The List Manager will not scroll beyond the data bounds of the list. If the automatic drawing mode is enabled, this function does all necessary updating of the list.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Lists.h`

LSearch

Finds a cell whose data matches data that you specify. (Deprecated in Mac OS X v10.5.)

```
Boolean LSearch (
   const void *dataPtr,
   short dataLen,
   ListSearchUPP searchProc,
   Cell *theCell,
   ListHandle lHandle
);
```

Parameters

dataPtr
A pointer to the data being searched for.

dataLen
The length in bytes of the data being searched for.

searchProc
A pointer to a function to be used to compare the data being searched for with cell data. If `NULL`, the Text Utilities Package function `IUMagIDString` is used.

If either the function pointed to by `searchProc` or `IUMagIDString` returns 0, `LSearch` has found a match; otherwise, it checks the next cell in the list.

theCell
A pointer to the first cell to be searched. If the function finds a match, this parameter is, on return, a pointer to the coordinates of the first cell whose data matches the data being searched for.

lHandle
The list to be searched.

Return Value
If the function finds a match, `TRUE`. Otherwise, `FALSE`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Lists.h`

LSetCell

Changes the data contained in a cell. (Deprecated in Mac OS X v10.5.)

```
void LSetCell (
   const void *dataPtr,
   short dataLen,
   Cell theCell,
   ListHandle lHandle
);
```

Parameters

dataPtr

A pointer to the new data for a cell.

dataLen

The length in bytes of the new data.

theCell

The coordinates of the cell to hold the new data.

lHandle

The list containing the cell given in the `theCell` parameter.

Discussion

Any previous cell data in `theCell` is replaced. If there is insufficient memory in the heap, the function may fail to set the cell's data. If the cell coordinates specified by the `theCell` parameter are invalid, the function does nothing.

If the data of a visible cell is changed and the automatic drawing mode is enabled, the function updates the list.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Lists.h`

LSetDrawingMode

Changes the automatic drawing mode specified when creating a list. (Deprecated in Mac OS X v10.5.)

```
void LSetDrawingMode (
   Boolean drawIt,
   ListHandle lHandle
);
```

Parameters

drawIt

Indicates whether the List Manager should enable the automatic drawing mode. Specify `TRUE` to enable the automatic drawing mode. Specify `FALSE` to disable the automatic drawing mode.

lHandle

The list whose drawing mode is being changed.

Discussion
Your application can use the `LSetDrawingMode` function to enable or disable automatic drawing of lists. If your application uses `LSetDrawingMode` to temporarily disable list drawing, then it must call the `LDraw` (page 1182) function to draw a cell when its appearance changes, or when new rows or columns are added to the list. .

While the automatic drawing mode is turned off, all cell drawing and highlighting are disabled, and the scroll bar does not function properly. Thus, your application should disable the automatic drawing mode only for short periods of time. After enabling it, your application should ensure that the list is redrawn.

This function is also available as the `LDoDraw` function.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Lists.h`

LSetSelect

Selects or deselects a cell. (Deprecated in Mac OS X v10.5.)

```
void LSetSelect (
   Boolean setIt,
   Cell theCell,
   ListHandle lHandle
);
```

Parameters

setIt
Indicates whether the function should select or deselect the specified cell. Specify `TRUE` to select the cell. If the cell is already selected, the function does nothing. Specify `FALSE` to deselect the cell. If the cell is already deselected, the function does nothing.

theCell
The cell to be selected or deselected.

lHandle
The list containing the cell to be selected or deselected.

Discussion
If a cell's selection status is changed and the cell is visible, `LSetSelect` redraws the cell.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Lists.h`

LSize

Changes the size of a list. (Deprecated in Mac OS X v10.5.)

```
void LSize (
   short listWidth,
   short listHeight,
   ListHandle lHandle
);
```

Parameters

listWidth

The new width (in pixels) of the list's visible rectangle.

listHeight

The new height (in pixels) of the list's visible rectangle.

lHandle

The list whose size is being changed.

Discussion

This function adjusts the lower-right side of the list so that the list's visible rectangle is the width and height specified by the `listWidth` and `listHeight` parameters.

Because the list's visible rectangle does not include room for the scroll bars, your application should make `listWidth` 15 pixels less than the desired width of the list if it contains a vertical scroll bar, and it should make `listHeight` 15 pixels less than the desired height of the list if it contains a horizontal scroll bar.

The contents of the list and the scroll bars are adjusted and redrawn as necessary. However, this function does not draw a border around the list's rectangle. Also, it does not erase any portions of the old list that may still be visible. This approach should not be a problem if your application only calls `LSize` after the user resizes a window containing a list in its lower-right corner.

Usually, you need to call this function only after calling the Window Manager function `SizeWindow`.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Lists.h`

LUpdate

Responds to an update event. (Deprecated in Mac OS X v10.5.)

```
void LUpdate (
   RgnHandle theRgn,
   ListHandle lHandle
);
```

Parameters

theRgn

The visible region of the list's port after a call to the Window Manager's `BeginUpdate` function.

lHandle
The list to be updated.

Discussion
This function redraws all visible cells in the list specified by the `lHandle` parameter that intersect the region specified by the parameter `theRgn`. It also redraws the scroll bars if they intersect the region.

You should bracket calls to `LUpdate` by calls to the Window Manager functions `BeginUpdate` and `EndUpdate`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Lists.h`

NewListClickLoopUPP

Creates a new universal procedure pointer (UPP) to a list click loop callback function. (Deprecated in Mac OS X v10.5.)

```
ListClickLoopUPP NewListClickLoopUPP (
   ListClickLoopProcPtr userRoutine
);
```

Parameters
userRoutine

Return Value
See the description of the `ListClickLoopUPP` data type.

Discussion
See the `ListClickLoopProcPtr` (page 1200) callback for more information.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In
`Lists.h`

NewListDefUPP

Creates a new universal procedure pointer (UPP) to a list definition callback function. (Deprecated in Mac OS X v10.5.)

```
ListDefUPP NewListDefUPP (
   ListDefProcPtr userRoutine
);
```

Parameters

userRoutine

Return Value
See the description of the `ListDefUPP` data type.

Discussion
See the `ListDefProcPtr` (page 1201) callback for more information.

Carbon Porting Notes

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

`Lists.h`

NewListSearchUPP

Creates a new universal procedure pointer (UPP) to a list search callback function. (Deprecated in Mac OS X v10.5.)

```
ListSearchUPP NewListSearchUPP (
   ListSearchProcPtr userRoutine
);
```

Parameters

userRoutine

Return Value
See the description of the `ListSearchUPP` data type.

Discussion
See the `ListSearchProcPtr` (page 1204) callback for more information.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In
`Lists.h`

RegisterListDefinition

(Deprecated in Mac OS X v10.5.)

```
OSStatus RegisterListDefinition (
   SInt16 inResID,
   ListDefSpecPtr inDefSpec
);
```

Parameters

inResID

inDefSpec

Return Value
A result code.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Lists.h`

SetListCellIndent

(Deprecated in Mac OS X v10.5.)

```
void SetListCellIndent (
   ListHandle list,
   Point *indent
);

```

Parameters

list

view

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Lists.h`

Callbacks

ListClickLoopProcPtr

Defines a pointer to a list click loop callback function. Your list click loop callback function overrides the standard click-loop function that is used to select cells and automatically scroll a list.

```
typedef Boolean (*ListClickLoopProcPtr)
(
);
```

If you name your function `MyListClickLoopProc`, you would declare it like this:

```
Boolean MyListClickLoopProc ();
```

Parameters

Return Value
A value indicating whether the `LClick` function should continue tracking the mouse. Your function should return `TRUE` if you wish `LClick` to continue to track the mouse, and `FALSE` if `LClick` should stop and return immediately.

Discussion
If your application defines a custom click-loop function, then the `LClick` (page 1179) function repeatedly calls the function until the user releases the mouse button. A click-loop function may perform any processing desired when it is executed.

Because no parameters are passed to the click-loop function, your click-loop function probably needs to access a global variable that contains a handle to the list record, which contains information about the location of the cursor and other information potentially of interest to a click-loop function. You might also create a global variable that stores the state of the modifier keys immediately before a call to the `LClick` function. You would need to set these global variables immediately before calling `LClick`.

The pointer to your function, which you provide in the list record structure, should be a universal procedure pointer (UPP). The definition of the UPP data type for your list click loop function is as follows:

```
typedef (ListClickLoopProcPtr) ListClickLoopUPP;
```

Before using your list click loop function, you must first create a new universal procedure pointer to it, using the `NewListClickLoopUPP` (page 1194) function, as shown here:

```
ListClickLoopUPP MyListClickLoopUPP;
MyListClickLoopUPP = NewListClickLoopUPP(&MyListClickLoopProc)
```

You then use `MyListClickLoopUPP` in the `lClickLoop` field of the `ListRec` (page 1209) structure for your list. The `LClick` (page 1179) function calls your list click loop function while the user holds down the mouse button. If you wish to call your own list click loop function, you can use the `InvokeListClickLoopUPP` (page 1173) function:

```
continueTracking = InvokeListClickLoopUPP(MyListClickLoopUPP);
```

When you are finished using your list click loop callback function, you should dispose of the universal procedure pointer associated with it, using the `DisposeListClickLoopUPP` (page 1164) function.

```
DisposeListClickLoopUPP(MyListClickLoopUPP);
```

A click-loop function does not execute at interrupt time. Instead, it is called directly by the `LClick` function. Thus, a click-loop function can allocate memory, and it does not need to adjust the value contained in the A5 register.

Special Considerations

A click-loop function does not execute at interrupt time. Instead, it is called directly by the `LClick` function. Thus, a click-loop function can allocate memory, and it does not need to adjust the value contained in the A5 register.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Lists.h`

ListDefProcPtr

Defines a pointer to a list definition callback function. Your list definition callback function defines a custom list display.

```
typedef void (*ListDefProcPtr) (
    SInt16 lMessage,
    Boolean lSelect,
    Rect *lRect,
    Cell lCell,
    SInt16 lDataOffset,
    SInt16 lDataLen,
    ListHandle lHandle
);
```

If you name your function `MyListDefProc`, you would declare it like this:

```
void MyListDefProc (
    SInt16 lMessage,
    Boolean lSelect,
    Rect * lRect,
    Cell lCell,
    SInt16 lDataOffset,
    SInt16 lDataLen,
    ListHandle lHandle
);
```

Parameters

lMessage

A value that identifies the operation to be performed. See "List Definition Constants" (page 1214).

lSelect

Indicates whether the cell specified by the `lCell` parameter should be highlighted. This parameter is defined only for the `lDrawMessage` and `lHiliteMsg` messages.

lRect

A pointer to the rectangle (in local coordinates of the list's graphics port) that encloses the specified cell. Although this parameter is defined as a pointer, your list definition function must not change the coordinates of the rectangle. This parameter is defined only for the `lDrawMessage` and `lHiliteMsg` messages.

lCell

The coordinates of the cell to be drawn or highlighted. This parameter is defined only for the `lDrawMessage` and `lHiliteMsg` messages.

lDataOffset

The location of the cell data associated with the specified cell. The location is specified as an offset from the beginning of the relocatable block referenced by the `cells` field of the list record. This parameter is defined only for the `lDrawMessage` and `lHiliteMsg` messages.

lDataLen

The length in bytes of the cell data associated with the specified. This parameter is defined only for the `lDrawMessage` and `lHiliteMsg` messages.

lHandle

A handle to the list for which a message is being sent. Your application can access the list's list record, or it can call List Manager functions to manipulate the list.

Discussion

Your application can write a list definition function to customize list display. For example, you can write a list definition function to support the display of color icons. A custom list definition function must be compiled as a code resource of type `'LDEF'` and added to the resource file of the application that needs to use it.

The List Manager calls your list definition function whenever an application using the function creates a new list with the `LNew` (page 1186) function, needs a cell to be drawn, needs a cell's highlighting state to be reversed, or has called the `LDispose` (page 1181) function to dispose of a list.

The pointer to your list definition function should be a universal procedure pointer (UPP). The definition of the UPP data type for your definition function is as follows:

```
typedef (ListDefProcPtr) ListDefUPP;
```

Before using your list definition function, you must first create a new universal procedure pointer to it, using the `NewListDefUPP` (page 1194) function, as shown here:

```
ListDefUPP MyListDefUPP;
MyListDefUPP = NewListDefUPP(&MyListDefProc)
```

The List Manager automatically invokes your list definition function when a new list is created. If you wish to call your own list definition callback function, you can use the `InvokeListDefUPP` (page 1173) function:

```
InvokeListDefUPP(lMessage, lSelect, &lRect, lCell, lDataOffset,
       lDataLen, lHandle, MyListDefUPP)
```

When you are finished with your list definition function, you should dispose of the universal procedure pointer associated with it, using the `DisposeListDefUPP` (page 1165) function.

```
DisposeListDefUPP(MyListDefUPP);
```

Because a list definition function is stored in a code resource, it cannot have its own global variables that it accesses through the A5 register. (Some development systems, however, may allow code resources to access global variables through some other register, such as A4. See your development system's documentation for more information.) If your list definition function needs access to global data, it might store a handle to such data in the `refCon` or `userHandle` fields of the list record; however, applications would not then be able to use these fields for their own purposes.

Special Considerations

Because a list definition function is stored in a code resource, it cannot have its own global variables that it accesses through the A5 register. (Some development systems, however, may allow code resources to access global variables through some other register, such as A4. See your development system's documentation for more information.) If your list definition function needs access to global data, it might store a handle to such data in the `refCon` or `userHandle` fields of the list record; however, applications would not then be able to use these fields for their own purposes.

Availability
Available in Mac OS X v10.0 and later.

`Lists.h`

ListNotificationProcPtr

```
typedef void (*ListNotificationProcPtr)
(
    ListHandle theList,
    ListNotification notification,
    SInt32 param
);
```

If you name your function `MyListNotificationProc`, you would declare it like this:

```
void MyListNotificationProc (
    ListHandle theList,
    ListNotification notification,
    SInt32 param
);
```

Parameters

theList

notification

param

ListSearchProcPtr

Defines a pointer to a list search callback function. Your list search callback function compares data in a search field to the contents of a list cell.

```
typedef SInt16 (*ListSearchProcPtr) (
    Ptr aPtr,
    Ptr bPtr,
    SInt16 aLen,
    SInt16 bLen
);
```

If you name your function `MyListSearchProc`, you would declare it like this:

```
short MyListSearchProc (
    Ptr aPtr,
    Ptr bPtr,
    short aLen,
    short bLen
);
```

Parameters

aPtr

A pointer to the data contained in a cell.

bPtr

A pointer to the data for which you are searching.

aLen

The number of bytes of data contained in the cell.

bLen

The number of bytes of data for which you are searching.

Return Value
If the cell data matches the search data, your function should return 0. Otherwise, your search function should return 1.

Discussion
You can pass a pointer to your search function as the third parameter to the `LSearch` function. A search function must compare the data defined by the `aPtr` and `aLen` parameters with the data defined by the `bPtr` and `bLen` parameters. Your function can use any technique you choose to compare the data.

If you do not wish to create your own search function, your application can specify `NULL` as a parameter to `LSearch`, in place of a pointer to your function. `LSearch` then uses the Text Utilities function `IUMagIDString`, the default search function. The `IUMagIDString` function returns 0 if the search data exactly matches the cell data, but `IUMagIDString` considers the strings `'Rose'` and `'rosé'` to be equivalent. If your application simply needs a search function that works like `IUMagIDString` but considers `'Rose'` to be different from `'rosé'`, the Text Utilities provides the case-sensitive comparison function `IUMagString`. Instead of writing a custom function, your application can simply pass `@IUMagString` as the third parameter to the `LSearch` function.

The pointer which you pass to the `LSearch` function should be a universal procedure pointer (UPP). The definition of the UPP data type for your search function is as follows:

```
typedef (ListSearchProcPtr) ListSearchUPP;
```

Before using your search function, you must first create a universal procedure pointer to it, using the `NewListSearchUPP` `NewListSearchUPP` (page 1195) function, as shown here:

```
ListSearchUPP MyListSearchUPP;
MyListSearchUPP = NewListSearchUPP(&MyListSearchProc)
```

You then pass `MyListSearchUPP` to the `LSearch` function, which will call your custom search function on each cell it searches. If you wish to call your own list search function, use the `InvokeListSearchUPP` (page 1174) function:

```
isMatch = InvokeListSearchUPP(aPtr, bPtr, aLen, bLen,
                    MyListSearchUPP);
```

When you are finished with your list search callback function, you should dispose of the universal procedure pointer associated with it, using the `DisposeListSearchUPP` (page 1165) function:

```
DisposeListSearchUPP(MyListSearchUPP);
```

A search function does not execute at interrupt time. Instead, it is called directly by the `LSearch` function. Thus, a search function can allocate memory, and it does not need to adjust the value contained in the A5 register.

Special Considerations

A search function does not execute at interrupt time. Instead, it is called directly by the `LSearch` function. Thus, a search function can allocate memory, and it does not need to adjust the value contained in the A5 register.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Lists.h`

Data Types

Cell

```
typedef Point Cell;
```

Discussion
The `Cell` data type defines a cell record. The functions `LGetSelect` (page 1184), `LSetSelect` (page 1192), `LSetCell` (page 1190), `LAddToCell` (page 1177), `LClrCell` (page 1179), `LGetCellDataLocation` (page 1183), `LGetCell` (page 1183), `LDraw` (page 1182), `LSearch` (page 1190), `LNextCell` (page 1187), `LRect` (page 1188), and `LLastClick` (page 1185) use the `Cell` data type to specify the coordinates of a cell in a list.

Note that column and row numbers are 0-based. Also note that this reference designates cells using the notation (column–1, row–1), so that a cell with coordinates (2,5) is in the third column and sixth row of a list. You specify a cell with coordinates (2,5) by setting the cell's `h` field to 2 and its `v` field to 5.

    ListBounds dataBounds;
    DataHandle cells;
    short maxIndex;
    short cellArray[1];
};
typedef struct ListRec ListRec;
typedef ListRec * ListPtr;
typedef ListPtr * ListHandle
```

Fields

`rView`
: The rectangle in which the list's visible rectangle is located, in local coordinates of the graphics port specified by the `port` field. Note that the list's visible rectangle does not include the area needed for the list's scroll bars. The width of a vertical scroll bar (which equals the height of a horizontal scroll bar) is 15 pixels.

`port`
: The graphics port of the window containing the list.

`indent`
: The location, relative to the upper-left corner of a cell, at which drawing should begin. List definition functions should set this field to a value appropriate to the type of data that a cell in a list is to contain.

`cellSize`
: The size in pixels of each cell in the list. When your application creates a list, it can either specify the cell size or let the List Manager calculate the cell size. You should not change the `cellSize` field directly; if you need to change the cell size after creating a list, use the `LCellSize` (page 1178) function.

`visible`
: The cells in a list that are visible within the area specified by the `rView` field. The List Manager sets the `left` and `top` fields of `visible` to the coordinates of the first visible cell; however, the List Manager sets the `right` and `bottom` fields so that each is 1 greater than the horizontal and vertical coordinates of the last visible cell. For example, if a list contains 4 columns and 10 rows but only the first 2 columns and the first 5 rows are visible (that is, the last visible cell has coordinates (1,4)), the List Manager sets the `visible` field to (0,0,2,5).

`vScroll`
: A control handle for a list's vertical scroll bar, or `NULL` if a list does not have a vertical scroll bar.

`hScroll`
: A control handle for a list's horizontal scroll bar, or `NULL` if a list does not have a horizontal scroll bar.

`selFlags`
: Indicates the selection flags for a list. When your application creates a list, the List Manager clears the `selFlags` field to 0. This defines the List Manager's default selection algorithm. To change the default behavior for a particular list, set the desired bits in the list's `selFlags` field. See "Selection Flags" (page 1217).

`lActive`
: Indicates whether the list is active (`TRUE` if active, `FALSE` if inactive).

`lReserved`
: Reserved.

`listFlags`
: Indicates whether the List Manager should automatically scroll the list if the user clicks the list and then drags the cursor outside the list display rectangle. See "List Flags" (page 1215) for the values used in this field.

  By default, the List Manager enables horizontal autoscrolling for a list if the list includes a horizontal scroll bar, and enables vertical autoscrolling for a list if the list includes a vertical scroll bar.

`clikTime`
: The time in ticks of the last click in the list. If your application depends on the value contained in this field, then your application should update the field if the application selects a list item in response to keyboard input.

`clikLoc`
: The location in local coordinates of the last click in the list.

`mouseLoc`
: Indicates the current location of the cursor in local coordinates. This value is continuously updated by the `LClick` function after the user clicks a list.

`lClickLoop`
: A universal procedure pointer to your click loop callback function, which is repeatedly called by the `LClick` (page 1179) function, or NULL if the default click-loop function is to be used.

`lastClick`
: The coordinates of the last cell in the list that was clicked. This may not be the same as the last cell selected if the user selects a range of cells by Shift-dragging or Command-dragging. If your application depends on the value contained in this field, then your application should update the field whenever your application selects a list item in response to keyboard input.

`refCon`
: 4 bytes for use by your application.

`listDefProc`
: A handle to the code for the list definition function that defines how the list is drawn.

`userHandle`
: 4 bytes that your application can use as needed. For example, your application might use this field to store a handle to additional storage associated with the list. However, the `LDispose` (page 1181) function does not automatically release this storage when disposing of the list.

`dataBounds`
: The range of cells in a list. When your application creates a list, it specifies the initial bounds of the list. As your application adds rows and columns, the List Manager updates this field. The List Manager sets the `left` and `top` fields of `dataBounds` to the coordinates of the first cell in the list; the List Manager sets the `right` and `bottom` fields so that each is 1 greater than the horizontal and vertical coordinates of the last cell. For example, if a list contains 4 columns and 10 rows (that is, the last cell in the list has coordinates (3,9)), the List Manager sets the `dataBounds` field to (0,0,4,10).

`cells`
: A handle to a relocatable block used to store cell data. Your application should not change the contents of this relocatable block directly.

`maxIndex`
: Used internally.

`cellArray`
: Offsets to data that indicate the location of different cells' data within the data handle specified by the `cells` parameter. Your application should not access this field directly.

Discussion
Functions in the List Manager interface use the `ListHandle` datatype to identify a list. The `ListHandle` type uses a `ListRec` structure to maintain information about a list. The `ListRec` data type defines a list record.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Lists.h`

ListRef

```
typedef ListHandle ListRef;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Lists.h`

ListSearchUPP

```
typedef ListSearchProcPtr ListSearchUPP;
```

Discussion
For more information, see the description of the ListSearchUPP () callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Lists.h`

StandardIconListCellDataRec

```
struct StandardIconListCellDataRec {
    Handle iconHandle;
    short font;
    short face;
    short size;
    Str255 name;
};
typedef struct StandardIconListCellDataRec StandardIconListCellDataRec;
typedef StandardIconListCellDataRec * StandardIconListCellDataPtr;
```

Fields
`iconHandle`
`font`
`face`
`size`
`name`

Carbon Porting Notes

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Lists.h`

Constants

kListDefProcPtr

```
enum {
    kListDefProcPtr = 0,
    kListDefUserProcType = kListDefProcPtr,
    kListDefStandardTextType = 1,
    kListDefStandardIconType = 2
};
```

Constants

`kListDefProcPtr`
Available in Mac OS X v10.0 and later.
Declared in `Lists.h`.

`kListDefUserProcType`
Available in Mac OS X v10.0 and later.
Declared in `Lists.h`.

`kListDefStandardTextType`
Available in Mac OS X v10.0 and later.
Declared in `Lists.h`.

`kListDefStandardIconType`
Available in Mac OS X v10.0 and later.
Declared in `Lists.h`.

lDrawingModeOff

```
enum {
    lDrawingModeOff = 8,
    lDoVAutoscroll = 2,
    lDoHAutoscroll = 1
};
```

Constants

`lDrawingModeOff`
Available in Mac OS X v10.0 and later.
Declared in `Lists.h`.

`lDoVAutoscroll`
Set this bit to 1 if you wish to allow automatic vertical scrolling.
Available in Mac OS X v10.0 and later.
Declared in `Lists.h`.

`lDoHAutoscroll`
Set this bit to 1 if you wish to allow automatic horizontal scrolling.
Available in Mac OS X v10.0 and later.
Declared in `Lists.h`.

lDrawingModeOffBit

```
enum {
    lDrawingModeOffBit = 3,
    lDoVAutoscrollBit = 1,
    lDoHAutoscrollBit = 0
};
```

Constants

`lDrawingModeOffBit`
Available in Mac OS X v10.0 and later.
Declared in `Lists.h`.

`lDoVAutoscrollBit`
Available in Mac OS X v10.0 and later.
Declared in `Lists.h`.

`lDoHAutoscrollBit`
Available in Mac OS X v10.0 and later.
Declared in `Lists.h`.

List Definition Constants

```
enum {
    lInitMsg = 0,
    lDrawMsg = 1,
    lHiliteMsg = 2,
    lCloseMsg = 3
};
```

Constants

`lInitMsg`
In response to the `lInitMsg` message, your list definition function should perform any special initialization needed for a list. For example, the function might set fields of the list record, such as the `cellSize` and `indent` fields, to appropriate values. Your list definition function does not necessarily need to do anything in response to the initialization message. If it does nothing, then memory is still allocated for the list, and fields of the list record are set to the same values as they would be set to if the default list definition function were being used.
Available in Mac OS X v10.0 and later.
Declared in `Lists.h`.

`lDrawMsg`
Your list definition function should draw the cell specified by the `theCell` parameter after receiving an `lDrawMsg` message. The function must ensure that it does not draw anywhere but within the rectangle specified by the `cellRect` parameter. If the `selected` parameter is `TRUE`, then your list definition function should draw the cell in its highlighted state; otherwise, it should draw the cell without highlighting. When drawing, your list definition function should take care not to permanently change any characteristics of the drawing environment.
Available in Mac OS X v10.0 and later.
Declared in `Lists.h`.

`lHiliteMsg`

Your list definition function should respond to the `lHiliteMsg` message by reversing the selection status of the cell contained within the rectangle specified by the `cellRect` parameter. If a cell is highlighted, your list definition function should remove the highlighting; if a cell is not highlighted, your list definition function should highlight it.

Available in Mac OS X v10.0 and later.

Declared in `Lists.h`.

`lCloseMsg`

The List Manager sends your list definition function an `lCloseMsg` message before it disposes of a list and its data. Your list definition function need only respond to this message if additional memory has been allocated for the list. For example, your list definition function might allocate a relocatable block in response to the `lInitMsg` message. In this case, your list definition function would need to dispose of this relocatable block in response to the `lCloseMsg` message. Or, if your list definition function defines cells simply to contain pointers or handles to data stored elsewhere in memory, it would need to dispose of that memory in response to the `lCloseMsg` message.

Available in Mac OS X v10.0 and later.

Declared in `Lists.h`.

Discussion
The List Manager passes these values to your `ListDefProcPtr` (page 1201) function to identify the operation to be performed.

List Flags

Constants

Discussion
The following constants define bits in the `listFlags` field of the `ListRec` (page 1209) structure that determine whether horizontal autoscrolling and vertical autoscrolling are enabled:.

listNotifyNothing

```
enum {
    listNotifyNothing = 'nada',
    listNotifyClick = 'clik',
    listNotifyDoubleClick = 'dblc',
    listNotifyPreClick = 'pclk'
};
```

Constants

`listNotifyNothing`

`listNotifyClick`

`listNotifyDoubleClick`

`listNotifyPreClick`

lOnlyOneBit

```
enum {
    lOnlyOneBit = 7,
    lExtendDragBit = 6,
    lNoDisjointBit = 5,
    lNoExtendBit = 4,
    lNoRectBit = 3,
    lUseSenseBit = 2,
    lNoNilHiliteBit = 1
};
```

Constants

`lOnlyOneBit`
Available in Mac OS X v10.0 and later.
Declared in `Lists.h`.

`lExtendDragBit`
Available in Mac OS X v10.0 and later.
Declared in `Lists.h`.

`lNoDisjointBit`
Available in Mac OS X v10.0 and later.
Declared in `Lists.h`.

`lNoExtendBit`
Available in Mac OS X v10.0 and later.
Declared in `Lists.h`.

`lNoRectBit`
Available in Mac OS X v10.0 and later.
Declared in `Lists.h`.

`lUseSenseBit`
Available in Mac OS X v10.0 and later.
Declared in `Lists.h`.

`lNoNilHiliteBit`
Available in Mac OS X v10.0 and later.
Declared in `Lists.h`.

Selection Flags

```
enum {
    lOnlyOne = -128,
    lExtendDrag = 64,
    lNoDisjoint = 32,
    lNoExtend = 16,
    lNoRect = 8,
    lUseSense = 4,
    lNoNilHilite = 2
};
```

Constants

`lOnlyOne`
Specify this value if you wish to allow only one item to be selected at once.
Available in Mac OS X v10.0 and later.
Declared in `Lists.h`.

`lExtendDrag`
Specify this value if you wish to enable selection of multiple items by dragging without the Shift key.
Available in Mac OS X v10.0 and later.
Declared in `Lists.h`.

`lNoDisjoint`
Specify this value if you wish to prevent discontinuous selections using the Command key.
Available in Mac OS X v10.0 and later.
Declared in `Lists.h`.

`lNoExtend`
Specify this value if you wish to prevent extending Shift key selections. All items are deselected before responding to Shift-click.
Available in Mac OS X v10.0 and later.
Declared in `Lists.h`.

`lNoRect`
Specify this value if you wish to select all items in the cursor's path during Shift-drag.
Available in Mac OS X v10.0 and later.
Declared in `Lists.h`.

`lUseSense`
Specify this value if you wish to allow the user to deselect one or more items using the Shift key
Available in Mac OS X v10.0 and later.
Declared in `Lists.h`.

`lNoNilHilite`
Specify this value if you wish to disable the highlighting of empty cells.
Available in Mac OS X v10.0 and later.
Declared in `Lists.h`.

Discussion
The `ListRec` (page 1209) structure uses these values in the `selFlags` field to indicate the List Manager's default selection algorithm. Use these values additively to select more than one selection option.

Menu Manager Reference

Framework: Carbon/Carbon.h

Declared in Menus.h

Overview

You can use the Menu Manager to create and manage the menus in your application. Menus allow the user to view or choose from a list of choices and commands that your application provides. All Mac OS applications should provide these standard menus: the Application menu, the File menu, and the Edit menu.

Carbon supports the Menu Manager, with the following changes:

- Your application must use the functions defined by the Menu Manager whenever it creates and disposes of Menu Manager data structures. Some applications, for example, create menus by using the Resource Manager function `GetResource` (instead of the Menu Manager function `GetMenu`) and dispose of them by calling `ReleaseResource` instead of `DisposeMenu`. This practice is not supported in Carbon.
- The `MenuInfo` structure is opaque in Carbon. You must revise your application so that it accesses Menu Manager data structures only through accessor functions.
- Menu color information tables are not recommended in Carbon.
- You are strongly encouraged to adopt the standard Mac OS menu definition functions (also known as MDEFs) in your application. Your menus will then inherit the systemwide appearance and, furthermore, take advantage of other Menu Manager enhancements planned for the future. If you decide to customize the appearance of a menu and you are deploying your application for Mac OS X v10.3 and later, you should use a custom HIView instead of a custom menu definition function.

Functions by Task

Function descriptions are grouped by the tasks for which you use the functions. For an alphabetical list of functions, go to the API index at the end of the document.

Creating and Disposing of Menus

`CreateNewMenu` (page 1246)
Creates a new, untitled, empty menu.

`DuplicateMenu` (page 1255)
Creates a new menu that is a copy of another menu.

`DisposeMenu` (page 1253)
Decrements the retain count of a menu.

`CreateCustomMenu` (page 1245)
Creates a new, untitled, empty menu using a custom menu definition function.

`RegisterMenuDefinition` (page 1318)
Registers a binding between a resource ID and a menu definition function.

`SetMenuDefinition` (page 1329)
Sets the menu definition structure for a menu.

`GetMenuDefinition` (page 1271)
Obtains the menu definition structure for a menu.

`CreateStandardFontMenu` (page 1247)
Creates a standard font menu.

`UpdateStandardFontMenu` (page 1349)
Updates a standard Font menu.

`ReleaseMenu` (page 1319) Deprecated in Mac OS X v10.5
Decrements the retain count of a menu.

`RetainMenu` (page 1321) Deprecated in Mac OS X v10.5
Increments the reference count of a menu.

Manipulating the Root Menu

`AcquireRootMenu` (page 1229)
Get the menu whose contents are displayed in the menubar.

`SetRootMenu` (page 1347)
Sets the menu whose contents are displayed in the menubar.

Manipulating the Menu Bar

`HideMenuBar` (page 1291)
Conceals the menu bar.

`ShowMenuBar` (page 1348)
Displays the menu bar.

`IsMenuBarVisible` (page 1303)
Reports whether the menu bar is currently visible.

`FlashMenuBar` (page 1259)
Highlights a menu title or the entire menu bar.

`SetMenuBar` (page 1327)
Sets the current menu list to a specified menu list.

`GetMenuBar` (page 1268)
Gets a handle to a copy of the current menu list.

`DrawMenuBar` (page 1255)
Draws the menu bar based on the current menu list.

`InvalMenuBar` (page 1301)
Invalidates the menu bar.

`GetMBarHeight` (page 1265)
Determines the current height of the menu bar.

`DuplicateMenuBar` (page 1256)
Duplicates a menubar handle.

`DisposeMenuBar` (page 1253)
Releases a menubar handle.

Adding and Removing Menus

`InsertMenu` (page 1294)
Inserts an existing menu into the current menu list.

`DeleteMenu` (page 1248)
Deletes an existing menu from the current menu list.

`ClearMenuBar` (page 1237)
Deletes all menus from the current menu list.

`GetMenuRetainCount` (page 1286) Deprecated in Mac OS X v10.5
Returns the retain count of this menu.

Manipulating and Accessing Menu Characteristics

`GetMenuRef` (page 1286)
Obtains a menu reference corresponding to a menu ID.

`GetMenuHandle` (page 1273)
Obtains a menu reference corresponding to a menu ID.

`SetMenuTitleWithCFString` (page 1346)
Sets the title of a menu to the text contained in a CFString.

`CopyMenuTitleAsCFString` (page 1243)
Returns a CFString containing the title of a menu.

`GetMenuType` (page 1289)
Gets the display type (pulldown, hierarchical, or popup) of a menu.

`SetMenuTitleIcon` (page 1345)
Sets the title of a menu to be an icon.

`GetMenuTitleIcon` (page 1288)
Retrieves the icon, if any, being used as the title of a menu.

`SetMenuID` (page 1333)
Assigns a menu ID to a menu.

`GetMenuID` (page 1274)
Obtains the ID of a menu.

`LMGetTheMenu` (page 1308)
Returns the menu ID of the currently highlighted menu in the menu bar.

`SetMenuHeight` (page 1332)
Set the height of a menu.

`GetMenuHeight` (page 1274)
Obtains the height of a menu, in pixels.

`SetMenuWidth` (page 1347)
Sets the width of a menu.

`GetMenuWidth` (page 1289)
Obtains the width of the menu, in pixels.

`CalcMenuSize` (page 1234)
Recalculates the horizontal and vertical dimensions of a menu.

`IsMenuSizeInvalid` (page 1306)
Determines if a menu's size is invalid and should be recalculated.

`GetMenuAttributes` (page 1268)
Gets the attributes of a menu.

`ChangeMenuAttributes` (page 1235)
Changes the attributes of a menu.

`IsValidMenu` (page 1308)
Determines if a menu is valid.

`SetMenuFlashCount` (page 1331) Deprecated in Mac OS X v10.5
Specifies whether a menu should fade slowly or immediately disappear when closing.

Drawing Menus and Menu Items

`HiliteMenu` (page 1291)
Highlights or unhighlights menu titles.

`UpdateInvalidMenuItems` (page 1348)
Redraws the invalid items of an open menu.

`InvalidateMenuEnabling` (page 1299)
Requests that the menu's enable state be recalculated.

`InvalidateMenuItems` (page 1299)
Invalidates a group of menu items so that they will be redrawn when `UpdateInvalidMenuItems` is next called.

`InvalidateMenuSize` (page 1300)
Invalidates the menu size so that it will be recalculated when next displayed.

`IsMenuBarInvalid` (page 1302)
Determines if the menubar is invalid and should be redrawn.

`IsMenuItemInvalid` (page 1305)
Determines if a menu item is invalid and should be redrawn.

`EraseMenuBackground` (page 1258) Deprecated in Mac OS X v10.5
Erases the menu background to prepare for additional drawing.

`ScrollMenuImage` (page 1322) Deprecated in Mac OS X v10.5
Scrolls a portion of the menu image.

Adding and Deleting Menu Items

`CopyMenuItems` (page 1242)
Copies menu items from one menu to another.

`DeleteMenuItem` (page 1249)
Deletes an item from a menu.

`DeleteMenuItems` (page 1250)
Deletes multiple menu items.

Associating Data With Menu Items

`SetMenuItemProperty` (page 1341)
Associates data with a menu item.

`SetMenuCommandProperty` (page 1329)
Sets the property data for a menu item with the specified command ID.

`GetMenuItemProperty` (page 1281)
Obtains a piece of data that has been previously associated with a menu item.

`GetMenuCommandProperty` (page 1270)
Retrieves property data for a menu item with the specified command ID.

`GetMenuItemPropertySize` (page 1283)
Obtains the size of a piece of data that has been previously associated with a menu item.

`GetMenuCommandPropertySize` (page 1271)
Retrieves the size of the property data for a menu item with the specified command ID.

`RemoveMenuItemProperty` (page 1320)
Removes a piece of data that has been previously associated with a menu item.

`RemoveMenuCommandProperty` (page 1319)
Removes a property from a menu item with the specified command ID.

`GetMenuItemPropertyAttributes` (page 1282)
Gets the attributes of a menu item property.

`ChangeMenuItemPropertyAttributes` (page 1236)
Changes the attributes of a menu item property.

`SetMenuItemRefCon` (page 1342)
Sets application-specific information for a menu item.

`GetMenuItemRefCon` (page 1284)
Obtains application-specific information for a menu item.

Enabling Menus and Menu Items

`CountMenuItems` (page 1244)
Obtains the number of menu items in a menu

`CountMenuItemsWithCommandID` (page 1244)
Counts the menu items with a specified command ID.

`EnableMenuItem` (page 1257)
Enables a menu item or a menu.

`EnableMenuCommand` (page 1257)
Enables the menu item with a specified command ID.

`DisableMenuItem` (page 1251)
Disables a menu item or a menu.

`DisableMenuCommand` (page 1251)
Disables the menu item with a specified command ID.

`EnableAllMenuItems` (page 1256)
Enables all items in a menu.

`DisableAllMenuItems` (page 1250)
Disables all items in a menu.

`IsMenuItemEnabled` (page 1303)
Reports whether a given menu or menu item is enabled.

`IsMenuCommandEnabled` (page 1303)
Determines if the menu item with a specified command ID is enabled.

`MenuHasEnabledItems` (page 1310)
Determines if any items in a menu are enabled.

`EnableMenuItemIcon` (page 1258)
Enables the icon associated with a menu item.

`DisableMenuItemIcon` (page 1252)
Disables the icon associated with a menu item.

`IsMenuItemIconEnabled` (page 1304)
Reports whether a given menu item icon is enabled.

Manipulating Menu Item Text

`SetMenuItemTextWithCFString` (page 1344)
Sets the text of a menu item to the text contained in a CFString.

`CopyMenuItemTextAsCFString` (page 1243)
Returns a CFString containing the text of a menu item.

`AppendMenuItemTextWithCFString` (page 1231)
Appends a new menu item with text from a CFString.

`InsertMenuItemTextWithCFString` (page 1296)
Inserts a new menu item with text from a CFString.

`GetMenuFont` (page 1272)
Obtains the font used in a menu.

`SetMenuFont` (page 1331)
Sets the font to be used in a menu.

`GetMenuItemFontID` (page 1277)
Obtains a menu item's font ID.

`SetMenuItemFontID` (page 1335)
Sets the font for a menu item.

`GetFontFamilyFromMenuSelection` (page 1260)
Gets the font family reference and style from the menu identifier and menu item number returned by the function `MenuSelect`.

`SetItemStyle` (page 1325)
Sets a menu item's text style.

`GetItemStyle` (page 1264)
Returns a menu item's text style.

`GetMenuItemTextEncoding` (page 1285) Deprecated in Mac OS X v10.5
Obtains the text encoding used for a menu item's text.

`SetMenuItemTextEncoding` (page 1343) Deprecated in Mac OS X v10.5
Sets the text encoding for a menu item's text.

Manipulating and Accessing Menu Item Characteristics

`SetMenuItemIconHandle` (page 1338)
Sets a menu item's icon.

`GetMenuItemIconHandle` (page 1279)
Obtains a handle to a menu item's icon.

`SetItemMark` (page 1324)
Sets the mark of a menu item.

`SetMenuCommandMark` (page 1328)
Locates the menu item with a specified command ID and sets its mark character.

`GetItemMark` (page 1263)
Returns a menu item's mark.

`GetMenuCommandMark` (page 1269)
Locates the menu item with a specified command ID and returns its mark character.

`CheckMenuItem` (page 1237)
Adds or removes a check mark from a menu item.

`SetMenuItemIndent` (page 1338)
Sets the indent level of a menu item.

`GetMenuItemIndent` (page 1279)
Gets the indent level of a menu item.

`SetMenuItemKeyGlyph` (page 1339)
Sets the command key glyph code for a menu item.

`GetMenuItemKeyGlyph` (page 1280)
Obtains the keyboard glyph for a menu item's keyboard equivalent.

`SetMenuItemModifiers` (page 1340)
Sets the modifier key(s) that must be pressed with a character key to select a particular menu item.

`GetMenuItemModifiers` (page 1281)
Obtains the modifier keys that must be pressed with a character key to select a particular menu item.

`SetMenuItemCommandID` (page 1333)
Sets a menu item's command ID.

`GetMenuItemCommandID` (page 1275)
Obtains a menu item's command ID.

`SetMenuItemHierarchicalMenu` (page 1337)
Attaches a submenu to a menu item.

`GetMenuItemHierarchicalMenu` (page 1278)
Returns the submenu attached to a menu item.

`SetMenuItemCommandKey` (page 1334)
Sets the keyboard equivalent of a menu item.

`GetMenuItemCommandKey` (page 1276)
Gets the keyboard equivalent of a menu item.

`GetIndMenuItemWithCommandID` (page 1261)
Finds a menu item with a specified command ID.

`SetMenuItemData` (page 1335)
Sets multiple attributes of a menu item at once.

`CopyMenuItemData` (page 1241)
Obtains multiple menu item attributes at once.

`GetMenuItemAttributes` (page 1275)
Gets the attributes of a menu item.

`ChangeMenuItemAttributes` (page 1235)
Changes the attributes of a menu item.

`GetItemIcon` (page 1262) Deprecated in Mac OS X v10.5
Returns a menu item's icon or text encoding.

`GetMenuItemHierarchicalID` (page 1277) Deprecated in Mac OS X v10.5
Obtains the menu ID of a specified submenu.

`SetItemIcon` (page 1323) Deprecated in Mac OS X v10.5
Sets a menu item's icon or text encoding.

`SetMenuItemHierarchicalID` (page 1336) Deprecated in Mac OS X v10.5
Attaches a submenu to a menu item.

Responding to Menu Events and User Selections

`IsMenuKeyEvent` (page 1305)
Determines if an event corresponds to a menu command key.

`GetMenuTrackingData` (page 1288)
Gets information about the menu currently selected by the user.

`CancelMenuTracking` (page 1234)
Cancels menu tracking.

`MenuSelect` (page 1312)
Allows the user to choose a menu item from a menu in the menu bar.

`MenuChoice` (page 1309)
Returns the menu ID and index of the menu item under the cursor.

`IsShowContextualMenuEvent` (page 1307)
Determines whether a particular Carbon event could invoke a contextual menu.

`ContextualMenuSelect` (page 1239)
Displays a contextual menu.

PopUpMenuSelect (page 1316)
Displays a pop-up menu without using the standard pop-up control definition function.

Handling Contextual Menu Plugins

CMPluginExamineContext (page 1238)
An application-defined callback function that examines the context in a contextual menu CFPlugin.

CMPluginHandleSelection (page 1238)
An application-defined callback function that handles menu item selection in a contextual menu CFPlugin.

CMPluginPostMenuCleanup (page 1239)
An application-defined callback function that handles any post-selection cleanup in a contextual menu CFPlugin.

Obsolete Functions

GetItemCmd (page 1262)
Returns the value of a menu item's keyboard equivalent field.

GetMenu (page 1266)
Creates a menu from the specified menu and extended menu resources.

GetMenuExcludesMarkColumn (page 1272)
Returns whether a menu contains space for mark characters.

GetNewMBar (page 1290)
Reads in the definition of a menu bar from an 'MBAR' resource.

IsShowContextualMenuClick (page 1306)
Determines whether a particular event could invoke a contextual menu.

MenuEvent (page 1309)
Maps a keyboard combination from the event structure to the keyboard equivalent of a menu item in a menu in the current menu list.

SetItemCmd (page 1322)
Sets the value of the keyboard equivalent field of a menu item.

SetMenuExcludesMarkColumn (page 1330)
Sets whether a menu contains space for mark characters.

AppendMenu (page 1229) Deprecated in Mac OS X v10.5
Appends one or more items to a menu previously created.

AppendMenuItemText (page 1231) Deprecated in Mac OS X v10.5
Appends a menu item to a menu.

AppendResMenu (page 1232) Deprecated in Mac OS X v10.5
Searches all resource files open to your application for a given resource type and appends the names of any resources it finds to a specified menu.

DeleteMCEntries (page 1248) Deprecated in Mac OS X v10.5
Deletes a menu item entry, a menu title entry, the menu bar entry, or all menu item entries of a specific menu from your application's menu color information table.

DisposeMCInfo (page 1252) Deprecated in Mac OS X v10.5
Disposes of a menu color information table.

DisposeMenuDefUPP (page 1254) Deprecated in Mac OS X v10.5
Disposes of universal procedure pointer to a custom menu definition.

GetMCEntry (page 1265) Deprecated in Mac OS X v10.5
Gets information about an entry in an application's menu color information table.

GetMCInfo (page 1266) Deprecated in Mac OS X v10.5
Returns a handle to a copy of your application's menu color information table.

GetMenuItemText (page 1285) Deprecated in Mac OS X v10.5
Obtains the text of a menu item.

GetMenuTitle (page 1287) Deprecated in Mac OS X v10.5
Obtains the title of the menu

InitContextualMenus (page 1292) Deprecated in Mac OS X v10.5
Adds a program to the system registry of contextual menu clients.

InsertFontResMenu (page 1293) Deprecated in Mac OS X v10.5
Inserts menu items from a font resource.

InsertIntlResMenu (page 1293) Deprecated in Mac OS X v10.5
Inserts menu items from an internationalized resource.

InsertMenuItem (page 1295) Deprecated in Mac OS X v10.5
Inserts one or more items into a menu previously created.

InsertMenuItemText (page 1296) Deprecated in Mac OS X v10.5
Inserts a menu item into a menu.

InsertResMenu (page 1297) Deprecated in Mac OS X v10.5
Searches all resource files open to your application for a given resource type and inserts the names of any resources it finds in the specified menu.

InvokeMenuDefUPP (page 1301) Deprecated in Mac OS X v10.5
Calls your custom menu definition through a universal procedure pointer.

MenuKey (page 1311) Deprecated in Mac OS X v10.5
Maps a character key with the command key to determine the keyboard equivalent of a menu item in a menu in the current menu list.

NewMenu (page 1314) Deprecated in Mac OS X v10.5
Creates an empty menu with a specified title and menu ID.

NewMenuDefUPP (page 1315) Deprecated in Mac OS X v10.5
Creates a new univeral procedure pointer to your custom menu definition.

ProcessIsContextualMenuClient (page 1317) Deprecated in Mac OS X v10.5
Determines whether a given program is a contextual menu client.

SetMCEntries (page 1326) Deprecated in Mac OS X v10.5
Sets entries in an application's menu color information table.

SetMCInfo (page 1326) Deprecated in Mac OS X v10.5
Makes a copy of your application's menu color information table.

SetMenuItemText (page 1342) Deprecated in Mac OS X v10.5
Sets menu item text to a specified string.

SetMenuTitle (page 1345) Deprecated in Mac OS X v10.5
Sets the title of a menu.

Functions

AcquireRootMenu

Get the menu whose contents are displayed in the menubar.

```
MenuRef AcquireRootMenu (
   void
);
```

Return Value
The current root menu. See page for a description of the `MenuRef` data type. If no root menu currently exists, the Menu Manager creates one and returns its menu reference.

Discussion
This function increments the reference count of the root menu. The caller should call `ReleaseMenu` (page 1319) when done with the menu.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

AppendMenu

Appends one or more items to a menu previously created. (Deprecated in Mac OS X v10.5.)

Not recommended

```
void AppendMenu (
    MenuRef menu,
    ConstStr255Param data
);
```

Parameters

menu

The menu to which you wish to append the menu item or items.

data

A Pascal string that defines the characteristics of the new menu item or items. Note that in most cases you should store the text of a menu item in a resource, so that your menu items can be more easily localized. The `AppendMenu` function appends the menu items in the order in which they are listed in the data parameter.

Discussion
Note that unless you are supporting legacy code, you should use the `AppendMenuItemTextWithCFString` (page 1231) function instead.

The AppendMenu function appends any defined menu items to a previously-created menu. The menu items are added to the end of the menu. You specify the text of any menu items and their characteristics in the data parameter. You can embed metacharacters in the string to define various characteristics of a menu item.

Table 15-1 (page 1230) lists the metacharacters that you can specify in the data parameter:

Table 15-1 Metacharacters available to pass in AppendMenu

Metacharacter	Description
; or Return	Separates menu items.
^	When followed by an icon number, defines the icon for the item. If the keyboard equivalent field contains 0x1C, this number is interpreted as a text encoding.
!	When followed by a character, defines the mark for the item. If the keyboard equivalent field contains 0x1B or the equivalent constant hMenuCmd, this value is interpreted as the menu ID of a submenu of this menu item.
<	When followed by one or more of the characters B, I, U, O, and S, defines the character style of the item to Bold, Italic, Underline, Outline, or Shadow, respectively.
/	When followed by a character, defines the keyboard equivalent for the item. When followed by 0x1B or the equivalent constant hMenuCmd, specifies that this menu item has a submenu. To specify that the menu item has a text encoding, small icon, or reduced icon, use the SetItemCmd function to set the keyboard equivalent field to 0x1C, 0x1D, or 0x1E, respectively.
(	Defines the menu item as disabled.

You can specify any, all, or none of these metacharacters in the text string. The metacharacters that you specify aren't displayed in the menu item. (To use any of these metacharacters in the text of a menu item, first use AppendMenu, specifying at least one character as the item's text, and then use the function SetMenuItemText (page 1342) to set the item's text to the desired string.)

If you add menu items using the AppendMenu function, you should define the text and any marks or keyboard equivalents in resources for easier localization.

You can specify the first character that defines the text of a menu item as a hyphen to create a divider line. The string in the data parameter can be blank (containing one or more spaces), but it should not be an empty string.

If you do not define a specific characteristic of a menu item, the AppendMenu function assigns the default characteristic to the menu item. If you do not define any characteristic other than the text for a menu item, the AppendMenu function inserts the menu item so that it appears in the menu as an enabled item, without an icon or a mark, in the plain character style, and without a keyboard equivalent.

You can use AppendMenu to append items to a menu regardless of whether the menu is in the current menu list.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Related Sample Code
Simple DrawSprocket

Declared In
`Menus.h`

AppendMenuItemText

Appends a menu item to a menu. (Deprecated in Mac OS X v10.5.)

Not recommended

```
OSStatus AppendMenuItemText (
   MenuRef menu,
   ConstStr255Param inString
);
```

Parameters

menu

The menu to which the item is to be appended.

inString

A Pascal string containing the text of the menu item to append. You can pass a string containing any characters, and these characters will be presented verbatim in the menu item.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
Note that unless you are supporting legacy code, you should use the `AppendMenuItemTextWithCFString` (page 1231) function instead.

The `AppendMenuItemText` function appends the menu item containing the specified string to a menu, without evaluating the string for metacharacters, as the pre–Mac OS 8.5 Menu Manager function `AppendMenu` does. You may wish to use `AppendMenuItemText` if you need to present non-alphanumeric characters in a menu item.

The appended menu item appears at the end of the menu as an enabled item. If you wish to place the menu item elsewhere than at the end of the menu you should use the function `InsertMenuItemText` (page 1296).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Menus.h`

AppendMenuItemTextWithCFString

Appends a new menu item with text from a CFString.

```
OSStatus AppendMenuItemTextWithCFString (
   MenuRef inMenu,
   CFStringRef inString,
   MenuItemAttributes inAttributes,
   MenuCommand inCommandID,
   MenuItemIndex *outNewItem
);
```

Parameters

menu

The menu to which to append the new item.

inString

The text of the new item.

inAttributes

The attributes of the new item.

inCommandID

The command ID of the new item.

outNewItem

On exit, the index of the new item. May be `NULL` if the caller does not need this information.

Return Value

A result code. See "Menu Manager Result Codes" (page 1399).

Discussion

The Menu Manager will make its own copy of the CFString before returning from this function. Modifying the string after calling `AppendMenuItemTextWithCFString` will have no effect on the menu item's actual text. The caller may release the string after the call.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

BSDLLCTest

HID Explorer

Declared In

`Menus.h`

AppendResMenu

Searches all resource files open to your application for a given resource type and appends the names of any resources it finds to a specified menu. (Deprecated in Mac OS X v10.5.)

Not recommended

```
void AppendResMenu (
   MenuRef theMenu,
   ResType theType
);
```

Parameters

theMenu

The menu to which to append the names of any resources of a given type that `AppendResMenu` finds.

theType

A four-character code that identifies the resource type for which to search.

Discussion

Unless you must support legacy code, you should not use functions like `AppendResMenu` ,which assumes that menu items to append are stored in resources.

If you want to insert fonts into a menu, you should call `CreateStandardFontMenu` (page 1247) instead.

The `AppendResMenu` function searches all resource files open to your application for resources of the type defined by the parameter `theType`. It appends the names of any resources it finds of the given type to the end of the specified menu. `AppendResMenu` appends the names of found resources in alphabetical order; it does not alphabetize items already in the menu. The `AppendResMenu` function does not add resources with names that begin with a period (.) or a percent sign (%) to the menu.

`AppendResMenu` assigns default characteristics to each menu item. Each appended menu item appears in the menu as an enabled item, without an icon or a mark, in the plain character style, and without a keyboard equivalent.

Note that for applications using CarbonLib, you no longer need to call `AppendResMenu` add resources of type `'DRVR '` to your Apple menu; CarbonLib does this for you automatically.

If you specify that `AppendResMenu` append resources of type `'FONT '` or `'FOND '`, the Menu Manager performs special processing for any resources it finds that have font numbers greater than 0x4000. If the script system associated with the font name is installed in the system, `AppendResMenu` stores information in the `itemDefinitions` array (in the `itemIcon` and `itemCmd` fields for that item) in the menu structure. This allows the Menu Manager to display the font name in the correct script.

Special Considerations

The `AppendResMenu` function calls the Resource Manager function `SetResLoad` (specifying `true` in the `load` parameter) before returning. The `AppendResMenu` function reads the resource data of the resources it finds into memory. If your application does not want the Resource Manager to read resource data into memory when your application calls other functions that read resources, you need to call `SetResLoad` and specify `false` in the `load` parameter after `AppendResMenu` returns.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Related Sample Code

`Menus.h`

CalcMenuSize

Recalculates the horizontal and vertical dimensions of a menu.

```
void CalcMenuSize (
   MenuRef theMenu
);
```

Parameters

theMenu

The menu whose dimensions need recalculating.

Discussion

The `CalcMenuSize` function uses the menu definition function of the specified menu to calculate the dimensions of the menu. In most cases, your application does not need to use the `CalcMenuSize` function.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Menus.h`

CancelMenuTracking

Cancels menu tracking.

```
OSStatus CancelMenuTracking (
   MenuRef inRootMenu,
   Boolean inImmediate,
   UInt32 inDismissalReason
);
```

Parameters

inRootMenu

The root menu of the tracking session to dismiss. For menu bar tracking, pass the result from `AcquireRootMenu` (page 1229); for popup menu tracking, pass the menu that was passed to `PopUpMenuSelect` (page 1316).

inImmediate

Pass `true` if you want the open menus to disappear immediately, `false` if you want them to fade out.

inDismissalReason

Why the menu is being dismissed. This value is passed in the `kEventMenuEndTracking` event. You can pass the constants in "Menu Dismissal Constants" (page 1397). If you pass zero here, the `kEventMenuEndTracking` event contains `kMenuDismissedByCancelMenuTracking`.

Return Value

A result code. See "Menu Manager Result Codes" (page 1399).

Availability

Available in Mac OS X v10.3 and later.

Not available to 64-bit applications.

Declared In
Menus.h

ChangeMenuAttributes

Changes the attributes of a menu.

```
OSStatus ChangeMenuAttributes (
   MenuRef menu,
   MenuAttributes setTheseAttributes,
   MenuAttributes clearTheseAttributes
);
```

Parameters

menu
The menu whose attributes you want to change.

setTheseAttributes
The attributes to add to the menu. See "Menu Attribute Constants" (page 1375) for a list of possible values.

clearTheseAttributes
The attributes to remove from the menu. See "Menu Attribute Constants" (page 1375) for a list of possible values.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
Menus.h

ChangeMenuItemAttributes

Changes the attributes of a menu item.

```
OSStatus ChangeMenuItemAttributes (
   MenuRef menu,
   MenuItemIndex item,
   MenuItemAttributes setTheseAttributes,
   MenuItemAttributes clearTheseAttributes
);
```

Parameters

menu
The menu.

item
The index of the menu item.

setTheseAttributes
The attributes to add to the menu item. See "Menu Item Attribute Constants" (page 1377) for a list of possible values.

clearTheseAttributes
The attributes to remove from the menu item.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

ChangeMenuItemPropertyAttributes

Changes the attributes of a menu item property.

```
OSStatus ChangeMenuItemPropertyAttributes (
   MenuRef menu,
   MenuItemIndex item,
   OSType propertyCreator,
   OSType propertyTag,
   OptionBits attributesToSet,
   OptionBits attributesToClear
);
```

Parameters
menu
The menu containing the menu item whose properties you want ot change.
item
The index of the menu item.
propertyCreator
The creator code of the property.
propertyTag
The property tag.
attributesToSet
The attributes to add to the menu item property.
attributesToClear
The attributes to remove from the menu item property.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
Currently you can only specify the `kMenuPropertyPersistent` attribute (See "Menu Item Property Attribute Constant" (page 1395)), which currently has no effect on Mac OS X. Therefore, `SetMenuItemPropertyAttributes` is not useful at this time.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
Menus.h

CheckMenuItem

Adds or removes a check mark from a menu item.

```
void CheckMenuItem (
    MenuRef theMenu,
    short item,
    Boolean checked
);
```

Parameters

theMenu
The menu containing the menu item to check or uncheck.

item
The menu index of the item to check or uncheck.

checked
Pass `true` to add a check, `false` to remove it.

Discussion
You can also add or remove a check mark using the `SetItemMark` (page 1324) function.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
Menus.h

ClearMenuBar

Deletes all menus from the current menu list.

```
void ClearMenuBar (
   void
);
```

Discussion
The `ClearMenuBar` function deletes all menus from the current menu list. `ClearMenuBar` decrements the reference count of each menu in the menu list; if the reference count reaches zero, the memory associated with the menu is released. To explicitly release the memory occupied by a menu, use `DisposeMenu` (page 1253).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
Menus.h

CMPluginExamineContext

An application-defined callback function that examines the context in a contextual menu CFPlugin.

```
OSStatus CMPluginExamineContext (
   void *thisInstance,
   const AEDesc *inContext,
   AEDescList *outCommandPairs
);
```

Parameters

thisInstance

The instance of this plugin.

inContext

The Apple event descriptor describing the selection that invoked the contextual menu.

outCommandPairs

On return, `outCommandPairs` points to an array of Apple event descriptors, each of which contains information about a menu item to display in the contextual menu.

Return Value

A result code. See "Menu Manager Result Codes" (page 1399).

Discussion

Your contextual menu plugin must implement this function to determine what menu items to display given the user selection. The Apple event descriptor for each menu item contains the information to display in the item (such as text) and a command ID.

Availability

Available in Mac OS X v10.1 and later.

Declared In

`Menus.h`

CMPluginHandleSelection

An application-defined callback function that handles menu item selection in a contextual menu CFPlugin.

```
OSStatus CMPluginHandleSelection (
   void *thisInstance,
   AEDesc *inContext,
   SInt32 inCommandID
);
```

Parameters

thisInstance

The instance of this plugin.

inContext

The Apple event descriptor describing the selection that invoked the contextual menu.

inCommandID

The command ID associated with the user's menu item selection.

Return Value

A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
Your contextual menu plugin must implement this function to handle a user's selection of an item in the contextual menu. The command ID indicates which of the choices you gave in `CMPluginExamineContext` the user selected, so you can use that and the user selection stored in the `inContext` parameter to execute the conxtexual menu selection appropriately.

Availability
Available in Mac OS X v10.1 and later.

Declared In
`Menus.h`

CMPluginPostMenuCleanup

An application-defined callback function that handles any post-selection cleanup in a contextual menu CFPlugin.

```
void CMPluginPostMenuCleanup (
   void *thisInstance
);
```

Parameters

`thisInstance`
The instance of this plugin.

Discussion
Your contextual menu plugin must implement this function to handle any necessary cleanup required after displaying the contextual menu. If no cleanup is needed, you can simply return from this function.

Availability
Available in Mac OS X v10.1 and later.

Declared In
`Menus.h`

ContextualMenuSelect

Displays a contextual menu.

```
OSStatus ContextualMenuSelect (
   MenuRef inMenu,
   Point inGlobalLocation,
   Boolean inReserved,
   UInt32 inHelpType,
   ConstStr255Param inHelpItemString,
   const AEDesc *inSelection,
   UInt32 *outUserSelectionType,
   MenuID *outMenuID,
   MenuItemIndex *outMenuItem
);
```

Parameters

inMenu

The menu containing application commands to display. The caller creates this menu based on the current context, the mouse location, and the current selection (if it was the target of the mouse). If you pass `NULL`, only system commands are displayed.

inGlobalLocation

The location (in global coordinates) of the mouse near which the menu is to be displayed.

inReserved

Reserved for future use. Pass `false` for this parameter.

inHelpType

An identifier specifying the type of help provided by the application; see "Contextual Menu Help Type Constants" (page 1369).

inHelpItemString

The string containing the text to be displayed for the help menu item. This string is unused unless you also pass the constant `kCMOtherHelp` in the `inHelpType` parameter.

inSelection

A pointer to an object specifier for the current selection. This allows the system to examine the selection and add special system commands accordingly. Passing a value of `NULL` indicates that no selection should be examined, and most likely, no special system actions will be included.

outUserSelectionType

A pointer to an unsigned 32-bit value. On return, the value indicates what the user selected from the contextual menu; see "Contextual Menu Selection Type Constants" (page 1370) for a list of possible values.

outMenuID

A pointer to a signed 16-bit value. On return, if `outUserSelectionType` is set to `kCMMenuItemSelected`, the value is set to the menu ID of the chosen item.

outMenuItem

A pointer to an unsigned 16-bit value. On return, if `outUserSelectionType` is set to `kCMMenuItemSelected`, the value is set to the index of the menu item chosen.

Return Value

A result code. See "Menu Manager Result Codes" (page 1399). Returns `userCanceledErr` and sets `outUserSelectionType` to `kCMNothingSelected` if the user selects an item that requires no additional actions on your part.

Discussion
If your application uses the standard window handler, you may want to install handlers for the `kEventWindowContextualMenuSelect` or `kEventControlContextualMenuClick` events and call `ContextualMenuSelect` from within your handler. The standard window handler automatically detects contextual menu clicks and sends the `kEventWindowContextualMenuSelect` and `kEventControlContextualMenuClick` events.

If the `IsShowContextualMenuEvent` function returns `true` or you receive the appropriate contextual menu Carbon event, you should call the `ContextualMenuSelect` function after generating your own menu and preparing an Apple Event descriptor (`AEDesc`) that describes the item for which your application is displaying a contextual menu. This descriptor may contain an object specifier or raw data and will be passed to all contextual menu plug-ins.

The system will add other items before displaying the contextual menu, and it will remove those items before returning, leaving the menu in its original state.

After all the system commands are added, the contextual menu is displayed and tracked. If the user selects one of the system items, it is handled by the system and the call returns as though the user didn't select anything from the menu. If the user selects any other item (or no item at all), the Menu Manager passes back appropriate values in the parameters `outUserSelectionType`, `outMenuID`, and `outMenuItem`.

Your application should provide visual feedback indicating the item that was clicked upon. For example, a click on an icon should highlight the icon, while a click on editable text should not eliminate the current selection.

If the `outUserSelectionType` parameter contains `kCMMenuItemSelected`, you should look at the `outMenuID` and `outMenuItem` parameters to determine what menu item the user chose and handle it appropriately. If the `outUserSelectionType` parameter contains `kCMShowHelpSelected`, you should open the proper help sequence.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

CopyMenuItemData

Obtains multiple menu item attributes at once.

```
OSStatus CopyMenuItemData (
   MenuRef inMenu,
   MenuItemID inItem,
   Boolean inIsCommandID,
   MenuItemDataPtr ioData
);
```

Parameters

menu

The menu whose attributes you want to get. Note that if you pass `true` for the `inIsCommandID` parameter, you can pass `NULL` here, in which case the Menu Manager searches the root menu for the first menu that matches the specified command ID.

item
The menu item index or the command ID of the menu item.

isCommandID
A Boolean value indicating whether the value passed for the `inItem` parameter is a command ID or a menu item index. Pass `true` to indicate a command ID, `false` to indicate that it is a menu item index. If you pass `true`, the Menu Manager returns the data for the first menu item that matches the specified command ID.

outData
A pointer to a `MenuItemDataRec` structure. Before calling, you should set the `whichData` field to indicate what data you want to obtain. (Individual fields may also require initialization before calling.) On return, the structure contains the data you requested. For more details on the types of data you can obtain, see "Menu Item Data Flags" (page 1390).

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
You can use this function to obtain multiple menu item attributes simultaneously, which is often more efficient than making several different calls. For example, a menu definition function could use `CopyMenuItemData` to obtain all the individual attributes necessary for drawing a menu all at once.

This function returns copies of the data in the menu, so you should release any data in the `MenuItemDataRec` structure that was allocated dynamically (such as the CFString item text).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

CopyMenuItems

Copies menu items from one menu to another.

```
OSStatus CopyMenuItems (
   MenuRef inSourceMenu,
   MenuItemIndex inFirstItem,
   ItemCount inNumItems,
   MenuRef inDestMenu,
   MenuItemIndex inInsertAfter
);
```

Parameters

inSourceMenu
The menu from which to copy items.

inFirstItem
The first item to copy.

inNumItems
The number of items to copy.

inDestMenu
The menu to which to copy items.

inInsertAfter
The menu item in the destination menu after which to insert the copied items. Pass zero to insert items at the beginning of the menu. Note that you cannot specify an index value greater than the number of items in the destination menu.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

CopyMenuItemTextAsCFString

Returns a CFString containing the text of a menu item.

```
OSStatus CopyMenuItemTextAsCFString (
   MenuRef inMenu,
   MenuItemIndex inItem,
   CFStringRef *outString
);
```

Parameters
menu
The menu containing the item.
item
The item whose text you want to copy.
outString
On exit, a CFString containing the item's text. The caller must release this string when it is no longer needed.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

CopyMenuTitleAsCFString

Returns a CFString containing the title of a menu.

```
OSStatus CopyMenuTitleAsCFString (
   MenuRef inMenu,
   CFStringRef *outString
);
```

Parameters

inMenu

The menu whose title you want to obtain.

outString

On exit, a CFString containing the menu's title. This string must be released by the caller.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

CountMenuItems

Obtains the number of menu items in a menu

```
UInt16 CountMenuItems (
   MenuRef theMenu
);
```

Parameters

theMenu

The menu whose items you want to count.

Return Value
The number of menu items in the menu.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
HID Explorer

Declared In
`Menus.h`

CountMenuItemsWithCommandID

Counts the menu items with a specified command ID.

```
ItemCount CountMenuItemsWithCommandID (
   MenuRef inMenu,
   MenuCommand inCommandID
);
```

Parameters

menu

The menu in which to begin searching for items with the specified command ID. Pass `NULL` to begin searching with the root menu. The search will descend into all submenus of this menu.

commandID

The command ID for which to search.

Return Value
The number of menu items that match the specified command ID.

Version Notes
In CarbonLib 1.0.x, this function always returns zero or one; it stops after finding the first menu item with the specified command ID. In CarbonLib 1.1 and Mac OS X v10.0, it will count all menu items with the specified command ID.

In Mac OS X v10.0 and CarbonLib 1.0 through 1.4, this function searches only top-level menus (that is, those that are visible in the menu bar) and submenus of top-level menus. It does not search hierarchical menus that are in the menu bar but are not submenus of a top-level menu. For example, it does not search menus that are inserted for use in a popup menu. In Mac OS X v10.1 and later, and CarbonLib 1.5 and later, this function also searches hierarchical menus.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

CreateCustomMenu

Creates a new, untitled, empty menu using a custom menu definition function.

```
OSStatus CreateCustomMenu (
   const MenuDefSpec *inDefSpec,
   MenuID inMenuID,
   MenuAttributes inMenuAttributes,
   MenuRef *outMenuRef
);
```

Parameters

inDefSpec

A data structure that specifies a custom menu definition function.

inMenuID

The menu ID to use for the new menu.

inMenuAttributes

The menu attributes to use for the new menu. See "Menu Attribute Constants" (page 1375) for a list of possible values.

outMenuRef
On exit, contains the new menu.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
Similar to `CreateNewMenu` (page 1246), but also allows you to create a menu from a custom menu definition function This definition can be procedure pointer–based or HIView-based, which you specify in the `MenuDefSpec` structure. (Note that HIView–based menus are available only in Mac OS X v10.3 and later.)

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

CreateNewMenu

Creates a new, untitled, empty menu.

```
OSStatus CreateNewMenu (
   MenuID inMenuID,
   MenuAttributes inMenuAttributes,
   MenuRef *outMenuRef
);
```

Parameters
inMenuID
The menu ID to use for the new menu. Note that zero is a valid ID in Carbon.

inMenuAttributes
The menu attributes to use for the new menu. See "Menu Attribute Constants" (page 1375) for a list of possible values.

outMenuRef
On exit, contains the new menu.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
Unless you need to create new menus on-the-fly, you should not use functions like `CreateNewMenu` that create menus programmatically. Instead, you should define menus in Interface Builder, store them as nib files, and then call the Interface Builder Services function `CreateMenuFromNib` to create them.

`CreateNewMenu` is preferred over `NewMenu` because it allows you to specify the menu's attributes and it does not require you to specify a `Str255`-based menu title. To set the menu title, you should use `SetMenuTitleWithCFString` (page 1346).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
Menus.h

CreateStandardFontMenu

Creates a standard font menu.

```
OSStatus CreateStandardFontMenu (
   MenuRef menu,
   MenuItemIndex afterItem,
   MenuID firstHierMenuID,
   OptionBits options,
   ItemCount *outHierMenuCount
);
```

Parameters

menu
The menu to which you want to add the font items.

afterItem
The item number of the menu item after which the new menu items are to be added. If you want to insert the new items before the first menu items, specify 0. If you want to insert the items after the last item in the menu, specify a number greater than or equal to the last item in the menu. Otherwise, specify the item number for the menu item after which you want to insert new items.

firstHierMenuID
The first menu ID to use if any hierarchical menus are created. This ID is incremented for each additional hierarchical menu.

options
An option bits structure that specifies the behavior for the Font menu. Specify the `Hierarchical Font Menu Option Constant` (page 1375) if you want to construct a hierarchical font menu.

outHierMenuCount
On return, this parameter contains the number of hierarchical menus attached to the standard font menu. This value may be `NULL` if the hierarchical menus count is not useful. For example, if the only submenus in your application are those created by `CreateStandardFontMenu`, then you don't need to worry about the hierarchical menu count, as any existing submenu must be a font menu.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
You should use this function instead of the functions `AppendResMenu` (page 1232) or `InsertResMenu` (page 1297) to designate objects in the font database as menu items in the Font menu. The fonts objects will appear by name.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
Menus.h

DeleteMCEntries

Deletes a menu item entry, a menu title entry, the menu bar entry, or all menu item entries of a specific menu from your application's menu color information table. (Deprecated in Mac OS X v10.5.)

Not recommended

```
void DeleteMCEntries (
   MenuID menuID,
   short menuItem
);
```

Parameters

menuID

The menu ID that the `DeleteMCEntries` function should use to determine which entry to delete from the menu color information table. Specify 0 in the `menuID` parameter (and the `menuItem` parameter) to delete the menu bar entry. Specify the menu ID of a menu in the current menu list in the `menuID` parameter and 0 in the `menuItem` parameter to delete a specific menu title entry. Specify the menu ID of a menu in the current menu list in the `menuID` parameter and an item number in the `menuItem` parameter to delete a specific menu item entry.

menuItem

The menu item that the `DeleteMCEntries` function should use to determine which entry to delete from the menu color information table. If you specify 0 in this parameter, `DeleteMCEntries` deletes either the menu bar entry or menu title entry, depending on the value of the `menuID` parameter. If you specify the item number of a menu item in this parameter and the menu ID of a menu in the current menu list in the `menuID` parameter, `DeleteMCEntries` deletes a specific menu item entry. You can also delete all menu item entries for a specific menu from your application's menu color information table by specifying the constant `mctAllItems`.

Discussion

If the `DeleteMCEntries` function does not find the specified entry in your application's menu color information table, it does not delete the entry. Your application should not delete the last entry in your application's menu color information table.

If any of the deleted entries changes the menu bar color or a menu title color, your application should call `DrawMenuBar` (page 1255) to update the menu bar.

Carbon Porting Notes

`DeleteMCEntries` does nothing, because the Appearance Manager doesn't use color tables.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Menus.h`

DeleteMenu

Deletes an existing menu from the current menu list.

```
void DeleteMenu (
    MenuID menuID
);
```

Parameters

menuID

The menu ID of the menu to delete from the current menu list. If the menu list does not contain a menu with the specified menu ID, `DeleteMenu` does nothing.

Discussion

The `DeleteMenu` function deletes the menu identified by the specified menu ID from the current menu list. `DeleteMenu` decrements the reference count of the menu, and if the reference count reaches zero, the memory occupied by the menu is released. To explicitly release the memory occupied by the menu, use `DisposeMenu` (page 1253).

