field of the profile header with the `cmQualityMask` mask, right shift 16 bits, then compare the result to the enumerated constants shown here. For more information on the quality flag, see "Flag Mask Definitions for Version 2.x Profiles" (page 983).

When you start a color-matching session, ColorSync sends all involved profiles to the color management module (CMM). The CMM extracts the information it needs from the profiles and stores an internal representation in private memory. ColorSync's default CMM samples the input space and stores the results in a lookup table, a common technique that speeds up conversion for runtime applications. The size of the table is based on the quality flag setting in the source profile header. The setting of the quality flag can affect the memory requirements, accuracy, and speed of the color-matching session. In general, the higher the quality setting, the larger the lookup table, the more accurate the matching, and the slower the matching process. Note however, that the default CMM currently produces the same results for both normal and draft mode.

Rendering Intent Values for Version 2.x Profiles

Define the four possible values for the rendering intent bits of the `renderingIntent` field of the `CM2Header` structure.

```
enum {
    cmPerceptual = 0,
    cmRelativeColorimetric = 1,
    cmSaturation = 2,
    cmAbsoluteColorimetric = 3
};
```

Constants

`cmPerceptual`

All the colors of a given gamut can be scaled to fit within another gamut. This intent is best suited to realistic images, such as photographic images.

Available in Mac OS X v10.0 and later.

Declared in `CMICCProfile.h`.

`cmRelativeColorimetric`

The colors that fall within the gamuts of both devices are left unchanged. This intent is best suited to logo images.

Available in Mac OS X v10.0 and later.

Declared in `CMICCProfile.h`.

`cmSaturation`
: The relative saturation of colors is maintained from gamut to gamut. This intent is best suited to bar graphs and pie charts in which the actual color displayed is less important than its vividness.

  Available in Mac OS X v10.0 and later.

  Declared in `CMICCProfile.h`.

`cmAbsoluteColorimetric`
: This approach is based on a device-independent color space in which the result is an idealized print viewed on a ideal type of paper having a large dynamic range and color gamut.

  Available in Mac OS X v10.0 and later.

  Declared in `CMICCProfile.h`.

Discussion
The ColorSync Manager defines the structure `CM2Header` (page 875) to represent the profile header for the version 2.x profile format defined by the ICC. The `renderingIntent` field of the `CM2Header` structure is an unsigned long value whose bits specify information about a profile. The ICC reserves the use of bits 0 to 15 and has assigned values to bits 0 and 1. Bits 16 to 31 are reserved for use by color management system (CMS) vendors.

Rendering intent controls the approach a CMM uses to translate the colors of an image to the color gamut of a destination device. Your application can set a profile's rendering intent, for example, based on a user's choice of the preferred approach for rendering an image.

Because rendering intent is specified by the low two bits, and because no other bits are currently defined for this field, you can use the constants defined here to test or set the value of the entire field, without concern for possible information stored in other bits.

Screen Encoding Tags

Specify tags to use for screen encodings.

```
enum {
    cmPrtrDefaultScreens = 0,
    cmLinesPer = 1
};
```

Constants
`cmPrtrDefaultScreens`
: Use printer default screens; can have an associated value of `0` for `false` or `1` for `true`.

  Available in Mac OS X v10.0 and later.

  Declared in `CMICCProfile.h`.

`cmLinesPer`
: Lines per unit; can have an associated value of `0` for lines per centimeter or `1` for lines per inch.

  Available in Mac OS X v10.0 and later.

  Declared in `CMICCProfile.h`.

Spot Function Values

Speicfy values for spot functions.

```
enum {
    cmSpotFunctionUnknown = 0,
    cmSpotFunctionDefault = 1,
    cmSpotFunctionRound = 2,
    cmSpotFunctionDiamond = 3,
    cmSpotFunctionEllipse = 4,
    cmSpotFunctionLine = 5,
    cmSpotFunctionSquare = 6,
    cmSpotFunctionCross = 7
};
```

Constants

`cmSpotFunctionUnknown`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmSpotFunctionDefault`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmSpotFunctionRound`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmSpotFunctionDiamond`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmSpotFunctionEllipse`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmSpotFunctionLine`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmSpotFunctionSquare`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmSpotFunctionCross`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

Standard Oberver

Standard observer measurement type encodings.

```
enum {
    cmStdobsUnknown = 0x00000000,
    cmStdobs1931TwoDegrees = 0x00000001,
    cmStdobs1964TenDegrees = 0x00000002
};
```

Constants

`cmStdobsUnknown`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmStdobs1931TwoDegrees`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmStdobs1964TenDegrees`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

Tag Type Information

Defines a constant for 2.0 tag type information.

```
enum {
    cmNumHeaderElements = 10
};
```

Constants

`cmNumHeaderElements`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

Technology Tag Descriptions

Define descriptor tags for technologies.

```
enum {
    cmTechnologyDigitalCamera = 'dcam',
    cmTechnologyFilmScanner = 'fscn',
    cmTechnologyReflectiveScanner = 'rscn',
    cmTechnologyInkJetPrinter = 'ijet',
    cmTechnologyThermalWaxPrinter = 'twax',
    cmTechnologyElectrophotographicPrinter = 'epho',
    cmTechnologyElectrostaticPrinter = 'esta',
    cmTechnologyDyeSublimationPrinter = 'dsub',
    cmTechnologyPhotographicPaperPrinter = 'rpho',
    cmTechnologyFilmWriter = 'fprn',
    cmTechnologyVideoMonitor = 'vidm',
    cmTechnologyVideoCamera = 'vidc',
    cmTechnologyProjectionTelevision = 'pjtv',
    cmTechnologyCRTDisplay = 'CRT ',
    cmTechnologyPMDisplay = 'PMD ',
    cmTechnologyAMDisplay = 'AMD ',
    cmTechnologyPhotoCD = 'KPCD',
    cmTechnologyPhotoImageSetter = 'imgs',
    cmTechnologyGravure = 'grav',
    cmTechnologyOffsetLithography = 'offs',
    cmTechnologySilkscreen = 'silk',
    cmTechnologyFlexography = 'flex'
};
```

Constants

`cmTechnologyDigitalCamera`
Available in Mac OS X v10.1 and later.
Declared in `CMICCProfile.h`.

`cmTechnologyFilmScanner`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmTechnologyReflectiveScanner`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmTechnologyInkJetPrinter`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmTechnologyThermalWaxPrinter`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmTechnologyElectrophotographicPrinter`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmTechnologyElectrostaticPrinter`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmTechnologyDyeSublimationPrinter`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmTechnologyPhotographicPaperPrinter`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmTechnologyFilmWriter`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmTechnologyVideoMonitor`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmTechnologyVideoCamera`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmTechnologyProjectionTelevision`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmTechnologyCRTDisplay`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmTechnologyPMDisplay`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmTechnologyAMDisplay`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmTechnologyPhotoCD`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmTechnologyPhotoImageSetter`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmTechnologyGravure`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmTechnologyOffsetLithography`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmTechnologySilkscreen`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmTechnologyFlexography`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

Use Types

Specify use types.

```
enum {
    cmInputUse = 'inpt',
    cmOutputUse = 'outp',
    cmDisplayUse = 'dply',
    cmProofUse = 'pruf'
};
```

Constants

`cmInputUse`
Available in Mac OS X v10.0 and later.
Declared in `CMApplication.h`.

`cmOutputUse`
Available in Mac OS X v10.0 and later.
Declared in `CMApplication.h`.

`cmDisplayUse`
Available in Mac OS X v10.0 and later.
Declared in `CMApplication.h`.

`cmProofUse`
Available in Mac OS X v10.0 and later.
Declared in `CMApplication.h`.

Discussion
Used for the function `CMGetProfileByUse` and `SetDefaultProfileByUse`.

Video Card Gamma Storage Types

Specify data storage type constants.

```
enum {
    cmVideoCardGammaTableType = 0,
    cmVideoCardGammaFormulaType = 1
};
```

Constants

`cmVideoCardGammaTableType`
The video card gamma data is stored in a table format. See `CMVideoCardGammaTable` (page 941) for a description of the table format.
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmVideoCardGammaFormulaType`
The video card gamma tag data is stored as a formula. See `CMVideoCardGammaFormula` (page 940) for a description of the formula format.
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

Discussion
A video card gamma profile tag can store gamma data either as a formula or as a table of values. You use a storage type constant to specify which data storage type the tag uses.

If the video card uses a different format than the format you specify (for example, the card uses data in table format and you supply data in formula format), ColorSync will adapt the data you supply to match the format the card expects.

Version Notes
Starting with version 2.5, ColorSync supports an optional profile tag for video card gamma. The tag specifies gamma information, stored either as a formula or in table format, to be loaded into the video card when the profile containing the tag is put into use. As of version 2.5, the only ColorSync function that attempts to take advantage of video card gamma data is `CMSetProfileByAVID` (page 808).

Video Card Gamma Tags

Specify video card gamma information.

```
enum {
    cmPS2CRDVMSizeTag = 'psvm',
    cmVideoCardGammaTag = 'vcgt',
    cmMakeAndModelTag = 'mmod',
    cmProfileDescriptionMLTag = 'dscm',
    cmNativeDisplayInfoTag = 'ndin'
};
```

Constants

`cmPS2CRDVMSizeTag`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmVideoCardGammaTag`
Constant for profile tag that specifies video card gamma information. When you create a tag to store video card gamma data in a profile, you use the `cmVideoCardGammaTag` constant to specify the tag.
Starting with version 2.5, ColorSync supports an optional profile tag for video card gamma. The tag specifies gamma information, stored either as a formula or in table format, to be loaded into the video card when the profile containing the tag is put into use. As of version 2.5, the only ColorSync function that attempts to take advantage of video card gamma data is `CMSetProfileByAVID` (page 808).
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmMakeAndModelTag`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmProfileDescriptionMLTag`
Available in Mac OS X v10.0 and later.
Declared in `CMICCProfile.h`.

`cmNativeDisplayInfoTag`
Available in Mac OS X v10.1 and later.
Declared in `CMICCProfile.h`.

Video Card Gamma Signatures

Specify signatures used for video card gamma information.

```
enum {
    cmSigPS2CRDVMSizeType = 'psvm',
    cmSigVideoCardGammaType = 'vcgt',
    cmSigMakeAndModelType = 'mmod',
    cmSigNativeDisplayInfoType = 'ndin',
    cmSigMultiLocalizedUniCodeType = 'mluc'
};
```

Constants

`cmSigPS2CRDVMSizeType`

Available in Mac OS X v10.0 and later.

Declared in `CMICCProfile.h`.

`cmSigVideoCardGammaType`

Constant that specifies video card gamma type signature in a video card gamma profile tag. That is, you use this constant to set the `typeDescriptor` field of the `CMVideoCardGammaType` (page 941) structure. There is currently only one type possible for a video card gamma tag.

Starting with version 2.5, ColorSync supports an optional profile tag for video card gamma. The tag specifies gamma information, stored either as a formula or in table format, to be loaded into the video card when the profile containing the tag is put into use. As of version 2.5, the only ColorSync function that attempts to take advantage of video card gamma data is `CMSetProfileByAVID` (page 808).

Available in Mac OS X v10.0 and later.

Declared in `CMICCProfile.h`.

`cmSigMakeAndModelType`

Available in Mac OS X v10.0 and later.

Declared in `CMICCProfile.h`.

`cmSigNativeDisplayInfoType`

Available in Mac OS X v10.1 and later.

Declared in `CMICCProfile.h`.

`cmSigMultiLocalizedUniCodeType`

Available in Mac OS X v10.0 and later.

Declared in `CMICCProfile.h`.

Result Codes

The most common result codes returned by ColorSync Manager are listed below.

Result Code	Value	Description
`noErr`	0	No error Available in Mac OS X v10.0 and later.
`cmProfileError`	-170	There is something wrong with the content of the profile Available in Mac OS X v10.0 and later.

Result Code	Value	Description
cmMethodError	-171	An error occurred during the CMM arbitration process that determines the CMM to use Available in Mac OS X v10.0 and later.
cmMethodNotFound	-175	CMM not present Available in Mac OS X v10.0 and later.
cmProfileNotFound	-176	Responder error Available in Mac OS X v10.0 and later.
cmProfilesIdentical	-177	Profiles are the same Available in Mac OS X v10.0 and later.
cmCantConcatenateError	-178	Profiles cannot be concatenated Available in Mac OS X v10.0 and later.
cmCantXYZ	-179	CMM does not handle XYZ color space Available in Mac OS X v10.0 and later.
cmCantDeleteProfile	-180	Responder error Available in Mac OS X v10.0 and later.
cmUnsupportedDataType	-181	Responder error Available in Mac OS X v10.0 and later.
cmNoCurrentProfile	-182	Responder error Available in Mac OS X v10.0 and later.
cmElementTagNotFound	-4200	The tag you specified is not in the specified profile Available in Mac OS X v10.0 and later.
cmIndexRangeErr	-4201	Tag index out of range Available in Mac OS X v10.0 and later.
cmCantDeleteElement	-4202	Cannot delete the specified profile element Available in Mac OS X v10.0 and later.
cmFatalProfileErr	-4203	Returned from File Manager while updating a profile file in response to CMUpdateProfile; profile content may be corrupted Available in Mac OS X v10.0 and later.
cmInvalidProfile	-4204	Profile reference is invalid or refers to an inappropriate profile Available in Mac OS X v10.0 and later.

Result Code	Value	Description
`cmInvalidProfileLocation`	-4205	Operation not supported for this profile location Available in Mac OS X v10.0 and later.
`cmInvalidSearch`	-4206	Bad search handle Available in Mac OS X v10.0 and later.
`cmSearchError`	-4207	Internal error occurred during profile search Available in Mac OS X v10.0 and later.
`cmErrIncompatibleProfile`	-4208	Unspecified profile error Available in Mac OS X v10.0 and later.
`cmInvalidColorSpace`	-4209	Profile color space does not match bitmap type Available in Mac OS X v10.0 and later.
`cmInvalidSrcMap`	-4210	Source pixel map or bitmap was invalid Available in Mac OS X v10.0 and later.
`cmInvalidDstMap`	-4211	Destination pix/bit map was invalid Available in Mac OS X v10.0 and later.
`cmNoGDevicesError`	-4212	Begin matching or end matching—no graphics devices available Available in Mac OS X v10.0 and later.
`cmInvalidProfileComment`	-4213	Bad profile comment during `drawpicture` Available in Mac OS X v10.0 and later.
`cmRangeOverFlow`	-4214	One or more output color value overflows in color conversion; all input color values will be converted and the overflow will be clipped Available in Mac OS X v10.0 and later.
`cmCantCopyModifiedV1Profile`	-4215	It is illegal to copy version 1.0 profiles that have been modified Available in Mac OS X v10.0 and later.
`cmNamedColorNotFound`	-4216	The specified named color was not found in the specified profile Available in Mac OS X v10.0 and later.
`cmCantGamutCheckError`	-4217	Gamut checking not supported by this color world—that is, the color world does not contain a gamut table because it was built with gamut checking turned off Available in Mac OS X v10.0 and later.

Result Code	Value	Description
cmDeviceDBNotFoundErr	-4227	Preferences not found or loaded; returned by a CM device integration routine. Available in Mac OS X v10.0 and later.
cmDeviceAlreadyRegistered	-4228	Device already registered; returned by a CM device integration routine. Available in Mac OS X v10.0 and later.
cmDeviceNotRegistered	-4229	Device not found; returned by a CM device integration routine. Available in Mac OS X v10.0 and later.
cmDeviceProfilesNotFound	-4230	Profiles not found; returned by a CM device integration routine. Available in Mac OS X v10.0 and later.
cmInternalCFErr	-4231	CoreFoundation failure; returned by a CM device integration routine. Available in Mac OS X v10.0 and later.

Dictionary Manager Reference (Not Recommended)

Framework: ApplicationServices/ApplicationServices.h

Declared in Dictionary.h

Overview

Important: The Dictionary Manager is deprecated as of Mac OS X v10.5 and is not available to 64-bit applications. Instead, use the APIs presented by Dictionary Services, which are described in *Dictionary Services Programming Guide* and *Dictionary Services Reference*.

The Dictionary Manager facilitates the use of dictionary files by such programs as spelling checkers and input methods. The Dictionary Manager separates dictionary data from the code that accesses the data.

The Dictionary Manager uses access method plug-ins to mediate access to the dictionary's data. The use of access-method plug-ins allows the Dictionary Manager to support a variety of data and does not require the internal structure of a dictionary to conform to a fixed format.

Dictionary Manager functions with the prefix "DCM" are Carbon-compliant. However, these functions are available only on systems that have the Japanese language kit installed.

Functions by Task

Obtaining the Version Number

`DCMLibraryVersion` (page 1055) Deprecated in Mac OS X v10.5
Obtains the version number of the Dictionary Manager.

Working With a List of Dictionaries

You can use the functions in this section to obtain a list of the dictionaries available on the system. You can create a list of dictionaries, count the available dictionaries, and obtain the dictionary ID for each available dictionary.

`DCMCountObjectIterator` (page 1030) Deprecated in Mac OS X v10.5
Obtains the number of dictionaries in a list.

`DCMCreateDictionaryIterator` (page 1033) Deprecated in Mac OS X v10.5
Obtains a list of the dictionaries available on the system.

DCMDisposeObjectIterator (page 1037) Deprecated in Mac OS X v10.5
Disposes of a iterator.

DCMIterateObject (page 1055) Deprecated in Mac OS X v10.5
Obtains the object ID for a dictionary from a list of available dictionaries.

DCMResetObjectIterator (page 1060) Deprecated in Mac OS X v10.5
Resets an iterator to the start of the dictionary list.

Obtaining Access Method Information

DCMCreateAccessMethodIterator (page 1032) Deprecated in Mac OS X v10.5
Obtains a list of the available access methods.

DCMGetAccessMethodIDFromName (page 1040) Deprecated in Mac OS X v10.5
Obtains the ID for access method.

Working With a Dictionary File

DCMCloseDictionary (page 1029) Deprecated in Mac OS X v10.5
Closes a dictionary.

DCMCompactDictionary (page 1030) Deprecated in Mac OS X v10.5
Compacts a dictionary.

DCMCountRecord (page 1031) Deprecated in Mac OS X v10.5
Return number of records in a dictionary.

DCMDeleteDictionary (page 1035) Deprecated in Mac OS X v10.5
Deletes a dictionary.

DCMDeriveNewDictionary (page 1036) Deprecated in Mac OS X v10.5
Create a new dictionary based on an existing dictionary.

DCMGetDictionaryIDFromFile (page 1041) Deprecated in Mac OS X v10.5
Obtains the ID associated with a dictionary file.

DCMGetDictionaryIDFromRef (page 1042) Deprecated in Mac OS X v10.5
Obtains the dictionary ID associated with a dictionary reference.

DCMGetFileFromDictionaryID (page 1049) Deprecated in Mac OS X v10.5
Obtains the file specification associated with a dictionary ID.

DCMNewDictionary (page 1056) Deprecated in Mac OS X v10.5
Creates a new dictionary.

DCMOpenDictionary (page 1057) Deprecated in Mac OS X v10.5
Opens a dictionary.

DCMRegisterDictionaryFile (page 1058) Deprecated in Mac OS X v10.5
Registers a dictionary.

DCMReorganizeDictionary (page 1059) Deprecated in Mac OS X v10.5
Reorganizes a dictionary.

DCMUnregisterDictionary (page 1062) Deprecated in Mac OS X v10.5
Unregisters a dictionary.

Changing Access Privileges

`DCMGetDictionaryWriteAccess` (page 1044) Deprecated in Mac OS X v10.5
Obtains write access for an open dictionary.

`DCMReleaseDictionaryWriteAccess` (page 1059) Deprecated in Mac OS X v10.5
Releases write access to a dictionary.

Getting and Setting Dictionary Properties

`DCMGetDictionaryProperty` (page 1042) Deprecated in Mac OS X v10.5
Obtains the data associated with a property tag.

`DCMGetDictionaryPropertyList` (page 1043) Deprecated in Mac OS X v10.5
Obtains a list of property tags from a dictionary.

`DCMSetDictionaryProperty` (page 1061) Deprecated in Mac OS X v10.5
Sets a property for a dictionary. Set the properties to a dictionary.

Working With Dictionary Records

`DCMAddRecord` (page 1028) Deprecated in Mac OS X v10.5
Add a new record to a dictionary.

`DCMCountRecordIterator` (page 1032) Deprecated in Mac OS X v10.5
Returns the number of records contained in a list of search results.

`DCMDeleteRecord` (page 1035) Deprecated in Mac OS X v10.5
Delete specified record from the dictionary.

`DCMDisposeRecordIterator` (page 1037) Deprecated in Mac OS X v10.5
Disposes of a list of search results.

`DCMFindRecords` (page 1038) Deprecated in Mac OS X v10.5
Obtains a list of dictionary records that meet specified criteria.

`DCMGetNextRecord` (page 1050) Deprecated in Mac OS X v10.5
Obtains the next specified record.

`DCMGetNthRecord` (page 1051) Deprecated in Mac OS X v10.5
Return records in a specified order within the dictionary.

`DCMGetPrevRecord` (page 1052) Deprecated in Mac OS X v10.5
Obtains the previous record. Return the record previous to the specified record.

`DCMGetRecordSequenceNumber` (page 1053) Deprecated in Mac OS X v10.5
Obtains the sequence number for the specified record in a dictionary.

`DCMIterateFoundRecord` (page 1053) Deprecated in Mac OS X v10.5
Retrieves one record from a list of search results.

Working With Fields in a Single Record

`DCMCreateFieldInfoRecord` (page 1033) Deprecated in Mac OS X v10.5
Creates a field information record.

DCMGetDictionaryFieldInfo (page 1040) Deprecated in Mac OS X v10.5
Obtains field information for a specified field in a dictionary record.

DCMGetFieldAttributes (page 1045) Deprecated in Mac OS X v10.5
Obtains the field attributes for a field information record.

DCMGetFieldData (page 1046) Deprecated in Mac OS X v10.5
Obtains data from one or more fields in a specified record.

DCMGetFieldDefaultData (page 1047) Deprecated in Mac OS X v10.5
Obtains default data for a field information record.

DCMGetFieldFindMethods (page 1047) Deprecated in Mac OS X v10.5
Obtains the search methods for a field information record.

DCMGetFieldMaxRecordSize (page 1048) Deprecated in Mac OS X v10.5
Obtains the maximum data size for a field in a dictionary record.

DCMGetFieldTagAndType (page 1048) Deprecated in Mac OS X v10.5
Obtains the field tag and type associated with a field information record.

DCMSetFieldData (page 1061) Deprecated in Mac OS X v10.5
Set the data to a specific field of a specified record.

Functions

DCMAddRecord

Add a new record to a dictionary. (Deprecated in Mac OS X v10.5.)

```
OSStatus DCMAddRecord (
   DCMDictionaryRef dictionaryRef,
   DCMFieldTag keyFieldTag,
   ByteCount keySize,
   ConstLogicalAddress keyData,
   Boolean checkOnly,
   const AEDesc *dataList,
   DCMUniqueID *newUniqueID
);
```

Parameters

dictionaryRef
A reference to the dictionary to which you want to add a record. You obtain a dictionary reference when you call the function DCMOpenDictionary (page 1057).

keyFieldTag
The field tag that specifies the record you want to add.

keySize
The size of the keyData parameter.

keyData
The key data of the record you want to add. You are responsible for allocating this buffer.

checkOnly
If true is specified, only a duplication check of records is carried out, and actual addition of records is not carried out.

dataList

A pointer to the data contained in the record you want to add. The `AEDesc` data structure contains two fields: A four-character code that specifies the type of data in the structure and an opaque storage type that points to the storage for the descriptor data. Each of the data structures in the `dataList` array specifies a field name (the four-character code) in the dictionary record and the data associated with that field. You must first call the function `DCMCreateFieldInfoRecord` (page 1033) to create this array of data structures. When you create the data list, you must include all of the fields specified by the masks `kDCMIndexedFieldMask`, `kDCMRequiredFieldMask`, and `kDCMIdentifyFieldMask` as attributes of the field properties of the applicable dictionary.

newUniqueID

On output, the unique ID of the added record. If the added record is a duplicate record, the function returns the result `dcmDupRecordErr` and the unique ID of the existing record is returned in the `newUniqueID` parameter.

Return Value
A result code. See "Dictionary Manager Result Codes" (page 1080).

Discussion
When `checkOnly` is specified as `true`, if duplicate records do not exist, `noErr` is returned, and the `newUniqueID` value is undefined. When `checkOnly` is specified as `false`, if the same record exists, only the field data within that record is overwritten, and the unique ID of that record is returned as `newUniqueID`, and `dcmDupRecordErr` is returned as the return value. If the same record does not exist, the record is added, and the uniqueID of the added record is returned as `newUniqueID`, and `noErr` is returned as the return value.

Availability
Available in CarbonLib 1.0 and later when running Japanese Mac OS 8.5 or later, or other Mac OS 8.5 or later with the Japanese Language Kit.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Dictionary.h`

DCMCloseDictionary

Closes a dictionary. (Deprecated in Mac OS X v10.5.)

```
OSStatus DCMCloseDictionary (
   DCMDictionaryRef dictionaryRef
);
```

Parameters

dictionaryRef

A reference to the dictionary you want to close. You obtain a dictionary reference when you call the function `DCMOpenDictionary` (page 1057).

Return Value
A result code. See "Dictionary Manager Result Codes" (page 1080).

Availability
Available in CarbonLib 1.0 and later when running Japanese Mac OS 8.5 or later, or other Mac OS 8.5 or later with the Japanese Language Kit.

Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Dictionary.h`

DCMCompactDictionary

Compacts a dictionary. (Deprecated in Mac OS X v10.5.)

```
OSStatus DCMCompactDictionary (
   DCMDictionaryID dictionaryID,
   DCMProgressFilterUPP progressProc,
   UInt32 userData
);
```

Parameters

dictionaryID
The ID of the dictionary you want to compact. You obtain a dictionary ID when you call the functions `DCMRegisterDictionaryFile` (page 1058) or `DCMGetDictionaryIDFromFile` (page 1041).

progressProc
A universal procedure pointer (UPP) to your progress callback function. This callback is not supported.

userData
Data needed by your progress callback function.

Return Value
A result code. See "Dictionary Manager Result Codes" (page 1080).

Discussion
The function `DCMCompactDictionary` organizes the contents of a dictionary to reduce the size of the dictionary as much as possible. You cannot add additional records to a dictionary after you have compacted it unless you call the function `DCMReorganizeDictionary` (page 1059) to expand the capacity of the dictionary.

Availability
Available in CarbonLib 1.0 and later when running Japanese Mac OS 8.5 or later, or other Mac OS 8.5 or later with the Japanese Language Kit.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Dictionary.h`

DCMCountObjectIterator

Obtains the number of dictionaries in a list. (Deprecated in Mac OS X v10.5.)

```
ItemCount DCMCountObjectIterator (
   DCMObjectIterator iterator
);
```

Parameters

iterator

The list of available dictionaries. You obtain this list by calling the function `DCMCreateDictionaryIterator` (page 1033) or `DCMCreateAccessMethodIterator` (page 1032).

Return Value

The number of dictionaries contained in the list specified by the `iterator` parameter.

Availability

Available in CarbonLib 1.0 and later when running Japanese Mac OS 8.5 or later, or other Mac OS 8.5 or later with the Japanese Language Kit.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Dictionary.h`

DCMCountRecord

Return number of records in a dictionary. (Deprecated in Mac OS X v10.5.)

```
OSStatus DCMCountRecord (
   DCMDictionaryID dictionaryID,
   ItemCount *count
);
```

Parameters

dictionaryID

The ID of dictionary whose records you want to count. You obtain a dictionary ID when you call the functions `DCMRegisterDictionaryFile` (page 1058) or `DCMGetDictionaryIDFromFile` (page 1041).

count

On output, the number of records in the dictionary.

Return Value

A result code. See "Dictionary Manager Result Codes" (page 1080).

Availability

Available in CarbonLib 1.0 and later when running Japanese Mac OS 8.5 or later, or other Mac OS 8.5 or later with the Japanese Language Kit.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Dictionary.h`

DCMCountRecordIterator

Returns the number of records contained in a list of search results. (Deprecated in Mac OS X v10.5.)

```
ItemCount DCMCountRecordIterator (
   DCMFoundRecordIterator recordIterator
);
```

Parameters

recordIterator

A reference to list of search results. You obtain a list of search results by calling the function DCMFindRecords (page 1038).

Return Value

The number of records in the list specified by the recordIterator parameter.

Availability

Available in CarbonLib 1.0 and later when running Japanese Mac OS 8.5 or later, or other Mac OS 8.5 or later with the Japanese Language Kit.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

Dictionary.h

DCMCreateAccessMethodIterator

Obtains a list of the available access methods. (Deprecated in Mac OS X v10.5.)

```
OSStatus DCMCreateAccessMethodIterator (
   DCMAccessMethodIterator *accessMethodIterator
);
```

Parameters

accessMethodIterator

On output, a list of access methods.

Return Value

A result code. See "Dictionary Manager Result Codes" (page 1080).

Discussion

You can operate on the list of access methods created by the function DCMCreateAccessMethodIterator by calling the functions DCMCountObjectIterator (page 1030), DCMIterateObject (page 1055), DCMResetObjectIterator (page 1060), and DCMDisposeObjectIterator (page 1037). You use this function along with the function DCMGetAccessMethodIDFromName (page 1040) to obtain the accessMethodID that you supply to the function DCMNewDictionary (page 1056) to create a new dictionary.

Normally you should not need to call this function because the Dictionary Manager handles the mapping of a dictionary to its access method.

Availability

Available in CarbonLib 1.0 and later when running Japanese Mac OS 8.5 or later, or other Mac OS 8.5 or later with the Japanese Language Kit.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Dictionary.h`

DCMCreateDictionaryIterator

Obtains a list of the dictionaries available on the system. (Deprecated in Mac OS X v10.5.)

```
OSStatus DCMCreateDictionaryIterator (
   DCMDictionaryIterator *dictionaryIterator
);
```

Parameters

`dictionaryIterator`

On output, a reference to the list of available dictionaries. You are responsible for disposing of this list when you no longer need it.

Return Value
A result code. See "Dictionary Manager Result Codes" (page 1080).

Discussion
The function `DCMCreateDictionaryIterator` scans the dictionary directories, registers the dictionaries found, and returns a list of dictionaries. In Mac OS X, the Dictionary Manager searches `(User's home)/Library/Dictionaries/`, `/Library/Dictionaries/`, and their subdirectories. In Mac OS 9, it searches the Extensions folder, Preferences folder, and their subfolders.

Availability
Available in CarbonLib 1.0 and later when running Japanese Mac OS 8.5 or later, or other Mac OS 8.5 or later with the Japanese Language Kit.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Dictionary.h`

DCMCreateFieldInfoRecord

Creates a field information record. (Deprecated in Mac OS X v10.5.)

```
OSStatus DCMCreateFieldInfoRecord (
   DescType fieldTag,
   DescType fieldType,
   ByteCount maxRecordSize,
   DCMFieldAttributes fieldAttributes,
   AEDesc *fieldDefaultData,
   ItemCount numberOfFindMethods,
   DCMFindMethod findMethods[],
   AEDesc *fieldInfoRecord
);
```

Parameters

fieldTag

The tag for the field you want to create.

fieldType

The data type of the field.

maxRecordSize

The maximum size of the data in the field.

fieldAttributes

The attributes associated with the field. See "Field Attributes" (page 1073) for more information.

fieldDefaultData

On input, points to the default data for the field.

numberOfFindMethods

The number of search methods associated with the field.

findMethods

On input, an array of search methods associated with the field. See "Search Methods" (page 1078) for more information.

fieldInfoRecord

On output, points to the field information record for the newly-created field.

Return Value

A result code. See "Dictionary Manager Result Codes" (page 1080).

Discussion

You can add multiple fields in the form of an `AEDescList` data structure by repeatedly calling the function `DCMCreateFieldInfoRecord`. You use the field information record (`fieldInfoRecord`) when you call the function `DCMNewDictionary`. However, when calling the function for the first time, you must set the `descriptorType` of the `fieldInfoRecord` to `typeNull`.

Availability

Available in CarbonLib 1.0 and later when running Japanese Mac OS 8.5 or later, or other Mac OS 8.5 or later with the Japanese Language Kit.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Dictionary.h`

DCMDeleteDictionary

Deletes a dictionary. (Deprecated in Mac OS X v10.5.)

```
OSStatus DCMDeleteDictionary (
   DCMDictionaryID dictionaryID
);
```

Parameters

dictionaryID

The ID of dictionary you want to delete. You obtain a dictionary ID when you call the functions `DCMRegisterDictionaryFile` (page 1058) or `DCMGetDictionaryIDFromFile` (page 1041).

Return Value

A result code. See "Dictionary Manager Result Codes" (page 1080). Returns the result `dcmDictionaryBusyErr` if another application has this dictionary open.

Discussion

The function `DCMDeleteDictionary` deletes the dictionary specified by the `dictionaryID` parameter.

Availability

Available in CarbonLib 1.0 and later when running Japanese Mac OS 8.5 or later, or other Mac OS 8.5 or later with the Japanese Language Kit.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Dictionary.h`

DCMDeleteRecord

Delete specified record from the dictionary. (Deprecated in Mac OS X v10.5.)

```
OSStatus DCMDeleteRecord (
   DCMDictionaryRef dictionaryRef,
   DCMFieldTag keyFieldTag,
   ByteCount keySize,
   ConstLogicalAddress keyData,
   DCMUniqueID uniqueID
);
```

Parameters

dictionaryRef

A reference to the dictionary from which you want to delete a record. You obtain a dictionary reference when you call the function `DCMOpenDictionary` (page 1057).

keyFieldTag

The field tag that specifies the record you want to delete.

keySize

The size of the `keyData` parameter.

keyData

The key data of the record you want to delete. You are responsible for allocating this buffer.

uniqueID
The unique ID of the record you want to delete.

Return Value
A result code. See "Dictionary Manager Result Codes" (page 1080).

Availability
Available in CarbonLib 1.0 and later when running Japanese Mac OS 8.5 or later, or other Mac OS 8.5 or later with the Japanese Language Kit.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Dictionary.h`

DCMDeriveNewDictionary

Create a new dictionary based on an existing dictionary. (Deprecated in Mac OS X v10.5.)

```
OSStatus DCMDeriveNewDictionary (
   DCMDictionaryID srcDictionary,
   const FSSpec *newDictionaryFile,
   ScriptCode scriptTag,
   Boolean invisible,
   ItemCount recordCapacity,
   DCMDictionaryID *newDictionary
);
```

Parameters

srcDictionary
The ID of dictionary from which you want to derive a dictionary. You obtain a dictionary ID when you call the functions `DCMRegisterDictionaryFile` (page 1058) or `DCMGetDictionaryIDFromFile` (page 1041).

newDictionaryFile
A pointer to an `FSSpec` structure that specifies the file name and location for the newly-created dictionary. This is an input parameter.

scriptTag
The script code of the file specified by the `newDictionaryFile` parameter.

invisible
A Boolean value that specifies whether the dictionary is available through the Dictionary Manager. Pass `true` if you do not want the dictionary to be available, `false` otherwise. If you set invisible to `true`, that dictionary is no longer seen by such functions as `DCMCreateDictionaryIterator`, so it becomes a dictionary that cannot be accessed from any application other than the application that created the dictionary.

recordCapacity
The number of records that can be stored in the dictionary. You can supply an approximate value if you do not know the exact number.

newDictionary
On output, points to the ID of the newly-created dictionary.

Return Value
A result code. See "Dictionary Manager Result Codes" (page 1080).

Discussion
The function `DCMDeriveNewDictionary` creates an new dictionary file based on an existing dictionary specified in the `srcDictionary` parameter, with the same field configuration and properties, but does not contain the data from the source. The new dictionary is created with the name and at the location specified by the `newDictionaryFile` parameter. The newly-created dictionary is read-write enabled even if the source dictionary is read-only.

Availability
Available in CarbonLib 1.0 and later when running Japanese Mac OS 8.5 or later, or other Mac OS 8.5 or later with the Japanese Language Kit.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Dictionary.h`

DCMDisposeObjectIterator

Disposes of a iterator. (Deprecated in Mac OS X v10.5.)

```
OSStatus DCMDisposeObjectIterator (
   DCMObjectIterator iterator
);
```

Parameters

iterator
The list of available dictionaries that you want to dispose of.You obtain this list by calling the function `DCMCreateDictionaryIterator` (page 1033) or `DCMCreateAccessMethodIterator` (page 1032).

Return Value
A result code. See "Dictionary Manager Result Codes" (page 1080).

Discussion
You must dispose of a dictionary iterator when you no longer need it by calling the function `DCMDisposeObjectIterator` (page 1037).

Availability
Available in CarbonLib 1.0 and later when running Japanese Mac OS 8.5 or later, or other Mac OS 8.5 or later with the Japanese Language Kit.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Dictionary.h`

DCMDisposeRecordIterator

Disposes of a list of search results. (Deprecated in Mac OS X v10.5.)

```
OSStatus DCMDisposeRecordIterator (
   DCMFoundRecordIterator recordIterator
);
```

Parameters

recordIterator

A reference to the list of search results you want to dispose of. You obtain a list of search results by calling the function `DCMFindRecords` (page 1038).

Return Value

A result code. See "Dictionary Manager Result Codes" (page 1080).

Availability

Available in CarbonLib 1.0 and later when running Japanese Mac OS 8.5 or later, or other Mac OS 8.5 or later with the Japanese Language Kit.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Dictionary.h`

DCMFindRecords

Obtains a list of dictionary records that meet specified criteria. (Deprecated in Mac OS X v10.5.)

```
OSStatus DCMFindRecords (
   DCMDictionaryRef dictionaryRef,
   DCMFieldTag keyFieldTag,
   ByteCount keySize,
   ConstLogicalAddress keyData,
   DCMFindMethod findMethod,
   ItemCount preFetchedDataNum,
   DCMFieldTag preFetchedData[],
   ItemCount skipCount,
   ItemCount maxRecordCount,
   DCMFoundRecordIterator *recordIterator
);
```

Parameters

dictionaryRef

A reference to the dictionary you want to search. You obtain a dictionary reference when you call the function `DCMOpenDictionary` (page 1057).

keyFieldTag

A tag that specifies the field to search through. See "Field Data Tags" (page 1074) for a list of the fields you can specify for an Apple Japanese dictionary.

keySize

The length of the keyword specified by the `keyData` parameter.

keyData

The string for which you want to search.

findMethod

The search method to use. See "Search Methods" (page 1078) for a description of the methods you can supply.

preFetchedDataNum

The number of items in the `preFetchedData` array.

preFetchedData

An array of the tags obtained during the search. See "Field Data Tags" (page 1074) for a list of the field tags that can be obtained for an Apple Japanese dictionary.

skipCount

The number of records you want to skip during the search. You can use this value along with the `maxRecordCount` parameter to search through a dictionary in chunks. For example, if you want to obtain 10 matches at a time, the first time you search you should set the `skipCount` parameter to 0 and the `maxRecordCount` to 10. The second time you search you set `skipCount` to 10 and `maxRecordCount` to10. Each subsequent time you search, you increment `skipCount` by 10, keeping `maxRecordCount` set to10.

maxRecordCount

The maximum number of results to return. Pass 0 if you want all matching records returned. If the number of matching records is smaller than the maximum number of results to return, the search is terminated and the matching records returned in the `recordIterator` parameter. See the description of the `skipCount` parameter for information on how to use `maxRecordCount` to search through a dictionary in chunks.

recordIterator

On return, a reference to list of search results.

Return Value

A result code. See "Dictionary Manager Result Codes" (page 1080).If a match is not found, the function returns `dcmNoRecordErr`, and the `recordIterator` value is undefined.

Discussion

The function `DCMFindRecords` uses the specified key and search method to return a list of matching records. Search results are returned as a reference to a list of matching records. After you obtain this list, you can call the function `DCMGetFieldData` to retrieve each result in the list.

You can use the `preFetchedData` parameter to obtain a list of tags during the search. Data specified as pre-fetched are actually retrieved at the same time as the search key is retrieved, so you can specify data tags the need to be accessed fast and immediately after searching. In other words, you can avoid accessing and loading data that are not going to be used immediately by omitting those tags from the `preFetchedData` list. (You can retrieve those data later by calling the function `DCMGetFieldData` (page 1046).) For example: An application that searches pictures by date, displays the found titles in the list, and shows the picture only if the title is double-clicked, the key is "date", the pre-fetched data is "title", and the "picture" is retrieved later if needed by calling the function `DCMGetFieldData` (page 1046).

You pass the record iterator (`recordIterator`) as a parameter to the function DCM `DCMCountRecordIterator` (page 1032) to obtain the number of items in the list. You can obtain the individual items in the list by passing the record iterator to the function `DCMIterateFoundRecord` (page 1053). Your application is responsible for disposing of the record iterator when you no longer need it by calling the function `DCMDisposeRecordIterator` (page 1037).

Availability

Available in CarbonLib 1.0 and later when running Japanese Mac OS 8.5 or later, or other Mac OS 8.5 or later with the Japanese Language Kit.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Dictionary.h`

DCMGetAccessMethodIDFromName

Obtains the ID for access method. (Deprecated in Mac OS X v10.5.)

```
OSStatus DCMGetAccessMethodIDFromName (
   ConstStr63Param accessMethodName,
   DCMAccessMethodID *accessMethodID
);
```

Parameters

accessMethodName
The name of access method whose ID you want to obtain.

accessMethodID
On output, the ID for the access method specified by the `accessMethodName` parameter.

Return Value
A result code. See "Dictionary Manager Result Codes" (page 1080).

Discussion
You can use this function to obtain the `accessMethodID` that you supply to the function `DCMNewDictionary` (page 1056) to create a new dictionary.

Normally you should not need to call this function because the Dictionary Manager handles the mapping of a dictionary to its access method.

Availability
Available in CarbonLib 1.0 and later when running Japanese Mac OS 8.5 or later, or other Mac OS 8.5 or later with the Japanese Language Kit.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Dictionary.h`

DCMGetDictionaryFieldInfo

Obtains field information for a specified field in a dictionary record. (Deprecated in Mac OS X v10.5.)

```
OSStatus DCMGetDictionaryFieldInfo (
   DCMDictionaryID dictionaryID,
   DCMFieldTag fieldTag,
   AEDesc *fieldInfoRecord
);
```

Parameters

dictionaryID

The ID of dictionary from which you want to obtain field information. You obtain a dictionary ID when you call the functions `DCMRegisterDictionaryFile` (page 1058) or `DCMGetDictionaryIDFromFile` (page 1041).

fieldTag

The tag of the field whose field information you want to obtain. If you pass `'****'` (`typeWildCard`) as the field tag, all of the field information contained in the specified dictionary is returned in the `fieldInfoRecord` parameter.

fieldInfoRecord

On return, points to the field information for the specified field. You are responsible for disposing of this structure by calling the Apple Event Manager function `AEDisposeDesc`.

Return Value

A result code. See "Dictionary Manager Result Codes" (page 1080).

Availability

Available in CarbonLib 1.0 and later when running Japanese Mac OS 8.5 or later, or other Mac OS 8.5 or later with the Japanese Language Kit.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Dictionary.h`

DCMGetDictionaryIDFromFile

Obtains the ID associated with a dictionary file. (Deprecated in Mac OS X v10.5.)

```
OSStatus DCMGetDictionaryIDFromFile (
   const FSSpec *fileRef,
   DCMDictionaryID *dictionaryID
);
```

Parameters

fileRef

The file specification for the dictionary whose ID you want to obtain.

dictionaryID

On output, points to the ID for the dictionary specified by the `fileRef` parameter.