The `DeleteMenu` function first checks the submenu portion of the current menu list for a menu ID with the specified ID. If it finds such a menu, it deletes that menu and returns. If `DeleteMenu` doesn't find the menu in the submenu portion, it checks the regular portion of the current menu list.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Menus.h`

DeleteMenuItem

Deletes an item from a menu.

```
void DeleteMenuItem (
   MenuRef theMenu,
   MenuItemIndex item
);
```

Parameters

theMenu

The menu from which you want to delete the menu item.

item

The item number of the menu item to delete. If you specify 0 or a number greater than the last item in the menu, `DeleteMenuItem` does not delete any item from the menu.

Discussion

The `DeleteMenuItem` function deletes a specified menu item from a menu. You should not delete items from an existing menu unless the user expects the menu (such as a menu that lists open documents) to change.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Menus.h`

DeleteMenuItems

Deletes multiple menu items.

```
OSStatus DeleteMenuItems (
   MenuRef inMenu,
   MenuItemIndex inFirstItem,
   ItemCount inNumItems
);
```

Parameters

inMenu

The menu from which to delete items.

inFirstItem

The first item to delete.

inNumItems

The number of items to delete.

Return Value

A result code. See "Menu Manager Result Codes" (page 1399).

Discussion

You can call this function rather than calling `DeleteMenuItem` (page 1249) multiple times.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Related Sample Code

HID Explorer

Declared In

`Menus.h`

DisableAllMenuItems

Disables all items in a menu.

```
void DisableAllMenuItems (
   MenuRef theMenu
);
```

Parameters

theMenu

The menu whose items you want to disable.

Discussion

This function is equivalent to older code that masked the `enableFlags` field of the `MenuInfo` structure (now opaque in Carbon) with `0x01`. It disables all items (including items past item 31) but does not affect the state of the menu title.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In
Menus.h

DisableMenuCommand

Disables the menu item with a specified command ID.

```
void DisableMenuCommand (
   MenuRef inMenu,
   MenuCommand inCommandID
);
```

Parameters

theMenu

The menu in which to begin searching for the item. Pass NULL to begin searching with the root menu. The search will descend into all submenus of this menu.

commandID

The command ID of the menu item to be disabled. If more than one item has this command ID, only the first will be disabled.

Discussion
If you have access to the menu item index, in most cases you should use DisableMenuItem (page 1251) instead, as that function is faster and requires no searching.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
CarbonSketch

Declared In
Menus.h

DisableMenuItem

Disables a menu item or a menu.

```
void DisableMenuItem (
   MenuRef theMenu,
   MenuItemIndex item
);
```

Parameters

theMenu

The menu containing the item to be disabled.

item

The index of the menu item that you wish to disable. Pass 0 to specify the menu title (disabling the entire menu).

Discussion
The DisableMenuItem function disables a menu item (and any associated icon) so that the user cannot choose the item from the menu.

Note that `EnableMenuItem` calls the `InvalMenuBar` (page 1301) function to update the menu bar the next time through the event loop.

See also the `EnableMenuItem` (page 1257) and `IsMenuItemEnabled` (page 1303) functions.

Carbon Porting Notes

Note that the implementation of Carbon on Mac OS 8.1 only supports disabling menu items less than or equal to 31.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Related Sample Code

QTCarbonShell

Declared In

`Menus.h`

DisableMenuItemIcon

Disables the icon associated with a menu item.

```
void DisableMenuItemIcon (
   MenuRef theMenu,
   MenuItemIndex item
);
```

Parameters

theMenu

The menu containing the icon to be disabled.

item

The index of the menu item containing the icon.

Discussion

Your application can use the `DisableMenuItemIcon` function to dim individual menu item icons. The menu item that contains the icon is unaffected by calling `DisableMenuItemIcon`. That is, if `DisableMenuItemIcon` disables an enabled menu item's icon, the menu item itself will remain enabled. Calling `DisableMenuItemIcon` on the icon of a menu item that is currently disabled will cause the icon to be disabled once the menu item is re-enabled.

See also the functions `EnableMenuItemIcon` (page 1258) and `IsMenuItemIconEnabled` (page 1304).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Menus.h`

DisposeMCInfo

Disposes of a menu color information table. (Deprecated in Mac OS X v10.5.)

Not recommended

```
void DisposeMCInfo (
   MCTableHandle menuCTbl
);
```

Parameters

menuCTbl

The handle to the menu color information table you want to remove.

Discussion

The `DisposeMCInfo` function disposes of the menu color information table referred to by the `menuCTbl` parameter.

Carbon Porting Notes

`DisposeMCInfo` does nothing, because Appearance Manager doesn't use color tables.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Menus.h`

DisposeMenu

Decrements the retain count of a menu.

```
void DisposeMenu (
   MenuRef theMenu
);
```

Parameters

theMenu

The menu whose retain count to decrement. If the retain count falls to zero, the menu is destroyed.

Discussion

The reference that you pass in the `theMenu` parameter is not valid after `DisposeMenu` returns. This function is identical to `ReleaseMenu` (page 1319).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Related Sample Code

HID Explorer

Declared In

`Menus.h`

DisposeMenuBar

Releases a menubar handle.

```
OSStatus DisposeMenuBar (
   MenuBarHandle inMbar
);
```

Parameters

mbar

The menubar handle to release.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
Carbon applications should call this function when releasing a handle returned from `GetNewMBar` (page 1290), `GetMenuBar` (page 1268), or `DuplicateMenuBar` (page 1256). Doing so ensures that the reference counts of the menus in the menubar handle can be decremented when the handle is released.

Do not call the Memory Manager function `DisposeHandle` to release such a handle.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

DisposeMenuDefUPP

Disposes of universal procedure pointer to a custom menu definition. (Deprecated in Mac OS X v10.5.)

Not recommended

```
void DisposeMenuDefUPP (
   MenuDefUPP userUPP
);
```

Parameters

userUPP

Carbon Porting Notes

Apple discourages you from writing and using your own menu definition functions and encourages you to use the system-supplied menu definition function instead. New features that have previously been missing are now available in the system-supplied menu definition function. Since Appearance Manager 1.0 (in Mac OS 8.0), for example, the system-supplied menu definition function has supported extended menu item command key modifiers and glyphs. And in Carbon, the system-supplied menu definition function supports dynamic items, which allow the contents of a menu item to be redrawn while the menu is displayed in response to the user pressing a modifier key on the keyboard.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Menus.h`

DrawMenuBar

Draws the menu bar based on the current menu list.

```
void DrawMenuBar ();
```

Discussion
The `DrawMenuBar` function draws (or redraws) the menu bar according to the current menu list. Note that most Menu Manager calls that affect the menu bar call `InvalMenuBar` (page 1301) so that the menu bar is redrawn the next time through the event loop; however, you can call `DrawMenuBar` if you want the changes to appear immediately.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
Simple DrawSprocket

Declared In
`Menus.h`

DuplicateMenu

Creates a new menu that is a copy of another menu.

```
OSStatus DuplicateMenu (
   MenuRef inSourceMenu,
   MenuRef *outMenu
);
```

Parameters

inSourceMenu
The menu to duplicate.

outMenu
On exit, a copy of the source menu.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
Unlike `RetainMenu` (page 1321), `DuplicateMenu` creates an entirely new menu that is an exact copy of the original menu. The menu definition for the new menu will receive an initialization message/event after the menu has been fully created.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

DuplicateMenuBar

Duplicates a menubar handle.

```
OSStatus DuplicateMenuBar (
   MenuBarHandle inMbar,
   MenuBarHandle *outMbar
);
```

Parameters

inMbar

The menubar handle to duplicate.

outMBar

On exit, contains the new menubar handle.

Return Value

A result code. See "Menu Manager Result Codes" (page 1399).

Discussion

Carbon applications should use this function when duplicating a handle returned from `GetMenuBar` or `GetNewMBar`. Doing so ensures that the reference counts of the menus in the menubar handle can be incremented when the handle is duplicated.

Do not use Memory Manager APIs (`HandToHand`, `NewHandle`, and so on) to duplicate such a handle.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Menus.h`

EnableAllMenuItems

Enables all items in a menu.

```
void EnableAllMenuItems (
   MenuRef theMenu
);
```

Parameters

theMenu

The menu whose items to enable.

Discussion

This function is equivalent to older code that OR'd the `enableFlags` field of the `MenuInfo` structure (now opaque in Carbon) with 0xFFFFFFFE. It enables all items (including items past item 31) but does not affect the state of the menu title.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Menus.h`

EnableMenuCommand

Enables the menu item with a specified command ID.

```
void EnableMenuCommand (
   MenuRef inMenu,
   MenuCommand inCommandID
);
```

Parameters

inMenu

The menu in which to begin searching for the item. Pass `NULL` to begin searching with the root menu. The search will descend into all submenus of this menu.

inCommandID

The command ID of the menu item to be enabled. If more than one item has this command ID, only the first will be enabled.

Discussion

If you have access to the menu item index, in most cases you should use `EnableMenuItem` (page 1257) instead, as that function is faster and requires no searching. For example, when receiving a `kEventCommandUpdateStatus` event, the `HICommand` structure contains both the menu item's command ID and index. If you wanted to enable the menu item, you should call `EnableMenuItem` (page 1257).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Related Sample Code

CarbonSketch

QTCarbonShell

Declared In

`Menus.h`

EnableMenuItem

Enables a menu item or a menu.

```
void EnableMenuItem (
    MenuRef theMenu,
    MenuItemIndex item
);
```

Parameters

theMenu

The menu containing the item to be enabled.

item

The item number of the menu item that you wish to enable. If you pass 0, `EnableMenuItem` enables the menu title and all items in the menu that were not previously individually disabled.

Discussion

The `EnableMenuItem` function enables a menu item so that the user can choose the item from the menu. If the menu item has an associated icon, that icon is also enabled, unless the icon was previously individually disabled with the function `DisableMenuItemIcon` (page 1252).

Note that `EnableMenuItem` calls the `InvalMenuBar` (page 1301) function to update the menu bar the next time through the event loop.

See also the `DisableMenuItem` (page 1251) and `IsMenuItemEnabled` (page 1303) functions.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
QTCarbonShell

Declared In
`Menus.h`

EnableMenuItemIcon

Enables the icon associated with a menu item.

```
void EnableMenuItemIcon (
   MenuRef theMenu,
   MenuItemIndex item
);
```

Parameters

theMenu
The menu containing the icon to be enabled.

item
The item number of the menu item containing the icon.

Discussion
Your application can use the `EnableMenuItemIcon` function to enable individual menu item icons that have been previously disabled by a call to the function `DisableMenuItemIcon` (page 1252). The menu item that contains the icon is unaffected by calling `EnableMenuItemIcon`. Note that enabling the icon of a currently disabled menu item has no visual effect; however, once the menu item is enabled, the icon is also enabled.

See also the `DisableMenuItemIcon` (page 1252) and `IsMenuItemIconEnabled` (page 1304) functions.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

EraseMenuBackground

Erases the menu background to prepare for additional drawing. (Deprecated in Mac OS X v10.5.)

```
OSStatus EraseMenuBackground (
   MenuRef inMenu,
   const Rect *inEraseRect,
   CGContextRef inContext
);
```

Parameters

inMenu

The menu whose background you want to erase.

inEraseRect

The bounds of the area to erase, in the local coordinates of the current port.

inContext

The Core Graphics context to erase. If set to `NULL`, this function creates a new context based on the current port.

Return Value

A result code. See "Menu Manager Result Codes" (page 1399).

Discussion

Typically you use this function only if you are implementing message-based custom menu definition functions. HIView-based custom menus and normal application code do not need to call `EraseMenuBackground`.

Before calling the Appearance Manager function `DrawThemeMenuBackground`, you must erase the current menu background. Themes such as Aqua draw the menu background using an alpha channel, so if the old background is not erased, portions of the old image will show through the menu background.

Availability

Available in Mac OS X v10.1 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Menus.h`

FlashMenuBar

Highlights a menu title or the entire menu bar.

```
void FlashMenuBar (
   MenuID menuID
);
```

Parameters

menuID

The menu ID of the menu whose title you want to highlight. Pass zero in this parameter to signal a visual alert (that is, flash the entire screen) If you pass a menu ID that is not in the menubar, `FlashMenuBar` returns immediately without flashing the bar or any menu title.

Discussion

Call this function twice if you want the menu or menu bar to blink.

Only one menu title can be highlighted at a time. If no menus are currently highlighted, calling `FlashMenuBar` with a specific menu ID highlights the title of that menu. If you call `FlashMenuBar` again specifying another menu ID that is different from that of the previously highlighted menu title, `FlashMenuBar` restores the previously highlighted menu to normal and then highlights the title of the specified menu.

If you pass zero for the menu ID, this function flashes the entire screen, as if an alert had occurred while the user had specified the "Flash the screen when an alert sound occurs" checkbox in the Universal Access preference pane.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

GetFontFamilyFromMenuSelection

Gets the font family reference and style from the menu identifier and menu item number returned by the function `MenuSelect`.

```
OSStatus GetFontFamilyFromMenuSelection (
   MenuRef menu,
   MenuItemIndex item,
   FMFontFamily *outFontFamily,
   FMFontStyle *outStyle
);
```

Parameters

menu
A menu handle.

item
A menu item index.

outFontFamily
A pointer to the font family reference associated with the menu item.

outStyle
A pointer to the font style associated with the menu item.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
You use this function to obtain information from a font menu created using `CreateStandardFontMenu` (page 1247), `AppendResMenu` (page 1232), `InsertFontResMenu` (page 1293), `InsertIntlResMenu` (page 1293), or `InsertResMenu` (page 1297).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

GetIndMenuItemWithCommandID

Finds a menu item with a specified command ID.

```
OSStatus GetIndMenuItemWithCommandID (
   MenuRef inMenu,
   MenuCommand inCommandID,
   UInt32 inItemIndex,
   MenuRef *outMenu,
   MenuItemIndex *outIndex
);
```

Parameters

inMenu

The menu in which to begin searching for items with the specified command ID. Pass `NULL` to begin searching with the root menu. The search will descend into all submenus of this menu.

inCommandID

The command ID for which to search.

inItemIndex

The 1-based index of the menu item to retrieve. In CarbonLib 1.0.x, this parameter must be 1. In CarbonLib 1.1 and Mac OS X 1.0, this parameter may vary from 1 to the number of menu items with the specified command ID.

outMenu

On exit, the menu containing the menu item with the specified command ID.

outIndex

On exit, the item index of the menu item with the specified command ID.

Return Value

A result code. See "Menu Manager Result Codes" (page 1399).

Discussion

This API searches the specified menu and its submenus for the n'th menu item with the specified command ID. You often want to use this function in conjunction with `CountMenuItemsWithCommandID` (page 1244).

Version Notes

In CarbonLib 1.1 and earlier, only the first menu item will be returned. In CarbonLib 1.2 and Mac OS X v10.0 and later, this API will iterate over all menu items with the specified command ID and return the `itemIndex`'th one.

In Mac OS X v10.0 and CarbonLib 1.0 through 1.4, this function searches only top-level menus (that is, those that are visible in the menu bar) and submenus of top-level menus. It does not search hierarchical menus that are in the menu bar but are not submenus of a top-level menu. For example, it does not search menus that are inserted for use in a popup menu. In Mac OS X v10.1 and later, and CarbonLib 1.5 and later, this function also searches hierarchical menus.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Related Sample Code

CarbonSketch

Declared In

`Menus.h`

GetItemCmd

Returns the value of a menu item's keyboard equivalent field.

Not recommended

```
void GetItemCmd (
   MenuRef theMenu,
   MenuItemIndex item,
   CharParameter *cmdChar
);
```

Parameters

theMenu

The menu containing the menu item whose keyboard equivalent you want to obtain.

item

An integer representing the item number of the menu item whose keyboard equivalent you want to determine.

cmdChar

On output, an integer representing the item's keyboard equivalent field. The Menu Manager uses this value to map keyboard equivalents to menu commands or to indicate special characteristics of the menu item.

If the value referenced through the `cmdChar` parameter contains 0x1B, the menu item has a submenu; a value of 0x1C indicates that the item has a text encoding; a value of 0x1D indicates that the Menu Manager reduces the item's `'ICON'` resource; and a value of 0x1E indicates that the item has an `'SICN'` resource.

Discussion

You should call `GetMenuItemCommandKey` (page 1276) , `GetMenuItemHierarchicalID` (page 1277) , and `GetMenuItemTextEncoding` (page 1285) instead of `GetItemCmd` to obtain a menu item's keyboard equivalent and text encoding and to determine that a menu item has a submenu.

The `GetItemCmd` function returns the value in the keyboard equivalent field of the specified menu item in the value pointed to by the `cmdChar` parameter (or 0 if the item doesn't have a keyboard equivalent, submenu, text encoding, reduced icon, or small icon).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Menus.h`

GetItemIcon

Returns a menu item's icon or text encoding. (Deprecated in Mac OS X v10.5.)

```
void GetItemIcon (
   MenuRef theMenu,
   MenuItemIndex item,
   short *iconIndex
);
```

Parameters

theMenu

The menu containing the item.

item

The menu index of the item.

iconIndex

On output, an integer representing the menu item's icon or text encoding. For menu items that do not specify 0x1C in the keyboard equivalent field, a value from 1 through 255 if the menu item has an icon associated with it and is 0 otherwise representing the item's icon number.

Discussion

In most cases, you should use `GetMenuItemTextEncoding` (page 1285) rather than `GetItemIcon` to get the menu item's text encoding.

The `GetItemIcon` function returns the icon number or text encoding of the specified menu item through the `iconIndex` parameter (or 0 if the item doesn't have an icon or a text encoding). If the menu item's keyboard equivalent field contains 0x1C, the returned number represents the text encoding of the menu item. Otherwise, the returned number represents the item's icon number.

In the `iconIndex` parameter, you can add 256 to the icon number to generate the resource ID of the `'cicn'`, `'ICON '`, or `'SICN '` resource that describes the icon of the menu item. For example, if the `GetItemIcon` function returns 5 as the icon number, then the icon of the menu item is described by an icon resource with resource ID 261.

For menu items that contain 0x1C in the keyboard equivalent field, the `GetItemIcon` function returns the text encoding of the menu item. The Menu Manager displays the menu item using this text encoding if the corresponding script system is installed.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Menus.h`

GetItemMark

Returns a menu item's mark.

```
void GetItemMark (
   MenuRef theMenu,
   MenuItemIndex item,
   CharParameter *markChar
);
```

Parameters

theMenu

The menu containing the item.

item

The menu index of the item.

markChar

On output, an integer representing the mark of the menu item or its submenu (item has a submenu). See the Font Manager for a list of character marking constants that this function can obtain. This parameter is set to 0 if the menu item has neither mark nor submenu.

Discussion

You should call `GetMenuItemHierarchicalID` (page 1277) instead of `GetItemMark` to obtain the menu ID of a menu item's submenu. However, you can still use `GetItemMark` to obtain the mark of a menu item.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Related Sample Code

QTCarbonShell

Declared In

`Menus.h`

GetItemStyle

Returns a menu item's text style.

```
void GetItemStyle (
   MenuRef theMenu,
   MenuItemIndex item,
   Style *chStyle
);
```

Parameters

theMenu

The menu containing the item.

item

The menu index of the item.

chStyle

On output, an integer representing the menu item's text style. The functions returns one of the following constants: `normal`, `bold`, `italic`, `underline`, `outline`, `shadow`, `condense`, and `extend`.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In
`Menus.h`

GetMBarHeight

Determines the current height of the menu bar.

```
short GetMBarHeight (
   void
);
```

Return Value
The current height, in pixels, of the menu bar.

Discussion
The `GetMBarHeight` function determines the menu bar height based on factors such as the current script system and theme.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

GetMCEntry

Gets information about an entry in an application's menu color information table. (Deprecated in Mac OS X v10.5.)

Not recommended

```
MCEntryPtr GetMCEntry (
   MenuID menuID,
   short menuItem
);
```

Parameters

`menuID`

The menu ID that the `GetMCEntry` function should use to return information about the menu color information table. Specify 0 in the `menuID` parameter (and the `menuItem` parameter) to get the menu bar entry. Specify the menu ID of a menu in the current menu list in the `menuID` parameter and 0 in the `menuItem` parameter to get a specific menu title entry. Specify the menu ID of a menu in the current menu list in the `menuID` parameter and an item number in the `menuItem` parameter to get a specific menu item entry.

`menuItem`

The menu item that the `GetMCEntry` function should use to return information about the menu color information table. If you specify 0 in this parameter, `GetMCEntry` returns either the menu bar entry or the menu title entry, depending on the value of the `menuID` parameter. If you specify the item number of a menu item in this parameter and the menu ID of a menu in the current menu list in the `menuID` parameter, `GetMCEntry` returns a specific menu item entry.

Return Value
A menu bar entry, a menu title entry, or a menu item entry according to the values specified in the `menuID` and `menuItem` parameters. If the `GetMCEntry` function finds the specified entry in your application's menu color information table, it returns a pointer to a structure of data type `MCEntry`. If the specified entry is not found, `GetMCEntry` returns `null`. The menu color information table is relocatable, so the pointer returned by the `GetMCEntry` function may not be valid across functions that may move or purge memory. Your application should make a copy of the menu color entry structure if necessary. See page for a description of the `MCEntry` data structure.

Carbon Porting Notes

`GetMCEntry` does nothing, because Appearance Manager doesn't use color tables.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Menus.h`

GetMCInfo

Returns a handle to a copy of your application's menu color information table. (Deprecated in Mac OS X v10.5.)

Not recommended

```
MCTableHandle GetMCInfo (
   void
);
```

Return Value
A handle to a copy of your application's menu color information table. If the copy fails, `GetMCInfo` returns `null`.

Carbon Porting Notes

The Menu Manager ignores color tables in Mac OS X, so there is no reason to call `GetMCInfo`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Menus.h`

GetMenu

Creates a menu from the specified menu and extended menu resources.

Not recommended

```
MenuRef GetMenu (
    short resourceID
);
```

Parameters

resourceID

The resource ID of the menu and extended menu that defines the characteristics of the menu. You typically use the same number for a menu's resource ID as the number that you specify for the menu ID in the menu resource.

Return Value

The new menu. You can use the returned menu handle to refer to this menu in most Menu Manager functions. If `GetMenu` is unable to read the menu or menu definition function from the resource file, `GetMenu` returns `null`. See the description of the `MenuRef` data type.

Discussion

Unless you must support legacy code, you should not use functions like `GetMenu` that rely on menus stored as resources. Instead, you should define menus in Interface Builder, store them as nib files, and then call the Interface Builder Services function `CreateMenuFromNib` to create them.

`GetMenu` reads the menu definition function into memory (if not already present) and stores a handle to the menu definition function in the menu structure. `GetMenu` does not insert the newly created menu into the current menu list.

You typically use the `GetMenu` function only when you create submenus; you can create all your pull-down menus at once using the function `GetNewMBar`, and you can create pop-up menus using the standard pop-up menu button control definition function.

After reading the `'MENU'` resource, `GetMenu` searches for an extended menu resource and an `'mctb'` resource with the same resource ID as the `'MENU'` resource. If the specified `'mctb'` resource exists, `GetMenu` uses `SetMCEntries` to add the entries defined by the resource to the application's menu color information table. If the `'mctb'` resource does not exist, `GetMenu` uses the default colors specified in the menu bar entry of the application's menu color information. If neither a menu bar entry nor a `'mctb'` resource exists, `GetMenu` uses the standard colors for the menu.

Storing the definitions of your menus in resources (especially menu titles and menu items) makes your application easier to localize.

After creating a menu with `GetMenu` or `NewMenu` (page 1314) , use `InsertMenuItem` (page 1295) , `AppendMenu` (page 1229) , or `InsertResMenu` (page 1297) to add menu items to the menu. To add a menu created by `GetMenu` to the current menu list, use `InsertMenu` (page 1294). To update the menu bar with any new menu titles, use `DrawMenuBar` (page 1255).

Menus in a resource must not be purgeable nor should the resource lock bit be set. Do not define a "circular" hierarchical menu—that is, a hierarchical menu in which a submenu has a submenu whose submenu is a hierarchical menu higher in the chain.

Special Considerations

To release the memory associated with a menu that you created using `GetMenu`, first call `DeleteMenu` to remove the menu from the current menu list and to remove any entries for this menu in your application's menu color information table then call `DisposeMenu` to dispose of the menu structure.

Carbon Porting Notes

In Carbon, the `GetMenu` function always returns a newly created `MenuRef`. Prior to Carbon, `GetMenu` would first check if the menu was already in memory. If so, `GetMenu` would return the in-memory copy. This behavior is no longer supported.

Carbon does not support custom menu definitions stored in 'MDEF' resources. If you want to specify a custom menu definition for `GetMenu`, you must compile your definition function directly in your application and then register the function by calling `RegisterMenuDefinition` (page 1318). When `GetMenu` gets a `resourceID` value that doesn't recognize, it checks a special mapping table to find the pointer that's registered for the `resourceID` parameter. It then calls that function to implement your menu.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

GetMenuAttributes

Gets the attributes of a menu.

```
OSStatus GetMenuAttributes (
   MenuRef menu,
   MenuAttributes *outAttributes
);
```

Parameters

menu
The menu.

outAttributes
On exit, contains the attributes of the menu. See "Menu Attribute Constants" (page 1375) for a list of possible values.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

GetMenuBar

Gets a handle to a copy of the current menu list.

```
MenuBarHandle GetMenuBar (
   void
);
```

Return Value
A handle to a copy of the current menu list. See the description of the `MenuBarHandle` data type.

Discussion
The `GetMenuBar` function creates a copy of the current menu list and returns a handle to the copy. You can save the returned menu list and then add menus to or remove menus from the current menu list using `InsertMenu` (page 1294) , `DeleteMenu` (page 1248) , or `ClearMenuBar` (page 1237). You can later restore the saved menu list using `SetMenuBar` (page 1327).

To release the memory occupied by a saved menu list, use the `DisposeMenuBar` (page 1253) function.

`GetMenuBar` doesn't copy the menu structures, just the menu list (which contains handles to the menu structures). Do not dispose of any menus in a saved menu list if you wish to restore the menu list later.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

GetMenuCommandMark

Locates the menu item with a specified command ID and returns its mark character.

```
OSStatus GetMenuCommandMark (
   MenuRef inMenu,
   MenuCommand inCommandID,
   UniChar *outMark
);
```

Parameters

theMenu
The menu in which to begin searching for the item. Pass `NULL` to begin searching with the root menu. The search will descend into all submenus of this menu.

commandID
The command ID of the menu item to be examined. If more than one item has this command ID, only the first will be examined.

outMark
On exit, the menu item's mark character.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
If you have access to the menu item index, in most cases you should use `GetItemMark` (page 1263) instead, as that function is faster and requires no searching.

Availability
Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In
`Menus.h`

GetMenuCommandProperty

Retrieves property data for a menu item with the specified command ID.

```
OSStatus GetMenuCommandProperty (
   MenuRef inMenu,
   MenuCommand inCommandID,
   OSType inPropertyCreator,
   OSType inPropertyTag,
   ByteCount inBufferSize,
   ByteCount *outActualSize,
   void *inPropertyBuffer
);
```

Parameters

inMenu
The menu in which to search for the command ID. Pass `NULL` to begin searching with the root menu. The search will descend into all submenus of this menu.

inCommandID
The command ID of the menu item containing the property. Note that if more than one item has the same command ID, only the first match is used.

inPropertyCreator
The four-character creator code of the application.

inPropertyTag
The four-character tag of the property to obtain.

inBufferSize
The size of the buffer to hold the retrieved data, in bytes.

outActualSize
The actual size of the property data. If you do not need this information, pass `NULL`.

inPropertyBuffer
A pointer to the buffer in which to place the data. On return, the buffer contains the property data.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
If you have access to the menu item index, in most cases you should use `GetMenuItemProperty` (page 1281) instead, as that function is faster and requires no searching.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

GetMenuCommandPropertySize

Retrieves the size of the property data for a menu item with the specified command ID.

```
OSStatus GetMenuCommandPropertySize (
   MenuRef inMenu,
   MenuCommand inCommandID,
   OSType inPropertyCreator,
   OSType inPropertyTag,
   ByteCount *outSize
);
```

Parameters

menu

The menu in which to search for the command ID. Pass `NULL` to begin searching with the root menu. The search will descend into all submenus of this menu.

commandID

The command ID of the menu item containing the property. If more than one menu item has the same command ID, only the first match is used.

propertyCreator

The four-character creator code of the application.

propertyTag

The four-character tag of the property data whose size you want to obtain.

size

On return, contains the size of the property data.

Return Value

A result code. See "Menu Manager Result Codes" (page 1399).

Discussion

If you have access to the menu item index, in most cases you should use `GetMenuItemPropertySize` (page 1283) instead, as that function is faster and requires no searching.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Menus.h`

GetMenuDefinition

Obtains the menu definition structure for a menu.

```
OSStatus GetMenuDefinition (
   MenuRef menu,
   MenuDefSpecPtr outDefSpec
);
```

Parameters

menu

The menu whose menu definition structure you want to obtain.

outDefSpec
On return, a pointer to the menu's `MenuDefSpec` structure.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
Note that you cannot use this function to obtain the standard system menu definition. If you call `GetMenuDefinition` on a menu that uses the standard system MDEF or menu content HIView, the function returns `menuUsesSystemDefErr`.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

GetMenuExcludesMarkColumn

Returns whether a menu contains space for mark characters.

Not recommended

```
Boolean GetMenuExcludesMarkColumn (
   MenuRef menu
);
```

Parameters

menu
The menu whose width is to be examined.

Return Value
Returns `true` if the menu currently contains no space for mark characters; `false` if the menu is currently drawn in its full width, with space for mark characters.

Discussion
See also the `SetMenuExcludesMarkColumn` (page 1330) function.

Carbon Porting Notes

You should instead inspect the `kMenuExcludesMarkColumn` menu attribute using the `GetMenuAttributes` function.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

GetMenuFont

Obtains the font used in a menu.

```
OSStatus GetMenuFont (
   MenuRef menu,
   SInt16 *outFontID,
   UInt16 *outFontSize
);
```

Parameters

menu

The menu whose font is to be obtained.

outFontID

On input, a pointer to a signed 16-bit integer. On return, this value identifies the font family ID for the menu font. Note that this is the menu item font, not the menu title font.

outFontSize

On input, a pointer to an unsigned 16-bit integer. On return, this value identifies the size of the font, in points.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
Your application may use the `GetMenuFont` function to retrieve the font used for an individual menu, such as a pop-up menu.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

GetMenuHandle

Obtains a menu reference corresponding to a menu ID.

```
MenuRef GetMenuHandle (
   MenuID menuID
);
```

Parameters

menuID

The menu ID of the menu whose reference you want to obtain. (Note that this is not the resource ID, although you often assign the menu ID so that it matches the resource ID.) You assign a menu ID in a nib file or in the 'MENU' resource of a menu. If you do not define your menus in nib files or in 'MENU' resources, you can assign a menu ID using `NewMenu` (page 1314) or `SetMenuID` (page 1333).

Return Value
The menu corresponding to the specified ID. If the specified menu is not in the current menu list, `GetMenuHandle` returns `NULL`. See the description of the `MenuRef` data type.

Discussion
You can also call this function as `GetMenuRef (menuID);`.

Use the `GetMenuHandle` function to obtain the menu reference for any of your application's pull-down menus or submenus in the current menu list, other than the Help menu. You can also use the Help Manager function `HMGetHelpMenuHandle` to get a handle for your application's Help menu.

Special Considerations

To get a menu reference for a pop-up menu that you create using the pop-up control definition function, call the Control Manager functions `GetControlData` and `GetControlDataSize`, passing the tag constant `kControlPopupButtonMenuRefTag` in the `tagName` parameter to specify the menu reference.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
Simple DrawSprocket

Declared In
`Menus.h`

GetMenuHeight

Obtains the height of a menu, in pixels.

```
SInt16 GetMenuHeight (
   MenuRef menu
);
```

Parameters

menu
The menu whose height you want to obtain.

Return Value
The height of the menu, in pixels.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

GetMenuID

Obtains the ID of a menu.

```
MenuID GetMenuID (
   MenuRef menu
);
```

Parameters

menu

Return Value
The menu ID of the menu. See the description of the `MenuID` data type.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

GetMenuItemAttributes

Gets the attributes of a menu item.

```
OSStatus GetMenuItemAttributes (
   MenuRef menu,
   MenuItemIndex item,
   MenuItemAttributes *outAttributes
);
```

Parameters

menu
The menu.

item
The index of the menu item.

outAttributes
On exit, contains the attributes of the menu item. See "Menu Item Attribute Constants" (page 1377) for a list of possible values.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

GetMenuItemCommandID

Obtains a menu item's command ID.

```
OSErr GetMenuItemCommandID (
   MenuRef inMenu,
   MenuItemIndex inItem,
   MenuCommand *outCommandID
);
```

Parameters

inMenu
The menu that contains the menu item whose command ID you want to obtain.

inItem
The menu index of the item.

outCommandID

Pass a pointer to an unsigned 32-bit integer value. On return, the value is set to the item's command ID.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
After a successful call to `MenuSelect`, `MenuEvent` (page 1309) , or `MenuKey` (page 1311), call the `GetMenuItemCommandID` function to get a menu item's command ID. You can use a menu item's command ID as a position-independent method of signalling a specific action in an application.

See also the function `SetMenuItemCommandID` (page 1333).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

GetMenuItemCommandKey

Gets the keyboard equivalent of a menu item.

```
OSStatus GetMenuItemCommandKey (
   MenuRef inMenu,
   MenuItemIndex inItem,
   Boolean inGetVirtualKey,
   UInt16 *outKey
);
```

Parameters

inMenu

The menu containing the item.

inItem

The item whose keyboard equivalent you want to retrieve.

inGetVirtualKey

Indicates whether to retrieve the item's character code (`false`) or virtual keycode equivalent (`true`).

outKey

On exit, the keyboard equivalent of the item.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
A menu item's keyboard equivalent may be either a character code or a virtual keycode. An item's character code and virtual keycode are stored separately and may contain different values, but only one is used by the Menu Manager at any given time. When requesting a menu item's virtual keycode equivalent, you should first check that the item is using a virtual keycode by testing the `kMenuItemAttrUseVirtualKey` attribute for that item. If this attribute is not set, the item's virtual keycode is ignored by the Menu Manager. Note that zero is a valid virtual keycode, so you cannot test the returned keycode against zero to determine if the item is using a virtual keycode equivalent. You must test the `kMenuItemAttrUseVirtualKey` attribute.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

GetMenuItemFontID

Obtains a menu item's font ID.

```
OSErr GetMenuItemFontID (
   MenuRef inMenu,
   MenuItemIndex inItem,
   SInt16 *outFontID
);
```

Parameters

inMenu
The menu that contains the menu item for which you wish to get a font ID.

inItem
The menu index of the item.

outFontID
Pass a pointer to a signed 16-bit integer value. On return, the value is set to the font ID for the menu item.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
See also the function `SetMenuItemFontID` (page 1335).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

GetMenuItemHierarchicalID

Obtains the menu ID of a specified submenu. (Deprecated in Mac OS X v10.5.)

```
OSErr GetMenuItemHierarchicalID (
   MenuRef inMenu,
   MenuItemIndex inItem,
   MenuID *outHierID
);
```

Parameters

inMenu
The menu that contains the menu item for which you wish to get the submenu's menu ID.

inItem
The menu index of the item.

outHierID
Pass a pointer to a signed 16-bit integer value. On return, the value is set to the menu ID of the submenu.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Menus.h`

GetMenuItemHierarchicalMenu

Returns the submenu attached to a menu item.

```
OSStatus GetMenuItemHierarchicalMenu (
   MenuRef inMenu,
   MenuItemIndex inItem,
   MenuRef *outHierMenu
);
```

Parameters
inMenu
The parent menu.

inItem
The parent item.

outHierMenu
On exit, the item's submenu, or `NULL` if it does not have one.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
`GetMenuItemHierarchicalMenu` will return the submenu attached to a menu item regardless of how the submenu was specified. If the submenu was specified by menu ID (using `SetItemCmd` or `SetMenuItemHierarchicalID`), `GetMenuItemHierarchicalMenu` will return the currently installed menu with that ID, if any. The only case where `GetMenuItemHierarchicalMenu` will fail to return the item's submenu is when the submenu is specified by menu ID, but the submenu is not currently inserted in the menu bar.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

GetMenuItemIconHandle

Obtains a handle to a menu item's icon.

```
OSErr GetMenuItemIconHandle (
   MenuRef inMenu,
   MenuItemIndex inItem,
   UInt8 *outIconType,
   Handle *outIconHandle
);
```

Parameters

inMenu

The menu that contains the menu item for which you wish to obtain the handle.

inItem

The menu index of the item.

outIconType

Pass a pointer to an unsigned 8-bit value. On return, the value specifies the type of icon (`'ICON'`, `'cicn'`, `'SICN'`, icon suite, `CGImageRef`, or `IconRef`) for which you are obtaining a handle. If the menu item has no icon attached, this parameter will contain `kMenuNoIcon`. See "Menu Item Icon Type Constants" (page 1394) for descriptions of possible values.

outIconHandle

Pass a pointer to a handle. On return, `outIconHandle` contains a handle to the icon that is attached to the menu item. If the menu item has no icon attached, this parameter contains `NULL`.

Return Value

A result code. See "Menu Manager Result Codes" (page 1399).

Discussion

The `GetMenuItemIconHandle` function gets the icon handle and type of icon of the specified menu item. If you wish to get a resource-based menu item icon, call `GetItemIcon`.

See also the function `SetMenuItemIconHandle` (page 1338).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Menus.h`

GetMenuItemIndent

Gets the indent level of a menu item.

```
OSStatus GetMenuItemIndent (
   MenuRef inMenu,
   MenuItemIndex inItem,
   UInt32 *outIndent
);
```

Parameters

inMenu

The menu containing the item.

inItem
The item whose indent level you want to retrieve.

outIndent
On exit, the indent level of the item.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
The indent level of an item is an amount of extra space added to the left of the item's icon or checkmark. The level is simply a number, starting at zero, which the Menu Manager multiplies by a constant to get the indent in pixels. The default indent level is zero.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

GetMenuItemKeyGlyph

Obtains the keyboard glyph for a menu item's keyboard equivalent.

```
OSErr GetMenuItemKeyGlyph (
   MenuRef inMenu,
   MenuItemIndex inItem,
   SInt16 *outGlyph
);
```

Parameters
inMenu
The menu that contains the menu item for which you wish to get the keyboard glyph.

inItem
The menu index of the item.

outGlyph
A pointer to a signed 16-bit integer value. On return the value is set to the modifier key glyph. For a description of available keyboard glyphs, see "Menu Glyph Constants" (page 1382).

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
See also the function `SetMenuItemKeyGlyph` (page 1339).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

GetMenuItemModifiers

Obtains the modifier keys that must be pressed with a character key to select a particular menu item.

```
OSErr GetMenuItemModifiers (
   MenuRef inMenu,
   MenuItemIndex inItem,
   UInt8 *outModifiers
);
```

Parameters

inMenu

The menu that contains the menu item for which you wish to get the modifier key(s).

inItem

The menu index of the item.

outModifiers

A pointer to an unsigned 8-bit value. On return, the bits of the value are set to indicate the modifier keys that can be used in selecting the menu item; see "Modifier Key Mask Constants" (page 1396).

Return Value

A result code. See "Menu Manager Result Codes" (page 1399).

Discussion

See also the function `SetMenuItemModifiers` (page 1340).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Menus.h`

GetMenuItemProperty

Obtains a piece of data that has been previously associated with a menu item.

```
OSStatus GetMenuItemProperty (
   MenuRef menu,
   MenuItemIndex item,
   OSType propertyCreator,
   OSType propertyTag,
   ByteCount bufferSize,
   ByteCount *actualSize,
   void *propertyBuffer
);
```

Parameters

menu

The menu containing the item to be examined for associated data.

item

The index number of the menu item or 0 if the data is associated with the menu as a whole.

propertyCreator

A four-character code. Pass your program's signature (also called a creator), as registered through Apple Developer Technical Support. If your program is of a type that would not normally have a signature (for example, a plug-in), you should still register and use a signature in this case, even though your program's file may not have the same creator code as the signature that you register. The `'macs'` property signature is reserved for the system and may not be used.

propertyTag

A four-character code. Pass the application-defined code identifying the data.

bufferSize

The size of the data to be obtained. If this is unknown, use the function `GetMenuItemPropertySize` (page 1283) to get the data's size. If the size specified in the `bufferSize` parameter does not match the actual size of the property, `GetMenuItemProperty` only retrieves data up to the size specified or up to the actual size of the property, whichever is smaller, and an error is returned.

actualSize

On input, a pointer to an unsigned 32-bit integer. On return, this value is set to the actual size of the associated data. You may pass `NULL` for the `actualSize` parameter if you are not interested in this information.

propertyBuffer

On input, a pointer to a buffer. On return, this buffer contains a copy of the data that is associated with the specified menu item.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
You may use the function `GetMenuItemProperty` to obtain a copy of data previously set with the function `SetMenuItemProperty` (page 1341).

See also the `RemoveMenuItemProperty` (page 1320) function.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
HID Explorer
QTCarbonShell

Declared In
`Menus.h`

GetMenuItemPropertyAttributes

Gets the attributes of a menu item property.

```
OSStatus GetMenuItemPropertyAttributes (
   MenuRef menu,
   MenuItemIndex item,
   OSType propertyCreator,
   OSType propertyTag,
   OptionBits *attributes
);
```

Parameters

menu

The menu containing the item whose properties you want to obtain.

item

The menu index of the item.

propertyCreator

The creator code of the property.

propertyTag

The property tag.

attributes

On exit, contains the attributes of the property.

Return Value

A result code. See "Menu Manager Result Codes" (page 1399).

Discussion

Currently the only attribute you can receive from this function is the `kMenuPropertyPersistent` attribute (See "Menu Item Property Attribute Constant" (page 1395)), which currently has no effect on Mac OS X. Therefore, `GetMenuItemPropertyAttributes` is not useful at this time.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Menus.h`

GetMenuItemPropertySize

Obtains the size of a piece of data that has been previously associated with a menu item.

```
OSStatus GetMenuItemPropertySize (
   MenuRef menu,
   MenuItemIndex item,
   OSType propertyCreator,
   OSType propertyTag,
   ByteCount *size
);
```

Parameters

menu

The menu containing the item to be examined for associated data.

item

The index number of the menu item or 0 if the data is associated with the menu as a whole.

propertyCreator

A four-character code. Pass your program's signature, as registered through Apple Developer Technical Support. If your program is of a type that would not normally have a signature (for example, a plug-in), you should still register and use a signature in this case, even though your program's file may not have the same creator code as the signature that you register. The `'macs'` property signature is reserved for the system and may not be used.

propertyTag

A four-character code. Pass the application-defined code identifying the data.

size

On input, a pointer to an unsigned 32-bit integer. On return, this value is set to the actual size of the data.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
If you want to retrieve a piece of associated data with the function `GetMenuItemProperty` (page 1281) , you will typically need to use the `GetMenuItemPropertySize` function beforehand to determine the size of the associated data.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

GetMenuItemRefCon

Obtains application-specific information for a menu item.

```
OSErr GetMenuItemRefCon (
   MenuRef inMenu,
   MenuItemIndex inItem,
   URefCon *outRefCon
);
```

Parameters

inMenu

The menu that contains the menu item for which you wish to get information.

inItem

The menu index of the item. In CarbonLib 1.6 and later and Mac OS X v10.2 and later, you may pass zero to obtain the reference constant for the menu itself.

outRefCon

A pointer to an unsigned 32-bit integer value. On return, the value is set to the reference constant associated with the menu item.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
If you have assigned any data to a menu item using `SetMenuItemRefCon` (page 1342) function, you can read it using the `GetMenuItemRefCon` function.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

GetMenuItemText

Obtains the text of a menu item. (Deprecated in Mac OS X v10.5.)

Not recommended

```
void GetMenuItemText (
   MenuRef theMenu,
   MenuItemIndex item,
   Str255 itemString
);
```

Parameters

theMenu
The menu containing the item.

item
The menu index of the item.

itemString
On output, the menu item's text string.

Discussion
Unless you need to support legacy code, you should use the `CopyMenuItemTextAsCFString` (page 1243) instead.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Related Sample Code
CarbonSketch

Declared In
`Menus.h`

GetMenuItemTextEncoding

Obtains the text encoding used for a menu item's text. (Deprecated in Mac OS X v10.5.)

```
OSErr GetMenuItemTextEncoding (
   MenuRef inMenu,
   MenuItemIndex inItem,
   TextEncoding *outScriptID
);
```

Parameters

inMenu

The menu containing the menu item whose text encoding you wish to obtain.

inItem

The menu index of the item.

outScriptID

A pointer to a `TextEncoding` value. On return, the value is set to the script code of the text encoding used in the menu item's text.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
If a menu item has a command code of 0x1C when `GetMenuItemTextEncoding` is called, `GetMenuItemTextEncoding` gets the value in the icon field of the menu item.

See also the function `SetMenuItemTextEncoding` (page 1343).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Menus.h`

GetMenuRef

Obtains a menu reference corresponding to a menu ID.

```
MenuRef GetMenuHandle (
    MenuID menuID
);
#define GetMenuRef GetMenuHandle
```

Discussion
This is simply a redefinition of the `GetMenuHandle` (page 1273) function.

Declared In
`Menus.h`

GetMenuRetainCount

Returns the retain count of this menu. (Deprecated in Mac OS X v10.5.)

```
ItemCount GetMenuRetainCount (
   MenuRef inMenu
);
```

Parameters

inMenu

The menu whose retain count you want to obtain.

Return Value
The retain count for the menu.

Version Notes
In Mac OS X v10.2 and later, all menus are Core Foundation CFTypes, so you can also call `CFGetRetainCount` instead of `GetMenuRetainCount`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Menus.h`

GetMenuTitle

Obtains the title of the menu (Deprecated in Mac OS X v10.5.)

Not recommended

```
StringPtr GetMenuTitle (
   MenuRef menu,
   Str255 title
);
```

Parameters

menu

title

The menu title, as a Str255 string.

Return Value
A pointer to the menu title.

Discussion
Unless you need to support legacy code, you should use the `CopyMenuTitleAsCFString` (page 1243) function instead.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Menus.h`

GetMenuTitleIcon

Retrieves the icon, if any, being used as the title of a menu.

```
OSStatus GetMenuTitleIcon (
   MenuRef inMenu,
   UInt32 *outType,
   void **outIcon
);
```

Parameters

inMenu

The menu whose icon title to retrieve.

outType

On exit, contains the type of icon being used as the title of the menu. Contains `kMenuNoIcon` if the menu does not have an icon title.

outIcon

On exit, contains the icon reference, icon suite reference, or Core Graphics image reference of the icon being used as the title of the menu. If the menu does not have an icon title, this parameter is set to `NULL`.

Return Value

A result code. See "Menu Manager Result Codes" (page 1399).

Discussion

This function does not increment the reference count of the returned icon, so the caller should not attempt to release it.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Menus.h`

GetMenuTrackingData

Gets information about the menu currently selected by the user.

```
OSStatus GetMenuTrackingData (
   MenuRef theMenu,
   MenuTrackingData *outData
);
```

Parameters

menu

The menu about which to get tracking information. Pass `NULL` to get information about the most recently opened menu; for example, if the user has selected a menu that contains a submenu, and the submenu is open, then `GetMenuTrackingData` returns the submenu not its parent menu.

outData

On exit, contains tracking data about the menu.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399). If the menu is not currently open, `menuNotFoundErr` is returned.

Discussion
You can call this function only during menu tracking. As the standard menu definition automatically handles tracking, you would probably need this function only when writing a custom menu definition.

This function replaces direct access to the pre-Carbon low-memory globals `TopMenuItem`, `AtMenuBottom`, `MenuDisable`, and `mbSaveLoc`. See the Carbon Porting Notes for `MenuDefProcPtr` (page 1349) for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Menus.h`

GetMenuType

Gets the display type (pulldown, hierarchical, or popup) of a menu.

```
OSStatus GetMenuType (
   MenuRef theMenu,
   UInt16 *outType
);
```

Parameters

theMenu
The menu whose type to get.

outType
On exit, the type of the menu. The returned value will be one of the Appearance Manager `ThemeMenuType` constants: `kThemeMenuTypePullDown`, `kThemeMenuTypePopUp`, or `kThemeMenuTypeHierarchical`. The `kThemeMenuTypeInactive` bit is never set.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
You can call this function only when the menu is displayed. If the menu is not currently open, an error is returned. The display type of a menu may vary from one menu tracking session to another; for example, the same menu might be displayed as a pulldown menu and as a popup menu.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

GetMenuWidth

Obtains the width of the menu, in pixels.

```
SInt16 GetMenuWidth (
   MenuRef menu
);
```

Parameters

menu

The menu whose width you want to obtain.

Return Value
The width of the menu, in pixels.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
Menus.h

GetNewMBar

Reads in the definition of a menu bar from an 'MBAR' resource.

Not recommended

```
MenuBarHandle GetNewMBar (
   short menuBarID
);
```

Parameters

menuBarID

The resource ID of an 'MBAR' resource that specifies the menus for a menu bar.

Return Value
A handle to the menu list. (If the resource isn't already in memory, GetNewMBar reads it into memory.) If GetNewMBar can't read the resource, GetNewMBar returns NULL. See the description of the MenuBarHandle data type.

Discussion
Unless you must support legacy code, you should not use functions like GetNewMBar that rely on menus and menu bars stored as resources. Instead, you should define menus in Interface Builder, store them as nib files, and then call the Interface Builder Services functions CreateMenuFromNib, CreateMenuBarFromNib, or SetMenuBarFromNibto create them.

The GetNewMBar function reads in the definition of a menu bar and its associated menus from an 'MBAR ' resource. The 'MBAR ' resource identifies the order of menus contained in its menu bar. For each menu, it also specifies the menu's resource ID. The GetNewMBar function reads in each menu from the 'MENU ' resource with the resource ID specified in the 'MBAR ' resource.

The GetNewMBar function creates a menu list for the menu bar defined by the 'MBAR ' resource and returns a handle to the menu list. GetNewMBar uses GetMenu (page 1266) to read in each individual menu.

After reading in menus from an 'MBAR ' resource, use SetMenuBar to make the menu list created by GetNewMBar the current menu list. Then use DrawMenuBar (page 1255) to update the menu bar.

To release the memory occupied by a menu list, use the function DisposeMenuBar (page 1253)

Special Considerations

The `GetNewMBar` function first saves the current menu list and then clears the current menu list and your application's menu color information table. It then creates a new menu list. Before returning a handle to the new menu list, the `GetNewMBar` function restores the current menu list to the previously saved menu list, but `GetNewMBar` does not restore the previous menu color information table. To save and then restore your application's current menu color information table, call the function `GetMCInfo` (page 1266) before `GetNewMBar` and call `SetMCInfo` (page 1326) afterward.

While you supply only the resource ID of an 'MBAR' resource to the `GetNewMBar` function, your application often needs to use the menu IDs defined in each of your menus' 'MENU' resources. Most Menu Manager functions require either a menu ID or a handle to a menu structure to perform operations on a specific menu. For menus in the current menu list, you can use the `GetMenuHandle` (page 1273) function to get the handle to a menu structure for a menu with a given menu ID.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Menus.h`

HideMenuBar

Conceals the menu bar.

```
void HideMenuBar (
   void
);
```

Discussion

The `HideMenuBar` function makes the menu bar invisible and unselectable by the user. You can use this function to enable full-screen display; however, in Mac OS X v10.2 and later, you should call the `SetSystemUIMode` function (available in `MacApplication.h`) instead.

Note that calling this function causes the `kEventMenuBarHidden` event to be sent to the application target (if your application has registered for the event).

Also see the `ShowMenuBar` (page 1348) and `IsMenuBarVisible` (page 1303) functions.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Related Sample Code

HideMenuBar

Declared In

`Menus.h`

HiliteMenu

Highlights or unhighlights menu titles.

```
void HiliteMenu (
   MenuID menuID
);
```

Parameters

menuID

The menu ID of the menu whose title should be highlighted. If the menu title of the specified menu is already highlighted, `HiliteMenu` does nothing. If the menu ID is 0 or the specified menu ID isn't in the current menu list, `HiliteMenu` unhighlights whichever menu title is currently highlighted (if any).

Discussion

The `IsMenuKeyEvent` (page 1305), `MenuSelect` (page 1312), `MenuEvent` (page 1309), and `MenuKey` (page 1311) functions highlight the title of the menu containing the item chosen by the user. After performing the chosen task, your application should unhighlight the menu title by calling `HiliteMenu` and passing 0 in the `menuID` parameter.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Related Sample Code

Simple DrawSprocket

Declared In

`Menus.h`

InitContextualMenus

Adds a program to the system registry of contextual menu clients. (Deprecated in Mac OS X v10.5.)

Not recommended

```
OSStatus InitContextualMenus (
   void
);
```

Return Value

A result code. See "Menu Manager Result Codes" (page 1399).

Discussion

Your program should call the `InitContextualMenus` function early in your startup code to register your application as a contextual menu client. If you do not register your program, some system-level functions may respond as though your program does not use contextual menus. Not registering your program may also cause `ProcessIsContextualMenuClient` (page 1317) to return an incorrect value.

Carbon Porting Notes

You do not need to call this function before using contextual menus in Mac OS X.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In
Menus.h

InsertFontResMenu

Inserts menu items from a font resource. (Deprecated in Mac OS X v10.5.)

Not recommended

```
void InsertFontResMenu (
   MenuRef theMenu,
   MenuItemIndex afterItem,
   short scriptFilter
);
```

Parameters

theMenu
The menu to add the fonts to.

afterItem
The menu item after which you want to add the fonts.

scriptFilter
The script filter you want to use.

Discussion
Unless you need to do script filtering, you should use `CreateStandardFontMenu` (page 1247)instead.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
Menus.h

InsertIntlResMenu

Inserts menu items from an internationalized resource. (Deprecated in Mac OS X v10.5.)

Not recommended

```
void InsertIntlResMenu (
   MenuRef theMenu,
   ResType theType,
   MenuItemIndex afterItem,
   short scriptFilter
);
```

Parameters

theMenu
The menu to add the menu items to.

theType
The resource to retrieve the menu items from.

afterItem
The menu item after which you want to add the new items.

scriptFilter
The script filter you want to use.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Menus.h`

InsertMenu

Inserts an existing menu into the current menu list.

```
void InsertMenu (
    MenuRef theMenu,
    MenuID beforeID
);
```

Parameters

theMenu
The menu to insert.

beforeID
An integer that indicates where in the current menu list the menu should be inserted. `InsertMenu` inserts the menu into the current menu list before the menu whose menu ID is specified in the `beforeID` parameter. If the number in the `beforeID` parameter is 0 (or it isn't the ID of any menu in the menu list), `InsertMenu` adds the new menu after all others (except before the Help menu). If the menu is already in the current menu list or the menu list is already full, `InsertMenu` does nothing.

To insert a submenu into the current menu list, specify –1 or the equivalent constant `kInsertHierarchicalMenu` for the `beforeID` parameter. The submenus in the submenu portion of the menu list do not have to be currently associated with a hierarchical menu item; you can store submenus in the menu list and later specify that a menu item has a submenu if needed. However, note that during command key matching the Menu Manager scans all menus in the menu list for modifiers, including submenus that are not associated with any menu item.

You can also specify –1 for the `beforeID` parameter to insert a pop-up menu into the current menu list. However, if you use the standard pop-up control definition function, the pop-up control automatically inserts the menu into the current menu list according to the needs of the pop-up control.

Discussion
Menus inserted using this function are added to a menu list attached to the current root menu. To obtain or set this root menu, call `AcquireRootMenu` (page 1229) and `SetRootMenu` (page 1347) respectively.

Inserting a menu in the root menu (menu bar) increments its reference count; removing the menu decrements its reference count.

To change a menu title, call `SetMenuItemTextWithCFString` (page 1344).

Availability
Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Related Sample Code
Simple DrawSprocket

Declared In
`Menus.h`

InsertMenuItem

Inserts one or more items into a menu previously created. (Deprecated in Mac OS X v10.5.)

Not recommended

```
void InsertMenuItem (
    MenuRef theMenu,
    ConstStr255Param itemString,
    short afterItem
);
```

Parameters

theMenu

The menu to which you wish to add the menu item or items.

itemString

A string that defines the characteristics of the new menu items. Note that in most cases you should store the text of a menu item in a nib file or resource, so that your menu items can be more easily localized. You can specify the contents of the `itemString` parameter using metacharacters; the function `InsertMenuItem` accepts the same metacharacters as the `AppendMenu` (page 1229) function. However, if you specify multiple items, the `InsertMenuItem` function inserts the items in the reverse of their order in the `itemString` parameter.

afterItem

The item number of the menu item after which the new menu items are to be added. Specify 0 in the `afterItem` parameter to insert the new items before the first menu item; specify the item number of a current menu item to insert the new menu items after it; specify a number greater than or equal to the last item in the menu to append the new items to the end of the menu.

Discussion
Note that unless you are supporting legacy code, you should use the `InsertMenuItemTextWithCFString` (page 1296) function instead.

If you do not define a specific characteristic of a menu item, the `InsertMenuItem` function assigns the default characteristic to the menu item. If you do not define any characteristic other than the text for a menu item, the `InsertMenuItem` function inserts the menu item so that it appears in the menu as an enabled item, without an icon or a mark, in the plain character style, and without a keyboard equivalent.

You can use `InsertMenuItem` to insert items into a menu regardless of whether the menu is in the current menu list.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Menus.h`

InsertMenuItemText

Inserts a menu item into a menu. (Deprecated in Mac OS X v10.5.)

Not recommended

```
OSStatus InsertMenuItemText (
   MenuRef menu,
   ConstStr255Param inString,
   MenuItemIndex afterItem
);
```

Parameters

menu
The menu into which the item is to be inserted.

inString
A Pascal string containing the text of the menu item to insert. You can pass a string containing any characters, and these characters will be presented verbatim in the menu item.

afterItem
The item number of the menu item after which the new menu item is to be inserted. Specify 0 to insert the new menu item at the top of the menu, before the first menu item. Specify a value greater than or equal to the last menu item to append the new item to the end of the menu.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion

Note that unless you are supporting legacy code, you should use the `InsertMenuItemTextWithCFString` (page 1296) function instead.

The `InsertMenuItemText` function inserts an enabled menu item containing the specified string into a menu, without evaluating the string for metacharacters, as the pre–Mac OS 8.5 Menu Manager function `InsertMenuItem` does. You may wish to use `InsertMenuItemText` if you have a need to present non-alphanumeric characters in a menu item.

See also the `AppendMenuItemText` (page 1231) function.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Menus.h`

InsertMenuItemTextWithCFString

Inserts a new menu item with text from a CFString.

```
OSStatus InsertMenuItemTextWithCFString (
   MenuRef inMenu,
   CFStringRef inString,
   MenuItemIndex inAfterItem,
   MenuItemAttributes inAttributes,
   MenuCommand inCommandID
);
```

Parameters

menu

The menu in which to insert the new item.

inString

The text of the new item.

inAfterItem

The item after which to insert the new item. Pass zero to insert the item at the beginning of the menu. If the index value is greater than the number of items in the menu, the item is inserted at the end of the menu.

inAttributes

The attributes of the new item.

inCommandID

The command ID of the new item.

Return Value

A result code. See "Menu Manager Result Codes" (page 1399).

Discussion

If the CFString is mutable, the Menu Manager will make its own copy of the CFString before returning from `InsertMenuItemWithCFString`. Modifying the string after calling `InsertMenuItemTextWithCFString` will have no effect on the menu item's actual text.

If the CFString is immutable, the Menu Manager increments the reference count of the string before returning.

The caller may release the string after calling `InsertMenuItemTextWithCFString`.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Menus.h`

InsertResMenu

Searches all resource files open to your application for a given resource type and inserts the names of any resources it finds in the specified menu. (Deprecated in Mac OS X v10.5.)

Not recommended

```
void InsertResMenu (
   MenuRef theMenu,
   ResType theType,
   MenuItemIndex afterItem
);
```

Parameters

theMenu

The menu to which to add the names of any resources of a given type that `InsertResMenu` finds.

theType

A four-character code that identifies the resource type for which to search.

afterItem

A number that indicates where in the menu to insert the names of any resources of the given type that `InsertResMenu` finds. Specify 0 in the `afterItem` parameter to insert the items before the first menu item; specify the item number of a menu item already in the menu to insert the items after the specified item number. If you specify a number greater than or equal to the last item in the menu, the items are inserted at the end of the menu.

Discussion

Unless you must support legacy code, you should not use functions like `InsertResMenu` that rely on searching the resource chain. Prior to Carbon, you used `InsertResMenu` primarily to create an Apple menu (by passing `'DRVR'` for the resource type or to create a font menu (by passing `'FONT'`). In Carbon, the Apple menu is created for you automatically, and you should call `CreateStandardFontMenu` (page 1247) to create a font menu.

The `InsertResMenu` function searches all resource files open to your application for resources of the type defined by the parameter `theType`. The specified menu must have been previously created using `NewMenu` (page 1314) , `GetMenu` (page 1266) , or `GetNewMBar` (page 1290). `InsertResMenu` adds the names of found resources after the specified menu item in alphabetical order; it does not alphabetize items already in the menu.

The `InsertResMenu` function does not add resources with names that begin with a period (.) or a percent sign (%) to the menu.

The `InsertResMenu` function assigns default characteristics to each menu item. Each appended menu item appears in the menu as an enabled item, without an icon or a mark, in the plain character style, and without a keyboard equivalent.

If you specify that `InsertResMenu` add resources of type `'DRVR '` to your Apple menu, `InsertResMenu` adds the name (and icon) of each item in the Apple Menu Items folder to the menu.

If you specify that `InsertResMenu` add resources of type `'FONT '` or `'FOND '`, the Menu Manager performs special processing for any resources it finds that have font numbers greater than 0x4000. If the script associated with the font name is currently active, `InsertResMenu` stores information in the `itemDefinitions` array (in the `itemIcon` and `itemCmd` fields for that item) in the menu structure that allows the Menu Manager to display the font name in the correct script.

Special Considerations

The `InsertResMenu` function calls the Resource Manager function `SetResLoad` (specifying `true` in the `load` parameter) before returning. The `InsertResMenu` function reads the resource data of the resources it finds into memory. If your application does not want the Resource Manager to read resource data into memory when your application calls other functions that read resources, you need to call the Resource Manager function `SetResLoad` and specify `false` in the `load` parameter after `InsertResMenu` returns.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Menus.h`

InvalidateMenuEnabling

Requests that the menu's enable state be recalculated.

```
OSStatus InvalidateMenuEnabling (
   MenuRef inMenu
);
```

Parameters

inMenu

The menu whose enable states should be recalculated. Pass `NULL` to recalculate enable states for all menus in the root menu.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
State changes in an application can cause changes in enable state of a menu's menu items. For example, selecting a block of text would usually require the Copy menu item to become enabled. Menu items are typically updated in response to a `kEventCommandUpdateStatus` Carbon event. However, the update event usually occurs only before an command key press or a click in the menu bar. To explicitly update the enable states for a menu, you can call `InvalidateMenuEnabling`.

Note that the Carbon Event Manager automatically requests recalculation of enable states for all top-level menus when

- it dispatches a user event
- the user focus changes
- the active window changes

so in many cases you may not need to explicitly call this function.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

InvalidateMenuItems

Invalidates a group of menu items so that they will be redrawn when `UpdateInvalidMenuItems` is next called.

```
OSStatus InvalidateMenuItems (
   MenuRef inMenu,
   MenuItemIndex inFirstItem,
   ItemCount inNumItems
);
```

Parameters

inMenu

The menu whose items to invalidate.

inFirstItem

The first item to invalidate.

inNumItems

The number of items to invalidate.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
Menu items are automatically invalidated when their contents are changed using Menu Manager APIs while the menu is open. However, you might need to use this function if you have a custom menu definition that draws based on information not contained in the menu. For example, say you have a custom menu definition that draws a menu item using a color stored elsewhere in an application-defined data structure. If you change the color in the data structure, there is no way for the menu definition to know this has occurred. Calling `InvalidateMenuItems` after changing the color in the structure indicates that the menu should be redrawn.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

InvalidateMenuSize

Invalidates the menu size so that it will be recalculated when next displayed.

```
OSStatus InvalidateMenuSize (
   MenuRef inMenu
);
```

Parameters

inMenu

The menu whose size you want to invalidate.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
Prior to Carbon, the technique for invalidating the menu size was to set the width and height to -1. Although this technique still works, for best compatibility you should call `InvalidateMenuSize` so that the Menu Manager has explicit notification that the menu is invalid.

Availability
Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In
`Menus.h`

InvalMenuBar

Invalidates the menu bar.

```
void InvalMenuBar (
   void
);
```

Discussion
The `InvalMenuBar` function marks the menu bar as changed and in need of updating. When the Carbon Event Manager checks incoming events for regions that require updating, the Carbon Event Manager also checks to determine whether the menu bar requires updating (because of a call to `InvalMenuBar`). If the menu bar needs updating, the Carbon Event Manager calls the `DrawMenuBar` (page 1255) function to draw the menu bar.

You can use `InvalMenuBar` instead of `DrawMenuBar` to minimize blinking in the menu bar. For example, if you have several application-defined functions that can change the enabled state of a menu and each calls `DrawMenuBar`, you can replace the calls to `DrawMenuBar` with calls to `InvalMenuBar`. In this way the menu bar is redrawn only once instead of multiple times in quick succession. If you need to make immediate changes to the menu bar, use `DrawMenuBar`. If you want to redraw the menu bar at most once each time through your event loop, use `InvalMenuBar`. Note. however, that most Menu Manager calls that affect the menu bar call `InvalMenuBar` (page 1301) before returning. so you probably won't need to call it yourself.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

InvokeMenuDefUPP

Calls your custom menu definition through a universal procedure pointer. (Deprecated in Mac OS X v10.5.)

Not recommended

```
void InvokeMenuDefUPP (
   short message,
   MenuRef theMenu,
   Rect *menuRect,
   Point hitPt,
   short *whichItem,
   MenuDefUPP userUPP
);
```

Parameters

message

theMenu

menuRect

hitPt

whichItem

userUPP

Carbon Porting Notes

Apple discourages you from writing and using your own menu definition functions and encourages you to use the system-supplied menu definition function instead. New features that have previously been missing are now available in the system-supplied menu definition function. Since Appearance Manager 1.0 (in Mac OS 8.0), for example, the system-supplied menu definition function has supported extended menu item command key modifiers and glyphs. And in Carbon, the system-supplied menu definition function supports dynamic items, which allow the contents of a menu item to be redrawn while the menu is displayed in response to the user pressing a modifier key on the keyboard.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Menus.h`

IsMenuBarInvalid

Determines if the menubar is invalid and should be redrawn.

```
Boolean IsMenuBarInvalid (
   MenuRef rootMenu
);
```

Parameters

rootMenu

The root menu for the menubar to be examined. Pass `NULL` to check the state of the current menubar.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Menus.h`

IsMenuBarVisible

Reports whether the menu bar is currently visible.

```
Boolean IsMenuBarVisible (
   void
);
```

Return Value
Returns `true` if the menu bar is currently visible; otherwise, `false`.

Discussion
Also see the `HideMenuBar` (page 1291) and `ShowMenuBar` (page 1348) functions.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

IsMenuCommandEnabled

Determines if the menu item with a specified command ID is enabled.

```
Boolean IsMenuCommandEnabled (
   MenuRef inMenu,
   MenuCommand inCommandID
);
```

Parameters

inMenu
The menu in which to begin searching for the item. Pass `NULL` to begin searching with the root menu. The search will descend into all submenus of this menu.

inCommandID
The command ID of the menu item to examine. If more than one item has this command ID, only the first will be examined.

Discussion
If you have access to the menu item index, in most cases you should use `IsMenuItemEnabled` (page 1303) instead, as that function is faster and requires no searching.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

IsMenuItemEnabled

Reports whether a given menu or menu item is enabled.

```
Boolean IsMenuItemEnabled (
   MenuRef menu,
   MenuItemIndex item
);
```

Parameters

menu

The menu containing the item to be examined.

item

The item number of the menu item. Pass 0 to specify the menu title and determine whether the menu as a whole is enabled.

Return Value
Returns `true` if the menu item is currently enabled; otherwise, `false`.

Discussion
Your application can use the `IsMenuItemEnabled` function to determine whether specific menu items, even those with item numbers greater than 31, are currently enabled and can therefore be selected by the user.

Note that this function ignores the enable state of the menu when returning the enable state of a menu item. For example, if you call `IsMenuItemEnabled` on an enabled item while its parent menu is disabled, the function still returns `true`.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

IsMenuItemIconEnabled

Reports whether a given menu item icon is enabled.

```
Boolean IsMenuItemIconEnabled (
   MenuRef menu,
   MenuItemIndex item
);
```

Parameters

menu

The menu containing the icon to be examined.

item

The item number of the menu item containing the icon.

Return Value
Returns `true` if the menu item icon is currently enabled; otherwise, `false`.

Discussion
Your application can use the `IsMenuItemIconEnabled` function to determine whether a specific menu item's icon is currently enabled or dimmed.

See also the functions `DisableMenuItemIcon` (page 1252) and `EnableMenuItemIcon` (page 1258).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

IsMenuItemInvalid

Determines if a menu item is invalid and should be redrawn.

```
Boolean IsMenuItemInvalid (
   MenuRef inMenu,
   MenuItemIndex inItem
);
```

Parameters

inMenu
The menu whose item to examine.

inItem
The item to examine.

Return Value
Returns `true` if the menu is invalid, `false` otherwise.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

IsMenuKeyEvent

Determines if an event corresponds to a menu command key.

```
Boolean IsMenuKeyEvent (
   MenuRef inStartMenu,
   EventRef inEvent,
   MenuEventOptions inOptions,
   MenuRef *outMenu,
   MenuItemIndex *outMenuItem
);
```

Parameters

inStartMenu
The menu to search. `IsMenuKeyEvent` searches for matching menu items in this menu and all of its submenus. Pass `NULL` to search the current menu bar contents.

inEvent
The event to match against. Non-keyboard events are ignored.

inOptions
Options controlling how to search. See "Menu Event Option Constants" (page 1381) for possible options. Pass `kNilOptions` for the default behavior.

outMenu
On exit, the menu containing the matching item. Set to `NULL` if no match was made.

outMenuItem
On exit, the menu item that matched. Set to `NULL` if no match was made.

Discussion
By default, `IsMenuKeyEvent` searches the menus in the current menu bar and highlights the menu title of the menu containing the selected item.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

IsMenuSizeInvalid

Determines if a menu's size is invalid and should be recalculated.

```
Boolean IsMenuSizeInvalid (
   MenuRef inMenu
);
```

Parameters

inMenu
The menu whose size you want to examine.

Return Value
Set to `true` if the menu size is invalid, `false` otherwise.

Discussion
Prior to Carbon, the technique for determining if a menu's size is invalid was to check if the width or height was -1. This technique is not always reliable in Carbon due to implementation changes in the Menu Manager, so you should use `IsMenuSizeInvalid` instead.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

IsShowContextualMenuClick

Determines whether a particular event could invoke a contextual menu.

Not recommended

```
Boolean IsShowContextualMenuClick (
   const EventRecord *inEvent
);
```

Parameters

inEvent

A pointer to the event structure that describes the event to examine.

Return Value

If `true`, the contextual menu should be displayed; if `false`, not.

Discussion

Before calling the `IsShowContextualMenuClick` function, you should call `InitContextualMenus` (page 1292). If no error is returned, you can then call `IsShowContextualMenuClick`.

Unless you must support the legacy `WaitNextEvent` event model, you should use the Carbon event–based `IsShowContextualMenuEvent` (page 1307) function instead. In addition, some users may choose to use a two-button mouse with their Macintosh computers, in which case a right-click does not return `true` with `IsShowContextualMenuClick` unless the mouse manufacturer's driver software deliberately returns Control-left-click in place of the right-click. If you want to properly recognize the right-click to invoke a contextual menu, you should use the `IsShowContextualMenuEvent` (page 1307) function.

Applications should call `IsShowContextualMenuClick` when they receive non-null events. If `IsShowContextualMenuClick` returns `true`, your application should generate its own menu and Apple Event descriptor (`AEDesc`), and then call `ContextualMenuSelect` (page 1239) to display and track the contextual menu, and then handle the user's choice.

If the mouse-down event did not invoke a contextual menu, then the application should check to see if the event occurred in the menu bar (using the `FindWindow` function) and, if so, call `MenuSelect` to allow the user to choose a command from the menu bar.

See also "Contextual Menu Gestalt Selector Constants" (page 1368).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Menus.h`

IsShowContextualMenuEvent

Determines whether a particular Carbon event could invoke a contextual menu.

```
Boolean IsShowContextualMenuEvent (
   EventRef inEvent
);
```

Parameters

inEvent

The event to examine.

Return Value

Returns `true` if the application should display a contextual menu, `false` otherwise.

Discussion
If your application supports Carbon events, you should use this function in place of the older `IsShowContextualMenuClick` (page 1306). This function also properly supports right-click activation of contextual menus, while `IsShowContextualMenuClick` (page 1306) does not.

However, if your application uses the standard window handler, you probably don't need to use `IsShowContextualMenuEvent`, because the standard window handler automatically detects contextual menu clicks and sends the `kEventWindowContextualMenuSelect` and `kEventControlContextualMenuClick` events.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

IsValidMenu

Determines if a menu is valid.

```
Boolean IsValidMenu (
   MenuRef inMenu
);
```

Parameters

inMenu
The menu to check for validity.

Return Value
Indicates whether the menu is valid.

Discussion
The Menu Manager keeps a table that maps menu references to their corresponding (opaque) `MenuData` structures. A menu is considered valid if its menu reference appears in that table.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

LMGetTheMenu

Returns the menu ID of the currently highlighted menu in the menu bar.

```
MenuID LMGetTheMenu (
   void
);
```

Return Value
A value which contains the menu ID of the currently highlighted menu in the menu bar.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

MenuChoice

Returns the menu ID and index of the menu item under the cursor.

```
SInt32 MenuChoice (
   void
);
```

Return Value
The high-order word of the function result contains the menu ID of the menu, and the low-order word contains the item number of the menu item chosen by the user. The `MenuChoice` function returns 0 as the low-order word of its function result if the mouse button was released while the cursor was in the menu bar or outside the menu.

Discussion
You can use this function in the rare cases that you want to take action based upon the selection of a disabled menu item. For example, say the user is in contextual help mode (activated by pressing the Help key) and wants to get help information about a disabled menu item. You can use `MenuChoice` to determine which item the user selected and provide help for that item.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

MenuEvent

Maps a keyboard combination from the event structure to the keyboard equivalent of a menu item in a menu in the current menu list.

Not recommended

```
UInt32 MenuEvent (
   const EventRecord *inEvent
);
```

Parameters
inEvent
A pointer to the event structure containing the keyboard equivalent.

Return Value
A value that indicates the menu ID (in the high 16 bits) and menu item (in the low 16 bits) that the user chose. If the given character does not map to an enabled menu item in the current menu list, `MenuEvent` returns 0 in its high-order word and the low-order word is undefined.

Discussion
Note that unless your application uses the `WaitNextEvent` event model, you should use the Carbon event–based `IsMenuKeyEvent` (page 1305) instead.

The `MenuEvent` function does not distinguish between uppercase and lowercase letters. This allows a user to invoke a keyboard equivalent command, such as the Copy command, by pressing the Command key and "c" or "C". For consistency between applications, you should define the keyboard equivalents of your commands so that they appear in uppercase in your menus.

If the given character maps to an enabled menu item in the current menu list, `MenuEvent` highlights the menu title of the chosen menu, returns the menu ID in the high-order word of its function result, and returns the chosen menu item in the low-order word of its function result. After performing the chosen task, your application should unhighlight the menu title using the `HiliteMenu` function.

You should not define menu items with identical keyboard equivalents. The `MenuEvent` function scans the menus from right to left and the items from top to bottom. If you have defined more than one menu item with identical keyboard equivalents, `MenuEvent` returns the first one it finds.

The `MenuEvent` function first searches the regular portion of the current menu list for a menu item with a keyboard equivalent matching the given key. If it doesn't find one there, it searches the submenu portion of the current menu list. If the given key maps to a menu item in a submenu, `MenuEvent` highlights the menu title in the menu bar that the user would normally pull down to begin traversing to the submenu. Your application should perform the desired command and then unhighlight the menu title.

Note that some keyboard equivalents are reserved for use by the system, such as Command–Shift–3 annd Command-Shift-4 (for taking screen shots).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

MenuHasEnabledItems

Determines if any items in a menu are enabled.

```
Boolean MenuHasEnabledItems (
   MenuRef theMenu
);
```

Parameters

theMenu
The menu whose items to examine.

Return Value
Returns `true` if one or more items in the menu are enabled, `false` otherwise.

Discussion
This function is equivalent to pre-Carbon code that compared the `enableFlags` field of the `MenuInfo` structure (now opaque in Carbon) with 0. It checks the enable state of all items to see if any are enabled, but ignores the state of the menu title. It will return `true` even if the menu title is disabled.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

MenuKey

Maps a character key with the command key to determine the keyboard equivalent of a menu item in a menu in the current menu list. (Deprecated in Mac OS X v10.5.)

Not recommended

```
SInt32 MenuKey (
   CharParameter ch
);
```

Parameters

ch

The 1-byte character that represents the key pressed by the user in combination with the Command key.

Return Value
A value containing the menu ID and menu item that corresponds to the given character.If the given character does not map to an enabled menu item in the current menu list, `MenuKey` returns 0 in its high-order word and the low-order word is undefined.

Discussion
Note that unless your application uses the `WaitNextEvent` event model, you should use the Carbon event–based `IsMenuKeyEvent` (page 1305) instead. Even when using the `WaitNextEvent` model, you should probably use `MenuEvent` (page 1309), as that function supports the Shift, Option, and Control modifier keys in addition to the Command key

The `MenuKey` function determines whether the key combination maps to a current menu item when the user presses another key while holding down the Command key.

`MenuKey` does not distinguish between uppercase and lowercase letters. This allows a user to invoke a keyboard equivalent command, such as the Copy command, by pressing the Command key and “c” or “C”. For consistency between applications, you should define the keyboard equivalents of your commands so that they appear in uppercase in your menus.

You should not define menu items with identical keyboard equivalents. The `MenuKey` function scans the menus from right to left and the items from top to bottom. If you have defined more than one menu item with identical keyboard equivalents, `MenuKey` returns the first one it finds.

If the given character maps to an enabled menu item in the current menu list, `MenuKey` highlights the menu title of the chosen menu, returns the menu ID in the high-order word of its function result, and returns the chosen menu item in the low-order word of its function result. After performing the chosen task, your application should unhighlight the menu title using the `HiliteMenu` function.

The `MenuKey` function first searches the regular portion of the current menu list for a menu item with a keyboard equivalent matching the given key. If it doesn't find one there, it searches the submenu portion of the current menu list. If the given key maps to a menu item in a submenu, `MenuKey` highlights the menu title in the menu bar that the user would normally pull down to begin traversing to the submenu. Your application should perform the desired command and then unhighlight the menu title.

You shouldn't assign a Command–Shift–number key sequence to a menu item as its keyboard equivalent Command–Shift–number key sequences are reserved for use as `'FKEY '` resources. Command–Shift–number key sequences are not returned to your application, but instead are processed by the Event Manager. The Event Manager invokes the `'FKEY '` resource with a resource ID that corresponds to the number that activates it.

Apple reserves the Command-key codes 0x1B through 0x20 to indicate meanings other than keyboard equivalents. `MenuKey` ignores these character codes and returns a function result of 0 if you specify any of these values in the `ch` parameter. Your application should not use these character codes for its own use

Carbon Porting Notes

Carbon does not support desk accessories, so `MenuKey` cannot be used in OS X to pass keyboard equivalents to desk accessories.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Related Sample Code

Simple DrawSprocket

Declared In

`Menus.h`

MenuSelect

Allows the user to choose a menu item from a menu in the menu bar.

```
SInt32 MenuSelect (
   Point startPt
);
```

Parameters

`startPt`

The location of the cursor at the time the mouse button was first pressed, in global coordinates. Your application retrieves this point from the `kEventParamMouseLocation` parameter of a Carbon event, or the `where` field of the `EventRecord` structure.

Return Value

If the user chooses an enabled menu item (including any item from a submenu), the `MenuSelect` function returns a value as its function result that indicates which menu and menu item the user chose. The high-order word of the function result contains the menu ID of the menu, and the low-order word contains the item number of the menu item chosen by the user.

Discussion
If your application uses Carbon events, you probably don't need to use this function. The standard event handler installed by the Carbon Event Manager function `RunApplicationEventLoop` calls `MenuSelect` for you to begin tracking when the user clicks in a menu. If you do not call `RunApplicationEventLoop`, however, you will need to use this function to initiate menu tracking.

When the user presses the mouse button while the cursor is in the menu bar, your application receives a mouse-down event. To handle mouse-down events in the menu bar, pass the location of the cursor at the time of the mouse-down event as the `startPt` parameter to `MenuSelect`. The `MenuSelect` function displays and removes menus as the user moves the cursor over menu titles in the menu bar, and it handles all user interaction until the user dismisses the menu.

As the user drags the cursor through the menu bar, the `MenuSelect` function highlights the title of the menu the cursor is currently over and displays all items in that menu. If the user moves the cursor so that it is over a different menu, the `MenuSelect` function removes the previous menu and unhighlights its menu title.

The `MenuSelect` function highlights and unhighlights menu items as the user drags the cursor over the items in a menu. The `MenuSelect` function highlights a menu item if the item is enabled and the cursor is currently over it; it removes such highlighting when the user moves the cursor to another menu item. The `MenuSelect` function does not highlight disabled menu items.

If the user chooses an enabled menu item (including any item from a submenu), the `MenuSelect` function returns a value as its function result that indicates which menu and menu item the user chose. The high-order word of the function result contains the menu ID of the menu, and the low-order word contains the item number of the menu item chosen by the user.The `MenuSelect` function leaves the menu title highlighted; after performing the chosen task your application should unhighlight the menu title using the `HiliteMenu` (page 1291) function.

If the user chooses an item from a submenu, `MenuSelect` returns the menu ID of the submenu in the high-order word and the item chosen by the user in the low-order word of its function result. The `MenuSelect` function also highlights the title of the menu in the menu bar that the user originally displayed in order to begin traversing to the submenu. After performing the chosen task, your application should unhighlight the menu title.

If the user releases the mouse button while the cursor is over a disabled item, in the menu bar, or outside of any menu, the `MenuSelect` function returns 0 in the high-order word of its function result and the low-order word is undefined. If it is necessary for your application to find the item number of the disabled item, your application can call `MenuChoice` (page 1309) to return the menu ID and menu item.

Note that `MenuSelect` sends a number of Carbon events during menu tracking:

- `kEventMenuBeginTracking` when tracking begins, before displaying any menus. An event handler for this event may return `userCanceledErr` to prevent menu tracking from occurring.
- `kEventMenuEndTracking` after tracking was completed.
- `kEventMenuChangeTrackingMode` when the user switches from the mouse to the keyboard to navigate through menus, or vice versa.
- `kEventMenuOpening` is sent to each menu that the user opens, just before it opens. An event handler for this event may return `userCanceledErr` to prevent menu tracking from occurring.
- `kEventMenuClosed` is sent to each menu that the user closes.
- `kEventMenuPopulate` is sent to a menu just before it is opened in a menu tracking session. This event is sent only once per menu tracking session.

- `kEventMenuEnableItems` is sent to a menu just before it is opened in a menu tracking session. This event is sent only once per menu tracking session.
- `kEventCommandUpdateStatus` is sent to a menu just before it is opened in a menu tracking session. This event is sent only once per menu tracking session.
- `kEventMenuTargetItem` is sent to a menu when the mouse passes over a menu item or if the keyboard is used to select a menu item. This event is sent for both enabled and disabled menu items, and is also sent when the mouse is over a menu title.
- `kEventCommandProcess` is sent to a menu when the user chooses one of its menu items.

For more details about these Carbon events, see the *Carbon Event Manager Reference*.

Carbon Porting Notes

Carbon does not support desk accessories, so `MenuSelect` cannot be used in Mac OS X to pass keyboard equivalents to desk accessories.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
Simple DrawSprocket

Declared In
`Menus.h`

NewMenu

Creates an empty menu with a specified title and menu ID. (Deprecated in Mac OS X v10.5.)

Not recommended

```
MenuRef NewMenu (
   MenuID menuID,
   ConstStr255Param menuTitle
);
```

Parameters

`menuID`

The ID for the menu. The menu ID is a number that identifies the menu. Menu IDs in Carbon can be any value, but Apple recommends that the ID be either zero or positive. A menu ID of zero is a valid ID. IDs of submenus should similarly be zero or a positive value.

`menuTitle`

The title of the new menu. Note that in most cases you should store the titles of menus in resources, so that your menu titles can be more easily localized.

Return Value
A menu reference. If the `NewMenu` function is unable to create the menu structure, it returns `NULL`. See the description of the `MenuRef` data type.

Discussion
Unless you must support legacy code, you should not use functions like `NewMenu`. If you need to create menus programmatically, you can call `CreateNewMenu` (page 1246); otherwise you should define menus in Interface Builder, store them as nib files, and then call the Interface Builder Services function `CreateMenuFromNib` to create them.

The `NewMenu` function creates a menu with the specified title, assigns it the specified menu ID, and returns a handle to the menu structure. It sets up the menu structure to use the standard menu definition function (and it reads the standard menu definition function into memory if it isn't already there). `NewMenu` does not insert the newly created menu into the current menu list.

After creating a menu with `NewMenu`, use `AppendMenu` (page 1229) , `InsertMenuItem` (page 1295) , `AppendResMenu` (page 1232) , or `InsertResMenu` (page 1297) to add menu items to the menu. To add a menu created by `NewMenu` to the current menu list, use `InsertMenu` (page 1294). In Carbon, you do not need to call `DrawMenuBar` (page 1255) to update the menu bar, as the Menu Manager automatically invalidates andredraws the menu bar.

Menus in a resource must not be purgeable nor should the resource lock bit be set. Do not define a "circular" hierarchical menu—that is, a hierarchical menu in which a submenu has a submenu whose submenu is a hierarchical menu higher in the chain.

Special Considerations

To release the memory associated with a menu that you created using `NewMenu`, first call `DeleteMenu` (page 1248) to remove the menu from the current menu list and to remove any entries for this menu in your application's menu color information table then call `DisposeMenu` (page 1253) to dispose of the menu structure. Note that in Carbon, the Menu Manager automatically invalidates and redraws the menu bar after disposing of a menu.

Version Notes
Note that if you are running on Mac OS 8.1 and earlier, the menu ID of a submenu must be within the range 0 to 255.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Simple DrawSprocket

Declared In
`Menus.h`

NewMenuDefUPP

Creates a new univeral procedure pointer to your custom menu definition. (Deprecated in Mac OS X v10.5.)

Not recommended

```
MenuDefUPP NewMenuDefUPP (
   MenuDefProcPtr userRoutine
);
```

Parameters

userRoutine

Return Value
See the description of the `MenuDefUPP` data type.

Carbon Porting Notes

Apple discourages you from writing and using your own menu definition functions and encourages you to use the system-supplied menu definition function instead. New features that have previously been missing are now available in the system-supplied menu definition function. Since Appearance Manager 1.0 (in Mac OS 8.0), for example, the system-supplied menu definition function has supported extended menu item command key modifiers and glyphs. And in Carbon, the system-supplied menu definition function supports dynamic items, which allow the contents of a menu item to be redrawn while the menu is displayed in response to the user pressing a modifier key on the keyboard.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In
`Menus.h`

PopUpMenuSelect

Displays a pop-up menu without using the standard pop-up control definition function.

```
SInt32 PopUpMenuSelect (
   MenuRef menu,
   short top,
   short left,
   MenuItemIndex popUpItem
);
```

Parameters

menu

The pop-up menu to be displayed.

top

The y-coordinate of the top-left corner of the selected menu item when the menu opens. This value should be in global coordinates.

left

The x-coordinate of the top-left corner of the selected menu item when the menu opens. This value should be in global coordinates.

popUpItem

The index of the menu item to display at the global point (`top`, `left`). If you pass zero, the first menu item is positioned at the indicated point.

Return Value
The menu ID of the chosen menu in the high 16-bit word of the function result and the chosen menu item index value in the low 16-bit word. If no item was selected, the result is zero.

Discussion
If your application uses the standard pop-up control definition function, your application does not need to use the `PopUpMenuSelect` function. `PopUpMenuSelect` uses the location specified by the `top` and `left` parameters to determine where to display the specified item of the pop-up menu. `PopUpMenuSelect` displays the pop-up menu so that the menu item specified in the `popUpItem` parameter appears highlighted at the specified location.

The `PopUpMenuSelect` function highlights and unhighlights menu items and handles all user interaction until the user releases the mouse button.

Note that `PopUpMenuSelect` sends a number of Carbon events during menu tracking (these are the same as those sent for `MenuSelect` (page 1312)):

- `kEventMenuBeginTracking` when tracking begins, before displaying any menus. An event handler for this event may return `userCanceledErr` to prevent menu tracking from occurring.
- `kEventMenuEndTracking` after tracking was completed.
- `kEventMenuChangeTrackingMode` when the user switches from the mouse to the keyboard to navigate through menus, or vice versa.
- `kEventMenuOpening` is sent to each menu that the user opens, just before it opens. An event handler for this event may return `userCanceledErr` to prevent menu tracking from occurring.
- `kEventMenuClosed` is sent to each menu that the user closes.
- `kEventMenuPopulate` is sent to a menu just before it is opened in a menu tracking session. This event is sent only once per menu tracking session.
- `kEventMenuEnableItems` is sent to a menu just before it is opened in a menu tracking session. This event is sent only once per menu tracking session.
- `kEventCommandUpdateStatus` is sent to a menu just before it is opened in a menu tracking session. This event is sent only once per menu tracking session.
- `kEventMenuTargetItem` is sent to a menu when the mouse passes over a menu item or if the keyboard is used to select a menu item. This event is sent for both enabled and disabled menu items, and is also sent when the mouse is over a menu title.
- `kEventCommandProcess` is sent to a menu when the user chooses one of its menu items.

For more details about these Carbon events, see the *Carbon Event Manager Programming Guide*.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

ProcessIsContextualMenuClient

Determines whether a given program is a contextual menu client. (Deprecated in Mac OS X v10.5.)

Not recommended

```
Boolean ProcessIsContextualMenuClient (
   ProcessSerialNumber *inPSN
);
```

Parameters

inPSN

A pointer to the ID of the process containing the program.

Return Value

`true` if the program in the process uses contextual menus; otherwise, `false`.

Discussion

In Mac OS X, you do not need to call `InitContextualMenus` (page 1292) to register your application, so this function call is unnecessary.

The `ProcessIsContextualMenuClient` function checks the system registry of contextual menu clients and returns `true` if the program in the given process supports contextual menus. However, the program must have been registered as a client using `InitContextualMenus` (page 1292).

See also "Contextual Menu Gestalt Selector Constants" (page 1368).

Version Notes

This function is available with Appearance Manager 1.0 and later.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Menus.h`

RegisterMenuDefinition

Registers a binding between a resource ID and a menu definition function.

```
OSStatus RegisterMenuDefinition (
   SInt16 inResID,
   MenuDefSpecPtr inDefSpec
);
```

Parameters

inResID

An MDEF resource ID, as used in a `'MENU'` resource.

inDefSpec

Specifies the `MenuDefUPP` that should be used for menus with the given MDEF proc ID. Pass `NULL` if you want to unregister the menu definition.

Return Value

A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
Mac OS X does not allow you to store custom menu definitions in resources. However, some older functions such as `GetMenu` expect an `'MDEF'` resource ID to be in the `'MENU'` resource when creating menus . To work around this, you can use `RegisterMenulDefinition` to register "virtual" resource IDs for your menu definition functions. When `GetMenu` (or a similar function) attempts to access an `'MDEF'` resource, the Menu Manager uses the menu definition specified by the `MenuDefSpec` structure instead.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

ReleaseMenu

Decrements the retain count of a menu. (Deprecated in Mac OS X v10.5.)

```
OSStatus ReleaseMenu (
   MenuRef inMenu
);
```

Parameters

inMenu
The menu whose retain count to decrement. If the retain count falls to zero, the menu is destroyed.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
The reference that you pass in the `theMenu` parameter is not valid after `DisposeMenu` returns. This function is identical to `DisposeMenu` (page 1253).

Version Notes
In Mac OS X v10.2 and later, all menus are Core Foundation CFTypes, so you can optionally call `CFRelease` instead of `ReleaseMenu`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Related Sample Code
QTCarbonShell

Declared In
`Menus.h`

RemoveMenuCommandProperty

Removes a property from a menu item with the specified command ID.

```
OSStatus RemoveMenuCommandProperty (
   MenuRef inMenu,
   MenuCommand inCommandID,
   OSType inPropertyCreator,
   OSType inPropertyTag
);
```

Parameters

inMenu

The menu in which to begin searching for the item. Pass `NULL` to begin searching with the root menu. The search will descend into all the submenus of this menu.

inCommandID

The command ID of the menu item whose property you want to remove. If more than one item has the same command ID, only the first will be modified.

inPropertyCreator

The four-character creator code for the application.

inPropertyTag

The four-character tag identifying the property to remove.

Return Value

A result code. See "Menu Manager Result Codes" (page 1399).

Discussion

If you have access to the menu item index, in most cases you should use `RemoveMenuItemProperty` (page 1320) instead, as that function is faster and requires no searching.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Menus.h`

RemoveMenuItemProperty

Removes a piece of data that has been previously associated with a menu item.

```
OSStatus RemoveMenuItemProperty (
   MenuRef menu,
   MenuItemIndex item,
   OSType propertyCreator,
   OSType propertyTag
);
```

Parameters

menu

The menu containing the item whose associated data is to be removed.

item

The index number of the menu item or 0 if the data is associated with the menu as a whole.

propertyCreator

A four-character code. Pass your program's signature, as registered through Apple Developer Technical Support. If your program is of a type that would not normally have a signature (for example, a plug-in), you should still register and use a signature in this case, even though your program's file may not have the same creator code as the signature that you register. The `'macs'` property signature is reserved for the system and may not be used.

propertyTag

A four-character code. Pass the application-defined code identifying the associated data.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
Your application may remove data set with the `SetMenuItemProperty` (page 1341) function by calling the `RemoveMenuItemProperty` function.

When a menu is destroyed, all of its properties are removed automatically.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

RetainMenu

Increments the reference count of a menu. (Deprecated in Mac OS X v10.5.)

```
OSStatus RetainMenu (
   MenuRef inMenu
);
```

Parameters

inMenu

The menu whose reference count you want to increment.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
`RetainMenu` does not create a new menu. It simply adds one to the reference count.

Version Notes
In Mac OS X v10.2 and later, all menus are Core Foundation CFTypes, so you can optionally call `CFRetain` instead of `RetainMenu`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Menus.h`

ScrollMenuImage

Scrolls a portion of the menu image. (Deprecated in Mac OS X v10.5.)

```
OSStatus ScrollMenuImage (
   MenuRef inMenu,
   const Rect *inScrollRect,
   int inHScroll,
   int inVScroll,
   CGContextRef inContext
);
```

Parameters

inMenu

The menu to scroll.

inScrollRect

The bounds of the area to scroll.

inHScroll

The distance to scroll horizontally, in pixels.

inVScroll

The distance to scroll vertically, in pixels.

inContext

The Core Graphics context to scroll. If you pass `NULL`, the function creates a context based on the current port.

Return Value

A result code. See "Menu Manager Result Codes" (page 1399).

Discussion

Scrolling menus on Mac OS X using `ScrollRect` or other QuickDraw functions destroys the alpha channel data, so you should use `ScrollMenuImage` instead.

Availability

Available in Mac OS X v10.1 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Menus.h`

SetItemCmd

Sets the value of the keyboard equivalent field of a menu item.

Not recommended

```
void SetItemCmd (
   MenuRef theMenu,
   MenuItemIndex item,
   CharParameter cmdChar
);
```

Parameters

theMenu

The menu containing the item.

item

The menu index of the item.

cmdChar

The value to set for the item's keyboard equivalent field. The Menu Manager uses this value to map keyboard equivalents to menu s or to define special characteristics of the menu item.

To indicate that the menu item has a submenu, specify 0x1B in the `cmdChar` parameter; specify a value of 0x1C to indicate that the item has a special text encoding; specify a value of 0x1D to indicate that the Menu Manager should reduce the item's `'ICON'` resource to the size of a small icon; and specify a value of 0x1E to indicate that the item has an `'SICN'` resource.

The values 0x01 through 0x1A, as well as 0x1F and 0x21, are reserved for use by Apple. You should not use any of these reserved values in the `cmdChar` parameter.

Discussion

You should call `SetMenuItemCommandKey` (page 1334) , `SetMenuItemHierarchicalID` (page 1336) , and `SetMenuItemTextEncoding` (page 1343) instead of `SetItemCmd` to set a menu item's keyboard equivalent and text encoding and to indicate that a menu item has a submenu.

You usually define the keyboard equivalents and other characteristics of your menu items in the `'MENU'` resource rather than using the `SetItemCmd` function. The `SetItemCmd` function sets the value in the keyboard equivalent field of the specified menu item to the value specified by the `cmdChar` parameter (you can specify 0 if the item doesn't have a keyboard equivalent, submenu, text encoding, reduced icon, or small icon). If you specify that the item has a submenu, you should provide the menu ID of the submenu as the item's marking character. If you specify that the item has a special text encoding, you must provide the text encoding in the icon field of the menu item. If you specify that the item has an `'SICN'` or a reduced `'ICON'` resource, you must provide the icon number in the icon field of the item.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Menus.h`

SetItemIcon

Sets a menu item's icon or text encoding. (Deprecated in Mac OS X v10.5.)

```
void SetItemIcon (
   MenuRef theMenu,
   MenuItemIndex item,
   short iconIndex
);
```

Parameters

theMenu

The menu containing the item.

item

The menu index of the item.

iconIndex

An integer representing the icon number or text encoding for the specified menu item. If the menu item's keyboard equivalent field does not contain 0x1C, the `SetItemIcon` function sets the icon number of the item's icon to the number defined in this parameter. The icon number you specify should be a value from 1 through 255 (or from 1 through 254 if the item has a small or reduced icon) or 0 if the item does not have an icon.

The Menu Manager adds 256 to the icon number to generate the resource ID of the '`cicn`' or '`ICON`' resource that describes the icon of the menu item. For example, if you specify 5 as the value of the `iconIndex` parameter, when the Menu Manager needs to draw the item, it looks for an icon resource with resource ID 261.

If the menu item's keyboard equivalent field contains 0x1C, the `SetItemIcon` function sets the text encoding of the menu item to the number defined in the `iconIndex` parameter. The Menu Manager displays the menu item using the specified text encoding if the corresponding script system is installed.

You can specify 0 in the `iconIndex` parameter to indicate that the item uses the current system script and does not have an icon number.

Discussion

In most cases, you should use `SetMenuItemTextEncoding` (page 1343) rather than `SetItemIcon` to set the menu item's text encoding.

The `SetItemIcon` function sets the icon number (for resource-based icons) or text encoding of the specified menu item to the value in the `iconIndex` parameter. To use handle-based icons, call `SetMenuItemIconHandle` (page 1338). Usually you display menu items in the current system script; however, if needed, you can use the `SetItemIcon` function to set the text encoding of a menu item. For an item's text encoding to be set, the keyboard equivalent field of the item must contain 0x1C. If the keyboard equivalent field contains any other value, the `SetItemIcon` function interprets the specified number as the item's icon number.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Menus.h`

SetItemMark

Sets the mark of a menu item.

```
void SetItemMark (
   MenuRef theMenu,
   MenuItemIndex item,
   CharParameter markChar
);
```

Parameters

theMenu

The menu containing the item.

item

The menu index of the item.

markChar

The mark of the menu item or its submenu (if the item has a submenu). To set the submenu associated with this menu item, specify the menu ID of the submenu in the `markChar` parameter. You can pass the character marking constants defined in the Font Manager. Pass 0 (`noMark`)if the menu item has neither mark nor submenu.

Discussion

You should call `SetMenuItemHierarchicalID` (page 1336) instead of `SetItemMark` to set the menu ID of a menu item's submenu. However, you can still use `SetItemMark` to set the mark of a menu item.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Related Sample Code

QTCarbonShell

Declared In

`Menus.h`

SetItemStyle

Sets a menu item's text style.

```
void SetItemStyle (
   MenuRef theMenu,
   MenuItemIndex item,
   StyleParameter chStyle
);
```

Parameters

theMenu

The menu containing the item.

item

The menu index of the item.

chStyle

An integer representing the menu item's text style. You can choose from the following constants: `normal`, `bold`, `italic`, `underline`, `outline`, `shadow`, `condense`, and `extend`.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In
Menus.h

SetMCEntries

Sets entries in an application's menu color information table. (Deprecated in Mac OS X v10.5.)

Not recommended

```
void SetMCEntries (
   short numEntries,
   MCTablePtr menuCEntries
);
```

Parameters

numEntries
The number of entries contained in the array of menu color entry structures.

menuCEntries
A pointer to an array of menu color entry structures. Specify the number of structures in the array in the numEntries parameter.

Discussion
The SetMCEntries function sets any specified menu bar entry, menu title entry, or menu item entry according to the values specified in the menu color entry structures. If an entry already exists for a specified menu color entry, the SetMCEntries function updates the entry in your application's menu color information table with the new values. If the entry doesn't exist, it is added to your application's menu color information table.

If any of the added entries specify a new menu bar color or new menu title colors, your application should call DrawMenuBar (page 1255) to update the menu bar with the new colors.

Special Considerations

The SetMCEntries function may move or purge memory. Your application should make sure that the array specified by the menuCEntries parameter is nonrelocatable before calling SetMCEntries.

Carbon Porting Notes

SetMCEntries does nothing, because Appearance Manager doesn't use color tables.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
Menus.h

SetMCInfo

Makes a copy of your application's menu color information table. (Deprecated in Mac OS X v10.5.)

Not recommended

```
void SetMCInfo (
   MCTableHandle menuCTbl
);
```

Parameters

menuCTbl

A handle to a copy of your application's menu color information table.

Discussion

The `SetMCInfo` function copies the table specified by the `menuCTbl` parameter to your application's menu color information table. If successful, the `SetMCInfo` function is responsible for disposing of your application's current menu color information table, so your application does not need to explicitly dispose of the current table.

Your application should call the Memory Manager function `MemError` to determine whether the `SetMCInfo` function successfully copied the table. If the `SetMCInfo` function cannot successfully copy the table, it does not dispose of the current menu color information table and the `MemError` function returns a nonzero result code. If the `SetMCInfo` function is able to successfully copy the table, it disposes of the current menu color information table and the `MemError` function returns the `noErr` result code.

If the menu color information table specifies a new menu bar color or new menu title colors, your application should call `DrawMenuBar` (page 1255) after calling `SetMCInfo`.

Note that `GetNewMBar` (page 1290) does not save your application's current menu color information table. If your application changes menu bars, you can save and restore your application's current menu color information table by calling `GetMCInfo` (page 1266) before `GetNewMBar` and calling `SetMCInfo` afterward.

Carbon Porting Notes

`SetMCInfo` does nothing, because Appearance Manager doesn't use color tables.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Menus.h`

SetMenuBar

Sets the current menu list to a specified menu list.

```
void SetMenuBar (
   MenuBarHandle mbar
);
```

Parameters

mbar

A handle to a menu list that specifies the menus for a menu bar. You should specify a handle returned by `GetMenuBar` (page 1268) or `GetNewMBar` (page 1290).

Discussion
The `SetMenuBar` function copies the given menu list to the current menu list. As with `GetMenuBar` (page 1268) , `SetMenuBar` doesn't copy the menu structures, just the menu list (which contains handles to the menu structures).

You can use `SetMenuBar` to restore a menu list that you previously saved using `GetMenuBar` or to set the current menu list to a menu list created from a nib file or from `GetNewMBar` (page 1290).

The `SetMenuBar` function sets the current menu list and calls `InvalMenuBar` (page 1301) so the menu bar can be updated the next time through the event loop; if you want to redraw the menu bar immediately, call the `DrawMenuBar` (page 1255) function.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
BSDLLCTest

Declared In
`Menus.h`

SetMenuCommandMark

Locates the menu item with a specified command ID and sets its mark character.

```
OSStatus SetMenuCommandMark (
   MenuRef inMenu,
   MenuCommand inCommandID,
   UniChar inMark
);
```

Parameters

inMenu
The menu in which to begin searching for the item. Pass `NULL` to begin searching with the root menu. The search will descend into all submenus of this menu.

inCommandID
The command ID of the menu item to be modified. If more than one item has this command ID, only the first will be modified.

inMark
The new mark character. While this is a Unicode character, only the low byte is currently used as the mark character, and it is interpreted using the application text encoding.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
If you have access to the menu item index, in most cases you should use `SetItemMark` (page 1324) instead, as that function is faster and requires no searching.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
Menus.h

SetMenuCommandProperty

Sets the property data for a menu item with the specified command ID.

```
OSStatus SetMenuCommandProperty (
   MenuRef inMenu,
   MenuCommand inCommandID,
   OSType inPropertyCreator,
   OSType inPropertyTag,
   ByteCount inPropertySize,
   const void *inPropertyData
);
```

Parameters

inMenu

inCommandID

The command ID of the menu item whose property you want to set. If more than one item has the same command ID, only the first item's property is set.

inPropertyCreator

The four-character creator code for the application.

inPropertyTag

The four-character tag for the property you want to set.

inPropertySize

The side of the property data, in bytes.

inPropertyData

The property data to set.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
If you have access to the menu item index, in most cases you should use `SetMenuItemProperty` (page 1341) instead, as that function is faster and requires no searching.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
Menus.h

SetMenuDefinition

Sets the menu definition structure for a menu.

```
OSStatus SetMenuDefinition (
   MenuRef menu,
   const MenuDefSpec *defSpec
);
```

Parameters

menu

The menu whose menu definition structure you want to set.

defSpec

The new menu definition structure.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
You can use this function to change your menu definition on-the-fly.

Availability
Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In
`Menus.h`

SetMenuExcludesMarkColumn

Sets whether a menu contains space for mark characters.

Not recommended

```
OSStatus SetMenuExcludesMarkColumn (
   MenuRef menu,
   Boolean excludesMark
);
```

Parameters

menu

The menu whose width is to be set.

excludesMark

Pass `true` to specify that the menu be drawn without space for mark characters; `false` to specify that the menu be drawn in its full width, with space for mark characters.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
Your application may use the `SetMenuExcludesMarkColumn` function to set the width of an individual menu, so that no space is provided for mark characters such as checkmarks, dashes, or notification symbols (diamonds).

The `SetMenuExcludesMarkColumn` function is only recommended for use with pop-up menus, and then only in special cases. Mac OS human interface guidelines require that all standard (menu bar) menus include space for mark characters, and pop-up menus that present user-selectable attributes or commands should

also contain space for marks. If a pop-up menu does not present a list of user-selectable attributes or commands, as is the case with the Mac OS 8.5 Window Manager window proxy pop-up menus that display a standard file system path, then narrowing the menu to exclude space for marks may be appropriate.

See also the `GetMenuExcludesMarkColumn` (page 1272) function.

Carbon Porting Notes

You should instead set the `kMenuExcludesMarkColumn` menu attribute using the `ChangeMenuAttributes` (page 1235) function.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Menus.h`

SetMenuFlashCount

Specifies whether a menu should fade slowly or immediately disappear when closing. (Deprecated in Mac OS X v10.5.)

Modified

```
void SetMenuFlashCount (
   short count
);
```

Parameters

count

See the Discussion.

Discussion

Unlike the classic Mac OS version, `SetMenuFlashCount` no longer lets you set the flash count for a menu. In Mac OS X, the flash count is always 1, and it not user adjustable.

Passing zero for the `count` parameter causes menus to disappear immediately when closing; passing any nonzero parameter causes the menus to fade out when closing (the default).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Menus.h`

SetMenuFont

Sets the font to be used in a menu.

```
OSStatus SetMenuFont (
   MenuRef menu,
   SInt16 inFontID,
   UInt16 inFontSize
);
```

Parameters

menu

The menu whose font is to be set.

inFontID

The font family ID for the font to be used. Pass 0 to use the current system font. Note that this is the font to be used in the menu items, not the menu title. You cannot change the menu title font.

inFontSize

The size, in points, of the font to be used. Valid font size values range from 9 to 24 points, inclusive. Pass 0 to use the font size of the current system font.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
Your application may use the `SetMenuFont` function to set the font for an individual menu, such as a pop-up menu. This function sets the font used by all the menu items in the menu. If you want to set the font of only a particular menu item, use the `SetMenuItemFontID` (page 1335) function instead.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

SetMenuHeight

Set the height of a menu.

```
void SetMenuHeight (
   MenuRef menu,
   SInt16 height
);
```

Parameters

menu

The menu whose height you want to set.

height

The height of the menu, in pixels.

Discussion
Calling `CalcMenuSize` (page 1234) on the menu overwrites the menu height you set with this function.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
Menus.h

SetMenuID

Assigns a menu ID to a menu.

```
void SetMenuID (
   MenuRef menu,
   MenuID menuID
);
```

Parameters

menu
The menu you want to assign an ID to.

menuID
The menu ID to assign.

Discussion
In most cases you assign an ID to a menu when you first create it, but you can use this function to change it later.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
Menus.h

SetMenuItemCommandID

Sets a menu item's command ID.

```
OSErr SetMenuItemCommandID (
   MenuRef inMenu,
   MenuItemIndex inItem,
   MenuCommand inCommandID
);
```

Parameters

inMenu
The menu that contains the menu item whose command ID you want to set.

inItem
The menu index of the item.

inCommandID
An integer representing the command ID that you wish to set.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
You can use a menu item's command ID as a position-independent method of signalling a specific action in an application. See *Carbon Event Manager Programming Guide* for more information about command IDs.

Note that Apple reserves all command IDs that contain all lowercase letters; your application is free to use any command ID containing uppercase characters.

See also the function `GetMenuItemCommandID` (page 1275).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

SetMenuItemCommandKey

Sets the keyboard equivalent of a menu item.

```
OSStatus SetMenuItemCommandKey (
   MenuRef inMenu,
   MenuItemIndex inItem,
   Boolean inSetVirtualKey,
   UInt16 inKey
);
```

Parameters

inMenu
The menu containing the item.

inItem
The item whose keyboard equivalent you want to set.

inSetVirtualKey
Indicates whether to set the item's character code (`false`) or virtual keycode equivalent. (`true`).

inKey
The character code or virtual keycode equivalent to set.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
A menu item's keyboard equivalent may be either a character code or a virtual keycode. The character code is always used to draw the item's keyboard equivalent in the menu, but either may be used for keyboard equivalent matching by `MenuEvent` and `IsMenuKeyEvent`, depending on whether the `kMenuItemAttrUseVirtualKey` item attribute is set. If `SetMenuItemCommandKey` is used to set the virtual keycode equivalent for a menu item, it also automatically sets the `kMenuItemAttrUseVirtualKey` item attribute. To make the menu item stop using the virtual keycode equivalent and use the character code equivalent instead, use `ChangeMenuItemAttributes` to clear the `kMenuItemAttrUseVirtualKey` item attribute.

Version Notes
Prior to Mac OS X v10.3, passing a character code in the range 0x1A to 0x21 (the range of command key metacharacters such as `hMenuCmd`) returned an error. In Mac OS X v10.3 and later, the Menu Manager interprets codes in this range as the ASCII character for that value, and displays the appropriate command key glyph. For example, passing `hMenuCmd` would set the keyboard equivalent to be command-Escape, because the value of `hMenuCmd` (0x1B) is the character code for the Escape character.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

SetMenuItemData

Sets multiple attributes of a menu item at once.

```
OSStatus SetMenuItemData (
   MenuRef inMenu,
   MenuItemID inItem,
   Boolean inIsCommandID,
   const MenuItemDataRec *inData
);
```

Parameters

inMenu
The menu whose attributes you want to set. Note that if you pass `true` for the `inIsCommandID` parameter, you can pass `NULL` here, in which case the Menu Manager searches the root menu for the first menu that matches the specified command ID.

inItem
The menu item index or the command ID of the menu item.

inIsCommandID
A Boolean value indicating whether the value passed for the `inItem` parameter is a command ID or a menu item index. Pass `true` to indicate a command ID, `false` to indicate that it is a menu item index. If you pass `true`, the Menu Manager sets the data for the first menu item that matches the specified command ID.

inData
A pointer to a `MenuItemDataRec` structure. Before calling, you should set the `whichData` field to indicate what data you want to set and fill out those fields appropriately. For more details on the types of data you can set, see "Menu Item Data Flags" (page 1390).

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
This function is often more efficient than calling individual accessor functions if you want to set multiple attributes simultaneously.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

SetMenuItemFontID

Sets the font for a menu item.

```
OSErr SetMenuItemFontID (
   MenuRef inMenu,
   MenuItemIndex inItem,
   SInt16 inFontID
);
```

Parameters

inMenu

The menu that contains the menu item for which you wish to set the font.

inItem

The menu index of the item.

inFontID

An integer representing the font ID that you wish to set.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
You can use this function to set up a font menu that displays item in its appropriate font. If you want to set the font for all the items in a menu, you can use the `SetMenuFont` (page 1331) function.

See also the function `GetMenuItemFontID` (page 1277).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

SetMenuItemHierarchicalID

Attaches a submenu to a menu item. (Deprecated in Mac OS X v10.5.)

```
OSErr SetMenuItemHierarchicalID (
   MenuRef inMenu,
   MenuItemIndex inItem,
   MenuID inHierID
);
```

Parameters

inMenu

The menu that contains the menu item to which you wish to attach a submenu.

inItem

The menu index of the item.

inHierID

An integer representing the menu ID of the submenu you wish to attach. This menu should be inserted into the menu list by calling `InsertMenu` with the `kInsertHierarchicalMenu` constant.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
The `SetMenuItemHierarchicalID` function should be called instead of setting the keyboard equivalent to 0x1B. You should call `SetMenuItemHierarchicalID` instead of `SetItemMark` to set the menu ID of a menu item's submenu. However, you can still use `SetItemMark` to set the mark of a menu item.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Menus.h`

SetMenuItemHierarchicalMenu

Attaches a submenu to a menu item.

```
OSStatus SetMenuItemHierarchicalMenu (
   MenuRef inMenu,
   MenuItemIndex inItem,
   MenuRef inHierMenu
);
```

Parameters
inMenu
The parent menu.
inItem
The parent item.
inHierMenu
The submenu to attach. Pass `NULL` to remove an existing submenu.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
Using `SetMenuItemHierarchicalMenu`, it is possible to directly specify the submenu for a menu item without specifying its menu ID. It is not necessary to insert the submenu into the hierarchical portion of the menubar, and it is not necessary for the submenu to have a unique menu ID. Simply use 0 as the menu ID for the submenu, and identify selections from the menu by command ID.

The Menu Manager will increment the reference count of the submenu that you specify, and the submenu's reference count will be decremented automatically when the parent menu item is deleted or the parent menu is disposed.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

SetMenuItemIconHandle

Sets a menu item's icon.

```
OSErr SetMenuItemIconHandle (
   MenuRef inMenu,
   MenuItemIndex inItem,
   UInt8 inIconType,
   Handle inIconHandle
);
```

Parameters

inMenu

The menu that contains the menu item for which you wish to set an icon.

inItem

The menu index of the item.

inIconType

Pass a value representing the type of icon (`'ICON'`, `'cicn'`, `'SICN'`, icon suite, or `IconRef`) you wish to attach; see "Menu Item Icon Type Constants" (page 1394) for descriptions of possible values.

inIconHandle

Pass a handle to the icon you wish to attach to a menu item.

Return Value

A result code. See "Menu Manager Result Codes" (page 1399).

Discussion

The `SetMenuItemIconHandle` function sets the icon of a menu item with an icon handle instead of a resource ID. `SetMenuItemIconHandle` allows you to set icons of type `'ICON'`, `'cicn'`, `'SICN'`, `IconRef`, `CGImageRef`, as well as icon suites. To set resource-based icons for a menu item, call `SetItemIcon`.

With the exception of types `IconRef` and `CGImageRef`,disposing of the menu will not dispose of the icon handles set by this function. The Menu Manager retains `IconRef`, `CGImageRef` icons and releases them when the menu is disposed or the menu item is removed. For all other icon types, your application should dispose of the icons when you dispose of the menu, to prevent memory leaks.

See also the function `GetMenuItemIconHandle` (page 1279).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Related Sample Code

QTCarbonShell

Declared In

`Menus.h`

SetMenuItemIndent

Sets the indent level of a menu item.

```
OSStatus SetMenuItemIndent (
   MenuRef inMenu,
   MenuItemIndex inItem,
   UInt32 inIndent
);
```

Parameters

inMenu

The menu containing the item.

inItem

The item whose indent level you want to set.

inIndent

The new indent level of the item.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
The indent level of an item is an amount of extra space added to the left of the item's icon or checkmark. The level is simply a number, starting at zero, which the Menu Manager multiplies by a constant to get the indent in pixels. The default indent level is zero.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

SetMenuItemKeyGlyph

Sets the command key glyph code for a menu item.

```
OSErr SetMenuItemKeyGlyph (
   MenuRef inMenu,
   MenuItemIndex inItem,
   SInt16 inGlyph
);
```

Parameters

inMenu

The menu that contains the menu item for which you wish to substitute a keyboard glyph.

inItem

The menu index of the item.

inGlyph

An integer representing the substitute glyph to display. Pass 0 to remove an existing glyph code. For a description of available keyboard glyphs, see "Menu Glyph Constants" (page 1382).

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
The `SetMenuItemKeyGlyph` function overrides the character that would normally be displayed in a menu item's keyboard equivalent with a substitute keyboard glyph. This is useful if the keyboard glyph in the font doesn't match the actual character generated. For example, you might use this function to display function keys.

In addition, the glyph code you specify is used for command key matching if the menu item does not already have a command key or virtual keycode assigned to it.

See also the function `GetMenuItemKeyGlyph` (page 1280).

Version Notes
In CarbonLib 1.2 and later and Mac OS X v10.0 and later, the Menu Manager automatically draws the appropriate glyph for a menu item that has a virtual keycode assigned to it; you do not have to set both virtual keycode and the glyph.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

SetMenuItemModifiers

Sets the modifier key(s) that must be pressed with a character key to select a particular menu item.

```
OSErr SetMenuItemModifiers (
   MenuRef inMenu,
   MenuItemIndex inItem,
   UInt8 inModifiers
);
```

Parameters

inMenu
The menu that contains the menu item for which you wish to set the modifier key(s).

inItem
The menu index of the item.

inModifiers
A value representing the modifier key(s) to be used in selecting the menu item; see "Modifier Key Mask Constants" (page 1396).

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
You can call the `SetMenuItemModifiers` function to change the modifier key(s) you can include with a character key to create your keyboard equivalent. For example, you can change Command-x to Command-Option-Shift-x. By default, the Command key is always specified; you can remove it by calling `SetMenuItemModifiers` with the `kMenuNoCommandModifier` mask constant, or (if you are using a nib file) by unchecking the appropriate command checkbox in the Interface Builder menu item inspector.

See also the function `GetMenuItemModifiers` (page 1281).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

SetMenuItemProperty

Associates data with a menu item.

```
OSStatus SetMenuItemProperty (
   MenuRef menu,
   MenuItemIndex item,
   OSType propertyCreator,
   OSType propertyTag,
   ByteCount propertySize,
   const void *propertyData
);
```

Parameters

menu
The menu containing the item with which you wish to associate data.

item
The index number of the menu item or 0 if the data is to be associated with the menu as a whole.

propertyCreator
A four-character code. Pass your program's signature, as registered through Apple Developer Technical Support. If your program is of a type that would not normally have a signature (for example, a plug-in), you should still register and use a signature in this case, even though your program's file may not have the same creator code as the signature that you register. The `'macs'` property signature is reserved for the system and may not be used.

propertyTag
A four-character code that identifies the property to set. You define the tag your application uses to identify the data; this code is not to be confused with the file type for the data, but may coincide if you wish.

propertySize
The size of the data.

propertyData
A pointer to the data.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
You may use the `SetMenuItemProperty` function to associate arbitrary data, tagged with an identifying code, with a menu item.

See also the `GetMenuItemProperty` (page 1281) and `RemoveMenuItemProperty` (page 1320) functions.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
HID Explorer
QTCarbonShell

Declared In
`Menus.h`

SetMenuItemRefCon

Sets application-specific information for a menu item.

```
OSErr SetMenuItemRefCon (
   MenuRef inMenu,
   MenuItemIndex inItem,
   URefCon inRefCon
);
```

Parameters

inMenu
The menu that contains the menu item with which you wish to associate information.

inItem
The menu index of the item. In CarbonLib 1.6 and later and Mac OS X v10.2 and later, you may pass zero to set a reference constant for the menu itself.

inRefCon
An unsigned 32-bit integer value. Pass a reference constant to associate with the menu item.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
If you have any data you want to associate with a menu item, you can do so using the `SetMenuItemRefCon` function. Note that you can also use `SetMenuItemProperty` (page 1341), which allows more flexibility in specifying application-specific data.

See also the function `GetMenuItemRefCon` (page 1284).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

SetMenuItemText

Sets menu item text to a specified string. (Deprecated in Mac OS X v10.5.)

Not recommended

```
void SetMenuItemText (
   MenuRef theMenu,
   MenuItemIndex item,
   ConstStr255Param itemString
);
```

Parameters

theMenu

The menu containing the item.

item

The menu index of the item.

itemString

The menu item's text string. This parameter must not be `NULL` or an empty (zero-length) string. Do not use meta–font characters in this parameter.

Your menu item text string must be limited to 250 bytes. 251 or more bytes will cause the Menu Manager to crash.

Discussion

The `SetMenuItemText` function does not recognize any metacharacters used by `AppendMenu` (page 1229) and `InsertMenuItem` (page 1295).

If you set the text of a menu item using the `SetMenuItemText` function, you should store the text in a string resource so that your application can be more easily localized.

Carbon Porting Notes

n Carbon, you should use the `SetMenuItemTextWithCFString` (page 1344) function instead.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Menus.h`

SetMenuItemTextEncoding

Sets the text encoding for a menu item's text. (Deprecated in Mac OS X v10.5.)

```
OSErr SetMenuItemTextEncoding (
   MenuRef inMenu,
   MenuItemIndex inItem,
   TextEncoding inScriptID
);
```

Parameters

inMenu

The menu containing the menu item whose text encoding you wish to set.

inItem

The menu index of the item.

inScriptID

The script code that corresponds to the text encoding you wish to set.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
If a menu item has a command code of 0x1C when `SetMenuItemTextEncoding` is called, the values in the menu item's command key and icon ID fields are cleared and replaced with the value in the `inScriptID` parameter of `SetMenuItemTextEncoding`.

See also the function `GetMenuItemTextEncoding` (page 1285).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Menus.h`

SetMenuItemTextWithCFString

Sets the text of a menu item to the text contained in a CFString.

```
OSStatus SetMenuItemTextWithCFString (
   MenuRef inMenu,
   MenuItemIndex inItem,
   CFStringRef inString
);
```

Parameters

inMenu
The menu containing the item.

inItem
The item whose text you want to set.

inString
The CFString containing the new menu item text.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
If the CFString is mutable, the Menu Manager will make its own copy of the CFString before returning from `SetMenuItemTextWithCFString`. Modifying the string after calling `SetMenuItemTextWithCFString` will have no effect on the item's actual text.

If the CFString is immutable, the Menu Manager increments the reference count of the string before returning.

The caller may release the string after calling `SetMenuItemTextWithCFString`.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
BSDLLCTest

Declared In
Menus.h

SetMenuTitle

Sets the title of a menu. (Deprecated in Mac OS X v10.5.)

Not Recommended

```
OSStatus SetMenuTitle (
   MenuRef menu,
   ConstStr255Param title
);
```

Parameters

menu
The menu whose title you want to set.

title
A string containing the menu title to set.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
Unless you need to support legacy code, you should use the `SetMenuTitleWithCFString` (page 1346) function instead.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
Menus.h

SetMenuTitleIcon

Sets the title of a menu to be an icon.

```
OSStatus SetMenuTitleIcon (
   MenuRef inMenu,
   UInt32 inType,
   void *inIcon
);
```

Parameters

inMenu
The menu whose title to set.

inType
The type of icon being used to specify the icon title; use `kMenuNoIcon` to remove the icon from the menu title. The supported types are `kMenuIconSuiteType`, `kMenuIconRefType`, and (in Mac OS X v10.3 and later) `kMenuIconCGImageRefType`.

inIcon

The icon; this parameter must be `NULL` if `inType` is `kMenuNoIcon`. The supported icon formats are `IconSuiteRef`, `IconRef`, and (in Mac OS X v10.3 and later) `CGImageRef`.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
The Menu Manager takes ownership of the supplied icon after this call. When a menu with an title icon is disposed, the Menu Manager will dispose the icon as well. The Menu Manager will also dispose of the current title icon when a new text or icon title is supplied for a menu. If you specify an `IconRef` or `CGImageRef`, the Menu Manager will increment its reference count, so you can release your reference to the `IconRef` without invalidating the Menu Manager's copy. The menu bar is invalidated by this call and will be redrawn at the first opportunity.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

SetMenuTitleWithCFString

Sets the title of a menu to the text contained in a CFString.

```
OSStatus SetMenuTitleWithCFString (
   MenuRef inMenu,
   CFStringRef inString
);
```

Parameters

inMenu

The menu whose title you want to set.

inString

The string containing the new menu title text.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
If the string is mutable, the Menu Manager will make its own copy of the CFString before returning from `SetMenuTitleWithCFString`. Modifying the string after calling `SetMenuTitleWithCFString` will then have no effect on the menu's actual title.

If the string is immutable, the Menu Manager simply increments the string's reference count.

The caller may release the string after calling `SetMenuTitleWithCFString`.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

SetMenuWidth

Sets the width of a menu.

```
void SetMenuWidth (
   MenuRef menu,
   SInt16 width
);
```

Parameters

menu

The menu whose width you want to set.

width

The width of the menu, in pixels.

Discussion

Calling `CalcMenuSize` (page 1234) on the menu overwrites the menu width you set with this function.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Menus.h`

SetRootMenu

Sets the menu whose contents are displayed in the menubar.

```
OSStatus SetRootMenu (
   MenuRef inMenu
);
```

Parameters

inMenu

The new root menu.

Return Value

A result code. See "Menu Manager Result Codes" (page 1399).

Discussion

The root menu should contain one menu item for each top-level menu to be displayed in the menu bar. Each menu item in turn should have a submenu that was specified using `SetMenuItemHierarchicalMenu` (page 1337).

You can use the `SetRootMenu` function along with the `AcquireRootMenu` (page 1229) function to save and restore the contents of the menu bar. Note that calling `SetRootMenu` sets the contents of the hierarchical portion of the menu list as well as the top-level menus displayed in the menu bar. Before returning the root menu, `AcquireRootMenu` calls `InsertMenu` (page 1294) with the `kInsertHierarchialMenu` option to attach to the root menu a list of the menus that are currently inserted into the hierarchical portion of the menu. `SetRootMenu` reinserts any attached hierarchical menus into the hierarchical portion of the menu list. If you pass a newly-created menu to `SetRootMenu`, the hierarchical menu list is cleared and is empty.

Calling `SetRootMenu` also implicitly retains the new root menu, and you should release it at the appropriate time by calling `ReleaseMenu` (page 1319).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

ShowMenuBar

Displays the menu bar.

```
void ShowMenuBar (
   void
);
```

Discussion
The `ShowMenuBar` function makes the menu bar visible and selectable by the user.

Note that calling this function also causes a `kEventMenuBarShown` event to be sent to the application target (if your application has registered for the event).

See also the `HideMenuBar` (page 1291) and `IsMenuBarVisible` (page 1303) functions.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

UpdateInvalidMenuItems

Redraws the invalid items of an open menu.

```
OSStatus UpdateInvalidMenuItems (
   MenuRef inMenu
);
```

Parameters
inMenu
The menu whose menu items you want to update.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
This function redraws menu items in an open menu that has either had some visible aspect of its menu items change (such as their enable state) or has been invalidated by a call to `InvalidateMenuItems` (page 1299).

It is not necessary to use `UpdateInvalidMenuItems` if you are using Carbon's built-in support for dynamic items based on modifier key state. However, if you are modifying items dynamically using your own implementation, you should call `UpdateInvalidMenuItems` after completing your modifications for a single menu. It will redraw any items that have been marked as invalid, and clear the invalid flag for those items.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

UpdateStandardFontMenu

Updates a standard Font menu.

```
OSStatus UpdateStandardFontMenu (
   MenuRef menu,
   ItemCount *outHierMenuCount
);
```

Parameters

menu
The menu you want to update.

outHierMenuCount
The number of hierarchical menus attached to the standard Font menu. This value may be `NULL` if the hierarchical menus count is not useful. For example, if the only submenus in your application are those created by `CreateStandardFontMenu`, then you don't need to worry about the hierarchical menu count, as any existing submenu must be a font menu.

Return Value
A result code. See "Menu Manager Result Codes" (page 1399).

Discussion
`UpdateStandardFontMenu` calls the Font Manager function `FMGetFontGeneration` to determine if the fonts have changed and returns immediately without modifying the font menu if no changes occurred. As there is little overhead if no fonts have changed, you can call this function whenever you think it may be useful; for example, when your application is activated, or whenever you receive a `kEventMenuPopulate` event for the font menu.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

`Menus.h`

Callbacks

MenuDefProcPtr

Defines a pointer to a custom menu definition callback function. Your menu definition callback function draws the menu items in the menu, determines which item the user chose from the menu, and calculates the menu's dimensions.

Not recommended

```
typedef void (*MenuDefProcPtr) (
    SInt16 message,
    MenuRef theMenu,
    Rect *menuRect,
    Point hitPt,
    SInt16 *whichItem
);
```

If you name your function `MyMenuDefProc`, you would declare it like this:

```
void *MyMenuDefProc (
    SInt16 message,
    MenuRef theMenu,
    Rect *menuRect,
    Point hitPt,
    SInt16 *whichItem
);
```

Parameters

message

A constant that identifies the operation the menu definition function should perform; see "Custom Menu Definition Message Constants" (page 1372) and "Obsolete Menu Definition Messages" (page 1374) for a description of the messages that your menu definition function can receive. Your menu definition function should not respond to any value other than these defined messages. Other messages are reserved for internal use by Apple Computer, Inc.

theMenu

The menu that the operation should affect. This menu reference may refer to a regular menu or a popup menu.

menuRect

A pointer to the rectangle (in global coordinates) in which the menu is located.

hitPt

A mouse location (in global coordinates). The Menu Manager provides information in this parameter to the menu definition function when the `kMenuFindItemsMsg` or `kMenuPopUpMsg` messages are sent.

whichItem

A pointer to a value that specifies the item number of the menu item to act upon, or a pointer to a data structure related to one or more menu items. The data pointed to depends on the message sent; see the discussion for specifics.

Discussion

Carbon does not let you store menu definitions as resources. If you need to upgrade legacy code, see the *Carbon Porting Guide* for information about converting your resource-based definitions. See the Carbon Porting Notes for this callback for additional information about changes to older messages and access to low-memory global data.

On Mac OS X v10.3 and later, all standard menus are implemented as HIViews, and custom menus can be implemnented as custom HIViews. If you want to create custom menu definitions, you should subclass the HIMenuView class. See Introducing HIView in Carbon User Experience documentation for more information.

When you define your menus, you specify the menu definition function the Menu Manager should use when managing them. You'll usually want to use the standard menu definition function for your application. However, if you need a feature not provided by the standard menu definition function (for example, if you want to include more graphics in your menus), you can choose to write your own menu definition function.

The menu definition function is responsible for drawing the contents of the menu and its menu items, determining whether the cursor is in a displayed menu, highlighting and unhighlighting menu items, and calculating a menu's dimensions. To create an instance of your custom menu, call the `CreateCustomMenu` (page 1245) function.

The Menu Manager calls your menu definition function whenever it needs your definition function to perform a certain action on a specific menu. The action your menu definition function should perform depends on the value of the `message` parameter. When the Menu Manager requests your menu definition function to perform an action on a menu, it provides your function with the appropriate menu reference. This allows your function to access the data in the menu structure and to use any data in the variable data portion of the menu structure to appropriately handle the menu items.

Your menu definition function should support the following messages:

- `kMenuInitMsg`

  The Menu Manager sends this message when creating a menu to give your menu definition a chance to perform any required initialization. If an error occurs during initialization, your menu definition should return a nonzero error code in the `*whichItem` parameter. This error is then returned by the function used to create the menu.

- `kMenuDisposeMsg`

  Sent when a menu is destroyed. The Menu Manager sends this message to give your menu definition a chance to release or dispose of any related data.

- `kMenuFindItemMsg`

  Sent when the Menu Manager is displaying a menu and needs to know what item is under the mouse.

  The `whichItem` parameter points to a `MenuTrackingData` structure. On entry, the `menu`, `virtualMenuTop`, and `virtualMenuBottom` fields of this structure are valid. Your menu definition should determine which item, if any, contains the point passed to you in the `hitPt` parameter and fill in the `itemUnderMouse`, `itemSelected`, and `itemRect` fields. If an item is found, the menu definition should always fill in the `itemUnderMouse` and `itemRect` fields. The menu definition should only fill in the `itemSelected` field if the item is available for selection; if it is unavailable (because it is disabled, or for some other reason), the menu definition should set the `itemSelected` field to zero.

  The index values placed in the `itemUnderMouse` and `itemSelected` fields should be less than or equal to the number of items returned by `CountMenuItems` (page 1244) on this menu. These values should also be identical if both are nonzero. The `itemUnderMouse` field should always be nonzero if the mouse is actually over an item.

  The menu definition should not highlight the found item in response to this message, as the Menu Manager will send a separate `kMenuHiliteItemMsg` to request highlighting of the item.

  If the menu definition supports scrolling, it should scroll the menu during this message, and update the `virtualMenuTop` and `virtualMenuBottom` fields of the MenuTrackingData to indicate the menu's new scrolled position.

  If the menu definition uses QuickDraw to draw while scrolling, it should draw into the current port.

  If the menu definition uses CoreGraphics to draw while scrolling, it should use the `CGContextRef` passed in the context field of the `MDEFHiliteItemData` structure. Menu definitions must use the `ScrollMenuImage` (page 1322) function, if available, to scroll the menu contents. (This function is available in CarbonLib 1.5 and later, and in Mac OS X 10.1 and later.) `ScrollMenuImage` properly supports scrolling the alpha channel in the menu's image data. Use of the QuickDraw function `ScrollRect` to scroll the menu contents will result in the alpha channel being set to 0xFF (opaque) and the menu will no longer be translucent.

The menu definition should not modify the `menu` field of the `MenuTrackingData` structure.

- `kMenuHiliteItemMsg`

  Sent when the Menu Manager is displaying a menu and needs to highlight a newly selected item.

  The `whichItem` parameter points to a `MDEFHiliteItemData` structure. The menu definition should unhighlight the item in the `previousItem` field, if non-zero, and highlight the item in the `newItem` field.

  If the menu definition is using the Appearance Manager's menu drawing APIs, you should use the `EraseMenuBackground` (page 1258) function to erase the old menu contents before unhighlighting a menu item. This is necessary because the background of a menu is translucent in Aqua, and if the old highlight is not erased first, it will show through the new unhighlighted menu background.

  If the menu definition uses QuickDraw to draw, it should draw into the current port. If it uses CoreGraphics to draw, it should use the `CGContextRef` passed in the context field of the `MDEFHiliteItemData` structure.

- `kMenuDrawItemsMsg`

  Sent when the Menu Manager is displaying a menu and needs to redraw a portion of the menu. This message is used by the dynamic menu item support code in the Menu Manager; for example, if items five and six in a menu are a dynamic group, the Menu Manager will send a `kMenuDrawItemsMsg` message when the group's modifier key is pressed or released to redraw the appropriate item, but no other items in the menu.

  The whichItem parameter for this message points to an `MDEFDrawItemsData` structure. The menu definition should redraw the items starting with `firstItem` and ending with `lastItem`, inclusive.

  If the menu definition uses QuickDraw to draw, it should draw into the current port. If it uses CoreGraphics to draw, it should use the `CGContextRef` passed in the context field of the `MDEFHiliteItemData` structure.

- `kMenuDrawMsg`

  Sent when the Menu Manager is displaying a menu and needs to redraw the entire menu.

  The `whichItem` parameter is actually a pointer to a `MenuTrackingData` structure. On entry, the menu field of this structure is valid. The menu definition should draw the menu and, if it supports scrolling, should also fill in the `virtualMenuTop` and `virtualMenuBottom` fields of the structure to indicate the menu's initial unscrolled position; typically, `virtualMenuTop` would be set to the same value as the top coordinate of the menu bounds, and `virtualMenuBottom` would be set to `virtualMenuTop` plus the virtual height of the menu.

  If the menu definition uses QuickDraw to draw, it should draw into the current port. If it uses CoreGraphics to draw, it should use the `CGContextRef` passed in the context field of the `MDEFHiliteItemData` structure.

- `kMenuSizeMsg`

  Sent when the Menu Manager needs to determine the size of a menu.

  The menu definition should calculate the width and height of the menu and store the sizes into the menu with `SetMenuWidth` (page 1347) and `SetMenuHeight` (page 1332). If the `gestaltMenuMgrSendsMenuBoundsToDefProc` bit is set in the Menu Manager's Gestalt value, then the `hitPt` parameter sent with this message is the maximum width (`hitPt.h`) and height (`hitPt.v`) of the menu. The menu definition should ensure that the width and height that it places in the menu do not exceed these values. If the gestalt bit is not set, the menu definition should just use the main display device's (`GDevice`) width and height as constraints on the menu's width and height.

- `kMenuPopUpMsg`

  Sent when the Menu Manager is about to display a popup menu. The Menu Manager uses the menu definition function to support pop-up menus that are not implemented as controls. If your menu definition function supports pop-up menus, it should respond appropriately to the `kMenuPopUpMsg` message.

  The menu definition should calculate the appropriate menu bounds to contain the menu based on the requested menu location and selected item. It should write the menu's bounds into the `Rect` structure passed by the `menuRect` parameter. If the `gestaltMenuMgrSendsMenuBoundsToDefProc` bit is set in the Menu Manager's Gestalt value, then the `menuRect` parameter on entry to this message contains a constraint rectangle, in global coordinates, outside of which the popup menu should not be positioned. The menu definition should take these constraint bounds into account as it calculates the menu bounds. If the gestalt bit is not set, the menu definition should use the bounds of the display device (`GDevice`) containing the menu's top left corner as a constraint on the menu's position.

  The `hitPt` parameter is the requested location for the top left corner of the menu. The coordinates of this parameter are swapped from their normal order; `hitPt.h` contains the vertical coordinate and `hitPt.v` contains the horizontal coordinate.

  On entry, the `whichItem` parameter points at a menu item index which is requested to be the initial selection when the menu is displayed. After calculating the menu's bounds, the menu definition should write the menu's virtual top coordinate into the location pointed at by the `whichItem` parameter. If displaying the menu at the requested location does not require scrolling, the virtual top will be the same as the menu bounds top; if the menu must scroll to fit in the requested location, the virtual top may be different.

- `kMenuCalcItemMsg`

  Sent when the Menu Manager needs to know the bounds of a menu item.

  The menu definition should calculate the size of the menu item specified by the `whichItem` parameter and store the bounds in the `Rect` structure specified by the `menuRect` parameter. Some sample menu definition code provided by Apple has previously shown an implementation of this message that always sets the top left corner of the item bounds to (0,0), regardless of the item's actual position in the menu. For best future compatibility, menu definitions should begin storing an item bounds that gives the item's actual position in the menu based on the menu's current virtual top. For example, if the virtual menu top starts at 20, then the menu definition would calculate an item bounds for the first item that starts at (0,20), an item bounds for the second item that starts at (0,40), and so on. The menu definition should call `GetMenuTrackingData` (page 1288)to get the menu's current virtual position, and use zero for the menu top if `GetMenuTrackingData` returns an error.

- `kMenuThemeSavvyMsg`

  Sent by the Menu Manager to determine whether the menu definition uses the Appearance Manager menu-drawing functions to draw its menu. If it does, the menu definition should return `kThemeSavvyMenuResponse` in the location pointed to by `whichItem`. If the menu definition draws its own custom content without using the Appearance Manager menu-drawing functions, it should ignore this message.

The Menu Manager defines the data type `MenuDefUPP` to identify the universal procedure pointer for an application-defined menu definition function:

```
typedef UniversalProcPtr MenuDefUPP;
```

You typically use the `NewMenuDefProc` function like this:

```
MenuDefUPP myMenuDefProc;
```

```
myMenuDefProc = NewMenuDefProc(MyMenu);
```

Carbon Porting Notes

Prior to Carbon, menu definitions needed to use several low-memory globals to communicate with the Menu Manager. These globals have all been replaced or made obsolete in Carbon, as follows:

- `MenuDisable`

  `MenuDisable` is now set automatically by the Menu Manager using the value returned in the itemUnderMouse field of the MenuTrackingData structure passed to kMenuFindItemMsg.

- `TopMenuItem, AtMenuBottom`

  `TopMenuItem` and `AtMenuBottom` are now set automatically by the Menu Manager using the values returned in the `virtualMenuTop` and `virtualMenuBottom` fields of the `MenuTrackingData` structure passed to `kMenuDrawMsg` and `kMenuFindItemMsg`.

- `mbSaveLoc`

  This undocumented low-memory global was used by older menu definitions to store the bounding rect of the currently selected item and to avoid drawing glitches while the menu definition was scrolling the contents of a menu that had submenus. The Menu Manager now automatically sets the selected item bounds using the value returned in the itemRect field of the MenuTrackingData structure passed to kMenuFindItemMsg. In order to correctly support scrolling of menus with submenus, a menu definition should verify, before scrolling the menu contents, that no submenus of the scrolling menu are currently visible. A menu definition can use `GetMenuTrackingData` to verify this condition, as follows:

  ```
  Boolean SafeToScroll( MenuRef menuBeingScrolled )
   {
          MenuTrackingData lastMenuData;
          return GetMenuTrackingData( NULL, &lastMenuData ) ==  noErr
                              && lastMenuData.menu == menuBeingScrolled;
      }
  ```

  If `SafeToScroll` returns `false`, the menu definition should not scroll the menu.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

Data Types

HMenuBarHeader

Defines a list of hierarchical menus that have been inserted into a menu bar.

```
struct HMenuBarHeader {
    UInt16 lastHMenu;
    PixMapHandle menuTitleBits;
};
typedef struct HMenuBarHeader HMenuBarHeader;
```

Fields

`lastHMenu`
Offset from the start of the header to the last menu in the array of `HMenuBar` structures.

`menuTitleBits`
The saved bits behind the highlighted menu title. This value is undefined in menu bar handles returned by `GetNewMBar` (page 1290) or `GetMenuBar` (page 1268).

Discussion

The hierarchical portion of the menu bar follow the nonhierarchical portion in a menu bar handle. The hierarchical section consists of the `HMenuBarHeader` structure followed by an array of `HMenuBarMenu` (page 1355) structures.

You insert a hierarchical menu by specifying -1 for the `beforeID` parameter in `InsertMenu` (page 1294).

Availability

Available in Mac OS X v10.2 and later.

Declared In

`Menus.h`

HMenuBarMenu

Defines a hierarchical menu.

```
struct HMenuBarMenu {
    MenuRef menu;
    SInt16 reserved;
};
typedef struct HMenuBarMenu HMenuBarMenu;
```

Fields

`menu`
The menu.

`reserved`
Currently unused.

Availability

Available in Mac OS X v10.2 and later.

Declared In

`Menus.h`

MCEntry

Specifies a menu color information table

Not recommended

```
struct MCEntry {
    MenuID mctID;
    short mctItem;
    RGBColor mctRGB1;
    RGBColor mctRGB2;
    RGBColor mctRGB3;
    RGBColor mctRGB4;
    short mctReserved;
};
typedef struct MCEntry MCEntry;
typedef MCEntry * MCEntryPtr;
typedef MCEntry MCTable[1];
```

Fields

`mctID`

Defines, along with the `mctItem` field, whether the entry is a menu bar entry, a menu title entry, or a menu item entry. The `mctID` field contains either a menu ID or 0 (for a menu bar).

`mctItem`

Defines, along with the `mctID` field, whether the entry is a menu bar entry, a menu title entry, or a menu item entry. The `mctItem` field contains either a menu item number or 0 (for a menu bar or menu title).

`mctRGB1`

Specifies color information for the entry, as follows. For a menu bar entry, this value is the default color for menu titles. For a menu title entry, this value is the title color of a specific menu. For a menu item entry, this value is the mark color for a specific item.

`mctRGB2`

Specifies color information for the entry, as follows. For a menu bar entry, this value is the default background color of a displayed menu. For a menu title entry, this value is the default color for the menu bar. For a menu item entry, this value is the color for the text of a specific item.

`mctRGB3`

Specifies color information for the entry, as follows. For a menu bar entry, this value is the default color of items in a displayed menu. For a menu title entry, this value is the default color for items in a specific menu. For a menu item entry, this value is the color for the modifier of a specific item.

`mctRGB4`

Specifies color information for the entry, as follows. For a menu bar entry, this value is the default color of the menu bar. For a menu title entry, this value is the background color of a specific menu. For a menu item entry, this value is the background color of a specific menu.

`mctReserved`

Reserved.

Discussion

The menu color information table defines the standard color for the menu bar, menu titles, menu items, and the background color of a displayed menu. If you do not add any menu color entries to this table, the Menu Manager draws your menus using the current default colors. Using the menu color information table to define custom colors for your menus is not recommended with Appearance Manager 1.0 and later.

When the Appearance Manager is available and you are using standard menus, if you do not include a menu bar entry in your menu color information table, only the menu title color and menu item text color values from menu color entries are used. If you do include a menu bar entry in your menu color information table, all menu colors are used, and the menus revert to a standard System 7 appearance.

If you are creating your own custom menu definition function, all entries in the table are used.

You can add custom colors to your menus by adding entries to your application's menu color information table, using Menu Manager functions or by defining these entries in an 'mctb' resource. Note that the menu color information table uses a format different from the standard color table format.

The value of the `mctID` field in the last entry in a menu color information table is `mctLastIDIndic`, and the rest of the fields of the last entry are reserved. The Menu Manager automatically creates the last entry in a menu color information table; your application should not use the value `mctLastIDIndic` as the menu ID of a menu if you wish to add a menu color entry for it.

The contents of a menu color table entry structure are interpreted differently, depending upon the values of the `mctID` and `mctItem` fields. Depending upon the value of these fields, the `MCEntry` structure represents a menu bar entry, a menu title entry, a menu item entry, or the last entry.

A *menu bar entry* is defined by a menu color entry structure that contains 0 in both the `mctID` and `mctItem` fields. You can define only one menu bar entry in a menu color information table. If you don't provide a menu bar entry for your application's menu color information table, the Menu Manager uses the standard menu bar colors (black text on a white background), and it uses the standard colors for the other menu elements. You can provide a menu bar entry to specify default colors for the menu title, the background of a displayed menu, the items in a menu, and the menu bar. The color information fields for a menu bar entry are interpreted as follows:

- `mctRGB1` specifies the default color for menu titles. If a menu doesn't have a menu title entry, the Menu Manager uses the value in this field as the color of the menu title.
- `mctRGB2` specifies the default color for the background of a displayed menu. If a menu doesn't have a menu title entry, the Menu Manager uses the value in this field as the color of the menu's background when it is displayed.
- `mctRGB3` specifies the default color for the items in a displayed menu. If a menu item doesn't have a menu item entry or a default color defined in a menu title entry, the Menu Manager uses the value in this field as the color of the menu item.
- `mctRGB4` specifies the default color for the menu bar. If a menu doesn't have a menu bar entry (and doesn't have any menu title entries), the Menu Manager uses the standard colors for the menu bar.

A *menu title entry* is defined by a menu color entry structure that contains a menu ID in the `mctID` field and 0 in the `mctItem` field. You can define only one menu title entry for each menu. If you don't provide a menu title entry for a menu in your application's menu color information table, the Menu Manager uses the colors defined by the menu bar entry. If a menu bar entry doesn't exist, the Menu Manager uses the standard colors (black on white). You can provide a menu title entry to specify a color for the title and background of a specific menu and a default color for its items. The color information fields for a menu title entry are interpreted as follows:

- `mctRGB1` specifies the color for the menu title of the specified menu. If a menu doesn't have a menu title entry, the Menu Manager uses the default value defined in the menu bar entry.
- `mctRGB2` specifies the default color for the menu bar. If a menu color information table doesn't have a menu bar entry, the Menu Manager uses the value in this field as the color of the menu bar. If a menu bar entry already exists, the Menu Manager replaces the value in the mctRGB2 field of the menu title entry with the value defined in the mctRGB4 field of the menu bar entry.
- `mctRGB3` specifies the default color for the items in the menu. If a menu item doesn't have a menu item entry or a default color defined in a menu bar entry, the Menu Manager uses the value in this field as the color of the menu item.
- `mctRGB4` specifies the color for the background of the menu.