Return Value

A result code. See "Dictionary Manager Result Codes" (page 1080). If the file is not a dictionary, the result `dcmNotDictionaryErr` is returned. If the dictionary is not yet registered, the result `dcmBadDictionaryErr` is returned.

Availability
Available in CarbonLib 1.0 and later when running Japanese Mac OS 8.5 or later, or other Mac OS 8.5 or later with the Japanese Language Kit.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Dictionary.h`

DCMGetDictionaryIDFromRef

Obtains the dictionary ID associated with a dictionary reference. (Deprecated in Mac OS X v10.5.)

```
DCMDictionaryID DCMGetDictionaryIDFromRef (
   DCMDictionaryRef dictionaryRef
);
```

Parameters

`dictionaryRef`

A reference to the dictionary whose ID you want to obtain. You obtain a dictionary reference when you call the function `DCMOpenDictionary` (page 1057).

Return Value
On return, the ID of the dictionary specified by the `dictionaryRef` parameter. If `dictionaryRef` is invalid, the result `kDCMInvalidObjectID` is returned. See page for a description of the `DCMDictionaryID` data type.

Availability
Available in CarbonLib 1.0 and later when running Japanese Mac OS 8.5 or later, or other Mac OS 8.5 or later with the Japanese Language Kit.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Dictionary.h`

DCMGetDictionaryProperty

Obtains the data associated with a property tag. (Deprecated in Mac OS X v10.5.)

```
OSStatus DCMGetDictionaryProperty (
   DCMDictionaryID dictionaryID,
   DCMFieldTag propertyTag,
   ByteCount maxPropertySize,
   ByteCount *actualSize,
   LogicalAddress propertyValue
);
```

Parameters

dictionaryID

The ID of dictionary whose property you want to obtain. You obtain a dictionary ID when you call the functions `DCMRegisterDictionaryFile` (page 1058) or `DCMGetDictionaryIDFromFile` (page 1041).

propertyTag

The property tag whose data you want to obtain.

maxPropertySize

The size of the data specified by the `propertyValue` parameter.

actualSize

On output, the actual size of the data specified by the `propertyValue` parameter.

propertyValue

On output, points to the property data.

Return Value

A result code. See "Dictionary Manager Result Codes" (page 1080). Returns the result `dcmBadPropertyErr` if the property tag does not exist.

Discussion

If you don't know the size of the property whose data you want to obtain, you need to call this function twice as follows:

- The first time you call the function `DCMGetProperty`, pass the dictionary ID, the property tag, `0` for the `maxPropertySize` parameter and `Null` for `propertyValue`. Then allocate a `propertyValue` buffer of the size returned by the `actualSize` parameter.
- The second time you call the function `DCMGetProperty`, pass the dictionary ID, the property tag, the correct size for the `maxPropertySize` parameter, and the `propertyValue` buffer of the appropriate size.

Availability

Available in CarbonLib 1.0 and later when running Japanese Mac OS 8.5 or later, or other Mac OS 8.5 or later with the Japanese Language Kit.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Dictionary.h`

DCMGetDictionaryPropertyList

Obtains a list of property tags from a dictionary. (Deprecated in Mac OS X v10.5.)

```
OSStatus DCMGetDictionaryPropertyList (
   DCMDictionaryID dictionaryID,
   ItemCount maxPropertyNum,
   ItemCount *numProperties,
   DCMFieldTag propertyTag[]
);
```

Parameters

dictionaryID

The ID of dictionary whose list of property tags you want to obtain. You obtain a dictionary ID when you call the functions `DCMRegisterDictionaryFile` (page 1058) or `DCMGetDictionaryIDFromFile` (page 1041).

maxPropertyNum

The maximum number of property tags in the list.

numProperties

On output, the number of properties actually contained in the dictionary.

propertyTag

On output, an array of the property tags contained in the dictionary. You are responsible for allocating an array of the appropriate size.

Return Value

A result code. See "Dictionary Manager Result Codes" (page 1080).

Discussion

The function `DCMGetDictionaryPropertyList` returns a list of property tags in the specified dictionary. You need to call this function twice. The first time you call the function to get the number of properties. Then you must allocate a `propertyTag` array of the appropriate size. You call the function a second time to get the actual list of tags.

Availability

Available in CarbonLib 1.0 and later when running Japanese Mac OS 8.5 or later, or other Mac OS 8.5 or later with the Japanese Language Kit.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Dictionary.h`

DCMGetDictionaryWriteAccess

Obtains write access for an open dictionary. (Deprecated in Mac OS X v10.5.)

```
OSStatus DCMGetDictionaryWriteAccess (
   DCMDictionaryRef dictionaryRef,
   Duration timeOutDuration
);
```

Parameters

dictionaryRef

A reference to the dictionary for which you want to obtain write access. You obtain a dictionary reference when you call the function `DCMOpenDictionary` (page 1057).

timeOutDuration

The maximum amount of time to wait for write access. This parameter is currently not used.

Return Value
A result code. See "Dictionary Manager Result Codes" (page 1080). Returns the result `dcmPermissionErr` if the dictionary is read-only dictionary or if another application has write access.

Discussion
When you call the function `DCMOpenDictionary` (page 1057), the dictionary opens with read-only access. You must call the function `DCMGetDictionaryWriteAccess` to obtain write privileges. You can obtain write access only if a dictionary is already opened and no other application has write access to that dictionary. You should release write privileges as soon as you no longer need write access, by calling the function `DCMReleaseDictionaryWriteAccess` (page 1059).

Availability
Available in CarbonLib 1.0 and later when running Japanese Mac OS 8.5 or later, or other Mac OS 8.5 or later with the Japanese Language Kit.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Dictionary.h`

DCMGetFieldAttributes

Obtains the field attributes for a field information record. (Deprecated in Mac OS X v10.5.)

```
OSStatus DCMGetFieldAttributes (
   const AEDesc *fieldInfoRecord,
   DCMFieldAttributes *attributes
);
```

Parameters

fieldInfoRecord

On input, points to the field information record whose attributes you want to obtain.

attributes

On output, points to the attributes obtained from the field information record. See "Field Attributes" (page 1073)for more information.

Return Value
A result code. See "Dictionary Manager Result Codes" (page 1080).

Availability
Available in CarbonLib 1.0 and later when running Japanese Mac OS 8.5 or later, or other Mac OS 8.5 or later with the Japanese Language Kit.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Dictionary.h`

DCMGetFieldData

Obtains data from one or more fields in a specified record. (Deprecated in Mac OS X v10.5.)

```
OSStatus DCMGetFieldData (
   DCMDictionaryRef dictionaryRef,
   DCMFieldTag keyFieldTag,
   ByteCount keySize,
   ConstLogicalAddress keyData,
   DCMUniqueID uniqueID,
   ItemCount numOfData,
   const DCMFieldTag dataTag[],
   AEDesc *dataList
);
```

Parameters

dictionaryRef

A reference to the dictionary that contains the field data you want to obtain. You obtain a dictionary reference when you call the function `DCMOpenDictionary` (page 1057).

keyFieldTag

A field tag that specifies the data you want to obtain.

keySize

The size of the `keyData` parameter.

keyData

The key data of the record you whose field you want to obtain. You are responsible for allocating this buffer.

uniqueID

The unique ID of the record whose field you want to obtain.

numOfData

The number of data fields tags in the `dataTag` array.

dataTag

A list of the data field to obtain.

dataList

On return, points to a list of obtained data. The data obtained is returned in t as an `AERecord` data structure. You can retrieve data from specific field using the Apple Event Manager function `AEGetKeyPtr`. You are responsible for disposing of the `dataList` array by calling the Apple Event Manager function `AEDisposeDesc`.

Return Value

A result code. See "Dictionary Manager Result Codes" (page 1080).

Availability

Available in CarbonLib 1.0 and later when running Japanese Mac OS 8.5 or later, or other Mac OS 8.5 or later with the Japanese Language Kit.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Dictionary.h`

DCMGetFieldDefaultData

Obtains default data for a field information record. (Deprecated in Mac OS X v10.5.)

```
OSStatus DCMGetFieldDefaultData (
   const AEDesc *fieldInfoRecord,
   DescType desiredType,
   AEDesc *fieldDefaultData
);
```

Parameters

fieldInfoRecord

On input, points to the field information record whose default data you want to obtain.

desiredType

The data type of the default data.

fieldDefaultData

On output, points to the default data obtained from the field information record.

Return Value

A result code. See "Dictionary Manager Result Codes" (page 1080).

Availability

Available in CarbonLib 1.0 and later when running Japanese Mac OS 8.5 or later, or other Mac OS 8.5 or later with the Japanese Language Kit.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Dictionary.h`

DCMGetFieldFindMethods

Obtains the search methods for a field information record. (Deprecated in Mac OS X v10.5.)

```
OSStatus DCMGetFieldFindMethods (
   const AEDesc *fieldInfoRecord,
   ItemCount findMethodsArrayMaxSize,
   DCMFindMethod findMethods[],
   ItemCount *actualNumberOfFindMethods
);
```

Parameters

fieldInfoRecord

On input, points to the field information record whose search methods you want to obtain.

findMethodsArrayMaxSize

The number of elements in the `findMethods` array.

findMethods

On output, an array of search methods obtained from the field information record. See "Search Methods" (page 1078) for more information.

actualNumberOfFindMethods

On output, the actual number of search methods obtained from the field information array.

Return Value
A result code. See "Dictionary Manager Result Codes" (page 1080).

Availability
Available in CarbonLib 1.0 and later when running Japanese Mac OS 8.5 or later, or other Mac OS 8.5 or later with the Japanese Language Kit.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Dictionary.h`

DCMGetFieldMaxRecordSize

Obtains the maximum data size for a field in a dictionary record. (Deprecated in Mac OS X v10.5.)

```
OSStatus DCMGetFieldMaxRecordSize (
   const AEDesc *fieldInfoRecord,
   ByteCount *maxRecordSize
);
```

Parameters
fieldInfoRecord
On input, points to the field information record whose maximum data size you want to obtain.
maxRecordSize
On output, points to the maximum data size obtained from the field information record.

Return Value
A result code. See "Dictionary Manager Result Codes" (page 1080).

Availability
Available in CarbonLib 1.0 and later when running Japanese Mac OS 8.5 or later, or other Mac OS 8.5 or later with the Japanese Language Kit.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Dictionary.h`

DCMGetFieldTagAndType

Obtains the field tag and type associated with a field information record. (Deprecated in Mac OS X v10.5.)

```
OSStatus DCMGetFieldTagAndType (
   const AEDesc *fieldInfoRecord,
   DCMFieldTag *fieldTag,
   DCMFieldType *fieldType
);
```

Parameters

fieldInfoRecord

On input, points to the field information record whose field tag and type you want to obtain.

fieldTag

On output, points to the field tag obtained from the field information record.

fieldType

On output, points to the field tag type obtained from the field information record.

Return Value

A result code. See "Dictionary Manager Result Codes" (page 1080).

Availability

Available in CarbonLib 1.0 and later when running Japanese Mac OS 8.5 or later, or other Mac OS 8.5 or later with the Japanese Language Kit.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Dictionary.h`

DCMGetFileFromDictionaryID

Obtains the file specification associated with a dictionary ID. (Deprecated in Mac OS X v10.5.)

```
OSStatus DCMGetFileFromDictionaryID (
   DCMDictionaryID dictionaryID,
   FSSpec *fileRef
);
```

Parameters

dictionaryID

The ID of the dictionary whose file specification you want to obtain. You obtain a dictionary ID when you call the functions `DCMRegisterDictionaryFile` (page 1058) or `DCMGetDictionaryIDFromFile` (page 1041).

fileRef

On output, points to the file specification for the dictionary specified by the `dictionaryID` parameter.

Return Value

A result code. See "Dictionary Manager Result Codes" (page 1080).

Availability

Available in CarbonLib 1.0 and later when running Japanese Mac OS 8.5 or later, or other Mac OS 8.5 or later with the Japanese Language Kit.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In
`Dictionary.h`

DCMGetNextRecord

Obtains the next specified record. (Deprecated in Mac OS X v10.5.)

```
OSStatus DCMGetNextRecord (
   DCMDictionaryRef dictionaryRef,
   DCMFieldTag keyFieldTag,
   ByteCount keySize,
   ConstLogicalAddress keyData,
   DCMUniqueID uniqueID,
   ByteCount maxKeySize,
   ByteCount *nextKeySize,
   LogicalAddress nextKeyData,
   DCMUniqueID *nextUniqueID
);
```

Parameters

dictionaryRef
A reference to the dictionary whose record you want to obtain. You obtain a dictionary reference when you call the function `DCMOpenDictionary` (page 1057).

keyFieldTag
The field tag that specifies the data you want to obtain.

keySize
The size of the `keyData` parameter. If you pass `0`, the first record in the dictionary is returned.

keyData
The key data of the reference record.

uniqueID
The unique ID of the reference record.

maxKeySize
The size of the buffer for the `nextKeyData` parameter.

nextKeySize
On output, the actual size of the buffer for the `nextKeyData` parameter.

nextKeyData
On output, points to the next key of the specified record. You must allocate this buffer.

nextUniqueID
On output, the unique ID of the found record.

Return Value
A result code. See "Dictionary Manager Result Codes" (page 1080).

Availability
Available in CarbonLib 1.0 and later when running Japanese Mac OS 8.5 or later, or other Mac OS 8.5 or later with the Japanese Language Kit.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Dictionary.h`

DCMGetNthRecord

Return records in a specified order within the dictionary. (Deprecated in Mac OS X v10.5.)

```
OSStatus DCMGetNthRecord (
   DCMDictionaryRef dictionaryRef,
   DCMFieldTag keyFieldTag,
   ItemCount serialNum,
   ByteCount maxKeySize,
   ByteCount *keySize,
   LogicalAddress keyData,
   DCMUniqueID *uniqueID
);
```

Parameters

dictionaryRef
A reference to the dictionary whose record you want to obtain. You obtain a dictionary reference when you call the function `DCMOpenDictionary` (page 1057).

keyFieldTag
The field tag that specifies the data you want to obtain.

serialNum
A value that specifies the location of the record within the dictionary. You can obtain this value by calling the function `DCMGetRecordSequenceNumber` (page 1053).

maxKeySize
The maximum size of the `keyData` parameter.

keySize
On output, the size of the `keyData` parameter.

keyData
The key data of the record you want to obtain. You are responsible for allocating this buffer.

uniqueID
On output, the unique ID of the found record.

Return Value
A result code. See "Dictionary Manager Result Codes" (page 1080).

Availability
Available in CarbonLib 1.0 and later when running Japanese Mac OS 8.5 or later, or other Mac OS 8.5 or later with the Japanese Language Kit.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Dictionary.h`

DCMGetPrevRecord

Obtains the previous record. Return the record previous to the specified record. (Deprecated in Mac OS X v10.5.)

```
OSStatus DCMGetPrevRecord (
   DCMDictionaryRef dictionaryRef,
   DCMFieldTag keyFieldTag,
   ByteCount keySize,
   ConstLogicalAddress keyData,
   DCMUniqueID uniqueID,
   ByteCount maxKeySize,
   ByteCount *prevKeySize,
   LogicalAddress prevKeyData,
   DCMUniqueID *prevUniqueID
);
```

Parameters

dictionaryRef

A reference to the dictionary whose record you want to obtain. You obtain a dictionary reference when you call the function `DCMOpenDictionary` (page 1057).

keyFieldTag

The field tag that specifies the data you want to obtain.

keySize

The size of the `keyData` parameter. If you pass `0`, the last record in the dictionary is returned.

keyData

The key data of the reference record.

uniqueID

The unique ID of the record reference record.

maxKeySize

The size of the buffer for the `prevKeyData` parameter.

prevKeySize

On output, the actual size of the buffer for the `prevKeyData` parameter.

prevKeyData

On output, points to the previous key of the specified record. You must allocate this buffer.

prevUniqueID

On output, the unique ID of the found record.

Return Value

A result code. See "Dictionary Manager Result Codes" (page 1080).

Availability

Available in CarbonLib 1.0 and later when running Japanese Mac OS 8.5 or later, or other Mac OS 8.5 or later with the Japanese Language Kit.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Dictionary.h`

DCMGetRecordSequenceNumber

Obtains the sequence number for the specified record in a dictionary. (Deprecated in Mac OS X v10.5.)

```
OSStatus DCMGetRecordSequenceNumber (
   DCMDictionaryRef dictionaryRef,
   DCMFieldTag keyFieldTag,
   ByteCount keySize,
   ConstLogicalAddress keyData,
   DCMUniqueID uniqueID,
   ItemCount *sequenceNum
);
```

Parameters

dictionaryRef

A reference to the dictionary whose record sequence number you want to obtain. You obtain a dictionary reference when you call the function `DCMOpenDictionary` (page 1057).

keyFieldTag

The field tag that specifies the data you want to obtain.

keySize

The size of the `keyData` parameter.

keyData

The key data of the record whose sequence number you want to obtain.

uniqueID

The unique ID of the record whose sequence number you want to obtain.

sequenceNum

On output, a value that specifies the order of the record in the dictionary. The first record in a dictionary has the value 1. Subsequent records are numbered sequentially.

Return Value

A result code. See "Dictionary Manager Result Codes" (page 1080).

Availability

Available in CarbonLib 1.0 and later when running Japanese Mac OS 8.5 or later, or other Mac OS 8.5 or later with the Japanese Language Kit.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Dictionary.h`

DCMIterateFoundRecord

Retrieves one record from a list of search results. (Deprecated in Mac OS X v10.5.)

```
OSStatus DCMIterateFoundRecord (
   DCMFoundRecordIterator recordIterator,
   ByteCount maxKeySize,
   ByteCount *actualKeySize,
   LogicalAddress keyData,
   DCMUniqueID *uniqueID,
   AEDesc *dataList
);
```

Parameters

recordIterator

A reference to list of search results. You obtain a list of search results by calling the function DCMFindRecords (page 1038).

maxKeySize

The size of the keyData parameter.

actualKeySize

On output, the actual size of the buffer needed for the data specified by the keyData parameter.

keyData

On output, the key of the retrieved data.

uniqueID

On output, the unique ID of the retrieved record. This value is guaranteed to be unique among records with the same key data; but it is not unique among all records in the dictionary. You can use the unique ID in conjunction with the retrieved key data to specify individual records within the dictionary when you call the functions DCMGetNextRecord (page 1050), DCMGetPrevRecord (page 1052), DCMGetRecordSequenceNumber (page 1053), DCMDeleteRecord (page 1035), DCMGetFieldData (page 1046), and DCMSetFieldData (page 1061).

dataList

On output, the data associated with the key specified by the keyData parameter.

Return Value

A result code. See "Dictionary Manager Result Codes" (page 1080). The function returns the result dcmIterationCompleteErr when the final record is retrieved.

Discussion

The function DCMIterateFoundRecord retrieves one record from a list of search results referenced by a record iterator. You can retrieve all of the records referenced by a record iterator by repeatedly calling the DCMIterateFoundRecord function.

The data associated with the fields specified in the preFetchedData parameter is returned to dataList in the form of an AERecord. (See DCMFindRecords (page 1038) for more information on pre-fetched data). It is possible to retrieve data by specifying the field tag and data type, and use the AEGetKeyPtr and so forth of the Apple Event Manager. You application is responsible for disposing of dataList by calling the Apple Event Manager function AEDisposeDesc.

Only pre-fetched data can be retrieved here since these data are already retrieved. Other data can be retrieved later by calling the function DCMGetFieldData (page 1046).

Availability

Available in CarbonLib 1.0 and later when running Japanese Mac OS 8.5 or later, or other Mac OS 8.5 or later with the Japanese Language Kit.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In
`Dictionary.h`

DCMIterateObject

Obtains the object ID for a dictionary from a list of available dictionaries. (Deprecated in Mac OS X v10.5.)

```
OSStatus DCMIterateObject (
   DCMObjectIterator iterator,
   DCMObjectID *objectID
);
```

Parameters

iterator

The list of available dictionaries. You obtain this list by calling the function `DCMCreateDictionaryIterator` (page 1033) or `DCMCreateAccessMethodIterator` (page 1032).

objectID

On output, the object ID of the dictionary.

Return Value
A result code. See "Dictionary Manager Result Codes" (page 1080).

Discussion
The first time you call the function `DCMIterateObject` it retrieves the object ID of the first dictionary in the list. The next time you call the function, it retrieves the object ID of the next dictionary in the list. You can obtain all object IDs by repeatedly calling this function. If you call the function after you obtain the object ID for the last dictionary, the function returns the result `dcmIterationCompleteErr`.

You can reset the iterator to the first dictionary in the list by calling the function `DCMResetObjectIterator` (page 1060). When you no longer need the iterator, you must dispose of it by calling the function `DCMDisposeObjectIterator` (page 1037).

Availability
Available in CarbonLib 1.0 and later when running Japanese Mac OS 8.5 or later, or other Mac OS 8.5 or later with the Japanese Language Kit.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In
`Dictionary.h`

DCMLibraryVersion

Obtains the version number of the Dictionary Manager. (Deprecated in Mac OS X v10.5.)

```
UInt32 DCMLibraryVersion (
   void
);
```

Parameters

Return Value
The library version number.

Discussion
The function `DCMLibraryVersion` returns the version of the installed Dictionary Manager in the same format as the `'vers'` resource. That is, the version number is returned in Binary-Coded Decimal (BCD) format in the high-order word, and the release stage information is returned in the low-order word. For example, the version 1.1.1 library returns 0x01118000.

Availability
Available in CarbonLib 1.0 and later when running Japanese Mac OS 8.5 or later, or other Mac OS 8.5 or later with the Japanese Language Kit.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In
`Dictionary.h`

DCMNewDictionary

Creates a new dictionary. (Deprecated in Mac OS X v10.5.)

```
OSStatus DCMNewDictionary (
   DCMAccessMethodID accessMethodID,
   const FSSpec *newDictionaryFile,
   ScriptCode scriptTag,
   const AEDesc *listOfFieldInfoRecords,
   Boolean invisible,
   ItemCount recordCapacity,
   DCMDictionaryID *newDictionary
);
```

Parameters

accessMethodID

The ID of access method to use for the dictionary. You can obtain an access method ID by calling the function `DCMGetAccessMethodIDFromName` (page 1040).

newDictionaryFile

On output, a pointer to an `FSSpec` structure that specifies the dictionary file to be created.

scriptTag

The code of the script system in which the filename of the dictionary file is to be displayed.

listOfFieldInfoRecords

A pointer to an array of `AEDesc` data structures. The `AEDesc` data structure contains two fields: A four-character code that specifies the type of data in the structure and an opaque storage type that points to the storage for the descriptor data. Each of the data structures in the `listOfFieldInfoRecords` array specifies a field name (the four-character code) in the dictionary record and the data associated with that field. You must first call the function `DCMCreateFieldInfoRecord` (page 1033) to create this array of data structures.

invisible

A Boolean value that specifies whether the dictionary is available through the Dictionary Manager. Pass `true` if you do not want the dictionary to be available, `false` otherwise. If you set invisible to `true`, that dictionary is no longer seen by such functions as `DCMCreateDictionaryIterator`, so it becomes a dictionary that cannot be accessed from any application other than the application that created the dictionary.

recordCapacity

The number of records that can be stored in the dictionary. You can supply an approximate value if you do not know the exact number.

newDictionary

On output, points to the ID of the newly-created dictionary.

Return Value

A result code. See "Dictionary Manager Result Codes" (page 1080).

Discussion

The function `DCMNewDictionary` creates a new dictionary file and registers that dictionary with the Dictionary Manager. You need to specify the access method to use in creating the dictionary. The Dictionary Manager does not operate directly on a dictionary. Instead it accesses dictionaries using the access method specified for the dictionary. The access method mediates between the dictionary and the Dictionary Manager, so that the Dictionary Manager does not need to know anything about the physical format of the dictionary. As a result, the dictionary can have an free-form internal structure. You can also to use an existing dictionary as long as the dictionary has its own access method.

Availability

Available in CarbonLib 1.0 and later when running Japanese Mac OS 8.5 or later, or other Mac OS 8.5 or later with the Japanese Language Kit.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Dictionary.h`

DCMOpenDictionary

Opens a dictionary. (Deprecated in Mac OS X v10.5.)

```
OSStatus DCMOpenDictionary (
   DCMDictionaryID dictionaryID,
   ByteCount protectKeySize,
   ConstLogicalAddress protectKey,
   DCMDictionaryRef *dictionaryRef
);
```

Parameters

dictionaryID

The ID of the dictionary you want to open. You obtain a dictionary ID when you register a dictionary by calling the function `DCMRegisterDictionaryFile` (page 1058) or `DCMGetDictionaryIDFromFile` (page 1041).

protectKeySize

The size of the keyword specified by the `protectKey` parameter. This parameter is optional. Pass `0` if you do not plan to provide a password.

protectKey

The keyword to use when opening the dictionary. An access method can use the `protectKey` parameter as a password to restrict access to the dictionary. This parameter is optional. Pass `NULL` if you do not plan to provide a password.

dictionaryRef
On output, a reference to the opened dictionary.

Return Value
A result code. See "Dictionary Manager Result Codes" (page 1080).

Discussion
The function `DCMOpenDictionary` opens the dictionary specified by the dictionary ID and obtains a reference to the dictionary (`dictionaryRef`). You can pass this reference as a parameter to other Dictionary Manager functions to access the records in the dictionary.

Availability
Available in CarbonLib 1.0 and later when running Japanese Mac OS 8.5 or later, or other Mac OS 8.5 or later with the Japanese Language Kit.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Dictionary.h`

DCMRegisterDictionaryFile

Registers a dictionary. (Deprecated in Mac OS X v10.5.)

```
OSStatus DCMRegisterDictionaryFile (
   const FSSpec *dictionaryFile,
   DCMDictionaryID *dictionaryID
);
```

Parameters
dictionaryFile
The file specification for the dictionary you want to register.
dictionaryID
On output, points to the ID of the registered dictionary. A dictionary ID is not persistent across system restarts.

Return Value
A result code. See "Dictionary Manager Result Codes" (page 1080).

Discussion
You should use this function only when the target dictionary is not in default location (see`DCMCreateDictionaryIterator` (page 1033)). Otherwise, dictionaries should be already registered and you can obtain the `dictionaryID` by calling the function `DCMGetDictionaryIDFromFile` (page 1041) or `DCMCreateDictionaryIterator` (page 1033).

You can only use registered dictionaries. You pass the dictionary ID obtained from the function `DCMRegisterDictionaryFile` when you call other Dictionary Manager functions.

Availability
Available in CarbonLib 1.0 and later when running Japanese Mac OS 8.5 or later, or other Mac OS 8.5 or later with the Japanese Language Kit.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In
`Dictionary.h`

DCMReleaseDictionaryWriteAccess

Releases write access to a dictionary. (Deprecated in Mac OS X v10.5.)

```
OSStatus DCMReleaseDictionaryWriteAccess (
   DCMDictionaryRef dictionaryRef,
   Boolean commitTransaction
);
```

Parameters

dictionaryRef

A reference to the dictionary for which you want to release write access. You obtain a dictionary reference when you call the function `DCMOpenDictionary` (page 1057).

commitTransaction

A Boolean value that specifies whether or not to write changed to the dictionary. Pass `true` to write changes to the dictionary. Pass `false` to cancel changes. The dictionary must support transaction processing for this parameter to have an effect. This parameter is currently not used.

Return Value
A result code. See "Dictionary Manager Result Codes" (page 1080).

Availability
Available in CarbonLib 1.0 and later when running Japanese Mac OS 8.5 or later, or other Mac OS 8.5 or later with the Japanese Language Kit.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Dictionary.h`

DCMReorganizeDictionary

Reorganizes a dictionary. (Deprecated in Mac OS X v10.5.)

```
OSStatus DCMReorganizeDictionary (
   DCMDictionaryID dictionaryID,
   ItemCount extraCapacity,
   DCMProgressFilterUPP progressProc,
   UInt32 userData
);
```

Parameters

dictionaryID

The ID of dictionary you want to reorganize. You obtain a dictionary ID when you call the functions `DCMRegisterDictionaryFile` (page 1058) or `DCMGetDictionaryIDFromFile` (page 1041).

extraCapacity
The number of additional records you want to add. This number can be approximate.

progressProc
A universal procedure pointer (UPP) to a progress callback function. This callback is not supported.

userData
Data needed by your progress callback function.

Return Value
A result code. See "Dictionary Manager Result Codes" (page 1080).

Discussion
The function `DCMReorganizeDictionary` reorganizes the contents of the dictionary specified by the `dictionaryID` parameter, expanding the dictionary to allow for the additional number of records specified by the `extraCapacity` parameter.

Availability
Available in CarbonLib 1.0 and later when running Japanese Mac OS 8.5 or later, or other Mac OS 8.5 or later with the Japanese Language Kit.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Dictionary.h`

DCMResetObjectIterator

Resets an iterator to the start of the dictionary list. (Deprecated in Mac OS X v10.5.)

```
OSStatus DCMResetObjectIterator (
   DCMObjectIterator iterator
);
```

Parameters

iterator
The list of available dictionaries. You obtain this list by calling the function `DCMCreateDictionaryIterator` (page 1033) or `DCMCreateAccessMethodIterator` (page 1032).

Return Value
A result code. See "Dictionary Manager Result Codes" (page 1080).

Discussion
If you want to retrieve the object ID for a dictionary in the list, call the function `DCMIterateObject` (page 1055). When you no longer need the iterator, you must dispose of it by calling the function `DCMDisposeObjectIterator` (page 1037).

Availability
Available in CarbonLib 1.0 and later when running Japanese Mac OS 8.5 or later, or other Mac OS 8.5 or later with the Japanese Language Kit.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Dictionary.h`

DCMSetDictionaryProperty

Sets a property for a dictionary. Set the properties to a dictionary. (Deprecated in Mac OS X v10.5.)

```
OSStatus DCMSetDictionaryProperty (
   DCMDictionaryID dictionaryID,
   DCMFieldTag propertyTag,
   ByteCount propertySize,
   ConstLogicalAddress propertyValue
);
```

Parameters

dictionaryID
The ID of dictionary whose property you want to set. You obtain a dictionary ID when you call the functions `DCMRegisterDictionaryFile` (page 1058) or `DCMGetDictionaryIDFromFile` (page 1041).

propertyTag
The property tag whose data you want to set.

propertySize
The size of data pointed to by the `propertyValue` parameter.

propertyValue
A pointer to the property data to be set.

Return Value
A result code. See "Dictionary Manager Result Codes" (page 1080). Returns the result `dcmPermissionErr` if the property already exists and it is a read-only property.

Discussion
If the specified properties already exists and it is a writable property, the property data is replaced. If the property does not exist, it is created.

Availability
Available in CarbonLib 1.0 and later when running Japanese Mac OS 8.5 or later, or other Mac OS 8.5 or later with the Japanese Language Kit.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Dictionary.h`

DCMSetFieldData

Set the data to a specific field of a specified record. (Deprecated in Mac OS X v10.5.)

```
OSStatus DCMSetFieldData (
   DCMDictionaryRef dictionaryRef,
   DCMFieldTag keyFieldTag,
   ByteCount keySize,
   ConstLogicalAddress keyData,
   DCMUniqueID uniqueID,
   const AEDesc *dataList
);
```

Parameters

dictionaryRef

A reference to the dictionary that contains the field data you want to set. You obtain a dictionary reference when you call the function `DCMOpenDictionary` (page 1057).

keyFieldTag

Tag of applicable key field.

keySize

The size of the `keyData` parameter.

keyData

The key data of the record you whose field you want to set.

uniqueID

The unique ID of the record whose field you want to obtain.

dataList

A pointer to the list of data you want to set. The `AEDesc` data structure contains two fields: A four-character code that specifies the type of data in the structure and an opaque storage type that points to the storage for the descriptor data. Each of the data structures in the `dataList` array specifies a field name (the four-character code) in the dictionary record and the data associated with that field. You must first call the function `DCMCreateFieldInfoRecord` (page 1033) to create this array of data structures.

Return Value

A result code. See "Dictionary Manager Result Codes" (page 1080).

Availability

Available in CarbonLib 1.0 and later when running Japanese Mac OS 8.5 or later, or other Mac OS 8.5 or later with the Japanese Language Kit.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Dictionary.h`

DCMUnregisterDictionary

Unregisters a dictionary. (Deprecated in Mac OS X v10.5.)

```
OSStatus DCMUnregisterDictionary (
   DCMDictionaryID dictionaryID
);
```

Parameters

dictionaryID

Return Value
A result code. See "Dictionary Manager Result Codes" (page 1080). Returns `dcmDictionaryBusyErr` if the dictionary is in use by another client.

Discussion
You should use this function only for dictionaries that you registered by calling the function `DCMRegisterDictionaryFile` (page 1058).

Availability
Available in CarbonLib 1.0 and later when running Japanese Mac OS 8.5 or later, or other Mac OS 8.5 or later with the Japanese Language Kit.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Dictionary.h`

Callbacks

DCMProgressFilterProcPtr

Displays the progress state of a reorganization or compaction operation.

```
typedef Boolean (*DCMProgressFilterProcPtr)
(
    Boolean determinateProcess,
    UInt16 percentageComplete,
    UInt32 callbackUD
);
```

If you name your function `MyDCMProgressFilterProc`, you would declare it like this:

```
Boolean DCMProgressFilterProcPtr (
    Boolean determinateProcess,
    UInt16 percentageComplete,
    UInt32 callbackUD
);
```

Discussion
You supply this callback as a parameter to the `DCMReorganizeDictionary` (page 1059) and `DCMCompactDictionary` (page 1030) functions.

Availability
Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In
`Dictionary.h`

Data Types

DCMAccessMethodID

Represents an access method ID.

```
typedef DCMObjectID DCMAccessMethodID;
```

Discussion
See `DCMGetAccessMethodIDFromName` (page 1040).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Dictionary.h`

DCMAccessMethodIterator

Represents a list of access methods.

```
typedef DCMObjectIterator DCMAccessMethodIterator;
```

Discussion
See `DCMCreateAccessMethodIterator` (page 1032).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Dictionary.h`

DCMDictionaryHeader

Contains header information for a dictionary.

```
struct DCMDictionaryHeader {
    FourCharCode headerSignature;
    UInt32 headerVersion;
    ByteCount headerSize;
    Str63 accessMethod;
};
typedef struct DCMDictionaryHeader DCMDictionaryHeader;
```

Fields

`headerSignature`
: The header signature must be `'dict'`.

`headerVersion`
: The version of header information. The current version is specified by the constant `kDCMDictionaryHeaderVersion`.

`headerSize`
: The size of the header information. The current size is 76 bytes.

`accessMethod`
: The library name of the access method.

Discussion

The internal structure of dictionaries used by the Dictionary Manager can be broadly divided into three structures: dictionary header section, dictionary property section, and data record section. However, internal structures apart from the dictionary header section rely on the access method and can be freely defined, so you must be aware that this is strictly a structural model for dictionaries viewed from outside.

Dictionary files that are managed by the Dictionary Manager have a dictionary header at the start of its data fork in a defined format, and this header must contain a signature which indicates that it is a dictionary supported by the Dictionary Manager. The file must also contain basic information such as the name of the access method which can manage this dictionary. The dictionary header is the only information in the dictionary that can be accessed without the use of an access method.

The dictionary property section contains information about the dictionary as a whole, such as access restrictions (whether it is write enabled, whether its content can be downloaded). Properties are managed by tags, and it is possible to define and save different types of information.

The data record section contains registered data records. Each data record is further divided into fields," and these are managed using tags which represent the meaning of the data—for example, 'yomi' (read) and 'hins' (part of speech). At least one field in a record must be a key field. The key field is used as an index, and tag and key data for this field are used to find records. When searching through records, you can specify other field tags in addition to the key field, thereby enabling a variety of data to be obtained at once.

Each field in a record has field attributes that specify the field's data type, maximum data length, and default data The key data field also has an attribute that specifies the search methods it supports.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Dictionary.h`

DCMDictionaryID

Represents the ID associated with a specific dictionary.

```
typedef DCMObjectID DCMDictionaryID;
```

Discussion
When you call the function `DCMRegisterDictionaryFile` (page 1058) to register a dictionary, the Dictionary Manager assigned a unique ID that you need to use in subsequent calls to the Dictionary Manager. The `DCMDictionaryID` value is not persistent across system restarts, so you must not save this value for future use. Each time your application launches or the system starts up you need to obtain the newly-assigned `DCMDictionaryID` value.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Dictionary.h`

DCMDictionaryIterator

Represents a list of dictionaries.

```
typedef DCMObjectIterator DCMDictionaryIterator;
```

Discussion
See `DCMCreateDictionaryIterator` (page 1033).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Dictionary.h`

DCMDictionaryRef

Represents a reference to a dictionary.

```
typedef DCMObjectRef DCMDictionaryRef;
```

Discussion
You can obtain a dictionary reference by calling the function `DCMOpenDictionary` (page 1057). You need this reference to operate on the dictionary.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Dictionary.h`

DCMFieldTag

Represents a field inside a dictionary.

```
typedef DescType DCMFieldTag;
```

Discussion
A field tag is a 4-byte value used to identify a fields. A field must be unique within a dictionary. See "Field Data Tags" (page 1074) for more information.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Dictionary.h`

DCMFieldType

Represents the data type of the data stored in a field.

```
typedef DescType DCMFieldType;
```

Discussion
A field tag is a 4-byte value used to specify the data type contained in a field. The basic definition is the data type defined by Apple Event Manager. "Field Data Types" (page 1074).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Dictionary.h`

DCMFoundRecordIterator

Represents a reference to an opaque list of search results.

```
typedef struct OpaqueDCMFoundRecordIterator * DCMFoundRecordIterator;
```

Discussion
See `DCMFindRecords` (page 1038) for more information.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Dictionary.h`

DCMObjectID

Represents a reference to an opaque dictionary ID.

```
typedef struct OpaqueDCMObjectID * DCMObjectID;
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Dictionary.h`

DCMObjectIterator

Defines a reference to an opaque dictionary object iterator.

```
typedef struct OpaqueDCMObjectIterator * DCMObjectIterator;
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Dictionary.h`

DCMObjectRef

Defines a reference to an opaque dictionary reference.

```
typedef struct OpaqueDCMObjectRef * DCMObjectRef;
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Dictionary.h`

DCMProgressFilterUPP

Defines a universal procedure pointer (UPP) to a progress filter callback.

```
typedef DCMProgressFilterProcPtr DCMProgressFilterUPP;
```

Discussion
For more information see `DCMProgressFilterProcPtr` (page 1063). You pass a progress filter callback UPP to the functions `DCMReorganizeDictionary` (page 1059) and `DCMCompactDictionary` (page 1030).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Dictionary.h`

DCMUniqueID

Represents the unique ID of a record in a dictionary.

```
typedef UInt32 DCMUniqueID;
```

Discussion
This ID is used in many functions. For example, see `DCMGetNextRecord` (page 1050),`DCMGetPrevRecord` (page 1052), and `DCMGetNthRecord` (page 1051).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Dictionary.h`

Constants

Access Method Features

Specify features associated with an access method.

```
enum {
    kDCMCanUseFileDictionaryMask = 0x00000001,
    kDCMCanUseMemoryDictionaryMask = 0x00000002,
    kDCMCanStreamDictionaryMask = 0x00000004,
    kDCMCanHaveMultipleIndexMask = 0x00000008,
    kDCMCanModifyDictionaryMask = 0x00000010,
    kDCMCanCreateDictionaryMask = 0x00000020,
    kDCMCanAddDictionaryFieldMask = 0x00000040,
    kDCMCanUseTransactionMask = 0x00000080
};
typedef OptionBits DCMAccessMethodFeature;
```

Constants

`kDCMCanUseFileDictionaryMask`
Specifies the file dictionary mask.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Dictionary.h`.

`kDCMCanUseMemoryDictionaryMask`
Specifies the memory dictionary mask
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Dictionary.h`.

`kDCMCanStreamDictionaryMask`
Specifies t the stream dictionary mask

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Dictionary.h`.

`kDCMCanHaveMultipleIndexMask`
Specifies the multiple index mask

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Dictionary.h`.

`kDCMCanModifyDictionaryMask`
Specifies the modify dictionary mask

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Dictionary.h`.

`kDCMCanCreateDictionaryMask`
Specifies the create dictionary mask

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Dictionary.h`.

`kDCMCanAddDictionaryFieldMask`
Specifies to use the add dictionary field mask

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Dictionary.h`.

`kDCMCanUseTransactionMask`
Specifies to use the use transaction dictionary mask

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Dictionary.h`.

Discussion
The Dictionary Manager does not operate directly on a dictionary. Instead it accesses dictionaries using the access method specified for the dictionary. The access method mediates between the dictionary and the Dictionary Manager, so that the Dictionary Manager does not need to know anything about the physical format of the dictionary. As a result, the dictionary can have an free-form internal structure. You can also to use an existing dictionary as long as the dictionary has its own access method.

Normally (except when you create a dictionary) you do not need to recognize the existence of the access method.

Dictionary Classes

Specify dictionary classes associated with the property `pDCMClass`.

```
enum {
    kDCMUserDictionaryClass = 0,
    kDCMSpecificDictionaryClass = 1,
    kDCMBasicDictionaryClass = 2
};
```

Constants

`kDCMUserDictionaryClass`
Indicates a user dictionary.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Dictionary.h`.

`kDCMSpecificDictionaryClass`
Indicates a specific dictionary.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Dictionary.h`.

`kDCMBasicDictionaryClass`
Indicates a basic dictionary.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Dictionary.h`.

Dictionary Information Constants

Specify various data in a dictionary.

```
enum {
    kDictionaryFileType = 'dict',
    kDCMDictionaryHeaderSignature = 'dict',
    kDCMDictionaryHeaderVersion = 2
};
```

Constants

`kDictionaryFileType`
Specify the file type.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Dictionary.h`.

`kDCMDictionaryHeaderSignature`
Specify the header in a dictionary.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Dictionary.h`.

`kDCMDictionaryHeaderVersion`
Specify the header version.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Dictionary.h`.

Dictionary Properties

Specify standard dictionary properties.

```
enum {
    pDCMAccessMethod = 'amtd',
    pDCMPermission = 'perm',
    pDCMListing = 'list',
    pDCMMaintenance = 'mtnc',
    pDCMLocale = 'locl',
    pDCMClass = pClass,
    pDCMCopyright = 'info'
};
```

Constants

`pDCMAccessMethod`
Specifies an access method; the associated data type is `typeChar` and is read-only. This property is required.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Dictionary.h`.

`pDCMPermission`
Specifies a permission level; the associated data type is `typeUInt16`. This property is required.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Dictionary.h`.

`pDCMListing`
Specifies whether or not to allow data to be downloaded from the dictionary; the associated data type is `typeUInt16`. This property is optional.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Dictionary.h`.

`pDCMMaintenance`
This property is obsolete.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Dictionary.h`.

`pDCMLocale`
: Specifies a script code for the dictionary contents; the associated data type is `typeUInt32`. The default is `kLocaleIdentifierWildCard`. This property is optional.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Dictionary.h`.

`pDCMClass`
: Specifies a dictionary class; the associated data type is `typeUInt16`. The possible values are `kDCMUserDictionaryClass`, `kDCMSpecificDictionaryClass`), and `kDCMBasicDictionaryClass`. This property is optional.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Dictionary.h`.

`pDCMCopyright`
: Specifies copyright information; the associated data type is `typeChar` and is read-only.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Dictionary.h`.

Discussion
Of the properties listed here, the only property that must always be supported is the `pDCMPermission` property. If a existing property is set by calling the function `DCMSetDictionaryProperty` (page 1061) the property data is overwritten, except if the property is defined as read-only property. However, some read-write properties can be restricted so they can be modified only by an access method.

Functions that obtain data from a dictionary cannot be used on any dictionary whose `pDCMListing` property is set to `kDCMProhibitListing`. In this case, the function trying to obtain the data returns the result `dcmPermissionErr`. This means the dictionary data is protected because it is impossible to output the contents of the dictionary as text.

Field Attributes

Specify attributes for fields in a dictionary.