A *menu item entry* is defined by a menu color entry structure that contains a menu ID in the `mctID` field and an item number in the `mctItem` field. You can define only one menu item entry for each menu item. If you don't provide a menu item entry for an item in your application's menu color information table, the Menu Manager uses the colors defined by the menu title entry (or by the menu bar entry if the menu containing the item doesn't have a menu title entry). If neither a menu title entry nor a menu bar entry exists, the Menu Manager draws the mark, text, and modifier in black. You can provide a menu item entry to specify a color for the mark, text, and keyboard equivalent of a specific menu item. The color information fields for a menu item entry are interpreted as follows:

- `mctRGB1` specifies the color for the mark of the menu item. If a menu item doesn't have a menu item entry, the Menu Manager uses the default value defined in the menu title entry or the menu bar entry.
- `mctRGB2` specifies the color for the text of the menu item. If a menu item doesn't have a menu item entry, the Menu Manager uses the default value defined in the menu title entry or the menu bar entry. The Menu Manager also draws a black-and-white icon of a menu item using the same color as defined by the `mctRGB2` field. (Use a `'cicn'` resource to provide a menu item with a color icon.)
- `mctRGB3` specifies the color for the modifier of the menu item. If a menu item doesn't have a menu item entry, the Menu Manager uses the default value defined in the menu title entry or the menu bar entry.
- `mctRGB4` specifies the color for the background of the menu. If the menu color information table doesn't have a menu title entry for the menu this item is in, or doesn't have a menu bar entry, the Menu Manager uses the value in this field as the background color of the menu. If a menu title entry already exists, the Menu Manager replaces the value in the `mctRGB4` field of the menu item entry with the value defined in the `mctRGB4` field of the menu title entry (or with the `mctRGB2` field of the menu bar entry).

You can use the `GetMCInfo` (page 1266) function to get a copy of your application's menu color information table and the `SetMCEntries` (page 1326) function to set entries of your application's menu color information table, or you can provide `'mctb'` resources that define the color entries for your menus.

The `GetMenu` (page 1266), `GetNewMBar` (page 1290), and `ClearMenuBar` (page 1237) functions can also modify the entries in the menu color information table. The `GetMenu` function looks for an `'mctb'` resource with a resource ID equal to the value in the `menuID` parameter. If it finds one, it adds the entries to the application's menu color information table.

The `GetNewMBar` function builds a new menu color information table when it creates the new menu list. If you want to save the current menu color information table, call `GetMCInfo` before calling `GetNewMBar`.

The `ClearMenuBar` function reinitializes both the current menu list and the menu color information table.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Menus.h`

MDEFDrawData

Contains information needed to draw a menu.

```
struct MDEFDrawData {
    MenuTrackingData trackingData;
    void * context;
};
typedef struct MDEFDrawData MDEFDrawData;
typedef MDEFDrawData * MDEFDrawDataPtr;
```

Fields

`trackingData`

A data structure containing information about the menu to be drawn. Your menu definition should fill in the `virtualMenuTop` and `virtualMenuBottom` fields of this structure while drawing the menu.

`context`

The Core Graphics context that your menu definition should draw into. The Menu Manager flushes the context after returning from the menu definition.

Discussion

The Menu Manager passes this structure to your custom menu definition in the `whichItem` parameter of the `kMenuDrawMsg` message.

Availability

Available in Mac OS X v10.1 and later.

Declared In

`Menus.h`

MDEFDrawItemsData

Contains information about which menu items to redraw.

```
struct MDEFDrawItemsData {
    MenuItemIndex firstItem;
    MenuItemIndex lastItem;
    MenuTrackingData * trackingData;
    void * context;
};
typedef struct MDEFDrawItemsData MDEFDrawItemsData;
typedef MDEFDrawItemsData * MDEFDrawItemsDataPtr;
```

Fields

`firstItem`

The first item to draw.

`lastItem`

The last item to draw.

`trackingData`

Information about the menu's tracking state. The `virtualMenuTop` and `virtualMenuBottom` fields in this structure will be the most useful in handling the `DrawItems` message.

`context`

The Core Graphics drawing context that your menu definition should draw into. The Menu Manager flushes the context after returning from the menu definition.

Discussion

The Menu Manager passes this structure to your custom menu definition in the `whichItem` parameter of the `kMenuDrawItemsMsg` message.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Menus.h`

MDEFFindItemData

Contains information used to determine which item the user has currently selected.

```
struct MDEFFindItemData {
    MenuTrackingData trackingData;
    void * context;
};
typedef struct MDEFFindItemData MDEFFindItemData;
typedef MDEFFindItemData * MDEFFindItemDataPtr;
```

Fields

`trackingData`
A data structure containing information about the menu to be drawn. Your menu definition should fill in the `itemSelected`, `ItemUnderMouse`and `itemRect` fields of this structure after determining which item is under the specified point.

`context`
The Core Graphics context the menu definition should draw into if it needs to scroll the menu during the `kMenuFindItemMsg` message. The Menu Manager flushes the context after the menu definition returns.

Discussion
The Menu Manager passes this structure to your custom menu definition in the `whichItem` parameter of the `kMenuFindItemsMsg` message.

Availability
Available in Mac OS X v10.1 and later.

Declared In
`Menus.h`

MDEFHiliteItemData

Contains information about which menu items should be highlighted and unhighlighted as the user moves through the menus. .

```
struct MDEFHiliteItemData {
    MenuItemIndex previousItem;
    MenuItemIndex newItem;
    void * context;
};
typedef struct MDEFHiliteItemData MDEFHiliteItemData;
typedef MDEFHiliteItemData * MDEFHiliteItemDataPtr;
typedef MDEFHiliteItemData HiliteMenuItemData;
typedef MDEFHiliteItemDataPtr HiliteMenuItemDataPtr;
```

Fields

`previousItem`

The menu item that was previously selected. This item needs to be redrawn in an unhighlighted state. This parameter can be zero if no item was previously selected.

`newItem`

The menu item that is now selected. This item needs to be redrawn in a highlighted state. This parameter can be zero if no item is currently highlighted.

`context`

The Core Graphics context the menu definition should draw into. The Menu Manager flushes the context after the menu definition returns.

Discussion

This structure is used by menu definition functions, which receive a pointer to an `MDEFHiliteItemData` structure as the `whichItem` parameter during the `kMenuHiliteItemMsg` message.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Menus.h`

MenuBarHandle

A handle to a menu bar header.

```
typedef Handle MenuBarHandle;
```

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Menus.h`

MenuBarHeader

Defines a list of nonhierarchical menus that that have been placed in the menu bar.

```
struct MenuBarHeader {
    UInt16 lastMenu;
    SInt16 lastRight;
    SInt16 mbResID;
};
typedef struct MenuBarHeader MenuBarHeader;
```

Fields

`lastMenu`

Offset from the start of the header to the last menu in the array of `MenuBarMenu` (page 1362) structures, in bytes.

`lastRight`

The x-coordinate of the right edge of the rightmost menu, in global coordinates. This value is undefined in menu bar handles returned by `GetNewMBar` (page 1290) or `GetMenuBar` (page 1268).

`mbResID`

The MBDF resource ID. This value is undefined in menu bar handles returned by `GetNewMBar` (page 1290) or `GetMenuBar` (page 1268).

Discussion

This structure is contained within a menu bar handle (`MenuBarHandle`).

Availability

Available in Mac OS X v10.2 and later.

Declared In

`Menus.h`

MenuBarMenu

Defines a nonhierarchical menu.

```
struct MenuBarMenu {
    MenuRef menu;
    SInt16 menuLeft;
};
typedef struct MenuBarMenu MenuBarMenu;
```

Fields

`menu`

`menuLeft`

The x-coordinate of the left edge of the menu title, in global coordinates. This value is undefined in menu bar handles returned by `GetNewMBar` (page 1290) or `GetMenuBar` (page 1268).

Availability

Available in Mac OS X v10.2 and later.

Declared In

`Menus.h`

MenuCommand

Specifies a menu item's command ID.

```
typedef UInt32 MenuCommand;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
Menus.h

MenuCRsrc

Specifies a set of menu color table entries

Not recommended

```
struct MenuCRsrc {
    short numEntries;
    MCTable mcEntryRecs;
};
typedef struct MenuCRsrc MenuCRsrc;
typedef MenuCRsrc * MenuCRsrcPtr;
```

Fields
numEntries
mcEntryRecs

Availability
Available in Mac OS X v10.0 and later.

Declared In
Menus.h

MenuDefSpec

Defines the type of menu definition.

```
struct MenuDefSpec {
    MenuDefType defType
    union {
        MenuDefUPP defProc;
        struct {
                CFStringRef classID;
                EventRef initEvent;
                } view;
    } u;
};
typedef struct MenuDefSpec MenuDefSpec;
typedef MenuDefSpec * MenuDefSpecPtr;
```

Fields
defType
The type of menu definition. See "Menu Definition Type Constants" (page 1379) for a list of possible values.

`u.defproc`
: If the `defType` field is `kMenuDefProcPtr`, the menu definition is a older procedure pointer–based definition. This field then contains a UPP to the menu definition function.

`u.view.classID`
: If the `defType` field is `kMenuDefClassID`, the menu definition is HIView–based. This field then contains the ID of the HIView subclass that defines this menu.

`u.view.initEvent`
: If the `defType` field is `kMenuDefClassID`, the menu definition is HIView–based. This field then contains the initialization event for the HIView subclass if one exists. Otherwise, it is `NULL`.

Version Notes
HIView-based menu definitions are available in Mac OS X 10.3 and later.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Menus.h`

MenuDefUPP

Defines a universal procedure pointer to a menu definition function.

Not recommended

```
typedef MenuDefProcPtr MenuDefUPP;
```

Discussion
For more information, see the description of the `MenuDefProcPtr` (page 1349) callback.

Version Notes
In Mac OS X 10.3 and later, you should use HIView-based menu definitions instead.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Menus.h`

MenuHandle

Defines a menu reference.

```
typedef MenuRef MenuHandle;
```

Discussion
You should refer to menus using the `MenuRef` (page 1367) type instead.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Menus.h`

MenuID

Defines a menu ID.

```
typedef SInt16 MenuID;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Menus.h`

MenuItemDataRec

Used with the `SetMenuItemData` (page 1335) and `CopyMenuItemData` (page 1241) functions to get or change aspects of a menu item.

```
struct MenuItemDataRec {
    MenuItemDataFlags whichData;
    StringPtr text;
    UniChar mark;
    UniChar cmdKey;
    UInt32 cmdKeyGlyph;
    UInt32 cmdKeyModifiers;
    Style style;
    Boolean enabled;
    Boolean iconEnabled;
    UInt8 filler1;
    SInt32 iconID;
    UInt32 iconType;
    Handle iconHandle;
    MenuCommand cmdID;
    TextEncoding encoding;
    MenuID submenuID;
    MenuRef submenuHandle;
    SInt32 fontID;
    UInt32 refcon;
    OptionBits attr;
    CFStringRef cfText;
    Collection properties;
    UInt32 indent;
    UInt16 cmdVirtualKey;
};
typedef struct MenuItemDataRec MenuItemDataRec;
typedef MenuItemDataRec * MenuItemDataPtr;
```

Fields

`whichData`
The fields to be set or obtained. You pass a bit mask as specified by "Menu Item Data Flags" (page 1390) to indicate which values you want to get or set. The values themselves are set or populated in the fields that follow.

`text`
The menu item title, as an `Str255` string.

`mark`
The menu item's mark.

`cmdKey`
The menu item's command key. This can be either a character code or a virtual key code.

`cmdKeyGlyph`
The menu item's command key glyph.

`cmdKeyModifiers`
The menu item's command key modifiers.

`style`
The menu item's QuickDraw text style.

`enabled`
The menu item's enable state.

`iconEnabled`
The enable state of the menu item icon.

`filler1`
Reserved.

`iconID`
The icon resource ID of the menu item.

`iconHandle`
The icon handle of the menu item.

`cmdID`
The command ID for the menu item.

`encoding`
The text encoding of the menu item.

`submenuID`
The menu ID of the submenu associated with this menu item.

`submenuHandle`
The MenuRef of the submenu associated with this menu item.

`fontID`
The font ID for the menu item.

`refcon`
The reference constant associated with this menu item.

`attr`
The menu item's attributes.

`cfText`
The menu item's title, as a Core Foundation string.

`properties`
A collection holding the menu item's properties.

`indent`
The menu item's indent level.

`cmdVirtualKey`
The menu item's virtual key.

Discussion
When using this structure with `CopyMenuItemData` (page 1241) or `SetMenuItemData` (page 1335), the caller must first set the `whichData` field to a combination of `MenuItemDataFlags` indicating which specific data should be retrieved or set. Some fields also require initialization before calling `CopyMenuItemData` (page 1241); see "Menu Item Data Flags" (page 1390) for details.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Menus.h`

MenuItemID

Defines a menu item.

```
typedef UInt32 MenuItemID;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Menus.h`

MenuItemIndex

Specifies a particular menu item in a menu.

```
typedef UInt16 MenuItemIndex;
```

Discussion
The menu item index is one-based, so item 1 is the first menu item, item 2 is the second, and so on. Some functions allow you to pass an index of zero, which specifies the menu itself.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Menus.h`

MenuRef

Defines a menu.

```
typedef struct OpaqueMenuRef * MenuRef;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Menus.h`

MenuTrackingData

Contains information about the menu currently being displayed during menu tracking.

```
struct MenuTrackingData {
    MenuRef menu;
    MenuItemIndex itemSelected;
    MenuItemIndex itemUnderMouse;
    Rect itemRect;
    SInt32 virtualMenuTop;
    SInt32 virtualMenuBottom;
};
typedef struct MenuTrackingData MenuTrackingData;
typedef MenuTrackingData * MenuTrackingDataPtr;
```

Fields

`menu`

The menu.

`itemSelected`

The index of the menu item that is currently selected. This field should either match the `itemUnderMouse` field, or should be zero if the item under the mouse cannot be selected (for example, if the item is disabled).

`itemUnderMouse`

The index of the menu item that is currently under the mouse.

`itemRect`

The `Rect` that defines the area of the menu item currently under the mouse. Note that the `itemRect` field is not supported in CarbonLib and is always set to be empty. It is, however, supported in Mac OS X.

`virtualMenuTop`

The y-coordinate of the actual top of the menu. Because the user can scroll the menu, the menu top coordinate may be above the top of the visible screen (in which case it has a negative value).

`virtualMenuBottom`

The y-coordinate of the actual bottom of the menu. Because the user can scroll the menu, the menu bottom coordinate may be below the bottom of the visible screen

Discussion

You can call `GetMenuTrackingData` (page 1288) to obtain this structure during menu tracking.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Menus.h`

Constants

Contextual Menu Gestalt Selector Constants

Determine which contextual menu features are available.

```
enum {
    gestaltContextualMenuAttr = 'cmnu',
    gestaltContextualMenuUnusedBit = 0,
    gestaltContextualMenuTrapAvailable = 1,
    gestaltContextualMenuHasAttributeAndModifierKeys = 2,
    gestaltContextualMenuHasUnicodeSupport = 3
};
```

Constants

`gestaltContextualMenuAttr`
The `Gestalt` selector passed to the `Gestalt` function to determine whether contextual menu functions are available. Produces a value whose bits you should test to determine whether the contextual menu functions are available.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`gestaltContextualMenuUnusedBit`
Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`gestaltContextualMenuTrapAvailable`
If this bit is set, the contextual menu functions are available to 68K applications. If this bit is not set, these functions are not available to 68K applications.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`gestaltContextualMenuHasAttributeAndModifierKeys`
The contextual menu supports attributes and modifier keys.

Available in Mac OS X v10.2 and later.

Declared in `Menus.h`.

`gestaltContextualMenuHasUnicodeSupport`
The contextual menu supports Unicode text.

Available in Mac OS X v10.2 and later.

Declared in `Menus.h`.

Discussion

Mac OS X and all versions of Mac OS that shipped with CarbonLib support contextual menus, so you need to check only to see if certain features are available.

Contextual Menu Help Type Constants

Indicates what types of contextual menu help is available.

```
enum {
    kCMHelpItemNoHelp = 0,
    kCMHelpItemAppleGuide = 1,
    kCMHelpItemOtherHelp = 2,
    kCMHelpItemRemoveHelp = 3
};
```

Constants

`kCMHelpItemNoHelp`
The application does not support any help. The Menu Manager will put an appropriate help string into the menu and disable it.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kCMHelpItemAppleGuide`
The application supports Apple Guide help. The Menu Manager will put the name of the main Guide file into the menu and enable it.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kCMHelpItemOtherHelp`
The application supports some other form of help. In this case, the application must also pass a valid string into the `inHelpItemString` parameter of `ContextualMenuSelect`. This string will be the text of the help item in the menu, and the help item will be enabled.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kCMHelpItemRemoveHelp`
The application does not support any help. The Menu Manager will remove the Help item from the contextual menu.

Available in CarbonLib 1.6 and Mac OS X and later. Note however, that in CarbonLib, this constant is equivalent to `kCMItemNoHelp`, which only disables the Help item.

Available in Mac OS X v10.2 and later.

Declared in `Menus.h`.

Discussion

You can pass these constants in the `inHelpType` parameter of the function `ContextualMenuSelect` (page 1239) to specify the kind of help the application supports. Contextual menu help type constants are available with Appearance Manager 1.0 and later.

Contextual Menu Selection Type Constants

Indicates the type of item the user selected from a contextual menu.

```
enum {
    kCMNothingSelected = 0,
    kCMMenuItemSelected = 1,
    kCMShowHelpSelected = 3
};
```

Constants

`kCMNothingSelected`

The user did not choose an item from the contextual menu and the application should do no further processing of the event.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kCMMenuItemSelected`

The user chose one of the application's items from the menu. The application can examine the `outMenuID` and `outMenuItem` parameters of `ContextualMenuSelect` to see what the menu selection was, and it should then handle the selection appropriately.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kCMShowHelpSelected`

The user chose the Help item from the menu. The application should open an Apple Help database to a section appropriate for the selection. If the application supports some other form of help, it should be presented instead.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

Discussion

These constants are returned in the `outUserSelectionType` parameter of the function `ContextualMenuSelect` (page 1239) to specify what the user selected from the contextual menu. Contextual menu selection type constants are available with Appearance Manager 1.0 and later.

Contextual Menu Item Content Constants

Specify contents of menu items in contextual menus.

```
enum {
    keyContextualMenuName = 'pnam',
    keyContextualMenuCommandID = 'cmcd',
    keyContextualMenuSubmenu = 'cmsb',
    keyContextualMenuAttributes = 'cmat',
    keyContextualMenuModifiers = 'cmmd'
};
```

Constants

`keyContextualMenuName`

The menu item text. In Mac OS X v10.1 and earlier, the data format must be either `typeChar` or `typeIntlText`. In Mac OS X v10.2 and later, you can also specify `typeStyledText`, `typeAEText`, `typeUnicodeText`, and `typeCFStringRef`. Note that if you specify `typeCFStringRef`, the Menu Manager releases the CFString reference after displaying the menu. If you need to hold onto the CFString reference, you should retain it before inserting it into the Apple event record (`AERecord`).

Available in Mac OS X v10.2 and later.

Declared in `Menus.h`.

`keyContextualMenuCommandID`
: The menu item command ID. The data format for this parameter must be `typeLongInteger`.

  Available in Mac OS X v10.2 and later.

  Declared in `Menus.h`.

`keyContextualMenuSubmenu`
: The submenu of the menu item. You typically use this with the Apple Event Manager function `AEPutDesc` to add an entire `AEDesc` record (which contains the submenu) as the parameter data.

  Available in Mac OS X v10.2 and later.

  Declared in `Menus.h`.

`keyContextualMenuAttributes`
: Specifies the menu item attributes. The data format for this parameter must be `typeLongInteger`.

  Available in Mac OS X v10.2 and later.

  Declared in `Menus.h`.

`keyContextualMenuModifiers`
: Specifies the modifer keys for the menu item. The data format for this parameter must be `typeLongInteger`. By using this parameter along with the `keyContextualMenuAttributes` parameter, you can create dynamic contextual menu items that change according to the state of the modifier keys.

  Declared in `Menus.h`.

  Available in Mac OS X v10.2 and later.

Discussion
You use these keyword constants to specify parameters in an Apple Event record (`AERecord`) that defines a contextual menu item. Typically you assign these values in your ExamineContext method of a contextual menu plugin.

Custom Menu Definition Message Constants

Indicate messages used for non-HIView–based custom menu definitions.

```
enum {
    kMenuDrawMsg = 0,
    kMenuSizeMsg = 2,
    kMenuPopUpMsg = 3,
    kMenuCalcItemMsg = 5,
    kMenuThemeSavvyMsg = 7,
    kMenuInitMsg = 8,
    kMenuDisposeMsg = 9,
    kMenuFindItemMsg = 10,
    kMenuHiliteItemMsg = 11,
    kMenuDrawItemsMsg = 12,
    mDrawMsg = kMenuDrawMsg,
    mSizeMsg = kMenuSizeMsg,
    mPopUpMsg = kMenuPopUpMsg,
    mCalcItemMsg = kMenuCalcItemMsg
};
```

Constants

`kMenuDrawMsg`
Draw the menu in the specified rectangle.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuSizeMsg`
Calculate the dimensions of the menu rectangle and store them in the menu structure.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuPopUpMsg`
Calculate the dimensions of the pop-up menu.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuCalcItemMsg`
Calculate the dimensions of the specified menu item.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuThemeSavvyMsg`
Identify whether your menu definition function is theme-compliant. If so, your menu definition function should respond by passing back `kThemeSavvyMenuResponse` in the `whichItem` parameter. The Menu Manager then draws the menu background as appropriate for the current theme.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuInitMsg`
Perform any initializations required for the menu. Return an error code in `*whichItem` to indicate success or failure.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuDisposeMsg`
Dispose of the menu.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuFindItemMsg`
Determine the item underneath the mouse.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuHiliteItemMsg`
Highlight the specified menu item.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuDrawItemsMsg`
Draw the specified menu items.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`mDrawMsg`
Same as `kMenuDrawMsg`. Obsolete.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`mSizeMsg`
Same as `kMenuSizeMsg`. Obsolete.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`mPopUpMsg`
Same as `kMenuPopUpMsg`. Obsolete.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`mCalcItemMsg`
Same as `kMenuCalcItemMsg`. Obsolete.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

Discussion
For applications running on Mac OS X v10.3 and later, Apple recommends creating custom menu definitions using HIView subclasses rather than MDEF messages. See Introducing HIView for more information.

The Menu Manager passes a value defined by one of these constants in the `message` parameter of your menu definition function specifying what action your function must perform. Other messages are reserved for internal use by Apple Computer, Inc. For more information on how to respond to the various messages, see `MenuDefProcPtr` (page 1349).

Obsolete Menu Definition Messages

Older MDEF messages.

```
enum {
    mChooseMsg = 1,
    mDrawItemMsg = 4,
    kMenuChooseMsg = mChooseMsg,
    kMenuDrawItemMsg = mDrawItemMsg
};
```

Constants

`mChooseMsg`

Determine whether the specified mouse location is in an enabled menu item, and highlight or unhighlight the menu item appropriately. Carbon `MDEF`s must replace `mChooseMsg` with the new messages `kMenuFindItemMsg` and `kMenuHiliteItemMsg`.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`mDrawItemMsg`

Draw the specified menu item in the specified rectangle. `mDrawItemMsg` was used by the popup menu control in versions of the Mac OS prior to Mac OS 8.5, but is no longer used.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuChooseMsg`

Same as `mChooseMsg`.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuDrawItemMsg`

Same as `mDrawItemMsg`.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

Hierarchical Font Menu Option Constant

Indicates that the font menu should be hierarchical.

```
enum {
    kHierarchicalFontMenuOption = 0x00000001
};
```

Constants

`kHierarchicalFontMenuOption`

The parent menu displays the font families, with font variations (plain, bold, and so on) displayed in submenus.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

Discussion

Use this option constant when calling the `CreateStandardFontMenu` (page 1247) function.

Menu Attribute Constants

Specify menu attributes.

```
typedef UInt32 MenuAttributes;
enum {
    kMenuAttrExcludesMarkColumn = (1 << 0),
    kMenuAttrAutoDisable = (1 << 2),
    kMenuAttrUsePencilGlyph = (1 << 3),
    kMenuAttrHidden = (1 << 4),
    kMenuAttrCondenseSeparators = (1 << 5),
    kMenuAttrDoNotCacheImage = (1 << 6),
    kMenuAttrDoNotUseUserCommandKeys = (1 << 7)
};
```

Constants

`kMenuAttrExcludesMarkColumn`
No column space is allocated for the mark character when this menu is drawn.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuAttrAutoDisable`
The menu title is automatically disabled when all of its menu items are disabled.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuAttrUsePencilGlyph`
Use the pencil glyph from the Keyboard font (`kMenuPencilGlyph`) to draw the control modifier keys when drawing keyboard equivalents. Typically used only for Japanese input method menus.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuAttrHidden`
Do not draw the menu title, even when the menu is inserted in the menu bar. This attribute is useful for specifying keyboard equivalent commands that don't correspond with visible menu items. That is, you can add command key equivalents to to menu items and keep the menu itself from appearing in the menu.

Declared in `Menus.h`.

Available in Mac OS X v10.2 and later.

`kMenuAttrCondenseSeparators`
Hides extra separators to avoid blank spaces in a menu. That is, if separators exists at the beginning or end of a menu, or if multiple contiguous separators exist, the Menu Manager marks the extra separator items as hidden. The Menu Manager checks for extra separators whenever it recalculates the menu size.

Declared in `Menus.h`.

Available in Mac OS X v10.3 and later.

`kMenuAttrDoNotCacheImage`
Disables automatic caching of the menu image. Normally, the Menu Manager caches images of all HIView–based menus. (All standard menus are drawn using HIViews in Mac OS X v10.3 and later.) If you specify this attribute, the Menu Manager draws the menu each time it is displayed.

Declared in `Menus.h`.

Available in Mac OS X v10.3 and later.

`kMenuAttrDoNotUseUserCommandKeys`

Disables substitution of command key equivalents from the `NSUserKeysEquivalents` dictionary. By default, the Menu Manager checks for matches in the dictionary for every menu item. Note that this attribute is effective only if you set it when you create the menu; After the Menu Manager searches the dictionary and sets the user command keys (which occurs in the `CalcMenuSize` (page 1234), `GetMenuItemCommandKey` (page 1276), `GetItemCmd` (page 1262) and before command key matching), you cannot retrieve the original command keys. Similarly, clearing this attribute does not restore the original command keys.

Declared in `Menus.h`.

Available in Mac OS X v10.3 and later.

Discussion

Menu attributes control behavior of the entire menu. They are used with the `ChangeMenuAttributes` (page 1235) and `GetMenuAttributes` (page 1268).

Menu Item Attribute Constants

Specify attributes for menu items.

```
typedef UInt32 MenuItemAttributes;
enum {
    kMenuItemAttrDisabled = (1 << 0),
    kMenuItemAttrIconDisabled = (1 << 1),
    kMenuItemAttrSubmenuParentChoosable = (1 << 2),
    kMenuItemAttrDynamic = (1 << 3),
    kMenuItemAttrNotPreviousAlternate = (1 << 4),
    kMenuItemAttrHidden = (1 << 5),
    kMenuItemAttrSeparator = (1 << 6),
    kMenuItemAttrSectionHeader = (1 << 7),
    kMenuItemAttrIgnoreMeta = (1 << 8),
    kMenuItemAttrAutoRepeat = (1 << 9),
    kMenuItemAttrUseVirtualKey = (1 << 10),
    kMenuItemAttrCustomDraw = (1 << 11),
    kMenuItemAttrIncludeInCmdKeyMatching = (1 << 12),
    kMenuItemAttrAutoDisable = (1 << 13),
    kMenuItemAttrUpdateSingleItem = (1 << 14)
};
```

Constants

`kMenuItemAttrDisabled`

This menu item is disabled.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuItemAttrIconDisabled`

This menu item's icon is disabled.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuItemAttrSubmenuParentChoosable`

The user can select the parent item of a submenu.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuItemAttrDynamic`

This menu item changes dynamically based on the state of the modifier keys. For example, holding down the command key might change the menu item from “Select widget” to “Select all widgets.”

When a menu item has alternate dynamic states, you should group them together sequentially in the menu and assign them the same command key. A collection of menu item alternates is called a dynamic group.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuItemAttrNotPreviousAlternate`

This item is not part of the same dynamic group as the previous item. The Menu Manager determines which menu items belong to a dynamic group by examining the command keys of each item; if a menu item has the same command key as the previous item, the Menu Manager considers it to be part of the same dynamic group.

However, in some cases you may have sequential items with the same command key (or no command key at all) that should not be considered part of the same dynamic group. To distinguish the separation, you should set this flag for the first menu item in the new group.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuItemAttrHidden`

The menu item is not drawn when displaying the menu. The item is also not included in command-key matching unless the `kMenuItemAttrDynamic` or `kMenuItemIncludeInCmdKeyMatching` attribute is set.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuItemAttrSeparator`

The menu item is a separator; any text in the item is ignored.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuItemAttrSectionHeader`

The menu item is a menu section header; this item is disabled and not selectable.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuItemAttrIgnoreMeta`

Ignore the dash (-) metacharacter in this menu item. Dashes at the beginning of a menu item title traditionally signify that the menu item is a separator. However, in some cases you might want to display the dash in the title (for example, if you wanted the menu item to read “-40 degrees F.”)

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuItemAttrAutoRepeat`

The `IsMenuKeyEvent` (page 1305) event function recognizes this menu item when it receives an autorepeat keyboard event.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuItemAttrUseVirtualKey`
When `MenuEvent` (page 1309) and `IsMenuKeyEvent` (page 1305) compare this menu item's keyboard equivalent against a keyboard event, they use the item's virtual keycode equivalent rather than its character code equivalent.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuItemAttrCustomDraw`
This is a custom menu item. Setting this attribute causes custom menu item drawing Carbon events to be sent to your application. Available in CarbonLib 1.4 and Mac OS X v10.1 and later.

Available in Mac OS X v10.1 and later.

Declared in `Menus.h`.

`kMenuItemAttrIncludeInCmdKeyMatching`
If this attribute is set, functions such as `MenuKey` (page 1311), `MenuEvent` (page 1309) and `IsMenuKeyEvent` (page 1305) examine this menu item during command key matching. Typically, visible items are examined and hidden items (unless they have the `kMenuItemAttrDynamic` attribute set) are ignored during command key matching. However, by setting this attribute, you can force hidden items to be included in the matching. Available in CarbonLib 1.6 and Mac OS X v10.2 and later.

Available in Mac OS X v10.2 and later.

Declared in `Menus.h`.

`kMenuItemAttrAutoDisable`
Disables the menu item if it does not respond to the `kEventCommandUpdateStatus` event . That is, if no `kEventCommandUpdateStatus` handler is installed on this item, or if all the handlers installed for the update event return `eventNotHandledErr`, this item is automatically disabled. This attribute is useful if your application uses the `kEventCommandUpdateStatus` event to enable menu items; for example you no longer have to install an update status handler on the application target to disable menu items when there are no document windows open.

Available in Mac OS X v10.3 and later.

Declared in `Menus.h`.

`kMenuItemAttrUpdateSingleItem`
Update only the menu item that matches when searching available command keys. Normally when the Menu Manager does command key matching, it sends a `kEventMenuEnableItems` event to the menu containing the matching item and then sends a `kEventCommandUpdateStatus` to each item in the menu. Doing so can be inefficient, since in most cases only the item that matches needs to be updated. By setting this attribute, only the matching item receives the update event and `kEventMenuEnableItems` is not sent to the menu. If your application enables menu items solely through `kEventCommandUpdateStatus` event handlers, you should set this attribute for your menu items.

Declared in `Menus.h`.

Available in Mac OS X v10.3 and later.

Discussion
Menu item attributes control behavior of individual menu items. They are used with the `GetMenuItemAttributes` (page 1275) and `ChangeMenuItemAttributes` (page 1235) APIs.

Menu Definition Type Constants

Indicate the type of menu definition being used.

```
enum {
    kMenuDefProcPtr = 0,
    kMenuDefClassID = 1
};
typedef UInt32 MenuDefType;
```

Constants

`kMenuDefProcPtr`

A custom menu definition using the older MDEF messaging model.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuDefClassID`

A custom menu definition using an HIView subclass.

Available in Mac OS X v10.3 and later.

Declared in `Menus.h`.

Menu Definition Feature Constants

Indicate menu definition features.

```
enum {
    kThemeSavvyMenuResponse = 0x7473
};
```

Constants

`kThemeSavvyMenuResponse`

Indicates that the menu is Appearance theme–savvy.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

Discussion

The Menu Manager may pass the `kMenuThemeSavvyMsg` constant in the `message` parameter of your menu definition function to determine if your custom menu is theme-savvy (that is, whether it draws using Appearance Manager functions). In response, your menu definition function may respond with this flag in the `whichItem` parameter.

Menu Definition IDs

Specify options used in menu item functions.

```
enum {
    textMenuProc = 0,
    hMenuCmd = 27,
    hierMenu = -1,
    kInsertHierarchicalMenu = -1,
};
```

Constants

`textMenuProc`

The menu definition ID for menus that are not Appearance-compliant. When mapping is enabled, this constant is mapped to `kMenuStdMenuProc`, its Appearance-compliant equivalent. Not normally used.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`hMenuCmd`

Deprecated. Use `SetMenuItemHierarchicalMenu` (page 1337) or `SetMenuItemHierarchicalID` (page 1336) to specify a hierarchical menu instead.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`hierMenu`

Deprecated. Use `kInsertHierarchicalMenu` instead.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kInsertHierarchicalMenu`

Used with `InsertMenu` (page 1294) to insert a submenu or pop-up menu into the submenu portion of the current menu list.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kHIMenuAppendItem`

Pass to `InsertMenuItem` (page 1295), `InsertMenuItemText` (page 1296), or `InsertMenuItemTextWithCFString` (page 1296) to indicate that the new menu item should be added to the end of the menu. Note that you can simply call `AppendMenu` (page 1229), `AppendMenuItemText` (page 1231), or `AppendMenuItemTextWithCFString` (page 1231) instead.

Available in Mac OS X v10.3 and later.

Declared in `Menus.h`.

Discussion

A menu definition ID is supplied to the menu resource or a menu-creation function such as `NewMenu` to specify which menu definition function to use in creating the menu. The menu definition ID contains the resource ID of the menu definition function.

Menu Event Option Constants

Specify options when attempting to match a keyboard event to a menu item.

```
typedef UInt32 MenuEventOptions;
enum {
    kMenuEventIncludeDisabledItems = 0x0001,
    kMenuEventQueryOnly = 0x0002,
    kMenuEventDontCheckSubmenus = 0x0004
};
```

Constants

`kMenuEventIncludeDisabledItems`

Disabled items are examined for a match.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuEventQueryOnly`

Don't highlight the menu title if a match is found.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuEventDontCheckSubmenus`

Don't search the submenus of the starting menu when looking for a match.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

Discussion

Menu event options control how the menus are searched for an item matching a particular keyboard event. They are used with the `IsMenuKeyEvent` (page 1305) API.

Menu Glyph Constants

Specify menu glyphs.

```
enum {
     kMenuNullGlyph = 0x00,
     kMenuTabRightGlyph = 0x02,
     kMenuTabLeftGlyph = 0x03,
     kMenuEnterGlyph = 0x04,
     kMenuShiftGlyph = 0x05,
     kMenuControlGlyph = 0x06,
     kMenuOptionGlyph = 0x07,
     kMenuSpaceGlyph = 0x09,
     kMenuDeleteRightGlyph = 0x0A,
     kMenuReturnGlyph = 0x0B,
     kMenuReturnR2LGlyph = 0x0C,
     kMenuNonmarkingReturnGlyph = 0x0D,
     kMenuPencilGlyph = 0x0F,
     kMenuDownwardArrowDashedGlyph = 0x10,
     kMenuCommandGlyph = 0x11,
     kMenuCheckmarkGlyph = 0x12,
     kMenuDiamondGlyph = 0x13,
     kMenuAppleLogoFilledGlyph = 0x14,
     kMenuParagraphKoreanGlyph = 0x15,
     kMenuDeleteLeftGlyph = 0x17,
     kMenuLeftArrowDashedGlyph = 0x18,
     kMenuUpArrowDashedGlyph = 0x19,
     kMenuRightArrowDashedGlyph = 0x1A,
     kMenuEscapeGlyph = 0x1B,
     kMenuClearGlyph = 0x1C,
     kMenuLeftDoubleQuotesJapaneseGlyph = 0x1D,
     kMenuRightDoubleQuotesJapaneseGlyph = 0x1E,
     kMenuTrademarkJapaneseGlyph = 0x1F,
     kMenuBlankGlyph = 0x61,
     kMenuPageUpGlyph = 0x62,
     kMenuCapsLockGlyph = 0x63,
     kMenuLeftArrowGlyph = 0x64,
     kMenuRightArrowGlyph = 0x65,
     kMenuNorthwestArrowGlyph = 0x66,
     kMenuHelpGlyph = 0x67,
     kMenuUpArrowGlyph = 0x68,
     kMenuSoutheastArrowGlyph = 0x69,
     kMenuDownArrowGlyph = 0x6A,
     kMenuPageDownGlyph = 0x6B,
     kMenuAppleLogoOutlineGlyph = 0x6C,
     kMenuContextualMenuGlyph = 0x6D,
     kMenuPowerGlyph = 0x6E,
     kMenuF1Glyph = 0x6F,
     kMenuF2Glyph = 0x70,
     kMenuF3Glyph = 0x71,
     kMenuF4Glyph = 0x72,
     kMenuF5Glyph = 0x73,
     kMenuF6Glyph = 0x74,
     kMenuF7Glyph = 0x75,
     kMenuF8Glyph = 0x76,
     kMenuF9Glyph = 0x77,
     kMenuF10Glyph = 0x78,
     kMenuF11Glyph = 0x79,
     kMenuF12Glyph = 0x7A,
     kMenuF13Glyph = 0x87,
     kMenuF14Glyph = 0x88,
     kMenuF15Glyph = 0x89,
```

```
    kMenuControlISOGlyph = 0x8A,
    kMenuEjectGlyph = 0x8C
};
```

Constants

`kMenuNullGlyph`
The null character. Note that this glyph has no visible representation (that is, nothing appears in the menu).

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuTabRightGlyph`
The Tab-to-the-right key. Used in left to right script systems.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuTabLeftGlyph`
The Tab-to-the-left key. Used in right to left script systems.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuEnterGlyph`
The Enter key.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuShiftGlyph`
The Shift key.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuControlGlyph`
The Control key.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuOptionGlyph`
The Option key.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuSpaceGlyph`
The Space bar. Note that this glyph has no visible representation (that is, nothing appears in the menu).

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuDeleteRightGlyph`
The Delete-to-the-right key. Used in right-to-left script systems.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuReturnGlyph`
The Return key for left-to-right script systems.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuReturnR2LGlyph`
The Return key for right-to-left script systems.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuNonmarkingReturnGlyph`
The nonmarking Return key. Note that this glyph has no visible representation (that is, nothing appears in the menu).

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuPencilGlyph`
The Pencil key.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuDownwardArrowDashedGlyph`
The downward dashed arrow key.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuCommandGlyph`
The Command key.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuCheckmarkGlyph`
The Check mark key.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuDiamondGlyph`
The diamond mark.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuAppleLogoFilledGlyph`
The filled Apple logo.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuParagraphKoreanGlyph`
Unassigned. (Paragraph glyph in Korean)

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuDeleteLeftGlyph`
The Delete-to-the-left key.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuLeftArrowDashedGlyph`
The dashed left arrow key.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuUpArrowDashedGlyph`
The dashed up arrow key.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuRightArrowDashedGlyph`
The dashed right arrow key.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuEscapeGlyph`
The Escape key.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuClearGlyph`
The Clear key.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuLeftDoubleQuotesJapaneseGlyph`
Unassigned. (Left double quotation marks in Japanese)
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuRightDoubleQuotesJapaneseGlyph`
Unassigned (Right double quotation marks in Japanese)
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuTrademarkJapaneseGlyph`
Unassigned. (Trademark in Japanese)
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuBlankGlyph`
The blank key.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuPageUpGlyph`
The Page Up key.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuCapsLockGlyph`
The Caps Lock key.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuLeftArrowGlyph`
The left arrow key.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuRightArrowGlyph`
The right arrow key.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuNorthwestArrowGlyph`
The northwest arrow key
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuHelpGlyph`
The Help key.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuUpArrowGlyph`
The up arrow key.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuSoutheastArrowGlyph`
The southeast arrow key.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuDownArrowGlyph`
The down arrow key.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuPageDownGlyph`
The Page Down key.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuAppleLogoOutlineGlyph`
The outlined Apple logo.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuContextualMenuGlyph`
The contextual menu key
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuPowerGlyph`
The power key (that is, the startup key).
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuF1Glyph`
The F1 key.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuF2Glyph`
The F2 key.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuF3Glyph`
The F3 key.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuF4Glyph`
The F4 key.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuF5Glyph`
The F5 key.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuF6Glyph`
The F6 key.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuF7Glyph`
The F7 key.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuF8Glyph`
The F8 key.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuF9Glyph`
The F9 key.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuF10Glyph`
The F10 key.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuF11Glyph`
The F11 key.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuF12Glyph`
The F12 key.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuF13Glyph`
The F13 key.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuF14Glyph`
The F14 key.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuF15Glyph`
The F15 key.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuControlISOGlyph`
The ISO standard control key.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuEjectGlyph`
The Eject key (available in Mac OS X v10.2 and later).
Available in Mac OS X v10.2 and later.
Declared in `Menus.h`.

Discussion
Use these constants with `GetMenuItemKeyGlyph` (page 1280) and `SetMenuItemKeyGlyph` (page 1339).

Menu Item Data Flags

Indicate which fields of a `MenuItemDataRec` structure are to be copied or set.

```
enum {
    kMenuItemDataText = (1 << 0),
    kMenuItemDataMark = (1 << 1),
    kMenuItemDataCmdKey = (1 << 2),
    kMenuItemDataCmdKeyGlyph = (1 << 3),
    kMenuItemDataCmdKeyModifiers = (1 << 4),
    kMenuItemDataStyle = (1 << 5),
    kMenuItemDataEnabled = (1 << 6),
    kMenuItemDataIconEnabled = (1 << 7),
    kMenuItemDataIconID = (1 << 8),
    kMenuItemDataIconHandle = (1 << 9),
    kMenuItemDataCommandID = (1 << 10),
    kMenuItemDataTextEncoding = (1 << 11),
    kMenuItemDataSubmenuID = (1 << 12),
    kMenuItemDataSubmenuHandle = (1 << 13),
    kMenuItemDataFontID = (1 << 14),
    kMenuItemDataRefcon = (1 << 15),
    kMenuItemDataAttributes = (1 << 16),
    kMenuItemDataCFString = (1 << 17),
    kMenuItemDataProperties = (1 << 18),
    kMenuItemDataIndent = (1 << 19),
    kMenuItemDataCmdVirtualKey = (1 << 20),
    kMenuItemDataAllDataVersionOne = 0x000FFFFF,
    kMenuItemDataAllDataVersionTwo = kMenuItemDataAllDataVersionOne
| kMenuItemDataCmdVirtualKey
};
enum {
    kMenuItemDataAllData = kMenuItemDataAllDataVersionTwo
};
typedef UInt64 MenuItemDataFlags;
```

Constants

`kMenuItemDataText`

Set or return the `Str255` text of a menu using the `MenuItemDataRec.text` field. If getting the text, the text field must be initialized with a pointer to a `Str255` variable before calling `CopyMenuItemData`. If both `kMenuItemDataText` and `kMenuItemCFString` are set on entry to `CopyMenuItemData`, the API will determine whether the menu text was most recently set using a `Str255` or CFString, and return only that text format; the flags value for the other format will be cleared. Valid for both menu items and the menu title (if item number is 0).

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuItemDataMark`

Set or return the mark character of a menu item using the `MenuItemDataRec.mark` field. Valid only for menu items.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuItemDataCmdKey`
: Set or return the command key of a menu using the `MenuItemDataRec.cmdKey` field. Valid only for menu items.

  Available in Mac OS X v10.0 and later.

  Declared in `Menus.h`.

`kMenuItemDataCmdKeyGlyph`
: Set or return the command key glyph of a menu using the `MenuItemDataRec.cmdKeyGlyph` field. Valid only for menu items.

  Available in Mac OS X v10.0 and later.

  Declared in `Menus.h`.

`kMenuItemDataCmdKeyModifiers`
: Set or return the command key modifiers of a menu using the `MenuItemDataRec.cmdKeyModifiers` field. Valid only for menu items.

  Available in Mac OS X v10.0 and later.

  Declared in `Menus.h`.

`kMenuItemDataStyle`
: Set or return the QuickDraw text style of a menu item using the `MenuItemDataRec.style` field. Valid only for menu items.

  Available in Mac OS X v10.0 and later.

  Declared in `Menus.h`.

`kMenuItemDataEnabled`
: Set or return the enable state of a menu using the `MenuItemDataRec.enabled` field. Valid for both menu items and the menu itself (if the item number is zero).

  Available in Mac OS X v10.0 and later.

  Declared in `Menus.h`.

`kMenuItemDataIconEnabled`
: Set or return the enable state of the menu item icon using the `MenuItemDataRec.iconEnabled` field. Valid only for menu items.

  Available in Mac OS X v10.0 and later.

  Declared in `Menus.h`.

`kMenuItemDataIconID`
: Set or return the icon resource ID of the menu item icon using the `MenuItemDataRec.iconID` field. Valid only for menu items.

  Available in Mac OS X v10.0 and later.

  Declared in `Menus.h`.

`kMenuItemDataIconHandle`

Set or return the icon handle of a menu item using the `MenuItemDataRec.iconType` and `MenuItemDataRec.iconHandle` field. You must initialize both fields if you are setting the handle; both fields are returned when obtaining the handle.

The `iconType` field can contain one of the following constants: `kMenuIconType`, `kMenuShrinkIconType`, `kMenuSmallIconType`, `kMenuColorIcontype`, `kMenuIconSuiteType`, or `kMenuIconRefType`. The icon handle may be a handle to an `'ICON'` resource, a `'SICN'` resource, a `'cicn'` resource, an icon suite, or an icon reference. Valid only for menu items.

In Mac OS X v10.0 and later, the `iconType` field can also contain `kMenuCGImageType`, with the icon handle being of type `CGImageRef`.

In Mac OS X v10.1 and later, the `iconType` field can also contain `kMenuSystemIconSelectorType` or `kMenuIconResource`, which have icon handles of type `OSType` and `CFStringRef` respectively.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuItemDataCommandID`

Set or return the command ID of a menu using the `MenuItemDataRec.cmdID` field. Valid only for menu items.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuItemDataTextEncoding`

Set or return the text encoding of a menu item using the `MenuItemDataRec.encoding` field. Valid only for menu items.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuItemDataSubmenuID`

Set or return the menu ID of the submenu associated with this menu item using the `MenuItemDataRec.submenuID` field. Valid only for menu items.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuItemDataSubmenuHandle`

Set or return the menu reference (`MenuRef`) of the submenu associated with this menu using the `MenuItemDataRec.submenuHandle` field. Valid only for menu items.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuItemDataFontID`

Set or return the font ID associated with this menu item using the `MenuItemDataRec.fomtID` field. Valid only for menu items.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuItemDataRefcon`

Set or return the reference constant associated with this menu item using the `MenuItemDataRec.refcon` field. If you specified a menu item index of 0, you can set or obtain the menu reference constant.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuItemDataAttributes`
Set or return the attribute bits associated with this menu item using the `MenuItemDataRec.attr` field. If you specified a menu item index of 0, you can set or obtain a `MenuAttributes` bit field, not a `MenuItemAttributes` bit field.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuItemDataCFString`
Set or return the title of the menu item (as a Core Foundation string) using the `MenuItemDataRec.cFText` field. If you specified a menu item index of 0, you can set or obtain the menu title.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuItemDataProperties`
Set or return the properties of a menu using the `MenuItemDataRec.properties` field.

If setting properties, the `properties` field should contain a collection with the new properties; note that this will overwrite any existing properties with the same collection creator and tag.

If getting properties, you should set the `properties` field to either a valid collection or `NULL`. A valid collection is overwritten by the new properties. If you pass `NULL`, the `CopyMenuItemData` (page 1241) function allocates a new collection and returns it in the `properties` field.

You can set this flag for both menu items and the menu itself (if the item number is zero).

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuItemDataIndent`
Set or return the indent level of a menu item using the `MenuItemDataRec.indent` field. Valid only for menu items.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuItemDataCmdVirtualKey`
Set or return the virtual key code for this menu item using the `MenuItemDataRec.cmdVirtualKey` field. Valid only for menu items.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuItemDataAllDataVersionOne`
Sets all flags, except for `kMenuItemDataCmdVirtualKey`.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuItemDataAllDataVersionTwo`
Sets all flags, including `kMenuItemDataCmdVirtualKey`.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

Discussion
A `MenuItemDataFlags` value indicates which fields of a "MenuItemDataRec" (page 1365) structure should be used by the `CopyMenuItemData` (page 1241) or `SetMenuItemData` (page 1335) functions. All menu item data flags may be used when getting or setting the contents of a menu item; some may also be used when getting or setting information about the menu itself, if the item index given to `CopyMenuItemData` (page 1241) or `SetMenuItemData` (page 1335) is 0.

Menu Item Icon Type Constants

Specify types of icons to attach to menu items.

```
enum {
    kMenuNoIcon = 0,
    kMenuIconType = 1,
    kMenuShrinkIconType = 2,
    kMenuSmallIconType = 3,
    kMenuColorIconType = 4,
    kMenuIconSuiteType = 5,
    kMenuIconRefType = 6,
    kMenuCGImageRefType = 7,
    kMenuSystemIconSelectorType = 8,
    kMenuIconResourceType = 9
};
```

Constants

`kMenuNoIcon`
No icon.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuIconType`
Identifies an icon of type `'ICON'`.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuShrinkIconType`
Identifies a 32-by-32-pixel icon of type `'ICON'`, shrunk (at display time) to 16-by-16.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuSmallIconType`
Identifies an icon of type `'SICN'`.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuColorIconType`
Identifies an icon of type 'cicn'.
Available in Mac OS X v10.0 and later.
Declared in `Menus.h`.

`kMenuIconSuiteType`
Identifies an icon suite.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuIconRefType`
Identifies an icon of type `IconRef`. This value is supported under Mac OS 8.5 and later.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuCGImageRefType`
Identifies an icon of type `CGImageRef`.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuSystemIconSelectorType`
Identifies an `OSType` value that corresponds to an icon (type `IconRef`)registered with Icon Services under `kSystemIconsCreator`.

Available in Mac OS X v10.1 and later.

Declared in `Menus.h`.

`kMenuIconResourceType`
Identifies a CFString that names an icon resource in the main bundle of the application.

Available in Mac OS X v10.1 and later.

Declared in `Menus.h`.

Discussion
These constants specify the type of an icon attached to a menu item. They are passed in `SetMenuItemIconHandle` (page 1338) and obtained by `GetMenuItemIconHandle` (page 1279). Menu item icon type constants are available with Appearance Manager 1.0 and later.

Menu Item Property Attribute Constant

Define attributes to associate with menu item properties.

```
enum {
    kMenuPropertyPersistent = 0x00000001
};
```

Constants
`kMenuPropertyPersistent`
If this bit is set, the menu item property is saved when the menu is flattened.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

Menu Tracking Mode Constants

Indicates how the menu is being tracked.

```
typedef UInt32 MenuTrackingMode;
enum {
    kMenuTrackingModeMouse = 1,
    kMenuTrackingModeKeyboard = 2
};
```

Constants

`kMenuTrackingModeMouse`

Menus are being tracked using the mouse.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuTrackingModeKeyboard`

Menus are being tracked using the keyboard.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

Discussion

A menu tracking mode constant is part of the `kEventMenuBeginTracking` and `kEventMenuChangeTrackingMode` Carbon events. It indicates whether a menu is being tracked by mouse movement or by directional keyboard input.

Modifier Key Mask Constants

Specify modifier keys used with menu item selections.

```
enum {
    kMenuNoModifiers = 0,
    kMenuShiftModifier = (1 << 0),
    kMenuOptionModifier = (1 << 1),
    kMenuControlModifier = (1 << 2),
    kMenuNoCommandModifier = (1 << 3)
};
```

Constants

`kMenuNoModifiers`

If no bit is set, only the Command key is used in the keyboard equivalent.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuShiftModifier`

If this bit (bit 0) is set, the Shift key is used in the keyboard equivalent.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuOptionModifier`

If this bit (bit 1) is set, the Option key is used in the keyboard equivalent.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuControlModifier`
If this bit (bit 2) is set, the Control key is used in the keyboard equivalent.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

`kMenuNoCommandModifier`
If this bit (bit 3) is set, the Command key is not used in the keyboard equivalent.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

Discussion
You can use one or more of these mask constants to determine which modifier key(s) must be pressed along with a character key to create a keyboard equivalent for selecting a menu item. You set and obtain these constants by calling `SetMenuItemModifiers` (page 1340) and `GetMenuItemModifiers` (page 1281), respectively.

No Mark Marking Character Constant

Indicates that a menu item contains no marking characters.

```
enum {
    noMark = 0
};
```

Constants
`noMark`
No marking character to be associated with a menu or submenu item.

Available in Mac OS X v10.0 and later.

Declared in `Menus.h`.

Discussion
You can pass this constant, as well as those character marking constants defined in the Font Manager, in the `markChar` parameter of the function `SetItemMark` (page 1324) and the marking character field of the menu resource (of type '`MENU`') and return these constants in the `markChar` parameter of the function `GetItemMark` (page 1263) to specify the mark of a specific menu item or the menu ID of the submenu associated with the menu item.

Menu Dismissal Constants

Specify reasons why menu tracking ended.

```
enum {
kHIMenuDismissedBySelection   = 1,
kHIMenuDismissedByUserCancel  = 2,
kHIMenuDismissedByMouseDown   = 3,
kHIMenuDismissedByMouseUp     = 4,
kHIMenuDismissedByKeyEvent    = 5,
kHIMenuDismissedByAppSwitch   = 6,
kHIMenuDismissedByTimeout     = 7,
kHIMenuDismissedByCancelMenuTracking = 8,
kHIMenuDismissedByActivationChange = 9,
kHIMenuDismissedByFocusChange = 10
};
```

Constants

`kHIMenuDismissedBySelection`
The user selected a menu item.
Available in Mac OS X v10.3 and later.
Declared in `Menus.h`.

`kHIMenuDismissedByUserCancel`
The user cancelled menu tracking.
Available in Mac OS X v10.3 and later.
Declared in `Menus.h`.

`kHIMenuDismissedByMouseDown`
The user pressed the mouse someplace that did not result in a menu item selection.
Available in Mac OS X v10.3 and later.
Declared in `Menus.h`.

`kHIMenuDismissedByMouseUp`
The user released the mouse someplace that did not result in a menu item selection.
Available in Mac OS X v10.3 and later.
Declared in `Menus.h`.

`kHIMenuDismissedByKeyEvent`
A keyboard event occurred.
Available in Mac OS X v10.3 and later.
Declared in `Menus.h`.

`kHIMenuDismissedByAppSwitch`
The application with the menu is no longer frontmost.
Available in Mac OS X v10.3 and later.
Declared in `Menus.h`.

`kHIMenuDismissedByTimeout`
The menu tracking mode timed out.
Available in Mac OS X v10.3 and later.
Declared in `Menus.h`.

`kHIMenuDismissedByCancelMenuTracking`
The application called `CancelMenuTracking`.
Available in Mac OS X v10.3 and later.
Declared in `Menus.h`.

`kHIMenuDismissedByActivationChange`
The active window changed.

Available in Mac OS X v10.3 and later.

Declared in `Menus.h`.

`kHIMenuDismissedByFocusChange`
The user focus window changed, or the keyboard focus was removed from the current process.

Available in Mac OS X v10.3 and later.

Declared in `Menus.h`.

Discussion
The Carbon Event Manager passes these constants in the `kEventMenuEndTrackingEvent` to indicate why menu tracking ended.

Standard Menu Definition Constants

Specify the menu definitions for standard menus and menu bars.

```
enum {
    kMenuStdMenuProc = 63,
    kMenuStdMenuBarProc = 63
};
```

Constants
`kMenuStdMenuProc`
The menu definition ID for Appearance-compliant menus.

Available with Appearance Manager 1.0 and later.

Declared in `Menus.h`.

`kMenuStdMenuBarProc`
The menu bar definition ID for Appearance-compliant menu bars.

Available with Appearance Manager 1.0 and later.

Declared in `Menus.h`.

Result Codes

This table lists result codes defined for the Menu Manager.

Result Code	Value	Description
`menuPropertyInvalidErr`	-5603	You specified an Apple-reserved creator type in a menu property function. Available in Mac OS X v10.0 and later.
`menuPropertyNotFoundErr`	-5604	The specified property creator/ID combination was not found. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
`menuNotFoundErr`	-5620	The specified menu or menu ID wasn't found. Available in Mac OS X v10.0 and later.
`menuUsesSystemDefErr`	-5621	`GetMenuDefinition` failed because the menu uses the system menu definition. Available in Mac OS X v10.0 and later.
`menuItemNotFoundErr`	-5622	The specified menu item wasn't found. Available in Mac OS X v10.0 and later.
`menuInvalidErr`	-5623	The menu reference passed to the function was invalid. Available in Mac OS X v10.0 and later.

Navigation Services Reference

Framework: Carbon/Carbon.h

Declared in Navigation.h

Overview

Navigation Services is an application programming interface that allows your application to provide a user interface for navigating, opening, and saving Mac OS file objects.

This reference describes the application programming interface for Navigation Services, as introduced with CarbonLib 1.1. Navigation Services establishes a new model for creating, displaying, and processing dialogs. This new functionality gives you the ability to create truly modeless dialogs and provides support for Unicode and Mac OS X sheets.

Navigation Services replaces the Standard File Package, which is not supported in Carbon.

Functions by Task

Creating Dialogs

`NavGetDefaultDialogCreationOptions` (page 1437)
Determines the default attributes or behavior for dialogs.

Choosing Files, Folders and Volumes

`NavCreateChooseFileDialog` (page 1419)
Creates a Choose File dialog, which prompts the user to select a single file as the target of an operation.

`NavCreateChooseFolderDialog` (page 1420)
Creates a Choose Folder dialog, which prompts the user to select a folder as the target of an operation.

`NavCreateChooseVolumeDialog` (page 1422)
Creates a Choose Volume dialog, which prompts the user to select a volume.

`NavCreateChooseObjectDialog` (page 1421)
Creates a Choose Object dialog, which prompts the user to select a file. folder or volume.

`NavCreateGetFileDialog` (page 1423)
Creates an Open dialog, which prompts the user to select a file or files to be opened.

`NavCreateNewFolderDialog` (page 1424)
Creates a New Folder dialog.

Saving Files

`NavCreatePutFileDialog` (page 1426)
Creates a Save dialog, which prompts the user for the name and location of a file to be saved.

`NavCreateAskSaveChangesDialog` (page 1418)
Creates a dialog that asks the user whether to save changes.

`NavCreateAskReviewDocumentsDialog` (page 1417)
Creates a Review Changes dialog, which notifies the user of multiple unsaved documents and gives the user the option to review them.

`NavCreateAskDiscardChangesDialog` (page 1416)
Creates a dialog that asks the user whether to discard changes.

`NavDialogSetSaveFileName` (page 1435)
Specifies the current value of the filename text field in a Save dialog.

`NavDialogSetSaveFileExtensionHidden` (page 1435)
Sets the current state of extension hiding in a Save dialog.

`NavDialogGetSaveFileName` (page 1431)
Obtains the current value of the filename text field in a Save dialog.

`NavDialogGetSaveFileExtensionHidden` (page 1431)
Gets the current state of extension hiding in a Save dialog.

`NavCompleteSave` (page 1415)
Completes a save operation and performs any needed translation on the file.

`NavCreatePreview` (page 1425) Deprecated in Mac OS X v10.5
Creates a document preview in a specified file.

Customizing Dialogs

`NavCustomControl` (page 1429)
Allows your application to control various settings in Navigation Services dialogs.

`NavDialogSetFilterTypeIdentifiers` (page 1434)
Sets UTI filtering criteria for “get file” and “choose file” dialogs.

Running And Disposing of Dialogs

`NavDialogRun` (page 1433)
Displays a previously created dialog.

`NavDialogDispose` (page 1430)
Disposes of a dialog reference.

Obtaining Dialog Information

`NavDialogGetWindow` (page 1433)
Obtains a window reference for a dialog.

`NavDialogGetUserAction` (page 1432)
Reports the user action taken to dismiss a dialog.

`NavDialogGetReply` (page 1430)
Reports the results of a dialog session (unless cancelled or programmatically terminated).

`NavDisposeReply` (page 1436)
Releases the memory allocated for a `NavReplyRecord` structure after your application has finished using the structure.

Translating Files

`NavTranslateFile` (page 1445) Deprecated in Mac OS X v10.5
Provides a means for files opened through Navigation Services to be read from different file formats.

Identifying Navigation Services Availability

`NavServicesAvailable` (page 1444)
Reports whether the Navigation Services library is available on the user's system.

`NavLibraryVersion` (page 1440) Deprecated in Mac OS X v10.5
Reports the currently installed version of the Navigation Services shared library.

Working With Universal Procedure Pointers

`NewNavEventUPP` (page 1446)
Creates a new universal procedure pointer to your application-defined event–handling function.

`NewNavObjectFilterUPP` (page 1447)
Creates a new universal procedure pointer to your application-defined filter function.

`NewNavPreviewUPP` (page 1447)
Creates a new universal procedure pointer to your application-defined preview function.

`DisposeNavEventUPP` (page 1404)
Disposes of a UPP to an application-defined event–handling function.

`DisposeNavObjectFilterUPP` (page 1405)
Disposes of a UPP to an application-defined filter function.

`DisposeNavPreviewUPP` (page 1405)
Disposes of a UPP to an application-defined preview function.

`InvokeNavEventUPP` (page 1406)
Calls your application-defined event–handling function.

`InvokeNavObjectFilterUPP` (page 1406)
Calls your application-defined filter function.

`InvokeNavPreviewUPP` (page 1407)
Calls your application-defined preview function.

Deprecated Functions

`NavAskDiscardChanges` (page 1407) Deprecated in Mac OS X v10.5
Displays an alert box that asks the user whether to discard changes to a particular document.

`NavAskSaveChanges` (page 1408) Deprecated in Mac OS X v10.5
Displays a Save Changes alert box.

`NavChooseFile` (page 1409) Deprecated in Mac OS X v10.5
Creates a simple dialog box that prompts the user to select a file.

`NavChooseFolder` (page 1411) Deprecated in Mac OS X v10.5
Displays a dialog box that prompts the user to choose a folder or volume.

`NavChooseObject` (page 1412) Deprecated in Mac OS X v10.5
Displays a dialog box that prompts the user to choose a file, folder, or volume.

`NavChooseVolume` (page 1413) Deprecated in Mac OS X v10.5
Displays a dialog box that prompts the user to choose a volume.

`NavCustomAskSaveChanges` (page 1428) Deprecated in Mac OS X v10.5
Displays a Save Changes alert box with a custom alert message.

`NavGetDefaultDialogOptions` (page 1437) Deprecated in Mac OS X v10.5
Determines the default attributes or behavior for dialog boxes.

`NavGetFile` (page 1438) Deprecated in Mac OS X v10.5
Displays a dialog box that prompts the user to select a file or files to be opened.

`NavNewFolder` (page 1441) Deprecated in Mac OS X v10.5
Displays a dialog box that prompts the user to create a new folder.

`NavPutFile` (page 1442) Deprecated in Mac OS X v10.5
Displays a Save dialog box.

Unsupported Functions

`NavLoad` (page 1441)
Pre-loads the Navigation Services shared library.

`NavUnload` (page 1446)
Unloads the Navigation Services shared library.

`NavServicesCanRun` (page 1444)

Functions

DisposeNavEventUPP

Disposes of a UPP to an application-defined event–handling function.

```
void DisposeNavEventUPP (
   NavEventUPP userUPP
);
```

Parameters

userUPP

The UPP to dispose of.

Discussion

For more information on event–handling functions, see `NavEventProcPtr` (page 1448).

Availability

Available in CarbonLib 1.0 and later.

Available in Mac OS X 10.0 and later.

Related Sample Code

QTMetaData

Declared In

`Navigation.h`

DisposeNavObjectFilterUPP

Disposes of a UPP to an application-defined filter function.

```
void DisposeNavObjectFilterUPP (
   NavObjectFilterUPP userUPP
);
```

Parameters

userUPP

The UPP to dispose of.

Discussion

For more information on filter functions, see `NavObjectFilterProcPtr` (page 1449).

Availability

Available in CarbonLib 1.0 and later.

Available in Mac OS X 10.0 and later.

Declared In

`Navigation.h`

DisposeNavPreviewUPP

Disposes of a UPP to an application-defined preview function.

```
void DisposeNavPreviewUPP (
   NavPreviewUPP userUPP
);
```

Parameters

userUPP

The UPP to dispose of.

Discussion
For more information on preview functions, see `NavPreviewProcPtr` (page 1450).

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.

Declared In
`Navigation.h`

InvokeNavEventUPP

Calls your application-defined event–handling function.

```
void InvokeNavEventUPP (
   NavEventCallbackMessage callBackSelector,
   NavCBRecPtr callBackParms,
   void *callBackUD,
   NavEventUPP userUPP
);
```

Discussion
You should not need to use the function `InvokeNavEventUPP`, as the system calls your event–handling function for you.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.

Declared In
`Navigation.h`

InvokeNavObjectFilterUPP

Calls your application-defined filter function.

```
Boolean InvokeNavObjectFilterUPP (
   AEDesc *theItem,
   void *info,
   void *callBackUD,
   NavFilterModes filterMode,
   NavObjectFilterUPP userUPP
);
```

Discussion
You should not need to use the function `InvokeNavObjectFilterUPP`, as the system calls your filter function for you.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.

Declared In
`Navigation.h`

InvokeNavPreviewUPP

Calls your application-defined preview function.

```
Boolean InvokeNavPreviewUPP (
   NavCBRecPtr callBackParms,
   void *callBackUD,
   NavPreviewUPP userUPP
);
```

Discussion

You should not need to use the function `InvokeNavPreviewUPP`, as the system calls your preview function for you.

Availability

Available in CarbonLib 1.0 and later.

Available in Mac OS X 10.0 and later.

Declared In

`Navigation.h`

NavAskDiscardChanges

Displays an alert box that asks the user whether to discard changes to a particular document. (Deprecated in Mac OS X v10.5.)

Not recommended

```
OSErr NavAskDiscardChanges (
   NavDialogOptions *dialogOptions,
   NavAskDiscardChangesResult *reply,
   NavEventUPP eventProc,
   void *callBackUD
);
```

Parameters

dialogOptions

A pointer to a structure of type `NavDialogOptions` (page 1463). Before calling `NavAskDiscardChanges`, set up this structure to specify dialog box settings. In this case, the `savedFileName` field is the only one you must supply with a value.

reply

A pointer to a structure of type `NavAskDiscardChanges`. On return, the value describes the user's response to the Discard Changes alert box. For a description of the constants used to represent possible responses, see "Discard Changes Actions" (page 1475).

eventProc

A Universal Procedure Pointer (UPP) to your application-defined event-handling function. You obtain this UPP by calling the function `NewNavEventUPP`. Implementing an event-handling function allows your application to update windows after the user moves or resizes the dialog box. If you pass `NULL` in this parameter, the Discard Changes alert box is not movable. For more information on event-handling functions, see `NavEventProcPtr` (page 1448).

callBackUD

A pointer to a value set by your application. When the `NavAskDiscardChanges` function calls your event-handling function, the `callBackUD` value is passed back to your application.

Return Value
A result code. See "Navigation Services Result Codes" (page 1486).

Discussion
If your application provides a Revert to Saved command, you can use the `NavAskDiscardChanges` function to display a confirmation alert box when a user selects Revert to Saved for a document with unsaved changes. Navigation Services uses the string you supply in the `savedFileName` field of the `NavDialogOptions` structure you passed in the `dialogOptions` parameter to display the alert message, "Discard changes to [savedFilename]?".

Availability
Available in CarbonLib 1.0 and later when Navigation Services 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.

Carbon Porting Notes

Apple recommends you use the function `NavCreateAskDiscardChangesDialog` (page 1416) in order to take advantage of Mac OS X features like Unicode, long filenames and enhanced modality.

Declared In
`Navigation.h`

NavAskSaveChanges

Displays a Save Changes alert box. (Deprecated in Mac OS X v10.5.)

Not recommended

```
OSErr NavAskSaveChanges (
   NavDialogOptions *dialogOptions,
   NavAskSaveChangesAction action,
   NavAskSaveChangesResult *reply,
   NavEventUPP eventProc,
   void *callBackUD
);
```

Parameters

dialogOptions
A pointer to a structure of type `NavDialogOptions` (page 1463). Before calling `NavAskSaveChanges`, set up this structure to specify dialog box settings. When calling `NavAskSaveChanges`, the `clientName` and `savedFileName` fields are the only two fields you must supply with values.

action
A value of type `NavAskSaveChangesAction`. Pass a constant describing the user action that prompted the Save Changes alert box. For a description of the constants, see "Save Changes Requests" (page 1481).

reply
A pointer to a value of type `NavAskSaveChangesResult`. On return, the value describes the user's response to the Save Changes alert box. For a description of the constants used to represent possible responses, see "Save Changes Actions" (page 1481).

eventProc

A Universal Procedure Pointer (UPP) to your application-defined event-handling function. You obtain this UPP by calling the function `NewNavEventUPP`. Implementing an event-handling function allows your application to update windows after the user moves or resizes the dialog box. If you pass `NULL` in this parameter, the Save Changes alert box is not movable. For more information on event-handling functions, see `NavEventProcPtr` (page 1448).

callBackUD

A pointer to a value set by your application. When the `NavAskSaveChanges` function calls your event-handling function, the `callBackUD` value is passed back to your application.

Return Value
A result code. See "Navigation Services Result Codes" (page 1486).

Discussion
This function is useful when your application needs to display an alert when the user attempts to close a document or an application with unsaved changes.

Availability
Available in CarbonLib 1.0 and later when Navigation Services 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.

Carbon Porting Notes

Apple recommends you use the function `NavCreateAskSaveChangesDialog` (page 1418) in order to take advantage of Mac OS X features like Unicode, long filenames and enhanced modality.

Declared In
`Navigation.h`

NavChooseFile

Creates a simple dialog box that prompts the user to select a file. (Deprecated in Mac OS X v10.5.)

Not recommended

```
OSErr NavChooseFile (
   AEDesc *defaultLocation,
   NavReplyRecord *reply,
   NavDialogOptions *dialogOptions,
   NavEventUPP eventProc,
   NavPreviewUPP previewProc,
   NavObjectFilterUPP filterProc,
   NavTypeListHandle typeList,
   void *callBackUD
);
```

Parameters

defaultLocation

A pointer to an Apple event descriptor structure (`AEDesc`). Before calling `NavChooseFile`, you can set up a structure of `AEDesc` type `'typeFSS'` to specify a default location to be viewed. If you pass `NULL` in this parameter, Navigation Services displays the last location visited during a call to the `NavChooseFile` function. If the file system specification in the `AEDesc` structure does not describe a directory or volume, Navigation Services uses the desktop as the default location.

reply

A pointer to a structure of type `NavReplyRecord` (page 1458). Upon return, Navigation Services uses this structure to provide data to your application about the results of your `NavChooseFile` call.

dialogOptions

A pointer to a structure of type `NavDialogOptions` (page 1463). Before calling `NavChooseFile`, you can set up this structure to specify dialog box settings. If you pass `NULL` in this parameter, Navigation Services uses the defaults for all options. See "Dialog Configuration Options" (page 1471) for a description of the default settings.

eventProc

A Universal Procedure Pointer (UPP) to your application-defined event-handling function. You obtain this UPP by calling the function `NewNavEventUPP`. Implementing an event-handling function allows your application to update windows after the user moves or resizes the dialog box. If you pass `NULL` in this parameter, the Choose a File dialog box is not movable or resizable. For more information on event-handling functions, see `NavEventProcPtr` (page 1448).

previewProc

A Universal Procedure Pointer (UPP) to your application-defined preview function. Obtain this UPP by calling the function `NewNavPreviewUPP`. A preview function allows your application to draw previews or to override Navigation Services previews. For more information on preview functions, see `NavPreviewProcPtr` (page 1450).

filterProc

A Universal Procedure Pointer (UPP) to your application-defined filter function. Obtain this UPP by calling the function `NewNavObjectFilterUPP`. An application-defined filter function determines if a volume, directory, or file should be displayed in the browser list or pop-up menus. For more information on filter functions, see `NavObjectFilterProcPtr` (page 1449).

typeList

A handle to a structure of type `NavTypeList` (page 1460). Before calling `NavChooseFile`, you can set up this structure to declare file types that your application can open.

callBackUD

A pointer to a value set by your application. When the `NavChooseFile` function calls your event-handling function, the `callBackUD` value is passed back to your application.

Return Value
A result code. See "Navigation Services Result Codes" (page 1486).

Discussion
This function allows the user to choose a single file, such as a preferences file, for an action other than opening. The `NavChooseFile` function is similar to `NavGetFile` (page 1438), but is limited to selecting a single file.

The dialog box displayed by the `NavChooseFile` function does not display a Show menu. If you wish to control the files displayed by the browser list or the pop-up menus, you must specify a list of file types in the `typeList` parameter or specify a filter function in the `filterProc` parameter. If you specify a list of file types in the `typeList` parameter, the `NavChooseFile` function ignores the `signature` field of the `NavTypeList` structure. This means that all files of the types specified in the list of file types will be displayed, regardless of their application signature.

Availability
Available in CarbonLib 1.0 and later when Navigation Services 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.

Carbon Porting Notes

Apple recommends you use the function `NavCreateChooseFileDialog` (page 1419) in order to take advantage of Mac OS X features like Unicode, long filenames and enhanced modality.

Declared In

`Navigation.h`

NavChooseFolder

Displays a dialog box that prompts the user to choose a folder or volume. (Deprecated in Mac OS X v10.5.)

Not recommended

```
OSErr NavChooseFolder (
   AEDesc *defaultLocation,
   NavReplyRecord *reply,
   NavDialogOptions *dialogOptions,
   NavEventUPP eventProc,
   NavObjectFilterUPP filterProc,
   void *callBackUD
);
```

Parameters

defaultLocation

A pointer to an Apple event descriptor structure (`AEDesc`). Before calling `NavChooseFolder`, you can set up a structure of `AEDesc` type `'typeFSS'` to specify a default location to be viewed. If you pass `NULL` in this parameter, Navigation Services displays the last location visited during a call to the `NavChooseFolder` function. If the file system specification in the `AEDesc` structure does not describe a directory or volume, Navigation Services uses the desktop as the default location.

reply

A pointer to a structure of type `NavReplyRecord` (page 1458). Upon return, Navigation Services uses this structure to provide data to your application about the results of your `NavChooseFolder` call.

dialogOptions

A pointer to a structure of type `NavDialogOptions` (page 1463). Before calling `NavChooseFolder`, set up this structure to specify dialog box settings. If you pass `NULL` in this parameter, Navigation Services uses the defaults for all options. See "Dialog Configuration Options" (page 1471) for a description of the default settings.

eventProc

A Universal Procedure Pointer (UPP) to your application-defined event-handling function. You obtain this UPP by calling the function `NewNavEventUPP`. Implementing an event-handling function allows your application to update windows after the user moves or resizes the dialog box. If you pass `NULL` in this parameter, the dialog box is not movable or resizable. For more information on event-handling functions, see `NavEventProcPtr` (page 1448).

filterProc

A Universal Procedure Pointer (UPP) to your application-defined filter function. Obtain this UPP by calling the function `NewNavObjectFilterUPP`. An application-defined filter function determines if a volume, directory, or file should be displayed in the browser list or pop-up menus. For more information on filter functions, see `NavObjectFilterProcPtr` (page 1449).

callBackUD

A pointer to a value set by your application. When the `NavChooseFolder` function calls your event-handling function, the `callBackUD` value is passed back to your application.

Return Value
A result code. See "Navigation Services Result Codes" (page 1486).

Discussion
This function provides a way for your application to prompt the user to select a folder or volume. This might be useful if you need to install application files, for example.

Availability
Available in CarbonLib 1.0 and later when Navigation Services 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.

Carbon Porting Notes

Apple recommends you use the function `NavCreateChooseFolderDialog` (page 1420) in order to take advantage of Mac OS X features like Unicode, long filenames and enhanced modality.

Declared In
`Navigation.h`

NavChooseObject

Displays a dialog box that prompts the user to choose a file, folder, or volume. (Deprecated in Mac OS X v10.5.)

Not recommended

```
OSErr NavChooseObject (
   AEDesc *defaultLocation,
   NavReplyRecord *reply,
   NavDialogOptions *dialogOptions,
   NavEventUPP eventProc,
   NavObjectFilterUPP filterProc,
   void *callBackUD
);
```

Parameters

defaultLocation

A pointer to an Apple event descriptor structure (`AEDesc`). Before calling `NavChooseObject`, you can set up a structure of `AEDesc` type `'typeFSS'` to specify a default location to be viewed. If you pass `NULL` in this parameter, Navigation Services displays the last location visited during a call to the `NavChooseObject` function. If the file system specification in the `AEDesc` structure does not describe a directory or volume, Navigation Services uses the desktop as the default location.

reply

A pointer to a structure of type `NavReplyRecord` (page 1458). Upon return, Navigation Services uses this structure to provide data to your application about the results of your `NavChooseObject` call.

dialogOptions

A pointer to a structure of type `NavDialogOptions` (page 1463). Before calling `NavChooseObject`, set up this structure to specify dialog box settings. If you do not provide this structure, Navigation Services uses the defaults for all options. See "Dialog Configuration Options" (page 1471) for a description of the default settings.

eventProc

A Universal Procedure Pointer (UPP) to your application-defined event-handling function. You obtain this UPP by calling the function `NewNavEventUPP`. Implementing an event-handling function allows your application to update windows after the user moves or resizes the dialog box. If you pass `NULL` in this parameter, the dialog box is not movable or resizable. For more information on event-handling functions, see `NavEventProcPtr` (page 1448).

filterProc

A Universal Procedure Pointer (UPP) to your application-defined filter function. Obtain this UPP by calling the function `NewNavObjectFilterUPP`. An application-defined filter function determines if a volume, directory, or file should be displayed in the browser list or pop-up menus. For more information on filter functions, see `NavObjectFilterProcPtr` (page 1449).

callBackUD

A pointer to a value set by your application. When the `NavChooseObject` function calls your event-handling function, the `callBackUD` value is passed back to your application.

Return Value
A result code. See "Navigation Services Result Codes" (page 1486).

Discussion
This function is useful when you need to display a dialog box that prompts the user to choose a file object that might be a file, folder, or volume. If you want the user to choose a specific type of file object, you should use the function designed for that type of object; to select a file, for example, use the function `NavChooseFile` (page 1409).

Availability
Available in CarbonLib 1.0 and later when Navigation Services 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.

Carbon Porting Notes

Apple recommends you use the function `NavCreateChooseObjectDialog` (page 1421) in order to take advantage of Mac OS X features like Unicode, long filenames and enhanced modality.

Declared In
`Navigation.h`

NavChooseVolume

Displays a dialog box that prompts the user to choose a volume. (Deprecated in Mac OS X v10.5.)

Not recommended

```
OSErr NavChooseVolume (
   AEDesc *defaultSelection,
   NavReplyRecord *reply,
   NavDialogOptions *dialogOptions,
   NavEventUPP eventProc,
   NavObjectFilterUPP filterProc,
   void *callBackUD
);
```

Parameters

defaultSelection

A pointer to an Apple event descriptor structure (`AEDesc`). Before calling `NavChooseVolume`, you can set up a structure of `AEDesc` type `'typeFSS'` to specify a default location to be viewed. If you pass `NULL` in this parameter, Navigation Services displays the last location visited during a call to the `NavChooseVolume` function. If the file system specification in the `AEDesc` structure does not describe a directory or volume, Navigation Services uses the desktop as the default location.

reply

A pointer to a structure of type `NavReplyRecord` (page 1458). Upon return, Navigation Services uses this structure to provide data to your application about the results of your `NavChooseVolume` call.

dialogOptions

A pointer to a structure of type `NavDialogOptions` (page 1463). Before calling, set up this structure to specify dialog box settings. If you pass `NULL` in this parameter, Navigation Services uses the defaults for all options. See "Dialog Configuration Options" (page 1471) for a description of the default settings.

eventProc

A Universal Procedure Pointer (UPP) to your application-defined event-handling function. You obtain this UPP by calling the function `NewNavEventUPP`. Implementing an event-handling function allows your application to update windows after the user moves or resizes the dialog box. If you pass `NULL` in this parameter, the Choose a Volume dialog box is not movable or resizable. For more information on event-handling functions, see `NavEventProcPtr` (page 1448).

filterProc

A Universal Procedure Pointer (UPP) to your application-defined filter function. Obtain this UPP by calling the function `NewNavObjectFilterUPP`. An application-defined filter function determines if a volume, directory, or file should be displayed in the browser list or pop-up menus. For more information on filter functions, see `NavObjectFilterProcPtr` (page 1449).

callBackUD

A pointer to a value set by your application. When the `NavChooseVolume` function calls your event-handling function, the `callBackUD` value is passed back to your application.

Return Value

A result code. See "Navigation Services Result Codes" (page 1486).

Discussion

This function provides a way for your application to prompt the user to select a volume. This might be useful for a disk repair utility, for example.

Availability

Available in CarbonLib 1.0 and later when Navigation Services 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.5.

Carbon Porting Notes

Apple recommends you use the function `NavCreateChooseVolumeDialog` (page 1422) in order to take advantage of Mac OS X features like Unicode, long filenames and enhanced modality.

Declared In

`Navigation.h`

NavCompleteSave

Completes a save operation and performs any needed translation on the file.

```
OSErr NavCompleteSave (
   const NavReplyRecord *reply,
   NavTranslationOptions howToTranslate
);
```

Parameters

reply

A pointer to a structure of type `NavReplyRecord` (page 1458). Upon return, Navigation Services uses this structure to provide data to your application about the results of your `NavCompleteSave` call.

howToTranslate

A pointer to a structure of type `NavTranslationOptions`. Pass one of two values to specify how to perform any needed translation. For a description of the constants you can use to represent these values, see "Translation Options" (page 1483). Translating in-place causes the source file to be replaced by the translation. Translating to a copy results in a file name followed by the string "(converted)" to avoid unwanted replacement. If you call the `NavCompleteSave` function in response to a Save a Copy command, you should pass the `kNavTranslateInPlace` constant in this parameter.

Return Value

A result code. See "Navigation Services Result Codes" (page 1486). Since this function performs any needed translation, it may return a translation error.

Discussion

You should always call `NavCompleteSave` to complete any file saving operation performed with the `NavCreatePutFileDialog` function. `NavCompleteSave` performs any needed translation, so you do not have to use the function `NavTranslateFile` (page 1445) when saving. If you wish to turn off automatic translation, set to `false` the value of the `translationNeeded` field of the `NavReplyRecord` structure you pass in the `reply` parameter of the `NavPutFile` function. If you turn off automatic translation, your application is responsible for any required translation.

Availability

Available in CarbonLib 1.0 and later when Navigation Services 1.0 or later is present.

Available in Mac OS X 10.0 and later.

`Navigation.h`

NavCreateAskDiscardChangesDialog

Creates a dialog that asks the user whether to discard changes.

```
OSStatus NavCreateAskDiscardChangesDialog (
   const NavDialogCreationOptions *inOptions,
   NavEventUPP inEventProc,
   void *inClientData,
   NavDialogRef *outDialog
);
```

Parameters

inOptions

A pointer to a structure specifying options that control the appearance and behavior of the dialog. You must supply a string in the `saveFileName` field of this structure; otherwise the function returns `paramErr`.

inEventProc

A Universal Procedure Pointer (UPP) to your application's event-handling function. You are strongly advised to create and register an event-handling function, as described in `NavEventProcPtr` (page 1448). You must have an event-handling function in order to create modeless or window-modal (sheet) dialogs. Specify `NULL` in this parameter if you do not implement an event-handling function.

inClientData

A pointer to an application-defined value that is passed back to all callback functions. You can use this value to provide context information, for example. You may pass `NULL` in this parameter.

outDialog

On successful creation of a Discard Changes dialog, A pointer to a Navigation Services dialog reference that you can pass to the `NavDialogRun` (page 1433) function

Return Value

A result code.

Discussion

This function creates a dialog that gives the user the option of discarding unsaved changes to a file or cancelling the operation. This dialog is most commonly used when the user wants to revert to the last saved version of a document.

Once you have successfully created the Discard Changes dialog, you display it by calling the `NavDialogRun` (page 1433) function. After the user interacts with the dialog, you can obtain information about the dialog session by calling the `NavDialogGetReply` (page 1430) function. When you are finished with the dialog, dispose of it by calling the `NavDialogDispose` (page 1430) function.

This function replaces the `NavAskDiscardChanges` function and adds support for Unicode and new window modalities.

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X 10.0 and later.

Declared In

`Navigation.h`

NavCreateAskReviewDocumentsDialog

Creates a Review Changes dialog, which notifies the user of multiple unsaved documents and gives the user the option to review them.

```
OSStatus NavCreateAskReviewDocumentsDialog (
   const NavDialogCreationOptions *inOptions,
   ItemCount inDocumentCount,
   NavEventUPP inEventProc,
   void *inClientData,
   NavDialogRef *outDialog
);
```

Parameters

inOptions

A pointer to a structure specifying options that control the appearance and behavior of the dialog.

inDocumentCount

The number of documents needing review. This number appears in the text presented to the user. If the total number of unsaved documents is unknown, specify 0; Navigation Services uses a general message. You should not specify 1; this alert should be used only when more than one document needs review. For more information, see *Inside Mac OS X: Aqua Human Interface Guidelines*.

inEventProc

A universal procedure pointer (UPP) to an application-defined event-handling function. You are strongly advised to create and register an event-handling function, as described in `NavEventProcPtr` (page 1448). You must have an event-handling function in order to create modeless or window-modal (sheet) dialogs. Specify `NULL` in this parameter if you do not implement an event-handling function.

inClientData

A pointer to an application-defined value that is passed back to all callback functions.

outDialog

Upon successful completion, a reference to the created dialog.

Return Value

A result code. See "Navigation Services Result Codes" (page 1486).

Discussion

The Review Changes dialog tells the user how many unsaved documents there are and asks the user to choose one of the following options:

- review the unsaved documents
- don't save any documents
- cancel

Use of this dialog is appropriate when an application is quitting and there is more than one unsaved document. It is supported only on Mac OS X; prior to Mac O X, this dialog is not part of the application quit sequence.

Upon successful creation, the dialog is not visible; to present and run the dialog, call the `NavDialogRun` (page 1433) function. After the dialog is complete, dispose of it with the `NavDialogDispose` function. Upon dismissal of the dialog, the user's action is set to one of the following actions: `kNavUserActionReviewDocuments`, `kNavUserActionDiscardDocuments`, or `kNavUserActionCancel`. You can obtain this reply by calling the `NavDialogGetReply` (page 1430).

Availability
Not available in CarbonLib.
Available in Mac OS X 10.1 and later.

Related Sample Code
QTCarbonShell

Declared In
`Navigation.h`

NavCreateAskSaveChangesDialog

Creates a dialog that asks the user whether to save changes.

```
OSStatus NavCreateAskSaveChangesDialog (
   const NavDialogCreationOptions *inOptions,
   NavAskSaveChangesAction inAction,
   NavEventUPP inEventProc,
   void *inClientData,
   NavDialogRef *outDialog
);
```

Parameters

inOptions
A pointer to a structure specifying options that control the appearance and behavior of the dialog.

inAction
A value indicating whether the user is closing a document or quitting the application and thereby determines the message displayed to the user. To provide a customized message for the dialog, specify a non-`NULL` value in the `message` field of the structure provided in the *inOptions* parameter.

inEventProc
A Universal Procedure Pointer (UPP) to your application's event-handling function. You are strongly advised to create and register an event-handling function, as described in `NavEventProcPtr` (page 1448). You must have an event-handling function in order to create modeless or window-modal (sheet) dialogs. Specify `NULL` in this parameter if you do not implement an event-handling function.

inClientData
A pointer to an application-defined value that is passed back to all callback functions. You can use this value to provide context information, for example. You may pass `NULL` in this parameter.

outDialog
On successful creation of the Save Changes dialog, a pointer to a Navigation Services dialog reference that you can pass to the `NavDialogRun` (page 1433) function.

Return Value
A result code. See "Navigation Services Result Codes" (page 1486). A result code.

Discussion
This function creates a Save Changes dialog, which your application should display when the user attempts to close a document or quit the application with unsaved changes. The Save Changes dialog allows the user to choose one of the following options:

- save the changes
- discard the unsaved changes

- cancel the operation

Once you have successfully created the Save Changes dialog, you display it by calling the `NavDialogRun` (page 1433) function. After the user interacts with the dialog, you can obtain information about the dialog session by calling the `NavDialogGetReply` (page 1430) function. When you are finished with the dialog, dispose of it by calling the `NavDialogDispose` (page 1430) function.

If there is more than one document with unsaved changes when the user attempts to quit your application, you should display a Review Changes dialog instead. You can create a Review Changes dialog with the `NavCreateAskReviewDocumentsDialog` (page 1417) function.

This function replaces the `NavAskSaveChanges` function and adds support for Unicode and new window modalities.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X 10.0 and later.

Related Sample Code

NavCreateChooseFileDialog

Creates a Choose File dialog, which prompts the user to select a single file as the target of an operation.

```
OSStatus NavCreateChooseFileDialog (
   const NavDialogCreationOptions *inOptions,
   NavTypeListHandle inTypeList,
   NavEventUPP inEventProc,
   NavPreviewUPP inPreviewProc,
   NavObjectFilterUPP inFilterProc,
   void *inClientData,
   NavDialogRef *outDialog
);
```

Parameters

inOptions
A pointer to a structure specifying options that control the appearance and behavior of the dialog.

inTypeList
A structure specifying a creator signature and a list of file types to show in the Choose File dialog.

inEventProc
A Universal Procedure Pointer (UPP) to your application's event-handling function. You are strongly advised to create and register an event-handling function, as described in `NavEventProcPtr` (page 1448). You must have an event-handling function in order to create modeless or window-modal (sheet) dialogs. Specify `NULL` in this parameter if you do not implement an event-handling function.

inPreviewProc
A Universal Procedure Pointer (UPP) to your application's preview function. You may specify `NULL` if you don't need to register a preview function. For more information on preview functions, see `NavPreviewProcPtr` (page 1450).

inFilterProc

A Universal Procedure Pointer (UPP) to your application's filter function. You may specify `NULL` if you don't need to register a filter function. For more information on filter functions, see `NavObjectFilterProcPtr` (page 1449).

inClientData

A pointer to an application-defined value that is passed back to all callback functions. You can use this value to provide context information, for example. You may pass `NULL` in this parameter.

outDialog

On successful creation of a Choose File dialog, A pointer to a Navigation Services dialog reference that you can pass to the `NavDialogRun` (page 1433) function.

Return Value
A result code. See "Navigation Services Result Codes" (page 1486). A result code.

Discussion
Once you have successfully created the Choose File dialog, you display it by calling the `NavDialogRun` (page 1433) function. After the user interacts with the dialog, you can obtain information about the dialog session by calling the `NavDialogGetReply` (page 1430) function. NavCreateGetFileDialog

Creates an Open dialog, which prompts the user to select a file or files to be opened.

```
OSStatus NavCreateGetFileDialog (
   const NavDialogCreationOptions *inOptions,
   NavTypeListHandle inTypeList,
   NavEventUPP inEventProc,
   NavPreviewUPP inPreviewProc,
   NavObjectFilterUPP inFilterProc,
   void *inClientData,
   NavDialogRef *outDialog
);
```

Parameters

inOptions

A pointer to a structure specifying options that control the appearance and behavior of the dialog.

inTypeList
A structure specifying an application signature and a list of file types to show in the Open dialog.

inEventProc
A Universal Procedure Pointer (UPP) to your application's event-handling function. You are strongly advised to create and register an event-handling function, as described in `NavEventProcPtr` (page 1448). You must have an event-handling function in order to create modeless or window-modal (sheet) dialogs. Specify `NULL` in this parameter if you do not implement an event-handling function.

inPreviewProc
A Universal Procedure Pointer (UPP) to your application's preview function. You may specify `NULL` if you don't need to register a preview function. For more information on creating a preview function, see `NavPreviewProcPtr` (page 1450).

inFilterProc
A Universal Procedure Pointer (UPP) to your application's filter function. You may specify `NULL` if you don't need to register a filter function. For more information on creating a filter function, see `NavObjectFilterProcPtr` (page 1449).

inClientData
A pointer to an application-defined value that is passed back to all callback functions. You can use this value to provide context information, for example. You may pass `NULL` in this parameter.

outDialog
On successful creation of an Open dialog instance, this value specifies a Navigation Services dialog reference that you can pass to the `NavDialogRun` (page 1433) function.

Return Value
A result code. See "Navigation Services Result Codes" (page 1486). A result code.

Discussion
Once you have successfully created the Open dialog, you display it by calling the `NavDialogRun` (page 1433) function. After the user interacts with the dialog, you can obtain information about the dialog session by calling the `NavDialogGetReply` (page 1430) function. When you are finished with the dialog, you should dispose of it by calling the `NavDialogDispose` (page 1430) function.

This function replaces the `NavGetFile` function and adds support for Unicode and new window modalities.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X 10.0 and later.

Declared In
`Navigation.h`

NavCreateNewFolderDialog

Creates a New Folder dialog.

```
OSStatus NavCreateNewFolderDialog (
   const NavDialogCreationOptions *inOptions,
   NavEventUPP inEventProc,
   void *inClientData,
   NavDialogRef *outDialog
);
```

Parameters

inOptions

A pointer to a structure specifying options that control the appearance and behavior of the dialog.

inEventProc

A Universal Procedure Pointer (UPP) to your application's event-handling function. You are strongly advised to create and register an event-handling function, as described in `NavEventProcPtr` (page 1448). You must have an event-handling function in order to create modeless or window-modal (sheet) dialogs. Specify `NULL` in this parameter if you do not implement an event-handling function.

inClientData

A pointer to an application-defined value that is passed back to all callback functions. You can use this value to provide context information, for example. You may pass `NULL` in this parameter.

outDialog

On successful creation of a New Folder dialog, a pointer to a Navigation Services dialog reference that you can pass to the `NavDialogRun` (page 1433) function.

Return Value

A result code. See "Navigation Services Result Codes" (page 1486). A result code.

Discussion

Once you have successfully created the New Folder dialog, you display it by calling the `NavDialogRun` (page 1433) function. After the user interacts with the dialog, you can obtain information about the dialog session by calling the `NavDialogGetReply` (page 1430) function. When you are finished with the dialog, you should dispose of it by calling the `NavDialogDispose` (page 1430) function

Use the New Folder dialog to allow the user to create a new folder. Navigation Services creates the folder as specified by the user and returns a reference to the folder in the `selection` field of the reply record.

This function replaces the `NavNewFolder` function and adds support for Unicode and new window modalities.

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X 10.0 and later.

Declared In

`Navigation.h`

NavCreatePreview

Creates a document preview in a specified file. (Deprecated in Mac OS X v10.5.)

```
OSErr NavCreatePreview (
   AEDesc *theObject,
   OSType previewDataType,
   const void *previewData,
   Size previewDataSize
);
```

Parameters

theObject

A pointer to an Apple Event Descriptor (`AEDesc`) structure specifying the file in which to create the preview.

previewDataType

A four character code specifying the type of preview data to create. If you pass `NULL` in this parameter, Navigation Services creates a preview of type '`PICT`'.

previewData

A pointer to a buffer holding preview data. If you pass `NULL` in this parameter, Navigation Services provides its own data.

previewDataSize

A value specifying the size, in bytes, of the preview data you are providing. If you pass `NULL` in this parameter, Navigation Services provides its own data.

Return Value

A result code. See "Navigation Services Result Codes" (page 1486).

Discussion

This function creates a preview of the specified file and stores the data in an appropriate resource. If you call this function without passing in preview data, as in the following snippet, Navigation Services obtains and creates the preview automatically:

```
NavCreatePreview(theObject,0,NULL,0)
```

If the specified file is image-based ('`PICT`', '`JPEG`', etc.), Navigation Services creates a thumbnail custom icon for the file. Navigation Services does not create a custom icon if you pass in your own preview data.

Availability

Available in CarbonLib 1.0 and later when Navigation Services 2.0 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Navigation.h`

NavCreatePutFileDialog

Creates a Save dialog, which prompts the user for the name and location of a file to be saved.

```
OSStatus NavCreatePutFileDialog (
   const NavDialogCreationOptions *inOptions,
   OSType inFileType,
   OSType inFileCreator,
   NavEventUPP inEventProc,
   void *inClientData,
   NavDialogRef *outDialog
);
```

Parameters

inOptions

A pointer to a structure specifying options that control the appearance and behavior of the dialog.

inFileType

A four-character code specifying a file type for the file to be saved.

inFileCreator

A four-character code specifying a creator signature for the file to be saved. If you want to change or remove the top default item in the Format menu, pass `kNavGenericSignature`.

inEventProc

A Universal Procedure Pointer (UPP) to your application's event-handling function. You are strongly advised to create and register an event-handling function, as described in `NavEventProcPtr` (page 1448). You must have an event-handling function in order to create modeless or window-modal (sheet) dialogs. Specify `NULL` in this parameter if you do not implement an event-handling function.

inClientData

A pointer to an application-defined value that is passed back to all callback functions. You can use this value to provide context information, for example. You may pass `NULL` in this parameter.

outDialog

On successful creation of a Save dialog, a pointer to a Navigation Services dialog reference that you can pass to the `NavDialogRun` (page 1433) function.

Return Value

A result code. See "Navigation Services Result Codes" (page 1486). A result code.

Discussion

Once you have successfully created the Save dialog, you display it by calling the `NavDialogRun` (page 1433) function. After the user interacts with the dialog, you can obtain information about the dialog session by calling the `NavDialogGetReply` (page 1430) function. When you are finished with the dialog, you should dispose of it by calling the `NavDialogDispose` (page 1430) function.

This function replaces the `NavPutFile` function and adds support for Unicode and new window modalities.

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X 10.0 and later.

Related Sample Code

CarbonSketch

QTCarbonShell

Declared In

`Navigation.h`

NavCustomAskSaveChanges

Displays a Save Changes alert box with a custom alert message. (Deprecated in Mac OS X v10.5.)

Not recommended

```
OSErr NavCustomAskSaveChanges (
   NavDialogOptions *dialogOptions,
   NavAskSaveChangesResult *reply,
   NavEventUPP eventProc,
   void *callBackUD
);
```

Parameters

dialogOptions

A pointer to a structure of type `NavDialogOptions` (page 1463). Before calling `NavCustomAskSaveChanges`, set up this structure to specify dialog box settings. When calling `NavCustomAskSaveChanges`, the `message` field is the only field you must supply with a value.

reply

A pointer to a value of type `NavAskSaveChangesResult`. On return, the value describes the user's response to the Save Changes alert box. For a description of the constants used to represent possible responses, see "Save Changes Actions" (page 1481).

eventProc

A Universal Procedure Pointer (UPP) to your application-defined event-handling function. You obtain this UPP by calling the function `NewNavEventUPP`. Implementing an event-handling function allows your application to update windows after the user moves or resizes the dialog box. If you pass `NULL` in this parameter, the Save Changes alert box is not movable. For more information on event-handling functions, see `NavEventProcPtr` (page 1448).

callBackUD

A pointer to a value set by your application. When the `NavCustomAskSaveChanges` function calls your event-handling function, the `callBackUD` value is passed back to your application.

Return Value

A result code. See "Navigation Services Result Codes" (page 1486).

Discussion

This function is similar to the function `NavAskSaveChanges` (page 1408), except that you provide a custom alert message. This function is useful when you need to post a Save Changes alert box at times other than quitting or closing a file. Your application can display this alert box if a specified time interval has passed since the user last saved changes, for example.

Availability

Available in CarbonLib 1.0 and later when Navigation Services 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.5.

Carbon Porting Notes

Apple recommends you use the function `NavCreateAskSaveChangesDialog` in order to take advantage of Mac OS X features like Unicode, long filenames and enhanced modality. In order to provide a customized alert message, pass a non-null message string in the `NavDialogCreationOptions` structure passed to `NavCreateAskSaveChangesDialog`.

Declared In

`Navigation.h`

NavCustomControl

Allows your application to control various settings in Navigation Services dialogs.

```
OSErr NavCustomControl (
   NavDialogRef dialog,
   NavCustomControlMessage selector,
   void *parms
);
```

Parameters

dialog

A Navigation Services dialog reference. You can obtain this value from the `context` field of the structure of type `NavCBRec` (page 1451) specified in the `callBackParms` parameter of your event-handling function.

selector

A value of type `NavCustomControlMessage`. Pass one or more of the constants representing the possible values used to control various aspects of the active dialog. For a description of these constants, see "Custom Control Settings" (page 1465).

parms

A pointer to a configuration value. Some of the control setting constants passed in the `selector` parameter require that you provide an additional configuration value. For a description of which constants require configuration values, see "Custom Control Settings" (page 1465).

Return Value

A result code. See "Navigation Services Result Codes" (page 1486).

Discussion

If you provide an event-handling function and an event occurs in a Navigation Services dialog, Navigation Services calls your event-handling function and specifies one of the constants described in "Event Messages" (page 1475) in the `param` field of a `NavCBRec` (page 1451) structure. Navigation Services specifies this structure in the `callBackParms` parameter of your event-handling function. When Navigation Services supplies the `kNavCBStart` constant in the `param` field, your application can call the `NavCustomControl` function and pass one of the constants described in "Custom Control Settings" (page 1465) to control various aspects of the active Navigation Services dialog. For example, your application can tell Navigation Services to sort the browser list by date by calling the `NavCustomControl` function and passing the `kNavCtlSortBy` constant in the `selector` parameter and a pointer to the `kNavSortDateField` configuration constant in the `parms` parameter. (Some of the `NavCustomControlMessage` constants do not require a corresponding configuration constant.)

Note that your application can call the `NavCustomControl` function from within its event-handling function or its preview-drawing function.

Special Considerations

Navigation Services does not accept calls to the `NavCustomControl` function until an appropriate dialog box is fully initialized and displayed. Always check for the `kNavCBStart` constant, described in "Event Messages" (page 1475), in the `param` field of the `NavCBRec` structure before calling the `NavCustomControl` function.

Availability

Available in CarbonLib 1.0 and later when Navigation Services 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Declared In
`Navigation.h`

NavDialogDispose

Disposes of a dialog reference.

```
void NavDialogDispose (
   NavDialogRef inDialog
);
```

Parameters

inDialog
A Navigation Services dialog reference previously obtained by your application.

Discussion
Use this function to dispose of a dialog reference when you are completely finished with its associated dialog. You may call `NavDialogDispose` from within your application-defined event-handling function.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X 10.0 and later.

Related Sample Code
CarbonSketch
QTCarbonShell

Declared In
`Navigation.h`

NavDialogGetReply

Reports the results of a dialog session (unless cancelled or programmatically terminated).

```
OSStatus NavDialogGetReply (
   NavDialogRef inDialog,
   NavReplyRecord *outReply
);
```

Parameters

inDialog
A reference to a previously created dialog.

outReply
A pointer to a reply record you allocate to be filled out by Navigation Services.

Return Value
A result code. See "Navigation Services Result Codes" (page 1486).

Discussion
Call this function when you obtain a value other than `kNavUserActionCancel` or `kNavUserActionNone` from the `NavDialogGetUserAction` (page 1432) function. Upon completion of the `NavDialogGetReply` (page 1430) function, Navigation Services fills out the specified reply record with information about the dialog session. When you are finished with the reply record, remember to dispose of it by calling the `NavDisposeReply` function.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X 10.0 and later.

Related Sample Code
CarbonSketch
QTCarbonShell

Declared In
`Navigation.h`

NavDialogGetSaveFileExtensionHidden

Gets the current state of extension hiding in a Save dialog.

```
Boolean NavDialogGetSaveFileExtensionHidden (
   NavDialogRef inPutFileDialog
);
```

Parameters
`inPutFileDialog`
A reference to the Save dialog. You can create a Save dialog using the `NavCreatePutFileDialog` (page 1426) function.

Return Value
`True` if the extension is hidden; `false` if the extension is visible or if there is no extension.

Discussion
This function can be called at any time to determine if a Save dialog is hiding the file extension—if any—of the file to be saved.

Availability
Not available in CarbonLib.
Available in Mac OS X 10.1 and later.

Declared In
`Navigation.h`

NavDialogGetSaveFileName

Obtains the current value of the filename text field in a Save dialog.

```
CFStringRef NavDialogGetSaveFileName (
   NavDialogRef inPutFileDialog
);
```

Parameters

inPutFileDialog

A reference to a previously created dialog.

Return Value

A reference to the string containing the save filename. You should retain this string reference if you need the information after the dialog is dismissed. On Mac OS X, the full filename is returned, including any extension that may be hidden from the user. See the CFString documentation for a description of the `CFStringRef` data type.

Discussion

This function provides a Unicode-based replacement for using the `kNavGetEditFileName` selector with the `NavCustomControl` (page 1429) function.

Special Considerations

Note that you cannot use `NavDialogGetSaveFileName` with a Save dialog created using the `NavPutFile` function. You should instead create your Save dialog using the `NavCreatePutFileDialog` function.

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X 10.0 and later.

Declared In

`Navigation.h`

NavDialogGetUserAction

Reports the user action taken to dismiss a dialog.

```
NavUserAction NavDialogGetUserAction (
   NavDialogRef inDialog
);
```

Parameters

inDialog

A reference to a previously created dialog.

Return Value

One of the constants defined by the `NavUserAction` enumeration. This value indicates the user action that dismissed the dialog. See "User Actions" (page 1484) for a description of the values that may be returned here.

Discussion

If the dialog has not been dismissed or if the dialog was terminated by using the `kNavCtlTerminate` selector with the `NavCustomControl` (page 1429) function, the `NavDialogGetUserAction` (page 1432) function returns the `kNavUserActionNone` constant. When you obtain a value other than `kNavUserActionCancel` or `kNavUserActionNone` after returning from a file-handling dialog, Navigation Services fills out a reply record that you can obtain with the `NavDialogGetReply` (page 1430) function.

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X 10.0 and later.

Related Sample Code
CarbonSketch

Declared In
`Navigation.h`

NavDialogGetWindow

Obtains a window reference for a dialog.

```
WindowRef NavDialogGetWindow (
   NavDialogRef inDialog
);
```

Parameters

inDialog

A reference to a previously created dialog.

Return Value
A window reference for the specified dialog. Note that a valid dialog reference may not have a window associated with it until the `NavDialogRun` (page 1433) function is called. If no window is associated with the specified dialog, the `NavDialogGetWindow` (page 1433) function returns `NULL`.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X 10.0 and later.

Declared In
`Navigation.h`

NavDialogRun

Displays a previously created dialog.

```
OSStatus NavDialogRun (
   NavDialogRef inDialog
);
```

Parameters

inDialog

A reference to a previously created Navigation Services dialog.

Return Value
A result code. See "Navigation Services Result Codes" (page 1486).

Discussion
You must create a dialog before displaying it. To create a dialog, call one of the `NavCreate...Dialog` functions described in "Choosing Files, Folders and Volumes" (page 1401) and "Saving Files" (page 1402). If you specify an application-modal or system-modal dialog, the `NavDialogRun` (page 1433) function returns after the dialog is dismissed. If you specify a window-modal dialog (sheet) or a modeless dialog, the `NavDialogRun` (page 1433) function returns immediately; in order to know when the dialog has been dismissed, you must supply an event-handling function and watch for the `kNavCBUserAction` event.

After the user interacts with the dialog, you can obtain information about the dialog session by calling the `NavDialogGetReply` (page 1430) function.

Version Notes
On Mac OS 9 and earlier, all Navigation Services dialogs are modal, even if a window-modal or modeless dialog is requested. However, the `kNavCBUserAction` event is still sent to your event-handling function. It is possible to use a single programming model on both Mac OS 9 and on Mac OS X, provided you assume that the `NavDialogRun` function returns immediately after displaying the dialog.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X 10.0 and later.

Related Sample Code
CarbonSketch
QTCarbonShell

Declared In
`Navigation.h`

NavDialogSetFilterTypeIdentifiers

Sets UTI filtering criteria for "get file" and "choose file" dialogs.

```
OSStatus NavDialogSetFilterTypeIdentifiers (
   NavDialogRef inGetFileDialog,
   CFArrayRef inTypeIdentifiers
);
```

Parameters

inGetFileDialog

A Navigation Services dialog reference obtained from calling `NavCreateChooseFileDialog` (page 1419) or `NavCreateGetFileDialog` (page 1423).

inTypeIdentifiers

A Core Foundation array of uniform type identifiers. This array specifies the file types that you want your dialog to enable. If you pass an empty array, all files are filtered (and will appear dimmed in the dialog). If you pass `NULL`, all files are enabled.

The file types you specify here also appear in the popup menu (displayed using the localized name associated with the UTI), allowing the user to filter by a specific file type. The "All readable documents" selection displays all the types specified in the UTI array.

Return Value
A result code. See "Navigation Services Result Codes" (page 1486).

Discussion
For simple filtering by file type, you should use this function instead of writing a custom filter callback function. However, you can also use this call in conjunction with a filter callback; your custom filter callback is called after `NavDialogSetFilterTypeIdentifiers` performs the initial filtering.

This function supersedes the list of `OSType` values you can pass in the `inTypeList` parameter in dialog creation functions.

You can call this function at any time, even while the dialog is displayed. For example, say your dialog contained a custom menu item to filter by a specific type. When the user selects your menu item, you could call `NavDialogSetFilterTypeIdentifiers` with the UTI corresponding to that type, and the dialog will automatically update with the new filtering criteria.

For more information about uniform type identifiers, see *Uniform Type Identifiers Overview*

Availability
Available in Mac OS X v10.4 and later.

Declared In
`Navigation.h`

NavDialogSetSaveFileExtensionHidden

Sets the current state of extension hiding in a Save dialog.

```
OSStatus NavDialogSetSaveFileExtensionHidden (
   NavDialogRef inPutFileDialog,
   Boolean inHidden
);
```

Parameters

`inPutFileDialog`

A reference to the Save dialog. You can create a Save dialog using the `NavCreatePutFileDialog` (page 1426) function.

`inHidden`

A Boolean value indicating whether the file extension should be hidden. Pass `true` to hide the file extension; `false` to make any extension visible.

Return Value
A result code. See "Navigation Services Result Codes" (page 1486).

Discussion
This function can be called at any time to hide or show the extension of the file to be saved in a Save dialog. If the current filename has no extension, hiding the extension has no effect.

Availability
Not available in CarbonLib.
Available in Mac OS X 10.1 and later.

Declared In
`Navigation.h`

NavDialogSetSaveFileName

Specifies the current value of the filename text field in a Save dialog.

```
OSStatus NavDialogSetSaveFileName (
   NavDialogRef inPutFileDialog,
   CFStringRef inFileName
);
```

Parameters

inPutFileDialog

A reference to a previously created dialog.

inFileName

The filename to specify.

Return Value
A result code. See "Navigation Services Result Codes" (page 1486).

Discussion
This function may be called at any time to set the current filename for a save operation. You may use it to set an initial filename before calling `NavDialogRun`, or to change the filename dynamically while a dialog is running.

This function provides a Unicode-based replacement for using the `kNavSetEditFileName` selector with the `NavCustomControl` (page 1429) function.

Special Considerations

Note that you cannot use `NavDialogSetSaveFileName` with a Save dialog created using the `NavPutFile` function. You should instead create your Save dialog using the `NavCreatePutFileDialog` function.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X 10.0 and later.

Declared In
`Navigation.h`

NavDisposeReply

Releases the memory allocated for a `NavReplyRecord` structure after your application has finished using the structure.

```
OSErr NavDisposeReply (
   NavReplyRecord *reply
);
```

Parameters

reply

A pointer to a structure of type `NavReplyRecord` (page 1458) that your application has created.

Return Value
A result code. See "Navigation Services Result Codes" (page 1486).

Discussion
If your application calls a Navigation Services function that uses a structure of type `NavReplyRecord` (page 1458), you must use the `NavDisposeReply` function afterward to release the memory allotted for the `NavReplyRecord` structure.

Availability
Available in CarbonLib 1.0 and later when Navigation Services 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Related Sample Code
CarbonSketch
QTCarbonShell
QTMetaData

Declared In
`Navigation.h`

NavGetDefaultDialogCreationOptions

Determines the default attributes or behavior for dialogs.

```
OSStatus NavGetDefaultDialogCreationOptions (
   NavDialogCreationOptions *outOptions
);
```

Parameters

outOptions
A pointer to a `NavDialogCreationOptions` (page 1452) structure that you provide. On return, Navigation Services fills out the structure with default dialog configuration values.

Return Value
A result code. See "Navigation Services Result Codes" (page 1486).

Discussion
This function gives you a simple way to initialize a `NavDialogCreationOptions` (page 1452) structure and set default options before creating a Navigation Services dialog. After you create the `NavDialogCreationOptions` structure, you can change the configuration options before you call one of the dialog creation functions.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X 10.0 and later.

Related Sample Code
CarbonSketch
QTCarbonShell

Declared In
`Navigation.h`

NavGetDefaultDialogOptions

Determines the default attributes or behavior for dialog boxes. (Deprecated in Mac OS X v10.5.)

Not recommended

```
OSErr NavGetDefaultDialogOptions (
   NavDialogOptions *dialogOptions
);
```

Parameters

dialogOptions

A pointer to a structure of type `NavDialogOptions` (page 1463). On return, Navigation Services fills out the structure with default option values that your application can change as needed.

Return Value

A result code. See "Navigation Services Result Codes" (page 1486).

Discussion

This function gives you a simple way to initialize a structure of type `NavDialogOptions` (page 1463) and set the default dialog box options before calling one of the dialog box display functions. After you create the `NavDialogOptions` structure, you can supply it with the `NavDialogOptions` constants, described in "Dialog Configuration Options" (page 1471), to change the configuration options.

Availability

Available in CarbonLib 1.0 and later when Navigation Services 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.5.

Carbon Porting Notes

Apple recommends that you adopt the dialog creation functions (`NavCreate...Dialog`); you pass these functions a `NavDialogCreationOptions` (page 1452) structure rather than a `NavDialogOptions` (page 1463) structure.

Related Sample Code

QTMetaData

Declared In

`Navigation.h`

NavGetFile

Displays a dialog box that prompts the user to select a file or files to be opened. (Deprecated in Mac OS X v10.5.)

Not recommended

```
OSErr NavGetFile (
   AEDesc *defaultLocation,
   NavReplyRecord *reply,
   NavDialogOptions *dialogOptions,
   NavEventUPP eventProc,
   NavPreviewUPP previewProc,
   NavObjectFilterUPP filterProc,
   NavTypeListHandle typeList,
   void *callBackUD
);
```

Parameters

defaultLocation

A pointer to an Apple event descriptor structure (AEDesc). Before calling NavGetFile, you can set up a structure of AEDesc type 'typeFSS' to specify a default location to be viewed. If you pass NULL in this parameter, Navigation Services defaults to the last location visited during a call to the NavGetFile function. If the file system specification in the AEDesc structure does not describe a directory or volume, Navigation Services uses the desktop as the default location.

reply

A pointer to a structure of type NavReplyRecord (page 1458). Upon return, Navigation Services uses this structure to provide data to your application about the results of your NavGetFile call.

dialogOptions

A pointer to a structure of type NavDialogOptions (page 1463). Before calling NavGetFile, set up this structure to specify dialog box settings. If you pass NULL in this parameter, Navigation Services uses the defaults for all options. See "Dialog Configuration Options" (page 1471) for a description of the default settings.

eventProc

A Universal Procedure Pointer (UPP) to your application-defined event-handling function. You obtain this UPP by calling the function NewNavEventUPP. Implementing an event-handling function allows your application to update windows after the user moves or resizes the dialog box. If you pass NULL in this parameter, the Open dialog box is not movable or resizable. For more information on event-handling functions, see NavEventProcPtr (page 1448).

previewProc

A Universal Procedure Pointer (UPP) to your application-defined preview function. Obtain this UPP by calling the function NewNavPreviewUPP. A preview function allows your application to draw previews or to override Navigation Services previews. For more information on preview functions, see NavPreviewProcPtr (page 1450).

filterProc

A Universal Procedure Pointer (UPP) to your application-defined filter function. Obtain this UPP by calling the function NewNavObjectFilterUPP. An application-defined filter function determines if a volume, directory, or file should be displayed in the browser list or pop-up menus. For more information on filter functions, see NavObjectFilterProcPtr (page 1449).

typeList

A handle to a structure of type NavTypeList (page 1460). Before calling, set up this structure to declare file types that your application can open.

callBackUD

A pointer to a value set by your application. When the NavGetFile function calls your event-handling function, the callBackUD value is passed back to your application.

Return Value

A result code. See "Navigation Services Result Codes" (page 1486).

Discussion
After your application calls the `NavGetFile` function to display an Open dialog box and the user selects one or more files and clicks the Open button, `NavGetFile` closes the dialog box and returns references to the files to be opened in the `NavReplyRecord` structure. Your application should check the `validRecord` field of the `NavReplyRecord` structure; if this field is set to `true`, your application should open the files specified in the `selection` field of the `NavReplyRecord` structure.

Always dispose of the `NavReplyRecord` structure after completing the file opening operation by calling the function `NavDisposeReply` (page 1436). If you fail to use the `NavDisposeReply` function, memory used for the `NavReplyRecord` structure remains allocated and unavailable.

If you use the Show pop-up menu in an Open dialog box, your application must provide adequate kind strings to describe its native file types. For more information on `kind` strings, see Inside Macintosh: More Macintosh Toolbox.

Availability
Available in CarbonLib 1.0 and later when Navigation Services 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.

Carbon Porting Notes

Apple recommends you use the function `NavCreateGetFileDialog` (page 1423) in order to take advantage of Mac OS X features like Unicode, long filenames and enhanced modality.

Related Sample Code
QTMetaData

Declared In
`Navigation.h`

NavLibraryVersion

Reports the currently installed version of the Navigation Services shared library. (Deprecated in Mac OS X v10.5.)

```
UInt32 NavLibraryVersion (
   void
);
```

Return Value
An unsigned 32-bit integer. This value represents the version number (in binary-coded decimal) of Navigation Services installed on the user's system.

Discussion
If you want to use features that are present only in a specific version of Navigation Services, use the `NavLibraryVersion` function to determine which version of Navigation Services is installed.

Availability
Available in CarbonLib 1.0 and later when Navigation Services 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In
`Navigation.h`

NavLoad

Pre-loads the Navigation Services shared library.

Unsupported

```
OSErr NavLoad (
   void
);
```

Return Value
A result code. See "Navigation Services Result Codes" (page 1486).

Discussion
Use this function to pre-load the Navigation Services library. Pre-loading increases the memory used by your application, but it provides the best performance when using Navigation Services functions. If you don't use the `NavLoad` function, the Navigation Services shared library may not be loaded until your application calls one of the Navigation Services functions. If you use the `NavLoad` function, you must call the function `NavUnload` (page 1446) if you want to release reserved memory prior to quitting.

Availability
Available in CarbonLib 1.0 and later when Navigation Services 1.0 or later is present. Not available in Mac OS X.

Declared In
`Navigation.h`

NavNewFolder

Displays a dialog box that prompts the user to create a new folder. (Deprecated in Mac OS X v10.5.)

Not recommended

```
OSErr NavNewFolder (
   AEDesc *defaultLocation,
   NavReplyRecord *reply,
   NavDialogOptions *dialogOptions,
   NavEventUPP eventProc,
   void *callBackUD
);
```

Parameters
`defaultLocation`
A pointer to an Apple event descriptor structure (`AEDesc`). Before calling `NavNewFolder`, you can set up a structure of `AEDesc` type `'typeFSS'` to specify a default location to be viewed. If you pass `NULL` in this parameter, Navigation Services displays the last location visited during a call to the `NavNewFolder` function. If the file system specification in the `AEDesc` structure does not describe a directory or volume, Navigation Services uses the desktop as the default location.

reply

A pointer to a structure of type `NavReplyRecord` (page 1458). Upon return, Navigation Services uses this structure to provide data to your application about the results of the `NavNewFolder` function call.

dialogOptions

A pointer to a structure of type `NavDialogOptions` (page 1463). Before calling `NavNewFolder`, set up this structure to specify dialog box settings. If you pass `NULL` in this parameter, Navigation Services uses the defaults for all options. See "Dialog Configuration Options" (page 1471) for a description of the default settings.

eventProc

A Universal Procedure Pointer (UPP) to your application-defined event-handling function. You obtain this UPP by calling the function `NewNavEventUPP`. Implementing an event-handling function allows your application to update windows after the user moves or resizes the dialog box. If you pass `NULL` in this parameter, the dialog box is not movable or resizable. For more information on event-handling functions, see `NavEventProcPtr` (page 1448).

callBackUD

A pointer to a value set by your application. When the `NavNewFolder` function calls your event-handling function, the `callBackUD` value is passed back to your application.

Return Value
A result code. See "Navigation Services Result Codes" (page 1486).

Discussion
This function provides a way for your application to prompt the user to create a new folder. This might be useful for creating a project folder, for example.

Availability
Available in CarbonLib 1.0 and later when Navigation Services 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.

Carbon Porting Notes

Apple recommends you use the function `NavCreateNewFolderDialog` (page 1424) in order to take advantage of Mac OS X features like Unicode, long filenames and enhanced modality.

Declared In
`Navigation.h`

NavPutFile

Displays a Save dialog box. (Deprecated in Mac OS X v10.5.)

Not recommended

```
OSErr NavPutFile (
   AEDesc *defaultLocation,
   NavReplyRecord *reply,
   NavDialogOptions *dialogOptions,
   NavEventUPP eventProc,
   OSType fileType,
   OSType fileCreator,
   void *callBackUD
);
```

Parameters

defaultLocation

A pointer to an Apple event descriptor structure (`AEDesc`). Before calling `NavPutFile`, you can set up a structure of `AEDesc` type `'typeFSS'` to specify a default location to be viewed. If you pass `NULL` in this parameter, Navigation Services displays the last location visited during a call to the `NavPutFile` function. If the file system specification in the `AEDesc` structure does not describe a directory or volume, Navigation Services uses the desktop as the default location.

reply

A pointer to a structure of type `NavReplyRecord` (page 1458). Upon return, Navigation Services uses this structure to provide data to your application about the results of your `NavPutFile` call.

dialogOptions

A pointer to a structure of type `NavDialogOptions` (page 1463). Before calling `NavPutFile`, you can set up this structure to specify dialog box settings. If you pass `NULL` in this parameter, Navigation Services uses the defaults for all options. See "Dialog Configuration Options" (page 1471) for a description of the default settings.

eventProc

A Universal Procedure Pointer (UPP) to your application-defined event-handling function. You obtain this UPP by calling the function `NewNavEventUPP`. Implementing an event-handling function allows your application to update windows after the user moves or resizes the dialog box. If you pass `NULL` in this parameter, the Save dialog box is not movable or resizable. For more information on event-handling functions, see `NavEventProcPtr` (page 1448).

fileType

A four-character code. Pass the file type code for the document to be saved.

fileCreator

A four-character code. Pass the file creator code for the document to be saved. Under Navigation Services 2.0 or later, you may pass the "Generic File Signature Constant" (page 1479) constant if you want to override the types of files appearing in the Format popup.

callBackUD

A pointer to a value set by your application. When the `NavPutFile` function calls your event-handling function, the `callBackUD` value is passed back to your application.

Return Value

A result code. See "Navigation Services Result Codes" (page 1486). Note: If you specify the `kNavDontResolveAliases` constant as a dialog box option, as described in "Dialog Configuration Options" (page 1471), before calling the `NavPutFile` function, Navigation Services returns a `paramErr (-50)`.

Discussion

After your application calls the `NavPutFile` function to display a Save dialog box and the user selects a location, enters a filename, and clicks OK, `NavPutFile` closes the dialog box and returns references to the file to be saved in the `NavReplyRecord` structure. Your application should check the `validRecord` field of the `NavReplyRecord` structure; if this field is set to `true`, your application should save the file and call the function `NavCompleteSave` (page 1415).

If you specify the Format pop-up menu in a dialog box displayed by the `NavPutFile` function, your application must provide adequate kind strings to describe the file types available. If the user uses the Format menu to save a file to a format other than the file's native format, Navigation Services translates the file automatically. If you wish to turn off automatic translation, set to `false` the value of the `translationNeeded` field of the `NavReplyRecord` structure you pass in the `reply` parameter. If you turn off automatic translation, your application is responsible for any required translation.

Availability
Available in CarbonLib 1.0 and later when Navigation Services 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.

Carbon Porting Notes

Apple recommends you use the function `NavCreatePutFileDialog` (page 1426) in order to take advantage of Mac OS X features like Unicode, long filenames and enhanced modality.

Related Sample Code
QTMetaData

Declared In
`Navigation.h`

NavServicesAvailable

Reports whether the Navigation Services library is available on the user's system.

```
pascal Boolean NavServicesAvailable
```

Return Value
A Boolean value. This function returns `true` if Navigation Services is available, `false` if not.

Discussion
Use this function before attempting to use Navigation Services on Mac OS 8 and Mac OS 9. It is not necessary to call this function on Mac OS X, as Navigation Services is always available.

Special Considerations

There is a known problem with Navigation Services 1.0 that occurs if you call `NavServicesAvailable` more than once without the Appearance Manager being installed. Make sure that you check for the presence of the Appearance Manager before calling `NavServicesAvailable`.

Version Notes
Available in Navigation Services 1.0 and later.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Navigation.h`

NavServicesCanRun

Unsupported

```
Boolean NavServicesCanRun (
   void
);
```

Availability
Available in CarbonLib 1.0 and later when Navigation Services 1.0 or later is present. Not available in Mac OS X.

Declared In
`Navigation.h`

NavTranslateFile

Provides a means for files opened through Navigation Services to be read from different file formats. (Deprecated in Mac OS X v10.5.)

```
OSErr NavTranslateFile (
   const NavReplyRecord *reply,
   NavTranslationOptions howToTranslate
);
```

Parameters

reply

A pointer to a structure of type `NavReplyRecord` (page 1458). Upon return, Navigation Services uses this structure to provide translation information about the selected files.

howToTranslate

A value of type `NavTranslationOptions`. Pass one of these constants to tell Navigation Services how to perform the translation: either in-place or by making a copy of the file. For a description of the constants, see "Translation Options" (page 1483).

Return Value
A result code. See "Navigation Services Result Codes" (page 1486).

Discussion
Under automatic file translation, Navigation Services calls the `NavTranslateFile` function as necessary before returning from a file-opening function.

Your application can perform its own translation using the `NavReplyRecord` structure you specified in the `translateInfo` parameter. The `NavReplyRecord` structure contains a list of descriptors for the file or files to be opened and a corresponding list of translation specification records that can be passed to the Translation Manager. To determine if your application has to translate a file, your application can examine the `NavReplyRecord` structure to see if Navigation Services set the `translationNeeded` field to `true`. (The `translationNeeded` field of the `NavReplyRecord` structure is also set to `true` after returning from a `NavGetFile` call during which automatic translation was performed.) If you want to turn off automatic file translation, set the constant `kNavDontAutoTranslate` in the `dialogOptionFlags` field of the structure of type `NavDialogOptions` (page 1463) that you pass in the `dialogOptions` parameter of the file-opening function.

If your application uses the `NavTranslateFile` function after opening a file without automatic translation, Navigation Services checks to see if the source location can accept a new file. If the source location is not available (as occurs when the volume is locked or there is insufficient space), Navigation Services prompts the user to select a location in which to save the translated file. The same prompt may occur when automatic translation is enabled in an Open dialog box.

Availability
Available in CarbonLib 1.0 and later when Navigation Services 1.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In
`Navigation.h`

NavUnload

Unloads the Navigation Services shared library.

Unsupported

```
OSErr NavUnload (
   void
);
```

Return Value
A result code. See "Navigation Services Result Codes" (page 1486).

Discussion
This function allows your application to unload the Navigation Services library and release the memory reserved for it. If you use the function `NavLoad` (page 1441) to load the Navigation Services library, you must call the `NavUnload` function if you want to release reserved memory prior to quitting.

Availability
Available in CarbonLib 1.0 and later when Navigation Services 1.0 or later is present. Not available in Mac OS X.

Declared In
`Navigation.h`

NewNavEventUPP

Creates a new universal procedure pointer to your application-defined event–handling function.

```
NavEventUPP NewNavEventUPP (
   NavEventProcPtr userRoutine
);
```

Parameters
`userRoutine`
A pointer to your event–handling function.

Return Value
On return, a universal procedure pointer (UPP) to the event–handling function. See the description of the `NavEventUPP` data type.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.

Related Sample Code
CarbonSketch
QTMetaData

Declared In
`Navigation.h`

NewNavObjectFilterUPP

Creates a new universal procedure pointer to your application-defined filter function.

```
NavObjectFilterUPP NewNavObjectFilterUPP (
   NavObjectFilterProcPtr userRoutine
);
```

Parameters

`userRoutine`
A pointer to your filter function.

Return Value
On return, a universal procedure pointer (UPP) to the filter function. See the description of the `NavObjectFilterUPP` data type.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.

Declared In
`Navigation.h`

NewNavPreviewUPP

Creates a new universal procedure pointer to your application-defined preview function.

```
NavPreviewUPP NewNavPreviewUPP (
   NavPreviewProcPtr userRoutine
);
```

Parameters

`userRoutine`
A pointer to your preview function.

Return Value
On return, a universal procedure pointer (UPP) to the preview function. See the description of the `NavPreviewUPP` data type.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.

Declared In
`Navigation.h`

Callbacks

NavEventProcPtr

A pointer to an event-handling function that handles events such as window updating and resizing.

```
typedef void (*NavEventProcPtr) (
                NavEventCallbackMessage callBackSelector,
                NavCBRecPtr callBackParms,
                void * callBackUD);
```

If you name your function `MyNavEventProc`, you would declare it like this:

```
void MyNavEventProc (
            NavEventCallbackMessage callBackSelector,
            NavCBRecPtr callBackParms,
            void * callBackUD);
```

Parameters

callBackSelector

One of the values specified by the `NavEventCallbackMessage` data type. These values indicate which type of event your function must respond to. For a description of the constants that represent these values, see "Event Messages" (page 1475).

callBackParms

A pointer to a `NavCBRec` (page 1451) structure. Your application uses the data supplied in this structure to process the event.

callBackUD

A pointer to a value set by your application when it calls a Navigation Services dialog creation function. When Navigation Services calls your event-handling function, the `callBackUD` value is passed back to your application in this parameter.

Discussion

Register your event-handling function by passing a Universal Procedure Pointer (UPP) in the `eventProc` parameter of a Navigation Services dialog creation function. You obtain this UPP by calling the function `NewNavEventUPP` and passing a pointer to your event-handling function. If you determine that an event is appropriate for your event-handling function, you can call other functions to handle custom control drawing.

When events involve controls, your event-handling function must respond to events only for your application-defined controls. To determine which control is affected by an event, pass the `kNavCtlGetFirstControlID` constant, described in "Custom Control Settings" (page 1465), in the `selector` parameter of the function `NavCustomControl` (page 1429).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Navigation.h`

NavObjectFilterProcPtr

A pointer to a filter function that determines whether file objects should be displayed in the browser list and navigation menus.

```
typedef Boolean (*NavObjectFilterProcPtr)
(
                AEDesc * theItem,
                void * info,
                void * callBackUD,
                NavFilterModes filterMode);
```

If you name your function `MyNavObjectFilterProc`, you would declare it like this:

```
Boolean MyNavObjectFilterProc (
            AEDesc * theItem,
            void * info,
            void * callBackUD,
            NavFilterModes filterMode);
```

Parameters

theItem

A pointer to an Apple event descriptor structure (`AEDesc`). Navigation Services uses this structure to provide information about the object being passed to your filter function. Always check the Apple event descriptor type before deciding if an object needs to be filtered. Never assume that an object is a file specification, because the browser or pop-up menus may contain objects of other types. Make sure that your function only returns `true` if it recognizes the object.

info

A pointer to a `NavFileOrFolderInfo` (page 1456) structure. Navigation Services uses this structure to provide file or folder information about the item being passed to your filter function. This information is only valid for objects of descriptor types `'typeFSS'` or `'typeFSRef'`.

callBackUD

A pointer to a value set by your application when it calls a Navigation Services dialog creation function. When Navigation Services calls your filter function, the `callBackUD` value is passed back to your application in this parameter.

filterMode

A value representing which list of objects is currently being filtered. For a description of the constants used to represent these values, see "Object Filtering Constants" (page 1480).

Return Value

A Boolean value. If your application returns `true`, Navigation Services displays the object. If your application returns `false`, Navigation Services displays the object as dimmed.

Discussion

Register your filter function by passing a Universal Procedure Pointer (UPP) in the `filterProc` parameter of a dialog creation function. You obtain this UPP by calling the function `NewNavObjectFilterUPP` and passing a pointer to your filter function. Navigation Services calls your filter function to determine whether a file object should be displayed in the browser list or the pop-up menus.

If you use a filter function in conjunction with built-in translation, you should provide a list of file types to inform Navigation Services which document types your application can open. You can do so using the following methods:

- Call the `NavDialogSetFilterTypeIdentifiers` (page 1434) function on an existing dialog to filter by uniform type identifiers. This method is preferable in Mac OS X v10.4 and later.
- Provide a list of allowable `OSType` file types in the `inTypeList` parameter of a file-opening function such as `NavCreateGetFileDialog`

If you provide a list of file types, your filter callback is called only for the files that match the specified type list. For example, if you wanted to enable only text files below a certain size, you could use `NavDialogSetFilterTypeIdentifiers` (page 1434) to enable only text files, and then use a filter callback to screen for file size. You should make sure that your filter callback doesn't automatically eliminate a document type in the filter list (for example, if the list allows JPEG files and the callback eliminates everything but PICT files). This is to ensure that the user can always see some files when a particular file type is selected from the Enable popup menu.

If your filter function returns a result of `true`, Navigation Services displays the object. Note that this is the opposite of Standard File filter functions.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Navigation.h`

NavPreviewProcPtr

A pointer to a preview function that displays custom file previews.

```
typedef Boolean (*NavPreviewProcPtr)
(
                NavCBRecPtr callBackParms,
                void * callBackUD);
```

If you name your function `MyNavPreviewProc`, you would declare it like this:

```
Boolean MyNavPreviewProc (
        NavCBRecPtr callBackParms,
        void * callBackUD);
```

Parameters

`callBackParms`

A pointer to a `NavCBRec` (page 1451) structure. Navigation Services uses this structure to provide data needed for your function to draw the preview.

`callBackUD`

A pointer to a value set by your application when it calls a Navigation Services function such as `NavCreateGetFileDialog`. When Navigation Services calls your preview function, the `callBackUD` value is passed back to your application in this parameter.

Return Value
A Boolean value. Your application returns `true` if your preview function successfully draws the custom file preview. If your preview function returns `false`, Navigation Services displays the preview if the file contains a valid `'pnot'` resource. If your preview function returns `false` and a `'pnot'` resource is not available, Navigation Services displays a blank preview area.

Discussion
Register your preview function by passing the resulting Universal Procedure Pointer (UPP) in the `previewProc` parameter of a Navigation Services dialog creation function. You obtain this UPP by calling the function `NewNavPreviewUPP` and passing a pointer to your preview-drawing function. When the user selects a file, Navigation Services calls your preview-drawing function. Your preview function, in turn, calls the function `NavCustomControl` (page 1429) to determine if the preview area is visible and, if so, what its dimensions are.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Navigation.h`

Data Types

NavDialogRef

An opaque reference to an instance of a Navigation Services dialog.

```
typedef struct __NavDialog * NavDialogRef;
```

Discussion
Your application obtains a `NavDialogRef` by calling one of the dialog creation functions described in "Choosing Files, Folders and Volumes" (page 1401) and "Saving Files" (page 1402). Once you obtain a valid reference, you pass it to other functions in order to display and process dialogs. When you are completely finished using the reference, dispose of it by calling the function `NavDialogDispose` (page 1430). This data type is available in CarbonLib 1.1 and later and in Mac OS X. It replaces the `NavContext` data type previously used by Navigation Services.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Navigation.h`

NavCBRec

Provides information you can use for event-handling and customization.

```
struct NavCBRec {
    UInt16 version;
    NavDialogRef context;
    WindowRef window;
    Rect customRect;
    Rect previewRect;
    NavEventData eventData;
    NavUserAction userAction;
    char reserved[218];
};
typedef struct NavCBRec NavCBRec;
typedef NavCBRec * NavCBRecPtr;
```

Fields

`version`
: Identifies the version of this structure. This value is defined by the `kNavCBRecVersion` constant.

`context`
: An opaque object identifying the dialog instance.

`window`
: An opaque object identifying the dialog's window.

`customRect`
: A local coordinate rectangle describing the customization area available to your application. This determines how much room your application has to install custom controls.

`previewRect`
: A local coordinate rectangle describing the preview area available to your application's preview function. The minimum size is 145 pixels wide by 118 pixels high.

`eventData`
: A structure of type `NavEventData` (page 1454). This structure provides event-specific data to your `NavEventProcPtr` (page 1448) function.

`userAction`
: A constant specifying the action taken by the user, generating a `kNavCBUserAction` event. See "User Actions" (page 1484) for a description of the possible values for this field.

  This field is available in CarbonLib 1.1 and later or in Mac OS X version 10.0 and later.

`reserved`
: Reserved.

Discussion

The `NavCBRec` structure is passed to your application-defined event-handling and preview functions. For more information on event-handling and preview functions, see `NavEventProcPtr` (page 1448) and `NavPreviewProcPtr` (page 1450), respectively.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Navigation.h`

NavDialogCreationOptions

Contains dialog configuration settings you can pass to Navigation Services dialog creation functions.

```
struct NavDialogCreationOptions {
    UInt16 version;
    NavDialogOptionFlags optionFlags;
    Point location;
    CFStringRef clientName;
    CFStringRef windowTitle;
    CFStringRef actionButtonLabel;
    CFStringRef cancelButtonLabel;
    CFStringRef saveFileName;
    CFStringRef message;
    UInt32 preferenceKey;
    CFArrayRef popupExtension;
    WindowModality modality;
    WindowRef parentWindow;
    char reserved[16];
};
typedef struct NavDialogCreationOptions NavDialogCreationOptions;
```

Fields

`version`

Identifies the version of this structure. The structure version is represented by the `kNavDialogCreationOptionsVersion` constant.

`optionFlags`

One of several constants defined by the `NavDialogOptionFlags` data type as described in "Dialog Configuration Options" (page 1471).

`location`

A point describing the location of the upper-left corner of the dialog window, in global coordinates. If you set this field to (-1,-1), then the dialog window appears in the same location as when it was last closed. The size and location of the dialog window is persistent, but defaults to opening in the middle of the main screen if any portion is not visible when opened at the persistent location and size.

This field is ignored for sheet dialogs.

`clientName`

A string that identifies your application in the window title of file dialogs and in the message displayed for the Save Changes, Review Changes, and Ask Discard changes alerts.

On Mac OS 8 and 9, Navigation Services cannot maintain persistence information for your application if you do not provide this string.

`windowTitle`

A string that you can provide to override the default window title. If you pass `NULL`, the default window title is used.

`actionButtonLabel`

An alternative button title for the dialog's default button. If you pass `NULL`, the button uses the default label (Open or Save, for example.

`cancelButtonLabel`

An alternative button title for the dialog's Cancel button. If you pass `NULL`, the default button title is used.

`saveFileName`

The default filename for a file to be saved (Save dialog only). If you pass `NULL`, the filename field is blank.

`message`

For the file dialogs, a string for the banner, or prompt, below the browser list. This message can provide more descriptive instructions for the user. If you pass `NULL`, no banner appears and the browser list expands to fill that area.

For the Save Changes, Review Changes and Ask Discard Changes alerts, a string specifying a custom message that replaces the default message.

`preferenceKey`

An application-defined value that identifies which set of dialog preferences Navigation Services should use. If your application maintains multiple sets of preferences for a particular type of dialog, you can determine which set is active by specifying the appropriate value in the `preferenceKey` field. For example, an application may provide one set of preferences when it calls the function to open text files and a different set of preferences when opening movie files. If you do not wish to provide a preference key, specify 0 for the `preferenceKey` value.

`popupExtension`

A reference to an array of menu item strings. These strings are used to add extra menu items to the Show pop-up menu in an Open dialog or to the Format pop-up menu in a Save dialog. Your application can use this array to add additional document types to be opened or saved, or different ways of saving a file (with or without line breaks, for example).

`modality`

This value allows you to specify the modality of the dialog. The default modality for all dialogs is `kWindowModalityAppModal`. If you specify the `kWindowModalityWindowModal` constant to make a dialog appear as a sheet, you must provide a valid window reference in the `parentWindow` field. If you specify the `kWindowModalityWindowModal` constant on Mac OS 8 or 9, the modality is set to `kWindowModalityAppModal`.

This field is available in CarbonLib 1.1 and later or in Mac OS X version 10.0 and later.

`parentWindow`

A reference to the parent window for a sheet.

This field is available in CarbonLib 1.1 and later or in Mac OS X version 10.0 and later.

`reserved`

Reserved.

Discussion

When you create a Navigation Services dialog, using one of the `NavCreate...Dialog` creation functions, you must supply a `NavDialogCreationOptions` structure to specify the appearance and behavior of the dialog. You can initialize a `NavDialogCreationOptions` structure using the `NavGetDefaultDialogCreationOptions` (page 1437) function; this fills out the structure with the default dialog creation settings.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Navigation.h`

NavEventData

Contains event data for Navigation Services dialogs.

```
struct NavEventData {
    NavEventDataInfo eventDataParms;
    SInt16 itemHit;
};
typedef struct NavEventData NavEventData;
```

Fields

`eventDataParms`

A structure of type `NavEventDataInfo` (page 1455).

`itemHit`

A signed integer value. On return, this value represents the item number of the dialog item last clicked by the user. If the user clicks something other than a valid Navigation Services-generated control item, this value is -1.

Discussion

The `NavEventData` structure is passed to your application-defined event-handling or preview function in the `eventData` field of the `NavCBRec` structure.

The `NavEventData` structure contains a structure of type `NavEventDataInfo` (page 1455). In Navigation Services 1.1 or later, the `NavEventData` structure also contains a field describing the dialog item last clicked by the user.

Version Notes

`itemHit` field added in Navigation Services 1.1.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Navigation.h`

NavEventDataInfo

Provides event–handling data to your application.

```
union NavEventDataInfo {
    EventRecord * event;
    void * param;
};
typedef union NavEventDataInfo NavEventDataInfo;
```

Fields

`event`

A pointer to the `EventRecord` structure describing an event to be handled by your event-handling function.

`param`

A pointer to additional event data. In most cases, this data consists of an Apple event descriptor list (`AEDescList`) for the file or files affected by the event described in the `event` field. For example, if the event consists of the user making a selection in the browser list, the `AEDescList` specifies the file or files selected.

Availability

Available in Mac OS X v10.0 and later.

Declared In
`Navigation.h`

NavFileOrFolderInfo

Contains file or folder information for use by your application-defined filter function.

```
struct NavFileOrFolderInfo {
    UInt16 version
    Boolean isFolder
    Boolean visible
    UInt32 creationDate
    UInt32 modificationDate
    union {
        struct {
            Boolean locked;
            Boolean resourceOpen;
            Boolean dataOpen;
            Boolean reserved1;
            UInt32 dataSize;
            UInt32 resourceSize;
            FInfo finderInfo;
            FXInfo finderXInfo;
        } fileInfo;
        struct {
            Boolean shareable;
            Boolean sharePoint;
            Boolean mounted;
            Boolean readable;
            Boolean writeable;
            Boolean reserved2;
            UInt32 numberOfFiles;
            DInfo finderDInfo;
            DXInfo finderDXInfo;
            OSType folderType;
            OSType folderCreator;
            char reserved3[206];
        } folderInfo;
    } fileAndFolder;
};
typedef struct NavFileOrFolderInfo NavFileOrFolderInfo;
```

Fields

`version`
Identifies the version of this structure.

`isFolder`
A Boolean value. If this value is set to `true`, the object being described is a folder or volume; otherwise, the value is set to `false`. An alias to a folder or volume returns `true`. Check for the `kIsAlias` constant in the `fileAndFolder.folderInfo.finderDInfo` field to determine whether an object is an alias.

`visible`
A Boolean value. If this value is set to `true`, the object being described is visible in the browser list; otherwise, the value is set to `false`.

`creationDate`
The creation date of the object being described.

`modificationDate`
The modification date of the object being described.

`fileAndFolder.fileInfo.locked`
If `isFolder` is `false`, a Boolean value indicating whether the file is locked.

`fileAndFolder.fileInfo.resourceOpen`
If `isFolder` is `false`, a Boolean value indicating whether the resource fork of the file is open.

`fileAndFolder.fileInfo.dataOpen`
If `isFolder` is `false`, a Boolean value indicating whether the data fork of the file is open.

`fileAndFolder.fileInfo.reserved1`
Reserved.

`fileAndFolder.fileInfo.dataSize`
If `isFolder` is `false`, the size of the file's data fork.

`fileAndFolder.fileInfo.resourceSize`
If `isFolder` is `false`, the size of the file's resource fork.

`fileAndFolder.fileInfo.finderInfo`
If `isFolder` is `false`, a structure specifying further information about the file. See the Finder Interface documentation for more information on the `FInfo` structure.

`fileAndFolder.fileInfo.finderXInfo`
If `isFolder` is `false`, a structure specifying extended Finder information for the file. See the Finder Interface documentation for more information on the `FXInfo` structure.

`fileAndFolder.folderInfo.shareable`
If `isFolder` is `true`, a Boolean value indicating whether the folder is shareable.

`fileAndFolder.folderInfo.sharePoint`
If `isFolder` is `true`, a Boolean value indicating whether the folder is a share point.

`fileAndFolder.folderInfo.mounted`
If `isFolder` is `true`, a Boolean value indicating whether the folder is mounted.

`fileAndFolder.folderInfo.readable`
If `isFolder` is `true`, a Boolean value indicating whether the folder is readable.

`fileAndFolder.folderInfo.writeable`
If `isFolder` is `true`, a Boolean value indicating whether the folder is writeable.

`fileAndFolder.folderInfo.reserved2`
Reserved.

`fileAndFolder.folderInfo.numberOfFiles`
If `isFolder` is `true`, the number of files in the folder.

`fileAndFolder.folderInfo.finderDInfo`
If `isFolder` is `true`, a directory information structure describing the folder. See the Finder Interface documentation for further information on the `DInfo` structure.

`fileAndFolder.folderInfo.finderDXInfo`
If `isFolder` is `true`, an extended directory information structure describing the folder. See the Finder Interface documentation for further information on the `DXInfo` structure.

`fileAndFolder.folderInfo.folderType`
If `isFolder` is `true`, the package type (for structure version 1 or greater).

`fileAndFolder.folderInfo.folderCreator`
If `isFolder` is `true`, the creator code for the package (for structure version 1 or greater).

Discussion

The `NavFileOrFolderInfo` structure contains file or folder information for use by your application-defined filter function. Your filter function can determine whether the currently selected object is a file by checking the `isFolder` field of the `NavFileOrFolderInfo` structure for the value `false`. After making this determination, you can obtain more information about the object from the structure specified in the `fileAndFolder` field.

Special Considerations

The information in this structure is valid only for HFS file objects.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Navigation.h`

NavReplyRecord

Contains information about user interaction with a dialog.

```
struct NavReplyRecord {
    UInt16 version;
    Boolean validRecord;
    Boolean replacing;
    Boolean isStationery;
    Boolean translationNeeded;
    AEDescList selection;
    ScriptCode keyScript;
    FileTranslationSpecArrayHandle fileTranslation;
    UInt32 reserved1;
    CFStringRef saveFileName;
    Boolean saveFileExtensionHidden;
    UInt8 reserved2;
    char reserved[225];
};
typedef struct NavReplyRecord NavReplyRecord;
```

Fields

`version`
: Identifies the version of this structure. The structure version is represented by the constant `kNavReplyRecordVersion`.

`validRecord`
: A Boolean value of `true` if the user closes a dialog by pressing Return or Enter, or by clicking the default button in an Open or Save dialog. If this field is `false`, all other fields are unused and do not contain valid data.

`replacing`
: A Boolean value of `true` if the user chooses to save a file by replacing an existing file (thereby necessitating the removal or renaming of the existing file).

`isStationery`
: A Boolean value informing your application whether the file about to be saved should be saved as a stationery document.

`translationNeeded`
: A Boolean value indicating whether translation was or will be needed for files selected in Open and Save dialogs.

`selection`
: For a file-opening or file-choosing dialog, this is an Apple event descriptor list (`AEDescList`) containing references to items selected by the user. Navigation Services creates this list, which is automatically disposed of when your application calls the `NavDisposeReply` function. Some dialogs may return one or more items; you can determine the number of items in the list by calling the Apple Event Manager function `AECountItems`. Each selected HFS file object is described in an `AEDesc` structure of type `'typeFSS'` or `'typeFSRef'`. You can coerce this descriptor into a file reference to perform operations such as opening the file. If you use one of the Carbon-compliant dialog creation functions described in"Choosing Files, Folders and Volumes" (page 1401) and "Saving Files" (page 1402), the descriptor is of type `'typeFSS'` on Mac OS 8 or 9; on Mac OS X systems, this descriptor is of type `'typeFSRef'`.File-saving dialogs always return a single descriptor in the list. If you use the `NavCreatePutFileDialog` (page 1426) function, this descriptor specifies the directory where the file is to be saved. You can obtain the name for the save file from the `saveFileName` field.

`keyScript`
: The keyboard script system used for the filename.

`fileTranslation`
: A handle to a Translation Manager structure of type `FileTranslationSpec`. This structure contains a corresponding translation array for each file reference returned in the `selection` field. When opening files, Navigation Services performs the translation automatically unless you set the `kNavDontAutoTranslate` flag in the `dialogOptionFlags` field of the `NavDialogCreationOptions` (page 1452) structure. When Navigation Services performs an automatic translation, the `FileTranslationSpec` structure is strictly for the Translation Manager's use. If you turn off automatic translation, your application may use the `FileTranslationSpec` structure for your own translation scheme. If the user chooses a translation for a saved file, the `FileTranslationSpec` structure contains a single translation reference for the saved file and the `translationNeeded` field of the `NavReplyRecord` structure is set to `true`. The handle to the `FileTranslationSpec` structure is locked, so you can safely use dereferenced pointers.