```
enum {
    kDCMIndexedFieldMask = 0x00000001,
    kDCMRequiredFieldMask = 0x00000002,
    kDCMIdentifyFieldMask = 0x00000004,
    kDCMFixedSizeFieldMask = 0x00000008,
    kDCMHiddenFieldMask = 0x80000000
};
typedef OptionBits DCMFieldAttributes;
```

Constants
`kDCMIndexedFieldMask`
: Specifies a key field that can be used in search.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Dictionary.h`.

`kDCMRequiredFieldMask`
Specifies an essential field in which data must always be provided when adding a record.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Dictionary.h`.

`kDCMIdentifyFieldMask`
Specifies a field that can be used to identify the same record.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Dictionary.h`.

`kDCMFixedSizeFieldMask`
Specifies a fixed-size field.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Dictionary.h`.

`kDCMHiddenFieldMask`
Specfies a hidden field that is not returned by the function that obtains the field list.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Dictionary.h`.

Discussion
The records contained in a dictionary have a variety of fields. For example, a record in a dictionary for kana-kanji conversion, typically has a "read" key field which stores hiragana character strings that are found, as well as a "part of speech" and a "notation" fields that refers to the search results. These respective fields also require attributes such as data type, maximum length of stored data, and fixed length/variable length.

When you create a new dictionary using the Dictionary Manager, you can specify the fields to include in the dictionary and the attributes associated with each of those field.

Field Data Tags

Specify field tags in an Apple Japanese dictionary.

```
enum {
    kDCMJapaneseYomiTag = 'yomi',
    kDCMJapaneseHyokiTag = 'hyok',
    kDCMJapaneseHinshiTag = 'hins',
    kDCMJapaneseWeightTag = 'hind',
    kDCMJapanesePhoneticTag = 'hton',
    kDCMJapaneseAccentTag = 'acnt',
    kDCMJapaneseOnKunReadingTag = 'OnKn',
    kDCMJapaneseFukugouInfoTag = 'fuku'
};
```

Field Data Types

Specify the data types for the values associated with field tags.

```
enum {
    kDCMJapaneseYomiType = typeUnicodeText,
    kDCMJapaneseHyokiType = typeUnicodeText,
    kDCMJapaneseHinshiType = 'hins',
    kDCMJapaneseWeightType = typeShortInteger,
    kDCMJapanesePhoneticType = typeUnicodeText,
    kDCMJapaneseAccentType = 'byte',
    kDCMJapaneseOnKunReadingType = typeUnicodeText,
    kDCMJapaneseFukugouInfoType = 'fuku'
};
```

Constants

`kDCMJapaneseYomiType`
Specifies the data type is Unicode text.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Dictionary.h`.

`kDCMJapaneseHyokiType`
Specifies the data type is Unicode text.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Dictionary.h`.

`kDCMJapaneseHinshiType`
Specifies the data type is `'hins'`.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Dictionary.h`.

`kDCMJapaneseWeightType`
Specifies the data type is short integer.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Dictionary.h`.

`kDCMJapanesePhoneticType`
Specifies the data type is Unicode text.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Dictionary.h`.

`kDCMJapaneseAccentType`
Specifies the data type is `byte`.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Dictionary.h`.

`kDCMJapaneseOnKunReadingType`
Specifies the data type is Unicode text.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Dictionary.h`.

`kDCMJapaneseFukugouInfoType`
Specifies the data type is `'fuku'`.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Dictionary.h`.

Field Info Record Entries

Specifies tags for the entries in a field information record.

```
enum {
    keyDCMFieldTag = 'ftag',
    keyDCMFieldType = 'ftyp',
    keyDCMMaxRecordSize = 'mrsz',
    keyDCMFieldAttributes = 'fatr',
    keyDCMFieldDefaultData = 'fdef',
    keyDCMFieldName = 'fnam',
    keyDCMFieldFindMethods = 'ffnd'
};
```

Constants

`keyDCMFieldTag`
The data type of the associated data is `typeEnumeration`.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Dictionary.h`.

`keyDCMFieldType`
The data type of the associated data is `typeEnumeration`.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Dictionary.h`.

`keyDCMMaxRecordSize`
The data type of the associated data is `typeMagnitude`.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Dictionary.h`.

`keyDCMFieldAttributes`
Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Dictionary.h`.

`keyDCMFieldDefaultData`
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Dictionary.h`.

`keyDCMFieldName`
The data type of the associated data is `typeChar`.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Dictionary.h`.

`keyDCMFieldFindMethods`
The data associated with this field is a list (`typeAEList`) of `typeDCMFindMethod` values.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Dictionary.h`.

Field Info Record Types

Specify special types for a field information record.

```
enum {
    typeDCMFieldAttributes = 'fatr',
    typeDCMFindMethod = 'fmth'
};
```

Constants

`typeDCMFieldAttributes`
Specifies a data type for field attributes.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Dictionary.h`.

`typeDCMFindMethod`
Specifies a data type for search methods.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Dictionary.h`.

Listing Permissions

Specifies whether to allow or prohibit a dictionary from being listed.

```
enum {
    kDCMAllowListing = 0,
    kDCMProhibitListing = 1
};
```

Constants

`kDCMAllowListing`

Specifies to allow listing.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Dictionary.h`.

`kDCMProhibitListing`

Specifies to prohibit listing.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Dictionary.h`.

Discussion

A dictionary that is prohibited from being listed is available only to the application that created the dictionary.

Permission Levels

Specify permission levels for a dictionary.

```
enum {
    kDCMReadOnlyDictionary = 0,
    kDCMReadWriteDictionary = 1
};
```

Constants

`kDCMReadOnlyDictionary`

Specifies the dictionary is read-only.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Dictionary.h`.

`kDCMReadWriteDictionary`

Specifies the dictionary has read-write permission.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Dictionary.h`.

Search Methods

Specify search criteria.

```
enum {
    kDCMFindMethodExactMatch = kAEEquals,
    kDCMFindMethodBeginningMatch = kAEBeginsWith,
    kDCMFindMethodContainsMatch = kAEContains,
    kDCMFindMethodEndingMatch = kAEEndsWith,
    kDCMFindMethodForwardTrie = 'ftri',
    kDCMFindMethodBackwardTrie = 'btri'
};
typedef OSType DCMFindMethod;
```

Constants

`kDCMFindMethodExactMatch`
Specifies an exact match.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Dictionary.h`.

`kDCMFindMethodBeginningMatch`
Specifies the beginning must match. For example, cat matches catch and catalog.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Dictionary.h`.

`kDCMFindMethodContainsMatch`
Specifies the match can be contained in a string. (rat matches crater, decorate)
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Dictionary.h`.

`kDCMFindMethodEndingMatch`
Specifies the end must match. For example, bat matches combat and acrobat.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Dictionary.h`.

`kDCMFindMethodForwardTrie`
Specifies partial character string from the front. For example, theme matches the, them, and theme. Used for morphological analysis.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Dictionary.h`.

`kDCMFindMethodBackwardTrie`
Specfies partial character string from the back. For example, flash matches ash, lash, and flash. Used for morphological analysis.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Dictionary.h`.

Wild Card Values

Represent any field tag or field type.

```
enum {
    kDCMAnyFieldTag = typeWildCard,
    kDCMAnyFieldType = typeWildCard
};
```

Constants

`kDCMAnyFieldTag`

Specifies any field.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Dictionary.h`.

`kDCMAnyFieldType`

Specifies any type.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Dictionary.h`.

Result Codes

The most common result codes returned by Dictionary Manager are listed below.

Result Code	Value	Description
`dcmParamErr`	-7100	Bad parameter. Available in Mac OS X v10.0 and later.
`dcmNotDictionaryErr`	-7101	Not a dictionary. Available in Mac OS X v10.0 and later.
`dcmBadDictionaryErr`	-7102	Invalid dictionary. Available in Mac OS X v10.0 and later.
`dcmPermissionErr`	-7103	Invalid permission. Available in Mac OS X v10.0 and later.
`dcmDictionaryNotOpenErr`	-7104	Dictionary not opened. Available in Mac OS X v10.0 and later.
`dcmDictionaryBusyErr`	-7105	Dictionary is busy. Available in Mac OS X v10.0 and later.
`dcmBlockFullErr`	-7107	Dictionary block is full. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
dcmNoRecordErr	-7108	No such record. Available in Mac OS X v10.0 and later.
dcmDupRecordErr	-7109	Same record already exists. Available in Mac OS X v10.0 and later.
dcmNecessaryFieldErr	-7110	Missing the required field. Available in Mac OS X v10.0 and later.
dcmBadFieldInfoErr	-7111	Incomplete field. Available in Mac OS X v10.0 and later.
dcmBadFieldTypeErr	-7112	No such field type supported. Available in Mac OS X v10.0 and later.
dcmNoFieldErr	-7113	No such field exists. Available in Mac OS X v10.0 and later.
dcmBadKeyErr	-7115	Bad key information. Available in Mac OS X v10.0 and later.
dcmTooManyKeyErr	-7116	Too many key fields. Available in Mac OS X v10.0 and later.
dcmBadDataSizeErr	-7117	Data size too large. Available in Mac OS X v10.0 and later.
dcmBadFindMethodErr	-7118	Search method not supported. Available in Mac OS X v10.0 and later.
dcmBadPropertyErr	-7119	No such property exists. Available in Mac OS X v10.0 and later.
dcmProtectedErr	-7121	Need a keyword to use the dictionary. Available in Mac OS X v10.0 and later.
dcmNoAccessMethodErr	-7122	No such access method exists. Available in Mac OS X v10.0 and later.
dcmBadFeatureErr	-7124	Invalid access method feature. Available in Mac OS X v10.0 and later.
dcmIterationCompleteErr	-7126	Iteration complete; no more items in the iterator. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
dcmBufferOverflowErr	-7127	Data is larger than the buffer size. Available in Mac OS X v10.0 and later.

Display Manager Reference (Not Recommended)

Framework: Carbon/Carbon.h

Declared in Displays.h

Overview

Important: The Display Manager is deprecated in Mac OS X version 10.4 and later. The replacement is Quartz Display Services, a modern Mac OS X API that provides similar functionality. For more information, see *Quartz Display Services Reference*.

In Mac OS 9 and earlier, the Display Manager allowed users to dynamically change the arrangement and display modes of the monitors attached to their computers. The Display Manager was included in Carbon to facilitate the porting of legacy applications to Mac OS X. You should not use Display Manager functions in new application development. Instead, you should use Quartz Display Services.

Functions by Task

Adding and Removing Video Devices From the Device List

`DMAddDisplay` (page 1090) Deprecated in Mac OS X v10.4

Adds the `GDevice` structure for a video device to the device list. (Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

`DMDisposeDisplay` (page 1096) Deprecated in Mac OS X v10.4

Disposes of the `GDevice` structure for a video device. (Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

`DMDisposeList` (page 1097) Deprecated in Mac OS X v10.4

Disposes of a display mode list built by `DMNewDisplayModeList`. (Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

`DMGetIndexedDisplayModeFromList` (page 1107) Deprecated in Mac OS X v10.4

Obtains a display mode from the display mode list built by `DMNewDisplayModeList`. (Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

`DMNewDisplay` (page 1115) Deprecated in Mac OS X v10.4

Adds a video device to the device list and makes the device active. (Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

`DMNewDisplayModeList` (page 1117) Deprecated in Mac OS X v10.4
Builds a new display mode list for a specified video device. (Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

`DMRemoveDisplay` (page 1119) Deprecated in Mac OS X v10.4
Removes a video device from the device list. (Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

Changing Display Modes and Display Configurations

`DMBeginConfigureDisplays` (page 1091) Deprecated in Mac OS X v10.4
Allows your application to configure displays. You should generally never need to use this function. (Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

`DMBlockMirroring` (page 1092) Deprecated in Mac OS X v10.4
Disables video mirroring. You should generally never need to use this function. (Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

`DMDisableDisplay` (page 1095) Deprecated in Mac OS X v10.4
Makes a video device inactive by removing its display area from the desktop. You should generally never need to use this function. (Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

`DMEnableDisplay` (page 1099) Deprecated in Mac OS X v10.4
Reactivates a display made inactive with the function `DMDisableDisplay`. You should generally never need to use this function. (Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

`DMEndConfigureDisplays` (page 1099) Deprecated in Mac OS X v10.4
Ends configuration begun by `DMBeginConfigureDisplays`. You should generally never need to use this function. (Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

`DMMirrorDevices` (page 1111) Deprecated in Mac OS X v10.4
Turns on video mirroring. (Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

`DMMoveDisplay` (page 1112) Deprecated in Mac OS X v10.4
Moves the boundary rectangle for a video device. You should generally never need to use this function. (Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

`DMSetDisplayMode` (page 1125) Deprecated in Mac OS X v10.4
Sets the display mode and pixel depth for a video device. (Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

`DMSetMainDisplay` (page 1126) Deprecated in Mac OS X v10.4
Sets a display to be the main screen. You should generally never need to use this function. (Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

`DMUnblockMirroring` (page 1127) Deprecated in Mac OS X v10.4
Reenables video mirroring disabled by the function `DMUnblockMirroring`. You should generally never need to use this function. (Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

`DMUnmirrorDevice` (page 1127) Deprecated in Mac OS X v10.4
Turns off video mirroring. (Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

Determining Display Modes and Display Configurations

`DMCanMirrorNow` (page 1093) Deprecated in Mac OS X v10.4
Determines whether video mirroring can be activated on the user's computer system. (Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

`DMCheckDisplayMode` (page 1094) Deprecated in Mac OS X v10.4
Determines if a video device supports a particular display mode and pixel depth. (Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

`DMGetAVPowerState` (page 1100) Deprecated in Mac OS X v10.4
Obtains the current power state of a display. (Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

`DMGetDisplayMode` (page 1103) Deprecated in Mac OS X v10.4
Obtains the current display mode of a specified video display. (Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

`DMGetGraphicInfoByAVID` (page 1106) Deprecated in Mac OS X v10.4
Obtains information about the graphic display of a display device. (Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

`DMGetNameByAVID` (page 1108) Deprecated in Mac OS X v10.4
Obtains the name of a display device. (Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

`DMIsMirroringOn` (page 1110) Deprecated in Mac OS X v10.4
Determines if video mirroring is active. (Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

`DMQDIsMirroringCapable` (page 1117) Deprecated in Mac OS X v10.4
Determines if QuickDraw supports video mirroring on the user's system. (Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

`DMSaveScreenPrefs` (page 1122) Deprecated in Mac OS X v10.4
Saves the user's screen configuration preferences. (Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

`DMSetAVPowerState` (page 1123) Deprecated in Mac OS X v10.4
Sets the power state of a display device. (Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

Getting Video Devices

`DMGetDisplayIDByGDevice` (page 1102) Deprecated in Mac OS X v10.4
Obtains the display ID number for a video device. (Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

`DMGetFirstScreenDevice` (page 1104) Deprecated in Mac OS X v10.4
Returns a handle for the first video device in the device list. (Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

`DMGetGDeviceByDisplayID` (page 1105) Deprecated in Mac OS X v10.4
Obtains a handle for the video device with a specified display ID. (Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

`DMGetNextMirroredDevice` (page 1108) Deprecated in Mac OS X v10.4
Obtains a handle for a video device that mirrors another specified video device. (Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

`DMGetNextScreenDevice` (page 1109) Deprecated in Mac OS X v10.4
Returns a handle for the next video device in the device list. (Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

Registering and Unregistering Your Program

`DMRegisterExtendedNotifyProc` (page 1118) Deprecated in Mac OS X v10.4
Registers a function that responds to a Display Notice event outside of an event loop. (Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

`DMRemoveExtendedNotifyProc` (page 1120) Deprecated in Mac OS X v10.4
Removes your Display Notice event-handling function registered by the `DMRegisterExtendedNotifyProc` function. (Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

`DMSendDependentNotification` (page 1122) Deprecated in Mac OS X v10.4
Notifies dependent displays of changes in depth mode or configuration. (Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

Working With Universal Procedure Pointers for Display Manager Callbacks

`DisposeDMComponentListIteratorUPP` (page 1088) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

`DisposeDMDisplayListIteratorUPP` (page 1088) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

`DisposeDMDisplayModeListIteratorUPP` (page 1089) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

`DisposeDMExtendedNotificationUPP` (page 1089) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

`DisposeDMNotificationUPP` (page 1089) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

`DisposeDMProfileListIteratorUPP` (page 1090) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

`InvokeDMComponentListIteratorUPP` (page 1128) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

`InvokeDMDisplayListIteratorUPP` (page 1129) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

`InvokeDMDisplayModeListIteratorUPP` (page 1129) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

`InvokeDMExtendedNotificationUPP` (page 1129) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

`InvokeDMNotificationUPP` (page 1130) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

InvokeDMProfileListIteratorUPP (page 1130) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

NewDMComponentListIteratorUPP (page 1130) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

NewDMDisplayListIteratorUPP (page 1131) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

NewDMDisplayModeListIteratorUPP (page 1131) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

NewDMExtendedNotificationUPP (page 1131) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

NewDMNotificationUPP (page 1131) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

NewDMProfileListIteratorUPP (page 1132) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

Miscellaneous

DMConfirmConfiguration (page 1095) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

DMDisposeAVComponent (page 1096) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

DMDrawDesktopRect (page 1098) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

DMDrawDesktopRegion (page 1098) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

DMSetDisplayComponent (page 1124) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

DMSetEnableByAVID (page 1126) Deprecated in Mac OS X v10.4
(Deprecated. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

Functions

DisposeDMComponentListIteratorUPP

(Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
void DisposeDMComponentListIteratorUPP (
   DMComponentListIteratorUPP userUPP
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
Displays.h

DisposeDMDisplayListIteratorUPP

(Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
void DisposeDMDisplayListIteratorUPP (
   DMDisplayListIteratorUPP userUPP
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`Displays.h`

DisposeDMDisplayModeListIteratorUPP

(Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
void DisposeDMDisplayModeListIteratorUPP (
   DMDisplayModeListIteratorUPP userUPP
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`Displays.h`

DisposeDMExtendedNotificationUPP

(Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
void DisposeDMExtendedNotificationUPP (
   DMExtendedNotificationUPP userUPP
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`Displays.h`

DisposeDMNotificationUPP

(Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
void DisposeDMNotificationUPP (
   DMNotificationUPP userUPP
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
Displays.h

DisposeDMProfileListIteratorUPP

(Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
void DisposeDMProfileListIteratorUPP (
   DMProfileListIteratorUPP userUPP
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
Displays.h

DMAddDisplay

Adds the GDevice structure for a video device to the device list. (Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMAddDisplay (
   GDHandle newDevice,
   short driver,
   UInt32 mode,
   UInt32 reserved,
   UInt32 displayID,
   Component displayComponent,
   Handle displayState
);
```

Parameters

newDevice
A handle to the GDevice structure for the video device you want to add to the device list. The function DMNewDisplay (page 1115) usually initializes this structure.

driver
The reference number of the graphics device which you are adding to the device list. For most video devices, this information is set at system startup. The function DMAddDisplay passes the number supplied in this parameter to the InitGDevice function in its gdRefNum parameter.

mode
The depth mode. Used by the video device driver, this value sets the pixel depth and specifies color. The function DMAddDisplay passes the value supplied here to the function InitGDevice in its mode parameter.

reserved
Reserved for future expansion. Pass NULL in this parameter.

displayID
A unique identification for the display. For new displays, supply this parameter with the value 0, which causes the Display Manager to generate a unique display ID for this device. If this display was removed, then pass the display ID number of the current display in this parameter.

displayComponent
Reserved for future expansion. Pass NULL in this parameter.

displayState
If your application called DMNewDisplay (page 1115), you must pass the displayState handle obtained. Otherwise pass NULL in this parameter.

Return Value
A result code. See "Display Manager Result Codes" (page 1164).

Discussion
The DMAddDisplay function adds the display specified by the newDevice parameter as inactive. However, if the specified display is the only display, the Display Manager automatically makes it active. Otherwise, you must call the function DMEnableDisplay (page 1099) to make the specified display active.

The function DMNewDisplay (page 1115) automatically calls DMAddDisplay and DMEnableDisplay. The only time you ned to call DMAddDisplay directly is after the device has been removed by DMRemoveDisplay (page 1119) but not yet disposed of by DMDisposeDisplay (page 1096).

Special Considerations

Because this function may move or purge memory blocks or access handles, you cannot call it at interrupt time.

Generally, your application should not use this function, but should instead allow system software to maintain the device list. This function is described here for completeness only.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
Displays.h

DMBeginConfigureDisplays

Allows your application to configure displays. You should generally never need to use this function. (Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMBeginConfigureDisplays (
   Handle *displayState
);
```

Parameters

displayState
On return, a pointer to a handle to internal Display Manager information about the current display state. The DMEndConfigureDisplays (page 1099) function and many other functions require this parameter.

Return Value
A result code. See "Display Manager Result Codes" (page 1164).

Discussion
The `DMBeginConfigureDisplays` function tells the Display Manager to postpone Display Manager configuration checking, the rebuilding of desktop regions, and Apple event notification of Display Manager changes until your application uses the `DMEndConfigureDisplays` function.

You should call the function `DMBeginConfigureDisplays` before calling other Display Manager functions that configure the user's display. When calling functions that configure displays, you should pass the handle obtained by the `DMBeginConfigureDisplays` function. `DMBeginConfigureDisplays` causes system software to wait for your application to complete display changes before managing additional Display Manager events. When your application completes configuring the display environment, call the function `DMEndConfigureDisplays`.

Special Considerations

Because this function may move or purge memory blocks or access handles, you cannot call it at interrupt time.

Applications generally never need to use this function. In case you find a compelling need to change the user's display configuration, this function is described here for completeness. Note that if your application uses Display Manager functions to change the display configuration of the user's video devices, your application should make these changes only with the consent of the user. If your application must have a specific pixel depth, for example, it should display a dialog box that offers the user a choice between changing to that depth or canceling display of the image.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Displays.h`

DMBlockMirroring

Disables video mirroring. You should generally never need to use this function. (Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMBlockMirroring (
   void
);
```

Parameters

Return Value
A result code. See "Display Manager Result Codes" (page 1164).

Discussion
The function `DMBlockMirroring` disables video mirroring until the user restarts the computer or until an application calls the function `DMUnblockMirroring` (page 1127).

Special Considerations

Because this function may move or purge memory blocks or access handles, you cannot call it at interrupt time.

Applications generally never need to use this function. In case you find a compelling need to change the user's display configuration, this function is described here for completeness. Note that if your application uses Display Manager functions to change the display configuration of the user's video devices, your application should make these changes only with the consent of the user. If your application must have a specific pixel depth, for example, it should display a dialog box that offers the user a choice between changing to that depth or canceling display of the image.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Displays.h`

DMCanMirrorNow

Determines whether video mirroring can be activated on the user's computer system. (Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMCanMirrorNow (
   Boolean *canMirrorNow
);
```

Parameters

canMirrorNow
A pointer to a Boolean value; true indicates that mirroring can be activated; false indicates it cannot.

Return Value
A result code. See "Display Manager Result Codes" (page 1164).

Discussion
In the value pointed to by the `canMirrorNow` parameter, the `DMCanMirrorNow` function reports whether video mirroring can be activated. When the `canMirrorNow` parameter points to a value of true, then the computer uses a version of QuickDraw that supports video mirroring, has exactly two displays attached, and does not have mirror blocking in effect.

You can use the `DMQDIsMirroringCapable` (page 1117) function to determine whether the computer uses a version of QuickDraw that supports video mirroring. You can use the `DMBlockMirroring` (page 1092) function and the `DMUnblockMirroring` (page 1127) function to block and unblock video mirroring. To determine whether the user's computer system currently uses video mirroring, use the `DMIsMirroringOn` (page 1110) function.

Special Considerations

The `DMCanMirrorNow` function may move or purge memory blocks in the application heap. Your application should not call this function at interrupt time.

Version Notes
As of System Software version 7.5, only PowerBook computers support video mirroring.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Displays.h`

DMCheckDisplayMode

Determines if a video device supports a particular display mode and pixel depth. (Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMCheckDisplayMode (
   GDHandle theDevice,
   UInt32 mode,
   UInt32 depthMode,
   UInt32 *switchFlags,
   UInt32 reserved,
   Boolean *modeOk
);
```

Parameters

theDevice
A handle to the `GDevice` structure for the video device whose display mode and pixel depth you wish to check.

mode
The display mode you wish to check. You get a list of display modes by calling `DMGetDisplayMode` (page 1103).

depthMode
The pixel depth you wish to check. See "Video Depth Mode Values" for list of possible values.

switchFlags
On return, a pointer to a long integer that indicates if a video device will support the mode specified by the `mode` parameter and the pixel depth specified by the `depthMode` parameter. See "Switch Flags" (page 1163) for a description.

reserved
Reserved for future expansion. Pass `NULL` in this parameter.

modeOk
On return, a pointer to a `Boolean`. If `modeOk` points to a value of `true`, the user or your application can switch the display mode for the video device to the one specified by `mode`.

Return Value
A result code. See "Display Manager Result Codes" (page 1164).

Discussion
Usually, your application only needs to know if a video device supports a specific pixel depth. Thus your application can use the Color QuickDraw function `HasDepth`. The function `DMCheckDisplayMode` is essentially obsolete, and is here for completeness.

Special Considerations

Because this function may move or purge memory blocks or access handles, you cannot call it at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Displays.h`

DMConfirmConfiguration

(Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMConfirmConfiguration (
   DMModalFilterUPP filterProc,
   UInt32 confirmFlags,
   UInt32 reserved,
   Handle displayState
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Displays.h`

DMDisableDisplay

Makes a video device inactive by removing its display area from the desktop. You should generally never need to use this function. (Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMDisableDisplay (
   GDHandle disableDevice,
   Handle displayState
);
```

Parameters

`disableDevice`
A handle to the `GDevice` structure for the video device whose display you wish to disable.

`displayState`
If your application called `DMBeginConfigureDisplays` (page 1091), you must pass the `displayState` handle obtained. Otherwise pass `NULL` in this parameter.

Return Value
A result code. See "Display Manager Result Codes" (page 1164).

Discussion
You are not allowed to disable the last remaining display. Doing so will simply re-enable it. If you want to remove the last remaining display, thereby enabling the `GDevice` structure not associated with any video device, call the function `DMRemoveDisplay` (page 1119).

If you specify the device for the main screen in the `disableDevice` parameter, then `DMDisableDisplay` picks another device and makes it the new main screen.

If `DMDisableDisplay` results in setting a new main screen, the handle you pass in the `disableDevice` parameter does not point to the same `GDevice` structure after `DMDisableDisplay` completes; instead, it points to the `GDevice` structure for the new main screen. If you need to recover the `GDevice` structure for the device you disabled, determine its display ID by using the function `DMGetDisplayIDByGDevice` (page 1102) before calling `DMDisableDisplay`. Then use the function `DMGetGDeviceByDisplayID` (page 1105) to obtain its structure.

Special Considerations

Because this function may move or purge memory blocks or access handles, you cannot call it at interrupt time.

Applications generally never need to use this function. In case you find a compelling need to change the user's display configuration, this function is described here for completeness. Note that if your application uses Display Manager functions to change the display configuration of the user's video devices, your application should make these changes only with the consent of the user. If your application must have a specific pixel depth, for example, it should display a dialog box that offers the user a choice between changing to that depth or canceling display of the image.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Displays.h`

DMDisposeAVComponent

(Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMDisposeAVComponent (
   Component theAVComponent
);
```

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Displays.h`

DMDisposeDisplay

Disposes of the `GDevice` structure for a video device. (Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMDisposeDisplay (
   GDHandle disposeDevice,
   Handle displayState
);
```

Parameters

disposeDevice

A handle to the `GDevice` structure for a video device you want to delete.

displayState

If your application called `DMBeginConfigureDisplays` (page 1091), you must pass the `displayState` handle obtained. Otherwise pass `NULL` in this parameter.

Return Value

A result code. See "Display Manager Result Codes" (page 1164).

Discussion

The `DMDisposeDisplay` function disposes of a `GDevice` structure, releases the space allocated for it, and disposes of all the data structures allocated for it. The Display Manager calls this function when appropriate.

Special Considerations

Because this function may move or purge memory blocks or access handles, you cannot call it at interrupt time.

Generally, your application should not use this function, but should instead allow system software to maintain the device list. This function is described here for completeness only.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Displays.h`

DMDisposeList

Disposes of a display mode list built by `DMNewDisplayModeList`. (Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMDisposeList (
   DMListType panelList
);
```

Parameters

panelList

A value that specifies the display mode list you want to delete.

Return Value

A result code. See "Display Manager Result Codes" (page 1164).

Discussion

You should call the `DMDisposeList` function after you have iterated the mode list.

Special Considerations

Because this function may move or purge memory blocks or access handles, you cannot call it at interrupt time.

Generally, your application should not use this function, but should instead allow system software to maintain the device list. This function is described here for completeness only.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Displays.h`

DMDrawDesktopRect

(Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
void DMDrawDesktopRect (
   Rect *globalRect
);
```

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Displays.h`

DMDrawDesktopRegion

(Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
void DMDrawDesktopRegion (
   RgnHandle globalRgn
);
```

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Displays.h`

DMEnableDisplay

Reactivates a display made inactive with the function `DMDisableDisplay`. You should generally never need to use this function. (Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMEnableDisplay (
   GDHandle enableDevice,
   Handle displayState
);
```

Parameters

enableDevice

A handle to the `GDevice` structure for the video device whose display you wish to make active.

displayState

If your application called `DMBeginConfigureDisplays` (page 1091), you must pass the `displayState` handle obtained. Otherwise pass `NULL` in this parameter.

Return Value

A result code. See "Display Manager Result Codes" (page 1164).

Discussion

The function `DMEnableDisplay` reactivates the specified video device by adding its display area to the desktop.

If you add a display with the function `DMAddDisplay` (page 1090) and there are no active displays, the Display Manager will enable the added display.

Special Considerations

Because this function may move or purge memory blocks or access handles, you cannot call it at interrupt time.

Applications generally never need to use this function. In case you find a compelling need to change the user's display configuration, this function is described here for completeness. Note that if your application uses Display Manager functions to change the display configuration of the user's video devices, your application should make these changes only with the consent of the user. If your application must have a specific pixel depth, for example, it should display a dialog box that offers the user a choice between changing to that depth or canceling display of the image.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Displays.h`

DMEndConfigureDisplays

Ends configuration begun by `DMBeginConfigureDisplays`. You should generally never need to use this function. (Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMEndConfigureDisplays (
   Handle displayState
);
```

Parameters

displayState

Supply this parameter with the handle obtained by the `DMBeginConfigureDisplays` (page 1091) function.

Return Value

A result code. See "Display Manager Result Codes" (page 1164).

Discussion

The function `DMEndConfigureDisplays` resumes Display Manager configuration checking, the rebuilding of desktop regions, and Apple event notification of Display Manager changes, all of which are postponed when you use the function `DMBeginConfigureDisplays` (page 1091). Your application will then receive a single Display Notice event notifying your application of Display Manager changes, and your application can manage its windows accordingly.

Special Considerations

Because this function may move or purge memory blocks or access handles, you cannot call it at interrupt time.

Applications generally never need to use this function. In case you find a compelling need to change the user's display configuration, this function is described here for completeness. Note that if your application uses Display Manager functions to change the display configuration of the user's video devices, your application should make these changes only with the consent of the user. If your application must have a specific pixel depth, for example, it should display a dialog box that offers the user a choice between changing to that depth or canceling display of the image.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Displays.h`

DMGetAVPowerState

Obtains the current power state of a display. (Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMGetAVPowerState (
   AVIDType theID,
   AVPowerStatePtr getPowerState,
   UInt32 reserved1
);
```

Parameters

theID

The ID number of the display device whose power state you want to obtain.

getPowerState
A pointer to a structure of type `AVPowerStateRec` (page 1137). On return, this parameter points to a value specifying the current power state of display device.

reserved1
Reserved for future expansion. Pass NULL in this parameter.

Return Value
A result code. See "Display Manager Result Codes" (page 1164).

Special Considerations

Because this function may move or purge memory blocks or access handles, you cannot call it at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Displays.h`

DMGetDeskRegion

(Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMGetDeskRegion (
   RgnHandle *desktopRegion
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Displays.h`

DMGetDeviceAVIDByPortAVID

(Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMGetDeviceAVIDByPortAVID (
   AVIDType portAVID,
   AVIDType *deviceAVID
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Displays.h`

DMGetDeviceComponentByAVID

(Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMGetDeviceComponentByAVID (
   AVIDType theDeviceID,
   Component *theDeviceComponent,
   ComponentDescription *theDesciption,
   ResType *theDeviceKind
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Displays.h`

DMGetDisplayComponent

(Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMGetDisplayComponent (
   GDHandle theDevice,
   Component *displayComponent
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Displays.h`

DMGetDisplayIDByGDevice

Obtains the display ID number for a video device. (Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMGetDisplayIDByGDevice (
   GDHandle displayDevice,
   DisplayIDType *displayID,
   Boolean failToMain
);
```

Parameters

displayDevice

A handle to the `GDevice` structure for the video device whose display ID you wish to obtain.

displayID

On return, a pointer to the display ID for the video device specified by the `displayDevice` parameter.

failToMain

If `true` and the specified video device does not have a display ID, on return the function sets the `displayID` parameter to a pointer to the display ID of the video device for the main screen. If `false` and the specified video device does not have a display ID, the function returns the `kDMDisplayNotFoundErr` result code.

Return Value

A result code. See "Display Manager Result Codes" (page 1164).

Special Considerations

Because this function may move or purge memory blocks or access handles, you cannot call it at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Displays.h`

DMGetDisplayMode

Obtains the current display mode of a specified video display. (Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMGetDisplayMode (
   GDHandle theDevice,
   VDSwitchInfoPtr switchInfo
);
```

Parameters

theDevice

A handle to the `GDevice` structure for the video device whose display mode you wish to obtain.

switchInfo

On return, a pointer to an internal Display Manager structure containing display mode information.

Return Value

A result code. See "Display Manager Result Codes" (page 1164).

Special Considerations

Because this function may move or purge memory blocks or access handles, you cannot call it at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Displays.h`

DMGetEnableByAVID

(Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMGetEnableByAVID (
   AVIDType theAVID,
   Boolean *isAVIDEnabledNow,
   Boolean *canChangeEnableNow
);
```

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Displays.h`

DMGetFirstScreenDevice

Returns a handle for the first video device in the device list. (Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
GDHandle DMGetFirstScreenDevice (
   Boolean activeOnly
);
```

Parameters

`activeOnly`

If `true`, the `DMGetFirstScreenDevice` function returns a handle to the first of all active video devices. If `false`, the function returns a handle to the first of all video devices, active or not. You may use the Active Device Constants in this parameter. See "Active Device Only Values" (page 1148).

Return Value

If `activeOnly` is `true`, a handle to the `GDevice` structure for the first active video device. If `activeOnly` is `false`, a handle to the `GDevice` structure for the first video device. See the QuickDraw Manager documentation for a description of the `GDHandle` data type.

Discussion

The `DMGetFirstScreenDevice` function is useful if you want to find out more about the current mode.

You can use the function `DMGetNextScreenDevice` (page 1109) to loop through all of the video devices in the device list.

The `DMGetFirstScreenDevice` function is similar to the QuickDraw function `GetDeviceList`, except that when returning `GDevice` structures, `GetDeviceList` does not distinguish between inactive and active video devices or between the `GDevice` structures for video devices and the `GDevice` structures associated with no video devices.

Special Considerations

Because this function may move or purge memory blocks or access handles, you cannot call it at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Displays.h`

DMGetGDeviceByDisplayID

Obtains a handle for the video device with a specified display ID. (Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMGetGDeviceByDisplayID (
   DisplayIDType displayID,
   GDHandle *displayDevice,
   Boolean failToMain
);
```

Parameters

displayID
The display ID for the video device whose handle you wish to obtain.

displayDevice
On return, a pointer to the handle to the `GDevice` structure for the video device specified by the `displayID` parameter.

failToMain
If `true` and there is no video device associated with the `displayID` parameter, on return the function sets `displayDevice` to a pointer to the handle for the video device for the main screen. If `false` and there is no video device associated with the `displayID` parameter, the function returns the `kDMDisplayNotFoundErr` result code.

Return Value
A result code. See "Display Manager Result Codes" (page 1164).

Special Considerations

Because this function may move or purge memory blocks or access handles, you cannot call it at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`Displays.h`

DMGetGraphicInfoByAVID

Obtains information about the graphic display of a display device. (Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMGetGraphicInfoByAVID (
   AVIDType theID,
   PicHandle *theAVPcit,
   Handle *theAVIconSuite,
   AVLocationRec *theAVLocation
);
```

Parameters

theID
The ID number of the display device whose information you want to obtain.

theAVPcit
On return, a pointer to the handle for the picture structure you want to get.

theAVIconSuite
On return, a pointer to a handle whose structure reports the icon suite for a display device.

theAVLocation
On return, a pointer to the location structure for the device you want information about.

Return Value
A result code. See "Display Manager Result Codes" (page 1164).

Special Considerations

Because this function may move or purge memory blocks or access handles, you cannot call it at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Displays.h`

DMGetIndexedComponentFromList

(Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMGetIndexedComponentFromList (
   DMListType panelList,
   DMListIndexType itemIndex,
   UInt32 reserved,
   DMComponentListIteratorUPP listIterator,
   void *userData
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Displays.h`

DMGetIndexedDisplayModeFromList

Obtains a display mode from the display mode list built by `DMNewDisplayModeList`. (Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMGetIndexedDisplayModeFromList (
   DMListType panelList,
   DMListIndexType itemIndex,
   UInt32 reserved,
   DMDisplayModeListIteratorUPP listIterator,
   void *userData
);
```

Parameters

panelList
A value that specifies the list from which to obtain information about the display modes created by the function `DMNewDisplayModeList` (page 1117).

itemIndex
A value that specifies the index of the display mode you wish to obtain.

reserved
Reserved for future expansion. Pass `NULL` in this parameter.

listIterator
A universal procedure pointer. The iterator this pointer specifies supplies the function to be called with the information about the display mode specified by `theListCount`.

userData
A pointer you pass for `listIterator` usually used to obtain information about the display mode from the UPP and return it to the caller of `DMGetIndexedDisplayModeFromList`.

Return Value
A result code. See "Display Manager Result Codes" (page 1164).

Special Considerations

Because this function may move or purge memory blocks or access handles, you cannot call it at interrupt time.

Generally, your application should not use this function, but should instead allow system software to maintain the device list. This function is described here for completeness only.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Displays.h`

DMGetNameByAVID

Obtains the name of a display device. (Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMGetNameByAVID (
   AVIDType theID,
   UInt32 nameFlags,
   Str255 name
);
```

Parameters

theID
The ID number of the display device whose name you want to obtain.

nameFlags
Reserved for future expansion. Pass `NULL` in this parameter.

name
On return, a string containing the name of the display device specified by the parameter `theID`.

Return Value
A result code. See "Display Manager Result Codes" (page 1164).

Discussion
An AVID is really a display ID as an AVID references a video display just like a display ID. Developers planned to use AVIDs for an extended set of devices, however, they never did this.

Special Considerations

Because this function may move or purge memory blocks or access handles, you cannot call it at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Displays.h`

DMGetNextMirroredDevice

Obtains a handle for a video device that mirrors another specified video device. (Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMGetNextMirroredDevice (
   GDHandle gDevice,
   GDHandle *mirroredDevice
);
```

Parameters

gDevice

A handle to the `GDevice` structure for the video device that another video device mirrors.

mirroredDevice

On return, a pointer to the handle for the video device that displays a mirror image of the device specified in the `gDevice` parameter.

Return Value

A result code. See "Display Manager Result Codes" (page 1164).

Special Considerations

Because this function may move or purge memory blocks or access handles, you cannot call it at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Displays.h`

DMGetNextScreenDevice

Returns a handle for the next video device in the device list. (Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
GDHandle DMGetNextScreenDevice (
   GDHandle theDevice,
   Boolean activeOnly
);
```

Parameters

theDevice

A handle to the `GDevice` structure at which you want the function to begin. You can supply the handle returned by the function `DMGetFirstScreenDevice` or `DMGetNextScreenDevice`.

activeOnly

If `true`, the `DMGetNextScreenDevice` function returns a handle for the next active video device. If `false`, `DMGetNextScreenDevice` returns a handle for the next video device, active or not. You may use the Active Device Constants in this parameter. See "Active Device Only Values" (page 1148).

Return Value

If `activeOnly` is `true`, a handle to the next `GDevice` structure for an active video device. If `activeOnly` is `false`, a handle to the next `GDevice` structure for a video device. If there are no more `GDevice` structures in the list, `DMGetNextScreenDevice` returns `NULL`. See the QuickDraw Manager documentation for a description of the `GDHandle` data type.

Discussion
The `DMGetNextScreenDevice` function is similar to the QuickDraw function `GetNextDevice`, except that when returning `GDevice` structures, `GetNextDevice` does not distinguish between inactive and active video devices or between the `GDevice` structures for video devices and the `GDevice` structures associated with no video devices.

Special Considerations

Because this function may move or purge memory blocks or access handles, you cannot call it at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Displays.h`

DMGetPortComponentByAVID

(Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMGetPortComponentByAVID (
   DisplayIDType thePortID,
   Component *thePortComponent,
   ComponentDescription *theDesciption,
   ResType *thePortKind
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Displays.h`

DMIsMirroringOn

Determines if video mirroring is active. (Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMIsMirroringOn (
   Boolean *isMirroringOn
);
```

Parameters

`isMirroringOn`
On return, a pointer to a Boolean value; `true` indicates that mirroring is on; `false` indicates it is not.

Return Value
A result code. See "Display Manager Result Codes" (page 1164).

Special Considerations

Because this function may move or purge memory blocks or access handles, you cannot call it at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Displays.h`

DMMirrorDevices

Turns on video mirroring. (Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMMirrorDevices (
   GDHandle gD1,
   GDHandle gD2,
   Handle displayState
);
```

Parameters

gD1

A handle to the `GDevice` structure for the video device whose pixel image you want duplicated on another device.

gD2

A handle to the `GDevice` structure for the video device on which you want to duplicate the pixel image specified in the `gD1` parameter.

displayState

If your application called `DMBeginConfigureDisplays` (page 1091), you must pass the `displayState` handle obtained. Otherwise pass `NULL` in this parameter.

Return Value

A result code. See "Display Manager Result Codes" (page 1164).

Discussion

Your application should leave control of video mirroring to the user. However, if video mirroring is useful for your application (for example, if your application displays on-screen presentations), you might provide a control so that the user can switch to video mirroring directly from your application. In this case, `DMMirrorDevices` is useful to your application. Your control should also allow the user to turn video mirroring off; the function `DMUnmirrorDevice` (page 1127) supports this.

Special Considerations

Because this function may move or purge memory blocks or access handles, you cannot call it at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`Displays.h`

DMMoveDisplay

Moves the boundary rectangle for a video device. You should generally never need to use this function. (Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMMoveDisplay (
   GDHandle moveDevice,
   short x,
   short y,
   Handle displayState
);
```

Parameters

moveDevice
A handle to the `GDevice` structure for the video device whose boundary rectangle you wish to move.

x
The horizontal coordinate on the QuickDraw global coordinate plane for the point to which you want to move the upper-left corner of the boundary rectangle.

y
The vertical coordinate on the QuickDraw global coordinate plane for the point to which you want to move the upper-left corner of the boundary rectangle.

displayState
If your application called `DMBeginConfigureDisplays` (page 1091), you must pass the `displayState` handle obtained. Otherwise pass `NULL` in this parameter.

Return Value
A result code. See "Display Manager Result Codes" (page 1164).

Discussion
The `DMMoveDisplay` function moves the boundary rectangle for the specified video device to the point (`x` , `y`) in the QuickDraw global coordinate plane. If the video device controls the main screen, which always has the global coordinates (`0` , `0`), then all other video devices are offset by horizontal distance `x` and vertical distance `y`.