`reserved1`
: Reserved.

`saveFileName`
: If the reply record is filled out by a dialog created with the `NavCreatePutFileDialog` (page 1426) function, this field contains a string specifying the name of a file to be saved. This field contains the entire name of the file, regardless of whether or not any file extension is visible to the user. You can identify the directory in which the file is to be saved by checking the `selection` field.

  This field was added in structure version 1.

`saveFileExtensionHidden`
: A Boolean value indicating whether the extension on the name of the saved file should be hidden. Once the file has been saved, the client call the `NavCompleteSave` function. `NavCompleteSave` hides the extension on the file. However, the client needs to know that the extension is hidden so that it can display the document name correctly in the user interface, such as in window titles and menus. This field is only used if the client has requested extension preservation using the `kNavPreserveSaveFileExtension` dialog option flag. This field was added in structure version 2.

`reserved2`
: Reserved.

`reserved`
: Reserved.

Discussion
Navigation Services uses the `NavReplyRecord` structure to provide your application with information about the user's interactions with a Navigation Services dialog. If the dialog is created with the Carbon-compliant `NavCreate...Dialog` functions, you obtain the `NavReplyRecord` by calling the `NavDialogGetReply` (page 1430) function after your event-handling function receives the `kNavCBUserAction` event. If you create the dialog using one of the older functions, you pass the address of a `NavReplyRecord` directly to the function that invokes the dialog. When your application is through using the structure, remember to dispose of it by calling the function `NavDisposeReply` (page 1436).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Navigation.h`

NavTypeList

Defines a list of file types that your application is capable of opening.

```
struct NavTypeList {
    OSType componentSignature;
    short reserved;
    short osTypeCount;
    OSType osType[1];
};
typedef struct NavTypeList NavTypeList;
typedef NavTypeList * NavTypeListPtr;
```

Fields

`componentSignature`
A four character code specifying your application signature. If you want your application to be able to open all files of the types you specify in the `osType` field (regardless of which application created them), specify the `kNavGenericSignature` constant in this field.

`reserved`
Reserved.

`osTypeCount`
A number indicating how many file types are defined in the `osType` field.

`osType`
A list of file types your application can open.

Discussion
Your application uses the `NavTypeList` structure to define a list of file types that your application is capable of opening. Your application passes a pointer to this list to Navigation Services functions that display Open or Save dialogs. You may create this list dynamically or reference a Translation Manager `'open'` resource.

For more information on the `'open'` resource and the Translation Manager, see the "Translation Manager" chapter in *Inside Macintosh: More Macintosh Toolbox*.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Navigation.h`

NavEventUPP

Defines a universal procedure pointer (UPP) to an application-defined event–handling function.

```
typedef NavEventProcPtr NavEventUPP;
```

Discussion
For more information, see the description of the `NavEventProcPtr` (page 1448) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Navigation.h`

NavObjectFilterUPP

Defines a universal procedure pointer (UPP) to an application-defined filter function.

```
typedef NavObjectFilterProcPtr NavObjectFilterUPP;
```

Discussion
For more information, see the description of the `NavObjectFilterProcPtr` (page 1449) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Navigation.h`

NavPreviewUPP

Defines a universal procedure pointer (UPP) to an application-defined preview function.

```
typedef NavPreviewProcPtr NavPreviewUPP;
```

Discussion
For more information, see the description of the `NavPreviewProcPtr` (page 1450) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Navigation.h`

NavMenuItemSpec

Defines additional items in an Open dialog's Show pop-up menu or a Save dialog's Format pop-up menu.

```
struct NavMenuItemSpec {
    UInt16 version;
    OSType menuCreator;
    OSType menuType;
    Str255 menuItemName;
    char reserved[245];
};
typedef struct NavMenuItemSpec          NavMenuItemSpec;
typedef NavMenuItemSpec *               NavMenuItemSpecArrayPtr;
typedef NavMenuItemSpecArrayPtr *       NavMenuItemSpecArrayHandle;
typedef NavMenuItemSpecArrayPtr         NavMenuItemSpecPtr;
typedef NavMenuItemSpecArrayHandle      NavMenuItemSpecHandle;
```

Fields

`version`

Identifies the version of this structure. Be sure to specify the `kNavMenuItemSpecVersion` constant in this field.

`menuCreator`

A unique value set by your application. Navigation Services passes this value back to your application to identify the application type of the selected menu item.

`menuType`

A unique value set by your application. Navigation Services passes this value back to your application to identify the type of the selected menu item. Values from -1 to 10 are reserved for Navigation Services.

`menuItemName`

The item name that appears in the pop-up menu.

`reserved`

Reserved for future use.

Discussion

For information about file creators and file types, see *Inside Macintosh: Macintosh Toolbox Essentials*.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Navigation.h`

NavContext

An old name for `NavDialogRef`.

Not recommended

```
typedef NavDialogRef NavContext;
```

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Navigation.h`

NavDialogOptions

Contains dialog box configuration settings.

Not recommended

```
struct NavDialogOptions {
    UInt16 version;
    NavDialogOptionFlags dialogOptionFlags;
    Point location;
    Str255 clientName;
    Str255 windowTitle;
    Str255 actionButtonLabel;
    Str255 cancelButtonLabel;
    Str255 savedFileName;
    Str255 message;
    UInt32 preferenceKey;
    NavMenuItemSpecArrayHandle popupExtension;
    char reserved[494];
};
typedef struct NavDialogOptions NavDialogOptions;
```

Fields

`version`
: Identifies the version of this structure. Be sure to specify the `kNavDialogOptionsVersion` constant in this field.

`dialogOptionFlags`
: One of several constants defined by the `NavDialogOptionFlags` data type as described in "Dialog Configuration Options" (page 1471).

`location`
: The upper-left location of the dialog box (in global coordinates). If you set the `dialogOptionFlags` field to `NULL` or set this field to (-1,-1), then the dialog box appears in the same location as when last closed. The size and location of the dialog box is persistent, but defaults to opening in the middle of the main screen if any portion is not visible when opened at the persistent location and size.

`clientName`
: A string that identifies your application in the dialog box window title.

`windowTitle`
: A string that you can provide to override the default window title.

`actionButtonLabel`
: An alternative button title for the dialog box's action button. If you do not specify a title, the button will use the default label (Open or Save, for example.

`cancelButtonLabel`
: An alternative button title for the Cancel button in dialog boxes.

`savedFileName`
: The default filename for a saved file.

`message`
: The string for the banner, or prompt, below the browser list. This message can provide more descriptive instructions for the user. If you don't provide a message string, the browser list expands to fill that area.

`preferenceKey`

An application-defined value that identifies which set of dialog box preferences Navigation Services should use. If your application maintains multiple sets of preferences for a particular type of dialog box, you can determine which set is active by specifying the appropriate value in the `preferenceKey` field. For example, an application may allow one set of preferences when it calls the function `NavGetFile` (page 1438) to open text files and a different set of preferences when opening movie files. If you do not wish to provide a preference key, specify `NULL` for the `preferenceKey` value.

`popupExtension`

A handle to one or more structures of type `NavMenuItemSpec` (page 1461) used to add extra menu items to the Show pop-up menu in an Open dialog box or the Format pop-up menu in Save dialog boxes. Using `NavMenuItemSpec` structures allows your application to add additional document types to be opened or saved, or different ways of saving a file (with or without line breaks, for example).

`reserved`

Reserved for future use.

Carbon Porting Notes

The `NavDialogCreationOptions` (page 1452) structure is the recommended replacement for the `NavDialogOptions` structure. *`NavDialogCreationOptions`* uses CFString objects instead of Pascal strings, thereby adding support for Unicode. In addition, `NavDialogCreationOptions` adds fields for controlling window modality and setting the parent window (necessary for sheets on OS X).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Navigation.h`

Constants

Action State Constants

Let you block certain actions in dialogs.

```
typedef UInt32 NavActionState;
enum {
    kNavNormalState = 0x00000000,
    kNavDontOpenState = 0x00000001,
    kNavDontSaveState = 0x00000002,
    kNavDontChooseState = 0x00000004,
    kNavDontNewFolderState = 0x00000010
};
```

Constants

`kNavNormalState`

Allows all user actions. This is the default state.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavDontOpenState`
Prevents Navigation Services from opening files.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavDontSaveState`
Prevents Navigation Services from saving files.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavDontChooseState`
Prevents Navigation Services from choosing files.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavDontNewFolderState`
Prevents Navigation Services from creating new folders.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

Discussion
The `NavActionState` enumeration defines constants you can specify in the `parms` parameter of the function `NavCustomControl` (page 1429) in order to block certain actions in Navigation Services dialogs. When you specify these constants, you must also specify the `kNavSetActionState` constant in the `selector` parameter of the `NavCustomControl` function.

Version Notes
These constants are only available in Navigation Services 2.0 or later.

Custom Control Settings

Provide constants that allow you to control various aspects of the active dialog.

```
typedef SInt32 NavCustomControlMessage;
enum {
    kNavCtlShowDesktop = 0,
    kNavCtlSortBy = 1,
    kNavCtlSortOrder = 2,
    kNavCtlScrollHome = 3,
    kNavCtlScrollEnd = 4,
    kNavCtlPageUp = 5,
    kNavCtlPageDown = 6,
    kNavCtlGetLocation = 7,
    kNavCtlSetLocation = 8,
    kNavCtlGetSelection = 9,
    kNavCtlSetSelection = 10,
    kNavCtlShowSelection = 11,
    kNavCtlOpenSelection = 12,
    kNavCtlEjectVolume = 13,
    kNavCtlNewFolder = 14,
    kNavCtlCancel = 15,
    kNavCtlAccept = 16,
    kNavCtlIsPreviewShowing = 17,
    kNavCtlAddControl = 18,
    kNavCtlAddControlList = 19,
    kNavCtlGetFirstControlID = 20,
    kNavCtlSelectCustomType = 21,
    kNavCtlSelectAllType = 22,
    kNavCtlGetEditFileName = 23,
    kNavCtlSetEditFileName = 24,
    kNavCtlSelectEditFileName = 25,
    kNavCtlBrowserSelectAll = 26,
    kNavCtlGotoParent = 27,
    kNavCtlSetActionState = 28,
    kNavCtlBrowserRedraw = 29,
    kNavCtlTerminate = 30
};
```

Constants

`kNavCtlShowDesktop`

Tells Navigation Services to change the browser list location to the desktop.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavCtlSortBy`

Alerts Navigation Services that your application is setting a sort key in the browser list. In addition to the `kNavCtlSortBy` constant, your application passes one of the `NavSortKeyField` constants in the `parms` parameter of the function `NavCustomControl` (page 1429). For a description of the `NavSortKeyField` constants, see "File Sorting Constants" (page 1478).

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavCtlSortOrder`

Alerts Navigation Services that your application is setting sort order, either ascending or descending, in the browser list. In addition to passing the `kNavCtlSortOrder` constant, your application must pass one of the `NavSortOrder` constants in the `parms` parameter of the `NavCustomControl` function. For a description of the `NavSortOrder` constants, see "Sort Order Constants" (page 1482).

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavCtlScrollHome`
Tells Navigation Services to scroll the browser to the top of the file list.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavCtlScrollEnd`
Tells Navigation Services to scroll the browser to the bottom of the file list.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavCtlPageUp`
Tells Navigation Services to scroll the browser up one page length as a result of the user clicking the scroll bar above the scroll box.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavCtlPageDown`
Tells Navigation Services to scroll the browser down one page length as a result of the user clicking the scroll bar below the scroll box.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavCtlGetLocation`
Tells Navigation Services to return the current location. Navigation Services reports the current location by setting a pointer to an `AEDesc` structure in the `param` field of the structure of type `NavCBRec` (page 1451) that you specified in your event-handling function.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavCtlSetLocation`
Tells Navigation Services that your application wishes to set the location being viewed in the browser list. In addition to specifying the `kNavCtlSetLocation` constant, your application passes a pointer to an `AEDesc` structure describing the new location in the `parms` parameter of the `NavCustomControl` function.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavCtlGetSelection`
Tells Navigation Services to return the selected item or items in the browser. When you specify this constant, Navigation Services returns a pointer to an `AEDesc` structure describing the selected item(s) in the `param` field of the structure of type `NavCBRec` (page 1451) that you specified in your event-handling function. If the user deselects the current selection, the `AEDescList` returned by Navigation Services contains an empty reference. You can account for this case by using the function `AECountItems` and checking for a zero count.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavCtlSetSelection`

Tells Navigation Services to change the browser list selection. In addition to specifying the `kNavCtlSetSelection` constant, your application must pass a pointer to an `AEDescList` structure describing the selection in the `parms` parameter of the `NavCustomControl` function. If you want to deselect the current selection without making a new selection, pass `NULL` for the pointer. Note: If you specify this constant, Navigation Services notifies your event-handling function by setting the `kNavCBSelectEntry` constant twice; once when the previous selection is deselected, and once when the new selection is made.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavCtlShowSelection`

Tells Navigation Services to make the current selection visible in the browser list if the selection has been scrolled out of sight by the user.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavCtlOpenSelection`

Tells Navigation Services to open the current selection.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavCtlEjectVolume`

Tells Navigation Services to eject a volume. In addition to specifying this constant, you pass a pointer to the volume reference number (`vRefNum`) of the volume to be ejected in the `parms` parameter of the `NavCustomControl` function.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavCtlNewFolder`

Tells Navigation Services to create a new folder in the current browser location. In addition to specifying the `kNavCtlNewFolder` constant, your application passes a string representing the name of the new folder in the `parms` parameter of the `NavCustomControl` function.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavCtlCancel`

Tells Navigation Services to dismiss the Open or Save dialog as if the user had pressed the Cancel button.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavCtlAccept`

Tells Navigation Services to close the Open or Save dialog as if the user had pressed the Open or Save button. Navigation Services does not act on this constant if there is no current selection.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavCtlIsPreviewShowing`

Asks Navigation Services if the preview area is currently available. If you specify this constant, Navigation Services sets a pointer to a Boolean value in the `param` field of the `NavCBRec` (page 1451) structure that you specified in your event-handling function. This value is `true` if the preview area is available, `false` otherwise.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavCtlAddControl`

Tells Navigation Services to add one application-defined control to Open or Save dialogs. In addition to sending this message, your application passes a control handle in the `parms` parameter of the `NavCustomControl` function. Design the control in local coordinates.

Note: To avoid any unnecessary flickering or redrawing, ensure the control is initially invisible before specifying this constant. You may set the control to visible after Navigation Services supplies the `kNavCBStart` constant, described in "Event Messages" (page 1475), in the `param` field of the `NavCBRec` (page 1451) structure. If the user resizes the dialog, your application must move the control because it is not maintained by Navigation Services. If you use the `kNavCtlAddControlList` constant (described next) and you supply a `'DITL'` resource, you avoid the need to move the control yourself.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavCtlAddControlList`

Tells Navigation Services to add a list of application-defined dialog items to Open or Save dialogs. In addition to specifying this constant, your application passes a handle to a dialog item list or `'DITL'` resource in the `parms` parameter of the `NavCustomControl` function. Design the `'DITL'` resource in local coordinates. Navigation Services adds the custom items relative to the upper left corner of the customization area. If the user resizes the dialog, your custom items are moved automatically.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavCtlGetFirstControlID`

Asks Navigation Services to help you identify the first custom control in the dialog, in order to determine which custom control item was selected by the user. Navigation Services returns a pointer to a 16-bit integer that indicates the item number of the first custom control in the param field of the structure of type `NavCBRec` (page 1451) that you specified in your event-handling function. In your event-handling function, use the Dialog Manager function `FindDialogItem` to find out which item was selected. The `FindDialogItem` function returns 0 for the first item, 1 for the second and so on. To get the proper item number, add 1 to the `FindDialogItem` function result. The Open or Save dialog's standard controls precede yours, so use the formula `(itemHit - yourFirstItem + 1)` to determine which of your items was selected. Your application should not depend on any hardcoded value for the number of items, since this value is likely to change in the future.

Be sure to test the result from `FindDialogItem` to ensure that it describes a control that you defined. Your application must not respond to any controls that do not belong to it.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavCtlSelectCustomType`
Tells Navigation Services to set one of your custom menu items in the Show pop-up menu or the Format pop-up menu as the default selection. This is useful if you want to override the default pop-up menu selection. In addition to specifying this constant, pass a pointer to a `NavMenuItem` structure in the `parms` parameter of the `NavCustomControl` function. This structure describes the item you wish to have selected.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavCtlSelectAllType`
Tells Navigation Services to override the default menu item in the Type pop-up menu. By specifying one of the `NavPopupMenuItem` constants, described in "Menu Item Selection Constants" (page 1479), in the `parms` parameter of the `NavCustomControl` function, you can set the default item to All [AppName] Documents, All Readable Documents or All Documents.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavCtlGetEditFileName`
Tells Navigation Services to return the name of the file to be saved by a file-saving function. This would be useful if you wanted to automatically add an extension to the filename, for example. When you send this message, the `parms` parameter of the `NavCustomControl` function returns a `StringPtr` to a Pascal string containing the filename. Note that in Carbon, you can use the `NavDialogGetSaveFileName` (page 1431) function to obtain a Unicode string containing the filename.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavCtlSetEditFileName`
Tells Navigation Services that your application wishes to set the name of the file to be saved by a file-saving function. Your application normally specifies the `KNavCtlSetEditFileName` constant after modifying the filename obtained by specifying the `kNavCtlGetEditFileName` constant. In addition to specifying the `kNavCtlSetEditFileName` constant, your application passes a `StringPtr` to a Pascal string containing the filename in the `parms` parameter of the `NavCustomControl` function. Note that you can set the filename with a Unicode string by calling the `NavDialogSetSaveFileName` (page 1435) function.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavCtlSelectEditFileName`
(Navigation Services 1.1 or later) Tells Navigation Services to display the name of the file to be saved by the function with some or all of the filename string highlighted for selection. In addition to specifying the `kNavCtlSelectEditFileName` constant, your application passes a Control Manager structure of type `ControlEditTextSelectionRec` in the `parms` parameter of the `NavCustomControl` function in order to specify which part of the filename string to highlight. For more information on the `ControlEditTextSelectionRec` structure, see *Inside Mac OS X: Control Manager Reference*.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavCtlBrowserSelectAll`
(Navigation Services 2.0 or later.) Tells Navigation Services to select all files in the browser list.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavCtlGotoParent`
(Navigation Services 2.0 or later.) Tells Navigation Services to navigate to the parent folder or volume of the current selection.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavCtlSetActionState`
(Navigation Services 2.0 or later.) Prevents Navigation Services from handling certain user actions, such as opening or saving files. This is useful if you want to prevent the dismissal of a dialog until certain conditions are met, for example. Specify which actions to prevent by passing one or more of the constants defined by the `NavActionState` enumeration, described in "Action State Constants" (page 1464).

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavCtlBrowserRedraw`
(Navigation Services 2.0 or later.) Tells Navigation Services to refresh the browser list.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavCtlTerminate`
(Navigation Services 2.0 or later.) Tells Navigation Services to dismiss the current dialog. This constant is similar to `kNavCtlCancel`, except that using `kNavCtlTerminate` does not return an error code.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

Discussion
The `NavCustomControlMessage` data type defines constants that your application can pass in the `selector` parameter of the function `NavCustomControl` (page 1429) to control various aspects of the active dialog.

Dialog Configuration Options

Specify dialog configuration options.

```
typedef UInt32 NavDialogOptionFlags;
enum {
    kNavDefaultNavDlogOptions = 0x000000E4,
    kNavNoTypePopup = 0x00000001,
    kNavDontAutoTranslate = 0x00000002,
    kNavDontAddTranslateItems = 0x00000004,
    kNavAllFilesInPopup = 0x00000010,
    kNavAllowStationery = 0x00000020,
    kNavAllowPreviews = 0x00000040,
    kNavAllowMultipleFiles = 0x00000080,
    kNavAllowInvisibleFiles = 0x00000100,
    kNavDontResolveAliases = 0x00000200,
    kNavSelectDefaultLocation = 0x00000400,
    kNavSelectAllReadableItem = 0x00000800,
    kNavSupportPackages = 0x00001000,
    kNavAllowOpenPackages = 0x00002000,
    kNavDontAddRecents = 0x00004000,
    kNavDontUseCustomFrame = 0x00008000,
    kNavDontConfirmReplacement = 0x00010000,
    kNavPreserveSaveFileExtension = 0x00020000
};
```

Constants

`kNavDefaultNavDlogOptions`

Tells Navigation Services to use default configuration options. These default options include:

- no custom control titles
- no banner or prompt message
- automatic resolution of aliases
- support for file previews
- no display of invisible file objects
- support for multiple file selection
- support for stationery
- no package support
- all chosen items added to Recent list
- customization area is framed

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavNoTypePopup`

Tells Navigation Services not to display the Show pop-up menu in the Open dialog or the Format pop-up menu in the Save dialog.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavDontAutoTranslate`

Tells Navigation Services not to do automatic file translation. Normally a file chosen in an Open dialog that requires translation is automatically translated. Navigation Services informs your application that a file needs translating by setting the `translationNeeded` field of the `NavReplyRecord` (page 1458) structure to `true`. A translation specification array specified in the `fileTranslation` field of the `NavReplyRecord` structure contains the associated translation specification records. When you set the `kNavDontAutoTranslate` flag, your application is responsible for translation, either by calling the function `NavTranslate` or by performing the translation itself.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavDontAddTranslateItems`

Tells Navigation Services not to display file translation options in the Show pop-up menu.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavAllFilesInPopup`

Tells Navigation Services to add a pop-up menu item called All Documents, so the user can see a display of all files in the current directory.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavAllowStationery`

Tells Navigation Services to display a Stationery Option command in the Format pop-up menu of Save dialogs, so users can choose to save a file as a document or as stationery. This is a default option.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavAllowPreviews`

Tells Navigation Services to provide previews, when available, of selected files. This is a default option.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavAllowMultipleFiles`

Tells Navigation Services to allow users to select and open multiple files in the browser list by shift-clicking or using the Select All command. If you don't specify this constant, users can select multiple files for drag-and-drop operations, but the default button (normally titled Open) is disabled when multiple items are selected. Note that the user cannot add folders or volumes to a multiple selection.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavAllowInvisibleFiles`

Tells Navigation Services to show invisible file objects in the browser list.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavDontResolveAliases`

Tells Navigation Services not to resolve any alias selected by the user. If the user selects an alias with this option set, the file system specification returned by Navigation Services designates the alias file instead of its referenced original.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavSelectDefaultLocation`

Tells Navigation Services to select the default location in the browser list. By default, Navigation Services will open the browser list with the default location displayed, not selected. For example, if you define the System Folder as the default location and specify the `kNavSelectDefaultLocation` constant, the System Folder appears as the current selection in the browser list. Without this constant, the browser list displays the contents of the System Folder.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavSelectAllReadableItem`

Tells Navigation Services to show All Readable Documents as the default selection in the Show pop-up menu when the Open dialog is first displayed. If you do not specify this constant, Navigation Services shows the All [AppName] Documents menu item as the default selection in the Show pop-up menu when the Open dialog is first displayed.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavSupportPackages`

(Available in Navigation Services 2.0 and later.) Tells Navigation Services to allow packages to be displayed in the browser list.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavAllowOpenPackages`

(Available in Navigation Services 2.0 and later.) Tells Navigation Services to allow packages to be opened and navigated in the browser list.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavDontAddRecents`

(Available in Navigation Services 2.0 and later.) Tells Navigation Services not to add file objects to the Recent list after a dialog is closed. This is useful if you want to allow users to choose long lists of items without cluttering up the Recent list.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavDontUseCustomFrame`

(Available in Navigation Services 2.0 and later.) Tells Navigation Services not to draw a bevelled border around the customization area. The border is drawn by default, so you must specify this constant if you want to turn it off.

Note: Keep in mind that turning off the border may affect the placement of any controls you create in the customization area. This means your controls may appear differently in different versions of Navigation Services.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavDontConfirmReplacement`
(Mac OS X only.) Tells Navigation Services not to display an alert when the user attempts to save a file over another file with the same name.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavPreserveSaveFileExtension`
(Available in Navigation Services 3.1 and later.) Tells Navigation Services that the extension in the default filename should be preserved between dialog invocations and is initially hidden.

Available in Mac OS X v10.1 and later.

Declared in `Navigation.h`.

Discard Changes Actions

Describe the user response to a Discard Changes dialog.

```
typedef UInt32 NavAskDiscardChangesResult;
enum {
    kNavAskDiscardChanges = 1,
    kNavAskDiscardChangesCancel = 2
};
```

Constants

`kNavAskDiscardChanges`
User clicked the Okay button.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavAskDiscardChangesCancel`
User clicked the Cancel button.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

Discussion

After you display a dialog created using the `NavCreateAskDiscardChangesDialog` (page 1416) function, your application determines the result of the function call by checking the `eventData` field of a structure of type `NavCBRec` (page 1451) for one of the constants defined by the `NavAskDiscardChangesResult` data type.

Event Messages

Define messages sent to your event-handling function.

```
typedef SInt32 NavEventCallbackMessage;
enum {
    kNavCBEvent = 0,
    kNavCBCustomize = 1,
    kNavCBStart = 2,
    kNavCBTerminate = 3,
    kNavCBAdjustRect = 4,
    kNavCBNewLocation = 5,
    kNavCBShowDesktop = 6,
    kNavCBSelectEntry = 7,
    kNavCBPopupMenuSelect = 8,
    kNavCBAccept = 9,
    kNavCBCancel = 10,
    kNavCBAdjustPreview = 11,
    kNavCBUserAction = 12,
    kNavCBOpenSelection = (long)0x80000000
};
```

Constants

`kNavCBEvent`

Tells your application that an event has occurred (including an idle event), which provides an opportunity for your application to track controls, update other windows, and so forth. Your application can obtain the event record describing this event from the `event` field of the `NavCBRec` (page 1451) structure. The `kNavCBEvent` constant is the only message that needs to be processed by most applications that do not customize Open and Save dialogs.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavCBCustomize`

Tells your application to supply a dialog customization request. The `customRect` field of the `NavCBRec` (page 1451) structure defines a rectangle in the local coordinates of the dialog; the top-left coordinates define the anchor point for a customization rectangle. If you want to customize the dialog, your application responds to the `kNavCBCustomize` message by setting a value in the `customRect` field that completes the dimensions of the customization rectangle. After your application responds, Navigation Services inspects the `customRect` field to determine if the requested dimensions result in a dialog that can fit on the screen. If the dimensions are too large, then Navigation Services responds by setting the rectangle to the largest size that the screen can accommodate. Your application can continue to "negotiate" by examining the `customRect` field and requesting a different size until Navigation Services provides an acceptable rectangle value, at which time you should create your custom control or item list. The minimum size for the customization area is 400 pixels wide by 40 pixels high.

Note: Don't add new dialog items until your application receives the `kNavCBStart` event message constant.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavCBStart`

Tells your application that a dialog is ready to be displayed. After receiving the `kNavCBCustomize` event message constant, your event-handling function should wait for the `kNavCBStart` event message constant to ensure that your application can safely add dialog items. No additional data is provided to your application with this constant.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavCBTerminate`

Tells your application that the dialog is about to be closed, which means you must remove any user-interface items that were created in response to the `kNavCBStart` message. You can determine which user action closed the dialog by checking the `userAction` field of the `NavCBRec` (page 1451) structure.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavCBAdjustRect`

Tells your application that the dialog has been resized and the customization rectangle has been accordingly resized. Use the `customRect` field from the `NavCBRec` (page 1451) structure to determine the new customization rectangle size. Your application does not need to offset the controls; Navigation Services moves them automatically. Your application is responsible for any redrawing of the controls or handling events beyond moving the controls, however.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavCBNewLocation`

Tells your application that a new location is being viewed in the dialog. The `param` field of the `NavCBRec` (page 1451) structure contains a pointer to an `AEDesc` structure of type `'typeFSS'` describing the new location. This pointer is valid only during the execution of your event-handling function.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavCBShowDesktop`

Tells your application that the Open or Save dialog is showing the desktop view, consisting of the composite of all desktop folders from all mounted volumes. The `param` field of the `NavCBRec` (page 1451) structure contains a pointer to an `AEDescList` structure identifying the desktop location. This pointer is valid only during the execution of your event-handling function.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavCBSelectEntry`

Tells your application that an entry in the browser list has been selected or deselected by the user. The `param` field of the `NavEventDataInfo` structure contains a pointer to an `AEDescList` record of type `'typeFSS'` identifying the current selection. If the user deselects the current selection, the `AEDescList` record contains an empty reference. This pointer is valid only during the execution of your event-handling function.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavCBPopupMenuSelect`

Tells your application that a selection was made from the Open dialog's Show pop-up menu or Save dialog's Format pop-up menu. The`NavCBRec.eventData.eventDataParms.param` field contains a pointer to a `NavMenuItemSpec` structure describing the pop-up menu item selected. If the dialog was created using the Carbon-only `NavCreateXXXDialog` APIs, then the `menuType` field of the `NavMenuItemSpec` structure is set to the index into the client's CFArray of `popupExtension` strings in the `NavDialogCreationOptions` (page 1452) structure. This data is valid only during the execution of your event-handling function.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavCBAccept`
Tells your application that the user has pressed the Accept button.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavCBCancel`
Tells your application that the user has pressed the Cancel button.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavCBAdjustPreview`
Tells your application that the user has toggled the preview area on or off. The `param` field of the `NavCBRec` (page 1451) structure contains a pointer to a Boolean value of `true` if the preview area is toggled on and `false` if toggled off. This information is useful if your application creates custom controls in the preview area.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavCBUserAction`
(Available only in CarbonLib 1.1 and later and in Mac OS X version 10.0 and later.) Tells your application that the user has taken an action. To determine which action the user took, call the `NavDialogGetUserAction` (page 1432) function.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavCBOpenSelection`
(Navigation Services 2.0 or later.) Tells your application that the user has opened a file or chosen a file object. After detecting this constant, you can call the `NavCustomControl` (page 1429) function and specify one of the `NavActionState` constants, described in "Action State Constants" (page 1464), in order to block the opening or choosing action.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

File Sorting Constants

Let you specify a sort key for how files display in browser.

```
typedef UInt16 NavSortKeyField;
enum {
    kNavSortNameField = 0,
    kNavSortDateField = 1
};
```

Constants

`kNavSortNameField`
Sort by filename.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavSortDateField`
Sort by modification date.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

Discussion
Your application can determine the sort key for displayed files by passing the `kNavCtlSortBy` constant, described in "Custom Control Settings" (page 1465), in the `selector` parameter of the function `NavCustomControl` (page 1429), and passing one of the constants defined in the `NavSortKeyField` data type in the `parms` parameter of the `NavCustomControl` function.

Generic File Signature Constant

Defines a generic creator code.

```
enum {
    kNavGenericSignature = '****'
};
```

Constants
`kNavGenericSignature`
Tells Navigation Services to display all files of a specified type, regardless of the file's creator code.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

Discussion
To specify that your application can open all files of a given type (such as `'TEXT'`, for example), specify the `kNavGenericSignature` constant in the `componentSignature` field of the structure of type `NavTypeList` (page 1460) that you pass to a function that creates a file-opening dialog, such as `NavCreateGetFileDialog` (page 1423). You can also pass this constant in the `inFileCreator` parameter of the function `NavCreatePutFileDialog` (page 1426) in order to override the types of files appearing in the Format pop-up menu.

Version Notes
Added in Navigation Services 2.0

Menu Item Selection Constants

Let you specify the default selection in the Show pop-up menu.

```
typedef UInt16 NavPopupMenuItem;
enum {
    kNavAllKnownFiles = 0,
    kNavAllReadableFiles = 1,
    kNavAllFiles = 2
};
```

Constants
`kNavAllKnownFiles`
Tells Navigation Services to display all files identified as readable by your application.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavAllReadableFiles`
Tells Navigation Services to display all files identified as readable or translatable by your application.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavAllFiles`
Tells Navigation Services to display all files.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

Discussion
To set the default selection for the Show pop-up menu of an Open dialog box, your application passes the `kNavCtlSelectAllType` constant, described in "Custom Control Settings" (page 1465), in the `selector` parameter of the function `NavCustomControl` (page 1429) and passes one of the constants defined in the `NavPopupMenuItem` data type in the `parms` parameter of the `NavCustomControl` function.

Object Filtering Constants

Inform you which part of a dialog contains object being filtered.

```
typedef SInt16 NavFilterModes;
enum {
    kNavFilteringBrowserList = 0,
    kNavFilteringFavorites = 1,
    kNavFilteringRecents = 2,
    kNavFilteringShortCutVolumes = 3,
    kNavFilteringLocationPopup = 4
};
```

Constants
`kNavFilteringBrowserList`
The browser list contains the object being filtered.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavFilteringFavorites`
The Favorites pop-up menu contains the object being filtered.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavFilteringRecents`
The Recent pop-up menu contains the object being filtered.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavFilteringShortCutVolumes`
The Shortcuts pop-up menu contains the object being filtered.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavFilteringLocationPopup`
The object being filtered is the path described by the Location menu.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

Discussion
Navigation Services passes one of the constants defined by the `NavFilterModes` data type to the `filterMode` parameter of your application-defined filter function to tell your application whether the browser list or one of the navigation option pop-up menus contains the object currently being filtered.

Save Changes Actions

Describe the user response to a Save Changes dialog.

```
typedef UInt32 NavAskSaveChangesResult;
enum {
    kNavAskSaveChangesSave = 1,
    kNavAskSaveChangesCancel = 2,
    kNavAskSaveChangesDontSave = 3
};
```

Constants
`kNavAskSaveChangesSave`
User clicked the Save button.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavAskSaveChangesCancel`
User clicked the Cancel button.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavAskSaveChangesDontSave`
User clicked the Don't Save button.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

Discussion
When you create a Save dialog using the function `NavCreatePutFileDialog` (page 1426), you obtain the user's response by calling `NavDialogGetReply` (page 1430), specifying a `NavReplyRecord` (page 1458) structure in the `outReply` parameter. On completion, this structure contains a value represented by one of the constants defined by the `NavAskSaveChangesResult` data type.

Save Changes Requests

Describe the condition that prompts a Save Changes dialog.

```
typedef UInt32 NavAskSaveChangesAction;
enum {
    kNavSaveChangesClosingDocument = 1,
    kNavSaveChangesQuittingApplication = 2,
    kNavSaveChangesOther = 0
};
```

Constants

`kNavSaveChangesClosingDocument`
Requests a Save Changes alert that asks the user whether to save changes when closing a document.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavSaveChangesQuittingApplication`
Requests a Save Changes alert that asks the user whether to save changes when quitting your application.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavSaveChangesOther`
Requests a Save Changes alert that asks the user whether to save changes at some time other than closing or quitting. This is useful when your application prompts the user to save documents at timed intervals, for example.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

Discussion

Your application requests a Save Changes alert by specifying one of the following constants, defined by the `NavAskSaveChangesAction` data type, in the `inAction` parameter of the function `NavCreatePutFileDialog` (page 1426).

Sort Order Constants

Let you specify ascending or descending sort order in the browser.

```
typedef UInt16 NavSortOrder;
enum {
    kNavSortAscending = 0,
    kNavSortDescending = 1
};
```

Constants

`kNavSortAscending`
Sort in ascending order.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavSortDescending`
Sort in descending order.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

Discussion
Your application can specify the sort order for displayed files by passing the `kNavCtlSortOrder` constant in the `selector` parameter of the function `NavCustomControl` (page 1429) and passing one of the constants defined in the `NavSortOrder` data type in the `parms` parameter of the `NavCustomControl` function.

Translation Options

Let you specify how files are translated.

```
typedef UInt32 NavTranslationOptions;
enum {
    kNavTranslateInPlace = 0,
    kNavTranslateCopy = 1
};
```

Constants

`kNavTranslateInPlace`
Tells Navigation Services to replace the source file with the translation. This setting is the default for Save dialogs.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavTranslateCopy`
Tells Navigation Services to create a translated copy of the source file. This setting is the default for Open dialogs. The `NavCompleteSave` function always uses this setting under automatic translation.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

Discussion
Your application passes one of the `NavTranslationOptions` constants to the `howToTranslate` parameter to specify how files are to be translated by the function `NavTranslateFile` (page 1445).

User Actions

```
typedef UInt32 NavUserAction;
enum {
    kNavUserActionNone = 0,
    kNavUserActionCancel = 1,
    kNavUserActionOpen = 2,
    kNavUserActionSaveAs = 3,
    kNavUserActionChoose = 4,
    kNavUserActionNewFolder = 5,
    kNavUserActionSaveChanges = 6,
    kNavUserActionDontSaveChanges = 7,
    kNavUserActionDiscardChanges = 8,
    kNavUserActionReviewDocuments = 9,
    kNavUserActionDiscardDocuments = 10
};
```

Constants

`kNavUserActionNone`
The dialog is still running or was terminated programmatically.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavUserActionCancel`
The user pressed the Cancel button.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavUserActionOpen`
The user pressed the Open button in a file-opening dialog.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavUserActionSaveAs`
The user pressed the Save button in a file-saving dialog.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavUserActionChoose`
The user pressed the Choose button in a Choose dialog.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavUserActionNewFolder`
The user pressed the New Folder button in a New Folder dialog and Navigation Services created a folder.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavUserActionSaveChanges`
The user pressed the Save button in a Save Changes dialog.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavUserActionDontSaveChanges`
The user pressed the Don't Save button in a Save Changes dialog.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavUserActionDiscardChanges`
The user pressed the Discard button in a Discard Changes dialog.

Available in Mac OS X v10.0 and later.

Declared in `Navigation.h`.

`kNavUserActionReviewDocuments`
The user clicked the Review Unsaved button in the Review Documents dialog (used only on Mac OS X).

Available in Mac OS X v10.1 and later.

Declared in `Navigation.h`.

`kNavUserActionDiscardDocuments`
The user clicked the Discard Changes button in the Review Documents dialog (used only on Mac OS X).

Available in Mac OS X v10.1 and later.

Declared in `Navigation.h`.

Discussion
Navigation Services passes one of the constants defined by the `NavUserAction` enumeration to your application in the `userAction` field of a `NavCBRec` (page 1451) structure in order to indicate which action was taken by the user during a Navigation Services dialog.

NavDialogCreationOptions Version Constant

Represents the current version of the `NavDialogCreationOptions` structure.

```
enum {
        kNavDialogCreationOptionsVersion = 0
};
```

NavCBRec Version Constant

Represents the current version of the `NavCBRec` structure.

```
enum {
    kNavCBRecVersion = 1
};
```

NavFileOrFolder Version Constant

Represents the current version of the `NavFileOrFolder` structure.

```
enum {
    kNavFileOrFolderVersion = 1
};
```

NavMenuItemSpec Version Constant

Represents the current version of the `NavMenuItemSpec` structure.

```
enum {
    kNavMenuItemSpecVersion = 0
};
```

NavReplyRecord Version Constant

Represents the current version of the `NavReplyRecord` structure.

```
enum {
    kNavReplyRecordVersion = 2
};
```

Result Codes

The table below shows the most common result codes returned by Navigation Services.

Result Code	Value	Description
`kNavWrongDialogStateErr`	-5694	Dialog is not in correct state for requested operation (it must be running but is not, or vice versa. Available in Mac OS X v10.0 and later.
`kNavWrongDialogClassErr`	-5695	Requested operation is not valid for this type of dialog. Available in Mac OS X v10.0 and later.
`kNavInvalidSystemConfigErr`	-5696	One or more Navigation Services–required system components is missing or out of date. Available in Mac OS X v10.0 and later.
`kNavCustomControlMessageFailedErr`	-5697	Navigation Services did not accept a control message sent by your application. Available in Mac OS X v10.0 and later.
`kNavInvalidCustomControlMessageErr`	-5698	Your application sent an invalid custom control message. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
kNavMissingKindStringErr	-5699	No kind strings were provided to describe your application's native file types. Available in Mac OS X v10.0 and later.

Notification Manager Reference

Framework: Carbon/Carbon.h

Declared in Notification.h

Overview

The Notification Manager provides a notification service. It allows software running in the background (or otherwise unseen by the user) to communicate information to the user. For example, applications that manage lengthy background tasks (such as printing many documents or transferring large amounts of data to other machines) might need to inform the user that the operation is complete. These applications cannot use the standard methods of communicating with the user, such as alert or dialog boxes, because such windows might easily be obscured by the windows of other applications. Moreover, even if those windows are visible, the background application cannot be certain that the user is aware of the change. A more reliable method is needed to manage the communication between a background application and the user, who might be awaiting the completion of the background task while running some other application in the foreground.

In the same way, relatively invisible operations such as Time Manager tasks, VBL tasks, or device drivers might need to inform the user that some previously started routine is complete or perhaps that some error has rendered further execution undesirable or impossible.

In all these cases, the communication generally needs to occur in one direction only, from the background application (or task, or driver) to the user. The Notification Manager, included in system software versions 6.0 and later, allows you to alert the user by posting a notification, which is an audible or visible indication that your application (or other piece of software) requires the user's attention. You post a notification by issuing a notification request to the Notification Manager, which places your request in a queue. When your request reaches the top of the queue, the Notification Manager posts a notification to the user.

You can request three types of notification:

- **Polite notification.** A small icon blinks, by periodically alternating with the Apple menu icon (the Apple logo) or the Application menu icon in the menu bar.
- **Audible notification.** The Sound Manager plays the system alert sound or a sound contained in an 'snd ' resource.
- **Alert notification.** An alert box containing a short message appears on the screen. The user must dismiss the alert box (by clicking the OK button) before foreground processing can continue.

These types of notification are not mutually exclusive. For example, an application can request both audible and alert notifications. Moreover, if the requesting software is listed in the Application menu (and hence represents a process that is loaded into memory), you can instruct the Notification Manager to place a

diamond-shaped mark next to the name of the requesting process. The mark is usually intended to prompt the user to switch the marked application into the foreground. Finally, you can request that the Notification Manager execute a notification response procedure, which is executed as the final step in a notification.

Functions

DisposeNMUPP

Releases a universal procedure pointer (UPP) to a response callback function.

```
void DisposeNMUPP (
   NMUPP userUPP
);
```

Parameters

userUPP

A valid UPP, created by calling the function `NewNMUPP` (page 1490).

Availability

CarbonLib 1.0 and later. Mac OS X version 10.0 and later.

Declared In

`Notification.h`

InvokeNMUPP

Invokes a response callback function.

```
void InvokeNMUPP (
   NMRecPtr nmReqPtr,
   NMUPP userUPP
);
```

Parameters

nmReqPtr

A pointer to a notification request. For information about defining a notification request, see `NMRec` (page 1492).

userUPP

A response callback UPP, created by calling the function `NewNMUPP` (page 1490).

Availability

CarbonLib 1.0 and later. Mac OS X version 10.0 and later.

Declared In

`Notification.h`

NewNMUPP

Creates a universal procedure pointer (UPP) to a response callback function.

```
NMUPP NewNMUPP (
   NMProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to a response callback function. For more information about response callbacks, see `NMProcPtr` (page 1492).

Return Value

A new UPP. When you no longer need this UPP, you should call `DisposeNMUPP` (page 1490) to release it.

Availability

CarbonLib 1.0 and later. Mac OS X version 10.0 and later.

Declared In

`Notification.h`

NMInstall

Installs a notification request in the notification queue.

```
OSErr NMInstall (
   NMRecPtr nmReqPtr
);
```

Parameters

request

A pointer to a notification request record that the caller provides.

Return Value

A result code. If the result is non-zero, the Notification Manager cannot install the request because it contains invalid information. See "Notification Manager Result Codes" (page 1494).

Availability

CarbonLib 1.0 and later. Mac OS X version 10.0 and later.

Not available to 64-bit applications.

Declared In

`Notification.h`

NMRemove

Removes a notification request from the notification queue.

```
OSErr NMRemove (
   NMRecPtr nmReqPtr
);
```

Parameters

nmReqPtr

A pointer to a notification request record.

Return Value
A result code. If the result is non-zero, the Notification Manager cannot remove the request. See "Notification Manager Result Codes" (page 1494).

Availability
CarbonLib 1.0 and later. Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`Notification.h`

Callbacks

NMProcPtr

Defines a pointer to a response callback function. Your response callback function is executed as the final stage of a notification.

```
typedef void (*NMProcPtr) (
    NMRecPtr request
);
```

If you name your function `MyNMProc`, you would declare it like this:

```
void MyNMProc (
    NMRecPtr request
);
```

Parameters

request
A pointer to a notification request record.

Discussion
The `nmResp` field of the notification record defines a response function executed as the final stage of a notification. If no processing is necessary in response to the notification, then you can supply the value `NULL` in that field. If you supply a UPP to your own response function in the `nmResp` field, the Notification Manager passes it one parameter, a pointer to your notification request.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Notification.h`

Data Types

NMRec

Defines the record format of a notification request.

```
struct NMRec {
    QElemPtr qLink;
    short qType;
    short nmFlags;
    long nmPrivate;
    short nmReserved;
    short nmMark;
    Handle nmIcon;
    Handle nmSound;
    StringPtr nmStr;
    NMUPP nmResp;
    long nmRefCon;
};
typedef struct NMRec NMRec;
typedef NMRec * NMRecPtr;
```

Fields

`qLink`
: This field is used internally by the Notification Manager. You do not need to assign a value to this field.

`qType`
: Indicates the type of queue. You should assign the value `nmType` to this field.

`nmFlags`
: Reserved.

`nmPrivate`
: Reserved.

`nmReserved`
: Reserved.

`nmMark`
: In Mac OS, the item to mark in the Application menu. If you do not want to display a mark, assign 0 to this field.

  For additional information about the use of this field in Mac OS X, see the discussion below.

`nmIcon`
: In Mac OS, a handle to a small icon that is to blink periodically in the menu bar. If you do not want to display an icon, assign `NULL` to this field.

`nmSound`
: In Mac OS, a handle to a sound resource to be played. If you do not want to play a sound, assign `NULL` to this field.

`nmStr`
: A string to appear in the notification window. In Mac OS, if you do not want a notification window you should assign `NULL` to this field.

`nmResp`
: A UPP to a response callback function. If no processing is necessary in response to the notification, assign the value `NULL` to this field.

`nmRefCon`
: A long integer for private use by your application.

Discussion

In Mac OS X version 10.0, only the alert notification is supported.

In Mac OS X version 10.1 and later, mark and alert notifications are both supported. If you set the `nmMark` field to a non-zero value, your process icon will bounce in the dock.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Notification.h`

Result Codes

The most common result codes returned by the Notification Manager are listed in the table below.

Result Code	Value	Description
`nmTypErr`	-299	The notification request contains an invalid queue type. Available in Mac OS X v10.0 and later.

Gestalt Constants

You can check for version and feature availability information by using the Notification Manager selectors defined in the Gestalt Manager. For more information, see *Inside Mac OS X: Gestalt Manager Reference*.

Scrap Manager Reference (Not Recommended)

Framework: Carbon/Carbon.h

Declared in Scrap.h

Overview

Important: The Scrap Manager is deprecated in Mac OS X version 10.5 and later. The replacement API is the Pasteboard Manager. For more information, see *Pasteboard Manager Programming Guide*.

In Mac OS 9 and earlier, the Scrap Manager allowed applications to copy and paste data using the Clipboard. The Scrap Manager was included in Carbon to facilitate the porting of legacy applications to Mac OS X. Only the `LoadScrap` and `UnloadScrap` functions were retained from the original Scrap Manager. However, the Carbon Scrap Manager provided new features, including support for promises.

The Pasteboard Manager supersedes the Scrap Manager and the drag flavor functionality in the Drag Manager, adding greater flexibility in the type and quantity of data to be transferred. Pasteboard Manager pasteboards are also fully compatible with Cocoa pasteboards.

You should not use the Scrap Manager in new application development.

Functions by Task

Getting Information About the Scrap

`GetScrapFlavorCount` (page 1500) Deprecated in Mac OS X v10.5
Obtains a scrap flavor count to use with the `GetScrapFlavorInfoList` function. (Deprecated. Use `PasteboardCopyItemFlavors` instead.)

`GetScrapFlavorFlags` (page 1502) Deprecated in Mac OS X v10.5
Obtains information about a specified scrap flavor. (Deprecated. Use `PasteboardGetItemFlavorFlags` instead.)

`GetScrapFlavorInfoList` (page 1502) Deprecated in Mac OS X v10.5
Fills an array with items which each describe a corresponding flavor in the scrap. (Deprecated. Use `PasteboardCopyItemFlavors` instead.)

Reading Information From the Scrap

`GetCurrentScrap` (page 1499) Deprecated in Mac OS X v10.5
Obtains a reference to the current scrap. (Deprecated. Use `PasteboardCreate` instead.)

`GetScrapByName` (page 1499) Deprecated in Mac OS X v10.5
Obtains a reference to a named scrap. (Deprecated. Use `PasteboardCreate` instead.)

`GetScrapFlavorData` (page 1501) Deprecated in Mac OS X v10.5
Obtains the data for the specified flavor from the specified scrap. (Deprecated. Use `PasteboardCopyItemFlavorData` instead.)

`GetScrapFlavorSize` (page 1503) Deprecated in Mac OS X v10.5
Obtains the size of the data for a specified flavor from a scrap. (Deprecated. Use `PasteboardCopyItemFlavorData` instead.)

Writing Information to the Scrap

`ClearCurrentScrap` (page 1497) Deprecated in Mac OS X v10.5
Clears the current scrap. (Deprecated. Use `PasteboardClear` instead.)

`ClearScrap` (page 1498) Deprecated in Mac OS X v10.5
Clears a given scrap. (Deprecated. Use `PasteboardClear` instead.)

`PutScrapFlavor` (page 1505) Deprecated in Mac OS X v10.5
Puts data on or promises data to the specified scrap. (Deprecated. Use `PasteboardPutItemFlavor` instead.)

Transferring Data Between the Scrap in Memory and the Scrap on Disk

`LoadScrap` (page 1504) Deprecated in Mac OS X v10.5
Reads the scrap from the scrap file into memory.

`UnloadScrap` (page 1507) Deprecated in Mac OS X v10.5
Writes the scrap from memory to the scrap file.

Working With Scrap Promise Keeper Functions

`CallInScrapPromises` (page 1497) Deprecated in Mac OS X v10.5
Forces all promised flavors to be supplied. (Deprecated. Use `PasteboardResolvePromises` instead.)

`DisposeScrapPromiseKeeperUPP` (page 1498) Deprecated in Mac OS X v10.5
Disposes of a universal procedure pointer to a function that provides promised scrap data.

`InvokeScrapPromiseKeeperUPP` (page 1504) Deprecated in Mac OS X v10.5
Calls a universal procedure pointer to a function that provides promised scrap data.

`NewScrapPromiseKeeperUPP` (page 1505) Deprecated in Mac OS X v10.5
Creates a new universal procedure pointer to a function that provides promised scrap data.

`SetScrapPromiseKeeper` (page 1507) Deprecated in Mac OS X v10.5
Associates an application-defined promise-keeper function with a scrap or removes an associated promise-keeper. (Deprecated. Use `PasteboardSetPromiseKeeper` instead.)

Functions

CallInScrapPromises

Forces all promised flavors to be supplied. (Deprecated in Mac OS X v10.5. Use `PasteboardResolvePromises` instead.)

```
OSStatus CallInScrapPromises (
   void
);
```

Return Value
A result code. See "Scrap Manager Result Codes" (page 1514).

Discussion
Before quitting, your application should call `CallInScrapPromises` in order to ensure the user's ability to paste into other applications. Your application should call `CallInScrapPromises` even if your application does not explicitly promise any flavors.

It doesn't hurt to call `CallInScrapPromises` more than once, though promise-keeper functions may be asked to keep promises they already tried and failed.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Scrap.h`

ClearCurrentScrap

Clears the current scrap. (Deprecated in Mac OS X v10.5. Use `PasteboardClear` instead.)

```
OSStatus ClearCurrentScrap (
   void
);
```

Return Value
A result code. See "Scrap Manager Result Codes" (page 1514).

Discussion
Call `ClearCurrentScrap` immediately when the user requests a Copy or Cut operation, even if you maintain a private scrap. You should not wait until receiving a suspend event to call `ClearCurrentScrap`. You don't need to put any data on the scrap immediately, although it's perfectly fine to do so. You do need to call `GetCurrentScrap` (page 1499) after `ClearCurrentScrap` so you'll have a valid scrap reference to pass to other functions.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Scrap.h`

ClearScrap

Clears a given scrap. (Deprecated in Mac OS X v10.5. Use `PasteboardClear` instead.)

```
OSStatus ClearScrap (
   ScrapRef *inOutScrap
);
```

Parameters

inOutScrap

A pointer to a scrap reference. On input, this parameter should refer to the scrap to clear. On output, `ClearScrap` returns a reference to the cleared scrap.

Return Value
A result code. See "Scrap Manager Result Codes" (page 1514).

Discussion
`ClearScrap` will clear the scrap passed in and return the incremented `ScrapRef` value. `ClearScrap` behaves similarly to the `GetScrapByName` function when called with the `kScrapClearNamedScrap` option, with the benefit of not requiring a name in the event one is not available.

Availability
Available in Mac OS X v10.1 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Scrap.h`

DisposeScrapPromiseKeeperUPP

Disposes of a universal procedure pointer to a function that provides promised scrap data. (Deprecated in Mac OS X v10.5.)

```
void DisposeScrapPromiseKeeperUPP (
   ScrapPromiseKeeperUPP userUPP
);
```

Parameters

userUPP

The UPP to dispose of.

Discussion
See `ScrapPromiseKeeperProcPtr` (page 1508) for more information on promise keeper functions.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In
`Scrap.h`

GetCurrentScrap

Obtains a reference to the current scrap. (Deprecated in Mac OS X v10.5. Use `PasteboardCreate` instead.)

```
OSStatus GetCurrentScrap (
   ScrapRef *scrap
);
```

Parameters

scrap

A pointer to a scrap reference. On return, this scrap reference refers to the current scrap.

Return Value

A result code. See "Scrap Manager Result Codes" (page 1514).

Discussion

Your application can determine if the scrap contents have changed by storing the scrap reference returned by `GetCurrentScrap` and comparing it against the scrap reference returned by `GetCurrentScrap` at a later time. If the two scrap references are different, the scrap has changed.

Carbon applications should use `GetCurrentScrap` instead of checking the `convertClipboardFlag` in the `EventRecord`.

The `ScrapRef` obtained via `GetCurrentScrap` becomes invalid and unusable after the scrap is cleared. That is, the scrap reference is valid until a Carbon client calls `ClearCurrentScrap` (page 1497), a Classic client calls `ZeroScrap`, or a Cocoa client calls `declareTypes:owner:`.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Scrap.h`

GetScrapByName

Obtains a reference to a named scrap. (Deprecated in Mac OS X v10.5. Use `PasteboardCreate` instead.)

```
OSStatus GetScrapByName (
   CFStringRef name,
   OptionBits options,
   ScrapRef *scrap
);
```

Parameters

name

A CFString containing the name of the scrap to obtain. You may specify a standard scrap by passing one of the constants described in "Named Scraps" (page 1513) in this parameter.

options

A value indicating whether the specified scrap should be cleared after the reference is returned. See "Options for the GetScrapByName Function" (page 1513) for more information.

scrap
A pointer to a scrap reference. On return, this scrap reference refers to the scrap named in the `name` parameter.

Return Value
A result code. See "Scrap Manager Result Codes" (page 1514).

Discussion
`GetScrapByName` allows access to an indefinite number of public or private scraps. The constant `kScrapClipboardScrap` refers to the "current" scrap. `kScrapFindScrap` allows Carbon applications to interact seamlessly with Cocoa's global find scrap. Note that calling:

```
GetScrapByName( kScrapClipboardScrap, kScrapGetNamedScrap, &scrap  );
```

is an exact match to the call:

```
GetCurrentScrap( &scrap );
```

Additionally, a call to:

```
 GetScrapByName( kScrapClipboardScrap, kScrapClearNamedScrap, &scrap  );
```

is a replacement for the sequence:

```
ClearCurrentScrap();
GetCurrentScrap( &scrap );
```

You can use this API to generate your own private scraps to use as a high level interprocess communication between your main and helper applications. Apple recommends using the Java naming convention for your scraps, for example, com.mycompany.scrap.secret.

Availability
Available in Mac OS X v10.1 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Scrap.h`

GetScrapFlavorCount

Obtains a scrap flavor count to use with the `GetScrapFlavorInfoList` function. (Deprecated in Mac OS X v10.5. Use `PasteboardCopyItemFlavors` instead.)

```
OSStatus GetScrapFlavorCount (
   ScrapRef scrap,
   UInt32 *infoCount
);
```

Parameters
scrap
A reference to the scrap to get the flavor count for.
infoCount
A pointer to a count variable. On return, specifies the flavor count for the specified scrap.

Return Value
A result code. See "Scrap Manager Result Codes" (page 1514).

Discussion
For related information, see `GetScrapFlavorInfoList` (page 1502).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Scrap.h`

GetScrapFlavorData

Obtains the data for the specified flavor from the specified scrap. (Deprecated in Mac OS X v10.5. Use `PasteboardCopyItemFlavorData` instead.)

```
OSStatus GetScrapFlavorData (
   ScrapRef scrap,
   ScrapFlavorType flavorType,
   Size *byteCount,
   void *destination
);
```

Parameters

scrap
A reference to the scrap to get data from.

flavorType
The flavor type to obtain data for. Some flavor types are described in "Scrap Flavor Types" (page 1511).

byteCount
A pointer to a size variable. Before calling `GetScrapFlavorData`, specify the maximum number of bytes your buffer can contain. On return, `GetScrapFlavorData` provides the number of bytes of data that were actually available, even if this is more than you requested.

destination
A pointer to a buffer, local variable, or other storage location created and disposed of by your application. The size, in bytes, must be at least as large as the value you pass in the `byteCount` parameter. On return, this buffer contains the specified flavor data. The amount of data returned will not exceed the value you passed in `byteCount`, even if the number of bytes of available data is more than you specified in `byteCount`.

Return Value
A result code. See "Scrap Manager Result Codes" (page 1514).

Discussion
This function blocks until the specified flavor data is available.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Scrap.h`

GetScrapFlavorFlags

Obtains information about a specified scrap flavor. (Deprecated in Mac OS X v10.5. Use `PasteboardGetItemFlavorFlags` instead.)

```
OSStatus GetScrapFlavorFlags (
   ScrapRef scrap,
   ScrapFlavorType flavorType,
   ScrapFlavorFlags *flavorFlags
);
```

Parameters

scrap
A reference to the scrap to check.

flavorType
The flavor type to check for. Some scrap flavor types are described in "Scrap Flavor Types" (page 1511).

flavorFlags
A pointer to a variable of type `ScrapFlavorFlags`; values for this type are described in "Scrap Flavor Flags" (page 1512). On return, this variable contains information about the flavor specified by the `flavorType` parameter.

Return Value
A result code. See "Scrap Manager Result Codes" (page 1514).

Discussion
The `GetScrapFlavorFlags` function tells you whether the scrap contains data for a particular flavor and, if it does, provides some information about that flavor. This function never blocks, and is useful for deciding whether to enable the Paste item in your Edit menu, among other things.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Scrap.h`

GetScrapFlavorInfoList

Fills an array with items which each describe a corresponding flavor in the scrap. (Deprecated in Mac OS X v10.5. Use `PasteboardCopyItemFlavors` instead.)

```
OSStatus GetScrapFlavorInfoList (
   ScrapRef scrap,
   UInt32 *infoCount,
   ScrapFlavorInfo info[]
);
```

Parameters

scrap

A reference to the scrap to get the flavor information for.

infoCount

A pointer to a count variable. Before calling `GetScrapFlavorInfoList`, set the value to the number of flavors to get information for. Your application typically obtains the flavor count by calling `GetScrapFlavorCount` (page 1500).

On return, specifies the number of flavors for which information was supplied, which may be smaller than the number requested.

info

An array of type `ScrapFlavorInfo` (page 1509), whose size is indicated by the `infoCount` parameter. The array is created and disposed of by your application. On return, the array elements contain the flavor information.

Return Value

A result code. See "Scrap Manager Result Codes" (page 1514).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Scrap.h`

GetScrapFlavorSize

Obtains the size of the data for a specified flavor from a scrap. (Deprecated in Mac OS X v10.5. Use `PasteboardCopyItemFlavorData` instead.)

```
OSStatus GetScrapFlavorSize (
   ScrapRef scrap,
   ScrapFlavorType flavorType,
   Size *byteCount
);
```

Parameters

scrap

A reference to the scrap to get the flavor data size from.

flavorType

The flavor type to obtain the size for. Some flavor types are described in "Scrap Flavor Types" (page 1511).

byteCount

A pointer to a size variable. On return, this variable contains the byte count for the data of the specified flavor.

Return Value
A result code. See "Scrap Manager Result Codes" (page 1514).

Discussion
This function will block until the size of the data is available. This may mean blocking until the data itself is available, since some scrap senders don't know how big a flavor will be until they've made the flavor data. `GetScrapFlavorSize` is intended as a prelude to allocating memory and calling `GetScrapFlavorData` (page 1501).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Scrap.h`

InvokeScrapPromiseKeeperUPP

Calls a universal procedure pointer to a function that provides promised scrap data. (Deprecated in Mac OS X v10.5.)

```
OSStatus InvokeScrapPromiseKeeperUPP (
   ScrapRef scrap,
   ScrapFlavorType flavorType,
   void *userData,
   ScrapPromiseKeeperUPP userUPP
);
```

Return Value
A result code. See "Scrap Manager Result Codes" (page 1514).

Discussion
You should not need to use the function `InvokeScrapPromiseKeeperUPP`, as the system calls your scrap promise keeper function for you.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In
`Scrap.h`

LoadScrap

Reads the scrap from the scrap file into memory. (Deprecated in Mac OS X v10.5.)

```
OSStatus LoadScrap (
   void
);
```

Return Value
A result code. See "Scrap Manager Result Codes" (page 1514).

Discussion
The function allocates memory in your application's heap to hold the scrap before reading the scrap into memory. The scrap file is located in the System Folder of the startup volume and has the filename as indicated by the `scrapName` field of the scrap information structure (usually "Clipboard"). If the scrap is already in memory, this function does nothing.

Special Considerations

In Mac OS X, this function does nothing and is no longer necessary.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Scrap.h`

NewScrapPromiseKeeperUPP

Creates a new universal procedure pointer to a function that provides promised scrap data. (Deprecated in Mac OS X v10.5.)

```
ScrapPromiseKeeperUPP NewScrapPromiseKeeperUPP (
   ScrapPromiseKeeperProcPtr userRoutine
);
```

Parameters
`userRoutine`
A pointer to your scrap promise keeper function.

Return Value
A UPP to the scrap promise keeper function. See the description of the `ScrapPromiseKeeperUPP` data type.

Discussion
See `ScrapPromiseKeeperProcPtr` (page 1508) for more information on promise keeper functions.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In
`Scrap.h`

PutScrapFlavor

Puts data on or promises data to the specified scrap. (Deprecated in Mac OS X v10.5. Use `PasteboardPutItemFlavor` instead.)

```
OSStatus PutScrapFlavor (
   ScrapRef scrap,
   ScrapFlavorType flavorType,
   ScrapFlavorFlags flavorFlags,
   Size flavorSize,
   const void *flavorData
);
```

Parameters

scrap

A reference to the scrap to supply data or promises to.

flavorType

The flavor type to supply or promise the data for. Some flavor types are described in "Scrap Flavor Types" (page 1511).

flavorFlags

A variable of type `ScrapFlavorFlags` that you use to supply information about the flavor specified by the `flavorType` parameter. See "Scrap Flavor Flags" (page 1512) for a description of the values you can use in this parameter.

flavorSize

The size of the data you are supplying or promising, in bytes. If you don't know the size, pass `kScrapFlavorSizeUnknown` to place a promise for data of undetermined size on the scrap. If you pass 0 in this parameter, a flavor with no expected data—not a promise—is placed on the scrap, and the value of the *flavorData* parameter is ignored.

flavorData

A pointer to a buffer, local variable, or other storage location, created and disposed of by your application. Before calling `PutScrapFlavor` to put flavor data on the scrap, store the data in this buffer. For information on the number of bytes of data, see the description of the `flavorSize` parameter.

Pass `NULL` for this parameter to indicate you will provide data through a subsequent call to `PutScrapFlavor`, either later in the same code flow or during execution of your `ScrapPromiseKeeperProcPtr` (page 1508) callback.

The last time you can provide scrap flavor data is when your scrap promise-keeper function gets called. It is not possible to call `PutScrapFlavor` while handling a suspend event; suspend events under Carbon don't work the way they do under Mac OS 8 and 9.

Return Value

A result code. See "Scrap Manager Result Codes" (page 1514).

Discussion

`PutScrapFlavor` is different than `PutScrap` in that it includes a `ScrapRef` parameter and it supports promising a flavor for later delivery, rather than supplying it immediately.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Scrap.h`

SetScrapPromiseKeeper

Associates an application-defined promise-keeper function with a scrap or removes an associated promise-keeper. (Deprecated in Mac OS X v10.5. Use `PasteboardSetPromiseKeeper` instead.)

```
OSStatus SetScrapPromiseKeeper (
   ScrapRef scrap,
   ScrapPromiseKeeperUPP upp,
   const void *userData
);
```

Parameters

scrap

A reference to the scrap to set the promise-keeper function for.

upp

A universal procedure pointer to a scrap promise-keeper function. For more information, see `ScrapPromiseKeeperProcPtr` (page 1508)

You can remove a promise-keeper function from a scrap by passing `NULL` for this parameter.

userData

An untyped pointer to a buffer, local variable, or other storage location, created and disposed of by your application. This value is passed to the promise-keeper function specified by the `upp` parameter, which can do whatever it needs to do with the value. For example, you might pass a pointer or handle to some private scrap data that your promise-keeper function uses in fabricating one or more promised flavors.

If your promise-keeper function has no need for special user data, pass `NULL` for this parameter.

Return Value

A result code. See "Scrap Manager Result Codes" (page 1514).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Scrap.h`

UnloadScrap

Writes the scrap from memory to the scrap file. (Deprecated in Mac OS X v10.5.)

```
OSStatus UnloadScrap (
   void
);
```

Return Value

A result code. See "Scrap Manager Result Codes" (page 1514).

Discussion

This function releases the memory occupied by the scrap in your application's heap. The scrap file is located in the System Folder of the startup volume and has the filename as indicated by the `scrapName` field of the scrap information structure (usually "Clipboard"). If the scrap is already on the disk, this function does nothing.

Special Considerations

In Mac OS X, this function does nothing and is no longer necessary.

Availability

Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In

`Scrap.h`

Callbacks

ScrapPromiseKeeperProcPtr

Defines a pointer to a function the Scrap Manager calls to obtain promised scrap data for a specified flavor.

```
typedef OSStatus (*ScrapPromiseKeeperProcPtr)
(
                ScrapRef scrap,
                ScrapFlavorType flavorType,
                void * userData);
```

If you name your function `MyScrapPromiseKeeperCallback`, you would declare it like this:

```
OSStatus MyScrapPromiseKeeperCallback (

            ScrapRef scrap,
            ScrapFlavorType flavorType,
            void * userData);
```

Parameters

scrap

A reference to the scrap to which to supply the promised flavor data.

flavorType

The flavor type to supply the promised data for. Some scrap flavor types are described in "Scrap Flavor Types" (page 1511).

userData

An untyped pointer to a buffer, local variable, or other storage location, created and disposed of by your application, and supplied to the Scrap Manager by a previous call to `SetScrapPromiseKeeper` (page 1507). For example, this parameter might refer to a pointer or handle to some private scrap data which your promise-keeper function uses in fabricating one or more promised flavors.

This parameter may have a value of `NULL`.

Return Value

A result code. See "Scrap Manager Result Codes" (page 1514).

Discussion
To provide a pointer to your promise-keeper function, you create a universal procedure pointer (UPP), using the function `NewScrapPromiseKeeperUPP` (page 1505). You can do so with code similar to the following:

```
ScrapPromiseKeeperUPP MyPromiseKeeperUPP;
MyPromiseKeeperUPP = NewScrapPromiseKeeperUPP (&MyScrapPromiseKeeperCallback);
```

You can then associate the UPP with a scrap by passing `MyScrapPromiseKeeperCallback` as a parameter to the `SetScrapPromiseKeeper` (page 1507) function.

If a promised flavor is requested through `GetScrapFlavorData` (page 1501) or `GetScrapFlavorSize` (page 1503), the Scrap Manager calls the application's `ScrapPromiseKeeperProcPtr` function. The scrap promise-keeper function should call `PutScrapFlavor` (page 1505) as appropriate to fulfill its promises. Failure to do so—including returning an error or simply neglecting to keep a promise for a flavor—will result in errors being returned to corresponding callers of `GetScrapFlavorData` or `GetScrapFlavorSize`.

Under Mac OS X, the scrap promise-keeper function can be called during any call to `GetScrapFlavorData` or `GetScrapFlavorSize`. Under Mac OS 8 and 9, the Carbon Scrap Manager still must support non-Carbon callers of `GetScrap`, which does not know about promised flavors. As a result, the Carbon Scrap Manager must make sure all promises have been kept when the application is suspended.

It is okay to keep a promise without ever receiving a call to a scrap promise-keeper function. You should not call `WaitNextEvent` or any similar function from your promise-keeper function because the promise-keeper might be running at suspend event time.

After you are finished with a promise-keeper function, and have removed it by passing `NULL` to the `SetScrapPromiseKeeper` (page 1507) function, you can dispose of the UPP with the `DisposeScrapPromiseKeeperUPP` (page 1498) function. However, don't dispose of the UPP if any other scrap uses it or if you plan to use it again.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Scrap.h`

Data Types

ScrapFlavorInfo

Describes a single flavor within a scrap.

```
struct ScrapFlavorInfo {
    ScrapFlavorType flavorType;
    ScrapFlavorFlags flavorFlags;
};
typedef struct ScrapFlavorInfo ScrapFlavorInfo;
```

Fields
`flavorType`
The flavor type for the flavor. Some values for flavor types are described in "Scrap Flavor Types" (page 1511).

`flavorFlags`
The flavor flags for the flavor. Some values for flavor flags are described in "Scrap Flavor Flags" (page 1512).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Scrap.h`

ScrapRef

Defines a reference to a scrap.

```
typedef struct OpaqueScrapRef * ScrapRef;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Scrap.h`

ScrapPromiseKeeperUPP

Defines a universal procedure pointer to a scrap promise–keeper function.

```
typedef ScrapPromiseKeeperProcPtr ScrapPromiseKeeperUPP;
```

Discussion
See `ScrapPromiseKeeperProcPtr` (page 1508) for more information on scrap promise–keeper functions.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Scrap.h`

ScrapFlavorType

Defines a scrap flavor type.

```
typedef FourCharCode ScrapFlavorType;
```

Discussion
Some values for scrap flavor types are shown in "Scrap Flavor Types" (page 1511).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Scrap.h`

Constants

Scrap Flavor Types

Identify commonly used scrap flavor types.

```
enum {
    kScrapFlavorTypePicture = 'PICT',
    kScrapFlavorTypeText = 'TEXT',
    kScrapFlavorTypeTextStyle = 'styl',
    kScrapFlavorTypeMovie = 'moov',
    kScrapFlavorTypeSound = 'snd ',
    kScrapFlavorTypeUnicode = 'utxt',
    kScrapFlavorTypeUnicodeStyle = 'ustl'
};
```

Constants

`kScrapFlavorTypePicture`
Specifies the contents of a `PicHandle`.

Available in Mac OS X v10.0 and later.

Declared in `Scrap.h`.

`kScrapFlavorTypeText`
Specifies a stream of text characters.

Available in Mac OS X v10.0 and later.

Declared in `Scrap.h`.

`kScrapFlavorTypeTextStyle`
Specifies a style scrap structure. For more information, see `TEGetStyleScrapHandle` in *Inside Mac OS X: TextEdit Reference*.

Available in Mac OS X v10.0 and later.

Declared in `Scrap.h`.

`kScrapFlavorTypeMovie`
Specifies a reference to a QuickTime movie.

Available in Mac OS X v10.0 and later.

Declared in `Scrap.h`.

`kScrapFlavorTypeSound`
Specifies the contents of a `'snd '` resource. For more information, see the functions `SndRecord` and `SndPlay` in *Inside Mac OS X: Sound Manager Reference*.

Available in Mac OS X v10.0 and later.

Declared in `Scrap.h`.

`kScrapFlavorTypeUnicode`
Specifies a stream of 16-bit Unicode characters.

Available in Mac OS X v10.0 and later.

Declared in `Scrap.h`.

`kScrapFlavorTypeUnicodeStyle`
Specifies Unicode style information; defined by ATSUI and used by Textension.

Available in Mac OS X v10.0 and later.

Declared in `Scrap.h`.

Scrap Flavor Flags

Describe attributes of a scrap flavor.

```
enum {
    kScrapFlavorMaskNone = 0x00000000,
    kScrapFlavorMaskSenderOnly = 0x00000001,
    kScrapFlavorMaskTranslated = 0x00000002
};
typedef UInt32 ScrapFlavorFlags;
```

Constants

`kScrapFlavorMaskNone`
No flavors in the scrap.

Available in Mac OS X v10.0 and later.

Declared in `Scrap.h`.

`kScrapFlavorMaskSenderOnly`
The flavor is intended to be visible to the sender only. This is typically used to save a private flavor into the scrap so that other public promised flavors can be derived from it on demand. If another process put a flavor with this flag on the scrap, your process will never see the flavor, so you do not need to test for this flag.

Available in Mac OS X v10.0 and later.

Declared in `Scrap.h`.

`kScrapFlavorMaskTranslated`
The flavor has been translated (or will be translated when the promise is kept) from some other flavor in the scrap, either by the sender or by the Translation Manager.

Available in Mac OS X v10.0 and later.

Declared in `Scrap.h`.

Discussion

To determine the attributes of a scrap flavor, call the `GetScrapFlavorFlags` (page 1502) function.

Reserved Flavor Type

Identifies a flavor type reserved by the Scrap Manager.

```
enum {
    kScrapReservedFlavorType = 'srft'
};
```

Discussion

`kScrapReservedFlavorType` is a flavor type which is reserved for use by the Scrap Manager. If you pass it to the Scrap Manager, it will be rejected.

Unknown Flavor Data Size Constant

Indicates that the size of the scrap flavor data is unknown.

```
enum {
    kScrapFlavorSizeUnknown = -1
};
```

Discussion
When promising a scrap flavor, it is okay if you don't yet know how big the flavor data will be. In this case, pass `kScrapFlavorSizeUnknown` for the flavor data size.

Options for the GetScrapByName Function

Define options passed to the `GetScrapByName` function.

```
enum {
    kScrapGetNamedScrap = 0,
    kScrapClearNamedScrap = 0x00000001
};
```

Constants

`kScrapGetNamedScrap`
Get current named scrap without bumping or clearing the scrap.
Available in Mac OS X v10.1 and later.
Declared in `Scrap.h`.