A boundary rectangle is the rectangle that links the local coordinate system of a graphics port to QuickDraw's global coordinate system and defines the area of the pixel image or bit image into which QuickDraw can draw. The boundary rectangle is stored in either the pixel map or the bitmap contained in a `GDevice` structure.

The Display Manager will reposition overlapped or discontiguous boundary rects to create a non-overlapping contiguous desktop space.

Special Considerations

Because this function may move or purge memory blocks or access handles, you cannot call it at interrupt time.

Applications generally never need to use this function. In case you find a compelling need to change the user's display configuration, this function is described here for completeness. Note that if your application uses Display Manager functions to change the display configuration of the user's video devices, your application

should make these changes only with the consent of the user. If your application must have a specific pixel depth, for example, it should display a dialog box that offers the user a choice between changing to that depth or canceling display of the image.

Availability

Declared In
Displays.h

DMNewDisplay

Adds a video device to the device list and makes the device active. (Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMNewDisplay (
   GDHandle *newDevice,
   short driverRefNum,
   UInt32 mode,
   UInt32 reserved,
   DisplayIDType displayID,
   Component displayComponent,
   Handle displayState
);
```

Parameters

newDevice

A pointer to a handle to a `GDevice` structure for the video device that you want to add to the device list.

driverRefNum

The reference number of the video device which you are adding to the device list. This information is usually set at system startup. The function `DMAddDisplay` (page 1090) passes the value supplied here to the `InitGDevice` function in its `gdRefNum` parameter.

mode

The depth mode. Used by the video device driver, this value sets the pixel depth and specifies color. The function `DMAddDisplay` (page 1090) passes the value supplied here to the function `InitGDevice` in its `mode` parameter.

reserved

Reserved for future expansion. Pass `NULL` in this parameter.

displayID

A unique identification for the display. For new displays, supply this parameter with the value 0, which causes the Display Manager to generate a unique display ID for this device. If this display was removed, then pass the display ID of the current display in this parameter.

displayComponent

Reserved for future expansion. Pass `NULL` in this parameter.

displayState

If your application called `DMAddDisplay` (page 1090), you must pass the `displayState` handle obtained. Otherwise pass `NULL` in this parameter.

Return Value

A result code. See "Display Manager Result Codes" (page 1164).

Special Considerations

Because this function may move or purge memory blocks or access handles, you cannot call it at interrupt time.

Generally, your application should not use this function, but should instead allow system software to maintain the device list. This function is described here for completeness only.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Displays.h`

DMNewDisplayModeList

Builds a new display mode list for a specified video device. (Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMNewDisplayModeList (
   DisplayIDType displayID,
   UInt32 modeListFlags,
   UInt32 reserved,
   DMListIndexType *thePanelCount,
   DMListType *thePanelList
);
```

Parameters

displayID
The display ID for the video device that will have a new display mode list.

modeListFlags
Reserved for future expansion. Pass `NULL` in this parameter.

reserved
Reserved for future expansion. Pass `NULL` in this parameter.

thePanelCount
The number of entries in the display mode list specified by the `theList` parameter.

thePanelList
The display mode list for the specified video device.

Return Value

A result code. See "Display Manager Result Codes" (page 1164).

Special Considerations

Because this function may move or purge memory blocks or access handles, you cannot call it at interrupt time.

Generally, your application should not use this function, but should instead allow system software to maintain the device list. This function is described here for completeness only.

Availability

Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In

`Displays.h`

DMQDIsMirroringCapable

Determines if QuickDraw supports video mirroring on the user's system. (Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMQDIsMirroringCapable (
   Boolean *qdIsMirroringCapable
);
```

Parameters

qdIsMirroringCapable

On return, a pointer to the value `true` if QuickDraw supports video mirroring; otherwise, a pointer to the value `false`.

Return Value
A result code. See "Display Manager Result Codes" (page 1164).

Special Considerations

Because this function may move or purge memory blocks or access handles, you cannot call it at interrupt time.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`Displays.h`

DMRegisterExtendedNotifyProc

Registers a function that responds to a Display Notice event outside of an event loop. (Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMRegisterExtendedNotifyProc (
   DMExtendedNotificationUPP notifyProc,
   void *notifyUserData,
   unsigned short nofifyOnFlags,
   DMProcessInfoPtr whichPSN
);
```

Parameters

notifyProc

A pointer to your function that handles a Display Notice event.

notifyUserData

A pointer to caller-specific information which the Display Manager will return to your application when you request it.

notifyOnFlags

Reserved for future expansion. You should pass `kNilOptions` in this parameter.

whichPSN

A pointer to the Process Serial Number associated with your Display Notice event-handling function. If this process terminates, the Display Notice event-handling function is automatically removed. For example, the Monitors control panel supplies the Finder's process number when registering its Display Notice event-handling function.

Return Value
A result code. See "Display Manager Result Codes" (page 1164).

Discussion
When the Display Manager sends your function the Display Notice event, your application or utility should respond by moving or resizing its windows and updating any internally-maintained video device information as appropriate.

When you are finished with your notification function, remove it by calling `DMRemoveExtendedNotifyProc` (page 1120).

Special Considerations

Because this function may move or purge memory blocks or access handles, you cannot call it at interrupt time.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`Displays.h`

DMRegisterNotifyProc

(Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMRegisterNotifyProc (
   DMNotificationUPP notificationProc,
   DMProcessInfoPtr whichPSN
);
```

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`Displays.h`

DMRemoveDisplay

Removes a video device from the device list. (Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMRemoveDisplay (
   GDHandle removeDevice,
   Handle displayState
);
```

Parameters

removeDevice

A handle to the `GDevice` structure for the video device you want to remove from the device list. The function `DMRemoveDisplay` does not actually dispose of this structure, but instead removes it from the device list.

displayState
If your application called DMBeginConfigureDisplays (page 1091), you must pass the displayState handle obtained. Otherwise pass NULL in this parameter.

Return Value
A result code. See "Display Manager Result Codes" (page 1164).

Discussion
The function DMRemoveDisplay may call the function DMSetMainDisplay (page 1126), which causes the removeDevice parameter to contain a handle to the GDevice structure for the new main screen, not the video device whose handle was passed to DMRemoveDisplay. To recover the GDevice structure for the disabled device, determine its display ID by using the function DMGetDisplayIDByGDevice (page 1102) before calling DMRemoveDisplay. Then use the function DMGetGDeviceByDisplayID (page 1105) to obtain the GDevice structure for the specified device.

You are not allowed to disable the last remaining display using the DMDisableDisplay (page 1095) function. Doing so will simply re-enable it. If you want to remove the last remaining display, thereby enabling the GDevice structure not associated with any video device, you must call DMRemoveDisplay.

Special Considerations

Because this function may move or purge memory blocks or access handles, you cannot call it at interrupt time.

Generally, your application should not use this function, but should instead allow system software to maintain the device list. This function is described here for completeness only.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
Displays.h

DMRemoveExtendedNotifyProc

Removes your Display Notice event-handling function registered by the DMRegisterExtendedNotifyProc function. (Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMRemoveExtendedNotifyProc (
   DMExtendedNotificationUPP notifyProc,
   void *notifyUserData,
   DMProcessInfoPtr whichPSN,
   unsigned short removeFlags
);
```

Parameters

notifyProc
A pointer to your function you want to remove that handles a Display Notice event.

notifyUserData
A pointer to caller-specific information which the Display Manager will return to your application when you request it.

whichPSN

A pointer to the Process Serial Number associated with your Display Notice event-handling function. If this process terminates, the Display Notice event-handling function is automatically removed. For example, the Monitors control panel supplies the Finder's process number when registering its Display Notice event-handling function.

removeFlags

Reserved for future expansion. You should pass `kNilOptions` in this parameter.

Return Value
A result code. See "Display Manager Result Codes" (page 1164).

Special Considerations

Because this function may move or purge memory blocks or access handles, you cannot call it at interrupt time.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`Displays.h`

DMRemoveNotifyProc

(Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMRemoveNotifyProc (
   DMNotificationUPP notificationProc,
   DMProcessInfoPtr whichPSN
);
```

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`Displays.h`

DMResolveDisplayComponents

(Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMResolveDisplayComponents (
   void
);
```

Parameters

Return Value
A result code. See "Display Manager Result Codes" (page 1164).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Displays.h`

DMSaveScreenPrefs

Saves the user's screen configuration preferences. (Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMSaveScreenPrefs (
   UInt32 reserved1,
   UInt32 saveFlags,
   UInt32 reserved2
);
```

Parameters

reserved1
Reserved for future expansion. Pass `NULL` in this parameter.

saveFlags
Reserved for future expansion. Pass `NULL` in this parameter.

reserved2
Reserved for future expansion. Pass `NULL` in this parameter.

Return Value
A result code. See "Display Manager Result Codes" (page 1164).

Discussion
Usually when you change screen properties such as pixel depth, the changes will only be temporary and will usually reset after restarting. However, the function `DMSaveScreenPrefs` makes the current screen properties permanent.

Special Considerations

Because this function may move or purge memory blocks or access handles, you cannot call it at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Displays.h`

DMSendDependentNotification

Notifies dependent displays of changes in depth mode or configuration. (Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMSendDependentNotification (
   ResType notifyType,
   ResType notifyClass,
   AVIDType displayID,
   ComponentInstance notifyComponent
);
```

Parameters

notifyType

The resource type that identifies the engine that made the change. Examples might be component engines that control brightness, contrast, or screen size. You may pass zero in this parameter. See `DependentNotifyRec` (page 1138) for more information.

notifyClass

The resource type that identifies the class of change the user or engine has made, such as color depth, pixel size, or screen size. See `DependentNotifyRec` (page 1138) for more information.

displayID

The ID number of the dependent display which you want to notify of Display Manager events. On return, the Display Manager sets the `notifyPortID` constant of the `DependentNotifyRec` (page 1138) structure. See DependentNotifyRec (page 1138) for more information.

notifyComponent

A value that notifies the display component what engine, if any, caused a change in a dependent display. You may pass 0 in this parameter.

Return Value

A result code. See "Display Manager Result Codes" (page 1164).

Discussion

The Display Manager uses the `DMSendDependentNotification` function to send notifications to registered Display Notice event-handling functions. This function uses all its parameters to supply values for the `DependentNotifyRec` (page 1138) structure which is sent out to registrants. Generally, your application does not need to use this function.

Special Considerations

Because this function may move or purge memory blocks or access handles, you cannot call it at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Displays.h`

DMSetAVPowerState

Sets the power state of a display device. (Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMSetAVPowerState (
   AVIDType theID,
   AVPowerStatePtr setPowerState,
   UInt32 powerFlags,
   Handle displayState
);
```

Parameters

theID

The ID number of the display device whose power state you want to change.

setPowerState

On return, this parameter points to a value that your application can use to set the power state of a display device.

powerFlags

A value that specifies the power state to which a display device can be set.

displayState

A handle to internal Display Manager information about the current display state.

Return Value

A result code. See "Display Manager Result Codes" (page 1164).

Special Considerations

Because this function may move or purge memory blocks or access handles, you cannot call it at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Displays.h`

DMSetDisplayComponent

(Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMSetDisplayComponent (
   GDHandle theDevice,
   Component displayComponent
);
```

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Displays.h`

DMSetDisplayMode

Sets the display mode and pixel depth for a video device. (Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMSetDisplayMode (
   GDHandle theDevice,
   UInt32 mode,
   UInt32 *depthMode,
   long reserved,
   Handle displayState
);
```

Parameters

theDevice

A handle to the `GDevice` structure for the video device whose display mode and pixel depth you wish to set.

mode

The number used by a video device to identify its display mode. If you supply the value 0 in this parameter, `DMSetDisplayMode` uses the current display mode. To specify another display mode, use the function `DMNewDisplayModeList` (page 1117).

depthMode

A pointer to the desired pixel depth for the video device specified by `theDevice`. If you pass a pointer to 0, `DMSetDisplayMode` attempts to keep the current depth. If you pass a pointer to 1, 2, 4, 8, 16, or 32, `DMSetDisplayMode` attempts to set the device to use your specified pixel depth. If you supply a pointer to a value of 128 or greater, then `DMSetDisplayMode` sets the depth to the depth mode represented by the Video Depth Mode values. See "Video Depth Mode Values" for more information.

On return, this parameter contains a pointer to the new pixel depth. This value represents the depth mode closest to the one you requested when calling `DMSetDisplayMode`.

reserved

Reserved for future expansion. Pass `NULL` in this parameter.

displayState

If your application called `DMBeginConfigureDisplays` (page 1091), you must pass the `displayState` handle obtained. Otherwise pass `NULL` in this parameter.

Return Value

A result code. See "Display Manager Result Codes" (page 1164).

Special Considerations

Because this function may move or purge memory blocks or access handles, you cannot call it at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Displays.h`

DMSetEnableByAVID

(Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMSetEnableByAVID (
   AVIDType theAVID,
   Boolean doEnable,
   Handle displayState
);
```

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`Displays.h`

DMSetMainDisplay

Sets a display to be the main screen. You should generally never need to use this function. (Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMSetMainDisplay (
   GDHandle newMainDevice,
   Handle displayState
);
```

Parameters
`newMainDevice`

A handle to the `GDevice` structure for the video device whose display you wish to make the main screen.

`displayState`

If your application called `DMBeginConfigureDisplays` (page 1091), you must pass the `displayState` handle obtained. Otherwise pass `NULL` in this parameter.

Return Value
A result code. See "Display Manager Result Codes" (page 1164).

Discussion
After a call to the function `DMSetMainDisplay`, the handle specified by the parameter `newMainDevice` will point to the `GDevice` structure for the video device whose display, before calling `DMSetMainDisplay`, was the main screen. To obtain a handle to the main screen, you can use the Color QuickDraw function `GetMainDevice`.

`DMSetMainDisplay` moves the menu bar to the display for the video device specified by `newMainDevice`. QuickDraw maps the (0,0) origin point of the global coordinate system to the main screen's upper-left corner, and other screens are positioned adjacent to it.

Special Considerations
Because this function may move or purge memory blocks or access handles, you cannot call it at interrupt time.

Applications generally never need to use this function. In case you find a compelling need to change the user's display configuration, this function is described here for completeness. Note that if your application uses Display Manager functions to change the display configuration of the user's video devices, your application should make these changes only with the consent of the user. If your application must have a specific pixel depth, for example, it should display a dialog box that offers the user a choice between changing to that depth or canceling display of the image.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Displays.h`

DMUnblockMirroring

Reenables video mirroring disabled by the function `DMUnblockMirroring`. You should generally never need to use this function. (Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMUnblockMirroring (
   void
);
```

Parameters

Return Value
A result code. See "Display Manager Result Codes" (page 1164).

Special Considerations

Because this function may move or purge memory blocks or access handles, you cannot call it at interrupt time.

Applications generally never need to use this function. In case you find a compelling need to change the user's display configuration, this function is described here for completeness. Note that if your application uses Display Manager functions to change the display configuration of the user's video devices, your application should make these changes only with the consent of the user. If your application must have a specific pixel depth, for example, it should display a dialog box that offers the user a choice between changing to that depth or canceling display of the image.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Displays.h`

DMUnmirrorDevice

Turns off video mirroring. (Deprecated in Mac OS X v10.4. Use Quartz Display Services instead; see *Quartz Display Services Reference*.)

```
OSErr DMUnmirrorDevice (
   GDHandle gDevice,
   Handle displayState
);
```

Parameters

gDevice

A handle to the `GDevice` structure for the video device on which you no longer wish to mirror the pixel image of another device.

displayState

If your application called `DMBeginConfigureDisplays` (page 1091), you must pass the `displayState` handle obtained. Otherwise pass `NULL` in this parameter.

Return Value

A result code. See "Display Manager Result Codes" (page 1164).

Discussion

When the function `DMUnmirrorDevice` completes, the display controlled by the video device specified in the `gDevice` parameter no longer contains the mirror image of another display.

Your application should leave control of video mirroring to the user. However, if video mirroring is useful for your application (for example, if your application displays on-screen presentations), you might provide a control so that the user can switch to video mirroring directly from your application. In this case, the function `DMMirrorDevices` (page 1111) is useful for switching video mirroring on, and `DMUnmirrorDevice` function is useful for switching it off again.

Special Considerations

Because this function may move or purge memory blocks or access handles, you cannot call it at interrupt time.

Callbacks

DMComponentListIteratorProcPtr

```
typedef void (*DMComponentListIteratorProcPtr)
(
    void * userData,
    DMListIndexType itemIndex,
    DMComponentListEntryPtr componentInfo
);
```

If you name your function `MyDMComponentListIteratorProc`, you would declare it like this:

```
void MyDMComponentListIteratorProc (
    void * userData,
    DMListIndexType itemIndex,
    DMComponentListEntryPtr componentInfo
);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Displays.h`

DMDisplayListIteratorProcPtr

```
typedef void (*DMDisplayListIteratorProcPtr)
(
    void * userData,
    DMListIndexType itemIndex,
    DisplayListEntryPtr displaymodeInfo
);
```

If you name your function `MyDMDisplayListIteratorProc`, you would declare it like this:

```
void MyDMDisplayListIteratorProc (
    void * userData,
    DMListIndexType itemIndex,
    DisplayListEntryPtr displaymodeInfo
);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Displays.h`

DMDisplayModeListIteratorProcPtr

Defines a pointer to a list iterator callback function.

```
typedef void (*DMDisplayModeListIteratorProcPtr)
(
    void * userData,
    DMListIndexType itemIndex,
    DMDisplayModeListEntryPtr displaymodeInfo
);
```

If you name your function `MyDMDisplayModeListIteratorProc`, you would declare it like this:

```
void MyDMDisplayModeListIteratorProc (
    void * userData,
    DMListIndexType itemIndex,
    DMDisplayModeListEntryPtr displaymodeInfo
);
```

Parameters

userData
: A pointer to data about mode changes provided by the user.

itemIndex
: Specifies the list entry. See `DMListIndexType` (page 1145) for more information. This is the index passed into `DMGetIndexedDisplayModeFromList` (page 1107).

displaymodeInfo
: A pointer to a structure of type `DMDisplayModeListEntryRec` (page 1143) that provides display mode information.

Discussion

The function `DMGetIndexedDisplayModeFromList` (page 1107) uses this callback function to retrieve and return information about a display mode to the caller of `DMGetIndexedDisplayModeFromList`.

When you implement this function, the pointer you pass to the `DMGetIndexedDisplayModeFromList` function should be a universal procedure pointer with the following type definition:

```
typedef (DMDisplayModeListIteratorProcPtr)
DMDisplayModeListIteratorUPP;
```

To create a universal procedure pointer for your application-defined function, you should use the `NewDMDisplayModeListIteratorUPP` function as follows:

```
DMDisplayModeListIteratorUPP MyDMDisplayModeListIteratorUPP;
MyDMDisplayModeListIteratorUPP = NewDMDisplayModeListIteratorUPP
(&MyDMDisplayModeListIteratorCallback)
```

You can then pass `MyDMDisplayModeListIteratorUPP` in the `listIterator` parameter of the `DMGetIndexedDisplayModeFromList` (page 1107) function. When you no longer need the list iterator, you should dispose of the UPP using the `DisposeDMDisplayModeListIteratorUPP` function:

```
DisposeDMDisplayModeListIteratorUPP (
    MyDMDisplayModeListIteratorUPP);
```

Using this call ensures that the call is made through a universal procedure pointer.

Special Considerations

Because this function may move or purge memory blocks or access handles, you cannot call it at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Displays.h`

DMExtendedNotificationProcPtr

Defines a pointer to an extended notification callback function.

```
typedef void (*DMExtendedNotificationProcPtr)
(
    void * userData,
    short theMessage,
    void * notifyData
);
```

If you name your function `MyDMExtendedNotificationProc`, you would declare it like this:

```
void MyDMExtendedNotificationProc (
    void * userData,
    short theMessage,
    void * notifyData
);
```

Parameters

userData

A pointer you passed into `DMRegisterExtendedNotifyProc` (page 1118).

theMessage

A message selector. See "Notification Messages" (page 1159) for information on specific message selectors.

notifyData

A pointer to message-specific information data provided by the the Display Manager, described in "Notification Messages" (page 1159).

Discussion

Display Manager notification functions use this callback function when your application needs to know when certain events have occurred. The system software may implement these events or follow a user action. When these events occur, the Display Manager will send notification messages to registrants.

When you call the function `DMRegisterExtendedNotifyProc` (page 1118) you designate an application-defined function to handle the extended notification procedure.

When you implement this function, the pointer you pass to the `DMRegisterExtendedNotifyProc` function should be a universal procedure pointer with the following type definition:

```
typedef (DMExtendedNotificationProcPtr)             DMExtendedNotificationUPP;
```

To create a universal procedure pointer for your application-defined function, you should use the `NewDMExtendedNotificationProc` macro as follows:

```
DMExtendedNotificationUPP  MyExtendedNotificationUPP;
MyExtendedNotificationUPP = NewDMExtendedNotificationProc
(MyExtendedNotificationCallback);
```

You can then pass `MyExtendedNotificationUPP` in the `notifyProc` parameter of the `DMRegisterExtendedNotifyProc` (page 1118) function. When you no longer need notifications, you should remove it using the `DMRemoveExtendedNotifyProc` (page 1120) function. You sould also dispose of the UPP using the `DisposeDMExtendedNotificationUPP` function:

```
DisposeDMExtendedNotificationUPP(MyExtendedNotificationUPP);
```

Using this call ensures that the call is made through a universal procedure pointer.

Special Considerations

Because this function may move or purge memory blocks or access handles, you cannot call it at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Displays.h`

DMNotificationProcPtr

```
typedef void (*DMNotificationProcPtr)
(
    AppleEvent * theEvent
);
```

If you name your function `MyDMNotificationProc`, you would declare it like this:

```
void MyDMNotificationProc (
    AppleEvent * theEvent
);
```

Available in Mac OS X v10.0 and later.

Declared In
`Displays.h`

DMProfileListIteratorProcPtr

```
typedef void (*DMProfileListIteratorProcPtr)
(
    void * userData,
    DMListIndexType itemIndex,
    DMProfileListEntryPtr profileInfo
);
```

If you name your function `MyDMProfileListIteratorProc`, you would declare it like this:

```
void MyDMProfileListIteratorProc (
    void * userData,
    DMListIndexType itemIndex,
    DMProfileListEntryPtr profileInfo
);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Displays.h`

Data Types

AVLocationRec

```
struct AVLocationRec {
    unsigned long locationConstant;
};
typedef struct AVLocationRec AVLocationRec;
typedef AVLocationRec * AVLocationPtr;
```

Fields

`locationConstant`

Reserved for future expansion. Set this field to zero.

Discussion

The function `DMGetGraphicInfoByAVID` (page 1106) uses the `AVLocationRec` structure to get information about graphic displays.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Displays.h`

AVPowerStatePtr

```
typedef VDPowerStateRec * AVPowerStatePtr;
```

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Displays.h`

AVPowerStateRec

```
typedef VDPowerStateRec AVPowerStateRec;
```

Discussion

The functions `DMGetAVPowerState` (page 1100) and `DMSetAVPowerState` (page 1123) contain a parameter of type `AVPowerStatePtr`, which is a pointer to the `AVPowerStateRec` data type.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Displays.h`

DependentNotifyRec

```
struct DependentNotifyRec {
    ResType notifyType;
    ResType notifyClass;
    DisplayIDType notifyPortID;
    ComponentInstance notifyComponent;
    unsigned long notifyVersion;
    unsigned long notifyFlags;
    unsigned long notifyReserved;
    unsigned long notifyFuture;
};
typedef struct DependentNotifyRec DependentNotifyRec;
typedef DependentNotifyRec * DependentNotifyPtr;
```

Fields

`notifyType`
A value that specifies the type of engine, if any, that made the change. The Display Manager may set this field to zero.

`notifyClass`
A value specifying the class of change that occurred: for instance, color or screen size. This field uses a value supplied by the constant described under "Dependent Notification Constants" (page 1153) to specify the class of change that has occurred in a dependent display.

`notifyPortID`
Specifies which device was touched (`kInvalidDisplayID` specifies all or none).

`notifyComponent`
A value that indentifies the engine that made the change. The Display Manager may set this field to zero.

`notifyVersion`
Reserved for future expansion. The Display Manager sets this field to zero.

`notifyFlags`
Reserved for future expansion. The Display Manager sets this field to zero.

`notifyReserved`
Reserved for future expansion. The Display Manager sets this field to zero.

`notifyFuture`
Reserved for future expansion. The Display Manager sets this field to zero.

Discussion

The function `DMSendDependentNotification` (page 1122) uses the `notifyType` and `notifyClass` fields of the `DependentNotifyRec` structure.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Displays.h`

DisplayListEntryRec

```
struct DisplayListEntryRec {
    GDHandle displayListEntryGDevice;
    DisplayIDType displayListEntryDisplayID;
    UInt32 displayListEntryIncludeFlags;
    UInt32 displayListEntryReserved1;
    UInt32 displayListEntryReserved2;
    UInt32 displayListEntryReserved3;
    UInt32 displayListEntryReserved4;
    UInt32 displayListEntryReserved5;
};
typedef struct DisplayListEntryRec DisplayListEntryRec;
typedef DisplayListEntryRec * DisplayListEntryPtr;
```

Fields

`displayListEntryGDevice`
A value of type GDHandle.

`displayListEntryDisplayID`
A value of type `DisplayIDType` that specifies the display ID.

`displayListEntryIncludeFlags`
A value of type `UInt32` that specifies the reason this entry was included.

`displayListEntryReserved1`
Reserved for future expansion. Set this field to zero.

`displayListEntryReserved2`
Reserved for future expansion. Set this field to zero.

`displayListEntryReserved3`
Reserved for future expansion. Set this field to zero.

`displayListEntryReserved4`
Reserved for future expansion. Set this field to zero.

`displayListEntryReserved5`
Reserved for future expansion. Set this field to zero.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Displays.h`

DMComponentListEntryRec

```
struct DMComponentListEntryRec {
    DisplayIDType itemID;
    Component itemComponent;
    ComponentDescription itemDescription;
    ResType itemClass;
    DMFidelityType itemFidelity;
    ResType itemSubClass;
    Point itemSort;
    unsigned long itemFlags;
    ResType itemReserved;
    unsigned long itemFuture1;
    unsigned long itemFuture2;
    unsigned long itemFuture3;
    unsigned long itemFuture4;
};
typedef struct DMComponentListEntryRec DMComponentListEntryRec;
typedef DMComponentListEntryRec * DMComponentListEntryPtr;
```

Fields

`itemID`

`itemComponent`

`itemDescription`

`itemClass`

`itemFidelity`

`itemSubClass`

`itemSort`

Reserved for future expansion. Set this field to zero.

`itemFlags`

Reserved for future expansion. Set this field to zero.

`itemReserved`

`itemFuture1`

Reserved for future expansion. Set this field to zero.

`itemFuture2`

Reserved for future expansion. Set this field to zero.

`itemFuture3`

Reserved for future expansion. Set this field to zero.

`itemFuture4`

Reserved for future expansion. Set this field to zero.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Displays.h`

DMComponentListIteratorUPP

```
typedef DMComponentListIteratorProcPtr DMComponentListIteratorUPP;
```

Discussion
For more information, see the description of the `DMComponentListIteratorProcPtr` (page 1132) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Displays.h`

DMDepthInfoBlockRec

```
struct DMDepthInfoBlockRec {
    unsigned long depthBlockCount;
    DMDepthInfoPtr depthVPBlock;
    unsigned long depthBlockFlags;
    unsigned long depthBlockReserved1;
    unsigned long depthBlockReserved2;
};
typedef struct DMDepthInfoBlockRec DMDepthInfoBlockRec;
typedef DMDepthInfoBlockRec * DMDepthInfoBlockPtr;
```

Fields

`depthBlockCount`
Specifies the number of mode depths available.

`depthVPBlock`
Array of `DMDepthInfoRec` (page 1142).

`depthBlockFlags`
Reserved for future expansion.

`depthBlockReserved1`
Reserved for future expansion.

`depthBlockReserved2`
Reserved for future expansion.

Discussion
When you call the function `DMGetIndexedDisplayModeFromList` (page 1107) , the Display Manager passes a pointer to a `DMDisplayModeListEntryRec` (page 1143) structure to your application. Its field `displayModeDepthBlockInfo` is a pointer to a `DMDepthInfoBlockRec` structure.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Displays.h`

DMDepthInfoRec

```
struct DMDepthInfoRec {
    VDSwitchInfoPtr depthSwitchInfo;
    VPBlockPtr depthVPBlock;
    UInt32 depthFlags;
    UInt32 depthReserved1;
    UInt32 depthReserved2;
};
typedef struct DMDepthInfoRec DMDepthInfoRec;
typedef DMDepthInfoRec * DMDepthInfoPtr;
```

Fields

`depthSwitchInfo`
: A pointer to the structure `VDSwitchInfoRec`, which contains values that specify information on video switch modes and data.

`depthVPBlock`
: A pointer to the structure `VPBlock`, which supplies information about size, depth and format.

`depthFlags`
: Values from the video structure `VDVideoParametersInfoRec`, which specify color, size, and depth.

`depthReserved1`
: Reserved for future expansion.

`depthReserved2`
: Reserved for future expansion.

Discussion

This structure provides information that the structure `DMDepthInfoBlockRec` (page 1141) supplies to the function `DMGetIndexedDisplayModeFromList` (page 1107).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Displays.h`

DMDisplayListIteratorUPP

```
typedef DMDisplayListIteratorProcPtr DMDisplayListIteratorUPP;
```

Discussion

For more information, see the description of the `DMDisplayListIteratorProcPtr` (page 1133) callback function.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Displays.h`

DMDisplayModeListEntryRec

```
struct DMDisplayModeListEntryRec {
    UInt32 displayModeFlags;
    VDSwitchInfoPtr displayModeSwitchInfo;
    VDResolutionInfoPtr displayModeResolutionInfo;
    VDTimingInfoPtr displayModeTimingInfo;
    DMDepthInfoBlockPtr displayModeDepthBlockInfo;
    UInt32 displayModeVersion;
    StringPtr displayModeName;
    DMDisplayTimingInfoPtr displayModeDisplayInfo;
};
typedef struct DMDisplayModeListEntryRec DMDisplayModeListEntryRec;
typedef DMDisplayModeListEntryRec * DMDisplayModeListEntryPtr;
```

Fields

`displayModeFlags`
: A pointer to a video structure, `VDSwitchInfoRec`, which provides information you need to tell the driver how to switch into different configurations, bit depths, or resolutions. See the function `DMSetDisplayMode` (page 1125) for more information.

`displayModeSwitchInfo`
: A pointer to a `VDSwitchInfoRec` video structure, which provides information you need to tell the driver how to switch into different configurations, bit depths, or resolutions. See the function `DMSetDisplayMode` (page 1125) for more information.

`displayModeResolutionInfo`
: A pointer to a pointer to a `VDResolutionInfoRec` video structure, which provides information about horizontal pixels, maximum depth modes, and the vertical line of the specified display mode.

`displayModeTimingInfo`
: A pointer to a pointer to a `VDTimingInfoRec` video structure, which provides information about timing, format of the specified display mode.

`displayModeDepthBlockInfo`
: A pointer to a `DMDepthInfoBlockRec` (page 1141) structure, which provides information about available pixel formats and the `VPBlock`, including size and depth.

`displayModeVersion`
: The version of this structure. Currently it is version `kDisplayTimingInfoVersionOne`. See "Display Version Values" (page 1155) for more information.

`displayModeName`
: A string pointer giving the display mode name.

`displayModeDisplayInfo`
: A pointer to the `DMDisplayTimingInfoRec` (page 1144) data type. This data type supplies information about the quality and default values of the timing.

Discussion

The `DMDisplayModeListEntryRec` structure contains information about a display mode in a display mode list built by the function `DMNewDisplayModeList` (page 1117).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Displays.h`

DMDisplayModeListIteratorUPP

```
typedef DMDisplayModeListIteratorProcPtr DMDisplayModeListIteratorUPP;
```

Discussion
For more information, see the description of the `DMDisplayModeListIteratorProcPtr` (page 1133) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Displays.h`

DMDisplayTimingInfoRec

```
struct DMDisplayTimingInfoRec {
    UInt32 timingInfoVersion;
    UInt32 timingInfoAttributes;
    SInt32 timingInfoRelativeQuality;
    SInt32 timingInfoRelativeDefault;
    UInt32 timingInfoReserved[16];
};
typedef struct DMDisplayTimingInfoRec DMDisplayTimingInfoRec;
typedef DMDisplayTimingInfoRec * DMDisplayTimingInfoPtr;
```

Fields

`timingInfoVersion`
An unsigned 32 bit integer that shows the timing version. See "Display Version Values" (page 1155) for timing version values.

`timingInfoAttributes`
An unsigned 32 bit integer that the Display Manager sets to show timing attributes.

`timingInfoRelativeQuality`
A signed 32 bit integer whose flags the Display Manager sets to provide information on the quality of the timing.

`timingInfoRelativeDefault`
A signed 32 bit integer the Display Manager sets that specifies the relative default value of the timing.

`timingInfoReserved`
Reserved for future expansion.

Discussion
This structure supplies information about timing attributes, defaults and values to the structure `DMDisplayModeListEntryRec` (page 1143).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Displays.h`

DMExtendedNotificationUPP

```
typedef DMExtendedNotificationProcPtr DMExtendedNotificationUPP;
```

Discussion
For more information, see the description of the `DMExtendedNotificationProcPtr` (page 1134) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Displays.h`

DMFidelityType

```
typedef UInt32 DMFidelityType;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Displays.h`

DMListIndexType

```
typedef unsigned long DMListIndexType;
```

Discussion
The function `DMGetIndexedDisplayModeFromList` (page 1107) uses this data type to supply a list of display modes from which you can obtain information about a specified display mode.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Displays.h`

DMListType

```
typedef void * DMListType;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Displays.h`

DMMakeAndModelRec

```
struct DMMakeAndModelRec {
    ResType manufacturer;
    UInt32 model;
    UInt32 serialNumber;
    UInt32 manufactureDate;
    UInt32 makeReserved[4];
};
typedef struct DMMakeAndModelRec DMMakeAndModelRec;
typedef DMMakeAndModelRec * DMMakeAndModelPtr;
```

Fields

`manufacturer`
Represents the manufacturer of the specified display.

`model`
Represents the model name of the specified display.

`serialNumber`
Represents the serial number of the specified display.

`manufactureDate`
Represents the date of manufacture of the specified display.

`makeReserved`
Reserved for future expansion.

Discussion

This structure stores information about a specified monitor or display. If you need to keep track of configurations and user preferences, you can store that information in this structure.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Displays.h`

DMModalFilterUPP

```
typedef void * DMModalFilterUPP;
```

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Displays.h`

DMNotificationUPP

```
typedef DMNotificationProcPtr DMNotificationUPP;
```

Discussion

For more information, see the description of the `DMNotificationProcPtr` (page 1136) callback function.

Availability

Available in Mac OS X v10.0 and later.

Declared In
Displays.h

DMProcessInfoPtr

```
typedef void * DMProcessInfoPtr;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
Displays.h

DMProfileListEntryRec

```
struct DMProfileListEntryRec {
    CMProfileRef profileRef;
    Ptr profileReserved1;
    Ptr profileReserved2;
    Ptr profileReserved3;
};
typedef struct DMProfileListEntryRec DMProfileListEntryRec;
typedef DMProfileListEntryRec * DMProfileListEntryPtr;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
Displays.h

DMProfileListIteratorUPP

```
typedef DMProfileListIteratorProcPtr DMProfileListIteratorUPP;
```

Discussion
For more information, see the description of the DMProfileListIteratorProcPtr (page 1136) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
Displays.h

Constants

Active Device Only Values

```
enum {
    dmOnlyActiveDisplays = true,
    dmAllDisplays = false
};
```

Constants

`dmOnlyActiveDisplays`

Returns a handle to the `GDevice` structure for an active device only.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`dmAllDisplays`

Returns a handle to the `GDevice` structure for a device, active or not.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

Discussion

The functions `DMGetFirstScreenDevice` (page 1104) and `DMGetNextScreenDevice` (page 1109) contain the parameter `activeOnly` which you can specify with an Active Device Constant.

Apple Event Notification Keywords

```
enum {
    kAESystemConfigNotice = 'cnfg',
    kAEDisplayNotice = 'dspl',
    kAEDisplaySummary = 'dsum',
    keyDMConfigVersion = 'dmcv',
    keyDMConfigFlags = 'dmcf',
    keyDMConfigReserved = 'dmcr',
    keyDisplayID = 'dmid',
    keyDisplayComponent = 'dmdc',
    keyDisplayDevice = 'dmdd',
    keyDisplayFlags = 'dmdf',
    keyDisplayMode = 'dmdm',
    keyDisplayModeReserved = 'dmmr',
    keyDisplayReserved = 'dmdr',
    keyDisplayMirroredId = 'dmmi',
    keyDeviceFlags = 'dddf',
    keyDeviceDepthMode = 'dddm',
    keyDeviceRect = 'dddr',
    keyPixMapRect = 'dpdr',
    keyPixMapHResolution = 'dphr',
    keyPixMapVResolution = 'dpvr',
    keyPixMapPixelType = 'dppt',
    keyPixMapPixelSize = 'dpps',
    keyPixMapCmpCount = 'dpcc',
    keyPixMapCmpSize = 'dpcs',
    keyPixMapAlignment = 'dppa',
    keyPixMapResReserved = 'dprr',
    keyPixMapReserved = 'dppr',
    keyPixMapColorTableSeed = 'dpct',
    keySummaryMenubar = 'dsmb',
    keySummaryChanges = 'dsch',
    keyDisplayOldConfig = 'dold',
    keyDisplayNewConfig = 'dnew'
};
```

Constants

`kAESystemConfigNotice`
Keyword for the Event ID for a Display Notice event.
Available in Mac OS X v10.0 and later.
Declared in `Displays.h`.

`kAEDisplayNotice`
Keyword for a required parameter to a Display Notice event.
Available in Mac OS X v10.0 and later.
Declared in `Displays.h`.

`kAEDisplaySummary`
Available in Mac OS X v10.0 and later.
Declared in `Displays.h`.

`keyDMConfigVersion`
Keyword for the descriptor structure describing the version number for this Display Notice event.
Available in Mac OS X v10.0 and later.
Declared in `Displays.h`.

`keyDMConfigFlags`
Reserved for future expansion. Internal use only.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`keyDMConfigReserved`
Reserved for future expansion. Internal use only.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`keyDisplayID`
Keyword for the descriptor structure describing the display ID for the video device.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`keyDisplayComponent`
Unless you are disconnecting display components, this is for internal use only.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`keyDisplayDevice`
Keyword for the descriptor structure containing a handle to the `GDevice` structure for the video device.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`keyDisplayFlags`
Reserved for future expansion. Internal use only.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`keyDisplayMode`
Keyword for the descriptor structure containing the `sResource` number from the video device for this display mode.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`keyDisplayModeReserved`
Reserved for future expansion. Internal use only.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`keyDisplayReserved`
Reserved for future expansion. Internal use only.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`keyDisplayMirroredId`
Keyword for the display this device is mirrored to.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`keyDeviceFlags`
Keyword for the descriptor structure describing the attributes for the video device as maintained in the `gdFlags` field of the `GDevice` structure for the device.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`keyDeviceDepthMode`
Keyword for the descriptor structure describing the depth mode for the video device; that is, the value of the `gdMode` field in the `GDevice` structure for the device.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`keyDeviceRect`
Keyword for the descriptor structure describing the boundary rectangle of the video device; that is, the value of the `gdRect` field in the `GDevice` structure for the device.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`keyPixMapRect`
Keyword for the descriptor structure describing the boundary rectangle into which QuickDraw can draw; that is, the bounds field in the `PixMap` structure for the `GDevice` structure for the video device.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`keyPixMapHResolution`
Keyword for the descriptor structure describing the horizontal resolution of the pixel image in the `PixMap` structure for the `GDevice` structure for the video device.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`keyPixMapVResolution`
Keyword for the descriptor structure describing the vertical resolution of the pixel image in the `PixMap` structure for the `GDevice` structure for the video device.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`keyPixMapPixelType`
Keyword for the descriptor structure describing the storage format for the pixel image on the device; that is, the value of the `pixelType` field in the `PixMap` structure for the `GDevice` structure for the video device.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`keyPixMapPixelSize`
Keyword for the descriptor structure describing the pixel depth for the device; that is, the value of the `pixelSize` field in the `PixMap` structure for the `GDevice` structure for the video device.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`keyPixMapCmpCount`
Keyword for the descriptor structure containing the number of components used to represent a color for a pixel; that is, the value of the `cmpCount` field in the `PixMap` structure for the `GDevice` structure for the device.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`keyPixMapCmpSize`
Keyword for the descriptor structure describing the size in bits of each component for a pixel; that is, the value of the `cmpSize` field in the `PixMap` structure for the `GDevice` structure for the device.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`keyPixMapAlignment`
Reserved for future expansion. Internal use only.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`keyPixMapResReserved`
Reserved for future expansion. Internal use only.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`keyPixMapReserved`
Reserved for future expansion. Internal use only.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`keyPixMapColorTableSeed`
Keyword for the descriptor structure containing the value of the `ctSeed` field of the `ColorTable` structure for the `PixMap` structure for the `GDevice` structure for the video device.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`keySummaryMenubar`
Reserved for future expansion. Internal use only.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`keySummaryChanges`
Reserved for future expansion. Internal use only.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`keyDisplayOldConfig`
Keyword for the descriptor structure describing the video device's previous state.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`keyDisplayNewConfig`
Keyword for the descriptor structure describing the video device's new state.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

Discussion
The Display Manager sends an Apple event—the Display Notice event—to notify applications that it has changed the display environment. The keywords that specify the Display Notice event and its descriptor structures are described here.

Confirm Flags

```
enum {
    kForceConfirmBit = 0,
    kForceConfirmMask = (1 << kForceConfirmBit)
};
```

Constants
`kForceConfirmBit`
Indicates to force a confirm dialog.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`kForceConfirmMask`
Use to set or test for a forced confirm dialog.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

Dependent Notification Constants

```
enum {
    kDependentNotifyClassShowCursor = 'shcr',
    kDependentNotifyClassDriverOverride = 'ndrv',
    kDependentNotifyClassDisplayMgrOverride = 'dmgr',
    kDependentNotifyClassProfileChanged = 'prof'
};
```

Constants
`kDependentNotifyClassShowCursor`
The Display Manager sends an extended notification when a hidden cursor shows during a display unmirror.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`kDependentNotifyClassDriverOverride`
The Display Manager sends notification that a video driver has been overridden with a newer revision.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`kDependentNotifyClassDisplayMgrOverride`
The Display Manager sends notification that it has been upgraded with a newer revision.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`kDependentNotifyClassProfileChanged`
The Display Manager sends notification when the profile associated with a display changes.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

Discussion
The function `DMSendDependentNotification` (page 1122) contains the parameter `notifyClass` which you can specify with a Dependent Notification Constant.

Display/Device ID Constants

The Display Manager uses these values to help with the configuration of the display.

```
enum {
    kDummyDeviceID = 0x00FF,
    kInvalidDisplayID = 0x0000,
    kFirstDisplayID = 0x0100
};
```

Constants
`kDummyDeviceID`
This is the ID of the dummy display, used when the last “real” display is removed.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`kInvalidDisplayID`
This is the ID of the invalid display, which has been removed from the active display list.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`kFirstDisplayID`
When your application sets this bit it asks the Display Manager to return the ID of the first display device on the active display list.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

Display Gestalt Constants

```
enum {
    kDisplayGestaltDisplayCommunicationAttr = 'comm',
    kDisplayGestaltForbidI2CMask = (1 << 0),
    kDisplayGestaltUseI2CPowerMask = (1 << 1),
    kDisplayGestaltCalibratorAttr = 'cali',
    kDisplayGestaltBrightnessAffectsGammaMask = (1 << 0),
    kDisplayGestaltViewAngleAffectsGammaMask = (1 << 1)
};
```

Display Mode Flags

The structure `DMDisplayModeListEntryRec` uses these values for its `displayModeFlags` field.

```
enum {
    kDisplayModeListNotPreferredBit = 0,
    kDisplayModeListNotPreferredMask = (1 << kDisplayModeListNotPreferredBit)
};
```

Constants

`kDisplayModeListNotPreferredBit`
Indicates there is a better timing available and that this timing should be shown only if the user wants to see all options.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`kDisplayModeListNotPreferredMask`
(1 `kDisplayModeListNotPreferredBit`)

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

Display Version Values

```
enum {
    kDisplayTimingInfoVersionZero = 1,
    kDisplayTimingInfoReservedCountVersionZero = 16,
    kDisplayModeEntryVersionZero = 0,
    kDisplayModeEntryVersionOne = 1
};
```

Constants

`kDisplayTimingInfoVersionZero`
This relative information is always `NULL` in this version.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`kDisplayTimingInfoReservedCountVersionZero`
This relative information is always `NULL` in this version.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`kDisplayModeEntryVersionZero`
This relative information is always `NULL` in this version.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`kDisplayModeEntryVersionOne`
This relative information is always `NULL` in this version.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

Discussion
These values supply information to the structure `DMDisplayModeListEntryRec` (page 1143).

Fidelity Check Constants

```
enum {
    kNoFidelity = 0,
    kMinimumFidelity = 1,
    kDefaultFidelity = 500,
    kDefaultManufacturerFidelity = 1000
};
```

Get Name By AVID Mask

```
enum {
    kDMSupressNumbersMask = (1 << 0),
    kDMForceNumbersMask = (1 << 1),
    kDMSupressNameMask = (1 << 2)
};
```

Constants
`kDMSupressNumbersMask`
If the bit specified by this mask is set, the numbers are suppressed and only names are returned.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`kDMForceNumbersMask`
If the bit specified by this mask is set, the numbers are forced to always be shown–even on single display configs.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`kDMSupressNameMask`
If the bit specified by this mask is set, the names are suppressed and only numbers are returned.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

Include Masks

```
enum {
    kIncludeOnlineActiveDisplaysMask = (1 << 0),
    kIncludeOnlineDisabledDisplaysMask = (1 << 1),
    kIncludeOfflineDisplaysMask = (1 << 2),
    kIncludeOfflineDummyDisplaysMask = (1 << 3),
    kIncludeHardwareMirroredDisplaysMask = (1 << 4)
};
```

Item Flags

```
enum {
    kComponentListNotPreferredBit = 0,
    kComponentListNotPreferredMask = (1 << kComponentListNotPreferredBit)
};
```

Mode List Masks

```
enum {
    kDMModeListIncludeAllModesMask = (1 << 0),
    kDMModeListIncludeOfflineModesMask = (1 << 1),
    kDMModeListExcludeDriverModesMask = (1 << 2),
    kDMModeListExcludeDisplayModesMask = (1 << 3),
    kDMModeListExcludeCustomModesMask = (1 << 4),
    kDMModeListPreferStretchedModesMask = (1 << 5),
    kDMModeListPreferSafeModesMask = (1 << 6)
};
```

Constants

`kDMModeListIncludeAllModesMask`
Available in Mac OS X v10.0 and later.
Declared in `Displays.h`.

`kDMModeListIncludeOfflineModesMask`
Available in Mac OS X v10.0 and later.
Declared in `Displays.h`.

`kDMModeListExcludeDriverModesMask`
Available in Mac OS X v10.0 and later.
Declared in `Displays.h`.

`kDMModeListExcludeDisplayModesMask`
Available in Mac OS X v10.0 and later.
Declared in `Displays.h`.

`kDMModeListExcludeCustomModesMask`
Available in Mac OS X v10.0 and later.
Declared in `Displays.h`.

`kDMModeListPreferStretchedModesMask`

Prefer modes that are stretched over modes that are letterboxed when setting kDisplayModeListNotPreferredBit

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`kDMModeListPreferSafeModesMask`

Prefer modes that are safe over modes that are not when setting kDisplayModeListNotPreferredBit

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

Name Flags

```
enum {
    kSuppressNumberBit = 0,
    kSuppressNumberMask = 1,
    kForceNumberBit = 1,
    kForceNumberMask = 2,
    kSuppressNameBit = 2,
    kSuppressNameMask = 4
};
```

New Engine List Constants

```
enum {
    kAnyPanelType = 0,
    kAnyEngineType = 0,
    kAnyDeviceType = 0,
    kAnyPortType = 0
};
```

Notification Messages

```
enum {
    kDMNotifyRequestConnectionProbe = 0,
    kDMNotifyInstalled = 1,
    kDMNotifyEvent = 2,
    kDMNotifyRemoved = 3,
    kDMNotifyPrep = 4,
    kDMNotifyExtendEvent = 5,
    kDMNotifyDependents = 6,
    kDMNotifySuspendConfigure = 7,
    kDMNotifyResumeConfigure = 8,
    kDMNotifyRequestDisplayProbe = 9,
    kDMNotifyDisplayWillSleep = 10,
    kDMNotifyDisplayDidWake = 11,
    kExtendedNotificationProc = (1L << 16)
};
```

Constants

`kDMNotifyRequestConnectionProbe`

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`kDMNotifyInstalled`

The Display Manager provides this message during a callback function to if your application has installed an extended notification procedure pointer for the first time. The Display Manager provides this message in the `notifyData` parameter of `DMSendDependentNotification` (page 1122).

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`kDMNotifyEvent`
The Display Manager provides this message when an Apple event update occurs, after a display configuration change is made. This is the only time non-extended notifications are called.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`kDMNotifyRemoved`
The Display Manager provides this message when the function `DMSendDependentNotification` (page 1122) is called on your function.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`kDMNotifyPrep`
Before passing `kDMSNotifyRemoved`, the Display Manager provides this message to indicate that it is about to begin to configure. Calling `DMSendDependentNotification` (page 1122) tells the Display Manager to send this message.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`kDMNotifyExtendEvent`
Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`kDMNotifyDependents`
The Display Manager provides this message to `DMSendDependentNotification` (page 1122).

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`kDMNotifySuspendConfigure`
The Display Manager passes this selector to notify your UPP that configuration is temporarily suspended. For instance, if a video game makes a temporary change to the display configuration, the game is expected to resume configuration and restore video before allowing other applications to access the screen.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`kDMNotifyResumeConfigure`
The Display Manager passes this selector to notify your application when previously suspended configuration is resumed. Your application can then replace windows and icons, and change depth mode if necessary.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`kDMNotifyRequestDisplayProbe`
Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`kDMNotifyDisplayWillSleep`
This selector is only available in Mac OS X.

Available in Mac OS X v10.2 and later.

Declared in `Displays.h`.

`kDMNotifyDisplayDidWake`
This selector is only available in Mac OS X.

Available in Mac OS X v10.2 and later.

Declared in `Displays.h`.

`kExtendedNotificationProc`
Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

Discussion
Display Manager functions needed for dependency notification and event processing use the notification message selectors in extended application-defined functions. `DMRegisterExtendedNotifyProc` (page 1118) gets all these messages. Applications should update all information about the display configurations at this point.

Notification Types

```
enum {
    kFullNotify = 0,
    kFullDependencyNotify = 1
};
```

Constants
`kFullNotify`
The Display Manager sets this bit to provide the major Apple notification event.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`kFullDependencyNotify`
The Display Manager sets this bit to provide notification only to those applications that need to know about interrelated functionality. It is used for updating the user interface.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

Discussion
The function `DMSendDependentNotification` (page 1122) uses these values in the `notifyType` parameter.

Panel List Flags

```
enum {
    kAllowDuplicatesBit = 0
};
```

Port List Flags

```
enum {
    kPLIncludeOfflineDevicesBit = 0
};
```

Constants

`kPLIncludeOfflineDevicesBit`

Should offline devices be put into the port list (such as dummy display)

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

Reserved Count Constants

```
enum {
    kMakeAndModelReservedCount = 4
};
```

Constants

`kMakeAndModelReservedCount`

Indicates the number of reserved fields.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

Summary Change Flags

```
enum {
    kBeginEndConfigureBit = 0,
    kMovedDisplayBit = 1,
    kSetMainDisplayBit = 2,
    kSetDisplayModeBit = 3,
    kAddDisplayBit = 4,
    kRemoveDisplayBit = 5,
    kNewDisplayBit = 6,
    kDisposeDisplayBit = 7,
    kEnabledDisplayBit = 8,
    kDisabledDisplayBit = 9,
    kMirrorDisplayBit = 10,
    kUnMirrorDisplayBit = 11
};
```

Switch Flags

```
enum {
    kNoSwitchConfirmBit = 0,
    kDepthNotAvailableBit = 1,
    kShowModeBit = 3,
    kModeNotResizeBit = 4,
    kNeverShowModeBit = 5
};
```

Constants

`kNoSwitchConfirmBit`

If the Display Manager sets this bit the display mode is required to function correctly. Your application does not need to provide confirmation if the user switches to this mode.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`kDepthNotAvailableBit`

If the Display Manager sets this bit the pixel depth of the specified device is not available for the specified display mode.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`kShowModeBit`

If the Display Manager sets this bit your application should display this mode to the user, even though it may require confirmation.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`kModeNotResizeBit`

If the Display Manager sets this bit you should not use this mode to resize a display; this mode drives a different connector in cards than in a built-in display.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

`kNeverShowModeBit`

If the Display Manager sets this bit you should not show the mode in the user interface.

Available in Mac OS X v10.0 and later.

Declared in `Displays.h`.

Discussion

In its `switchFlags` parameter, the function `DMCheckDisplayMode` (page 1094) returns a pointer to a long integer that specifies flags in two of its bits. The constants represent bits that are set to 1. These bits are set by the Display Manager, not your application

Result Codes

The table below lists the result codes that are specific to the Display Manager.

Result Code	Value	Description
`kDMGenErr`	-6220	An indeterminate error occurred. Available in Mac OS X v10.0 and later.
`kDMMirroringOnAlready`	-6221	Video mirroring is already enabled. Available in Mac OS X v10.0 and later.
`kDMWrongNumberOfDisplays`	-6222	Wrong number of displays. Available in Mac OS X v10.0 and later.
`kDMMirroringBlocked`	-6223	Video is blocked. Available in Mac OS X v10.0 and later.
`kDMCantBlock`	-6224	Video mirroring is already enabled and can't be blocked; use `DMUnMirrorDevice`, then call `DMBlockMirroring` again. Available in Mac OS X v10.0 and later.
`kDMMirroringNotOn`	-6225	Video mirroring is not currently enabled. Available in Mac OS X v10.0 and later.
`kSysSWTooOld`	-6226	Some piece of system software is too old for the Display Manager to operate. Available in Mac OS X v10.0 and later.
`kDMSWNotInitializedErr`	-6227	The required pieces of system software are not initialized. Available in Mac OS X v10.0 and later.
`kDMDriverNotDisplayMgrAwareErr`	-6228	The video driver for the display does not support the Display Manager. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
kDMNotFoundErr	-6229	Available in Mac OS X v10.0 and later.
kDMDisplayNotFoundErr	-6229	There are no GDevice structures for displays in the device list. Available in Mac OS X v10.0 and later.
kDMDisplayAlreadyInstalledErr	-6230	The display is already in the device list and can't be added. Available in Mac OS X v10.0 and later.
kDMNoDeviceTableclothErr	-6231	Available in Mac OS X v10.0 and later.
kDMMainDisplayCannotMoveErr	-6231	Available in Mac OS X v10.0 and later.
kDMFoundErr	-6232	Item found Available in Mac OS X v10.0 and later.

Gestalt Constants

You can check for version and feature availability information by using the Display Manager Version selectors defined in the Gestalt Manager. For more information, see *Gestalt Manager Reference*.

Font Manager Reference

Framework: ApplicationServices/ApplicationServices.h

Declared in Fonts.h

Overview

As of Mac OS X version 10.5, all Font Manager functions but three (`FMFontGetCGFontRefFromFontFamilyInstance` (page 1178), `FMGetATSFontRefFromFont` (page 1179), and `FMGetFontFromATSFontRef` (page 1186)) are deprecated. Most were deprecated in Mac OS X v10.4. The Font Manager was the font management API for the QuickDraw framework, which is now deprecated.

There are several alternatives that provide better compatibility with the rest of Mac OS X than using QuickDraw font functions. You should consider the following:

- For drawing and measuring text, use Core Text on Mac OS X v10.5 and later to render text directly through a Quartz (Core Image) graphics context. See *Core Text Programming Guide* and *Core Text Reference Collection*. On Mac OS X v10.4 and earlier, you can use the Appearance Manager API or the ATSUI API. See *Appearance Manager Reference*, *ATSUI Programming Guide*, and *ATSUI Reference*.
- For accessing information on fonts tracked by the operating system, use Core Text on Mac OS X v10.5 and later. See *Core Text Programming Guide* and *Core Text Reference Collection*. On Mac OS X v10.4 and earlier, use the ATS for Fonts API. See *Apple Type Services for Fonts Programming Guide* and *Apple Type Services for Fonts Reference*.
- For accessing and modifying information on fonts in a Quartz graphics context, use the Quartz API. See *Quartz 2D Programming Guide* and *Quartz 2D Reference Collection*.

The Font Manager API was used to manage the fonts your application uses to display and print text. The Font Manager was used to determine the characteristics of a font, change certain font settings, favor outline fonts over bitmapped fonts, and manipulate fonts in memory.

Functions by Task

Activating and Deactivating Fonts

`FMGetGeneration` (page 1189) Deprecated in Mac OS X v10.5
Retrieves the value of the generation count. (Deprecated. Use `ATSGetGeneration` (page 678) instead.)

`FMActivateFonts` (page 1172) Deprecated in Mac OS X v10.4
Activates one or more fonts. (Deprecated. Use `ATSFontActivateFromFileReference` (page 647) instead.)

FMDeactivateFonts (page 1176) Deprecated in Mac OS X v10.4
Deactivates one or more fonts. (Deprecated. Use ATSFontDeactivate (page 651) instead.)

Accessing Font Objects

FMGetFontContainer (page 1179) Deprecated in Mac OS X v10.4
Obtains the file that contains data for a font. (Deprecated. Use ATSFontGetContainer (page 662) instead.)

FMGetFontFormat (page 1185) Deprecated in Mac OS X v10.4
Obtains the format identifier of a font.

FMGetFontGeneration (page 1187) Deprecated in Mac OS X v10.4
Obtains the generation count of a font. (Deprecated. Use ATSFontGetGeneration (page 665) instead.)

FMGetFontTable (page 1188) Deprecated in Mac OS X v10.4
Retrieves all or part of a data table for a font. (Deprecated. Use ATSFontGetTable (page 668) or CTFontCopyTable instead.)

FMGetFontTableDirectory (page 1189) Deprecated in Mac OS X v10.4
Obtains the table directory for a font.

Accessing Font Containers

FMGetFontContainerFromFontFamilyInstance (page 1180) Deprecated in Mac OS X v10.4
Obtains the font container associated with a font family instance. (Deprecated. Use ATSFontGetContainer (page 662) instead.)

FMGetFontFamilyResource (page 1184) Deprecated in Mac OS X v10.4
Obtains the font family resource for a font family. (Deprecated. Use ATSFontGetFontFamilyResource (page 664) instead.)

Accessing Font Family Objects

FMGetFontFamilyFromName (page 1181) Deprecated in Mac OS X v10.4
Returns the font family reference associated with a standard QuickDraw name. (Deprecated. Use ATSFontFamilyFindFromName (page 652) instead.)

FMGetFontFamilyGeneration (page 1182) Deprecated in Mac OS X v10.4
Obtains the generation count of a font family. (Deprecated. Use ATSFontFamilyGetGeneration (page 654) instead.)

FMGetFontFamilyName (page 1183) Deprecated in Mac OS X v10.4
Obtains the font family name associated with a font family reference. (Deprecated. Use ATSFontFamilyGetName (page 654) instead.)

FMGetFontFamilyTextEncoding (page 1185) Deprecated in Mac OS X v10.4
Obtains the text encoding used by a font family. (Deprecated. Use ATSFontFamilyGetEncoding (page 653) instead.)

Enumerating Font Data

`FMCreateFontFamilyInstanceIterator` (page 1173) Deprecated in Mac OS X v10.4
Creates a font family instance iterator that your application can use to access the member fonts associated with a font family.

`FMCreateFontFamilyIterator` (page 1174) Deprecated in Mac OS X v10.4
Creates a font family iterator that your application can use to access font family objects. (Deprecated. Use `ATSFontFamilyIteratorCreate` (page 655) instead.)

`FMCreateFontIterator` (page 1175) Deprecated in Mac OS X v10.4
Creates an iterator that your application can use to access fonts. (Deprecated. Use `ATSFontIteratorCreate` (page 671) instead.)

`FMDisposeFontFamilyInstanceIterator` (page 1176) Deprecated in Mac OS X v10.4
Disposes of a font family instance iterator.

`FMDisposeFontFamilyIterator` (page 1177) Deprecated in Mac OS X v10.4
Disposes of the contents of a font family iterator. (Deprecated. Use `ATSFontFamilyIteratorRelease` (page 658) instead.)

`FMDisposeFontIterator` (page 1177) Deprecated in Mac OS X v10.4
Disposes of a font iterator. (Deprecated. Use `ATSFontIteratorRelease` (page 673) instead.)

`FMGetNextFont` (page 1190) Deprecated in Mac OS X v10.4
Obtains the next font reference. (Deprecated. Use `ATSFontIteratorNext` (page 672) instead.)

`FMGetNextFontFamily` (page 1190) Deprecated in Mac OS X v10.4
Obtains the next font family reference. (Deprecated. Use `ATSFontFamilyIteratorNext` (page 657) instead.)

`FMGetNextFontFamilyInstance` (page 1191) Deprecated in Mac OS X v10.4
Obtains the next instance associated with a font family reference.

`FMResetFontFamilyInstanceIterator` (page 1192) Deprecated in Mac OS X v10.4
Resets the a font family instance iterator to the beginning of the iteration for the specified font family.

`FMResetFontFamilyIterator` (page 1193) Deprecated in Mac OS X v10.4
Resets a font family iterator to the beginning of the iteration. (Deprecated. Use `ATSFontFamilyIteratorReset` (page 658) instead.)

`FMResetFontIterator` (page 1194) Deprecated in Mac OS X v10.4
Resets a font iterator to the beginning of the iteration. (Deprecated. Use `ATSFontIteratorReset` (page 674) instead.)

Converting Font Data

`FMFontGetCGFontRefFromFontFamilyInstance` (page 1178)
Obtains the Quartz font associated with a typeface from a QuickDraw font family.

`FMGetATSFontRefFromFont` (page 1179)
Obtains the ATS font reference associated with a font object.

`FMGetFontFromATSFontRef` (page 1186)
Obtains the font object associated with an ATS font reference.

`FMGetATSFontFamilyRefFromFontFamily` (page 1179) Deprecated in Mac OS X v10.4
Obtains the ATS font family reference associated with a font family object.

`FMGetFontFamilyFromATSFontFamilyRef` (page 1181) Deprecated in Mac OS X v10.4
Obtains the font family associated with an ATS font family reference.

`FMGetFontFamilyInstanceFromFont` (page 1182) Deprecated in Mac OS X v10.4
Finds the font family reference and standard QuickDraw style associated with a font.

`FMGetFontFromFontFamilyInstance` (page 1187) Deprecated in Mac OS X v10.4
Obtains the font reference associated with a standard QuickDraw style and font family. (Deprecated. Use `CTFontCreateWithQuickdrawInstance` instead.)

Getting Font Information

`FetchFontInfo` (page 1171) Deprecated in Mac OS X v10.4
Obtains the information for a specific font. (Deprecated. There is no replacement function.)

`FMSwapFont` (page 1195) Deprecated in Mac OS X v10.4
Returns a pointer to the font output structure for a specified font. (Deprecated. There is no replacement function.)

`FontMetrics` (page 1195) Deprecated in Mac OS X v10.4
Obtains fractional measurements for the font, size, and style specified in the current graphics port. (Deprecated. There is no replacement function.)

`GetFNum` (page 1197) Deprecated in Mac OS X v10.4
Obtains the font family ID for a specified font family name. (Deprecated. Use `ATSFontFamilyFindFromName` (page 652) instead.)

`GetFontName` (page 1198) Deprecated in Mac OS X v10.4
Obtains the name of a font family that has a specified family ID number. (Deprecated. Use `ATSFontFamilyGetName` (page 654) instead.)

`OutlineMetrics` (page 1201) Deprecated in Mac OS X v10.4
Obtains font measurements for a block of text to be drawn in a specified outline font. (Deprecated. There is no replacement function.)

`RealFont` (page 1203) Deprecated in Mac OS X v10.4
Determines whether a font is available or is intended for use in a specified size. (Deprecated. There is no replacement function.)

Working With Outline Fonts

`GetOutlinePreferred` (page 1198) Deprecated in Mac OS X v10.4
Obtains the current preference for whether outline or bitmapped fonts are returned when the Font Manager receives a font request. (Deprecated. There is no replacement function.)

`GetPreserveGlyph` (page 1199) Deprecated in Mac OS X v10.4
Determines whether the Font Manager preserves the shapes of glyphs from outline fonts. (Deprecated. There is no replacement function.)

`IsOutline` (page 1200) Deprecated in Mac OS X v10.4
Determines whether the specified scaling factors will cause the Font Manager to choose an outline font for the current graphics port. (Deprecated. There is no replacement function.)

`SetOutlinePreferred` (page 1206) Deprecated in Mac OS X v10.4
Sets the preference for whether to use bitmapped or outline fonts when both kinds of fonts are available. (Deprecated. There is no replacement function.)

SetPreserveGlyph (page 1206) Deprecated in Mac OS X v10.4
Temporarily changes the default behavior of the Font Manager, so that it does not scale oversized glyphs. (Deprecated. There is no replacement function.)

Working with Antialiased Text

IsAntiAliasedTextEnabled (page 1199) Deprecated in Mac OS X v10.4
Checks whether antialiased text is enabled. (Deprecated. There is no replacement function.)

SetAntiAliasedTextEnabled (page 1204) Deprecated in Mac OS X v10.4
Enables or disables antialiased text for an application. (Deprecated. There is no replacement function.)

Working With Font Measurements and Scaling

QDTextBounds (page 1203) Deprecated in Mac OS X v10.4
Obtains a rectangle that specifies the bounds of QuickDraw text. (Deprecated. There is no replacement function.)

SetFractEnable (page 1204) Deprecated in Mac OS X v10.4
Enables or disables fractional glyph widths. (Deprecated. There is no replacement function.)

SetFScaleDisable (page 1205) Deprecated in Mac OS X v10.4
Enables or disables the computation of font scaling factors by the Font Manager for bitmapped glyphs. (Deprecated. There is no replacement function.)

Using the Current, System, and Application Fonts

GetAppFont (page 1196) Deprecated in Mac OS X v10.4
Returns the font family ID of the current application font. (Deprecated. There is no replacement function.)

GetDefFontSize (page 1197) Deprecated in Mac OS X v10.4
Determines the default size of the system font. (Deprecated. There is no replacement function.)

GetSysFont (page 1199) Deprecated in Mac OS X v10.4
Obtains the font family ID of the current system font. (Deprecated. There is no replacement function.)

Functions

FetchFontInfo

Obtains the information for a specific font. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr FetchFontInfo (
   SInt16 fontID,
   SInt16 fontSize,
   SInt16 fontStyle,
   FontInfo *info
);
```

Parameters

fontID

A signed, 16-bit integer that specifies the font ID of the font whose information you want to obtain.

fontSize

A signed, 16-bit integer that specifies the font size of the font whose information you want to obtain.

fontStyle

A signed, 16-bit integer that specifies the font style of the font whose information you want to obtain.

info

On output, points to a font information structure that contains measurement information (ascent, descent, width, and leading) for the specified font.

Return Value

A result code. See "Font Manager Result Codes" (page 1230).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Fonts.h`

FMActivateFonts

Activates one or more fonts. (Deprecated in Mac OS X v10.4. Use `ATSFontActivateFromFileReference` (page 647) instead.)

```
OSStatus FMActivateFonts (
   const FSSpec *iFontContainer,
   const FMFilter *iFilter,
   void *iRefCon,
   OptionBits iOptions
);
```

Parameters

iFontContainer

A pointer to the file specification of the file that contains the font data you want to activate. You can specify a directory or an individual font file.

iFilter

A pointer to a filter specification. This parameter is currently reserved for future use, so you should pass `NULL`.

iRefCon

An arbitrary 32-bit value specified by your application. This parameter is currently reserved for future use, so you should pass `NULL`.

iOptions

A value that specifies the scope to which the function applies. If you want the Font Manager to make the fonts visible only to your application, use the constant `kFMLocalActivationContext`. If you want the Font Manager to make fonts visible to all applications installed on the system, use the constant `kFMGlobalActivationContext`. See Activation Contexts (page 1224) for more information on these constants.

Return Value
A result code. See "Font Manager Result Codes" (page 1230).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Fonts.h`

FMCreateFontFamilyInstanceIterator

Creates a font family instance iterator that your application can use to access the member fonts associated with a font family. (Deprecated in Mac OS X v10.4.)

```
OSStatus FMCreateFontFamilyInstanceIterator (
   FMFontFamily iFontFamily,
   FMFontFamilyInstanceIterator *ioIterator
);
```

Parameters

iFontFamily

A reference to the font family you want to access.

ioIterator

A pointer to a structure of type `FMFontFamilyInstanceIterator`. On input, pass a pointer to an uninitialized structure. On output, its contents may have been changed and may include references to other data structures allocated by the system to maintain the structure's state. The iterator is positioned before the first member font of the font family. When you no longer need the font family instance iterator, you should call the function `FMDisposeFontFamilyInstanceIterator` to release the auxiliary data and memory allocated by the system.

Return Value
A result code. See "Font Manager Result Codes" (page 1230).

Discussion
A font family instance iterator is an opaque data structure used by the Font Manager to keep track of an iteration over currently active font family instances. A font family instance is a typeface and a size—an entry from the font association table.

When the font family iterator is initialized, it does not yet reference a font family instance. Do not attempt to modify the contents of a font family instance iterator.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Fonts.h`

FMCreateFontFamilyIterator

Creates a font family iterator that your application can use to access font family objects. (Deprecated in Mac OS X v10.4. Use `ATSFontFamilyIteratorCreate` (page 655) instead.)

```
OSStatus FMCreateFontFamilyIterator (
   const FMFilter *iFilter,
   void *iRefCon,
   OptionBits iOptions,
   FMFontFamilyIterator *ioIterator
);
```

Parameters

iFilter

A pointer to a filter specification. Pass `NULL` if you want to access all font family objects within the scope of your iteration. Otherwise, you can use this parameter to restrict the scope of the iteration to the font families that match a generation count or criteria you specify in a custom filter function. Pass the filter selector constant `kFMGenerationFilterSelector` to select a generation filter or the constant `kFMFontFamilyCallbackFilterSelector` to select a custom filter. See `FMFilterSelector` in the ATS Types Reference for more information on these constants.

iRefCon

An arbitrary 32-bit value specified by your application. If you are using a custom filter function, you can use this parameter to pass data to the custom filter function. If you are not using a custom filter function, pass `NULL`.

iOptions

A value that specifies the scope to which the font family iterator applies. If you want the Font Manager to apply the font family iterator only to the fonts accessible from your application use the `kFMLocalIterationScope` constant. If you want the Font Manager to apply the font family iterator to all fonts registered with the system use the constant `kFMGlobalIterationScope`. See Activation Contexts (page 1224) for more information on these constants.

ioIterator

A pointer to a structure of type `FMFontFamilyIterator`. On input, pass a pointer to an uninitialized structure. On output, the structure's contents may have been changed and may include references to other data structures allocated by the system to maintain the structure's state. When you no longer need the font family iterator, you should call the function `FMDisposeFontFamilyIterator` to release the auxiliary data and memory allocated by the system.

Return Value
A result code. See "Font Manager Result Codes" (page 1230).

Discussion
A font family iterator is an opaque data structure used by the Font Manager to keep track of an iteration over currently active font families. When the font family iterator is initialized, it does not yet reference a font family. Do not attempt to modify the contents of a font family iterator.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Fonts.h`

FMCreateFontIterator

Creates an iterator that your application can use to access fonts. (Deprecated in Mac OS X v10.4. Use `ATSFontIteratorCreate` (page 671) instead.)

```
OSStatus FMCreateFontIterator (
   const FMFilter *iFilter,
   void *iRefCon,
   OptionBits iOptions,
   FMFontIterator *ioIterator
);
```

Parameters

iFilter

A pointer to font filter specification. Pass `NULL` if you want to access all font objects within the scope of your iteration. Otherwise, you can use this parameter to restrict the scope of the iteration to font information that matches a technology, font container, or criteria you specify in a custom filter function. Pass the filter selector constant `kFMFontTechnologyFilterSelector` to select a font technology filter, the constant `kFMFontContainerFilterSelector` to select a font container filter, or the constant `kFMFontCallbackFilterSelector` to select a custom filter. See `FMFilterSelector` in the ATS Types Reference for more information on these constants.

iRefCon

An arbitrary 32-bit value specified by your application. If you are using a custom filter function, you can use this parameter to pass data to the custom filter function. If are not using a custom filter function, pass `NULL`.

iOptions

A value that specifies the scope to which the font iterator applies. If you want the Font Manager to apply the font iterator only to the fonts accessible from your application use the `kFMLocalIterationScope` constant. If you want the Font Manager to apply the font iterator to all fonts registered with the system use the constants `kFMGlobalIterationScope`. See Activation Contexts (page 1224) for more information on these constants.

ioIterator

A pointer to a structure of type `FMFontIterator`. On input, pass a pointer to an uninitialized structure. On output, the structure's contents may have been changed and may include references to other data structures allocated by the system to maintain the structure's state. When you no longer need the font iterator, you should call the function `FMDisposeFontIterator` to release the auxiliary data and memory allocated by the system.

Return Value
A result code. See "Font Manager Result Codes" (page 1230).

Discussion
A font iterator is an opaque structure used by the Font Manager to maintain font information in the context of the current application process. When the font iterator is initialized, it is not yet positioned on a font object. You should not attempt to modify the contents of a font iterator.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`Fonts.h`

FMDeactivateFonts

Deactivates one or more fonts. (Deprecated in Mac OS X v10.4. Use `ATSFontDeactivate` (page 651) instead.)

```
OSStatus FMDeactivateFonts (
   const FSSpec *iFontContainer,
   const FMFilter *iFilter,
   void *iRefCon,
   OptionBits iOptions
);
```

Parameters

iFontContainer

A pointer to the file specification of the file that contains the font data you want to deactivate. You can specify a directory or an individual font file.

iFilter

A pointer to a filter specification. This parameter is currently reserved for future use, so you should pass `NULL`.

iRefCon

An arbitrary 32-bit value specified by your application. This parameter is currently reserved for future use, so you should pass `NULL`.

iOptions

A value that specifies the scope to which the function applies. This parameter is currently reserved for future use, so you should pass `NULL`.

Return Value
A result code. See "Font Manager Result Codes" (page 1230).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Fonts.h`

FMDisposeFontFamilyInstanceIterator

Disposes of a font family instance iterator. (Deprecated in Mac OS X v10.4.)

```
OSStatus FMDisposeFontFamilyInstanceIterator (
   FMFontFamilyInstanceIterator *ioIterator
);
```

Parameters

ioIterator

A pointer to a font family instance iterator you created with the function `FMCreateFontFamilyInstanceIterator` (page 1173). If you try to use the font family instance iterator after disposing of its contents through this function, the Font Manager returns an error code to your application.

Return Value

A result code. See "Font Manager Result Codes" (page 1230).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Fonts.h`

FMDisposeFontFamilyIterator

Disposes of the contents of a font family iterator. (Deprecated in Mac OS X v10.4. Use `ATSFontFamilyIteratorRelease` (page 658) instead.)

```
OSStatus FMDisposeFontFamilyIterator (
   FMFontFamilyIterator *ioIterator
);
```

Parameters

ioIterator

A pointer to a font family iterator you created with the function `FMCreateFontFamilyIterator` (page 1174). If you try to use the font family iterator after disposing of its contents through this function, the Font Manager returns an error code to your application.

Return Value

A result code. See "Font Manager Result Codes" (page 1230).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Fonts.h`

FMDisposeFontIterator

Disposes of a font iterator. (Deprecated in Mac OS X v10.4. Use `ATSFontIteratorRelease` (page 673) instead.)

```
OSStatus FMDisposeFontIterator (
   FMFontIterator *ioIterator
);
```

Parameters

ioIterator

A pointer to a font iterator you created with the function `FMCreateFontIterator` (page 1175). If you try to use the font iterator after disposing of its contents through this function, the Font Manager returns an error code to your application.

Return Value

A result code. See "Font Manager Result Codes" (page 1230).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Fonts.h`

FMFontGetCGFontRefFromFontFamilyInstance

Obtains the Quartz font associated with a typeface from a QuickDraw font family.

```
OSStatus FMFontGetCGFontRefFromFontFamilyInstance (
   FMFontFamily iFontFamily,
   FMFontStyle iStyle,
   CGFontRef *oFont,
   FMFontStyle *oStyle
);
```

Parameters

iFontFamily

A QuickDraw font family.

iStyle

A QuickDraw font style.

oFont

A pointer to a Quartz font reference. On output, points to the Quartz font reference for the specified font family and style. You are responsible for allocating the memory for the Quartz font reference.

oStyle

On output, a pointer to an intrinsic font style. If a font object isn't found that matches the font family reference and font style you specify, the function returns the QuickDraw style that matches most closely.

Return Value

A result code. See "Font Manager Result Codes" (page 1230). If a font reference and intrinsic style are not found, the function returns a value of `kFMInvalidFontErr`.

Availability

Available in Mac OS X v10.4 and later.

Not available to 64-bit applications.

Declared In
`Fonts.h`

FMGetATSFontFamilyRefFromFontFamily

Obtains the ATS font family reference associated with a font family object. (Deprecated in Mac OS X v10.4.)

```
ATSFontFamilyRef FMGetATSFontFamilyRefFromFontFamily (
   FMFontFamily iFamily
);
```

Parameters

iFamily
A font family reference.

Return Value
The `ATSFontFamilyRef` associated with the font family object.

Availability
Available in Mac OS X v10.1 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Fonts.h`

FMGetATSFontRefFromFont

Obtains the ATS font reference associated with a font object.

```
ATSFontRef FMGetATSFontRefFromFont (
   FMFont iFont
);
```

Parameters

iFont
A font reference.

Return Value
The `ATSFontRef` associated with the font object.

Availability
Available in Mac OS X v10.1 and later.
Not available to 64-bit applications.

Declared In
`Fonts.h`

FMGetFontContainer

Obtains the file that contains data for a font. (Deprecated in Mac OS X v10.4. Use `ATSFontGetContainer` (page 662) instead.)

```
OSStatus FMGetFontContainer (
   FMFont iFont,
   FSSpec *oFontContainer
);
```

Parameters

iFont

A font reference.

oFontContainer

On output, a pointer to the file specification of the file that contains the font data.

Return Value
A result code. See "Font Manager Result Codes" (page 1230).

Discussion
You can pass the file specification returned by this function to the Resource Manager or File Manager to obtain the actual font data. However, if the font is an LWFN-class font, the outline data is located in a separate file from the font suitcase. The function `FMGetFontContainer` obtains the font suitcase. Your application is responsible for finding the individual outline files.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Fonts.h`

FMGetFontContainerFromFontFamilyInstance

Obtains the font container associated with a font family instance. (Deprecated in Mac OS X v10.4. Use `ATSFontGetContainer` (page 662) instead.)

```
OSStatus FMGetFontContainerFromFontFamilyInstance (
   FMFontFamily iFontFamily,
   FMFontStyle iStyle,
   FMFontSize iFontSize,
   FSSpec *oFontContainer
);
```

Parameters

iFontFamily

A font family reference for the font family whose container you want to obtain. You must pass a valid font family.

iStyle

The font style of the font family whose container you want to obtain. You must pass a valid font style.

iFontSize

The font size of the font family whose container you want to obtain. You must pass a valid font size.

oFontContainer

On output, a pointer to a file specification that specifies the name and location of the font container.

Return Value
A result code. See "Font Manager Result Codes" (page 1230).

Availability
Available in Mac OS X v10.1 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Fonts.h`

FMGetFontFamilyFromATSFontFamilyRef

Obtains the font family associated with an ATS font family reference. (Deprecated in Mac OS X v10.4.)

```
FMFontFamily FMGetFontFamilyFromATSFontFamilyRef (
   ATSFontFamilyRef iFamily
);
```

Parameters

iFamily
An ATS font family reference.

Return Value
The font family reference associated with the specified ATS font family reference.

Availability
Available in Mac OS X v10.1 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Fonts.h`

FMGetFontFamilyFromName

Returns the font family reference associated with a standard QuickDraw name. (Deprecated in Mac OS X v10.4. Use `ATSFontFamilyFindFromName` (page 652) instead.)

```
FMFontFamily FMGetFontFamilyFromName (
   ConstStr255Param iName
);
```

Parameters

iName
A QuickDraw font family name.

Return Value
A font family reference. The function returns `kInvalidFontFamily` if it cannot find a matching font family. See the ATS Types documentation for a description of the `FMFontFamily` data type.

Discussion
This function is a replacement for the `GetFNum` (page 1197) function. You should use the function `FMGetFontFamilyFromName` instead of the function `GetFNum` to assure your application supports font formats other than the resource fork TrueType and PostScript Type 1 fonts.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Fonts.h`

FMGetFontFamilyGeneration

Obtains the generation count of a font family. (Deprecated in Mac OS X v10.4. Use `ATSFontFamilyGetGeneration` (page 654) instead.)

```
OSStatus FMGetFontFamilyGeneration (
   FMFontFamily iFontFamily,
   FMGeneration *oGeneration
);
```

Parameters

iFontFamily
A font family reference.

oGeneration
On output, a pointer to the generation count for the font family associated with the font family reference.

Return Value
A result code. See "Font Manager Result Codes" (page 1230).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Fonts.h`

FMGetFontFamilyInstanceFromFont

Finds the font family reference and standard QuickDraw style associated with a font. (Deprecated in Mac OS X v10.4.)

```
OSStatus FMGetFontFamilyInstanceFromFont (
   FMFont iFont,
   FMFontFamily *oFontFamily,
   FMFontStyle *oStyle
);
```

Parameters

iFont
A font reference.

oFontFamily

A pointer to a font family reference. On output, points to the font family reference associated with the specified font. You are responsible for allocating the memory for the font family reference.

oStyle

A pointer to a font style. On output, points to the font style associated with the specified font. You are responsible for allocating the memory for the font style.

Return Value
A result code. See "Font Manager Result Codes" (page 1230).

Discussion
A font can be a member of more than one font family. This means if you call the function `FMGetFontFromFontFamilyInstance` (page 1187) and then call the function `FMGetFontFamilyInstanceFromFont`, you will not necessarily get the font family reference you supplied when you called `FMGetFontFromFontFamilyInstance`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Fonts.h`

FMGetFontFamilyName

Obtains the font family name associated with a font family reference. (Deprecated in Mac OS X v10.4. Use `ATSFontFamilyGetName` (page 654) instead.)

```
OSStatus FMGetFontFamilyName (
   FMFontFamily iFontFamily,
   Str255 oName
);
```

Parameters

iFontFamily

A font family reference.

oName

On output, the string contains the QuickDraw font family name. If the function does not find a name, it returns an empty string and a result code of `kFMInvalidFontFamilyErr`.

Return Value
A result code. See "Font Manager Result Codes" (page 1230).

Discussion
This function is a replacement for the `GetFontName` (page 1198) function. You should use the function `FMGetFontFamilyName` instead of the function `GetFontName` to assure your application supports font formats other than the resource fork TrueType and PostScript Type 1 fonts.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Fonts.h`

FMGetFontFamilyResource

Obtains the font family resource for a font family. (Deprecated in Mac OS X v10.4. Use `ATSFontGetFontFamilyResource` (page 664) instead.)

```
OSStatus FMGetFontFamilyResource (
   FMFontFamily iFontFamily,
   FMFontStyle iFontStyle,
   FMFontSize iFontSize,
   ByteCount iBufferSize,
   void *ioBuffer,
   ByteCount *oSize
);
```

Parameters

iFontFamily
A value of type `FMFontFamily` that specifies the font family whose resource you want to obtain. You must pass a valid font family.

iFontStyle
A value of type `FMFontStyle` that specifies the font style of the font family whose resource you want to obtain. You must pass a valid font style.

iFontSize
A value of type `FMFontSize` that specifies the font size of the font family whose resource you want to obtain. You must pass a valid font size.

iBufferSize
The size of the buffer (`ioBuffer`).

ioBuffer
A pointer to the buffer used to store a copy of the font family resource. On input, pass `NULL` if you want to obtain only the length of the font family resource, not its contents.

oSize
On output, the actual size of the buffer.

Return Value
A result code. See "Font Manager Result Codes" (page 1230).

Discussion
You should call the function `FMGetFontFamilyResource` twice. First, to get the length of the font family resource. Then after you allocate a buffer (`ioBuffer`) of the appropriate size, call the function a second time to obtain the contents of the font family resource.

Availability
Available in Mac OS X v10.1 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Fonts.h`

FMGetFontFamilyTextEncoding

Obtains the text encoding used by a font family. (Deprecated in Mac OS X v10.4. Use `ATSFontFamilyGetEncoding` (page 653) instead.)

```
OSStatus FMGetFontFamilyTextEncoding (
   FMFontFamily iFontFamily,
   TextEncoding *oTextEncoding
);
```

Parameters

iFontFamily

A font family reference.

oTextEncoding

On output, a pointer to the text encoding used by the font family associated with the font family reference.

Return Value

A result code. See "Font Manager Result Codes" (page 1230).

Discussion

This function is a replacement for the Script Manager function `FontToScript`. You should use the function `FMGetFontFamilyTextEncoding` instead of the function `FontToScript` to ensure your application supports font formats other than the resource fork TrueType and PostScript Type 1 fonts. Unlike the `FontToScript` function, the state of the font force flag is ignored and the script system of the font family is not mapped to zero even if the script system is disabled in the current application process.

Once you have obtained the text encoding, you can use Text Encoding Converter Manager function `RevertTextEncodingToScriptInfo` to extract the script as follows:

```
status = FMGetFontFamilyTextEncoding (myFontFamily, &myTextEncoding)

status = RevertTextEncodingToScriptInfo (myTextEncoding, &myScriptCode);
```

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Fonts.h`

FMGetFontFormat

Obtains the format identifier of a font. (Deprecated in Mac OS X v10.4.)

```
OSStatus FMGetFontFormat (
   FMFont iFont,
   FourCharCode *oFormat
);
```

Parameters

iFont

A font reference.

oFormat

On output, a pointer to a four-character-code that represents the format identifier of the font. See the discussion that follows for information on format identifiers.

Return Value
A result code. See "Font Manager Result Codes" (page 1230).

Discussion
A format identifier is a four-character-code, assigned to a font by a font vendor, that identifies the format of a font. Some of the identifiers currently supported in the Mac OS are:

- `'true'` TrueType fonts use the 32-bit hexadecimal value 0x00010000.
- `'LWFN'` PostScript Type 1 fonts ("LaserWriter Font") consist of two parts: a `'FOND'` resource (contained in a font or font suitcase resource file) whose style mapping table references PostScript font data for each typeface (style), stored in separate file. The separate data files have names derived from the PostScript name of the typeface.
- `'typ1'` PostScript Type 1 fonts are housed in packages that have an `'sfnt'` format (OpenType).
- `'OTTO'` PostScript compact font format (CFF) font data is housed in a package that has an `'sfnt'` format (OpenType).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Fonts.h`

FMGetFontFromATSFontRef

Obtains the font object associated with an ATS font reference.