`kScrapClearNamedScrap`
Acquire the named scrap, bumping and clearing the scrap.
Available in Mac OS X v10.1 and later.
Declared in `Scrap.h`.

Invalid Scrap Reference

Defines an invalid scrap reference.

```
#define kScrapRefNone ((ScrapRef)NULL)
```

Discussion
`kScrapRefNone` is guaranteed to be an invalid `ScrapRef`. This is convenient when initializing application variables.

Named Scraps

Specify Apple–defined scrap names for the `GetScrapByName` function.

```
#define kScrapClipboardScrap CFSTR("com.apple.scrap.clipboard")
#define kScrapFindScrap CFSTR("com.apple.scrap.find")
```

Constants

`kScrapClipboardScrap`

Traditional clipboard scrap.

Available in Mac OS X v10.1 and later.

Declared in `Scrap.h`.

`kScrapFindScrap`

Compatible with Cocoa's global find scrap.

Available in Mac OS X v10.1 and later.

Declared in `Scrap.h`.

Result Codes

The most common result codes returned by Scrap Manager are listed below.

Result Code	Value	Description
`needClearScrapErr`	-100	Scrap does not exist (same as `noScrapErr`) Available in Mac OS X v10.0 and later.
`noScrapErr`	-100	Scrap does not exist (not initialized) Available in Mac OS X v10.0 and later.
`noTypeErr`	-102	No data of the requested format type in scrap Available in Mac OS X v10.0 and later.
`scrapFlavorNotFoundErr`	-102	No data of the requested format type in scrap (same as `noTypeErr`) Available in Mac OS X v10.0 and later.
`internalScrapErr`	-4988	Scrap Manager has encountered an internal error Available in Mac OS X v10.0 and later.
`duplicateScrapFlavorErr`	-4989	Data (or a promise for data) of the specified format already exists in the scrap Available in Mac OS X v10.0 and later.
`badScrapRefErr`	-4990	Invalid scrap reference Available in Mac OS X v10.0 and later.
`processStateIncorrectErr`	-4991	Available in Mac OS X v10.0 and later.
`scrapPromiseNotKeptErr`	-4992	No data supplied for the promised flavor Available in Mac OS X v10.0 and later.

Result Code	Value	Description
noScrapPromiseKeeperErr	-4993	No scrap promise–keeper function set for the scrap Available in Mac OS X v10.0 and later.
nilScrapFlavorDataErr	-4994	Available in Mac OS X v10.0 and later.
scrapFlavorFlagsMismatchErr	-4995	Available in Mac OS X v10.0 and later.
scrapFlavorSizeMismatchErr	-4996	Available in Mac OS X v10.0 and later.
illegalScrapFlavorFlagsErr	-4997	Invalid scrap flavor flags Available in Mac OS X v10.0 and later.
illegalScrapFlavorTypeErr	-4998	Invalid scrap flavor Available in Mac OS X v10.0 and later.
illegalScrapFlavorSizeErr	-4999	Invalid size for scrap flavor data Available in Mac OS X v10.0 and later.

Gestalt Constants

You can check for version and feature availability information by using the Scrap Manager selectors defined in the Gestalt Manager. For more information see *Gestalt Manager Reference*.

Speech Recognition Manager Reference

Framework: Carbon/Carbon.h

Declared in SpeechRecognition.h

Overview

The Speech Recognition Manager provides speech recognition support in applications.

Functions by Task

Opening and Closing Recognition Systems

`SRCloseRecognitionSystem` (page 1524)
Closes a recognition system when your application is finished using it (for example, just before your application quits).

`SROpenRecognitionSystem` (page 1537)
Opens a recognition system.

Creating and Manipulating Recognizers

`SRCancelRecognition` (page 1522)
Cancels the attempt to recognize the current utterance.

`SRContinueRecognition` (page 1524)
Causes a recognizer to continue recognizing speech.

`SRGetLanguageModel` (page 1528)
Gets a recognizer's active language model.

`SRIdle` (page 1531)
Grants processing time to the Speech Recognition Manager if your application does not call `WaitNextEvent` frequently.

`SRNewRecognizer` (page 1535)
Creates a new recognizer.

`SRSetLanguageModel` (page 1543)
Sets a recognizer's active language model.

`SRStartListening` (page 1546)
Starts a recognizer listening and reporting results to your application.

`SRStopListening` (page 1547)
Stops a recognizer listening and reporting results to your application.

Managing Speech Objects

`SRGetProperty` (page 1529)
Gets the current value of a property of a speech object.

`SRGetReference` (page 1530)
Obtains an extra reference to a speech object.

`SRReleaseObject` (page 1540)
Releases a speech object.

`SRSetProperty` (page 1543)
Sets the value of a property of a speech object.

Traversing Speech Objects

`SRCountItems` (page 1525)
Determines the number of subitems in a container object.

`SRGetIndexedItem` (page 1527)
Gets a subitem in a container object.

`SRRemoveIndexedItem` (page 1541)
Removes a subitem from a container object.

`SRSetIndexedItem` (page 1542)
Replaces a subitem in a container object with some other object.

Creating Language Objects

`SRNewLanguageModel` (page 1531)
Creates a new language model.

`SRNewPath` (page 1534)
Creates a new path.

`SRNewPhrase` (page 1535)
Creates a new phrase.

`SRNewWord` (page 1536)
Creates a new word.

Manipulating Language Objects

`SRAddLanguageObject` (page 1521)
Adds a language object to some other language object.

`SRAddText` (page 1522)
Adds text to the contents of a language object.

SRChangeLanguageObject (page 1523)
Changes the contents of a language object.

SREmptyLanguageObject (page 1527)
Empties the contents of a language object.

SRNewLanguageObjectFromHandle (page 1533)
Creates a language object from the handle previously created by the SRPutLanguageObjectIntoHandle function.

SRNewLanguageObjectFromDataFile (page 1532)
Reads a language object from a data file.

SRPutLanguageObjectIntoHandle (page 1540)
Puts a language object (and any embedded languages objects it contains) into a handle.

SRPutLanguageObjectIntoDataFile (page 1539)
Puts a language object (and any embedded language objects it contains) into a data file.

SRRemoveLanguageObject (page 1541)
Removes a language object from another language object that contains it.

Using the System Feedback Window

SRDrawRecognizedText (page 1525)
Draws recognized text in the feedback window.

SRDrawText (page 1526)
Draws output text in the feedback window.

SRProcessBegin (page 1537)
Indicates that a recognition result is being processed.

SRProcessEnd (page 1538)
Indicates that a recognition result is done being processed.

SRSpeakAndDrawText (page 1544)
Draws output text in the feedback window and causes the feedback character in the feedback window to speak that text.

SRSpeakText (page 1545)
Causes the feedback character in the feedback window to speak a text string.

SRSpeechBusy (page 1546)
Determines if the feedback character in a feedback window is currently speaking.

SRStopSpeech (page 1547)
Terminates speech by the feedback character in a feedback window.

Creating, Invoking and Disposing UPPs

NewSRCallBackUPP (page 1520)
Creates a new universal procedure pointer (UPP) to a speech recognition callback function.

DisposeSRCallBackUPP (page 1520)
Disposes of a universal procedure pointer (UPP) to a speech recognition callback function.

InvokeSRCallBackUPP (page 1520)
Invokes your speech recognition callback function.

Functions

DisposeSRCallBackUPP

Disposes of a universal procedure pointer (UPP) to a speech recognition callback function.

```
void DisposeSRCallBackUPP (
   SRCallBackUPP userUPP
);
```

Parameters

userUPP

The UPP to dispose of.

Availability
Available in CarbonLib 1.0.2 and later.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechRecognition.h`

InvokeSRCallBackUPP

Invokes your speech recognition callback function.

```
void InvokeSRCallBackUPP (
   SRCallBackStruct *param,
   SRCallBackUPP userUPP
);
```

Discussion
You should not have to call the `InvokeSRCallbackUPP` function, as the system calls your speech recognition callback function for you.

Availability
Available in CarbonLib 1.0.2 and later.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechRecognition.h`

NewSRCallBackUPP

Creates a new universal procedure pointer (UPP) to a speech recognition callback function.

```
SRCallBackUPP NewSRCallBackUPP (
   SRCallBackProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your speech recognition callback function.

Return Value
A UPP to the speech recognition callback function. See the description of the `SRCallBackUPP` data type.

Availability
Available in CarbonLib 1.0.2 and later.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechRecognition.h`

SRAddLanguageObject

Adds a language object to some other language object.

```
OSErr SRAddLanguageObject (
   SRLanguageObject base,
   SRLanguageObject addon
);
```

Parameters

`base`

The language object to which to add the language object specified by the `addon` parameter.

`addon`

The language object to add on to the language object specified in the `base` parameter. For example, if `addon` specifies a word and `base` specifies a phrase, then `SRAddLanguageObject` appends that word to the end of that phrase.

Return Value
A result code. See "Speech Recognition Manager Result Codes" (page 1568).

Discussion
The `SRAddLanguageObject` function is useful for adding language objects to phrases, paths, and language models. For a phrase or a path, `SRAddLanguageObject` appends the specified object to the end of the phrase or path. For a language model, `SRAddLanguageObject` adds the specified object to the list of alternative recognizable utterances.

The language object to which you add an object acquires a new reference to that object. Accordingly, any changes you subsequently make to the added object are reflected in any object to which you added it. The base object releases its reference to the added object when the base object is disposed of.

`SRAddLanguageObject` does not alter the value of the reference constant property of the language object specified by the `base` parameter.

See `SRAddText` (page 1522) for a useful shortcut function.

Availability
Available in CarbonLib 1.0 and later when Speech Recognition 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechRecognition.h`

SRAddText

Adds text to the contents of a language object.

```
OSErr SRAddText (
   SRLanguageObject base,
   const void *text,
   SInt32 textLength,
   SRefCon refCon
);
```

Parameters

base

A language object to which to add the text.

text

A pointer to a buffer that contains the words or phrase to add to the contents of the specified language object.

textLength

The size, in bytes, of the specified text.

refCon

An application-defined reference constant. The value of the reference constant property of the new word or phrase representing the specified text is set to this value.

Return Value

A result code. See "Speech Recognition Manager Result Codes" (page 1568).

Discussion

The `SRAddText` function is useful for phrases, paths, and language models. If the `base` parameter specifies a path or language model, `SRAddText` is equivalent to calling `SRNewPhrase`, `SRAddLanguageObject`, and `SRReleaseObject` for the phrase specified by the `text` parameter and calling `SRSetProperty` to reset the value of the reference constant property of the new phrase.

If the `base` parameter specifies a phrase, `SRAddText` is equivalent to calling `SRNewPhrase`, `SRAddLanguageObject`, and `SRReleaseObject` for each distinguishable word in the `text` parameter and calling `SRSetProperty` to set the value of the reference constant property of the new words.

Availability

Available in CarbonLib 1.0 and later when Speech Recognition 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In

`SpeechRecognition.h`

SRCancelRecognition

Cancels the attempt to recognize the current utterance.

```
OSErr SRCancelRecognition (
   SRRecognizer recognizer
);
```

Parameters

recognizer

A recognizer.

Return Value
A result code. See "Speech Recognition Manager Result Codes" (page 1568).

Discussion
The `SRCancelRecognition` function instructs the recognizer specified by the `recognizer` parameter to stop recognizing speech. You need to call either `SRContinueRecognition` or `SRCancelRecognition` each time your application is notified that the user has started speaking (using Apple events or through an application-defined callback routine).

Availability
Available in CarbonLib 1.0 and later when Speech Recognition 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechRecognition.h`

SRChangeLanguageObject

Changes the contents of a language object.

```
OSErr SRChangeLanguageObject (
   SRLanguageObject languageObject,
   const void *text,
   SInt32 textLength
);
```

Parameters

languageObject
A language object.

text
A pointer to a buffer that contains the words or phrase to which the contents of the specified language object are to be changed.

textLength
The size, in bytes, of the specified text.

Return Value
A result code. See "Speech Recognition Manager Result Codes" (page 1568).

Discussion
`SRChangeLanguageObject` is a convenient shortcut for calling `SREmptyLanguageObject` and then `SRAddText`.

`SRChangeLanguageObject` does not alter the value of the reference constant property of the language object specified by the `languageObject` parameter.

If there are no other references to the language object specified by the `languageObject` parameter, calling `SRChangeLanguageObject` causes that object to be released.

If you want to swap rapidly among several language models, you should use the `SRSetLanguageObject` function instead of `SRChangeLanguageObject`. Or, you could use the `kSREnabled` property to rapidly enable and disable parts of the current language model to reflect the current context.

Availability
Available in CarbonLib 1.0 and later when Speech Recognition 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Declared In
`SpeechRecognition.h`

SRCloseRecognitionSystem

Closes a recognition system when your application is finished using it (for example, just before your application quits).

```
OSErr SRCloseRecognitionSystem (
   SRRecognitionSystem system
);
```

Parameters

system
A recognition system.

Return Value
A result code. See "Speech Recognition Manager Result Codes" (page 1568).

Discussion
The `SRCloseRecognitionSystem` function closes the recognition system specified by the `system` parameter. If any speech objects are still attached to that recognition system, they are disposed of and any references you have to those objects are thereby rendered invalid.

Availability
Available in CarbonLib 1.0 and later when Speech Recognition 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechRecognition.h`

SRContinueRecognition

Causes a recognizer to continue recognizing speech.

```
OSErr SRContinueRecognition (
   SRRecognizer recognizer
);
```

Parameters

recognizer
A recognizer.

Return Value
A result code. See "Speech Recognition Manager Result Codes" (page 1568).

Discussion
You need to call either `SRContinueRecognition` or `SRCancelRecognition` each time your application is notified that the user has started speaking (using Apple events or through an application-defined callback routine).

Availability
Available in CarbonLib 1.0 and later when Speech Recognition 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechRecognition.h`

SRCountItems

Determines the number of subitems in a container object.

```
OSErr SRCountItems (
   SRSpeechObject container,
   long *count
);
```

Parameters

container
A speech object.

count
On return, a pointer to a long containing the number of subitems in the specified speech object.

Return Value
A result code. See "Speech Recognition Manager Result Codes" (page 1568).

Discussion
This function is useful only for speech objects that have distinguishable subitems, such as phrases (which contain words), paths (which contain words, phrases, and language models), and language models (which contain words, phrases, paths, and possibly other language models).

Version Notes
In Speech Recognition Manager version 1.5, this function is useful only for operating on language objects (of type `SRLanguageObject`), although it is defined for all speech objects.

Availability
Available in CarbonLib 1.0 and later when Speech Recognition 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechRecognition.h`

SRDrawRecognizedText

Draws recognized text in the feedback window.

```
OSErr SRDrawRecognizedText (
   SRRecognizer recognizer,
   const void *dispText,
   SInt32 dispLength
);
```

Parameters

recognizer

A recognizer.

dispText

A pointer to a buffer that contains the text to be drawn.

dispLength

The size, in bytes, of the specified text.

Return Value

A result code. See "Speech Recognition Manager Result Codes" (page 1568).

Discussion

The `SRDrawRecognizedText` function draws the text specified by the `dispText` and `dispLength` parameters in the transcript portion of the feedback window associated with the recognizer specified by the `recognizer` parameter. The text is drawn in the style characteristic of all recognized text. You might want to use this function to display a recognized phrase using a different spelling than the one used in the language model.

If the value of the `kSRWantsResultTextDrawn` property of the specified recognizer is `TRUE` (which is the default value), a transcript of the text of a recognition result is automatically sent directly to the feedback window. As a result, you should call `SRDrawRecognizedText` only when the value of the recognizer's `kSRWantsResultTextDrawn` property is `FALSE`.

Availability

Available in CarbonLib 1.0 and later when Speech Recognition 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Declared In

`SpeechRecognition.h`

SRDrawText

Draws output text in the feedback window.

```
OSErr SRDrawText (
   SRRecognizer recognizer,
   const void *dispText,
   SInt32 dispLength
);
```

Parameters

recognizer

A recognizer.

dispText

A pointer to a buffer that contains the text to be drawn.

dispLength

The size, in bytes, of the specified text.

Return Value
A result code. See "Speech Recognition Manager Result Codes" (page 1568).

Discussion
The `SRDrawText` function draws the text specified by the `dispText` and `dispLength` parameters in the transcript portion of the feedback window associated with the recognizer specified by the `recognizer` parameter. The text is drawn in the style characteristic of all output text.

Availability
Available in CarbonLib 1.0 and later when Speech Recognition 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechRecognition.h`

SREmptyLanguageObject

Empties the contents of a language object.

```
OSErr SREmptyLanguageObject (
   SRLanguageObject languageObject
);
```

Parameters

`languageObject`
A language object.

Return Value
A result code. See "Speech Recognition Manager Result Codes" (page 1568).

Discussion
The `SREmptyLanguageObject` function empties the contents of the language object specified by the `languageObject` parameter. (For example, if `languageObject` specifies a phrase containing two words, calling `SREmptyLanguageObject` would result in a phrase that contains no words.) Any properties of that object that are not related to its contents are unchanged. In particular, `SREmptyLanguageObject` does not alter the value of the reference constant property of that language object.

If there are no other references to the words, phrases, and paths that were contained in the language object, calling `SREmptyLanguageObject` causes them to be disposed of.

Availability
Available in CarbonLib 1.0 and later when Speech Recognition 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechRecognition.h`

SRGetIndexedItem

Gets a subitem in a container object.

```
OSErr SRGetIndexedItem (
   SRSpeechObject container,
   SRSpeechObject *item,
   long index
);
```

Parameters

container

A speech object.

item

On return, a reference to the subitem in the specified speech object that has the specified index.

index

An integer ranging from 0 to one less than the number of subitems in the specified speech object. (You can call the `SRCountItems` function to determine the number of subitems contained in a speech object.) If the index you specify is not in this range, `SRGetIndexedItem` returns the result code `kSRParamOutOfRange`.

Return Value

A result code. See "Speech Recognition Manager Result Codes" (page 1568).

Discussion

This function is useful for iterating through all subitems in a container object.

`SRGetIndexedItem` increases the reference count of the specified speech object. You should call the `SRReleaseObject` function to release the object reference returned by `SRGetIndexedItem` when you are done using it. For example, you can get a reference to the third word in a phrase by executing this code:

```
myErr = SRGetIndexedItem(myPhrase, &myWord, 2)
```

Then, when you are finished using the word, you should execute this code:

```
myErr = SRReleaseObject(myWord);
```

Version Notes

In Speech Recognition Manager version 1.5, this function is useful only for operating on language objects (of type `SRLanguageObject`), although it is defined for all speech objects.

Availability

Available in CarbonLib 1.0 and later when Speech Recognition 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Declared In

`SpeechRecognition.h`

SRGetLanguageModel

Gets a recognizer's active language model.

```
OSErr SRGetLanguageModel (
   SRRecognizer recognizer,
   SRLanguageModel *languageModel
);
```

Parameters

recognizer

A recognizer.

languageModel

On return, a reference to the language model currently active for the specified recognizer.

Return Value

A result code. See "Speech Recognition Manager Result Codes" (page 1568).

Discussion

`SRGetLanguageModel` increases the reference count of the specified language model. You should call the `SRReleaseObject` function to release the language model reference returned by `SRGetLanguageModel` when you are done using it.

Availability

Available in CarbonLib 1.0 and later when Speech Recognition 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Declared In

`SpeechRecognition.h`

SRGetProperty

Gets the current value of a property of a speech object.

```
OSErr SRGetProperty (
   SRSpeechObject srObject,
   OSType selector,
   void *property,
   Size *propertyLen
);
```

Parameters

srObject

A speech object.

selector

A property selector. See "Recognizer Properties" (page 1564), "Recognizer Listen Key Properties" (page 1563), "Language Object Properties" (page 1557), and "Recognition System Properties" (page 1562) for lists of the available property selectors.

property

A pointer to a buffer into which the value of the specified property is to be copied.

propertyLen

On entry, a pointer to the length, in bytes, of the specified buffer. If the value is of a fixed size, then `propertyLen` should point to a variable of type `Size` that specifies that size. If the size of the value can vary (for example, if the value is a string), then `propertyLen` should point to a variable of type `Size` that specifies the number of bytes in the buffer pointed to by the `property` parameter.

On return, if the buffer is large enough to hold the returned property value and no error occurs, `SRGetProperty` sets `propertyLen` to the total number of bytes in the value of the specified property. If the buffer is not large enough to hold the returned property value, `SRGetProperty` sets `propertyLen` to the number of bytes required to store the requested property and returns the `kSRBufferTooSmall` error code.

Return Value
A result code. See "Speech Recognition Manager Result Codes" (page 1568).

Discussion
Not all selectors are valid for all types of speech objects. If the selector you specify does not specify a property of the specified speech object, `SRGetProperty` returns the result code `kSRCantGetProperty`.

If `SRGetProperty` returns an object reference, you must make sure to release that object reference (by calling `SRReleaseObject`) when you are finished using it. Most selectors do not cause `SRGetProperty` to return object references. For example, passing the selector `kSRSpelling` causes `SRGetProperty` to return a buffer of text, not an object reference.

Availability
Available in CarbonLib 1.0 and later when Speech Recognition 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechRecognition.h`

SRGetReference

Obtains an extra reference to a speech object.

```
OSErr SRGetReference (
   SRSpeechObject srObject,
   SRSpeechObject *newObjectRef
);
```

Parameters

srObject

A speech object.

newObjectRef

On return, a new reference to the specified speech object.

Return Value
A result code. See "Speech Recognition Manager Result Codes" (page 1568).

Discussion
The original object reference (contained in `srObject`) and the new reference (returned in `newObjectRef`) may have different values. Accordingly, you cannot simply compare two object references to determine whether they are references to the same speech object.

SRGetReference increases the reference count of the specified speech object. You should call the SRReleaseObject function to release the object reference returned by SRGetReference when you are done using it.

Availability
Available in CarbonLib 1.0 and later when Speech Recognition 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
SpeechRecognition.h

SRIdle

Grants processing time to the Speech Recognition Manager if your application does not call WaitNextEvent frequently.

```
OSErr SRIdle (
   void
);
```

Return Value
A result code. See "Speech Recognition Manager Result Codes" (page 1568).

Discussion
The SRIdle function grants processing time to the Speech Recognition Manager, thereby allowing it to process incoming sound and send recognition results.

Most applications do not need to call the SRIdle function. You need to call it only if your application does a significant amount of processing without periodically calling WaitNextEvent. If you do use the SRIdle function, you should call it often enough that the Speech Recognition Manager can perform its work.

Note, however, that if you call SRIdle and not WaitNextEvent, you give time to the recognizer but not to the feedback window. You must call WaitNextEvent periodically to have the feedback animations work correctly if your recognizer is using the standard feedback window.

Availability
Available in CarbonLib 1.0 and later when Speech Recognition 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
SpeechRecognition.h

SRNewLanguageModel

Creates a new language model.

```
OSErr SRNewLanguageModel (
   SRRecognitionSystem system,
   SRLanguageModel *model,
   const void *name,
   SInt32 nameLength
);
```

Parameters

system

A recognition system.

model

On return, a reference to a new empty language model associated with the specified recognition system.

name

A pointer to a buffer that contains the name of the language model. The name of the language model should be unique among all the language models your application creates, and it should be comprehensible to users. (For example, a language model that defined a list of names might be called "«Names»").

The convention that language model names begin with the character "«" and end with the character "»" is adopted to support future utilities that display the names of language models to the user (perhaps as part of showing the user what he or she can say).

nameLength

The size, in bytes, of the specified name.

Return Value

A result code. See "Speech Recognition Manager Result Codes" (page 1568).

Discussion

You can add language objects (that is, words, phrases, paths, and other language models) to a language model by calling the `SRAddText` and `SRAddLanguageObject` functions.

`SRNewLanguageModel` sets the reference count of the specified language model to 1. You should call the `SRReleaseObject` function to release the language model reference returned by `SRNewLanguageModel` when you are done using it.

You can get or set the name of an existing language model by calling the `SRGetProperty` or `SRSetProperty` functions with the `kSRSpelling` property selector.

Availability

Available in CarbonLib 1.0 and later when Speech Recognition 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Declared In

`SpeechRecognition.h`

SRNewLanguageObjectFromDataFile

Reads a language object from a data file.

```
OSErr SRNewLanguageObjectFromDataFile (
   SRRecognitionSystem system,
   SRLanguageObject *languageObject,
   short fRefNum
);
```

Parameters

system

A recognition system.

languageObject

On return, a reference to a new language object whose description is stored in the open data file that has the file reference number specified by the `fRefNum` parameter.

fRefNum

A file reference number of an open data file.

Return Value

A result code. See "Speech Recognition Manager Result Codes" (page 1568).

Discussion

`SRNewLanguageObjectFromDataFile` reads data beginning at the current file mark.

If the language object is successfully created and initialized, the file mark is left at the byte immediately following the language object description. Otherwise, if the language object data is not appropriately formatted, `SRNewLanguageObjectFromDataFile` returns the result code `kSRCantReadLanguageObject` as its function result and the file mark is not moved.

You should call the `SRReleaseObject` function to release the language object reference returned by `SRNewLanguageObjectFromDataFile` when you are done using it.

Availability

Available in CarbonLib 1.0 and later when Speech Recognition 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Declared In

`SpeechRecognition.h`

SRNewLanguageObjectFromHandle

Creates a language object from the handle previously created by the `SRPutLanguageObjectIntoHandle` function.

```
OSErr SRNewLanguageObjectFromHandle (
   SRRecognitionSystem system,
   SRLanguageObject *languageObject,
   Handle lObjHandle
);
```

Parameters

system

A recognition system.

languageObject

On return, a reference to a new language object created and initialized using the private data to which the `lobjHandle` parameter is a handle.

lObjHandle

A handle to a language object. The data specified by `lobjHandle` should have been created by a previous call to the `SRPutLanguageObjectIntoHandle` function; if that data is not appropriately formatted, `SRNewLanguageObjectFromHandle` returns the result code `kSRCantReadLanguageObject` as its function result.

Return Value
A result code. See "Speech Recognition Manager Result Codes" (page 1568).

Discussion
You can use this function to load language objects from resources (for example, by using the Resource Manager function `GetResource`).

You should call the `SRReleaseObject` function to release the language object reference returned by `SRNewLanguageObjectFromHandle` when you are done using it.

Availability
Available in CarbonLib 1.0 and later when Speech Recognition 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechRecognition.h`

SRNewPath

Creates a new path.

```
OSErr SRNewPath (
   SRRecognitionSystem system,
   SRPath *path
);
```

Parameters

system

A recognition system.

path

On return, a reference to a new empty path associated with the specified recognition system.

Return Value
A result code. See "Speech Recognition Manager Result Codes" (page 1568).

Discussion
You can then add objects to a path by calling the `SRAddText` or `SRAddLanguageObject` functions.

You should call the `SRReleaseObject` function to release the path reference returned by `SRNewPath` when you are done using it.

Availability
Available in CarbonLib 1.0 and later when Speech Recognition 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechRecognition.h`

SRNewPhrase

Creates a new phrase.

```
OSErr SRNewPhrase (
   SRRecognitionSystem system,
   SRPhrase *phrase,
   const void *text,
   SInt32 textLength
);
```

Parameters

system

A recognition system.

phrase

On return, a reference to a new phrase associated with the specified recognition system.

text

A pointer to a buffer that contains the words that comprise the phrase.

textLength

The size, in bytes, of the specified text.

Return Value

A result code. See "Speech Recognition Manager Result Codes" (page 1568).

Discussion

The phrase's contents (that is, the words that comprise the phrase) is specified by the `text` and `textLength` parameters. You can, if you wish, create a new empty phrase and then add words to it by calling the `SRAddText` or `SRAddLanguageObject` functions.

You should call the `SRReleaseObject` function to release the phrase reference returned by `SRNewPhrase` when you are done using it.

Availability

Available in CarbonLib 1.0 and later when Speech Recognition 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Declared In

`SpeechRecognition.h`

SRNewRecognizer

Creates a new recognizer.

```
OSErr SRNewRecognizer (
   SRRecognitionSystem system,
   SRRecognizer *recognizer,
   OSType sourceID
);
```

Parameters

system

A recognition system.

recognizer
On return, a reference to a new recognizer associated with the specified recognition system and using the specified speech source.

sourceID
A speech source ID. See "Speech Source Constants" (page 1567).

Return Value
A result code. See "Speech Recognition Manager Result Codes" (page 1568).

Discussion
`SRNewRecognizer` may need to load substantial amounts of data from disk into memory. As a result, you might want to change the cursor to the watch cursor before you call `SRNewRecognizer`.

You should call the `SRReleaseObject` function to release the object reference returned by `SRNewRecognizer` when you are done using it.

Availability
Available in CarbonLib 1.0 and later when Speech Recognition 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechRecognition.h`

SRNewWord

Creates a new word.

```
OSErr SRNewWord (
   SRRecognitionSystem system,
   SRWord *word,
   const void *text,
   SInt32 textLength
);
```

Parameters
system
A recognition system.

word
On return, a reference to a new word associated with the specified recognition system.

text
A pointer to a buffer that contains the characters that comprise the word.

textLength
The size, in bytes, of the specified text.

Return Value
A result code. See "Speech Recognition Manager Result Codes" (page 1568).

Discussion
You should call the `SRReleaseObject` function to release the word reference returned by `SRNewWord` when you are done using it.

Availability
Available in CarbonLib 1.0 and later when Speech Recognition 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Declared In
SpeechRecognition.h

SROpenRecognitionSystem

Opens a recognition system.

```
OSErr SROpenRecognitionSystem (
   SRRecognitionSystem *system,
   OSType systemID
);
```

Parameters

system
On return, a reference to the recognition system having the specified system ID.

systemID
A recognition system ID.

Return Value
A result code. See "Speech Recognition Manager Result Codes" (page 1568).

Discussion
Generally, you should open a single recognition system when your application starts up and close it (by calling the function SRCloseRecognitionSystem) before your application exits.

Availability
Available in CarbonLib 1.0 and later when Speech Recognition 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
SpeechRecognition.h

SRProcessBegin

Indicates that a recognition result is being processed.

```
OSErr SRProcessBegin (
   SRRecognizer recognizer,
   Boolean failed
);
```

Parameters

recognizer
A recognizer.

failed
A Boolean value that determines how the feedback gestures are to be altered and whether the response sound is to be played (FALSE) or not (TRUE).

Return Value
A result code. See "Speech Recognition Manager Result Codes" (page 1568).

Discussion
The `SRProcessBegin` function causes the Speech Recognition Manager to provide the relevant feedback (in the feedback window associated with the recognizer specified by the `recognizer` parameter) indicating that the application is in the process of responding to a spoken command. Currently, the gestures of the feedback character are changed to indicate that processing is occurring.

If you set the value of the recognizer's `kSRWantsAutoFBGestures` property to `FALSE`, you should call `SRProcessBegin` at the beginning of your response to a recognition result and `SRProcessEnd` at the end of your response. During the interval separating the two calls, the feedback character displays an appropriate set of gestures showing the user that the task is being processed. If you pass the value `TRUE` in the `failed` parameter (indicating that the recognition result cannot successfully be processed), the feedback character displays frowns, shrugs, or other appropriate gestures. In addition, when `failed` is `TRUE`, you do not need to call `SRProcessEnd` to end the processing. If you pass the value `FALSE` in the `failed` parameter but determine subsequently that the recognition result cannot successfully be processed, you should call `SRProcessEnd` with the `failed` parameter set to `TRUE`.

If the value of the `kSRWantsAutoFBGestures` property of the specified recognizer is `TRUE`, the Speech Recognition Manager calls `SRProcessBegin` internally before notifying your application of a recognition result, and it calls `SRProcessEnd` internally after your application is notified. As a result, you should call `SRProcessBegin` or `SRProcessEnd` only when the value of the recognizer's `kSRWantsAutoFBGestures` property is `FALSE`.

Because the default value of the `kSRWantsAutoFBGestures` property is `TRUE`, most applications do not need to call `SRProcessBegin`. Calling `SRProcessBegin` is useful, however, when you know the resulting action might take a significant amount of time.

Availability
Available in CarbonLib 1.0 and later when Speech Recognition 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechRecognition.h`

SRProcessEnd

Indicates that a recognition result is done being processed.

```
OSErr SRProcessEnd (
   SRRecognizer recognizer,
   Boolean failed
);
```

Parameters

`recognizer`
A recognizer.

`failed`
A Boolean value that determines how the feedback gestures are to be altered (`FALSE`) or not (`TRUE`).

Return Value
A result code. See "Speech Recognition Manager Result Codes" (page 1568).

Discussion
The `SRProcessEnd` function causes the Speech Recognition Manager to provide the relevant feedback (in the feedback window associated with the recognizer specified by the `recognizer` parameter) indicating that a recognition result is done being processed. Currently, the gestures of the feedback character are changed and a response sound is played.

If the value of the `kSRWantsAutoFBGestures` property of the specified recognizer is `TRUE`, the Speech Recognition Manager calls `SRProcessBegin` internally before notifying your application of a recognition result, and it calls `SRProcessEnd` internally after your application is notified. As a result, you should call `SRProcessBegin` or `SRProcessEnd` only when the value of the recognizer's `kSRWantsAutoFBGestures` property is `FALSE`.

Because the default value of the `kSRWantsAutoFBGestures` property is `TRUE`, most applications do not need to call `SRProcessBegin`. Calling `SRProcessBegin` is useful, however, when you know the resulting action might take a significant amount of time.

Availability
Available in CarbonLib 1.0 and later when Speech Recognition 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechRecognition.h`

SRPutLanguageObjectIntoDataFile

Puts a language object (and any embedded language objects it contains) into a data file.

```
OSErr SRPutLanguageObjectIntoDataFile (
   SRLanguageObject languageObject,
   short fRefNum
);
```

Parameters

`languageObject`
A language object.

`fRefNum`
A file reference number of an open data file into which the data describing the specified language object is to be put.

Return Value
A result code. See "Speech Recognition Manager Result Codes" (page 1568).

Discussion
The `SRPutLanguageObjectIntoDataFile` function puts a description of the language object specified by the `languageObject` parameter into the data file specified by the `fRefNum` parameter. Data are written starting at the current file mark, and the file mark is moved to the end of the written data.

Availability
Available in CarbonLib 1.0 and later when Speech Recognition 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechRecognition.h`

SRPutLanguageObjectIntoHandle

Puts a language object (and any embedded languages objects it contains) into a handle.

```
OSErr SRPutLanguageObjectIntoHandle (
   SRLanguageObject languageObject,
   Handle lobjHandle
);
```

Parameters

languageObject

A language object.

lobjHandle

A handle to a block of memory into which the data describing the specified language object is to be put. On entry, this handle can have a length of 0.

Return Value

A result code. See "Speech Recognition Manager Result Codes" (page 1568).

Discussion

The `SRPutLanguageObjectIntoHandle` function puts a description of the language object specified by the `languageObject` parameter into the block of memory specified by the `lobjHandle` parameter. This replaces the data in the handle and resizes the handle if necessary.

You can use Resource Manager functions (such as `AddResource`) to store language objects into resources.

Availability

Available in CarbonLib 1.0 and later when Speech Recognition 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In

`SpeechRecognition.h`

SRReleaseObject

Releases a speech object.

```
OSErr SRReleaseObject (
   SRSpeechObject srObject
);
```

Parameters

srObject

A speech object.

Return Value

A result code. See "Speech Recognition Manager Result Codes" (page 1568).

Discussion

If there are no other remaining references to the object, `SRReleaseObject` disposes of the memory occupied by the object.

Your application should balance every function call that returns an object reference with a call to `SRReleaseObject`. This means that every call to a function whose name begins with `SRNew` or `SRGet` that successfully returns an object reference must be balanced with a call to `SRReleaseObject`.

In addition, you should call `SRReleaseObject` to release references to `SRSearchResult` objects that are passed to your application (via an Apple event handler or a callback routine).

Availability
Available in CarbonLib 1.0 and later when Speech Recognition 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechRecognition.h`

SRRemoveIndexedItem

Removes a subitem from a container object.

```
OSErr SRRemoveIndexedItem (
   SRSpeechObject container,
   long index
);
```

Parameters

`container`
A speech object.

`index`
An integer ranging from 0 to one less than the number of subitems in the specified speech object. (You can call the `SRCountItems` function to determine the number of subitems contained in a speech object.) If the index you specify is not in this range, `SRRemoveIndexedItem` returns the result code `kSRParamOutOfRange`.

Return Value
A result code. See "Speech Recognition Manager Result Codes" (page 1568).

Discussion
The `SRRemoveIndexedItem` function removes from the speech object specified by the `container` parameter the subitem located at the position specified by the `index` parameter. If `SRRemoveIndexedItem` completes successfully, the number of subitems in the container object is reduced by 1, and the index of each subitem that follows the removed item is reduced by 1.

Version Notes
In Speech Recognition Manager version 1.5, this function is useful only for operating on language objects (of type `SRLanguageObject`), although it is defined for all speech objects.

Availability
Available in CarbonLib 1.0 and later when Speech Recognition 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechRecognition.h`

SRRemoveLanguageObject

Removes a language object from another language object that contains it.

```
OSErr SRRemoveLanguageObject (
   SRLanguageObject base,
   SRLanguageObject toRemove
);
```

Parameters

base

The language object containing the language object to remove.

toRemove

The language object to remove.

Return Value
A result code. See "Speech Recognition Manager Result Codes" (page 1568).

Discussion
The object specified by the `base` parameter should be a container one of whose subitems is the object specified by the `toRemove` parameter.

Availability
Available in CarbonLib 1.0 and later when Speech Recognition 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechRecognition.h`

SRSetIndexedItem

Replaces a subitem in a container object with some other object.

```
OSErr SRSetIndexedItem (
   SRSpeechObject container,
   SRSpeechObject item,
   long index
);
```

Parameters

container

A speech object.

item

A speech object.

index

An integer ranging from 0 to one less than the number of subitems in the specified speech object.

Return Value
A result code. See "Speech Recognition Manager Result Codes" (page 1568).

Discussion
The `SRSetIndexedItem` function replaces the subitem having the index specified by the `index` parameter in the container object specified by the `container` parameter with the speech object specified by the `item` parameter. A reference to the replacement item is maintained separately by the container; as a result, you can release any reference to that item if you no longer need it. The reference to the replaced item is removed from the container; if that reference was the last remaining reference to the object, the object is released.

Version Notes
In Speech Recognition Manager version 1.5, this function is useful only for operating on language objects (of type `SRLanguageObject`), although it is defined for all speech objects.

Availability
Available in CarbonLib 1.0 and later when Speech Recognition 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechRecognition.h`

SRSetLanguageModel

Sets a recognizer's active language model.

```
OSErr SRSetLanguageModel (
   SRRecognizer recognizer,
   SRLanguageModel languageModel
);
```

Parameters

recognizer
A recognizer.

languageModel
The language model you wish to become the active model for the specified recognizer.

Return Value
A result code. See "Speech Recognition Manager Result Codes" (page 1568).

Discussion
If no other references exist to the language model currently in use by the specified recognizer, calling `SRSetLanguageModel` with a different language model causes the current one to be released.

Availability
Available in CarbonLib 1.0 and later when Speech Recognition 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechRecognition.h`

SRSetProperty

Sets the value of a property of a speech object.

```
OSErr SRSetProperty (
   SRSpeechObject srObject,
   OSType selector,
   const void *property,
   Size propertyLen
);
```

Parameters

srObject

A speech object.

selector

A property selector. See "Recognizer Properties" (page 1564), "Recognizer Listen Key Properties" (page 1563), "Language Object Properties" (page 1557), and "Recognition System Properties" (page 1562) for lists of the available property selectors.

property

A pointer to a buffer containing the value to which the specified property is to be set.

propertyLen

The length, in bytes, of the specified buffer.

Return Value

A result code. See "Speech Recognition Manager Result Codes" (page 1568).

Discussion

The `SRSetProperty` function sets the value of the property of the speech object specified by the `srObject` parameter to the value specified through the `property` parameter. The `selector` parameter specifies which property is to be set and the `propertyLen` parameter specifies it size, in bytes.

Not all properties can be set. If you attempt to set a property that cannot be set, `SRSetProperty` returns the result code `kSRCantSetProperty` or `kSRBadSelector` as its function result.

Availability

Available in CarbonLib 1.0 and later when Speech Recognition 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Declared In

`SpeechRecognition.h`

SRSpeakAndDrawText

Draws output text in the feedback window and causes the feedback character in the feedback window to speak that text.

```
OSErr SRSpeakAndDrawText (
   SRRecognizer recognizer,
   const void *text,
   SInt32 textLength
);
```

Parameters

recognizer

A recognizer.

text

A pointer to a buffer that contains the text to be drawn and spoken.

textLength
The size, in bytes, of the specified text.

Return Value
A result code. See "Speech Recognition Manager Result Codes" (page 1568).

Availability
Available in CarbonLib 1.0 and later when Speech Recognition 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechRecognition.h`

SRSpeakText

Causes the feedback character in the feedback window to speak a text string.

```
OSErr SRSpeakText (
   SRRecognizer recognizer,
   const void *speakText,
   SInt32 speakLength
);
```

Parameters
recognizer
A recognizer.

speakText
A pointer to a buffer that contains the text to be spoken. The text pointed to by the `speakText` parameter can contain embedded speech commands to enhance the prosody of the spoken string.

speakLength
The size, in bytes, of the specified text.

Return Value
A result code. See "Speech Recognition Manager Result Codes" (page 1568).

Discussion
While speaking, the feedback character lip-syncs the spoken string using the Speech Synthesis Manager's phoneme callback routines. `SRSpeakText` uses the default voice and rate selected in the Speech control panel. (The Speech Synthesis Manager was formerly called the Speech Manager. Its name has been changed to distinguish it from the Speech Recognition Manager and to describe its operation more clearly.)

You can use the `SRSpeechBusy` function to determine whether the feedback character is already speaking. If it is, you can call the `SRStopSpeech` function to stop that speaking immediately.

The `SRSpeakText` function speaks the specified text but does not display it. Use the `SRSpeakAndDrawText` function if you want to speak and display the text.

Availability
Available in CarbonLib 1.0 and later when Speech Recognition 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In
`SpeechRecognition.h`

SRSpeechBusy

Determines if the feedback character in a feedback window is currently speaking.

```
Boolean SRSpeechBusy (
   SRRecognizer recognizer
);
```

Parameters

recognizer

A recognizer.

Return Value

On return, `true` if the feedback character in the feedback window associated with the recognizer specified by the `recognizer` parameter is currently speaking; otherwise `false`.

Availability

Available in CarbonLib 1.0 and later when Speech Recognition 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Declared In

`SpeechRecognition.h`

SRStartListening

Starts a recognizer listening and reporting results to your application.

```
OSErr SRStartListening (
   SRRecognizer recognizer
);
```

Parameters

recognizer

A recognizer.

Return Value

A result code. See "Speech Recognition Manager Result Codes" (page 1568).

Discussion

The `SRStartListening` function instructs the recognizer specified by the `recognizer` parameter to begin processing sound from its speech source and reporting its results to your application (either using Apple events or through a speech recognition callback routine).

You must already have built a language model and attached it to the recognizer (by calling the `SRSetLanguageModel` function) before you call `SRStartListening`.

Availability

Available in CarbonLib 1.0 and later when Speech Recognition 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Declared In

`SpeechRecognition.h`

SRStopListening

Stops a recognizer listening and reporting results to your application.

```
OSErr SRStopListening (
   SRRecognizer recognizer
);
```

Parameters

recognizer
A recognizer.

Return Value

A result code. See "Speech Recognition Manager Result Codes" (page 1568).

Discussion

The `SRStopListening` function instructs the recognizer specified by the `recognizer` parameter to stop processing sound from its speech source and reporting its results to your application.

Availability

Available in CarbonLib 1.0 and later when Speech Recognition 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In

`SpeechRecognition.h`

SRStopSpeech

Terminates speech by the feedback character in a feedback window.

```
OSErr SRStopSpeech (
   SRRecognizer recognizer
);
```

Parameters

recognizer
A recognizer.

Return Value

A result code. See "Speech Recognition Manager Result Codes" (page 1568).

Discussion

The `SRStopSpeech` function immediately terminates any speaking by the feedback character in the feedback window associated with the recognizer specified by the `recognizer` parameter.

Availability

Available in CarbonLib 1.0 and later when Speech Recognition 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Declared In

`SpeechRecognition.h`

Callbacks

SRCallBackProcPtr

Defines a pointer to a speech recognition callback function which is called whenever the recognizer encounters one of the events specified in its `kSRNotificationParam` property.

```
typedef void (*SRCallBackProcPtr) (
    SRCallBackStruct * param
);
```

If you name your function `MySRCallBackProc`, you would declare it like this:

```
void MySRCallBackProc (
    SRCallBackStruct * param
);
```

Parameters

param

A pointer to a speech recognition callback structure. See `SRCallBackStruct` (page 1549) for a description of this structure.

Discussion

You can receive notification of recognizer events either by installing an Apple event handler or by installing a speech recognition callback function. In general, you should use an Apple event handler to process recognition notifications. You should use callbacks only for executable code that cannot easily receive Apple events.

You can determine what event caused your function to be called by inspecting the `what` field of the speech recognition callback structure specified by the `param` parameter.

Because the Speech Recognition Manager is not fully reentrant, you should not call any of its functions other than `SRContinueRecognition` or `SRCancelRecognition` from within your speech recognition callback. Accordingly, your callback should simply queue the notification for later processing by your software (for instance, when it receives background processing time).

If the event is of type `kSRNotifyRecognitionBeginning` (which occurs only if you request speech-begun notifications), you must call either `SRContinueRecognition` or `SRCancelRecognition` before speech recognition can continue. A recognizer that has issued a recognition notification suspends activity until you call one of these two functions.

In general, when your speech recognition callback receives the `kSRNotifyRecognitionBeginning` notification, it should queue an indication for your main code both to adjust the current language model (if necessary) and to call the `SRContinueRecognition` function. When your callback receives the `kSRNotifyRecognitionDone` notification, it should queue an indication for your main code to handle the recognition result passed in the `message` field of the speech recognition callback structure specified by the `param` parameter. You should make sure, however, that the `message` field contains a valid reference to a recognition result by inspecting the `status` field of that structure; if `status` contains any value other than `noErr`, the contents of the `message` field are undefined.

When your callback is executed, your application is not the current process. As a result, some restrictions apply; for example, the current resource chain might not be that of your application.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`SpeechRecognition.h`

Data Types

SRCallBackParam

Defines a speech recognition callback parameter structure.

```
struct SRCallBackParam {
    SRCallBackUPP callBack;
    long refCon;
};
typedef struct SRCallBackParam SRCallBackParam;
```

Fields

`callBack`
: A UPP for a speech recognition callback function. You can use the function `NewSRCallBackUPP` to create this UPP.

`refCon`
: An application-defined reference constant. This value is passed to your callback routine in the `refcon` field of a speech recognition callback structure. You can pass any 4-byte value you wish.

Discussion
If you want to receive recognition notifications using a speech recognition callback routine instead of an Apple event handler, you must change the value of the `kSRCallBackParam` property of the current recognizer. The value of the `kSRCallBackParam` property is the address of a callback function parameter structure, defined by the `SRCallBackParam` data type.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`SpeechRecognition.h`

SRCallBackStruct

Defines a structure sent to your speech recognition callback function.

```
struct SRCallBackStruct {
    long what;
    long message;
    SRRecognizer instance;
    OSErr status;
    short flags;
    long refCon;
};
typedef struct SRCallBackStruct SRCallBackStruct;
```

Fields

`what`

A notification flag that indicates the kind of event that caused this notification to be issued. This field contains either `kSRNotifyRecognitionBeginning` or `kSRNotifyRecognitionDone`. See "Notification Flags" (page 1560) for complete details on the available notification flags.

`message`

If the value of the `status` field is `noErr` and the value of the `what` field is `kSRNotifyRecognitionDone`, this field contains a reference to a recognition result. Your callback routine can inspect the properties of this recognition result to determine what the user said.

Note that your callback routine must release this reference (by calling `SRReleaseObject`) when it is finished using it. If the value of the `status` field is not `noErr`, the value of this field is undefined.

`instance`

A reference to the recognizer that issued this notification. You should not call `SRReleaseObject` on this recognizer reference in response to a recognition notification.

`status`

An error code indicating the status of the recognition. If the value of this field is `noErr`, the `message` field contains a reference to a recognition result. If the value of this field is `kSRRecognitionDone` and the value of the `what` field is `kSRNotifyRecognitionDone`, the recognizer finished without error but nothing belonging to that recognizer was recognized; in this case, the `message` field does not contain a reference to a recognition result. If the value of this field is any other value, some other error occurred.

`flags`

Reserved for use by Apple Computer, Inc.

`refCon`

An application-defined reference constant. The value in this field is the value you passed in the `refcon` field of a callback function parameter structure (of type `SRCallBackParam`).

Discussion

When you receive a notification of recognition results through an application-defined callback function (instead of using an Apple event handler), the Speech Recognition Manager sends your callback function a pointer to a speech recognition callback structure, defined by the `SRCallBackStruct` data type.

For information on writing a speech recognition callback function, see `SRCallBackProcPtr` (page 1548).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`SpeechRecognition.h`

SRCallBackUPP

Defines a universal procedure pointer (UPP) to a speech recognition callback function.

```
typedef SRCallBackProcPtr SRCallBackUPP;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`SpeechRecognition.h`

SRLanguageModel

Represents a language model.

```
typedef SRLanguageObject SRLanguageModel;
```

Discussion
A language model is a list of zero or more words, phrases, or paths.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`SpeechRecognition.h`

SRLanguageObject

Represents a language object.

```
typedef SRSpeechObject SRLanguageObject;
```

Discussion
A language model is built using four kinds of objects, collectively called language objects: words, phrases, paths, and language models.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`SpeechRecognition.h`

SRPath

Represents a language object identifying a path.

```
typedef SRLanguageObject SRPath;
```

Discussion
A path is a sequence of zero or more words, phrases, or language models.

Availability
Available in Mac OS X v10.0 and later.

Declared In
SpeechRecognition.h

SRPhrase

Represents a language object identifying a phrase.

```
typedef SRLanguageObject SRPhrase;
```

Discussion
A phrase is a sequence of zero or more words.

Availability
Available in Mac OS X v10.0 and later.

Declared In
SpeechRecognition.h

SRRecognitionResult

Represents a recognition result which contains information about a recognized utterance.

```
typedef SRSpeechSource SRRecognitionResult;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
SpeechRecognition.h

SRRecognitionSystem

Represents a speech object identifying a recognition system.

```
typedef SRSpeechObject SRRecognitionSystem;
```

Discussion
A speech object is an instance of a speech class, which defines a set of properties for objects in the class. The behavior of a speech object is determined by the set of properties associated with the object's class. Recognition systems have the properties associated with the `SRRecognitionSystem` class of speech objects.

Availability
Available in Mac OS X v10.0 and later.

Declared In
SpeechRecognition.h

SRRecognizer

Represents a speech object identifying a speech recognizer.

```
typedef SRSpeechObject SRRecognizer;
```

Discussion
A speech object is an instance of a speech class, which defines a set of properties for objects in the class. The behavior of a speech object is determined by the set of properties associated with the object's class. Speech recognizers have the properties associated with the `SRRecognizer` class of speech objects.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`SpeechRecognition.h`

SRRejectionLevel

```
typedef  SRRejectionLevel;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`SpeechRecognition.h`

SRSpeechObject

Defines a reference to a speech object.

```
typedef struct OpaqueSRSpeechObject * SRSpeechObject;
```

Discussion
The Speech Recognition Manager is object oriented in the sense that many of its capabilities are accessed by creating and manipulating speech objects. A speech object is an instance of a speech class, which defines a set of properties for objects in the class. The behavior of a speech object is determined by the set of properties associated with the object's class.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`SpeechRecognition.h`

SRSpeechSource

Represents a speech object identifying a speech source.

```
typedef SRSpeechObject SRSpeechSource;
```

Discussion
A speech object is an instance of a speech class, which defines a set of properties for objects in the class. The behavior of a speech object is determined by the set of properties associated with the object's class. Speech sources have the properties associated with the `SRSpeechSource` class of speech objects.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`SpeechRecognition.h`

SRSpeedSetting

```
typedef  SRSpeedSetting;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`SpeechRecognition.h`

SRWord

Represents a language object identifying a word.

```
typedef SRLanguageObject SRWord;
```

Discussion
A word represents a single speakable word.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`SpeechRecognition.h`

Constants

Feedback and Listening Modes

Identify the feedback and listening modes of the recognition system.

```
enum {
    kSRNoFeedbackNoListenModes = 0,
    kSRHasFeedbackHasListenModes = 1,
    kSRNoFeedbackHasListenModes = 2
};
```

Constants

`kSRNoFeedbackNoListenModes`

If the feedback and listening modes value of a recognition system is set to `kSRNoFeedbackNoListenModes`, the next created recognizer has no feedback window and does not use the listening modes selected by the user in the Speech control panel. (For example, push-to-talk is a listening mode.)

Available in Mac OS X v10.0 and later.

Declared in `SpeechRecognition.h`.

`kSRHasFeedbackHasListenModes`

If the feedback and listening modes value of a recognition system is set to `kSRHasFeedbackHasListenModes`, the next created recognizer opens a feedback window that uses the listening modes selected by the user in the Speech control panel.

Available in Mac OS X v10.0 and later.

Declared in `SpeechRecognition.h`.

`kSRNoFeedbackHasListenModes`

If the feedback and listening modes value of a recognition system is set to `kSRNoFeedbackHasListenModes`, the next created recognizer has no feedback window but does use the listening modes selected by the user in the Speech control panel.

Available in Mac OS X v10.0 and later.

Declared in `SpeechRecognition.h`.

Apple Event Selectors

Define selectors that you can use to handle recognition notifications in your Apple event handler.

```
enum {
    kAESpeechDone = 'srsd',
    kAESpeechDetected = 'srbd'
};
enum {
    kAESpeechSuite = 'sprc'
};
enum {
    keySRRecognizer = 'krec',
    keySRSpeechResult = 'kspr',
    keySRSpeechStatus = 'ksst'
};
enum {
    typeSRRecognizer = 'trec',
    typeSRSpeechResult = 'tspr'
};
```

Constants

`kAESpeechDone`
The message ID for a speech-done event.
Available in Mac OS X v10.0 and later.
Declared in `SpeechRecognition.h`.

`kAESpeechDetected`
The message ID for a speech-detected event.
Available in Mac OS X v10.0 and later.
Declared in `SpeechRecognition.h`.

`kAESpeechSuite`
The Apple event suite for speech recognition events.
Available in Mac OS X v10.0 and later.
Declared in `SpeechRecognition.h`.

`keySRRecognizer`
The ID for the recognizer parameter.
Available in Mac OS X v10.0 and later.
Declared in `SpeechRecognition.h`.

`keySRSpeechResult`
The ID for the recognition result parameter.
Available in Mac OS X v10.0 and later.
Declared in `SpeechRecognition.h`.

`keySRSpeechStatus`
The ID for the speech status parameter, which is of type `typeShortInteger`.
Available in Mac OS X v10.0 and later.
Declared in `SpeechRecognition.h`.

`typeSRRecognizer`
The type for the recognizer parameter.
Available in Mac OS X v10.0 and later.
Declared in `SpeechRecognition.h`.

`typeSRSpeechResult`
The type for the recognition result parameter.

Available in Mac OS X v10.0 and later.

Declared in `SpeechRecognition.h`.

Discussion

Default Rejection Level

Represents a default rejection level.

```
enum {
    kSRDefaultRejectionLevel = 50
};
```

Language Object Properties

Define property selectors for language objects.

```
enum {
    kSRSpelling = 'spel',
    kSRLMObjType = 'lmtp',
    kSRRefCon = 'refc',
    kSROptional = 'optl',
    kSREnabled = 'enbl',
    kSRRepeatable = 'rptb',
    kSRRejectable = 'rjbl',
    kSRRejectionLevel = 'rjct'
};
```

Constants

`kSRSpelling`
The spelling of a language object. The value of this property is a variable-length string of characters. For an object of type `SRWord`, the value is the spelled word. For an object of type `SRPhrase`, the value is the concatenation of the spellings of each word in the phrase, separated by a language-dependent separation character (for example, by a space character). For an object of type `SRPath`, the value is the concatenation of the spellings of each word and language model name in the path. For an object of type `SRLanguageModel`, the value is the name of the language model. For any object, the string value does not include either a length byte (as in Pascal strings) or a null terminating character (as in C strings).

Available in Mac OS X v10.0 and later.

Declared in `SpeechRecognition.h`.

`kSRLMObjType`
The type of a language object. The value of this property is a four-character constant of type `OSType`; see the section "Language Object Types" (page 1559) for the values that are defined for this property. You cannot set a property of this type.

Available in Mac OS X v10.0 and later.

Declared in `SpeechRecognition.h`.

`kSRRefCon`

The reference constant. The value of this property is a 4-byte value specified by your application. By default, the value of a reference constant property is zero (0).

Available in Mac OS X v10.0 and later.

Declared in `SpeechRecognition.h`.

`kSROptional`

The optional flag. The value of this property is a Boolean value that indicates whether speaking the words, phrases, paths, and language models represented by the object is optional (`TRUE`) or required (`FALSE`). A user is not required to utter optional words, phrases, or language models. By default, the value of an object's optional flag is `FALSE`.

Available in Mac OS X v10.0 and later.

Declared in `SpeechRecognition.h`.

`kSREnabled`

The enabled flag. The value of this property is a Boolean value that indicates whether the object is enabled (`TRUE`) or disabled (`FALSE`). Disabled objects are ignored during speech recognition. By default, the value of an object's enabled flag is `TRUE`.

Available in Mac OS X v10.0 and later.

Declared in `SpeechRecognition.h`.

`kSRRepeatable`

The repeatable flag. The value of this property is a Boolean value that indicates whether the object is repeatable (`TRUE`) or not (`FALSE`). A user can utter a repeatable object more than once. By default, the value of an object's repeatable flag is `FALSE`.

Available in Mac OS X v10.0 and later.

Declared in `SpeechRecognition.h`.

`kSRRejectable`

The rejectable flag. The value of this property is a Boolean value that indicates whether the object is rejectable (`TRUE`) or not (`FALSE`). An object is rejectable if a recognition system can return the rejected word instead of that object. (The rejected word is the value of the `kSRRejectedWord` property of the recognition system.) By default, the value of an object's rejectable flag is `FALSE`. However, if an entire utterance is rejected, you can still get the rejected word. See "Recognition Result Properties" (page 1561).

Available in Mac OS X v10.0 and later.

Declared in `SpeechRecognition.h`.

`kSRRejectionLevel`

The rejection level. The value of this property is a 2-byte unsigned integer of type `SRRejectionLevel` between 0 and 100, inclusive, that determines how likely a recognizer is to reject a language object whose `kSRRejectable` property is `TRUE`. If an object's rejection level is close to 0, the recognizer is less likely to reject utterances (and hence more likely to return a result with phrases from the current language model, whether or not the user actually said something in that language model) if an object's rejection level is close to 100, the recognizer is more likely to reject utterances. You can set an object's rejection flag to `TRUE` and its rejection level to some appropriate value to reduce the likelihood that a recognizer will mistakenly recognize a random user utterance as part of the active language model. By default, the value of an object's rejection level is `50`.

Available in Mac OS X v10.0 and later.

Declared in `SpeechRecognition.h`.

Discussion
Every language object (that is, any instance of a subclass of the `SRLanguageObject` class) has a set of properties that you can inspect and change by calling the `SRGetProperty` and `SRSetProperty` functions. You specify a property by passing a property selector to those functions.

Language Object Types

Identify the four subclasses of the `SRLanguageObject` class.

```
enum {
    kSRLanguageModelType = 'lmob',
    kSRPathType = 'path',
    kSRPhraseType = 'phra',
    kSRWordType = 'word'
};
```

Constants

`kSRLanguageModelType`
A language model (that is, an object of type `SRLanguageModel`).
Available in Mac OS X v10.0 and later.
Declared in `SpeechRecognition.h`.

`kSRPathType`
A path (that is, an object of type `SRPath`).
Available in Mac OS X v10.0 and later.
Declared in `SpeechRecognition.h`.

`kSRPhraseType`
A phrase (that is, an object of type `SRPhrase`).
Available in Mac OS X v10.0 and later.
Declared in `SpeechRecognition.h`.

`kSRWordType`
A word (that is, an object of type `SRWord`).
Available in Mac OS X v10.0 and later.
Declared in `SpeechRecognition.h`.

Discussion
You can use these constants, for instance, to help interpret the value of a language object's `kSRLMObjType` property.

Listen Key Modes

Identify listen key modes.

```
enum {
    kSRUseToggleListen = 0,
    kSRUsePushToTalk = 1
};
```

Constants

`kSRUseToggleListen`

The recognizer interprets presses on the listen key as a toggle to turn listening on or off.

Available in Mac OS X v10.0 and later.

Declared in `SpeechRecognition.h`.

`kSRUsePushToTalk`

The recognizer listens only when the listen key is held down.

Available in Mac OS X v10.0 and later.

Declared in `SpeechRecognition.h`.

Discussion

You can get (but not set) a recognizer's listen key mode by accessing its property of type `kSRListenKeyMode`. That property's value is a 2-byte unsigned integer that determines whether the listen key operates in push-to-talk or toggle-listening mode.

Notification Flags

Identify the recognizer events that may be sent to an application.

```
enum {
    kSRNotifyRecognitionBeginning = 1L << 0,
    kSRNotifyRecognitionDone = 1L << 1
};
```

Constants

`kSRNotifyRecognitionBeginning`

If this bit is set, your application will be notified when the user starts speaking and recognition is ready to begin. When your application gets this notification, it must call either `SRContinueRecognition` or `SRCancelRecognition` in order for recognition either to continue or be canceled. If you do not call one of these functions, the recognizer will simply wait until you do (and hence appear to have quit working). Note that calling `SRCancelRecognition` cancels a recognition only for the application that requested it, not for all applications.

Available in Mac OS X v10.0 and later.

Declared in `SpeechRecognition.h`.

`kSRNotifyRecognitionDone`

If this bit is set, your application will be notified when recognition is finished and the result (if any) of that recognition is available.

Available in Mac OS X v10.0 and later.

Declared in `SpeechRecognition.h`.

Discussion

You can indicate which recognizer events you want your application be to notified of by setting the recognizer's notification property, which is a property of type `kSRNotificationParam`. That property's value is a 4-byte unsigned integer. The Speech Recognition Manager defines these masks for bits in that value.

Recognition Result Properties

Identify property selectors for recognition results.

```
enum {
    kSRTEXTFormat = 'TEXT',
    kSRPhraseFormat = 'lmph',
    kSRPathFormat = 'lmpt',
    kSRLanguageModelFormat = 'lmfm'
};
```

Constants

`kSRTEXTFormat`

The text format. The value of this property is a variable-length string of characters that is the text of the recognized utterance. If the utterance was rejected, this text is the spelling of the rejected word. The string value does not include either a length byte (as in Pascal strings) or a null terminating character (as in C strings).

Available in Mac OS X v10.0 and later.

Declared in `SpeechRecognition.h`.

`kSRPhraseFormat`

The phrase format. The value of this property is a phrase that contains one word (of type `SRWord`) for each word in the recognized utterance. If the utterance was rejected, this path or phrase contains one object, the rejected word. The reference constant value of the phrase is always 0, but each word in the phrase retains its own reference constant property value.

Available in Mac OS X v10.0 and later.

Declared in `SpeechRecognition.h`.

`kSRPathFormat`

The path format. The value of this property is a path that contains a sequence of words (of type `SRWord`) and phrases (of type `SRPhrase`) representing the text of the recognized utterance. If the utterance was rejected, this path or phrase contains one object, the rejected word. The reference constant value of the path is always 0, but each word or phrase in the path retains its own reference constant property value.

Available in Mac OS X v10.0 and later.

Declared in `SpeechRecognition.h`.

`kSRLanguageModelFormat`

The language model format. The value of this property is a language model that contains a copy of each word, phrase, path, and language model used in the recognized utterance. If the utterance was rejected, the value of this property is the rejected word (that is, the `kSRRejectedWord` property of the recognition system). The name and reference constant of this language model are the same as the name and reference constant of the active language model, and each subitem in the language model retains its own reference constant property value.

Available in Mac OS X v10.0 and later.

Declared in `SpeechRecognition.h`.

Discussion

Every recognition result object has a set of properties that you can inspect by calling the `SRGetProperty` function. You specify a property by passing a property selector to those functions.

`SRGetProperty` returns an object reference as the value of a recognition result's `kSRPhraseFormat`, `kSRPathFormat`, or `kSRLanguageModelFormat` property. You must make sure to release that object reference (by calling `SRReleaseObject`) when you are finished using it.

Recognition System IDs

Defines a recognition system ID.

```
enum {
    kSRDefaultRecognitionSystemID = 0
};
```

Constants

`kSRDefaultRecognitionSystemID`

The default speech recognition system.

Available in Mac OS X v10.0 and later.

Declared in `SpeechRecognition.h`.

Discussion

When you call `SROpenRecognitionSystem` to open a recognition system, you indicate the system to open by passing a recognition system ID.

Recognition System Properties

Define property selectors for recognition systems.

```
enum {
    kSRFeedbackAndListeningModes = 'fbwn',
    kSRRejectedWord = 'rejq',
    kSRCleanupOnClientExit = 'clup'
};
```

Constants

`kSRFeedbackAndListeningModes`

The feedback and listening modes of the recognition system. The value of this property is an integer that determines some of the features of a recognizer subsequently created by your application. See "Feedback and Listening Modes" (page 1554) for a description of the values possible here.

The default value for version 1.5 is `kSRNoFeedbackNoListenModes`, but most applications should set this to `kSRHasFeedbackHasListenModes`.

Available in Mac OS X v10.0 and later.

Declared in `SpeechRecognition.h`.

`kSRRejectedWord`

The rejected word of the recognition system. The value of this property is a value of type `SRWord` that will be returned in a recognition result object when a recognizer encounters an unrecognizable utterance. For example, if an utterance is rejected, the `kSRLMObjType` property of the rejection result is the rejected word. By default, a recognition system's rejected word is spelled "???" and has a reference constant of 0.

Available in Mac OS X v10.0 and later.

Declared in `SpeechRecognition.h`.

`kSRCleanupOnClientExit`

The cleanup mode of the recognition system. Applications should never set this property. If, however, you do not have a process ID (as issued by the Process Manager), you should set this property to `FALSE` so that speech objects you allocate will not be associated with any other process. By default, the value of a recognition system's cleanup mode is `TRUE`.

Available in Mac OS X v10.0 and later.

Declared in `SpeechRecognition.h`.

Discussion

A recognition system (that is, an instance of the `SRRecognitionSystem` class) has a set of properties that you can inspect and change by calling the `SRGetProperty` and `SRSetProperty` functions. You specify a property by passing a property selector to those functions.

Recognizer Listen Key Properties

Define listen key property selectors for recognizers.

```
enum {
    kSRListenKeyMode = 'lkmd',
    kSRListenKeyCombo = 'lkey',
    kSRListenKeyName = 'lnam',
    kSRKeyWord = 'kwrd',
    kSRKeyExpected = 'kexp'
};
```

Constants

`kSRListenKeyMode`

The listen key mode. The value of this property is a 2-byte unsigned integer that indicates whether the listen key operates in push-to-talk or toggle-listening mode. See "Listen Key Modes" (page 1559) for a description of the available listen key modes. The value of a recognizer's listen key mode is whatever the user has selected in the Speech control panel. This property is read-only you cannot set a property of this type.

Available in Mac OS X v10.0 and later.

Declared in `SpeechRecognition.h`.

`kSRListenKeyCombo`

The listen key combination property. The value of this property is a 2-byte unsigned integer that specifies the key combination the user must press for the listen key. The high-order byte of this value has the same format as the high-order byte of the `modifiers` field of an event record. The low-order byte of this value has the same format as the key code contained in the `message` field of an event record. The value of a recognizer's listen key combination property is whatever the user has selected in the Speech control panel. This property is read-only you cannot set a property of this type.

Available in Mac OS X v10.0 and later.

Declared in `SpeechRecognition.h`.

`kSRListenKeyName`

The listen key name property. The value of this property is a string (of type `Str63`) that represents the listen key combination specified by the `kSRListenKeyCombo` property. The value of a recognizer's listen key name property is whatever the user has selected in the Speech control panel. This property is read-only you cannot set a property of this type.

Available in Mac OS X v10.0 and later.

Declared in `SpeechRecognition.h`.

`kSRKeyWord`
: The key word property. The value of this property is a string (of type `Str255`) that represents the key word that must precede utterances when the recognizer is in toggle-listen mode. The value of a recognizer's key word property is whatever the user has selected in the Speech control panel. This property is read-only you cannot set a property of this type.

  Available in Mac OS X v10.0 and later.

  Declared in `SpeechRecognition.h`.

`kSRKeyExpected`
: The key expected flag. The value of this property is a Boolean value that indicates whether the recognizer expects the user to hold down a key or to utter the key word in order to have the recognizer begin listening (`TRUE`) or not (`FALSE`). The value of a recognizer's key expected flag is a function of the user's Speech control panel selections. This property is `TRUE` whenever text is visible below the feedback character in the lower-left corner of the feedback window. This property is read-only.

  Available in Mac OS X v10.0 and later.

  Declared in `SpeechRecognition.h`.

Discussion
Every recognizer has a set of properties that you can inspect and change by calling the `SRGetProperty` and `SRSetProperty` functions. You specify a property by passing a property selector to those functions.

The listen key properties are provided for use by applications that want to provide their own visual feedback. If your application uses the default feedback mechanisms, you do not need to access those properties.

Recognizer Properties

Define property selectors for recognizers.

```
enum {
    kSRNotificationParam = 'noti',
    kSRCallBackParam = 'call',
    kSRSearchStatusParam = 'stat',
    kSRAutoFinishingParam = 'afin',
    kSRForegroundOnly = 'fgon',
    kSRBlockBackground = 'blbg',
    kSRBlockModally = 'blmd',
    kSRWantsResultTextDrawn = 'txfb',
    kSRWantsAutoFBGestures = 'dfbr',
    kSRSoundInVolume = 'volu',
    kSRReadAudioFSSpec = 'aurd',
    kSRCancelOnSoundOut = 'caso',
    kSRSpeedVsAccuracyParam = 'sped'
};
```

Constants
`kSRNotificationParam`
: The notification property. The value of this property is a 4-byte unsigned integer whose bits encode the kinds of events of which the recognizer will notify your application. See the section "Notification Flags" (page 1560) for the bit masks that are defined for this property. By default, the value of a recognizer's notification property is `kSRNotifyRecognitionDone`.

  Available in Mac OS X v10.0 and later.

  Declared in `SpeechRecognition.h`.

`kSRCallBackParam`

The callback property. The value of this property is of type `SRCallBackParam` that determines whether recognition notifications are sent to your application via Apple events or via an application-defined callback routine. To specify a callback routine, set the value of this property to the address of a callback routine parameter structure. By default, the value of a recognizer's callback property is `NULL`, indicating that Apple events are to be used to report recognizer events.

Available in Mac OS X v10.0 and later.

Declared in `SpeechRecognition.h`.

`kSRSearchStatusParam`

The search status. The value of this property is a 4-byte unsigned integer whose bits indicate the current state of the recognizer. See the section "Search Status Flags" (page 1567) for the bit masks that are defined for this property. This property is read-only; you cannot set a property of this type.

Available in Mac OS X v10.0 and later.

Declared in `SpeechRecognition.h`.

`kSRAutoFinishingParam`

Available in Mac OS X v10.0 and later.

Declared in `SpeechRecognition.h`.

`kSRForegroundOnly`

The foreground-only flag. The value of this property is a Boolean value that indicates whether the recognizer is enabled only when your application is the foreground application (`TRUE`) or not (`FALSE`). By default, the value of a recognizer's foreground-only flag is `TRUE`.

Available in Mac OS X v10.0 and later.

Declared in `SpeechRecognition.h`.

`kSRBlockBackground`

The background-blocking flag. The value of this property is a Boolean value that indicates whether all recognizers owned by other applications are automatically disabled whenever your application is the foreground application (`TRUE`) or are not automatically disabled (`FALSE`). By default, the value of a recognizer's background-blocking flag is `FALSE`.

Available in Mac OS X v10.0 and later.

Declared in `SpeechRecognition.h`.

`kSRBlockModally`

The modal-blocking flag. The value of this property is a Boolean value that indicates whether the language model associated with this recognizer is the only active language model (`TRUE`) or not (`FALSE`). When this flag is `TRUE`, your application's recognizer blocks those of other applications even when it is not the foreground application in addition, the feedback window is hidden if you are not using it. Setting this property to `TRUE` prevents speech recognition from working for other applications, so you want to use this property only if your application is taking over the computer (like some games) or briefly attempting to constrain the language model severely. By default, the value of a recognizer's modal-blocking flag is `FALSE`.

Available in Mac OS X v10.0 and later.

Declared in `SpeechRecognition.h`.

`kSRWantsResultTextDrawn`

The text feedback flag. The value of this property is a Boolean value that indicates whether the results of a search are to be automatically displayed as text in the feedback window (`TRUE`) or not (`FALSE`). If you set the value of this property to `FALSE`, you should call `SRDrawRecognizedText` with a string representing what the user said. By default, the value of a recognizer's text feedback flag is `TRUE`.

Available in Mac OS X v10.0 and later.

Declared in `SpeechRecognition.h`.

`kSRWantsAutoFBGestures`

The automatic feedback gestures flag. The value of this property is a Boolean value that determines whether the feedback gestures are automatically drawn (`TRUE`) or not (`FALSE`). If you want more control over feedback behavior, you should set this property to `FALSE`; then call `SRProcessBegin` when you want to begin responding to a spoken request and `SRProcessEnd` when you are finished. During that time, the feedback character displays appropriate animated gestures to indicate that it is busy performing the task. By default, the value of a recognizer's automatic feedback gestures flag is `TRUE`.

Available in Mac OS X v10.0 and later.

Declared in `SpeechRecognition.h`.

`kSRSoundInVolume`

The sound input volume. The value of this property is a 2-byte unsigned integer between 0 and 100, inclusive, that indicates the current sound input volume. This property is read-only; you cannot set a property of this type.

Available in Mac OS X v10.0 and later.

Declared in `SpeechRecognition.h`.

`kSRReadAudioFSSpec`

The audio file property. You can use this property to perform speech recognition from an audio file. The value of this property is a pointer to a file system specification (a structure of type `FSSpec`). The file system specification indicates an AIFF file that contains raw audio data (16-bit audio data sampled at 22.050 kHz). After you create a new recognizer using the speech source ID `kSRCanned22kHzSpeechSource`, you must set this recognizer property to perform recognition from an audio file. Setting the audio source to a file also allows the Speech Recognition Manager to process sound data at system background time rather than at interrupt time or deferred task time.

Available in Mac OS X v10.0 and later.

Declared in `SpeechRecognition.h`.

`kSRCancelOnSoundOut`

The cancel during sound output flag. The value of this property is a Boolean value that indicates whether speech recognition is canceled whenever any sound is output by the computer during an utterance (`TRUE`) or whether speech recognition continues (`FALSE`). By default, the value of a recognizer's cancel during sound output flag is `TRUE`.

Available in Mac OS X v10.0 and later.

Declared in `SpeechRecognition.h`.

`kSRSpeedVsAccuracyParam`

Available in Mac OS X v10.0 and later.

Declared in `SpeechRecognition.h`.

Discussion

Every recognizer has a set of properties that you can inspect and change by calling the `SRGetProperty` and `SRSetProperty` functions. You specify a property by passing a property selector to those functions.

Search Status Flags

Indicate the status of a recognizer search.