```
FMFont FMGetFontFromATSFontRef (
   ATSFontRef iFont
);
```

Parameters

iFont

An ATS font reference.

Return Value
The font reference associated with the specified ATS font reference.

Availability
Available in Mac OS X v10.1 and later.
Not available to 64-bit applications.

Declared In
`Fonts.h`

FMGetFontFromFontFamilyInstance

Obtains the font reference associated with a standard QuickDraw style and font family. (Deprecated in Mac OS X v10.4. Use `CTFontCreateWithQuickdrawInstance` instead.)

```
OSStatus FMGetFontFromFontFamilyInstance (
   FMFontFamily iFontFamily,
   FMFontStyle iStyle,
   FMFont *oFont,
   FMFontStyle *oIntrinsicStyle
);
```

Parameters

iFontFamily

A font family reference.

iStyle

A font style.

oFont

A pointer to a font reference. On output, points to the font reference for the specified font family and style. You are responsible for allocating the memory for the font reference.

oIntrinsicStyle

On output, a pointer to an intrinsic font style. If a font object isn't found that matches the font family reference and font style you specify, the function returns the QuickDraw style that matches most closely.

Return Value

A result code. See "Font Manager Result Codes" (page 1230). If a font reference and intrinsic style are not found, the function returns a value of `kFMInvalidFontErr`.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Fonts.h`

FMGetFontGeneration

Obtains the generation count of a font. (Deprecated in Mac OS X v10.4. Use `ATSFontGetGeneration` (page 665) instead.)

```
OSStatus FMGetFontGeneration (
   FMFont iFont,
   FMGeneration *oGeneration
);
```

Parameters

iFont

A font reference.

oGeneration

On output, a pointer to a value that specifies the generation count of the font.

Return Value
A result code. See "Font Manager Result Codes" (page 1230).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Fonts.h`

FMGetFontTable

Retrieves all or part of a data table for a font. (Deprecated in Mac OS X v10.4. Use `ATSFontGetTable` (page 668) or `CTFontCopyTable` instead.)

```
OSStatus FMGetFontTable (
   FMFont iFont,
   FourCharCode iTag,
   ByteOffset iOffset,
   ByteCount iLength,
   void *iBuffer,
   ByteCount *oActualLength
);
```

Parameters

iFont
A font reference.

iTag
A tag that identifies the data table for a font.

iOffset
An offset to font table data you want to retrieve. The offset is relative to the beginning of the data table and is zero-based.

iLength
The size of the data buffer (`ioBuffer`) you allocate.

iBuffer
A pointer to the buffer used to store a copy of the font table. On input, pass `NULL` if you want to obtain only the length of the table, not its contents.

oActualLength
On output, the actual length of the font table.

Return Value
A result code. See "Font Manager Result Codes" (page 1230).

Discussion
You should call the function `FMGetFontTable` twice. First, call it to retrieve the length of the font table. Then, after you've allocated space for the `iBuffer` parameter, call the function a second time to obtain the contents of the font table.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`Fonts.h`

FMGetFontTableDirectory

Obtains the table directory for a font. (Deprecated in Mac OS X v10.4.)

```
OSStatus FMGetFontTableDirectory (
   FMFont iFont,
   ByteCount iLength,
   void *iBuffer,
   ByteCount *oActualLength
);
```

Parameters

iFont
A font reference.

iLength
The number of bytes in the buffer used to store a copy of the font table directory associated with the font.

iBuffer
A pointer to the buffer used to store a copy of the font table directory. On input, pass `NULL` if you want to obtain only the length of the table directory, not its contents.

oActualLength
On output, the length of the font table directory.

Return Value
A result code. See "Font Manager Result Codes" (page 1230).

Discussion
You should call the function `FMGetFontTableDirectory` twice. First, call it to retrieve the length of the font table directory. Then, after you've allocated space for the `iBuffer` parameter, call the function a second time to obtain the contents of the table directory.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Fonts.h`

FMGetGeneration

Retrieves the value of the generation count. (Deprecated in Mac OS X v10.5. Use `ATSGetGeneration` (page 678) instead.)

```
FMGeneration FMGetGeneration (
   void
);
```

Return Value
The generation count. See the ATS Types documentation for a description of the `FMGeneration` data type.

Discussion
Any operation that adds, deletes, or modifies one or more font families or fonts triggers an update of the global generation count. You can use this function in conjunction with the iteration functions to identify changes made to the font database.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Fonts.h`

FMGetNextFont

Obtains the next font reference. (Deprecated in Mac OS X v10.4. Use `ATSFontIteratorNext` (page 672) instead.)

```
OSStatus FMGetNextFont (
   FMFontIterator *ioIterator,
   FMFont *oFont
);
```

Parameters

ioIterator
A pointer to a font iterator you created using the function `FMCreateFontIterator`.

oFont
A pointer to a font reference. On output, points to the next font reference obtained by the font iterator. You are responsible for allocating the memory for the font reference.

Return Value
A result code. See "Font Manager Result Codes" (page 1230). If there are no more font objects to get, the function `FMGetNextFont` returns the result code `kFMIterationCompleted`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Fonts.h`

FMGetNextFontFamily

Obtains the next font family reference. (Deprecated in Mac OS X v10.4. Use `ATSFontFamilyIteratorNext` (page 657) instead.)

```
OSStatus FMGetNextFontFamily (
   FMFontFamilyIterator *ioIterator,
   FMFontFamily *oFontFamily
);
```

Parameters

ioIterator

A pointer to a font family iterator you created using the function `FMCreateFontFamilyIterator`.

oFontFamily

A pointer to a font family reference. On output, points to the font family reference obtained by the iterator. You are responsible for allocating memory for the font family reference.

Return Value

A result code. See "Font Manager Result Codes" (page 1230). If there are no more font family references to get, the function `FMGetNextFontFamily` returns the result code `kFMIterationCompleted`.

Discussion

If any changes are made to the font database while you are using the font family iterator, the iterator is invalidated and the function `FMGetNextFontFamily` returns the error `kFMIteratorScopeModified`. To remedy this error, your application must either restart or cancel the enumeration by calling the `FMResetFontFamilyIterator` (page 1193) or the `FMDisposeFontFamilyIterator` (page 1177) functions.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Fonts.h`

FMGetNextFontFamilyInstance

Obtains the next instance associated with a font family reference. (Deprecated in Mac OS X v10.4.)

```
OSStatus FMGetNextFontFamilyInstance (
   FMFontFamilyInstanceIterator *ioIterator,
   FMFont *oFont,
   FMFontStyle *oStyle,
   FMFontSize *oSize
);
```

Parameters

ioIterator

A pointer to a font family instance iterator you created with the function `FMCreateFontFamilyInstanceIterator` (page 1173).

oFont

A pointer to a font reference. On output, points to the font reference obtained by the iterator. You are responsible for allocating the memory for the font reference.

oStyle

A pointer to a font style. On output, points to the font style obtained by the iterator. You are responsible for allocating the memory for the font style.

oSize

A pointer to a font size. On output, points to the font size obtained by the iterator. You are responsible for allocating the memory for the font size.

Return Value
A result code. See "Font Manager Result Codes" (page 1230). If there is no more font family information to retrieve, the function `FMGetNextFontFamlyInstance` returns the status code `kFMIterationCompleted`.

Discussion
Instances are not necessarily retrieved in the order they are listed in a Font Association Table.

If any changes are made to the font database while your application is using the font family instance iterator, the iterator is invalidated and the function `FMGetNextFontFamilyInstance` (page 1191) returns the error `kFMIteratorScopeModified`. To remedy this error, your application must either call the `FMResetFontFamilyInstanceIterator` (page 1192) or the `FMDisposeFontFamilyInstanceIterator` (page 1176) functions.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Fonts.h`

FMResetFontFamilyInstanceIterator

Resets the a font family instance iterator to the beginning of the iteration for the specified font family. (Deprecated in Mac OS X v10.4.)

```
OSStatus FMResetFontFamilyInstanceIterator (
   FMFontFamily iFontFamily,
   FMFontFamilyInstanceIterator *ioIterator
);
```

Parameters

iFontFamily

A font family reference.

ioIterator

A pointer to a font family instance iterator you created with the function `FMCreateFontFamilyInstanceIterator`.

Return Value
A result code. See "Font Manager Result Codes" (page 1230).

Discussion
Once you have created a font family instance iterator, you can reuse it by calling the function `FMResetFontFamilyInstanceIterator`. This function sets the `iFontFamily` parameter to the new font family object you specify, and repositions the iterator so it is ready to get the first font family instance when you call the function `FMGetNextFontFamilyInstance` (page 1191).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`Fonts.h`

FMResetFontFamilyIterator

Resets a font family iterator to the beginning of the iteration. (Deprecated in Mac OS X v10.4. Use `ATSFontFamilyIteratorReset` (page 658) instead.)

```
OSStatus FMResetFontFamilyIterator (
   const FMFilter *iFilter,
   void *iRefCon,
   OptionBits iOptions,
   FMFontFamilyIterator *ioIterator
);
```

Parameters

iFilter

A pointer to a filter specification. Pass `NULL` if you want to access all font family objects within the scope of your iteration. Otherwise, you can use this parameter to restrict the scope of the iteration to the font families that match a generation count or criteria you specify in a custom filter function.

iRefCon

An arbitrary 32-bit value specified by your application. If you are using a custom filter function, you can use this parameter to pass data to the custom filter function. If you are not using a custom filter function, pass `NULL`.

iOptions

A value that specifies the scope to which the font family iterator applies. If you want the Font Manager to apply the font family iterator only to the fonts accessible from your application use the `kFMLocalIterationScope` constant. If you want the Font Manager to apply the font family iterator to all fonts registered with the system use the constant `kFMGlobalIterationScope`.

iOIterator

A pointer to a font family iterator you created with the function `FMCreateFontFamilyIterator`. On output, the font family iterator is reset.

Return Value
A result code. See "Font Manager Result Codes" (page 1230).

Discussion
Once you have created a font family iterator, you can reuse it by calling the function `FMResetFontFamilyIterator` (page 1193). This function sets the parameters to the new values you specify, and repositions the iterator so it is ready to get the first font family reference when you call the function `FMGetNextFontFamily` (page 1190).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Fonts.h`

FMResetFontIterator

Resets a font iterator to the beginning of the iteration. (Deprecated in Mac OS X v10.4. Use `ATSFontIteratorReset` (page 674) instead.)

```
OSStatus FMResetFontIterator (
   const FMFilter *iFilter,
   void *iRefCon,
   OptionBits iOptions,
   FMFontIterator *ioIterator
);
```

Parameters

iFilter

A pointer to font filter specification. Pass `NULL` if you want to access all font objects within the scope of your iteration. Otherwise, you can use this parameter to restrict the scope of the iteration to font information that matches a technology, font container, or criteria you specify in a custom filter function. Pass the filter selector constant `kFMFontTechnologyFilterSelector` to select a font technology filter, the constant `kFMFontContainerFilterSelector` to select a font container filter, or the constant `kFMFontCallbackFilterSelector` to select a custom filter. See `FMFilterSelector` in the ATS Types Reference for more information on these constants.

iRefCon

An arbitrary 32-bit value specified by your application. If you are using a custom filter function, you can use this parameter to pass data to the custom filter function. If are not using a custom filter function, pass `NULL`.

iOptions

A value that specifies the scope to which the font iterator applies. If you want the Font Manager to apply the font iterator only to the fonts accessible from your application use the `kFMLocalIterationScope` constant. If you want the Font Manager to apply the font iterator to all fonts registered with the system use the constant `kFMGlobalIterationScope`.

ioIterator

A pointer to a font iterator you created with the function `FMCreateFontIterator` (page 1175). On output, the font iterator is not positioned on a font object, and any information about font objects that were returned previously in the font iterator is no longer available.

Return Value

A result code. See "Font Manager Result Codes" (page 1230).

Discussion

Once you have created a font iterator, you can reuse it by calling the function `FMResetFontIterator` (page 1194). This function sets the parameters to the new values you specify, and repositions the iterator so it is ready to get the first font object when you call the function `FMGetNextFont` (page 1190).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Fonts.h`

FMSwapFont

Returns a pointer to the font output structure for a specified font. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
FMOutPtr FMSwapFont (
   const FMInput *inRec
);
```

Parameters

inRec

A pointer to the font input structure for which you want to obtain font output information. A font input structure contains the font family ID, the style requested, scaling factors, and other information that specifies the characteristics of the font that is requested.

Return Value

A pointer to a font output structure (`FMOutput`). The font output structure contains a handle to the font resource for the specified input font, along with information about the font, such as the ascent, descent, and leading measurements.

Discussion

The function `FMSwapFont` is typically called by QuickDraw and other parts of the system software to access font handles. QuickDraw calls the `FMSwapFont` function every time a QuickDraw text function is used.

In most cases you don't need to call this function. If you want to call the `FMSwapFont` function to get a handle to a font resource or information about a font, you must first create a font input structure and fill it with the appropriate information. You can use the pointer returned by `FMSwapFont` to access the font output structure. You cannot assume that the font resource pointed to by the `fontHandle` field of the font output structure returned by this function is of any particular type, such as `'NFNT'` or `'sfnt'`. If you need to access specific information in the font resource, call the Resource Manager function `GetResInfo` with the handle returned in the font output structure to determine the font resource type.

The pointer to the font output structure returned by the function `FMSwapFont` points to a structure allocated in low memory by the Font Manager. The same structure is reused for each call made to `FMSwapFont`. Do not free the memory allocated for this structure.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Fonts.h`

FontMetrics

Obtains fractional measurements for the font, size, and style specified in the current graphics port. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
void FontMetrics (
   FMetricRecPtr theMetrics
);
```

Parameters

theMetrics

A pointer to a font metrics structure. On output, the structure contains the font measurement information in fractional values.

Discussion

The `FontMetrics` function obtains measurements for the ascent, descent, leading, and width of the largest glyph in the font for the font, size, and style specified in the current graphics port.

The font metrics structure (of data type `FMetricRec`) contains a handle to the global width table, which in turn contains a handle to the associated font family resource for the current font (the font in the current graphics port). It also contains the values of four measurements for the current font.

The `FontMetrics` function is similar to the QuickDraw function `GetFontInfo` except that `FontMetrics` returns fractional values for greater accuracy in high-resolution printing. The `FontMetrics` function also does not take into account any additional widths that are added by QuickDraw when it applies styles to the glyphs in a font.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Fonts.h`

GetAppFont

Returns the font family ID of the current application font. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
short GetAppFont (
   void
);
```

Return Value

The font family ID of the current application font. This is the font family ID that has been mapped to 1 by the system software.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Fonts.h`

GetDefFontSize

Determines the default size of the system font. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
short GetDefFontSize (
   void
);
```

Return Value
The the default font size of the system font.

Discussion
You can determine the preferred size for either the system font or the application font of any enabled script system by calling the Script Manager function `GetScriptManagerVariable`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Fonts.h`

GetFNum

Obtains the font family ID for a specified font family name. (Deprecated in Mac OS X v10.4. Use `ATSFontFamilyFindFromName` (page 652) instead.)

Not recommended.

```
void GetFNum (
   ConstStr255Param name,
   short *familyID
);
```

Parameters

name
The font family name.

familyID
On output, a pointer to the font family ID for the font family specified in `name`. If the font specified in the parameter `name` does not exist, the font family ID contains 0.

Carbon Porting Notes

You should use the function `FMGetFontFamilyFromName` instead of the function `GetFNum`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
Fonts.h

GetFontName

Obtains the name of a font family that has a specified family ID number. (Deprecated in Mac OS X v10.4. Use ATSFontFamilyGetName (page 654) instead.)

Not recommended.

```
void GetFontName (
   short familyID,
   Str255 name
);
```

Parameters

familyID
The font family ID.

name
On output, this parameter contains the font family name for the font family specified in familyID. If the font specified in the familyID parameter does not exist, name contains an empty string.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
Fonts.h

GetOutlinePreferred

Obtains the current preference for whether outline or bitmapped fonts are returned when the Font Manager receives a font request. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
Boolean GetOutlinePreferred (
   void
);
```

Return Value
The value of the Font Manager's current preference for outline or bitmapped fonts. If GetOutlinePreferred returns TRUE, then the Font Manager will return an outline font when both an outline font and a bitmapped font are available for a particular request. If GetOutlinePreferred returns FALSE, then the Font Manager will return the bitmapped font when both types are available. See the Debugger Services documentation for a description of the Boolean data type.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
Fonts.h

GetPreserveGlyph

Determines whether the Font Manager preserves the shapes of glyphs from outline fonts. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
Boolean GetPreserveGlyph (
   void
);
```

Return Value
A `Boolean` value that indicates whether the Font Manager preserves the shapes of glyphs from outline fonts. Your application can set the value of this variable with the `SetPreserveGlyph` function. If `GetPreserveGlyph` returns `TRUE`, the Font Manager preserves glyph shapes; if `GetPreserveGlyph` returns `FALSE`, then the Font Manager scales glyphs to fit between the ascent and descent lines for the font in use.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Fonts.h`

GetSysFont

Obtains the font family ID of the current system font. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
short GetSysFont (
   void
);
```

Return Value
The current value of the font family ID of the current system font. This is the font family ID that has been mapped to 0 by the system software.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Fonts.h`

IsAntiAliasedTextEnabled

Checks whether antialiased text is enabled. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
Boolean IsAntiAliasedTextEnabled (
   SInt16 *oMinFontSize
);
```

Parameters

oMinFontSize

On output, points to the minimum font size for which antialiasing is enabled.

Return Value

Returns `true` if antialiased text is enabled; `false` otherwise.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Fonts.h`

IsOutline

Determines whether the specified scaling factors will cause the Font Manager to choose an outline font for the current graphics port. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
Boolean IsOutline (
   Point numer,
   Point denom
);
```

Parameters

numer

The numerators of the vertical and horizontal scaling factors. The `numer` parameter is of type `Point`, and contains two fields: `h` (the numerator of the ratio for horizontal scaling) and `v` (the numerator of the ratio for vertical scaling).

denom

The denominators of the vertical and horizontal scaling factors. The `denom` parameter is of type `Point`, and contains two fields: `h` (the denominator of the ratio for horizontal scaling) and `v` (the denominator of the ratio for vertical scaling).

Return Value

Returns `TRUE` if the Font Manager will choose an outline font for the current graphics port.

Discussion

The Font Manager uses the font scaling factors specified in the `numer` and `denom` parameters as well as the current preference (as set by the `SetOutlinePreferred` function) as criteria to choose which font to use.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Fonts.h`

OutlineMetrics

Obtains font measurements for a block of text to be drawn in a specified outline font. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSErr OutlineMetrics (
   short byteCount,
   const void *textPtr,
   Point numer,
   Point denom,
   short *yMax,
   short *yMin,
   FixedPtr awArray,
   FixedPtr lsbArray,
   RectPtr boundsArray
);
```

Parameters

byteCount

The number of bytes in the block of text that you want measured.

textPtr

A pointer to the block of text that for which you want to obtain font measurements.

numer

The numerators of the vertical and horizontal scaling factors. The `numer` parameter is of type `Point`, and contains two fields: `h` (the numerator of the ratio for horizontal scaling) and `v` (the numerator of the ratio for vertical scaling). The Font Manager applies these scaling factors to the current font when calculating the measurements for glyphs in the block of text.

denom

The denominators of the vertical and horizontal scaling factors. The `denom` parameter is of type `Point`, and contains two fields: `h` (the denominator of the ratio for horizontal scaling) and `v` (the denominator of the ratio for vertical scaling). The Font Manager applies these scaling factors to the current font when calculating the measurements for glyphs in the block of text.

yMax

On output, a pointer to the maximum y-value for the text. Pass `NULL` in this parameter if you don't want this value returned.

yMin

On output, a pointer to the minimum y-value for the text. Pass `NULL` in this parameter if you don't want this value returned.

awArray

A pointer to an array. On output the array is filled with the advance width measurements for the glyphs being measured. These measurements are in pixels, based on the point size and font scaling factors of the current font. There is an entry in this array for each glyph that is being measured.

The `awArray` parameter is of type `FixedPtr`. The `FixedPtr` data type is a pointer to an array, and each entry in the array is of type `Fixed`, which is 4 bytes in length. Multiply `byteCount` by 4 to calculate the memory you need in bytes.

If the `FractEnable` global variable has been set to `TRUE` through the `SetFractEnable` function, the values in `awArray` have fractional character widths. If `FractEnable` has been set to `FALSE`, the Font Manager returns integer values for the advance widths, with 0 in the decimal part of the values.

lsbArray

A pointer to an array. On output the array is filled with the left-side bearing measurements for the glyphs being measured. The measurements are in pixels, based on the point size of the current font. There is an entry in this array for each glyph that is being measured.

The `lsbArray` parameter is of type `FixedPtr`. The `FixedPtr` data type is a pointer to an array, and each entry in the array is of type `Fixed`, which is 4 bytes in length. Multiply `byteCount` by 4 to calculate the memory you need in bytes.

The fractional portion of left-side bearing values are retained.

boundsArray

A pointer to an array. On output the array is filled with the bounding boxes for the glyphs being measured. Bounding boxes are the smallest rectangles that fit around the pixels of the glyph. There is an entry in this array for each glyph that is being measured.

The coordinate system used to describe the bounding boxes is in pixel units, centered at the glyph origin, and with a vertical positive direction upwards. This is the opposite of the QuickDraw vertical orientation.

The `boundsArray` parameter is of type `RectPtr`. The `RectPtr` data type is a pointer to QuickDraw's `Rect` data type, which is 8 bytes in length. Multiply `byteCount` by 8 to calculate the memory you need in bytes. Allocate the memory needed for the array and pass a pointer to the array in the `boundsArray` parameter.

Return Value
A result code. See "Font Manager Result Codes" (page 1230).

Discussion
The `OutlineMetrics` function computes the maximum y-value, minimum y-value, advance widths, left-side bearings, and bounding boxes for a block of text. It uses the font, size, and style specified in the current graphics port. You can use these measurements when laying out text. You may need to adjust line spacing to accommodate exceptionally large glyphs.

The `OutlineMetrics` function works for outline fonts only and is the preferred method for measuring text that is drawn with an outline font.

When you are using `OutlineMetrics` to compute advance width values, left-side bearing values, or bounding boxes, you need to bear in mind that when a text block contains 2-byte characters, not every byte in the `awArray`, `lsbArray`, and `boundsArray` structures is used. Each of these arrays is indexed by the glyph index; thus, if you have five characters in a string, only the first five entries in each array contains a value. Call the Script Manager function `CharByte` to determine how many characters there are in the text block, and ignore the unused array entries (which occur at the end of each array).

If you don't want `OutlineMetrics` to compute one of these three values, pass `NULL` in the applicable parameter. Otherwise, allocate the amount of memory needed for the array and pass a pointer to it in this parameter.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Fonts.h`

QDTextBounds

Obtains a rectangle that specifies the bounds of QuickDraw text. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
void QDTextBounds (
   short byteCount,
   const void *textAddr,
   Rect *bounds
);
```

Parameters

byteCount

The number of bytes in the buffer that contains the text whose bounds you want to obtain.

textAddr

A pointer to a buffer that contains the text whose bounds you want to obtain. You must allocate this buffer.

bounds

On output, points to a rectangle that specifies the bounds of QuickDraw text.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Fonts.h`

RealFont

Determines whether a font is available or is intended for use in a specified size. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
Boolean RealFont (
   short fontNum,
   short size
);
```

Parameters

fontNum

The font family ID.

size

The font size requested.

Return Value

Returns `TRUE` if the requested size of the font is available. The function `RealFont` first checks for a bitmapped font from the specified family. If one is not available, `RealFont` checks next for an outline font. If neither kind of font is available, `RealFont` returns `FALSE`.

Discussion
If an outline font exists for the requested font family, `RealFont` normally considers the font to be available in any requested size. However, the font designer can include instructions in the font that outlines should not be used at certain point sizes, in which case the `RealFont` function considers the font unavailable and returns `FALSE`. The Font Manager determines whether the size is valid by testing the value of the smallest readable size element of the font family header table.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Fonts.h`

SetAntiAliasedTextEnabled

Enables or disables antialiased text for an application. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
OSStatus SetAntiAliasedTextEnabled (
   Boolean iEnable,
   SInt16 iMinFontSize
);
```

Parameters

`iEnable`
A `Boolean` value. Pass `true` to enable antialiased text or `false` to disable it.

`iMinFontSize`
A integer of type `SInt16` that specifies the minimum font size to which antialiasing should be enabled.

Return Value
A result code. See "Font Manager Result Codes" (page 1230).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Fonts.h`

SetFractEnable

Enables or disables fractional glyph widths. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
void SetFractEnable (
   Boolean fractEnable
);
```

Parameters

fractEnable

Specifies whether fractional widths or integer widths are to be used to determine glyph measurements. A value of TRUE indicates fractional glyph widths; a value of FALSE indicates integer glyph widths.

The SetFractEnable function assigns the value that you specify in the fractEnable parameter to the global variable FractEnable.

Discussion

The SetFractEnable function establishes whether or not the Font Manager provides fractional glyph widths to QuickDraw, which then uses them for advancing the pen during text drawing.

The Font Manager defaults to integer widths to ensure compatibility with existing applications. When fractional glyph widths are enabled, the Font Manager can determine the locations of glyphs more accurately than is possible with integer widths.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

Fonts.h

SetFScaleDisable

Enables or disables the computation of font scaling factors by the Font Manager for bitmapped glyphs. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
void SetFScaleDisable (
   Boolean fscaleDisable
);
```

Parameters

fscaleDisable

Specifies whether bitmapped fonts are to be scaled. A value of TRUE indicates that font scaling is disabled; a value of FALSE indicates that font scaling is enabled.

If you set the fscaleDisable parameter to TRUE, the Font Manager disables font scaling, which means it responds to a request for a font size that is not available by computing font scaling factors of 1/1 and returning a smaller, unscaled bitmapped font with the widths of the requested size. If you set the fscaleDisable parameter to FALSE, the Font Manager computes scaling factors for bitmapped fonts.

Discussion

QuickDraw performs the actual scaling of glyph bitmaps for bitmapped fonts by using the font scaling factors computed and returned by the Font Manager.

When font scaling is enabled, the Font Manager can scale a bitmapped glyph that is present in the System file to imitate the appearance of a bitmapped glyph in another point size that is not present. By default, the Font Manager scales fonts to ensure compatibility with existing applications.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Fonts.h`

SetOutlinePreferred

Sets the preference for whether to use bitmapped or outline fonts when both kinds of fonts are available. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
void SetOutlinePreferred (
   Boolean outlinePreferred
);
```

Parameters

`outlinePreferred`

Specifies whether the Font Manager chooses an outline font or a bitmapped font when both are available to fill a font request. A value of `TRUE` indicates an outline font; a value of `FALSE` indicates a bitmapped font.

If you want the Font Manager to choose outline fonts over any bitmapped font counterparts, set the `outlinePreferred` parameter to `TRUE`. If you want it to choose bitmapped fonts, set the `outlinePreferred` parameter to `FALSE`.

Discussion
If an outline font and a bitmapped font are both available for a font request, the default behavior for the Font Manager is to choose the bitmapped font, in order to maintain compatibility with documents that were created on computer systems on which outline fonts were not available. The `SetOutlinePreferred` function sets the Font Manager's current preference for either bitmapped or outline fonts when both are available.

If only outline fonts are available, the Font Manager chooses them regardless of the value of the `outlinePreferred` parameter. If only bitmapped fonts are available, they are chosen. The Font Manager chooses bitmapped versus outline fonts on a size basis, before it takes stylistic variations into account, which can lead to unexpected results.

The preference you set is valid only during the current session with your application. The `outlinePreferred` parameter does not set a global variable.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Fonts.h`

SetPreserveGlyph

Temporarily changes the default behavior of the Font Manager, so that it does not scale oversized glyphs. (Deprecated in Mac OS X v10.4. There is no replacement function.)

```
void SetPreserveGlyph (
   Boolean preserveGlyph
);
```

Parameters

preserveGlyph

Specifies whether or not glyphs from an outline font are scaled to fit between the ascent and descent lines. If you set the value of the `preserveGlyph` parameter to `TRUE`, the measurements of all glyphs are preserved, which means that your application may have to alter the leading between lines in a document if some of the glyphs extend beyond the ascent or descent lines. If you set the value of the `preserveGlyph` parameter to `FALSE`, all glyphs are scaled to fit between the ascent and descent lines.

Discussion

The `SetPreserveGlyph` function establishes how the Font Manager treats glyphs that do not fit between the ascent and descent lines for the current font. The default behavior for the Font Manager is to scale a glyph from an outline font so that it fits between the ascent and descent lines; however, this alters the appearance of the glyph.

You can determine the current behavior of the Font Manager in this regard by calling the `GetPreserveGlyph` function. To ensure that documents have the same appearance whenever they are opened, you need to call `GetPreserveGlyph` and save the value that it returns with your documents and restore it each time a document is displayed by your application.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

Data Types

Font and Font Family Data Structures

FMFontContainer

Represents a font container.

```
typedef UInt32 FMFontContainer;
```

FMFontInstance

Contains information for a font instance.

```
struct FMFontInstance {
    FMFont font;
    UInt32 fontInstanceIndex;
};
```

Fields

`font`
A font reference.

`fontInstanceIndex`
The index associated with the font.

FMFontSpecification

Contains a font family and style.

```
struct FMFontSpecification {
    FMFontFamily fontFamily;
    SInt16 style;
};
```

Fields

`fontFamily`
A font family reference.

`style`
A font style.

FontFamilyID

Represents the ID of a font family.

```
typedef FMFontFamily FontFamilyID;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Fonts.h`

Font Input and Output Structures

FMInput

Contains information about a specific font.

```
struct FMInput {
    SInt16 family;
    SInt16 size;
    Style face;
    Boolean needBits;
    SInt16 device;
    Point numer;
    Point denom;
    float x;
    float y;
    float width;
    float height;
    CGPoint origin;
    CGSize size;
};
```

Fields

`family`
The font family ID.

`size`
The point size of the font.

`face`
The font style. The defined QuickDraw styles are bold, italic, underline, outline, shadow, condense, and extend.

`needBits`
Indicates whether QuickDraw draws the glyphs. If QuickDraw does not draw the glyphs, as is the case for measurement functions such as `MeasureText`, then the glyph bitmaps do not have to be read or constructed. If QuickDraw draws the glyphs and the font is contained in a bitmapped font resource, all of the information describing the font, including the bit image, is read into memory.

`device`
This is no longer used. The high-order byte contains the printer driver reference number as defined in the old Printing Manager. The low-order byte is reserved.

`numer`
The numerators of the vertical and horizontal scaling factors. The `numer` field is of type `Point` and contains two fields: `h` (the numerator of the ratio for horizontal scaling) and `v` (the numerator of the ratio for vertical scaling).

`denom`
The denominators of the vertical and horizontal scaling factors. The `denom` field is of type `Point` and contains two fields: `h` (the denominator of the ratio for horizontal scaling) and `v` (the denominator of the ratio for vertical scaling).

Discussion

The font input structure, of data type `FMInput`, is used by QuickDraw when it requests a font from the Font Manager. You can also use this data type when you request a font with the `FMSwapFont` (page 1195) function.

FMOutPtr

Defines a reference to a font output structure.

```
typedef FMOutputPtr FMOutPtr;
```

Discussion
See FMOutput (page 1210).

Availability
Available in Mac OS X v10.0 and later.

Declared In
Fonts.h

FMOutput

Contains a handle to a font resource and measurement and display information about a specific font.

```
struct FMOutput {
    SInt16 errNum;
    Handle fontHandle;
    UInt8 boldPixels;
    UInt8 italicPixels;
    UInt8 ulOffset;
    UInt8 ulShadow;
    UInt8 ulThick;
    UInt8 shadowPixels;
    SInt8 extra;
    UInt8 ascent;
    UInt8 descent;
    UInt8 widMax;
    SInt8 leading;
    SInt8 curStyle;
    Point numer;
    Point denom;
};
typedef struct FMOutput FMOutput;
```

Fields

`errNum`
Reserved for use by Apple Computer, Inc.

`fontHandle`
A handle to the font resource. The font resource can be for either a bitmapped font or outline font resource.

`boldPixels`
A value used by QuickDraw to modify how it applies the bold style on the screen and on raster printers. Other display devices may handle styles differently.

`italicPixels`
A value used by QuickDraw to modify how it applies the italic style on the screen and on raster printers. Other display devices may handle styles differently.

`ulOffset`
A value used by QuickDraw to modify how it applies the underline style on the screen and on raster printers. Other display devices may handle styles differently.

`ulShadow`
A value used by QuickDraw to modify how it applies the underline shadow style on the screen and on raster printers. Other display devices may handle styles differently.

`ulThick`
: A value used by QuickDraw to modify how it applies the thickness of the underline style on the screen and on raster printers. Other display devices may handle styles differently.

`shadowPixels`
: A value used by QuickDraw to modify how it applies the shadow style on the screen and on raster printers. Other display devices may handle styles differently.

`extra`
: The number of pixels by which the styles have widened each glyph.

`ascent`
: The ascent measurement of the font. Any algorithmic styles or stretching that may be applied to the font are not taken into account for this value.

`descent`
: The descent measurement of the font. Any algorithmic styles or stretching that may be applied to the font are not taken into account for this value.

`widMax`
: The maximum width of the font. Any algorithmic styles or stretching that may be applied to the font are not taken into account for this value.

`leading`
: The leading assigned to the font. Any algorithmic styles or stretching that may be applied to the font are not taken into account for this value.

`curStyle`
: The actual style being made available for QuickDraw's text drawing, as opposed to the requested style.

`numer`
: The numerators of the vertical and horizontal scaling factors. The `numer` parameter is of type `Point`, and contains two fields: `h` (the numerator of the ratio for horizontal scaling) and `v` (the numerator of the ratio for vertical scaling).

`denom`
: The denominators of the vertical and horizontal scaling factors. The `demon` parameter is of type `Point`, and contains two fields: `h` (the denominator of the ratio for horizontal scaling) and `v` (the denominator of the ratio for vertical scaling).

Discussion

The font output structure, of data type `FMOutput`, contains a handle to a font and information about font measurements. It is filled in by the Font Manager upon responding to a font request. You can request a font using the `FMSwapFont` (page 1195) function.

The `bold`, `italic`, `ulOffset`, `ulShadow`, `ulThick`, and `shadow` values are all used to communicate to QuickDraw how to modify the way it renders each stylistic variation. Each byte value is taken from the font characterization table of the printer driver and is used by QuickDraw when it draws to a screen or raster printer.

The `ascent`, `descent`, `widMax`, and `leading` values can all be different in this structure than the corresponding values in the `FontInfo` structure that is produced by the `GetFontInfo` function in QuickDraw. This is because `GetFontInfo` takes into account any algorithmic styles or stretching that QuickDraw performs, while the Font Manager functions do not.

The `numer` and `denom` values are used to designate how font scaling is to be done. The values for these fields in the font output structure can be different than the values specified in the font input structure.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Fonts.h`

FMOutputPtr

Defines a pointer to a font output structure.

```
typedef FMOutput* FMOutputPtr;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Fonts.h`

Font Measurements

FMetricRec

Contains font measurements.

```
struct FMetricRec {
    Fixed ascent;
    Fixed descent;
    Fixed leading;
    Fixed widMax;
    Handle wTabHandle;
};
typedef struct FMetricRec FMetricRec;
```

Fields

`ascent`
: The measurement, in pixels, from the baseline to the ascent line of the font. You can determine the line height, in pixels, by adding the values of the `ascent`, `descent`, and `leading` fields of the font metrics structure.

`descent`
: The measurement, in pixels, from the baseline to the descent line of the font.

`leading`
: The measurement, in pixels, from the descent line to the ascent line below it.

`widMax`
: The width, in pixels, of the largest glyph in the font.

`wTabHandle`
: A handle to the global font width table.

Discussion
The font metrics structure (of data type `FMetricRec`) contains a handle to the global width table, which in turn contains a handle to the associated font family resource for the current font (the font in the current graphics port). It also contains the values of four measurements for the current font.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Fonts.h`

FMetricRecHandle

Defines a handle to a font metrics structure.

```
typedef FMetricRecPtr* FMetricRecHandle;
```

Discussion
See FMetricRec (page 1212).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Fonts.h`

FMetricRecPtr

Defines a pointer to a font metrics structure.

```
typedef FMetricRec* FMetricRecPtr;
```

Discussion
See FMetricRec (page 1212).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Fonts.h`

FontPointSize

Represents the point size of a font.

```
typedef FMFontSize FontPointSize;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Fonts.h`

Deprecated Data Types

The following data structures referenced by the low memory global variables of the Font Manager are deprecated in Mac OS X and CarbonLib 1.1. The low memory global variables are not shared between processes and may result in inconsistencies compared to previous releases of the system software. Changes made to the information contained in the low memory global variables, including any indirectly reference width tables, font family records, and font records, are not reflected in the global state of the Font Manager and may only be accessed through the font access and data management function of the Font Manager or ATS.

AsscEntry

Contains the size and style for a specific font.

```
struct AsscEntry {
    SInt16 fontSize;
    SInt16 fontStyle;
    SInt16 fontID;
};
```

Fields

`fontSize`
A font point size.

`fontStyle`
A font style.

`fontID`
A font Resource ID.

Discussion
The font association entry structure is used in `FontAssoc` (page 1216).

FamRec

Contains format information for a font family resource.

```
struct FamRec {
    SInt16 ffFlags;
    SInt16 ffFamID;
    SInt16 ffFirstChar;
    SInt16 ffLastChar;
    SInt16 ffAscent;
    SInt16 ffDescent;
    SInt16 ffLeading;
    SInt16 ffWidMax;
    SInt32 ffWTabOff;
    SInt32 ffKernOff;
    SInt32 ffStylOff;
    SInt16 ffProperty[9];
    SInt16 ffIntl[2];
    SInt16 ffVersion;
};
```

Fields

`ffFlags`
: Flags for family.

`ffFamID`
: Family ID number.

`ffFirstChar`
: ASCII code of first character.

`ffLastChar`
: ASCII code of last character.

`ffAscent`
: Maximum ascent for 1-point font.

`ffDescent`
: Maximum descent for 1-point font.

`ffLeading`
: Maximum leading for 1-point font.

`ffWidMax`
: Maximum glyph width for 1-point font.

`ffWTabOff`
: Offset to family glyph-width table.

`ffKernOff`
: Offset to kerning table.

`ffStylOff`
: Offset to style-mapping table.

`ffProperty`
: Style properties info.

`ffIntl`
: For international use.

`ffVersion`
: Version number.

Discussion
The font family structure, of data type `FamRec`, describes the format of the font family (`'FOND'`) resource. It is shown here as a guide to the format of the resource. The font family structure is not used directly by any Font Manager functions.

FontAssoc

Contains the number of entries in a font association table.

```
struct FontAssoc {
    SInt16 numAssoc;
};
```

Fields
`numAssoc`
Number of entries - 1.

Discussion
Each entry in the font association table is a font association entry structure, of data type `AsscEntry` (page 1214).

The font association table structure, which is part of the font family resource, maps a point size and style to a specific font that is part of the family. The table structure, of data type `FontAssoc`, consists of a count of the entries in the table and is followed by the entry structures.

FontRec

Contains information for a format of `'NFNT'` and, likewise, the `'FONT'` resource

```
struct FontRec {
    SInt16 fontType;
    SInt16 firstChar;
    SInt16 lastChar;
    SInt16 widMax;
    SInt16 kernMax;
    SInt16 nDescent;
    SInt16 fRectWidth;
    SInt16 fRectHeight;
    UInt16 owTLoc;
    SInt16 ascent;
    SInt16 descent;
    SInt16 leading;
    SInt16 rowWords;
};
typedef struct FontRec FontRec;
```

Fields
`fontType`
Font type.
`firstChar`
Character code of first glyph.
`lastChar`
Character code of last glyph.

`widMax`
Maximum glyph width.

`kernMax`
Negative of maximum glyph kern.

`nDescent`
Negative of descent.

`fRectWidth`
Width of font rectangle.

`fRectHeight`
Height of font rectangle.

`owTLoc`
Location of width/offset table.

`ascent`
Ascent.

`descent`
Descent.

`leading`
Leading.

`rowWords`
Row width of bit image / 2.

Discussion
The font structure, of data type `FontRec`, describes the format of `'NFNT'` and, likewise, the `'FONT'` resource. It is shown here as a guide to the format of the resource. The font structure is not used directly by any Font Manager functions.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Fonts.h`

FontRecHdl

Defines a handle to a font record.

```
typedef FontRecPtr* FontRecHdl;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Fonts.h`

FontRecPtr

Defines a pointer to a font record.

```
typedef FontRec* FontRecPtr;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Fonts.h`

KernEntry

Contains kerning information for a specific stylistic variation of the font family.

```
struct KernEntry {
    SInt16 kernStyle;
    SInt16 kernLength;
};
```

Fields

`kernStyle`
Length of this entry.

`kernLength`
Style to which this entry applies.

KernPair

Specifies a kerning value for a pair of glyphs.

```
struct KernPair {
    char kernFirst;
    char kernSecond;
    SInt16 kernWidth;
};
```

Fields

`kernFirst`
ASCII character code of the first character of a kerned pair.

`kernSecond`
ASCII character code of the second character of a kerned pair.

`kernWidth`
Kerning value in 1pt fixed format.

KernTable

Contains the number of entries in a kerning table.

```
struct KernTable {
    SInt16 numKerns;
};
```

Fields

`numKerns`
Number of subtable entries.

Discussion

The font family kerning table structure, which is part of the font family resource, contains a number of kerning subtable entries, with different subtables for different stylistic variations. The table structure, of data type `KernTable`, consists of a count of the entries in the table and is followed by the entry structures.

NameTable

Contains the base name and suffixes for a font family.

```
struct NameTable {
    SInt16 stringCount;
    Str255 baseFontName;
};
```

Fields

`stringCount`
The number of entries in the name table.

`baseFontName`
A string that specifies the base name and suffixes for a font family name.

StyleTable

Contains font style information

```
struct StyleTable {
    SInt16 fontClass;
    SInt32 offset;
    SInt32 reserved;
    char indexes[48];
};
```

Fields

`fontClass`
The font class of this table.

`offset`
Offset to glyph-encoding subtable.

`reserved`
Reserved.

`indexes`
Indexes into the font suffix name table. The font suffix name subtable structure, of data type `NameTable` (page 1219), contains the base name and suffixes for a font family.

Discussion
The style-mapping table structure, which is part of the font family resource, provides information that is used by printer drivers to implement font styles. Each font family can have its own character encoding and its own set of font suffix names for style designations. Each style of a font has its own name, typically created by adding a style suffix to the base name of the font.

WidEntry

Specifies a style for a glyph width.

```
struct WidEntry {
    SInt16 widStyle;
};
```

Fields
`widStyle`
The style to which the entry applies.

WidTable

Specifies the number of entries in a font family glyph-width table.

```
struct WidTable {
    SInt16 numWidths;
};
```

Fields
`numWidths`
The number of entries minus one.

Discussion
The font family glyph-width table structure, which is part of the font family resource, is used to specify glyph widths for the font family on a per-style basis.

WidthTable

Contains the widths of all the glyphs of a specific font.

```
struct WidthTable {
    Fixed tabData[256];
    Handle tabFont;
    SInt32 sExtra;
    SInt32 style;
    SInt16 fID;
    SInt16 fSize;
    SInt16 face;
    SInt16 device;
    Point inNumer;
    Point inDenom;
    SInt16 aFID;
    Handle fHand;
    Boolean usedFam;
    UInt8 aFace;
    SInt16 vOutput;
    SInt16 hOutput;
    SInt16 vFactor;
    SInt16 hFactor;
    SInt16 aSize;
    SInt16 tabSize;
};
typedef struct WidthTable WidthTable;
```

Fields

`tabData`
: The widths for the glyphs in the font, in standard 32-bit fixed-point format. If a glyph is missing in the font, its entry contains the width of the missing-character glyph.

`tabFont`
: A handle to the font resource used to build this table.

`sExtra`
: The average number of pixels by which QuickDraw widens each space in a line of text.

`style`
: The average number of pixels by which QuickDraw widens a line of text after applying a style.

`fID`
: The font family ID of the font represented by this table. This is the ID that was used in the request to build the table. It may be different from the ID of the font family that was used, which is indicated by the `aFID` field.

`fSize`
: The point size that was originally requested for the font represented by this table. The actual size used is specified in the `aSize` field.

`face`
: The font style that was originally requested for the font represented by this table. The actual style used is specified in the `aFace` field.

`device`
: The device ID of the device on which these widths may be used.

`inNumer`
: The numerators of the vertical and horizontal scaling factors. The `numer` parameter is of type `Point`, and contains two fields: `h` (the numerator of the ratio for horizontal scaling) and `v` (the numerator of the ratio for vertical scaling).

`inDenom`
: The denominators of the vertical and horizontal scaling factors. The `denom` parameter is of type `Point`, and contains two fields: `h` (the denominator of the ratio for horizontal scaling) and `v` (the denominator of the ratio for vertical scaling).

`aFID`
: The font family ID of the font family actually used to build this table. If the Font Manager could not find the font requested, this value may be different from the value of the `fID` field.

`fHand`
: The handle to the font family resource used to build this table.

`usedFam`
: Set to `TRUE` if the fixed-point family glyph widths were used rather than integer glyph widths.

`aFace`
: The font style of the font whose widths are contained in this table.

`vOutput`
: The factor by which glyphs are to be expanded vertically in the current graphics port. This is a 16-bit fixed-point number, with the integer part in the high-order byte and a fractional part in the low-order byte.

`hOutput`
: The factor by which glyphs are to be expanded horizontally in the current graphics port. This is a 16-bit fixed-point number, with the integer part in the high-order byte and a fractional part in the low-order byte.

`vFactor`
: The factor by which widths of the chosen font, after a style has been applied, have been increased vertically in the current graphics port. This is a 16-bit fixed-point number, with the integer part in the high-order byte and a fractional part in the low-order byte. The value of the `vFactor` field is not used by the Font Manager.

`hFactor`
: The factor by which widths of the chosen font, after a style has been applied, have been increased horizontally in the current graphics port. This is a 16-bit fixed-point number, with the integer part in the high-order byte and a fractional part in the low-order byte.

`aSize`
: The size of the font actually used to build this table. Both the point size and the font used to build this table may be different from the requested point size and font. If font scaling is disabled, the Font Manager may use a size different from the size requested and add more or less space to approximate the appearance of the font requested.

`tabSize`
: The total size of the global width table.

Discussion

The global width table structure, of data type `WidthTable`, contains the widths of all the glyphs of one font. The font family, point size, and style of this font are specified in this table. Your application should use the widths found in the global width table for placement of glyphs and words both on the screen and on the printed page. You can use the `FontMetrics` (page 1195) function to get a handle to the global width table. However, you should not assume that the table is the same size as shown in the structure declaration; it may be larger because of some private system-specific information that is attached to it.

Multiplying the values of the `hOutput` and `vOutput` fields by the values of the `hFactor` and `vFactor` fields, respectively, gives the font scaling. (Because the value of the `vFactor` field is ignored, the Font Manager multiplies the value of the `vOutput` field by 1.) The product of the value of the `hOutput` field and an entry in the global width table is the scaled width for that glyph.

The Font Manager gathers data for the global width table from one of three data structures:

1. The Font Manager looks in the font resource for a table that stores fractional glyph widths. For bitmapped fonts, the Font Manager uses the glyph-width table of the bitmapped font resource. For outline fonts, the Font Manager uses the advance width and left-side bearing values in the horizontal metrics table of the outline font. In both cases, the values are stored in 16-bit fixed format, with the integer part in the high-order byte and the fractional part in the low-order byte.
2. If there is no glyph-width table in the font resource, the Font Manager looks for the font family's glyph-width table in the font family resource, which contains fractional widths for a hypothetical 1-point font. The Font Manager calculates the actual values by multiplying these widths by the requested font size.
3. If there is no glyph-width table in the font family resource, and if the font is contained in a bitmapped font resource, the Font Manager derives the glyph widths from the integer widths contained in the glyph-width table of the bitmapped font resource. There is no corresponding table for the outline font resource.

Your application should obtain glyph widths either from the global width table or from the QuickDraw function `MeasureText`. The `MeasureText` function works only with text to be displayed on the screen, not with text to be printed. You can get the individual widths of glyphs of an outline font using the `OutlineMetrics` function. The `FontMetrics` function returns only the width of the largest glyph in a font contained in a bitmapped font resource.

Do not use the values from the global width table if your application is running on a computer on which non-Roman script systems are installed. You can check to see if a non-Roman script system is present by calling the `GetScriptManagerVariable` function with a selector of `smEnabled`; if the function returns a value greater than 0, at least one non-Roman script system is present and you need to call `MeasureText` to measure text that is displayed on the screen. Measuring text from a non-Roman script system for printing is handled by the printer driver.

For more information about the `MeasureText` function, see the documentation on "QuickDraw Text". See also the `FontMetrics` (page 1195) and `OutlineMetrics` (page 1201) functions.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Fonts.h`

WidthTableHdl

Defines a handle to a glyph width table.

```
typedef WidthTablePtr* WidthTableHdl;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Fonts.h`

WidthTablePtr

Defines a pointer to a glyph width table.

```
typedef WidthTable* WidthTablePtr;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Fonts.h`

Constants

Activation Contexts

Specify the scope of available fonts.

```
enum{
kFMDefaultActivationContext = kFMDefaultOptions,
kFMGlobalActivationContext = 0x00000001,
kFMLocalActivationContext = kFMDefaultActivationContext
}
```

Constants

`kFMDefaultActivationContext`
Specifies to use the default scope, which is local.
Available in Mac OS X v10.1 and later.
Declared in `Fonts.h`.

`kFMGlobalActivationContext`
Specifies the scope is global; fonts are available to all applications.
Available in Mac OS X v10.1 and later.
Declared in `Fonts.h`.

`kFMLocalActivationContext`
Specifies the scope is local; fonts are available only to the application.
Available in Mac OS X v10.1 and later.
Declared in `Fonts.h`.

Default Options

Specify the scope of fonts for an application.

```
enum {
    kFMDefaultOptions = kNilOptions
};
```

Constants

`kFMDefaultOptions`

Restricts the scope only to the fonts accessible to your application. This flag is also used when Apple has not yet defined options for a function that has an options parameter. When no options are defined yet, you can use `kFMDefaultOptions` as a neutral value to assure future compatibility.

Available in Mac OS X v10.0 and later.

Declared in `Fonts.h`.

Font ID Constants

Specify a font. These constants are deprecated.

```
enum {
    kFontIDNewYork = 2,
    kFontIDGeneva = 3,
    kFontIDMonaco = 4,
    kFontIDVenice = 5,
    kFontIDLondon = 6,
    kFontIDAthens = 7,
    kFontIDSanFrancisco = 8,
    kFontIDToronto = 9,
    kFontIDCairo = 11,
    kFontIDLosAngeles = 12,
    kFontIDTimes = 20,
    kFontIDHelvetica = 21,
    kFontIDCourier = 22,
    kFontIDSymbol = 23,
    kFontIDMobile = 24
};
```

Font Constants

Specify a font. These constants are deprecated.

```
enum {
    newYork = 2,
    geneva = 3,
    monaco = 4,
    venice = 5,
    london = 6,
    athens = 7,
    sanFran = 8,
    toronto = 9,
    cairo = 11,
    losAngeles = 12,
    times = 20,
    helvetica = 21,
    courier = 22,
    symbol = 23,
    mobile = 24
};
```

Discussion
You should use the functions `GetFNum` or `FMGetFontFamilyFromName` to find a font family from a standard QuickDraw name.

Global Scope Option

```
enum {
kFMUseGlobalScopeOption
};
```

Discussion
Use the constant `kFMGlobalIterationScope` instead; `kFMUseGlobalScopeOption` is deprecated.

Height and Width Constants

Specify proportional or fixed font heights and widths.

```
enum {
    propFont = 36864,
    prpFntH = 36865,
    prpFntW = 36866,
    prpFntHW = 36867,
    fixedFont = 45056,
    fxdFntH = 45057,
    fxdFntW = 45058,
    fxdFntHW = 45059,
    fontWid = 44208
};
```

Constants
`propFont`
Specifies a proportional font.
Available in Mac OS X v10.0 and later.
Declared in `Fonts.h`.

`prpFntH`
Specifies a proportional height font.
Available in Mac OS X v10.0 and later.
Declared in `Fonts.h`.

`prpFntW`
Specifies a proportional width font.
Available in Mac OS X v10.0 and later.
Declared in `Fonts.h`.

`prpFntHW`
Specifies a proportional width and height font.
Available in Mac OS X v10.0 and later.
Declared in `Fonts.h`.

`fixedFont`
Specifies a fixed font.
Available in Mac OS X v10.0 and later.
Declared in `Fonts.h`.

`fxdFntH`
Specifies a fixed height font.
Available in Mac OS X v10.0 and later.
Declared in `Fonts.h`.

`fxdFntW`
Specifies a fixed width font.
Available in Mac OS X v10.0 and later.
Declared in `Fonts.h`.

`fxdFntHW`
Specifies a fixed height and width font.
Available in Mac OS X v10.0 and later.
Declared in `Fonts.h`.

`fontWid`
Specifies a font width.
Available in Mac OS X v10.0 and later.
Declared in `Fonts.h`.

Iteration Scopes

Specify a scope over which to iterate.

```
enum{
kFMDefaultIterationScope = kFMDefaultOptions,
kFMGlobalIterationScope = 0x00000001,
kFMLocalIterationScope = kFMDefaultIterationScope
}
```

Constants

`kFMDefaultIterationScope`
Specifies to use the default.
Available in Mac OS X v10.1 and later.
Declared in `Fonts.h`.

`kFMGlobalIterationScope`
Specifies the scope is global, iterate over all applications.
Available in Mac OS X v10.1 and later.
Declared in `Fonts.h`.

`kFMLocalIterationScope`
Specifies the scope is local, restrict the iteration to the application.
Available in Mac OS X v10.1 and later.
Declared in `Fonts.h`.

Marking Character Constants

Specify a character to use for an active menu or submenu item.

```
enum {
    commandMark = 17,
    checkMark = 18,
    diamondMark = 19,
    appleMark = 20
};
```

Constants

`commandMark`
Specifies to use a command mark next to an active menu or submenu item.
Available in Mac OS X v10.0 and later.
Declared in `Fonts.h`.

`checkMark`
Specifies to use a check mark next to an active menu or submenu item.
Available in Mac OS X v10.0 and later.
Declared in `Fonts.h`.

`diamondMark`
Specifies to use a diamond mark next to an active menu or submenu item.
Available in Mac OS X v10.0 and later.
Declared in `Fonts.h`.

`appleMark`
Specifies to use an Apple character next to an active menu or submenu item.

Available in Mac OS X v10.0 and later.

Declared in `Fonts.h`.

Discussion
You can pass these constants in the `markChar` parameter of the Menu Manager function `GetItemMark` and the marking character field of the menu resource (of type `'MENU'`) and return these constants in the `markChar` parameter of the Menu Manager function `SetItemMark` to specify the mark of a specific menu item or the menu ID of the submenu associated with the menu item.

QuickTime User Interface Default Font

Defines the default font for the QuickTime user interface.

```
enum {
    kPlatformDefaultGuiFontID = applFont;
};
```

Constants
`kPlatformDefaultGuiFontID`
Specifies that the default font ID for the graphical user interface in QuickTime 3.0 should be the application font ID.

Available in Mac OS X v10.0 and later.

Declared in `Fonts.h`.

Discussion
This constant is used in QuickTime 3.0.

System and Application Fonts

Specify the current system and application fonts.

```
enum {
    systemFont = 0,
    applFont = 1
};
```

Constants
`systemFont`
Specifies the current System font.

Available in Mac OS X v10.0 and later.

Declared in `Fonts.h`.

`applFont`
Specifies the current application font.

Available in Mac OS X v10.0 and later.

Declared in `Fonts.h`.

Result Codes

The most common result codes returned by Font Manager are listed below.

Result Code	Value	Description
`kFMIterationCompleted`	-980	Iteration successfully completed. Available in Mac OS X v10.0 and later.
`kFMInvalidFontFamilyErr`	-981	The specified font family is invalid. Available in Mac OS X v10.0 and later.
`kFMInvalidFontErr`	-982	The specified font is invalid. Available in Mac OS X v10.0 and later.
`kFMIterationScopeModifiedErr`	-983	Iteration scope modified. Available in Mac OS X v10.0 and later.
`kFMTableAccessErr`	-984	The table specified is invalid or doesn't exist.
`kFMFontContainerAccessErr`	-985	Not able to access font container. Available in Mac OS X v10.0 and later.

Icon Services and Utilities Reference

Framework: Carbon/Carbon.h

Declared in Icons.h

Overview

The Icon Utilities allow your application (and system software) to manipulate and draw icons of any standard resource type in windows and if necessary in menus or dialog boxes. You need to use these routines only if you wish to draw icons in your application's windows or to draw icons whose resource types are not recognized by the Menu Manager and Dialog Manager in menus and dialog boxes.

To display an icon most effectively at a variety of sizes and bit depths, you should provide an icon family. You can then draw the appropriate member of the family for a given size and bit depth either by passing the family's resource ID to an Icon Utilities routine or by reading the family's icon resources into memory as an icon suite and passing the suite's handle to Icon Utilities routines.

Icon Services provides icon data to multiple Mac OS clients, including the Finder, extensions and applications. Using Icon Services to obtain icon data means you can provide efficient icon caching and release memory when you don't need icon data any longer. Icon Services provides the appropriate icon for any file object (file, folder, or volume), as well as other commonly used icons such as caution, note, or help icons in alert boxes, for example. The icons provided by Icon Services support a much larger palette of colors: up to 24 bits per pixel and an eight-bit mask. Icons are Appearance-compliant and appropriate to the active theme.

Functions by Task

Converting an Icon Mask to a Region

`IconIDToRgn` (page 1260) Deprecated in Mac OS X v10.5
: Converts the icon mask in an icon family to a region. (Deprecated. Use Icon Services instead.)

`IconMethodToRgn` (page 1261) Deprecated in Mac OS X v10.5
: Converts, to a region, the mask for an icon that `IconMethodToRgn` obtains with the aid of your icon getter callback function. (Deprecated. Use Icon Services instead.)

`IconSuiteToRgn` (page 1267) Deprecated in Mac OS X v10.5
: Converts the icon mask in an icon suite to a region. (Deprecated. Use Icon Services instead.)

Creating an Icon Suite

`AddIconToSuite` (page 1238) Deprecated in Mac OS X v10.5
Adds an icon to an icon suite. (Deprecated. Use Icon Services instead.)

`GetIconSuite` (page 1257) Deprecated in Mac OS X v10.5
Creates an icon suite in memory that contains handles to a specified icon family's resources. (Deprecated. Use Icon Services instead.)

`NewIconSuite` (page 1273) Deprecated in Mac OS X v10.5
Gets a handle to an empty icon suite. (Deprecated. Use Icon Services instead.)

Determining Whether a Point Is Within an Icon

`PtInIconID` (page 1285) Deprecated in Mac OS X v10.5
Determines whether a specified point is within an icon. (Deprecated. Use Icon Services instead.)

`PtInIconMethod` (page 1285) Deprecated in Mac OS X v10.5
Determines whether a specified point is within an icon obtained with the aid of your icon getter callback function. (Deprecated. Use Icon Services instead.)

`PtInIconSuite` (page 1288) Deprecated in Mac OS X v10.5
Determines whether a specified point is within an icon. (Deprecated. Use Icon Services instead.)

Determining Whether a Rectangle Intersects an Icon

`RectInIconID` (page 1289)
Hit-tests a rectangle against the appropriate icon mask from an icon family for a specified destination rectangle and alignment. (Deprecated. Use Icon Services instead.)

`RectInIconMethod` (page 1290)
Hit-tests a rectangle against an icon obtained by your icon getter callback function for a specified destination rectangle and alignment. (Deprecated. Use Icon Services instead.)

`RectInIconSuite` (page 1292)
Hit-tests a rectangle against the appropriate icon mask from an icon suite for a specified destination rectangle and alignment. (Deprecated. Use Icon Services instead.)

Disposing of Icon Suites

`DisposeIconSuite` (page 1241) Deprecated in Mac OS X v10.5
Releases the memory occupied by an icon suite. (Deprecated. Use Icon Services instead.)

Disposing of Icons

`DisposeCIcon` (page 1240) Deprecated in Mac OS X v10.5
Releases the memory occupied by a color icon structure. (Deprecated. Use Icon Services instead.)

Drawing Icons From an Icon Suite

`PlotIconSuite` (page 1282) Deprecated in Mac OS X v10.5
: Draws the icon described by an icon suite using the most appropriate icon in the suite for the current bit depth of the display device and the rectangle in which the icon is to be drawn. (Deprecated. Use Icon Services instead.)

Drawing Icons From Resources

`PlotCIcon` (page 1275) Deprecated in Mac OS X v10.5
: Draws a color icon of resource type `'cicn'` to which you have a handle. (Deprecated. Use Icon Services instead.)

`PlotCIconHandle` (page 1276) Deprecated in Mac OS X v10.5
: Draws an icon of resource type `'cicn'` to which you have a handle. (Deprecated. Use Icon Services instead.)

`PlotIcon` (page 1277) Deprecated in Mac OS X v10.5
: Draws an icon of resource type `'ICON'` to which you have a handle. (Deprecated. Use Icon Services instead.)

`PlotIconHandle` (page 1278) Deprecated in Mac OS X v10.5
: Draws an icon of resource type `'ICON'` or `'ICN#'` to which you have a handle. (Deprecated. Use Icon Services instead.)

`PlotIconID` (page 1279) Deprecated in Mac OS X v10.5
: Draws the icon described by an icon family. (Deprecated. Use Icon Services instead.)

`PlotIconMethod` (page 1280) Deprecated in Mac OS X v10.5
: Draws an icon obtained with the aid of your icon getter callback function. (Deprecated. Use Icon Services instead.)

`PlotSICNHandle` (page 1284) Deprecated in Mac OS X v10.5
: Draws a small icon of resource type `'SICN'` to which you have a handle. (Deprecated. Use Icon Services instead.)

Enabling and Disabling Custom Icons

`GetCustomIconsEnabled` (page 1245)
: Determines whether custom icons are enabled or disabled on a specified volume.

`SetCustomIconsEnabled` (page 1297)
: Enables or disables custom icons on a specified volume.

Flushing IconRef Data

`FlushIconRefs` (page 1242) Deprecated in Mac OS X v10.3
: Reclaims memory used by the specified icon if the memory is purgeable. (Deprecated. There is no replacement; this function was included to facilitate porting classic applications to Carbon, but it serves no useful purpose in Mac OS X.)

`FlushIconRefsByVolume` (page 1243) Deprecated in Mac OS X v10.3
On a given volume, reclaims memory used by purgeable icons. (Deprecated. There is no replacement; this function was included to facilitate porting classic applications to Carbon, but it serves no useful purpose in Mac OS X.)

Getting and Setting the Label for an Icon Suite

`GetSuiteLabel` (page 1259) Deprecated in Mac OS X v10.5
Gets the default label setting associated with an icon suite. (Deprecated. Use Icon Services instead.)

`SetSuiteLabel` (page 1300) Deprecated in Mac OS X v10.5
Specifies the default label associated with an icon suite. (Deprecated. Use Icon Services instead.)

Getting Label Information

`GetLabel` (page 1258) Deprecated in Mac OS X v10.5
Gets the color and string used for a given label in the Label menu of the Finder and in the Labels control panel. (Deprecated. Use Icon Services instead.)

Getting Icons From an Icon Suite

`GetIconFromSuite` (page 1249) Deprecated in Mac OS X v10.5
Gets an icon from an icon suite. (Deprecated. Use Icon Services instead.)

Getting Icons From Resources That Don't Belong to an Icon Family

`GetCIcon` (page 1244) Deprecated in Mac OS X v10.5
Gets a handle to a color icon of resource type `'cicn'`. (Deprecated. Use Icon Services instead.)

`GetIcon` (page 1246) Deprecated in Mac OS X v10.5
Gets a handle to an icon resource of type `'ICON'`. (Deprecated. Use Icon Services instead.)

IconRef Reference Counting

`AcquireIconRef` (page 1238)
Increments the reference count for an `IconRef`.

`GetIconRefOwners` (page 1255)
Provides the current reference count for an `IconRef`.

`ReleaseIconRef` (page 1296)
Decrements the reference count for an `IconRef`.

Modifying IconRef Data

`OverrideIconRef` (page 1274)
Replaces the bitmaps of one `IconRef` with those of another `IconRef`.

`RemoveIconRefOverride` (page 1297)
Restores the original bitmaps of an overridden `IconRef`.

`UpdateIconRef` (page 1301)
Forces an update of `IconRef` data.

`OverrideIconRefFromResource` (page 1275) Deprecated in Mac OS X v10.5
Replaces the bitmaps in an `IconRef` with bitmaps from a specified resource file. (Deprecated. Use `OverrideIconRef` (page 1274) instead.)

Obtaining Icon Data

`IsDataAvailableInIconRef` (page 1268)
Indicates whether an `IconRef` has the specified data.

`IsIconRefComposite` (page 1269)
Reports whether a specified `IconRef` has been composited.

`IsIconRefMaskEmpty` (page 1270)
Reports whether a specified mask is empty.

`IsValidIconRef` (page 1270)
Reports whether a specified `IconRef` is valid.

`GetIconSizesFromIconRef` (page 1256) Deprecated in Mac OS X v10.3
Provides an `IconSelectorValue` indicating the sizes and depths of icon data available for an `IconRef`. (Deprecated. Use `IsDataAvailableInIconRef` (page 1268) instead.)

Obtaining IconRef Values

`GetIconRef` (page 1249)
Provides an `IconRef` object for an icon in the desktop database or for a registered icon.

`GetIconRefFromFolder` (page 1252)
Provides an `IconRef` object for a folder with no custom icon.

`GetIconRefFromFileInfo` (page 1251)
Provides an `IconRef` object for a file with minimal file I/O.

`GetIconRefFromTypeInfo` (page 1254)
Provides an `IconRef` object with the specified type information.

`GetIconRefFromIconFamilyPtr` (page 1253)
Provides an `IconRef` object from a specified icon family.

`GetIconRefFromComponent` (page 1250)
Provides an `IconRef` object based on a specified component.

`GetIconRefFromFile` (page 1251) Deprecated in Mac OS X v10.5
Provides an `IconRef` object for a file, folder or volume. (Deprecated. Use `GetIconRefFromFileInfo` (page 1251) instead.)

Performing Operations on Icons in an Icon Suite

`ForEachIconDo` (page 1244) Deprecated in Mac OS X v10.5
Performs an action on one or more icons in an icon suite. (Deprecated. Use Icon Services instead.)

Reading, Copying, and Converting Icon Data

`GetIconFamilyData` (page 1248)
Obtains a copy of the raw icon data for an individual element in an icon family.

`IconRefToIconFamily` (page 1265)
Provides icon family data for a given `IconRef`.

`ReadIconFromFSRef` (page 1289)
Reads an icon ('`icns`') file into memory.

`SetIconFamilyData` (page 1299)
Provides new raw icon data for an individual element of an icon family.

`IconFamilyToIconSuite` (page 1259) Deprecated in Mac OS X v10.5
Provides icon suite data for a given icon family. (Deprecated. Use Icon Services instead.)

`IconSuiteToIconFamily` (page 1266) Deprecated in Mac OS X v10.5
Provides `IconFamily` data for a specified `IconSuite`. (Deprecated. Use Icon Services instead.)

`ReadIconFile` (page 1288) Deprecated in Mac OS X v10.5
Copies data from a given file into an icon family. (Deprecated. Use `ReadIconFromFSRef` (page 1289) instead.)

`WriteIconFile` (page 1302) Deprecated in Mac OS X v10.5
Copies data from a given icon family into a file. (Deprecated. Use the File Manager instead.)

Registering and Unregistering IconRef Values

`RegisterIconRefFromFSRef` (page 1293)
Registers an `IconRef` from a `.icns` file and associates it with a creator and type pair.

`RegisterIconRefFromIconFamily` (page 1294)
Adds an `iconFamily`-derived `IconRef` to the Icon Services registry.

`UnregisterIconRef` (page 1301)
Removes the specified icon data from the icon registry.

`RegisterIconRefFromIconFile` (page 1295) Deprecated in Mac OS X v10.5
Adds a file-derived `IconRef` to the Icon Services registry. (Deprecated. Use `RegisterIconRefFromFSRef` (page 1293) instead.)

`RegisterIconRefFromResource` (page 1295) Deprecated in Mac OS X v10.5
Adds a resource-derived `IconRef` to the Icon Services registry. (Deprecated. Use `RegisterIconRefFromFSRef` (page 1293) instead.)

Using IconRef Data

`CompositeIconRef` (page 1239)
Superimposes one `IconRef` onto another.

`GetIconRefVariant` (page 1255)
Specifies a transformation for a given `IconRef`.

`IconRefContainsCGPoint` (page 1262)
Returns a Boolean value indicating whether an icon contains a specified point.

`IconRefIntersectsCGRect` (page 1263)
Returns a Boolean value indicating whether an icon intersects a specified rectangle.

`IconRefToHIShape` (page 1264)
Converts an icon into an HIShape object.

`PlotIconRefInContext` (page 1281)
Plots an `IconRef` using Quartz.

`IconRefToRgn` (page 1265) Deprecated in Mac OS X v10.5
Converts an Icon Services icon into a QuickDraw region. (Deprecated. Use `IconRefToHIShape` (page 1264) instead.)

`PlotIconRef` (page 1281) Deprecated in Mac OS X v10.5
Draws an icon using appropriate size and depth data from an `IconRef`. (Deprecated. Use `PlotIconRefInContext` (page 1281) instead.)

`PtInIconRef` (page 1287) Deprecated in Mac OS X v10.5
Tests whether a specified point falls within an icon's mask. (Deprecated. Use `IconRefContainsCGPoint` (page 1262) instead.)

`RectInIconRef` (page 1292) Deprecated in Mac OS X v10.5
Tests whether a specified rectangle falls within an icon's mask. (Deprecated. Use `IconRefIntersectsCGRect` (page 1263) instead.)

Working With Icon Caches

`GetIconCacheData` (page 1246) Deprecated in Mac OS X v10.5
Gets the data associated with an icon cache. (Deprecated. Use Icon Services instead.)

`GetIconCacheProc` (page 1247) Deprecated in Mac OS X v10.5
Gets the icon getter function associated with an icon cache. (Deprecated. Use Icon Services instead.)

`LoadIconCache` (page 1270) Deprecated in Mac OS X v10.5
Loads into an icon cache a handle to the appropriate icon data for a specified destination rectangle and the current bit depth, for drawing later with a specified alignment and transform. (Deprecated. Use Icon Services instead.)

`MakeIconCache` (page 1272) Deprecated in Mac OS X v10.5
Gets a handle to an empty icon cache. (Deprecated. Use Icon Services instead.)

`SetIconCacheData` (page 1298) Deprecated in Mac OS X v10.5
Sets the data associated with an icon cache. (Deprecated. Use Icon Services instead.)

`SetIconCacheProc` (page 1299) Deprecated in Mac OS X v10.5
Sets the icon getter callback function associated with an icon cache. (Deprecated. Use Icon Services instead.)

Creating and Managing Universal Procedure Pointers

`NewIconActionUPP` (page 1272)
Creates a new universal procedure pointer (UPP) to an icon action callback function.

`NewIconGetterUPP` (page 1273)
Creates a new universal procedure pointer (UPP) to an icon getter callback function.

`DisposeIconActionUPP` (page 1241)
Disposes of the universal procedure pointer (UPP) to your icon action callback function.

`DisposeIconGetterUPP` (page 1241)
Disposes of the universal procedure pointer (UPP) to your icon getter callback function.

`InvokeIconActionUPP` (page 1268)
Calls your icon action callback function.

`InvokeIconGetterUPP` (page 1268)
Calls your icon getter callback function.

Functions

AcquireIconRef

Increments the reference count for an `IconRef`.

```
OSErr AcquireIconRef (
   IconRef theIconRef
);
```

Parameters

`theIconRef`
An `IconRef` whose reference count you wish to increment.

Return Value
A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`IconsCore.h`

AddIconToSuite

Adds an icon to an icon suite. (Deprecated in Mac OS X v10.5. Use Icon Services instead.)

```
OSErr AddIconToSuite (
   Handle theIconData,
   IconSuiteRef theSuite,
   ResType theType
);
```

Parameters

theIconData

A handle to the data for the new icon to be added to the icon suite. You can obtain a handle to icon data using various functions, such as `GetIcon` (page 1246) or `GetResource`.

The handle to the icon data is added at the location reserved for icon data of the type specified by `theType`. If the icon suite already includes a handle to icon data for that type, this function replaces the handle to the old data without disposing of it. In this case you may want to call the `GetIconFromSuite` (page 1249) function first to obtain the old handle so that you can dispose of it.

The handles that you add to the suite do not have to be associated with a resource fork. For example, your application might get icon data from the desktop database rather than reading it from a resource, or your application might read icon data from a resource and then detach it.

theSuite

A handle to the icon suite to which to add the icon.

theType

The resource type of the new icon. The resource type should be that of an icon family member.

Return Value

A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Discussion

This function is most often used to read icons into an empty icon suite created with the `NewIconSuite` (page 1273) function.

Special Considerations

This function may move or purge memory blocks in the application heap. For that reason, your application should not call it at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Icons.h`

CompositeIconRef

Superimposes one `IconRef` onto another.

```
OSErr CompositeIconRef (
   IconRef backgroundIconRef,
   IconRef foregroundIconRef,
   IconRef *compositeIconRef
);
```

Parameters

backgroundIconRef

A value to use as the background for the composite `IconRef`.

foregroundIconRef

A value to use as the foregound for the composite `IconRef`.

compositeIconRef

On completion, this points to an `IconRef` that is a composite of the specified background and foreground `IconRefs`.

Return Value
A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Discussion
This function provides an alternative to badging when you need to indicate a change of state.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`IconsCore.h`

DisposeCIcon

Releases the memory occupied by a color icon structure. (Deprecated in Mac OS X v10.5. Use Icon Services instead.)

```
void DisposeCIcon (
   CIconHandle theIcon
);
```

Parameters

theIcon

A handle to the color icon structure to dispose of, previously obtained from the `GetCIcon` (page 1244) function.

Discussion
To dispose of a handle obtained from `GetIcon` or `GetResource`, use the `ReleaseResource` function to release the memory occupied by the icon resource data.

Special Considerations

This function may move or purge memory blocks in the application heap. For that reason, your application should not call it at interrupt time.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In
`Icons.h`

DisposeIconActionUPP

Disposes of the universal procedure pointer (UPP) to your icon action callback function.

```
void DisposeIconActionUPP (
   IconActionUPP userUPP
);
```

Parameters

userUPP
The UPP to dispose of.

Discussion
See the `IconActionProcPtr` (page 1302) callback for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Icons.h`

DisposeIconGetterUPP

Disposes of the universal procedure pointer (UPP) to your icon getter callback function.

```
void DisposeIconGetterUPP (
   IconGetterUPP userUPP
);
```

Parameters

userUPP
The UPP to dispose of.

Discussion
See the `IconGetterProcPtr` (page 1303) callback for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Icons.h`

DisposeIconSuite

Releases the memory occupied by an icon suite. (Deprecated in Mac OS X v10.5. Use Icon Services instead.)

```
OSErr DisposeIconSuite (
   IconSuiteRef theIconSuite,
   Boolean disposeData
);
```

Parameters

theIconSuite

A handle to the icon suite to be disposed of.

disposeData

A Boolean value indicating whether or not to dispose of handles in the icon suite that are not associated with a resource fork.

Set this value to `TRUE` to automatically release icon data that is associated with the specified icon suite but not explicitly associated with a resource fork. If you set this value to `FALSE`, the function does not dispose of any icon data that is associated with the specified icon suite.

Return Value

A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Discussion

This function does not release the memory of any icons explicitly associated with an open resource fork, that is, any handles to icon resource data that your application added to the suite using the functions `GetIconSuite` (page 1257) or `AddIconToSuite` (page 1238). For handles to icon data that your application added to the icon suite using `AddIconToSuite` (for example, if your application read in an icon resource, detached it, then added the handle to the suite), you can request that `AddIconToSuite` release the memory associated with the handles.

Special Considerations

This function may move or purge memory blocks in the application heap. For that reason, your application should not call it at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Icons.h`

FlushIconRefs

Reclaims memory used by the specified icon if the memory is purgeable. (Deprecated in Mac OS X v10.3. There is no replacement; this function was included to facilitate porting classic applications to Carbon, but it serves no useful purpose in Mac OS X.)

```
OSErr FlushIconRefs (
   OSType creator,
   OSType iconType
);
```

Parameters

creator

The creator code of the file whose icon data is to be flushed.

iconType
The type code of the file whose icon data is to be flushed.

Return Value
A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Special Considerations

This function does nothing in Mac OS X.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.3.
Not available to 64-bit applications.

Declared In
`IconsCore.h`

FlushIconRefsByVolume

On a given volume, reclaims memory used by purgeable icons. (Deprecated in Mac OS X v10.3. There is no replacement; this function was included to facilitate porting classic applications to Carbon, but it serves no useful purpose in Mac OS X.)

```
OSErr FlushIconRefsByVolume (
   SInt16 vRefNum
);
```

Parameters

vRefNum
The volume whose icon cache is to be flushed.

Return Value
A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Discussion
Calling this function locks the bitmap data of all `IconRefs` with non-zero reference counts (that is, all `IconRefs` that are in use) on the volume. The Finder normally maintains a number of `IconRefs` with non-zero reference counts, so you should use the function `FlushIconRefs` (page 1242) instead of the `FlushIconRefsByVolume` function whenever feasible.

Special Considerations

This function does nothing in Mac OS X.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.3.
Not available to 64-bit applications.

Declared In
`IconsCore.h`

ForEachIconDo

Performs an action on one or more icons in an icon suite. (Deprecated in Mac OS X v10.5. Use Icon Services instead.)

```
OSErr ForEachIconDo (
   IconSuiteRef theSuite,
   IconSelectorValue selector,
   IconActionUPP action,
   void *yourDataPtr
);
```

Parameters

theSuite

A handle to an icon suite.

selector

Indicates which icons in the suite to perform the operation on. See "Icon Selector Constants" (page 1310) for a description of the values you can use in this parameter.

action

A universal procedure pointer to your icon action callback function. The `ForEachIconDo` function uses this icon action function to perform an action on the specified icons in the icon suite.

`ForEachIconDo` calls your icon action function once for each type of icon specified in the `selector` parameter. `ForEachIconDo` passes to your icon action function a handle to the icon to perform the action on. Your icon action function should perform any action as indicated by the `yourDataPtr` parameter and return a result code.

See the `IconActionProcPtr` (page 1302) callback for more information about icon action functions.

yourDataPtr

A pointer to data or other information required by your icon action function that is passed to your icon action function. Typically, you use this parameter to specify which action your icon action function should perform.

Return Value

A result code. See "Icon Services and Utilities Result Codes" (page 1324). The result code returned by your icon action function. If your icon action function returns a nonzero function result, `ForEachIconDo` immediately returns to the application.

Special Considerations

This function may move or purge memory blocks in the application heap. For that reason, your application should not call it at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Icons.h`

GetCIcon

Gets a handle to a color icon of resource type `'cicn'`. (Deprecated in Mac OS X v10.5. Use Icon Services instead.)

```
CIconHandle GetCIcon (
   SInt16 iconID
);
```

Parameters

iconID

The resource ID for an icon of resource type `'cicn'`. In general, you should specify your icon resources as purgeable.

Return Value

A handle to the `CIcon` (page 1305) structure for the icon, or `NULL` if the function could not find the resource.

Discussion

The function searches the current resource chain for the resource. If it finds the resource, it reads the resource, creates a color icon structure for the icon, and initializes the fields of the structure according to the information contained in the `'cicn'` resource.

To draw an icon obtained from this function in a specified rectangle, you can use either the `PlotCIcon` (page 1275) function, or the `PlotCIconHandle` (page 1276) function. The latter function allows you to specify transforms and alignments.

When you are finished with a handle obtained from this function, use the `DisposeCIcon` (page 1240) function to release the memory occupied by the color icon structure.

Special Considerations

This function may move or purge memory blocks in the application heap. For that reason, your application should not call it at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Icons.h`

GetCustomIconsEnabled

Determines whether custom icons are enabled or disabled on a specified volume.

```
OSErr GetCustomIconsEnabled (
   SInt16 vRefNum,
   Boolean *customIconsEnabled
);
```

Parameters

vRefNum

The volume whose status you are querying.

customIconsEnabled

On return, `customIconsEnabled` points to the value `true` if custom icons are enabled on the volume specified or `false` if custom icons are disabled on the volume specified.

Return Value

A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`IconsCore.h`

GetIcon

Gets a handle to an icon resource of type `'ICON'`. (Deprecated in Mac OS X v10.5. Use Icon Services instead.)

```
Handle GetIcon (
   SInt16 iconID
);
```

Parameters

iconID

The resource ID for an icon of resource type `'ICON'`. The function searches the current resource chain for the resource. In general, you should specify your icon resources as purgeable.

Return Value
A handle to the icon with the specified ID or `NULL` if the function could not find the resource.

Discussion
To draw an icon obtained from this function in a specified rectangle, you can use either the `PlotIcon` (page 1277) function, or the `PlotIconHandle` (page 1278) function. The latter function allows you to specify transforms and alignments.

When you are finished using a handle obtained from this function, use the `ReleaseResource` function to release the memory occupied by the icon resource data.

Special Considerations

This function may move or purge memory blocks in the application heap. For that reason, your application should not call it at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Icons.h`

GetIconCacheData

Gets the data associated with an icon cache. (Deprecated in Mac OS X v10.5. Use Icon Services instead.)

```
OSErr GetIconCacheData (
   IconCacheRef theCache,
   void **theData
);
```

Parameters

theCache

A handle to the icon cache whose data is desired.

theData

On return, a pointer to a pointer to the data associated with the icon cache.

You associate data with an icon cache when you first create the cache using the `MakeIconCache` (page 1272) function. You can also set this data using the `SetIconCacheData` (page 1298) function.

Return Value
A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Discussion
All the Icon Utilities functions that accept a handle to an icon suite also accept a handle to an icon cache.

Special Considerations

This function may move or purge memory blocks in the application heap. For that reason, your application should not call it at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Icons.h`

GetIconCacheProc

Gets the icon getter function associated with an icon cache. (Deprecated in Mac OS X v10.5. Use Icon Services instead.)

```
OSErr GetIconCacheProc (
   IconCacheRef theCache,
   IconGetterUPP *theProc
);
```

Parameters

theCache

A handle to the icon cache whose associated icon getter function is desired.

theProc

On return, a pointer to the universal procedure pointer to the icon getter callback function associated with the specified cache. See the `IconGetterProcPtr` (page 1303) callback for more information on icon getter functions.

Return Value
A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Discussion
All the Icon Utilities functions that accept a handle to an icon suite also accept a handle to an icon cache. An icon cache is like an icon suite except that it also contains a pointer to an icon getter callback function and a pointer to data that can be used as a reference constant. An icon cache typically does not contain handles to the icon resources for all icon family members. Instead, if the icon cache does not contain an entry for a specific type of icon in an icon family, the Icon Utilities functions call your application's icon getter function to retrieve the data for that icon type.

Special Considerations

This function may move or purge memory blocks in the application heap. For that reason, your application should not call it at interrupt time.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In
`Icons.h`

GetIconFamilyData

Obtains a copy of the raw icon data for an individual element in an icon family.

```
OSErr GetIconFamilyData (
   IconFamilyHandle iconFamily,
   OSType iconType,
   Handle h
);
```

Parameters

iconFamily

A handle to an `iconFamily` data structure to use as a source for icon data.

iconType

The format of the icon data you want to obtain.You may specify one of the icon types (as defined in `IconStorage.h` in the CoreServices/OSServices framework) or `'PICT'` in this parameter. For example, you can pass `kThumbnail32BitData` (`'it32'`), to obtain 65,536 bytes of raw bitmap data.

h

A handle to the icon data being returned. Icon Services resizes this handle as needed. If no data is available for the specified icon family, Icon Services sets the handle to 0.

Return Value
A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Icons.h`

GetIconFromSuite

Gets an icon from an icon suite. (Deprecated in Mac OS X v10.5. Use Icon Services instead.)

```
OSErr GetIconFromSuite (
   Handle *theIconData,
   IconSuiteRef theSuite,
   ResType theType
);
```

Parameters

theIconData

On return, a pointer to a handle to the data for the requested icon. If an icon of the specified type does not exist in the given icon suite, this parameter is `NULL`.

If you intend to dispose of the handle, pass a `NULL` handle to the `AddIconToSuite` (page 1238) function to delete the corresponding entry in the suite.

You can use the handle returned by this function to manipulate the icon data, for example, to alter its color or add three-dimensional shading. However, you should not use the returned handle to draw the icon with other Icon Utilities functions.

To plot an icon from an icon suite, you should normally use the `PlotIconSuite` (page 1282) function. The `PlotIconHandle` (page 1278) function may not draw the icon correctly if you pass it the handle returned in this parameter.

theSuite

A handle to the icon suite from which to get the icon.

theType

The resource type of the desired icon.

Return Value

A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Special Considerations

This function may move or purge memory blocks in the application heap. For that reason, your application should not call it at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Icons.h`

GetIconRef

Provides an `IconRef` object for an icon in the desktop database or for a registered icon.

```
OSErr GetIconRef (
   SInt16 vRefNum,
   OSType creator,
   OSType iconType,
   IconRef *theIconRef
);
```

Parameters

vRefNum

The volume where Icon Services should start to search for the desired icon. Pass the `kOnSystemDisk` constant if you are not sure which value to specify in this parameter.

creator

The creator code of the desired icon.

iconType

The type code of the desired icon.

theIconRef

On return, a pointer to an `IconRef` object. You are responsible for releasing the object by calling `ReleaseIconRef` (page 1296).

Return Value
A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Discussion
Icon Services defines constants for commonly-used system icons. You can pass one of these constants in the `iconType` parameter if you specify `kSystemIconsCreator` in the `creator` parameter. See "Folder Icon Constants" (page 1315) for a list of these constants.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`IconsCore.h`

GetIconRefFromComponent

Provides an `IconRef` object based on a specified component.

```
OSStatus GetIconRefFromComponent (
   Component inComponent,
   IconRef *outIconRef
);
```

Parameters

inComponent

The component whose icon data you want to obtain.

outIconRef

On return, a pointer to an `IconRef` object based on the `componentIconFamily` field of the specified component's `'thng'` resource. You are responsible for releasing the object by calling `ReleaseIconRef` (page 1296).

Return Value
A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Discussion
This function obtains an `IconRef` object based on the resource ID of an icon family. A component can provide an icon family in addition to the icon provided in the `componentIcon` field. Note that members of this icon family are not used by the Finder; you supply an icon family only so that other components or applications can display your component's icon in their user interfaces if needed.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`IconsCore.h`

GetIconRefFromFile

Provides an `IconRef` object for a file, folder or volume. (Deprecated in Mac OS X v10.5. Use `GetIconRefFromFileInfo` (page 1251) instead.)

```
OSErr GetIconRefFromFile (
   const FSSpec *theFile,
   IconRef *theIconRef,
   SInt16 *theLabel
);
```

Parameters

theFile
A pointer to the `FSSpec` structure specifying the file, folder or volume for the `IconRef`.

theIconRef
On return, a pointer to an `IconRef` object. You are responsible for releasing the object by calling `ReleaseIconRef` (page 1296).

theLabel
On return, a pointer to the file or folder's label.

Return Value
A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Discussion
Use this function if you have no information about the file object passed in the `theFile` parameter. If you have already called the File System Manager function `PBGetCatInfo`, you can use the function `GetIconRefFromFolder` (page 1252) if the object is a folder without custom icons or the function `GetIconRef` (page 1249) if the object is a file without custom icons.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`IconsCore.h`

GetIconRefFromFileInfo

Provides an `IconRef` object for a file with minimal file I/O.

```
OSStatus GetIconRefFromFileInfo (
    const FSRef *inRef,
    UniCharCount inFileNameLength,
    const UniChar *inFileName,
    FSCatalogInfoBitmap inWhichInfo,
    const FSCatalogInfo *inCatalogInfo,
    IconServicesUsageFlags inUsageFlags,
    IconRef *outIconRef,
    SInt16 *outLabel
);
```

Parameters

inRef

A pointer to an `FSRef` for the target file.

inFileNameLength

The length of the name of the target file.

inFileName

A pointer to the name of the target file.

inWhichInfo

The mask of the file information contained in the *inCatalogInfo* parameter.

inCatalogInfo

A pointer to the catalog information.

inUsageFlags

The usage flags for this call; use `kIconServicesNormalUsageFlag`.

outIconRef

On return, a pointer to an `IconRef` object. You are responsible for releasing the object by calling `ReleaseIconRef` (page 1296).

outLabel

On return, a pointer to the output label for the icon/file.

Return Value

A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Discussion

To minimize file operations, `FSGetCatalogInfo` should be called prior to calling this function. The information in the `FSCatalogInfo` structure should correspond to that specified by `kIconServicesCatalogInfoMask`. The name should be fetched and passed in. If either the name or the correct catalog information is not passed in, this function will do file operations for this information instead.

Availability

Available in Mac OS X v10.1 and later.

Declared In

`IconsCore.h`

GetIconRefFromFolder

Provides an `IconRef` object for a folder with no custom icon.

```
OSErr GetIconRefFromFolder (
   SInt16 vRefNum,
   SInt32 parentFolderID,
   SInt32 folderID,
   SInt8 attributes,
   SInt8 accessPrivileges,
   IconRef *theIconRef
);
```

Parameters

vRefNum

The volume where the folder is located.

parentFolderID

The ID of the desired folder's parent folder.

folderID

The ID of the desired folder.

attributes

The attributes of the desired folder. You can obtain this data from the `CInfoPBRec.dirInfo.ioFlAttrib` field of the folder's catalog information record.

accessPrivileges

The access privileges of the specified folder. You can obtain this data from the `CInfoPBRec.dirInfo.ioACUser` field of the folder's catalog information record.

theIconRef

On return, a pointer to an `IconRef` object. You are responsible for releasing the object by calling `ReleaseIconRef` (page 1296).

Return Value

A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Discussion

If you do not have the catalog information for a folder, use the function `GetIconRefFromFileInfo` (page 1251).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`IconsCore.h`

GetIconRefFromIconFamilyPtr

Provides an `IconRef` object from a specified icon family.

```
OSStatus GetIconRefFromIconFamilyPtr (
    const IconFamilyResource *inIconFamilyPtr,
    Size inSize,
    IconRef *outIconRef
);
```

Parameters

inIconFamilyPtr

A pointer to an icon family. See `IconStorage.h` for more information.

inSize
The size of the resource buffer containing the icon family.

outIconRef
On return, a pointer to an `IconRef` object that matches the specified inputs. You are responsible for releasing the object by calling `ReleaseIconRef` (page 1296).

Return Value
A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Discussion
Typically, you do not need to use this function.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`IconsCore.h`

GetIconRefFromTypeInfo

Provides an `IconRef` object with the specified type information.

```
OSErr GetIconRefFromTypeInfo (
    OSType inCreator,
    OSType inType,
    CFStringRef inExtension,
    CFStringRef inMIMEType,
    IconServicesUsageFlags inUsageFlags,
    IconRef *outIconRef
);
```

Parameters

inCreator
The creator code of the desired `IconRef`. You may pass 0 if the creator code is unknown.

inType
The type code of the desired `IconRef`. You may pass 0 if the type code is unknown.

inExtension
The file name extension of the desired `IconRef`. You may pass `NULL` if the extension is unknown.

inMIMEType
The MIME type of the desired `IconRef`. You may pass `NULL` if the MIME type is unknown.

inUsageFlags
The usage flags; use `kIconServicesNormalUsageFlag`.

outIconRef
On return, a pointer to an `IconRef` object that most closely matches the specified inputs. You are responsible for releasing the object by calling `ReleaseIconRef` (page 1296).

Return Value
A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Discussion
This function serves as a more versatile version of `GetIconRef` (page 1249). If you specify creator and type codes and do not specify the extension and MIME type, calling this function is equivalent to calling `GetIconRef (kOnSystemDisk, inCreator, inType)`. If none of the input parameters is specified or if no match is found, this function returns the generic document icon.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`IconsCore.h`

GetIconRefOwners

Provides the current reference count for an `IconRef`.

```
OSErr GetIconRefOwners (
   IconRef theIconRef,
   UInt16 *owners
);
```

Parameters

`theIconRef`
An `IconRef` whose reference count you wish to obtain.

`owners`
On return, a pointer to the value which represents the current reference count.

Return Value
A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Discussion
When an `IconRef`'s reference count reaches 0, all memory allocated for the `IconRef` is marked as disposable. Any subsequent attempt to use the `IconRef` returns a result code of `-2580` (`invalidIconRefErr`).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`IconsCore.h`

GetIconRefVariant

Specifies a transformation for a given `IconRef`.

```
IconRef GetIconRefVariant (
   IconRef inIconRef,
   OSType inVariant,
   IconTransformType *outTransform
);
```

Parameters

`inIconRef`
A value to be tested.

inVariant

A four-character value. You specify a variant by passing one of the following constants:

`kTileIconVariant` specifies a tiled icon.

`kRolloverIconVariant` specifies a rollover icon.

`kDropIconVariant` specifies a drop target icon.

`kOpenIconVariant` specifies an open icon.

`kOpenDropIconVariant` specifies a open drop target icon.

outTransform

On completion, this points to a transformation type that you pass to the function `PlotIconRef` (page 1281) for purposes of hit-testing.

Return Value

An `IconRef` value that you pass to the function `PlotIconRef` (page 1281) for purposes of hit-testing.

Discussion

Icon variants give you a simple way to indicate a temporary change of state by changing an icon's appearance. For example, if you specify the `kDropIconVariant` value when the user drags over a valid drop target, the `GetIconVariant` function provides the appropriate data for you to plot the variant with the function `PlotIconRef` (page 1281).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Icons.h`

GetIconSizesFromIconRef

Provides an `IconSelectorValue` indicating the sizes and depths of icon data available for an `IconRef`. (Deprecated in Mac OS X v10.3. Use `IsDataAvailableInIconRef` (page 1268) instead.)

```
OSErr GetIconSizesFromIconRef (
   IconSelectorValue iconSelectorInput,
   IconSelectorValue *iconSelectorOutputPtr,
   IconServicesUsageFlags iconServicesUsageFlags,
   IconRef theIconRef
);
```

Parameters

iconSelectorInput

The icon sizes and depths you are requesting from the `IconRef`. For a description of the possible values, see "Icon Selector Constants" (page 1310).

iconSelectorOutputPtr

On return, this points to a value describing the icon sizes and depths available for the specified `IconRef`. For a description of the possible values, see "Icon Selector Constants" (page 1310).

iconServicesUsageFlags

Reserved for future use. Pass the `kIconServicesNormalUsageFlag` constant in this parameter.

theIconRef

The icon family to query.

Return Value
A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Discussion
Note that this function may be very time-consuming, as Icon Services may have to search disks or even the network to obtain the requested data.

Special Considerations

Because this function is so time-consuming, it is more efficient to simply query the icon for particular data using the function `IsDataAvailableInIconRef` (page 1268).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.3.
Not available to 64-bit applications.

Declared In
`Icons.h`

GetIconSuite

Creates an icon suite in memory that contains handles to a specified icon family's resources. (Deprecated in Mac OS X v10.5. Use Icon Services instead.)

```
OSErr GetIconSuite (
   IconSuiteRef *theIconSuite,
   SInt16 theResID,
   IconSelectorValue selector
);
```

Parameters

theIconSuite
On return, a pointer to a handle to an icon suite for the requested icon family, for which this function allocates the memory. To release the memory occupied by an icon suite, you must use the `DisposeIconSuite` function.

theResID
The resource ID of the icons in the icon family to be read into memory. In general, you should specify your icon resources as purgeable.

selector
Indicates which icons from the icon family to include in the icon suite. See "Icon Selector Constants" (page 1310) for a description of the values you can use in this parameter.

Return Value
A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Discussion
When you create an icon suite from icon family resources, the associated resource file should remain open while you use Icon Utilities functions. If you call the `SetResLoad` function with the `load` parameter set to `FALSE` before you call this function, the suite is filled with unloaded resource handles.

When you create an icon suite using this function, it sets the default label for the suite to none. To set a new default label for an icon suite, use the `SetSuiteLabel` (page 1300) function. To perform operations on one or more icons in an icon suite, use the `ForEachIconDo` (page 1244) function. To draw the icon described by the icon suite using the icon family member that is most suitable for the current bit depth of the display device, use the `PlotIconSuite` (page 1282) function.

As an alternative to this function, you can also create an empty icon suite using the `NewIconSuite` (page 1273) function and then add icons to it one at a time using the `AddIconToSuite` (page 1238) function.

Special Considerations

This function may move or purge memory blocks in the application heap. For that reason, your application should not call it at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Icons.h`

GetLabel

Gets the color and string used for a given label in the Label menu of the Finder and in the Labels control panel. (Deprecated in Mac OS X v10.5. Use Icon Services instead.)

```
OSErr GetLabel (
   SInt16 labelNumber,
   RGBColor *labelColor,
   Str255 labelString
);
```

Parameters

labelNumber
An integer from 1 to 7 indicating which label's information is requested.

labelColor
On return, a pointer to the color of the specified label.

labelString
On return, the string associated with the specified label.

Return Value
A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Special Considerations

This function may move or purge memory blocks in the application heap. For that reason, your application should not call it at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Icons.h`

GetSuiteLabel

Gets the default label setting associated with an icon suite. (Deprecated in Mac OS X v10.5. Use Icon Services instead.)

```
SInt16 GetSuiteLabel (
   IconSuiteRef theSuite
);
```

Parameters

theSuite
A handle to an icon suite.

Return Value
The default label setting associated with the specified icon suite. The default label setting is an integer from 1 to 7 that specifies which of the label colors shown in the Finder's Label menu is applied to icons of that suite when your application displays them. The function returns 0 if the suite doesn't have a label. You can override the default label setting for a suite by specifying a label in the `transform` parameter of the `PlotIconSuite` (page 1282) function. To get information about the color and string for a specific label, you can use the `GetLabel` (page 1258) function.

Special Considerations

This function may move or purge memory blocks in the application heap. For that reason, your application should not call it at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Icons.h`

IconFamilyToIconSuite

Provides icon suite data for a given icon family. (Deprecated in Mac OS X v10.5. Use Icon Services instead.)

```
OSErr IconFamilyToIconSuite (
   IconFamilyHandle iconFamily,
   IconSelectorValue whichIcons,
   IconSuiteRef *iconSuite
);
```

Parameters

iconFamily
A handle to an `iconFamily` data structure to use as a source for icon data. For more information on the `IconFamily` data structure, see 'icns'.

whichIcons

The depths and sizes of icons to extract from the IconFamily data structure. For a description of the possible values, see "Icon Selector Constants" (page 1310).

iconSuite

On return, a pointer to the structure which contains icon data as specified in the `iconFamily` and `whichIcons` parameters. Icon Services returns `NULL` if no appropriate icon data is found.

Return Value
A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Icons.h`

IconIDToRgn

Converts the icon mask in an icon family to a region. (Deprecated in Mac OS X v10.5. Use Icon Services instead.)

```
OSErr IconIDToRgn (
   RgnHandle theRgn,
   const Rect *iconRect,
   IconAlignmentType align,
   SInt16 iconID
);
```

Parameters

theRgn

On return, a handle to the requested region. You must allocate memory for the region handle before calling this function.

The returned region corresponds to the icon's mask (the mask defined by either an `'ICN#'` or `'ics#'` resource in an icon family, according to the rectangle and alignment specified in the `iconRect` and `align` parameters).

Once you have a region that describes the icon mask for a given icon, you can use it to perform accurate hit-testing and outline dragging of the icon in your application.

iconRect

A pointer to the rectangle in which to draw the icon, specified in local coordinates of the current graphics port. The function uses this rectangle as the bounding box of the region. The function determines, from the size of the rectangle specified here, which icon mask to use from the specified icon family.

align

Specifies how the function should align the mask within the rectangle. See "Icon Alignment Constants" (page 1307) for a description of the values you can use in this parameter.

iconID

The resource ID of the icon for which to create a region. In general, you should specify your icon resources as purgeable.

Return Value
A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Special Considerations

This function may move or purge memory blocks in the application heap. For that reason, your application should not call it at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Icons.h`

IconMethodToRgn

Converts, to a region, the mask for an icon that `IconMethodToRgn` obtains with the aid of your icon getter callback function. (Deprecated in Mac OS X v10.5. Use Icon Services instead.)

```
OSErr IconMethodToRgn (
   RgnHandle theRgn,
   const Rect *iconRect,
   IconAlignmentType align,
   IconGetterUPP theMethod,
   void *yourDataPtr
);
```

Parameters

theRgn

On return, a handle to the requested region. You must allocate memory for the region handle before calling this function. Once you have a region that describes the icon mask for a given icon, you can use it to perform accurate hit-testing and outline dragging of the icon in your application.

iconRect

A pointer to the rectangle in which to draw the icon, specified in local coordinates of the current graphics port. The function obtains the data for the icon mask from your icon getter function and then converts the icon mask to a region. The function uses the rectangle specified in this parameter as the bounding box of the region.

align

Specifies how the function should align the mask within the rectangle. See "Icon Alignment Constants" (page 1307) for a description of the values you can use in this parameter.

theMethod

A universal procedure pointer to your icon getter callback function. `IconMethodToRgn` passes to your icon getter function the type of the icon to get and the value specified in the `yourDataPtr` parameter. The `IconMethodToRgn` function examines the size of the rectangle and requests the appropriate icon from your icon getter function—an icon of icon type `'ICN#'` or `'ics#'`. Your icon getter function should return a handle to the data of the requested icon type. The `IconMethodToRgn` function extracts the mask from the icon data that your icon getter function returns. If your icon getter function returns data that does not correspond to an icon of type `'ICN#'` or type `'ics#'`, `IconMethodToRgn` attempts to generate a mask from the returned data.

Your icon getter function can get the data for the icon and its mask using whatever method is appropriate to your application. For example, your application might maintain its own cache of icons (and pass a pointer to it in the `yourDataPtr` parameter) or use its icon getter function to get an icon from the desktop database.

See the `IconGetterProcPtr` (page 1303) callback for more information on creating an icon getter function.

Return Value
A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Special Considerations

This function may move or purge memory blocks in the application heap. For that reason, your application should not call it at interrupt time.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In
`Icons.h`

IconRefContainsCGPoint

Returns a Boolean value indicating whether an icon contains a specified point.

```
Boolean IconRefContainsCGPoint (
   const CGPoint *testPt,
   const CGRect *iconRect,
   IconAlignmentType align,
   IconServicesUsageFlags iconServicesUsageFlags,
   IconRef theIconRef
);
```

Parameters

testPt

A pointer to the point to be tested. The point should be specified in the coordinate system of the rectangle specified in the `iconRect` parameter.

iconRect

A pointer to the rectangle in which the icon appears. The rectangle you specify should be the same rectangle that you last used to draw the icon.

align
Specifies how the icon is aligned within the rectangle specified in the `iconRect` parameter. The alignment you specify should be the same alignment that you last used to draw the icon. See "`Icon Alignment Constants`" (page 1307) for a description of the values you can use in this parameter.

iconServicesUsageFlags
Reserved for future use. Pass the `kIconServicesNormalUsageFlag` constant in this parameter.

theIconRef
The icon to test.

Return Value
`TRUE` if the point is in the icon and `FALSE` if it is not.

Discussion
This function uses the size of the rectangle you specify to determine the optimal icon mask to represent the icon. The function uses the alignment information you specify to adjust the position of the mask inside its bounding rectangle, and then determines whether the specified point is within the mask.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`Icons.h`

IconRefIntersectsCGRect

Returns a Boolean value indicating whether an icon intersects a specified rectangle.

```
Boolean IconRefIntersectsCGRect (
   const CGRect *testRect,
   const CGRect *iconRect,
   IconAlignmentType align,
   IconServicesUsageFlags iconServicesUsageFlags,
   IconRef theIconRef
);
```

Parameters

testRect
A pointer to the rectangle to be tested. The rectangle should be specified in the coordinate system of the rectangle specified in the `iconRect` parameter.

iconRect
A pointer to the rectangle in which the icon appears. The rectangle you specify should be the same rectangle that you last used to draw the icon.

align
Specifies how the icon is aligned within the rectangle specified by the `iconRect` parameter. The alignment you specify should be the same alignment that you last used to draw the icon. See "Icon Alignment Constants" (page 1307) for a description of the values you can use in this parameter.

iconServicesUsageFlags
Reserved for future use. Pass the `kIconServicesNormalUsageFlag` constant in this parameter.

theIconRef
The icon to test.

Return Value
`TRUE` if the point is in the icon and `FALSE` if it is not.

Discussion
This function uses the size of the rectangle you specify in the `iconRect` parameter to determine the optimal icon mask to represent the icon. The function uses the alignment information you specify to adjust the position of the mask inside its bounding rectangle, and then determines whether the rectangle you specify in the `testRect` parameter intersects the mask.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`Icons.h`

IconRefToHIShape

Converts an icon into an HIShape object.

```
HIShapeRef IconRefToHIShape (
   const CGRect *iconRect,
   IconAlignmentType align,
   IconServicesUsageFlags iconServicesUsageFlags,
   IconRef theIconRef
);
```

Parameters

iconRect
A pointer to the rectangle defining the area that Icon Services uses as the bounding box of the shape.

align
A value which determines how Icon Services aligns the shape within the rectangle. For a description of possible values, see "Icon Alignment Constants" (page 1307).

iconServicesUsageFlags
Reserved for future use. Pass the `kIconServicesNormalUsageFlag` constant in this parameter.

theIconRef
The icon to be converted.

Return Value
An HIShape object, or `NULL` if the icon could not be converted.

Discussion
This function uses the size of the rectangle you specify to determine the optimal icon mask to represent the icon. The function uses the alignment information you specify to adjust the position of the mask inside its bounding rectangle, and then returns the shape of the mask.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`Icons.h`

IconRefToIconFamily

Provides icon family data for a given `IconRef`.

```
OSErr IconRefToIconFamily (
   IconRef theIconRef,
   IconSelectorValue whichIcons,
   IconFamilyHandle *iconFamily
);
```

Parameters

theIconRef

An `IconRef` to use as a source for icon data.

whichIcons

The depths and sizes of icons in the `iconFamily` data structure. For a description of the possible values, see "Icon Selector Constants" (page 1310).

iconFamily

On return, a pointer to a handle to the data structure which contains icon data as specified in the `IconRef` and `whichIcons` parameters. Icon Services returns `NULL` if no appropriate icon data is found. For more information on the `IconFamily` data structure, see 'icns'.

Return Value

A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Icons.h`

IconRefToRgn

Converts an Icon Services icon into a QuickDraw region. (Deprecated in Mac OS X v10.5. Use `IconRefToHIShape` (page 1264) instead.)

```
OSErr IconRefToRgn (
   RgnHandle theRgn,
   const Rect *iconRect,
   IconAlignmentType align,
   IconServicesUsageFlags iconServicesUsageFlags,
   IconRef theIconRef
);
```

Parameters

theRgn

A handle to the requested region. You must call the QuickDraw function `NewRegion` to allocate memory for the region handle before calling the `IconRefToRgn` function.

iconRect

A pointer to the rectangle defining the area that Icon Services uses as the bounding box of the region.

align

The value which determines how Icon Services aligns the region within the rectangle. For a description of possible return values, see "Icon Alignment Constants" (page 1307).

iconServicesUsageFlags
Reserved for future use. Pass the `kIconServicesNormalUsageFlag` constant in this parameter.

theIconRef
The `IconRef` for the icon family to use for drawing the requested region.

Return Value
A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Discussion
Icon Services uses the rectangle and alignment values to automatically select the icon used to generate the region data.

This function is similar to the Icon Utilities function `IconSuiteToRegion`.

Icon Services uses the icon's black-and-white mask to determine the region data, even if you provide a deep mask.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Icons.h`

IconSuiteToIconFamily

Provides `IconFamily` data for a specified `IconSuite`. (Deprecated in Mac OS X v10.5. Use Icon Services instead.)

```
OSErr IconSuiteToIconFamily (
   IconSuiteRef iconSuite,
   IconSelectorValue whichIcons,
   IconFamilyHandle *iconFamily
);
```

Parameters
iconSuite
The `IconSuiteRef` to use as a source for icon data.

whichIcons
The depths and sizes of icons to extract from the `iconFamily` data structure. For a description of the possible values, see "Icon Selector Constants" (page 1310).

iconFamily
On return, a pointer to a handle to the structure which contains icon data as specified in the `iconSuite` and `whichIcons` parameters. Icon Services returns `NULL` if no appropriate icon data is found. For more information on the `IconFamily` data structure, see 'icns'.

Return Value
A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In
`Icons.h`

IconSuiteToRgn

Converts the icon mask in an icon suite to a region. (Deprecated in Mac OS X v10.5. Use Icon Services instead.)

```
OSErr IconSuiteToRgn (
   RgnHandle theRgn,
   const Rect *iconRect,
   IconAlignmentType align,
   IconSuiteRef theIconSuite
);
```

Parameters

theRgn

On return, a handle to the requested region. You must allocate memory for the region handle before calling this function.

The returned region corresponds to the icon's mask (the mask defined by either an `'ICN#'` or `'ics#'` entry in an icon suite, according to the rectangle and alignment specified in the `iconRect` and `align` parameters).

Once you have a region that describes the icon mask for a given icon, you can use it to perform accurate hit-testing and outline dragging of the icon in your application.

iconRect

A pointer to the rectangle in which the icon is to be drawn, specified in local coordinates of the current graphics port. The function uses this rectangle as the bounding box of the region. The function determines, from the size of the rectangle specified here, which icon mask to use from the icon suite.

align

Specifies how the function should align the region within the rectangle. See "Icon Alignment Constants" (page 1307) for a description of the values you can use in this parameter.

theIconSuite

A handle to an icon suite.

Return Value
A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Special Considerations

This function may move or purge memory blocks in the application heap. For that reason, your application should not call it at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Icons.h`

InvokeIconActionUPP

Calls your icon action callback function.

```
OSErr InvokeIconActionUPP (
   ResType theType,
   Handle *theIcon,
   void *yourDataPtr,
   IconActionUPP userUPP
);
```

Return Value
A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Discussion
You should not need to use the function `InvokeIconActionUPP`, as the system calls your icon action callback function for you.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Icons.h`

InvokeIconGetterUPP

Calls your icon getter callback function.

```
Handle InvokeIconGetterUPP (
   ResType theType,
   void *yourDataPtr,
   IconGetterUPP userUPP
);
```

Discussion
You should not need to use the function `InvokeIconGetterUPP`, as the system calls your icon getter callback function for you.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Icons.h`

IsDataAvailableInIconRef

Indicates whether an `IconRef` has the specified data.

```
Boolean IsDataAvailableInIconRef (
   OSType inIconKind,
   IconRef inIconRef
);
```

Parameters

inIconKind

The icon data kind. See `IconStorage.h` for more information.

inIconRef

The icon reference whose data you want to check.

Return Value

`True` if the icon reference contains the indicated data, `False` otherwise.

Discussion

This function can be used to determine the optimal icon size if you plan to cache a bitmap image of the icon.

Availability

Available in Mac OS X v10.3 and later.

Declared In

`IconsCore.h`

IsIconRefComposite

Reports whether a specified `IconRef` has been composited.

```
OSErr IsIconRefComposite (
   IconRef compositeIconRef,
   IconRef *backgroundIconRef,
   IconRef *foregroundIconRef
);
```

Parameters

compositeIconRef

An `IconRef` that you wish to test to determine whether it has been composited.

backgroundIconRef

On return, this points to the `IconRef` value that forms the background of the `IconRef` specified in the `compositeIconRef` parameter. If the `IconRef` specified in the `compositeIconRef` parameter is not a composite, the return value is 0.

foregroundIconRef

On return, this points to the `IconRef` value that forms the foreground of the `IconRef` specified in the `compositeIconRef` parameter. If the `IconRef` specified in the `compositeIconRef` parameter is not a composite, the return value is 0.

Return Value

A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Discussion

The function `CompositeIconRef` (page 1239) allows the creation of a composite `IconRef` from a given background `IconRef` and a given foreground `IconRef`. The `IsIconRefComposite` function checks a specified `IconRef` to determine whether it is a composite and, if so, provides the background and foreground `IconRef` values.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`IconsCore.h`

IsIconRefMaskEmpty

Reports whether a specified mask is empty.

```
Boolean IsIconRefMaskEmpty (
   IconRef iconRef
);
```

Parameters

`iconRef`
An `IconRef` whose mask you wish to test.

Return Value
`true` if the mask associated with the given `IconRef` is empty, `false` otherwise.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Icons.h`

IsValidIconRef

Reports whether a specified `IconRef` is valid.

```
Boolean IsValidIconRef (
   IconRef theIconRef
);
```

Parameters

`theIconRef`
An `IconRef`.

Return Value
`true` if the specified `IconRef` is valid, `false` otherwise.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`IconsCore.h`

LoadIconCache

Loads into an icon cache a handle to the appropriate icon data for a specified destination rectangle and the current bit depth, for drawing later with a specified alignment and transform. (Deprecated in Mac OS X v10.5. Use Icon Services instead.)

```
OSErr LoadIconCache (
   const Rect *theRect,
   IconAlignmentType align,
   IconTransformType transform,
   IconCacheRef theIconCache
);
```

Parameters

theRect

A pointer to the rectangle in which to draw the icon, specified in local coordinates of the current graphics port. The function uses the rectangle specified in this parameter and the bit depth of the display device to determine which icon type to load into the cache.

align

Specifies how to align the icon within the rectangle. See "Icon Alignment Constants" (page 1307) for a description of the values you can use in this parameter.

transform

Specifies how to modify the appearance of the icon. See "Icon Transformation Constants" (page 1309) for a description of the values you can use in this parameter.

theIconCache

A reference to the icon cache into which to load the icon data.

Return Value

A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Discussion

This function can be useful, for example, if you suspect that the icon may be drawn at a time not convenient for loading resource data (for instance, when the resource fork isn't in the current resource chain). The function uses the same criteria as the `PlotIconSuite` (page 1282) function to select the icon to load.

This function uses the icon getter callback function associated with the icon cache to get the appropriate icon. The icon getter function returns a handle to the requested icon data, and `LoadIconCache` adds the returned handle to the entry for that icon in the icon cache.

After calling this function, you can pass the same parameters to `PlotIconSuite` to plot the icon data. Note that if you specify an alignment when you call `LoadIconCache`, then call `PlotIconSuite` and specify no alignment, `PlotIconSuite` draws the icon using the alignment that you originally specified to `LoadIconCache`.

All the Icon Utilities functions that accept a handle to an icon suite also accept a handle to an icon cache.

Special Considerations

This function may move or purge memory blocks in the application heap. For that reason, your application should not call it at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Icons.h`

MakeIconCache

Gets a handle to an empty icon cache. (Deprecated in Mac OS X v10.5. Use Icon Services instead.)

```
OSErr MakeIconCache (
   IconCacheRef *theCache,
   IconGetterUPP makeIcon,
   void *yourDataPtr
);
```

Parameters

theCache

On return, a pointer to a handle to the new, empty icon cache. The function allocates the necessary memory. You can add icon data to the new cache using the `LoadIconCache` (page 1270) function.

makeIcon

A universal procedure pointer to the icon getter callback function to associate with the icon cache. See the `IconGetterProcPtr` (page 1303) callback for more information on icon getter callback functions.

yourDataPtr

A pointer to the data to associate with the icon cache.

Return Value

A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Discussion

All the Icon Utilities functions that accept a handle to an icon suite also accept a handle to an icon cache. An icon cache is like an icon suite except that it also contains a pointer to an icon getter callback function and a pointer to data that can be used as a reference constant. An icon cache typically does not contain handles to the icon resources for all icon family members. Instead, if the icon cache does not contain an entry for a specific type of icon in an icon family, the Icon Utilities functions call your application's icon getter function to retrieve the data for that icon type.

Special Considerations

This function may move or purge memory blocks in the application heap. For that reason, your application should not call it at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Icons.h`

NewIconActionUPP

Creates a new universal procedure pointer (UPP) to an icon action callback function.

```
IconActionUPP NewIconActionUPP (
   IconActionProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your icon action function.

Return Value

A UPP to the icon action function.

Discussion

See the `IconActionProcPtr` (page 1302) callback for more information.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Icons.h`

NewIconGetterUPP

Creates a new universal procedure pointer (UPP) to an icon getter callback function.

```
IconGetterUPP NewIconGetterUPP (
   IconGetterProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your icon getter function.

Return Value

A UPP to the icon getter function.

Discussion

See the `IconGetterProcPtr` (page 1303) callback for more information.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Icons.h`

NewIconSuite

Gets a handle to an empty icon suite. (Deprecated in Mac OS X v10.5. Use Icon Services instead.)

```
OSErr NewIconSuite (
   IconSuiteRef *theIconSuite
);
```

Parameters

theIconSuite

On return, a pointer to a handle to a new, empty icon suite. Use the `AddIconToSuite` (page 1238) function to add handles to icon data.

Return Value

A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Discussion

When you create an icon suite using this function, it sets the default label for the suite to none. To set a new default label for an icon suite, use the `SetSuiteLabel` (page 1300) function. `NewIconSuite` allocates the memory for the icon suite handle. To release the memory occupied by an icon suite, you must use the `DisposeIconSuite` (page 1241) function.

Special Considerations

This function may move or purge memory blocks in the application heap. For that reason, your application should not call it at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Icons.h`

OverrideIconRef

Replaces the bitmaps of one `IconRef` with those of another `IconRef`.

```
OSErr OverrideIconRef (
   IconRef oldIconRef,
   IconRef newIconRef
);
```

Parameters

oldIconRef

A pointer to a value of type `IconRef` whose bitmaps are to be replaced.

newIconRef

A pointer to a value of type`IconRef` containing the replacement bitmaps.

Return Value

A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`IconsCore.h`

OverrideIconRefFromResource

Replaces the bitmaps in an `IconRef` with bitmaps from a specified resource file. (Deprecated in Mac OS X v10.5. Use `OverrideIconRef` (page 1274) instead.)

```
OSErr OverrideIconRefFromResource (
   IconRef theIconRef,
   const FSSpec *resourceFile,
   SInt16 resourceID
);
```

Parameters

theIconRef

An `IconRef` to be updated.

resourceFile

A pointer to the file system specification structure for the resource file containing the replacement bitmaps.

resourceID

The resource ID containing the replacement bitmaps. This value must be non-zero. You should provide a resource of type `'icns'` if possible. If an `'icns'` resource is not available, Icon Services uses standard icon suite resources, such as `'ICN#'`, instead.

Return Value

A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`IconsCore.h`

PlotCIcon

Draws a color icon of resource type `'cicn'` to which you have a handle. (Deprecated in Mac OS X v10.5. Use Icon Services instead.)

```
void PlotCIcon (
   const Rect *theRect,
   CIconHandle theIcon
);
```

Parameters

theRect

A pointer to the rectangle in which to draw the icon, specified in local coordinates of the current graphics port.

theIcon

A handle to the color icon structure of the color icon to draw. You can obtain a handle to the icon using the `GetCIcon` (page 1244) function, or `GetResource` or other Resource Manager functions.

Discussion

The `iconMask` field of the `CIcon` (page 1305) structure determines which pixels in the `iconPMap` field are drawn and which are not. Only pixels with 1s in corresponding positions in the `iconMask` field are drawn. If the screen depth is 1 or 2 bits per pixel, this function uses the `iconBMap` field instead of the `iconPMap` field (unless the `rowBytes` field of `IconBMap` contains 0, indicating that there is no bitmap for the icon).

When this function draws the icon, it uses the `bounds` field of `iconPMap` as the source rectangle of the image. If the destination rectangle is not the same size as the icon or its mask, the function stretches or shrinks the icon to fit. The icon's pixels are remapped to the current depth and color table, if necessary. The `bounds` fields of `iconPMap`, `iconBMap`, and `iconMask` are expected to be equal in size.

Unlike `PlotCIconHandle` (page 1276), this function does not allow you to specify any transforms or alignment. This function uses the QuickDraw function `CopyMask` and doesn't send any of its drawing commands through QuickDraw bottleneck functions. Therefore, calls to this function are not recorded as pictures.

Special Considerations

This function may move or purge memory blocks in the application heap. For that reason, your application should not call it at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Icons.h`

PlotCIconHandle

Draws an icon of resource type `'cicn'` to which you have a handle. (Deprecated in Mac OS X v10.5. Use Icon Services instead.)

```
OSErr PlotCIconHandle (
   const Rect *theRect,
   IconAlignmentType align,
   IconTransformType transform,
   CIconHandle theCIcon
);
```

Parameters

theRect

A pointer to the rectangle in which to draw the icon, specified in local coordinates of the current graphics port.

align

Specifies how the function should align the icon within the rectangle. See "Icon Alignment Constants" (page 1307) for a description of the values you can use in this parameter.

transform

Specifies how the function should modify the appearance of the icon. See "Icon Transformation Constants" (page 1309) for a description of the values you can use in this parameter.

theCIcon

A handle to the color icon structure of the icon to draw. You can obtain a handle to the icon using the `GetCIcon` (page 1244) function or `GetResource` or other Resource Manager functions.

Return Value
A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Discussion
Unlike `PlotCIcon` (page 1275), this function doesn't honor the current foreground and background colors.

Special Considerations

This function may move or purge memory blocks in the application heap. For that reason, your application should not call it at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Icons.h`

PlotIcon

Draws an icon of resource type `'ICON'` to which you have a handle. (Deprecated in Mac OS X v10.5. Use Icon Services instead.)

```
void PlotIcon (
   const Rect *theRect,
   Handle theIcon
);
```

Parameters

theRect

A pointer to the rectangle in which to draw the icon, specified in local coordinates of the current graphics port.

theIcon

A handle to the icon to draw. You must have previously obtained this handle using the `GetIcon` (page 1246) function, or `GetResource` or other Resource Manager functions.

Discussion
This function does not allow you to specify any transforms or alignment. The `PlotIcon` function uses the QuickDraw function `CopyBits` with the `srcCopy` transfer mode. To plot an icon of resource type `'ICON'` with a specified transform and alignment, use the `PlotIconHandle` (page 1278) function.

If the destination rectangle is not 32 by 32 pixels, the function stretches or shrinks the icon to fit.

Special Considerations

This function may move or purge memory blocks in the application heap. For that reason, your application should not call it at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Icons.h`

PlotIconHandle

Draws an icon of resource type `'ICON'` or `'ICN#'` to which you have a handle. (Deprecated in Mac OS X v10.5. Use Icon Services instead.)

```
OSErr PlotIconHandle (
   const Rect *theRect,
   IconAlignmentType align,
   IconTransformType transform,
   Handle theIcon
);
```

Parameters

theRect
A pointer to the rectangle in which to draw the icon, specified in local coordinates of the current graphics port.

align
Specifies how the function should align the icon within the rectangle. See "Icon Alignment Constants" (page 1307) for a description of the values you can use in this parameter.

transform
Specifies how the function should modify the appearance of the icon. See "Icon Transformation Constants" (page 1309) for a description of the values you can use in this parameter.

theIcon
A handle to the icon to draw. You must have previously obtained a handle to the icon using the `GetIcon` (page 1246) function, or `GetResource` or other Resource Manager functions.

Return Value
A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Discussion
To plot an icon from an icon suite, you should normally use `PlotIconSuite` (page 1282). This function may not draw the icon correctly if you pass it the handle returned in the `theIconData` parameter of `GetIconFromSuite` (page 1249).

Special Considerations

This function may move or purge memory blocks in the application heap. For that reason, your application should not call it at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Icons.h`

PlotIconID

Draws the icon described by an icon family. (Deprecated in Mac OS X v10.5. Use Icon Services instead.)

```
OSErr PlotIconID (
   const Rect *theRect,
   IconAlignmentType align,
   IconTransformType transform,
   SInt16 theResID
);
```

Parameters

theRect

A pointer to the rectangle, specified in local coordinates of the current graphics port, in which to draw the icon.

You cannot determine which icon from the family specified by `theResID` the function will draw. The function determines, from the size of the specified destination rectangle and the current bit depth of the display device, which icon of a given size to draw from an icon family. For example, if the destination rectangle has the coordinates (100,100,116,116) and the display device is set to 4-bit color, the function draws the icon of type `'ics4'` if that icon is available in the icon family.

If the width or height of a destination rectangle is greater than or equal to 32, the function uses the 32-by-32 pixel icon with the appropriate bit depth for the display device. If the destination rectangle is less than 32 by 32 pixels and greater than 16 pixels wide or 12 pixels high, `PlotIconID` uses the 16-by-16 pixel icon with the appropriate bit depth. If the destination rectangle's height is less than or equal to 12 pixels or its width is less than or equal to 16 pixels, `PlotIconID` uses the 12-by-16 pixel icon with the appropriate bit depth. (Typically only the Finder and Standard File Package use 12-by-16 pixel icons.)

The destination rectangle must be exactly 32 by 32 pixels, 16 by 16 pixels, or 12 by 16 pixels for the function to draw the icon without stretching it. If the destination rectangle is not one of these standard sizes, the function expands or shrinks the icon to fit.

align

Specifies how the function should align the icon within the rectangle. For example, you can specify that it center the icon within the rectangle or align it at one side or the other. The function moves the icon so that the edges of its mask align with the specified side or direction. See "Icon Alignment Constants" (page 1307) for a description of the values you can use here.

transform

Specifies how the function should modify the appearance of the icon. See "Icon Transformation Constants" (page 1309) for a description of the values you can use here.

theResID

The resource ID of the icon to draw. The icon resource must be of resource type `'ICN#'`, `'ics#'`, `'icl4'`, `'icl8'`, `'ics4'`, or `'ics8'`. In general, you should specify your icon resources as purgeable.

Return Value

A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Special Considerations

This function may move or purge memory blocks in the application heap. Your application should not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In
`Icons.h`

PlotIconMethod

Draws an icon obtained with the aid of your icon getter callback function. (Deprecated in Mac OS X v10.5. Use Icon Services instead.)

```
OSErr PlotIconMethod (
   const Rect *theRect,
   IconAlignmentType align,
   IconTransformType transform,
   IconGetterUPP theMethod,
   void *yourDataPtr
);
```

Parameters

theRect

A pointer to the rectangle in which to draw the icon, specified in local coordinates of the current graphics port.

align

Specifies how to align the icon within the specified rectangle. See "Icon Alignment Constants" (page 1307) for a description of the values you can use here.

transform

Specifies how the function should modify the appearance of the icon. See "Icon Transformation Constants" (page 1309) for a description of the values you can use here.

theMethod

A universal procedure pointer to your icon getter callback function. `PlotIconMethod` uses your icon getter function to obtain the icon to draw.

`PlotIconMethod` passes to your icon getter function the type of the icon to draw and the value specified in the `yourDataPtr` parameter. The `PlotIconMethod` function examines the current bit depth of the display devices and calls your icon getter function once for each display device that intersects the rectangle specified in the parameter `theRect`. Your icon getter function should return a handle to the requested icon's data. Your icon getter function can get the icon data using whatever method is appropriate to your application. For example, your application might maintain its own cache of icons or use its icon getter function to get an icon from the desktop database.

For more information see the `IconGetterProcPtr` (page 1303) callback.

yourDataPtr

A pointer to data that is passed to your icon getter callback function.

Return Value
A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Special Considerations

This function may move or purge memory blocks in the application heap. For that reason, your application should not call it at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Icons.h`

PlotIconRef

Draws an icon using appropriate size and depth data from an `IconRef`. (Deprecated in Mac OS X v10.5. Use `PlotIconRefInContext` (page 1281) instead.)

```
OSErr PlotIconRef (
   const Rect *theRect,
   IconAlignmentType align,
   IconTransformType transform,
   IconServicesUsageFlags theIconServicesUsageFlags,
   IconRef theIconRef
);
```

Parameters

theRect
A pointer to the rectangle where the icon is to be drawn.

align
A value specifying how Icon Services should align the icon within the rectangle.

transform
A value specifying how Icon Services should modify the appearance of the icon.

theIconServicesUsageFlags
Reserved for future use. Pass the `kIconServicesNormalUsageFlag` constant in this parameter.

theIconRef
The `IconRef` for the icon to draw.

Return Value
A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Discussion
This function is similar to the Icon Utilities function `PlotIconSuite`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Icons.h`

PlotIconRefInContext

Plots an `IconRef` using Quartz.

```
OSStatus PlotIconRefInContext (
   CGContextRef inContext,
   const CGRect *inRect,
   IconAlignmentType inAlign,
   IconTransformType inTransform,
   const RGBColor *inLabelColor,
   PlotIconRefFlags inFlags,
   IconRef inIconRef
);
```

Parameters

inContext
The graphics context to use.

inRect
A pointer to the rectangle to plot the icon in.

inAlign
The icon alignment. See "Icon Alignment Constants" (page 1307).

inTransform
The icon transform. See "Icon Transformation Constants" (page 1309).

inLabelColor
A pointer to the icon label color.

inFlags
The drawing flags to use; this is usually `kPlotIconRefNormalFlags`.

inIconRef
The `IconRef` to plot.

Return Value
A result code. See "Icon Services and Utilities Result Codes" (page 1324).

Availability
Available in Mac OS X v10.1 and later.

Declared In
`Icons.h`

PlotIconSuite

Draws the icon described by an icon suite using the most appropriate icon in the suite for the current bit depth of the display device and the rectangle in which the icon is to be drawn. (Deprecated in Mac OS X v10.5. Use Icon Services instead.)

```
OSErr PlotIconSuite (
   const Rect *theRect,
   IconAlignmentType align,
   IconTransformType transform,
   IconSuiteRef theIconSuite
);
```

Parameters

theRect

A pointer to the rectangle in which to draw the icon.

The function plots a single icon from the icon suite in the current graphics port. You cannot determine which icon from a given suite it will draw; the function bases this decision on the size of the specified destination rectangle and the current bit depth of the display device. For example, if the destination rectangle has the coordinates (100,100,116,116) and the display device is set to 4-bit color, the function draws the icon of type `'ics4'` if that icon is available in the icon suite.