```
enum {
    kSRIdleRecognizer = 1L << 0,
    kSRSearchInProgress = 1L << 1,
    kSRSearchWaitForAllClients = 1L << 2,
    kSRMustCancelSearch = 1L << 3,
    kSRPendingSearch = 1L << 4
};
```

Constants

`kSRIdleRecognizer`
If this bit is set, the search engine is not active and the user is able to make a new utterance.
Available in Mac OS X v10.0 and later.
Declared in `SpeechRecognition.h`.

`kSRSearchInProgress`
If this bit is set, a search is currently in progress.
Available in Mac OS X v10.0 and later.
Declared in `SpeechRecognition.h`.

`kSRSearchWaitForAllClients`
If this bit is set, a search is not currently in progress, but will begin as soon as every recognizer using the speech source used by this recognizer has called `SRContinueRecognition` to indicate that the search should begin.
Available in Mac OS X v10.0 and later.
Declared in `SpeechRecognition.h`.

`kSRMustCancelSearch`
If this bit is set, a search is about to be canceled (for example, because the recognizer determined a sound to be non-speech).
Available in Mac OS X v10.0 and later.
Declared in `SpeechRecognition.h`.

`kSRPendingSearch`
If this bit is set, a search is about to begin.
Available in Mac OS X v10.0 and later.
Declared in `SpeechRecognition.h`.

Discussion

You can determine the current status of a recognizer search by getting the recognizer's search status, which is a property of type `kSRSearchStatusParam`. That property's value is a 4-byte unsigned integer. The Speech Recognition Manager defines these masks for bits in that value.

Speech Source Constants

Identify Speech Recognition Manager-supported speech sources.

```
enum {
    kSRDefaultSpeechSource = 0,
    kSRLiveDesktopSpeechSource = 'dklv',
    kSRCanned22kHzSpeechSource = 'ca22'
};
```

Constants

`kSRDefaultSpeechSource`
The default speech source.

Available in Mac OS X v10.0 and later.

Declared in `SpeechRecognition.h`.

`kSRLiveDesktopSpeechSource`
Live desktop sound input.

Available in Mac OS X v10.0 and later.

Declared in `SpeechRecognition.h`.

`kSRCanned22kHzSpeechSource`
AIFF file based 16 bit, 22.050 KHz sound input.

Available in Mac OS X v10.0 and later.

Declared in `SpeechRecognition.h`.

Discussion

The Speech Recognition Manager supports several speech sources, which you can specify using these constants. In version 1.5, the default speech source is `kSRLiveDesktopSpeechSource`.

Result Codes

The most common result codes returned by Speech Recognition Manager are listed below.

Result Code	Value	Description
`kSRNotAvailable`	-5100	Requested service not available or applicable Available in Mac OS X v10.0 and later.
`kSRInternalError`	-5101	Internal system or hardware error condition Available in Mac OS X v10.0 and later.
`kSRComponentNotFound`	-5102	Required component cannot be located Available in Mac OS X v10.0 and later.
`kSROutOfMemory`	-5103	Not enough memory available Available in Mac OS X v10.0 and later.
`kSRNotASpeechObject`	-5104	Object is not valid Available in Mac OS X v10.0 and later.
`kSRBadParameter`	-5105	Invalid parameter specified Available in Mac OS X v10.0 and later.

Result Code	Value	Description
kSRParamOutOfRange	-5106	Parameter is out of valid range Available in Mac OS X v10.0 and later.
kSRBadSelector	-5107	Unrecognized selector specified Available in Mac OS X v10.0 and later.
kSRBufferTooSmall	-5108	Buffer is too small Available in Mac OS X v10.0 and later.
kSRNotARecSystem	-5109	Specified object is not a recognition system Available in Mac OS X v10.0 and later.
kSRFeedbackNotAvail	-5110	No feedback window associated with recognizer Available in Mac OS X v10.0 and later.
kSRCantSetProperty	-5111	Cannot set the specified property Available in Mac OS X v10.0 and later.
kSRCantGetProperty	-5112	Cannot get the specified property Available in Mac OS X v10.0 and later.
kSRCantSetDuringRecognition	-5113	Cannot set property during recognition Available in Mac OS X v10.0 and later.
kSRAlreadyListening	-5114	System is already listening Available in Mac OS X v10.0 and later.
kSRNotListeningState	-5115	System is not listening Available in Mac OS X v10.0 and later.
kSRModelMismatch	-5116	No acoustical models available to match request Available in Mac OS X v10.0 and later.
kSRNoClientLanguageModel	-5117	Cannot access specified language model Available in Mac OS X v10.0 and later.
kSRNoPendingUtterances	-5118	No utterances to search Available in Mac OS X v10.0 and later.
kSRRecognitionCanceled	-5119	Search was canceled Available in Mac OS X v10.0 and later.
kSRRecognitionDone	-5120	Search has finished, but nothing was recognized Available in Mac OS X v10.0 and later.

Result Code	Value	Description
kSROtherRecAlreadyModal	-5121	Another recognizer is already operating modally Available in Mac OS X v10.0 and later.
kSRHasNoSubItems	-5122	Specified object has no subitems Available in Mac OS X v10.0 and later.
kSRSubItemNotFound	-5123	Specified subitem cannot be located Available in Mac OS X v10.0 and later.
kSRLanguageModelTooBig	-5124	Language model too big to be built Available in Mac OS X v10.0 and later.
kSRAlreadyReleased	-5125	Specified object has already been released Available in Mac OS X v10.0 and later.
kSRAlreadyFinished	-5126	Specified language model has already been finished Available in Mac OS X v10.0 and later.
kSRWordNotFound	-5127	Spelling could not be found Available in Mac OS X v10.0 and later.
kSRNotFinishedWithRejection	-5128	Language model not finished with rejection Available in Mac OS X v10.0 and later.
kSRExpansionTooDeep	-5129	Language model is left recursive or is embedded too many levels Available in Mac OS X v10.0 and later.
kSRTooManyElements	-5130	Too many elements added to phrase, path, or other language object Available in Mac OS X v10.0 and later.
kSRCantAdd	-5131	Can't add specified type of object to the base language object Available in Mac OS X v10.0 and later.
kSRSndInSourceDisconnected	-5132	Sound input source is disconnected Available in Mac OS X v10.0 and later.
kSRCantReadLanguageObject	-5133	Cannot create language object from file or pointer Available in Mac OS X v10.0 and later.
kSRNotImplementedYet	-5199	Feature is not yet implemented Available in Mac OS X v10.0 and later.

Gestalt Constants

You can check for version and feature availability information by using the Speech Recognition Manager selectors defined in the Gestalt Manager. For more information see *Inside Mac OS X: Gestalt Manager Reference*.

Text Services Manager Reference

Framework: Carbon/Carbon.h

Declared in TextServices.h

Overview

The Text Services Manager ("TSM") provides an environment for applications to use non-application-specific text services. The Text Services Manager handles communication between client applications that request text services and the software modules, known as text service components, that provide them. The Text Services Manager exists so that these two types of programs can work together without needing to know anything about the internal structures or identities of each other.

A **client application** is any text-processing program that uses the Text Services Manager to request a service from a text service component. To accomplish this, a client application needs to make specific Text Services Manager calls during execution.

A **text service component** is a utility program that uses the Text Services Manager to provide a text service to an application. Text service components are registered components with the Component Manager. Text services can include many different types of specific text-handling tasks, including spell-checking, hyphenation, and handling the input of complex text.

The most prevalent category of text services are those that handle the entry of complex text, that is, input methods. A typical example of an input method is a service that converts keyboard input into text that cannot be directly entered via a keyboard. Text input in Japanese, Chinese, Korean, or Unicode usually requires an input method.

TSM introduces input modes in Mac OS X version 10.3. An **input mode** allows an input method to temporarily accept text input in a script other than the one it normally supports. An input method uses a CFDictionary to define the input modes it supports and the tag `kTextServiceInputModePropertyTag` to specify that the input method supports input modes. An application finds out what input modes are supported by an input method by calling the function `CopyTextServiceInputModeList`.

Also new in Mac OS X version 10.3 is a suite of Carbon events that allow a text service relatively direct access to a document's text content and text attributes, such as font and glyph information. To take advantage of this new functionality in TSM, all text and offsets in your application must map to and from a flattened Unicode space. Your application must also implement callback functions to handle the appropriate Carbon events.

Mac OS X version 10.4 introduces input mode palette configuration routines.

The Text Services Manager defines three separate programming interfaces:

- The first are functions implemented by the Text Services Manager and called by the application clients of text service components.

- The second are functions implemented by the Text Services Manager and called by text service components.
- The third are low-level functions implemented by text service components and called by either applications or the Text Services Manager.

Functions by Task

Applications - Facilitating User Interactions With Components

`CopyTextServiceInputModeList` (page 1579)
Obtains a copy of the set of input modes supported by a keyboard-class input method.

`TSMCopyInputMethodEnabledInputModes` (page 1606)
Obtain the array of the enabled (and visible) input modes for a component.

`TSMSelectInputMode` (page 1610)
Sets the specified input method input mode as the current input source.

`CloseTextService` (page 1578) Deprecated in Mac OS X v10.5
Closes a text service component, other than an input method, and disassociates it from the active TSM document.

`GetDefaultInputMethod` (page 1585) Deprecated in Mac OS X v10.5
Obtains the default input method text service component for a given script and language.

`GetDefaultInputMethodOfClass` (page 1586) Deprecated in Mac OS X v10.5
Obtains the default input method text service component for a given text service class.

`GetServiceList` (page 1589) Deprecated in Mac OS X v10.5
Obtains a list of the text service components of a specified type that are currently available.

`GetTextServiceLanguage` (page 1590) Deprecated in Mac OS X v10.5
Obtains the current input script and language.

`OpenTextService` (page 1597) Deprecated in Mac OS X v10.5
Opens a text service component, other than an input method, and associates it with a TSM document.

`SetDefaultInputMethod` (page 1601) Deprecated in Mac OS X v10.5
Sets a default input method to a given script and language.

`SetDefaultInputMethodOfClass` (page 1602) Deprecated in Mac OS X v10.5
Sets the default input method text service component for a given text service class.

`SetTextServiceLanguage` (page 1603) Deprecated in Mac OS X v10.5
Changes the current input script and language.

Applications - Managing TSM Documents

`NewTSMDocument` (page 1595)
Creates a TSM document and returns a handle to the document's ID.

`DeleteTSMDocument` (page 1582)
Closes all opened text service components for the TSM document.

`ActivateTSMDocument` (page 1577)
Informs the Text Services Manager that a TSM document is active.

`DeactivateTSMDocument` (page 1581)
Informs the Text Services Manager that a TSM document is inactive.

`FixTSMDocument` (page 1584)
Informs the Text Services Manager that user input for a TSM document has been interrupted.

`UseInputWindow` (page 1613)
Associates a floating input window with one or more TSM documents.

`TSMGetActiveDocument` (page 1607)
Obtains the active TSM document in the current application context.

`TSMSetInlineInputRegion` (page 1611) Deprecated in Mac OS X v10.5
Defines a region within a TSM document in which inline input can occur.

Components - Sending Events

`SendTextInputEvent` (page 1600)
Sends Carbon text input events from a text service component to a client application.

`SendAEFromTSMComponent` (page 1598) Deprecated in Mac OS X v10.5
Sends Apple events from a text service component to a client application.

Low Level - Accessing Text Service Properties

`SetTextServiceProperty` (page 1603)
Notifies a text service component that one of its properties has been selected.

`GetTextServiceProperty` (page 1591)
Notifies a text service component that it must identify the current value of one of its properties.

Low Level - Confirming Text Service Input

`FixTextService` (page 1583)
Notifies a text service component that it must complete the processing of any input that is in progress.

Low Level - Managing Text Service States

`InitiateTextService` (page 1593)
Notifies a text service component that it must perform any necessary set-up tasks and begin operating.

`ActivateTextService` (page 1577)
Notifies a text service component that its associated document window is becoming active.

`DeactivateTextService` (page 1580)
Notifies a text service component that its associated document window is becoming inactive.

`TerminateTextService` (page 1604)
Notifies a text service component that it must terminate its operations in preparation for closing.

`HidePaletteWindows` (page 1592)
Notifies a text service component that it must hide its floating windows.

`DeselectTextService` (page 1583) Deprecated in Mac OS X v10.5
Notifies TSM that an input method has been closed.

`IsTextServiceSelected` (page 1595) Deprecated in Mac OS X v10.5
Determines if a text service component is selected.

`SelectTextService` (page 1598) Deprecated in Mac OS X v10.5
Selects a text service.

Low Level - Querying Text Services

`GetTextServiceMenu` (page 1590)
Notifies a text service component that it must produce a handle to its menu.

`GetScriptLanguageSupport` (page 1588) Deprecated in Mac OS X v10.5
Notifies a text service component that it must produce a list of its supported languages and scripts.

Low Level - Sending Events to Text Services

`TextServiceEventRef` (page 1605)
Provides an opportunity for a text service component to handle a Carbon event.

Working With Document Properties

`TSMSetDocumentProperty` (page 1611)
Sets a property for a TSM document.

`TSMGetDocumentProperty` (page 1607)
Obtains a TSM document property.

`TSMRemoveDocumentProperty` (page 1610)
Removes a property from a TSM document.

Input Mode Palette Configuration

`InputModePaletteItemHit` (page 1594)
Informs an input method that a function button on the input mode palette was pressed.

`GetInputModePaletteMenu` (page 1587) Deprecated in Mac OS X v10.5
Obtains from an input method the menu to display for a pull-down menu on the input mode palette.

`TSMInputModePaletteLoadButtons` (page 1609) Deprecated in Mac OS X v10.5
Notifies the input mode palette of changes to the controls for an input method and replaces the current controls with the new control array.

`TSMInputModePaletteUpdateButtons` (page 1609) Deprecated in Mac OS X v10.5
Notifies the input mode palette of changes to the controls for an input method and updates the controls.

Functions

ActivateTextService

Notifies a text service component that its associated document window is becoming active.

```
ComponentResult ActivateTextService (
   ComponentInstance ts
);
```

Parameters

ts

A Component Manager value of type `ComponentInstance` that identifies the component being called. When the Text Services Manager makes this call, it passes the `ComponentInstance` value returned by its call to the `OpenComponent` function. If an application makes this call, it may use the `ComponentInstance` value obtained from the `kEventParamTextInputSendComponentInstance` parameter of the Carbon event or the `keyAEServerInstance` parameter of an Apple event sent by the component being called. Alternately, an application may obtain a `ComponentInstance` value from a prior call to the function `OpenTextService` (page 1597).

Return Value

See the Component Manager documentation for a description of the `ComponentResult` data type.

Discussion

Text service components must implement a function for this call.

The appropriate response to `ActivateTextService` is for the text service component to restore its active state, including displaying all floating windows if they have been hidden. (Note that typically an input-method component should not hide its windows in response to being deactivated. If the subsequent document being activated is using the same component's service, it would be irritating to the user to hide and then immediately redisplay the same windows. An input-method component should hide its windows only in response to a `HidePaletteWindows` call.) If the component is an input method, it should specify the redisplay of any unconfirmed text currently in the active input area.

The Text Services Manager makes this call either on its own or in response to application-interface calls it receives from client applications. Client applications may directly make this call, but the Text Services Manager does not then play a role in the connection between the client application making the call and the text service component receiving it.

Availability

Available in CarbonLib 1.0 and later when running Mac OS 8.1 or later.

Available in Mac OS X v 10.0 and later.

Not available to 64-bit applications.

Declared In

`TextServices.h`

ActivateTSMDocument

Informs the Text Services Manager that a TSM document is active.

```
OSErr ActivateTSMDocument (
   TSMDocumentID idocID
);
```

Parameters

idocID

A TSM document identification number created by a prior call to the `NewTSMDocument` (page 1595) function.

Return Value

A result code. See "Text Services Manager Result Codes" (page 1647).

Discussion

When a window that has an associated TSM document becomes active, your client application must call the `ActivateTSMDocument` function to inform the Text Services Manager that the document is activated and is ready to use text service components.

`ActivateTSMDocument` calls the equivalent text service component function `ActivateTextService` (page 1577) for all open text service components associated with the TSM document.

If a text service component has a menu, the Text Services Manager inserts the menu into the menu bar.

Availability

Available in CarbonLib 1.0 and later when running Mac OS 8.1 or later.

Available in Mac OS X v 10.0 and later.

Not available to 64-bit applications.

Declared In

`TextServices.h`

CloseTextService

Closes a text service component, other than an input method, and disassociates it from the active TSM document. (Deprecated in Mac OS X v10.5.)

```
OSErr CloseTextService (
   TSMDocumentID idocID,
   ComponentInstance aComponentInstance
);
```

Parameters

idocID

The identification number of a TSM document created by a prior call to the `NewTSMDocument` (page 1595) function.

aComponentInstance

The component instance created by a prior call to `OpenTextService` (page 1597).

Return Value

A result code. See "Text Services Manager Result Codes" (page 1647).

Discussion

When a user wants to close an opened text service component, your client application should call the function `CloseTextService`.

If the text service component displays a menu, the Text Services Manager removes the menu from the menu bar. This function is for closing text service components other than input methods. Your application does not need to open or close input methods.

Availability
Available in CarbonLib 1.0 and later when running Mac OS 8.1 or later.
Available in Mac OS X v 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`TextServices.h`

CopyTextServiceInputModeList

Obtains a copy of the set of input modes supported by a keyboard-class input method.

```
ComponentResult CopyTextServiceInputModeList (
   ComponentInstance ts,
   CFDictionaryRef *outInputModes
);
```

Parameters

ts

The component whose set of input modes you want to obtain.

outInputModes

On output, the CFDictionary contains the list of supported input modes. See the Discussion for more information on the structure and requirements of the dictionary.

Return Value
See the Component Manager documentation for a description of the `ComponentResult` data type.

Discussion
This function is supported by input methods that adopt the input mode protocol. If this component call is not supported by an input method, calls to functions that access text service properties (using the tag `kTextServiceInputModePropertyTag`) return the result `tsmComponentPropertyUnsupportedErr`.

The CFDictionary of input modes (available in TSM 2.2 and later) must have the following form:

```
<dict>
<key> kTSInputModeListKey </key>
<dict>
<key> modeSignature : (internal ascii name)</key>
<!-- This can be any of the generic input modes defined in this  file,-->
<!-- such as kTextServiceInputModeRoman,or can be a private input-->
<!-- mode such as CFSTR("com.apple.MyInputmethod.Japanese.CoolMode")  -->
 <dict>
<key>menuIconFile</key>
<string> (path for menu icon image file)</string>
<key>alternateMenuIconFile</key>
<string> (path for alternate menu icon image file, when item  is hilited)</string>
<key>paletteIconFile</key>
<string> (path for palette icon image file) </string>
<key>defaultState</key>
<boolean> (default on/off state) </boolean>
```

```
<key>script</key>
<string> (scriptCode string for this mode, for example, "smRoman")  </string>
<key>primaryInScript</key>
<boolean> (true if this is primary mode in this script) </boolean>
<key>isVisible</key>
<boolean> (true if this input mode should appear in System  UI) </boolean>
<key>keyEquivalentModifiers</key>
<integer> (modifiers)</integer>
<key>keyEquivalent</key>
<string> (key equivalent character) </string>
<key>JISKeyboardShortcut</key>
<integer> (optional: 0=none,1=hiragana, 2=katakana, 3=eisu)  </integer>
</dict>
</dict>
</dict>
```

This dictionary must also be present in the Info.plist for the component bundle, in addition to being available through this component call. Availability in the Info.plist allows retrieval of input modes by the system without opening the component. The component call is used whenever the system is notified of a change in the contents of the input mode list, such as when the name or key-equivalents of individual input modes have changed.

If, when the input method is first activated in a login session, the settings of the individual input modes (names or key-equivalents) differ from the default settings as found in the component bundle Info.plist, the system needs to be notified of the change. The input method does this by sending out the Carbon event `kEventTextInputInputMenuChanged`, just as when the change originally took place.

For more information on the dictionary keys used to define input modes and the input mode dictionary, see "Input Mode Dictionary Key" (page 1633) and "Individual Input Mode Keys" (page 1635).

Availability
Not available in CarbonLib.
Available in Mac OS X v 10.3 and later.
Not available to 64-bit applications.

Declared In
`TextServices.h`

DeactivateTextService

Notifies a text service component that its associated document window is becoming inactive.

```
ComponentResult DeactivateTextService (
   ComponentInstance ts
);
```

Parameters

ts

A Component Manager value of type `ComponentInstance` that identifies the component being called. When the Text Services Manager makes this call, it passes the `ComponentInstance` value returned by its call to the `OpenComponent` function. If an application makes this call, it may use the `ComponentInstance` value obtained from the `kEventParamTextInputSendComponentInstance` parameter of the Carbon event or the `keyAEServerInstance` parameter of an Apple event sent by the component being called. Alternately, an application may obtain a `ComponentInstance` value from a prior call to the function `OpenTextService` (page 1597).

Return Value
See the Component Manager documentation for a description of the `ComponentResult` data type.

Discussion
Text service components must implement a function for this call.

When it receives a `DeactivateTextService` call, the text service component is responsible for saving whatever state information it needs to save, so that it can restore the proper information when it becomes active again. Note that an input method should not confirm any unconfirmed text in the active input area, but should save it until reactivated.

A component other than an input method should hide all its floating windows and menus. However, an input-method component should not hide its windows in response to this call. If the subsequent document being activated is using the same component's service, it would be irritating to the user to hide and then immediately redisplay the same windows. An input-method component should hide its windows only in response to a `HidePaletteWindows` call.

The Text Services Manager makes this call either on its own or in response to application-interface calls it receives from client applications. Client applications may directly make this call, but the Text Services Manager does not then play a role in the connection between the client application making the call and the text service component receiving it.

Availability
Available in CarbonLib 1.0 and later when running Mac OS 8.1 or later.
Available in Mac OS X v 10.0 and later.
Not available to 64-bit applications.

Declared In
`TextServices.h`

DeactivateTSMDocument

Informs the Text Services Manager that a TSM document is inactive.

```
OSErr DeactivateTSMDocument (
   TSMDocumentID idocID
);
```

Parameters

idocID

A TSM document identification number created by a prior call to the `NewTSMDocument` (page 1595) function.

Return Value

A result code. See "Text Services Manager Result Codes" (page 1647).

Discussion

The `DeactivateTSMDocument` function lets you inform the Text Services Manager that a TSM document in your client application is no longer active and must temporarily stop using text service components.

The Text Services Manager calls the equivalent text service component function `DeactivateTextService` (page 1580) for any text service component associated with the TSM document being deactivated.

An application that supports inline input should always strive to have a TSM document active at all times. If a situation arises in which all TSM documents are inactive and keyboard input occurs, the Text Services Manager automatically interacts with the user via its floating input window. (This is the same floating window that the Text Services Manager displays if an application calls the function `UseInputWindow` (page 1613) with a value of `TRUE` for the `useWindow` parameter.)

Availability

Available in CarbonLib 1.0 and later when running Mac OS 8.1 or later.

Available in Mac OS X v 10.0 and later.

Not available to 64-bit applications.

Declared In

`TextServices.h`

DeleteTSMDocument

Closes all opened text service components for the TSM document.

```
OSErr DeleteTSMDocument (
   TSMDocumentID idocID
);
```

Parameters

idocID

A TSM document identification number created by a prior call to the `NewTSMDocument` (page 1595) function.

Return Value

A result code. See "Text Services Manager Result Codes" (page 1647).

Discussion
When your application disposes of a TSM document, it must call the `DeleteTSMDocument` function to inform the Text Services Manager that the document is no longer using text service components. `DeleteTSMDocument` invokes the Component Manager `CloseComponent` function for each open text service component associated with this document. It also disposes of the internal data structure for the TSM document.

Availability
Available in CarbonLib 1.0 and later when running Mac OS 8.1 or later.
Available in Mac OS X v 10.0 and later.
Not available to 64-bit applications.

Declared In
`TextServices.h`

DeselectTextService

Notifies TSM that an input method has been closed. (Deprecated in Mac OS X v10.5.)

```
OSStatus DeselectTextService (
   Component aComp
);
```

Parameters
aComp

Return Value
A result code. See "Text Services Manager Result Codes" (page 1647).

Discussion
This API is currently only intended for use by Character Palette class input methods. It allows such an input method to notify TSM that it has been closed by the user as a result of interaction with the input method's own UI, such a palette's close button, instead of via the normal UI provided by the System, such as the Keyboard Menu.

Availability
Not available in CarbonLib.
Available in Mac OS X v 10.2 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`TextServices.h`

FixTextService

Notifies a text service component that it must complete the processing of any input that is in progress.

```
ComponentResult FixTextService (
   ComponentInstance ts
);
```

Parameters

ts

A Component Manager value of type `ComponentInstance` that identifies the component being called. When the Text Services Manager makes this call, it passes the `ComponentInstance` value returned by its call to the `OpenComponent` function. If an application makes this call, it may use the `ComponentInstance` value obtained from the `kEventParamTextInputSendComponentInstance` parameter of the Carbon event or the `keyAEServerInstance` parameter of an Apple event sent by the component being called. Alternately, an application may obtain a `ComponentInstance` value from a prior call to the function `OpenTextService` (page 1597).

Return Value
See the Component Manager documentation for a description of the `ComponentResult` data type.

Discussion
Text service components must implement a function for this call.

For input method components, this function is equivalent to the user explicitly confirming text, but in this case the request comes instead from the application or from the Text Services Manager. Typically, users confirm text explicitly (such as by pressing the Return key), and input methods continually process these user events and send the confirmed text to client applications. Circumstances may arise, however, in which an application needs the input method to confirm and send input without an explicit confirmation from the user.

If, for example, the user clicks the mouse in text outside the active input area, that constitutes an implicit user acceptance of the text in the active input area. In this case, applications should explicitly terminate any active input by calling the `FixTSMDocument` (page 1584) function, which notifies the Text Services Manager. The Text Services Manager then calls the `FixTextService` function, which notifies the text service component that it must stop accepting further input and pass the current contents (both converted and unconverted) of the active input area as confirmed text to the client application.

Client applications may directly make this call, but the Text Services Manager does not then play a role in the connection between the client application making the call and the text service component receiving it.

Availability
Available in CarbonLib 1.0 and later when running Mac OS 8.1 or later.
Available in Mac OS X v 10.0 and later.
Not available to 64-bit applications.

Declared In
`TextServices.h`

FixTSMDocument

Informs the Text Services Manager that user input for a TSM document has been interrupted.

```
OSErr FixTSMDocument (
   TSMDocumentID idocID
);
```

Parameters

idocID

The identification number of a TSM document created by a prior call to the `NewTSMDocument` (page 1595) function.

Return Value

A result code. See "Text Services Manager Result Codes" (page 1647).

Discussion

Typically, an inline input text service component removes confirmed input from the active input area each time the user presses the Return key, and passes the confirmed text to your application through a Carbon event or an Apple event.

In certain situations, however, your client application may need to inform the text service component that input in the active input area of a specified TSM document has been interrupted, and that the text service component must confirm the text and terminate user input.In this case you call the `FixTSMDocument` function to give the input method text service component the opportunity to confirm any input in progress.

For instance, if the user clicks in the close box of the window in which active input is taking place, call `FixTSMDocument` before you close the window. The text service component will pass you the current contents (both converted and unconverted) of the active input area as confirmed text.

For simple activating and deactivating of your application's window, it is not necessary to confirm the text in the active inline area. The input method saves the text and restores it when your window is reactivated.

Availability

Available in CarbonLib 1.0 and later when running Mac OS 8.1 or later.

Available in Mac OS X v 10.0 and later.

Not available to 64-bit applications.

Declared In

`TextServices.h`

GetDefaultInputMethod

Obtains the default input method text service component for a given script and language. (Deprecated in Mac OS X v10.5.)

Not recommended.

```
OSErr GetDefaultInputMethod (
   Component *ts,
   ScriptLanguageRecord *slRecordPtr
);
```

Parameters

ts

A pointer to the component identifier of the input method text service component that is associated with the script and language combination given in the `slRecord` parameter.

slRecordPtr

A pointer to a structure of type `ScriptLanguageRecord` (page 1614). This structure describes the script and language combination that is associated with the input method text service specified in the `ts` parameter.

Return Value
A result code. See "Text Services Manager Result Codes" (page 1647).

Discussion
You should use the function `GetDefaultInputMethodOfClass` (page 1586) instead of this one.

The operating system uses `GetDefaultInputMethod` to find out which input method to activate when the user selects a new keyboard script from the Keyboard menu or by Command-key combination, or when an application calls `KeyScript` to change keyboard scripts. Your application should not typically need to call this function.

Version Notes
For systems prior to Mac OS X, in versions of Japanese system software starting with KanjiTalk 7, if the default input method is pre-KanjiTalk 7 and non-TSM-aware, `GetDefaultInputMethod` returns the error `tsmInputMethodIsOldErr`. In that case the `ts` parameter contains the script code of the old input method in its high-order word, and the reference ID of the old input method in its low-order word.

Availability
Not recommended. Available in CarbonLib 1.0 and later when running Mac OS 8.1 or later.
Available in Mac OS X v 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`TextServices.h`

GetDefaultInputMethodOfClass

Obtains the default input method text service component for a given text service class. (Deprecated in Mac OS X v10.5.)

```
OSStatus GetDefaultInputMethodOfClass (
   Component *aComp,
   ScriptLanguageRecord *slRecPtr,
   TextServiceClass tsClass
);
```

Parameters

aComp

On return, a pointer to the component identifier of the input method text service component that is associated with the script and language combination given in the `slRecord` parameter.

slRecPtr

On return, a pointer to a structure of type `ScriptLanguageRecord` (page 1614). This structure describes the script and language combination that is associated with the input method text service specified in the `ts` parameter.

tsClass

The text service class whose component and script language record you want to obtain. Pass `kKeyboardInputMethodClass` to specify a keyboard input method. Pass `kInkInputMethod` to specify an Ink input method.

Return Value
A result code. See "Text Services Manager Result Codes" (page 1647).

Discussion

Availability
Not available in CarbonLib.
Available in Mac OS X v 10.2 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`TextServices.h`

GetInputModePaletteMenu

Obtains from an input method the menu to display for a pull-down menu on the input mode palette. (Deprecated in Mac OS X v10.5.)

```
ComponentResult GetInputModePaletteMenu (
   ComponentInstance inInstance,
   UInt32 inItemID,
   CFArrayRef *outMenuItemsArray
);
```

Parameters

inInstance

The component instance.

inItemID

The item ID of the pull-down menu button.

outMenuItemsArray

On return, points to an array of menu items. A pull-down menu consists of an array of CFDictionary objects that contain the keys described in `Input Mode Palette Menu Definition Keys` (page 1633).

Return Value
Returns a non-null value on successful handling of the call.

Availability
Available in Mac OS X v 10.4 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`TextServices.h`

GetScriptLanguageSupport

Notifies a text service component that it must produce a list of its supported languages and scripts. (Deprecated in Mac OS X v10.5.)

```
ComponentResult GetScriptLanguageSupport (
   ComponentInstance ts,
   ScriptLanguageSupportHandle *scriptHdl
);
```

Parameters

ts

A Component Manager value of type `ComponentInstance` that identifies the component being called. When the Text Services Manager makes this call, it passes the `ComponentInstance` value returned by its call to the `OpenComponent` function. If an application makes this call, it may use the `ComponentInstance` value obtained from the `kEventParamTextInputSendComponentInstance` parameter of the Carbon event or the `keyAEServerInstance` parameter of an Apple event sent by the component being called. Alternately, an application may obtain a `ComponentInstance` value from a prior call to the function `OpenTextService` (page 1597).

scriptHdl

A handle to a structure of type `ScriptLanguageSupport` (page 1615). The handle must be either `NULL` or a valid handle. If it is `NULL`, the text service component allocates a new handle. If it is already a valid handle, the text service component resizes it as necessary. `GetScriptLanguageSupport` should produce a list of scripts and languages in this parameter.

Return Value

The return value should contain 0 if the list is correct, or an error value if an error occurred. See the Component Manager documentation for a description of the `ComponentResult` data type.

Discussion

Text service components must implement a function for this call.

In response to this call, the component should list all its supported scripts and languages, starting with the primary script and language as specified in the `componentFlags` field of its component description structure. The Text Services Manager makes the `GetScriptLanguageSupport` call after a component is opened via the Component Manager function `OpenComponent`. One of the Text Services Manager's uses of this script information is to determine whether to exchange information with the component in the Unicode text encoding.

For example, if a component is associated with a Macintosh script, but includes the `smUnicodeScript` constant in its enumeration of supported constants, then the Text Services Manager determines that the component produces and expects text in the Unicode encoding. Additionally, in this example, the Text Services Manager also concludes that the Unicode characters which the component supports are limited to those encoded in the repertoire of the encoding corresponding to the Macintosh script in the `componentFlags` field of its component description structure. Note that if the script specified in the `componentFlags` field is itself `smUnicodeScript`, the Text Services Manager imposes no restriction on the set of supported characters, and it treats the component as being capable of handling any Unicode character.

Client applications may directly make this call, but the Text Services Manager does not then play a role in the connection between the client application making the call and the text service component receiving it.

Availability

Available in CarbonLib 1.0 and later when running Mac OS 8.1 or later.

Available in Mac OS X v 10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In
TextServices.h

GetServiceList

Obtains a list of the text service components of a specified type that are currently available. (Deprecated in Mac OS X v10.5.)

```
OSErr GetServiceList (
   SInt16 numOfInterface,
   const OSType *supportedInterfaceTypes,
   TextServiceListHandle *serviceInfo,
   SInt32 *seedValue
);
```

Parameters

numOfInterface
The number of text service interface types supported by your client application.

supportedInterfaceTypes
A pointer to a value of type InterfaceTypeList (page 1614) specifying the kinds of text services that your program supports. This list helps the Text Services Manager locate text services of the correct interface type.

serviceInfo
A pointer to a handle to a structure of type TextServiceList (page 1616). If the handle is NULL, the Text Services Manager allocates the handle; otherwise, it assumes the handle is a valid text service component list handle, as defined by the TextServiceListHandle data type.

seedValue
A pointer to a value that indicates whether the list of text service components returned by GetServiceList may have been modified.

Return Value
A result code. See "Text Services Manager Result Codes" (page 1647).

Discussion
Your client application is responsible for providing a way—usually a menu—for the user to choose from among all available text service components. To get a list of available text service components to display in a menu, call the GetServiceList function. Be sure to filter out input methods, because the Keyboard menu already displays them.

When your application calls GetServiceList, the Text Services Manager locates all the text service components of the specified types and creates a text service component list, defined by the TextServiceList data type, containing an entry for each of the text service components.

It is possible to register text service components or withdraw them from registration at any time. Once it has compiled a list of text services, the Text Services Manager invokes the GetComponentListModSeed function and returns the value in the modseed parameter. You can save that value and, the next time you need to draw or regenerate the list of services, call the Component Manager GetComponentListModSeed function. If the seed value differs from the one you received from your last call to GetServiceList, you need to call GetServiceList once more to update the information. Alternately, you can simply call GetServiceList each time you need to update the list, although that may be less efficient.

Availability
Available in CarbonLib 1.0 and later when running Mac OS 8.1 or later.
Available in Mac OS X v 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`TextServices.h`

GetTextServiceLanguage

Obtains the current input script and language. (Deprecated in Mac OS X v10.5.)

```
OSErr GetTextServiceLanguage (
   ScriptLanguageRecord *slRecordPtr
);
```

Parameters

slRecordPtr

A pointer to a structure of type `ScriptLanguageRecord` (page 1614). Upon completion of the call, this structure describes the language supported by the default (current) text service component for the current keyboard script.

Return Value
A result code. See "Text Services Manager Result Codes" (page 1647).

Discussion
Your application should not typically need to call this function.

Availability
Available in CarbonLib 1.0 and later when running Mac OS 8.1 or later.
Available in Mac OS X v 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`TextServices.h`

GetTextServiceMenu

Notifies a text service component that it must produce a handle to its menu.

```
ComponentResult GetTextServiceMenu (
   ComponentInstance ts,
   MenuRef *serviceMenu
);
```

Parameters

ts

A Component Manager value of type `ComponentInstance` that identifies the component being called. When the Text Services Manager makes this call, it passes the `ComponentInstance` value returned by its call to the `OpenComponent` function. If an application makes this call, it may use the `ComponentInstance` value obtained from the `kEventParamTextInputSendComponentInstance` parameter of the Carbon event or the `keyAEServerInstance` parameter of an Apple event sent by the component being called. Alternately, an application may obtain a `ComponentInstance` value from a prior call to the function `OpenTextService` (page 1597).

serviceMenu

A pointer to a menu handle (defined by the Menu Manager `MenuHandle` data type) for the text service component that is to be updated. The menu handle may be preallocated or it may be `NULL`. If the menu handle is `NULL`, the text service component should allocate a new menu and return it. On Mac OS 8 and 9, note that all instances of a component must share a single menu handle, allocated in the system heap. On Mac OS X, all instances of a component must share a single menu handle within an application's context.

Return Value

If the text service component does not have a menu, it should return a `ComponentResult` value of `TSMHasNoMenuErr`. See the Component Manager documentation for a description of the `ComponentResult` data type.

Discussion

Text service components must implement a function for this call.

The Text Services Manager calls `GetTextServiceMenu` when a component is opened or activated, so that it can put the component's menu on the menu bar.

Client applications may directly make this call, but the Text Services Manager does not then play a role in the connection between the client application making the call and the text service component receiving it.

Availability

Available in CarbonLib 1.0 and later when running Mac OS 8.1 or later.

Available in Mac OS X v 10.0 and later.

Not available to 64-bit applications.

Declared In

`TextServices.h`

GetTextServiceProperty

Notifies a text service component that it must identify the current value of one of its properties.

```
ComponentResult GetTextServiceProperty (
   ComponentInstance ts,
   TextServicePropertyTag inPropertyTag,
   TextServicePropertyValue *outPropertyValue
);
```

Parameters

ts

A Component Manager value of type `ComponentInstance` that identifies the component being called. When the Text Services Manager makes this call, it passes the `ComponentInstance` value returned by its call to the `OpenComponent` function. If an application makes this call, it may use the `ComponentInstance` value obtained from the `kEventParamTextInputSendComponentInstance` parameter of the Carbon event or the `keyAEServerInstance` parameter of an Apple event sent by the component being called. Alternately, an application may obtain a `ComponentInstance` value from a prior call to the function `OpenTextService` (page 1597).

propertySelector

A constant identifying a general property of a text service. For descriptions of the system-defined property selectors, see "Text Service Properties" (page 1640).

result

On return, a constant specifying the value for a text service property. For descriptions of the system-defined property values, see "Text Service Properties" (page 1640).

Return Value

See the Component Manager documentation for a description of the `ComponentResult` data type.

Discussion

Text service components have the option of implementing a function for this call.

Both the Text Services Manager and client applications can call this function to manage text service properties. If client applications directly make this call, the Text Services Manager does not then play a role in the connection between the client application making the call and the text service component receiving it.

Availability

Available in CarbonLib 1.0 and later.

Available in Mac OS X v 10.0 and later.

Not available to 64-bit applications.

Declared In

`TextServices.h`

HidePaletteWindows

Notifies a text service component that it must hide its floating windows.

```
ComponentResult HidePaletteWindows (
   ComponentInstance ts
);
```

Parameters

ts

A Component Manager value of type `ComponentInstance` that identifies the component being called. When the Text Services Manager makes this call, it passes the `ComponentInstance` value returned by its call to the `OpenComponent` function. If an application makes this call, it may use the `ComponentInstance` value obtained from the `kEventParamTextInputSendComponentInstance` parameter of the Carbon event or the `keyAEServerInstance` parameter of an Apple event sent by the component being called. Alternately, an application may obtain a `ComponentInstance` value from a prior call to the function `OpenTextService` (page 1597).

Return Value

If the text service component has no palettes, it should return a `ComponentResult` value of `noErr`. See the Component Manager documentation for a description of the `ComponentResult` data type.

Discussion

Text service components must implement a function for this call.

If a window associated with a TSM document associated with your text service is being deactivated, your text service component receives the `DeactivateTextService` (page 1580) call. You should perform any necessary cleanup or other tasks associated with deactivating your current component instance. If your text service component is not an input method, you should also hide all floating windows associated with the document being deactivated. If your text service component is an input method and if the newly activated document does not use your text services, you receive the `HidePaletteWindows` call. When it receives a `HidePaletteWindows` call, your input method should hide all its floating and nonfloating windows associated with the component instance being deactivated. Its menus, if any, will be removed from the menu bar by the Text Services Manager.

The Text Services Manager makes this call either on its own or in response to application-interface calls it receives from client applications. Client applications may directly make this call, but the Text Services Manager does not then play a role in the connection between the client application making the call and the text service component receiving it.

Availability

Available in CarbonLib 1.0 and later when running Mac OS 8.1 or later.

Available in Mac OS X v 10.0 and later.

Not available to 64-bit applications.

Declared In

`TextServices.h`

InitiateTextService

Notifies a text service component that it must perform any necessary set-up tasks and begin operating.

```
ComponentResult InitiateTextService (
   ComponentInstance ts
);
```

Parameters

ts

A Component Manager value of type `ComponentInstance` that identifies the component being called. When the Text Services Manager makes this call, it passes the `ComponentInstance` value returned by its call to the `OpenComponent` function. If an application makes this call, it may use the `ComponentInstance` value obtained from the `kEventParamTextInputSendComponentInstance` parameter of the Carbon event or the `keyAEServerInstance` parameter of an Apple event sent by the component being called. Alternately, an application may obtain a `ComponentInstance` value from a prior call to the function `OpenTextService` (page 1597).

Return Value

This function should return a `ComponentResult` value of zero if there is no error, and an error code if there is one. See the Component Manager documentation for a description of the `ComponentResult` data type.

Discussion

Text service components must implement a function for this call.

The Text Services Manager can call `InitiateTextService` to any component that it has already opened with the Component Manager `OpenComponent` or `OpenDefaultComponent` functions. Text service components should be prepared to handle `InitiateTextService` calls at any time.

Any text service component can receive multiple `InitiateTextService` calls. The Text Services Manager calls `InitiateTextService` each time the user adds a text service to a TSM document, even if the text service component has already been opened. This provides an opportunity for the component to restart or to display user interface elements that the user may have closed.

The Text Services Manager makes this call either on its own or in response to application-interface calls it receives from client applications. Client applications may directly make this call, but the Text Services Manager does not then play a role in the connection between the client application making the call and the text service component receiving it.

Availability

Available in CarbonLib 1.0 and later when running Mac OS 8.1 or later.

Available in Mac OS X v 10.0 and later.

Not available to 64-bit applications.

Declared In

`TextServices.h`

InputModePaletteItemHit

Informs an input method that a function button on the input mode palette was pressed. (Deprecated in Mac OS X v10.5.)

```
ComponentResult InputModePaletteItemHit (
   ComponentInstance inInstance,
   UInt32 inItemID,
   UInt32 inItemState
);
```

Parameters

inInstance

The component instance.

inItemID

The item ID of the function button pressed on the palette.

inItemState

The new state of the button.

Return Value

Returns a non-null value on successful handling of the call.

Availability

Available in Mac OS X v 10.4 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`TextServices.h`

IsTextServiceSelected

Determines if a text service component is selected. (Deprecated in Mac OS X v10.5.)

```
Boolean IsTextServiceSelected (
   Component aComp
);
```

Parameters

aComp

The component you want to determine is selected or not.

Return Value

Returns `true` if the component is selected.

Availability

Not available in CarbonLib.

Available in Mac OS X v 10.3 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`TextServices.h`

NewTSMDocument

Creates a TSM document and returns a handle to the document's ID.

```
OSErr NewTSMDocument (
   SInt16 numOfInterface,
   InterfaceTypeList supportedInterfaceTypes,
   TSMDocumentID *idocID,
   SRefCon refcon
);
```

Parameters

numOfInterface

The number of text service interface types that your application supports.

supportedInterfaceTypes

A value of type `InterfaceTypeList` (page 1614) specifying the kinds of text services that your program supports. This list helps the Text Services Manager locate the text services that have the correct interface type.

idocID

Upon successful completion of the call, a pointer to the document identification number of the TSM document created. If `NewTSMDocument` fails to create a new TSM document, it returns an error and sets `idocID` to `NULL`.

refcon

A reference constant to be associated with the TSM document. This may have any value you wish.

Return Value

A result code. See "Text Services Manager Result Codes" (page 1647).

Discussion

Each time your client application calls the `NewTSMDocument` function, the Text Services Manager creates an internal structure called a TSM document and returns its ID.

If the call is successful, `NewTSMDocument` opens the default input method text service component of the current keyboard script and assigns it to this document. If `NewTSMDocument` returns `tsmScriptHasNoIMErr`, it has still created a valid TSM document, but has not associated an input method with it.

Starting in Mac OS X v10.3, the `NewTSMDocument` function turns on the `kTSMDocumentUnicodeInputWindowPropertyTag` implicitly for TSMDocuments of interface type `kUnicodeDocumentInterfaceType`. The effect is that Unicode input sources (keyboard layouts) can remain available, not only in an editing mode where Unicode is supported by an application, but also outside of editing mode where no TSMDocument in particular is active.

This change also provides compatibility with many applications that relied on Unicode input being available even without activating any of their own TSMDocuments, as well as other applications that do create their own Unicode TSMDocument but call the function `UseInputWindow` passing `true` (which was really an undefined operation in the original Unicode/TSM specification).

Availability

Available in CarbonLib 1.0 and later when running Mac OS 8.1 or later.

Available in Mac OS X v 10.0 and later.

Not available to 64-bit applications.

Declared In

`TextServices.h`

OpenTextService

Opens a text service component, other than an input method, and associates it with a TSM document. (Deprecated in Mac OS X v10.5.)

```
OSErr OpenTextService (
   TSMDocumentID idocID,
   Component aComponent,
   ComponentInstance *aComponentInstance
);
```

Parameters

idocID

The identification number of a TSM document created by a prior call to the `NewTSMDocument` (page 1595) function.

aComponent

A component identifier for this text service component. You can obtain the component identifier to pass in `aComponent` by comparing the menu item name selected by the user with the component item name found in a `TextServiceInfo` (page 1615) structure. You can obtain a `TextServiceInfo` structure by calling the function `GetServiceList` (page 1589) and examining the `fServices` field of the `TextServiceList` structure that it produces.

aComponentInstance

Upon completion of the call, a pointer to a component instance. This value identifies your application's connection to a text service component. You must supply this value if you call the text service functions provided by the component directly.

Return Value

A result code. See "Text Services Manager Result Codes" (page 1647).

Discussion

This function instructs the Text Services Manager to open a text service component, other than an input method, that a user has chosen and to associate it with a TSM document. The Text Services Manager opens the requested component by calling the Component Manager `OpenComponent` function.

If the specified text service component is already open, the Text Services Manager does not open it again and the `tsmComponentAlreadyOpenErr` error message is returned as a result code. Whether or not the text service is open, the Text Services Manager calls the functions `InitiateTextService` (page 1593) and `ActivateTextService` (page 1577) for the given text service and returns a valid component instance. Upon completion of the `OpenTextService` call, the selected text service component is initialized and active.

This function is for opening text service components other than input methods. Your application does not need to open or close input methods.

Availability

Available in CarbonLib 1.0 and later when running Mac OS 8.1 or later.

Available in Mac OS X v 10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`TextServices.h`

SelectTextService

Selects a text service. (Deprecated in Mac OS X v10.5.)

```
OSStatus SelectTextService (
   Component aComp
);
```

Parameters

aComp

The text service you want to select.

Return Value

A result code. See "Text Services Manager Result Codes" (page 1647).

Discussion

This function is intended for use by input methods in text service classes which are additive in nature, that is where the input method can operate in parallel to other input methods in the same class and other additive text service classes. An example of such a class is the Character Palette class. This function is not for use by traditional input methods, such as those that belong to the keyboard input method class.

Availability

Not available in CarbonLib.

Available in Mac OS X v 10.2 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`TextServices.h`

SendAEFromTSMComponent

Sends Apple events from a text service component to a client application. (Deprecated in Mac OS X v10.5.)

```
OSErr SendAEFromTSMComponent (
   const AppleEvent *theAppleEvent,
   AppleEvent *reply,
   AESendMode sendMode,
   AESendPriority sendPriority,
   SInt32 timeOutInTicks,
   AEIdleUPP idleProc,
   AEFilterUPP filterProc
);
```

Parameters

theAppleEvent

A pointer to the Apple event to be sent.

reply

A pointer to the reply Apple event returned by `SendAEFromTSMComponent`.

sendMode

The value that lets you specify one of the following modes specified by corresponding constants: the reply mode for the Apple event, the interaction level, the application switch mode, the reconnection mode, and the return receipt mode. To obtain the value for this parameter, add the appropriate constants. Comprehensive details about these constants are provided in the description of the Apple Event Manager `AESend` function.

sendPriority

The value that specifies whether to put the Apple event at the back of the event queue (set with the `kAENormalPriority` flag) or at the front of the queue (`kAEHighPriority` flag).

timeOutInTicks

The length of time (in ticks) that the client application is willing to wait for the reply or return receipt from the server application before it times out. If the value of this parameter is `kNoTimeOut`, the Apple event never times out.

idleProc

A pointer to a function for any tasks (such as displaying a globe, a wristwatch, or a spinning beach ball cursor) that the application performs while waiting for a reply or a return receipt.

filterProc

A pointer to a function that accepts certain incoming Apple events that are received while the handler waits for a reply or a return receipt and filters out the rest.

Return Value
A result code. See "Text Services Manager Result Codes" (page 1647).

Discussion
Component use of Apple events and the function `SendAEFromTSMComponent` is discouraged on Mac OS X. Text service components should use Carbon text input events and the function `SendTextInputEvent` (page 1600) on Mac OS X, instead. See "Carbon Porting Notes" below for more details.

The `SendAEFromTSMComponent` function is essentially a wrapper function for the Apple Event Manager function `AESend`. See the description of `AESend` for additional necessary information, including constants for the `sendMode` parameter and result codes.

`SendAEFromTSMComponent` identifies your text service component from the `keyAEServerInstance` parameter in the Apple event specified in the `theAppleEvent` parameter. If a reference constant in a TSM document that corresponds to this parameter is found in the internal data structures of the Text Services Manager, `SendAEFromTSMComponent` adds the reference constant as the `keyAETSMDocumentRefcon` parameter to the given Apple event before sending it to the application.

If the client application is not TSM-aware, `SendAEFromTSMComponent` routes the Apple events to the floating input window to allow bottom-line input.

If your text service component changes the environment in any way—such as by modifying the A5 world or changing the current zone—while constructing an Apple event, it must restore the previous settings before sending the Apple event.

Your text service component should always use the `kCurrentProcess` constant as the target address when it creates an Apple event to send to the Text Services Manager.

Availability
Available in CarbonLib 1.0 and later when running Mac OS 8.1 or later.
Available in Mac OS X v 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Carbon Porting Notes

Note that this function is superseded by the function `SendTextInputEvent` (page 1600) on Mac OS X only. With Mac OS X, text service components must be Carbon clients. This is in contrast to Mac OS 8 and 9, where text service components must not be Carbon clients. (This restriction is due to the fact that it is potentially destabilizing for a Carbon-based component to load Carbon in the context of a non-Carbon application.) Therefore, text service components use Carbon text input events and the `SendTextInputEvent` function only on Mac OS X. The function `SendAEFromTSMComponent` must be used by components running on Mac OS 8 and 9.

On any system, the Text Services Manager automatically converts component-originated text input events to the proper form for client applications. On Mac OS X, the Text Services Manager automatically converts component-originated Carbon events to Apple events, if a client application does not provide handlers for Carbon events. Conversely, on Mac OS 8 and 9, the Text Services Manager automatically converts component-originated Apple events to Carbon events and provides these Carbon events to applications, so they have the option of handling them.

Declared In
`TextServices.h`

SendTextInputEvent

Sends Carbon text input events from a text service component to a client application.

```
OSStatus SendTextInputEvent (
   EventRef inEvent
);
```

Parameters

inEvent
A reference to the Carbon event to be sent.

Return Value
A result code. See "Text Services Manager Result Codes" (page 1647). The `SendTextInputEvent` function returns `noErr` if the event is successfully handled. If the event is not handled, the function may return a Carbon Event Manager error, as well as Apple event or Text Encoding Conversion Manager errors.

Discussion
The `SendTextInputEvent` function allows a Carbon text service component on Mac OS X to send a Carbon text input event to the Text Services Manager for dispatching to a client application. This function can be used for events of Carbon event class `kEventClassTextInput` as well as for events of class `kEventClassTSMDocumentAccess`.

If the client application does not handle a particular Carbon text input event, the Text Services Manager converts the event to the corresponding Apple event and sends it again. An exception to this is when the application is not Unicode-aware (that is, the active TSM document was not created with the `kUnicodeDocument` interface type). In this case, a `kEventUnicodeForKeyEvent` Carbon event would not be converted to the corresponding Apple event (`kUnicodeNotFromInputMethod`). In every case, if the application handles neither the Unicode Carbon text input event nor the corresponding Apple event, the Text Services Manager converts the component's text input event into a stream of "classic" key events for delivery to `WaitNextEvent` clients.

If the application has no active TSM documents or has called the function `UseInputWindow` (page 1613) to request input via the Text Services Manager's floating input window—that is, if the application does not handle the event at all—the Text Services Manager routes the component's text input event to the floating input window to allow bottom-line input.

Availability
Not available in CarbonLib.
Available in Mac OS X v 10.0 and later.
Not available to 64-bit applications.

Carbon Porting Notes

Note that this function replaces the function `SendAEFromTSMComponent` (page 1598) on Mac OS X only. With Mac OS X, text service components must be Carbon clients. This is in contrast to Mac OS 8 and 9, where text service components must not be Carbon clients. (This restriction is due to the fact that it is potentially destabilizing for a Carbon-based component to load Carbon in the context of a non-Carbon application.) Therefore, text service components use Carbon text input events and the `SendTextInputEvent` function only on Mac OS X. The function `SendAEFromTSMComponent` must be used by components running on Mac OS 8 and 9.

On any system, the Text Services Manager automatically converts component-originated text input events to the proper form for client applications. On Mac OS X, the Text Services Manager automatically converts component-originated Carbon events to Apple events, if a client application does not provide handlers for Carbon events. Conversely, on Mac OS 8 and 9, the Text Services Manager automatically converts component-originated Apple events to Carbon events and provides these Carbon events to applications, so they have the option of handling them.

Declared In
`TextServices.h`

SetDefaultInputMethod

Sets a default input method to a given script and language. (Deprecated in Mac OS X v10.5.)

Not recommended.

```
OSErr SetDefaultInputMethod (
   Component ts,
   ScriptLanguageRecord *slRecordPtr
);
```

Parameters

ts

The component identifier of the input method to be associated with the script and language combination given in the `slRecord` parameter.

slRecordPtr

A pointer to a structure of type `ScriptLanguageRecord` (page 1614). This structure describes the script and language combination to be associated with the input method specified in the `ts` parameter.

Return Value
A result code. See "Text Services Manager Result Codes" (page 1647). If the script code and language code specified in the script-language structure are incompatible, `SetDefaultInputMethod` returns the error `paramErr`.

Discussion
You should use the function `SetDefaultInputMethodOfClass` (page 1602) instead of this one.

The operating system uses `SetDefaultInputMethod` to associate an input method text service component with a given script and language. The operating system calls this function when the user expresses input method preferences through the Keyboard menu, Keyboard control panel, or other device. The associations made with this function are permanent; that is, they persist after restart. Your application should not typically need to call this function.

Availability
Not recommended. Available in CarbonLib 1.0 and later when running Mac OS 8.1 or later.
Available in Mac OS X v 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`TextServices.h`

SetDefaultInputMethodOfClass

Sets the default input method text service component for a given text service class. (Deprecated in Mac OS X v10.5.)

```
OSStatus SetDefaultInputMethodOfClass (
   Component aComp,
   ScriptLanguageRecord *slRecPtr,
   TextServiceClass tsClass
);
```

Parameters

aComp
The component identifier of the input method to be associated with the script and language combination given in the `slRecord` parameter.

slRecPtr
A pointer to a structure of type `ScriptLanguageRecord` (page 1614). This structure describes the script and language combination to be associated with the input method specified in the `ts` parameter.

tsClass
The text service class whose component and script language record you want to obtain. Pass `kKeyboardInputMethodClass` to specify a keyboard input method. Pass `kInkInputMethod` to specify an Ink input method.

Return Value
A result code. See "Text Services Manager Result Codes" (page 1647).

Discussion

Availability
Not available in CarbonLib.
Available in Mac OS X v 10.2 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`TextServices.h`

SetTextServiceLanguage

Changes the current input script and language. (Deprecated in Mac OS X v10.5.)

```
OSErr SetTextServiceLanguage (
   ScriptLanguageRecord *slRecordPtr
);
```

Parameters

slRecordPtr

A pointer to a structure of type `ScriptLanguageRecord` (page 1614) specifying the new script and language combination.

Return Value
A result code. See "Text Services Manager Result Codes" (page 1647).

Discussion
The operating system calls this function when the user switches the keyboard script, so that the Text Services Manager can synchronize the input method with the current keyboard script.

Your application should not typically need to call this function.

Availability
Available in CarbonLib 1.0 and later when running Mac OS 8.1 or later.
Available in Mac OS X v 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`TextServices.h`

SetTextServiceProperty

Notifies a text service component that one of its properties has been selected.

```
ComponentResult SetTextServiceProperty (
   ComponentInstance ts,
   TextServicePropertyTag inPropertyTag,
   TextServicePropertyValue inPropertyValue
);
```

Parameters

ts

A Component Manager value of type `ComponentInstance` that identifies the component being called. When the Text Services Manager makes this call, it passes the `ComponentInstance` value returned by its call to the `OpenComponent` function. If an application makes this call, it may use the `ComponentInstance` value obtained from the `kEventParamTextInputSendComponentInstance` parameter of the Carbon event or the `keyAEServerInstance` parameter of an Apple event sent by the component being called. Alternately, an application may obtain a `ComponentInstance` value from a prior call to the function `OpenTextService` (page 1597).

propertySelector

A constant identifying a general property of a text service. For descriptions of the system-defined property selectors, see "Text Service Properties" (page 1640).

value

A constant specifying a particular value for the text service property. For descriptions of the system-defined property values, see "Text Service Properties" (page 1640).

Return Value
See the Component Manager documentation for a description of the `ComponentResult` data type.

Discussion
Text service components have the option of implementing a function for this call.

An application can call `SetTextServiceProperty` to request that a text service component use a specific feature or functionality of the component's program. For example, if an application knows that a Japanese input method which supports various typing methods is the currently active input method, the application can solicit the user's preference of typing methods. Then the application can call `SetTextServiceProperty` to request that the input method use the preferred typing method, for example, Roman or Kana. Currently, the only properties that are defined by the system are typing methods for Japanese input methods.

Both the Text Services Manager and client applications can call this function to manage text service properties. If client applications directly make this call, the Text Services Manager does not then play a role in the connection between the client application making the call and the text service component receiving it.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X v 10.0 and later.
Not available to 64-bit applications.

Declared In
`TextServices.h`

TerminateTextService

Notifies a text service component that it must terminate its operations in preparation for closing.

```
ComponentResult TerminateTextService (
   ComponentInstance ts
);
```

Parameters

ts

A Component Manager value of type `ComponentInstance` that identifies the component being called. When the Text Services Manager makes this call, it passes the `ComponentInstance` value returned by its call to the `OpenComponent` function. If an application makes this call, it may use the `ComponentInstance` value obtained from the `kEventParamTextInputSendComponentInstance` parameter of the Carbon event or the `keyAEServerInstance` parameter of an Apple event sent by the component being called. Alternately, an application may obtain a `ComponentInstance` value from a prior call to the function `OpenTextService` (page 1597).

Return Value
If the text service component needs to remain open, it should return an `OSErr` value in the component result return value. This could happen, for example, if the user chooses Cancel in response to a text service component dialog box. See the Component Manager documentation for a description of the `ComponentResult` data type.

Discussion
Text service components must implement a function for this call.

The Text Services Manager calls `TerminateTextService` before closing the component instance. A text service component must use this opportunity to confirm any inline input in progress. If this call is made to the last open instance of a text service component, the component should hide any open palette windows. If it is an input method, the component should not dispose of its menu handle if it has a menu.

The Text Services Manager makes this call either on its own or in response to application-interface calls it receives from client applications. Client applications may directly make this call, but the Text Services Manager does not then play a role in the connection between the client application making the call and the text service component receiving it.

Availability
Available in CarbonLib 1.0 and later when running Mac OS 8.1 or later.
Available in Mac OS X v 10.0 and later.
Not available to 64-bit applications.

Declared In
`TextServices.h`

TextServiceEventRef

Provides an opportunity for a text service component to handle a Carbon event.

```
ComponentResult TextServiceEventRef (
   ComponentInstance ts,
   EventRef event
);
```

Parameters

ts
A Component Manager value of type `ComponentInstance` that identifies the component being called. When the Text Services Manager makes this call, it passes the `ComponentInstance` value returned by its call to the `OpenComponent` function. If an application makes this call, it may use the `ComponentInstance` value obtained from the `kEventParamTextInputSendComponentInstance` parameter of the Carbon event or the `keyAEServerInstance` parameter of an Apple event sent by the component being called. Alternately, an application may obtain a `ComponentInstance` value from a prior call to the function `OpenTextService` (page 1597).

event
A reference to the Carbon event being passed to the component.

Return Value
If the text service component handles the event, it should return a nonzero value for `componentResult`. If it does not handle the event, it should return 0. Note that the Text Services Manager clones an event before passing it to a component, so any changes made to the contents of an event by the text service have no effect on the original event. See the Component Manager documentation for a description of the `ComponentResult` data type.

Discussion
Carbon text service components (that is, Mac OS X text services) must implement a function for this call.

The Text Services Manager automatically passes raw keyboard Carbon events (events of class `kEventClassKeyboard`) and some Carbon mouse events to text service components associated with an active TSM document. The Text Services Manager passes mouse-click events (`kEventMouseDown`, `kEventMouseUp`, `kEventMouseDragged`) to active text services directly. However, the Text Services Manager does not send `kEventMouseMoved` events to text service components. Instead, when a mouse-moved event occurs inside an inline input region (as registered via an application call to the `TSMSetInlineInputRegion` function), the Text Services Manager promotes the `kEventMouseMoved` event to the window-specific `kEventWindowCursorChange` event, which it then sends to the text service. For more details, see the function `TSMSetInlineInputRegion` (page 1611).

Both the Text Services Manager and client applications can call this function to send Carbon events to components. If client applications directly make this call, the Text Services Manager does not then play a role in the connection between the client application making the call and the text service component receiving it.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X v 10.0 and later.
Not available to 64-bit applications.

Declared In
`TextServices.h`

TSMCopyInputMethodEnabledInputModes

Obtain the array of the enabled (and visible) input modes for a component. (Deprecated in Mac OS X v10.5.)

```
Boolean TSMCopyInputMethodEnabledInputModes (
   Component inComponent,
   CFArrayRef *outInputModeArray
);
```

Parameters

inComponent
The component whose input modes you want to obtain.

outInputModeArray
On return, points to an array of the enabled and visible input modes for the specified component. This function is meaningful only for input methods that adopt the input mode protocol. If the component passed is not input mode-savvy, the returned array is `NULL`. It is the responsibility of the caller to release the returned array.

Discussion
You use this function to allow an input method to query the system for the subset of its own input modes that are enabled. This allows you to omit from the component UI any input modes that are disabled by the user or the system. The enabled input modes returned in the array are always visible ones. That is, the array contains those input modes for which `kTSInputModeIsVisibleKey` is true; non-visible input modes are not tracked by the system.

Availability
Available in Mac OS X v 10.3 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`TextServices.h`

TSMGetActiveDocument

Obtains the active TSM document in the current application context.

```
TSMDocumentID TSMGetActiveDocument (
   void
);
```

Parameters

Return Value
If the Text Services Manager has enabled bottom line input because no TSM document is active, `NULL` is returned. See the description of the `TSMDocumentID` data type.

Discussion
This function can be useful to identify whether the currently active TSM document belongs to the application, or whether it may belong to a control or a plug-in which has user focus within the application's window.

Availability
Available in CarbonLib 1.3 and later.
Available in Mac OS X v 10.0 and later.

Declared In
`TextServices.h`

TSMGetDocumentProperty

Obtains a TSM document property.

```
OSStatus TSMGetDocumentProperty (
   TSMDocumentID docID,
   TSMDocumentPropertyTag propertyTag,
   UInt32 bufferSize,
   UInt32 *actualSize,
   void *propertyBuffer
);
```

Parameters

docID

The `TSMDocumentID` that identifies the document whose property you want to obtain.

propertyTag

A tag that specifies the property you want to obtain.

bufferSize

The size of the data pointed to by the `propertyBuffer` parameter. See the Discussion for what to supply.

actualSize

On return, the actual size of the data.

propertyBuffer

On return, a pointer to the property data.

Return Value

A result code. See "Text Services Manager Result Codes" (page 1647).

Discussion

You can call the function `TSMGetDocumentProperty` to retrieve arbitrary data with a specific TSM document. You associated arbitrary data with a TSM document by calling the function `TSMSetDocumentProperty`.

Input methods can call the function `TSMGetDocumentProperty` to determine whether the application that owns the document supports the glyph ID specification (`kTSMDocumentPropertySupportGlyphInfo`).

You can call the function `TSMGetDocumentProperty` to check for the following predefined properties:

- `kUseFloatingWindowTag`. The presence of this property indicates the document is using bottom-line floating window for input. See "Collection Tags" (page 1644) for more information.
- `kUnicodeDocument`. The presence of this property indicates the document is Unicode-savvy. See "Unicode Identifiers" (page 1643) for more information.
- `kTSMTEInterfaceType`. The presence of this property indicates a TSM Text Edit interface. See "TSM Document Interfaces" (page 1642) for more information.
- `kTextService`. The presence of this property indicates the document is not Unicode-savvy. See "TSM Document Interfaces" (page 1642) for more information.

These properties do not have any data associated with them. If the function `TSMGetDocumentProperty` returns `noErr` when you call the function with one of these properties, it indicated the property is present.

Typically you need to call this function twice, as follows:

1. Pass the document ID for the document, the tag that specifies the property you want to obtain, 0 for the `bufferSize` parameter, `NULL` for the `actualSize` parameter, and `NULL` for the `propertyBuffer` parameter.

2. Allocate enough space for a buffer of the returned size, then call the function again, passing a pointer in the `propertyBuffer` parameter. On return, the pointer references the property data.

Availability
Not available in CarbonLib.
Available in Mac OS X v 10.2 and later.

Declared In
`TextServices.h`

TSMInputModePaletteLoadButtons

Notifies the input mode palette of changes to the controls for an input method and replaces the current controls with the new control array. (Deprecated in Mac OS X v10.5.)

```
void TSMInputModePaletteLoadButtons (
   CFArrayRef paletteButtonsArray
);
```

Parameters

`paletteButtonsArray`

A CFArray that contains descriptions of the controls. Use a CFDictionary to describe each control. See "Input Mode Palette Control Keys" (page 1634) for a description of the keys you can supply.

Availability
Available in Mac OS X v 10.4 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`TextServices.h`

TSMInputModePaletteUpdateButtons

Notifies the input mode palette of changes to the controls for an input method and updates the controls. (Deprecated in Mac OS X v10.5.)

```
void TSMInputModePaletteUpdateButtons (
   CFArrayRef paletteButtonsArray
);
```

Parameters

`paletteButtonsArray`

A CFArray that contains descriptions of the controls. Use a CFDictionary to describe each control. See "Input Mode Palette Control Keys" (page 1634) for a description of the keys you can supply.

Discussion
This function updates controls based on the control tag ID. It doe not replace or remove existing controls.

Availability
Available in Mac OS X v 10.4 and later.
Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In
`TextServices.h`

TSMRemoveDocumentProperty

Removes a property from a TSM document.

```
OSStatus TSMRemoveDocumentProperty (
   TSMDocumentID docID,
   TSMDocumentPropertyTag propertyTag
);
```

Parameters

docID

The `TSMDocumentID` that identifies the document whose property you want to obtain.

propertyTag

A tag that specifies the property you want to remove.

Return Value
A result code. See "Text Services Manager Result Codes" (page 1647).

Availability
Not available in CarbonLib.
Available in Mac OS X v 10.2 and later.

Declared In
`TextServices.h`

TSMSelectInputMode

Sets the specified input method input mode as the current input source. (Deprecated in Mac OS X v10.5.)

```
OSStatus TSMSelectInputMode (
   Component inComponent,
   CFStringRef inInputMode
);
```

Parameters

inComponent

The component whose input mode you want to set.

inInputMode

The input mode you want to set as the current input source.

Discussion
You use this function to allow an input method to select one of its own input modes as the current input source and update the Text Input menu icon in the menu bar. This function is only meaningful for input methods that adopt the input mode protocol.

Availability
Available in Mac OS X v 10.3 and later.
Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In
`TextServices.h`

TSMSetDocumentProperty

Sets a property for a TSM document.

```
OSStatus TSMSetDocumentProperty (
   TSMDocumentID docID,
   TSMDocumentPropertyTag propertyTag,
   UInt32 propertySize,
   void *propertyData
);
```

Parameters

docID
The `TSMDocumentID` that identifies the document whose property you want to set.

propertyTag
A tag that specifies the property you want to set.

propertySize
The size of the property data.

propertyData
A pointer to the property data.

Return Value
A result code. See "Text Services Manager Result Codes" (page 1647).

Discussion
You can call the function `TSMSetDocumentProperty` to associate arbitrary data with a specific TSM document. You can call the function `TSMGetDocumentProperty` to retrieve arbitrary data.

If your application supports input of unencoded glyphs you must notify the Text Service Manager and input methods by setting the glyph ID specification (`kTSMDocumentPropertySupportGlyphInfo`) as a property of each TSM document.

Availability
Not available in CarbonLib.
Available in Mac OS X v 10.2 and later.

Declared In
`TextServices.h`

TSMSetInlineInputRegion

Defines a region within a TSM document in which inline input can occur. (Deprecated in Mac OS X v10.5.)

```
OSStatus TSMSetInlineInputRegion (
   TSMDocumentID inTSMDocument,
   WindowRef inWindow,
   RgnHandle inRegion
);
```

Parameters

inTSMDocument

The identification number of a TSM document created by a prior call to the `NewTSMDocument` (page 1595) function.

inWindow

A reference to the window that contains the inline input session. You can pass `NULL` for this parameter to indicate the window that currently has user focus.

inRegion

The current inline input region. This region should be in coordinates local to the port associated with the window specified in the `inWindow` parameter. The region must be recomputed each time the text content of the inline input session changes (such as after an Update Active Input Area event) and when the region moves for other reasons (such as window resizing or scrolling). If you pass `NULL` for this parameter, the Text Service Manager defaults to intercepting mouse events for the window's entire content region.

Return Value

A result code. See "Text Services Manager Result Codes" (page 1647).

Discussion

The `TSMSetInlineInputRegion` function informs the Text Services Manager of the region occupied by an inline input session. If certain mouse events (such as clicks and mouse-moved events) occur within this region, the Text Services Manager forwards these events to the current input method, so the component can respond to the user's actions.

When a mouse-moved event occurs inside an inline input region (as registered via the `TSMSetInlineInputRegion` function), the Text Services Manager promotes the `kEventMouseMoved` event, after it has been received by the applicable control or window, to the window-specific `kEventWindowCursorChange` event. The Text Services Manager first delivers the `kEventWindowCursorChange` event to the active input method, then, if it is not handled, to any other active text services. If the event has still not been handled, the Text Services Manager finally passes the event to the application's `kEventWindowCursorChange` event handler, if any. This event-dispatching process gives applications that need to see the low-level mouse-moved events a chance to see these events first, while providing a mechanism for text services and applications to act on these events without conflict. After completing this process, the Carbon Event Manager converts any `kEventWindowCursorChange` event that remains unhandled to a "classic" mouse-moved event for `WaitNextEvent` clients.

If an application does not call this function, when an input method is active the Text Services Manager by default intercepts mouse events in the entire content region of the window that currently has user focus.

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X v 10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`TextServices.h`

UseInputWindow

Associates a floating input window with one or more TSM documents.

```
OSErr UseInputWindow (
   TSMDocumentID idocID,
   Boolean useWindow
);
```

Parameters

idocID

The TSM document ID of the particular TSM document to be associated with the floating input window. If `NULL`, this call affects all your application's TSM documents.

useWindow

Indicates whether to use the floating input window. Pass `TRUE` if you want to use a floating window; pass `FALSE` if you do not want to use a floating window.

Return Value

A result code. See "Text Services Manager Result Codes" (page 1647).

Discussion

The Text Services Manager provides a floating input window for your application's use if you call `UseInputWindow` with a value of `TRUE` in the `useWindow` parameter. To specify inline input instead, call `UseInputWindow` with a value of `FALSE` in the `useWindow` parameter.

The default value for `useWindow` is `FALSE`; if you do not call `UseInputWindow`, the Text Services Manager assumes that your application wants to use inline input. If your application wants to save the user's choice, it can put the last-used value for `useWindow` in a preferences file before quitting.

If you pass a valid TSM document ID for the `idocID` parameter, the `useWindow` parameter affects only that TSM document. If you pass `NULL` for the `idocID` parameter, the `useWindow` parameter affects all your application's TSM documents, including documents you create after making this call.

Availability

Available in CarbonLib 1.0 and later when running Mac OS 8.1 or later.

Available in Mac OS X v 10.0 and later.

Not available to 64-bit applications.

Declared In

`TextServices.h`

Data Types

TSM Document Interface Type

Defines an interface type for a TSM document.

```
typedef OSType TSMDocumentInterfaceType;
```

Discussion
As of Mac OS X version 10.3, TSM interface types are also stored as TSM document properties. Interface types are a subset of TSM document properties; not all properties are interface types. Once a TSM document is created, you can easily find out its interface types at document creation. See "TSM Document Interfaces" (page 1642) for a list of the possible interface types.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`TextServices.h`

InterfaceTypeList

An array of four-character codes identifying Text Services Manager interface types.

```
typedef OSType InterfaceTypeList[1];
```

Discussion
The `InterfaceTypeList` type is used in the function `NewTSMDocument` (page 1595) to identify the type of interfaces that an application supports and in the function `GetServiceList` (page 1589) to identify the types of interfaces that are currently available. See "TSM Document Interfaces" (page 1642) for a list of the possible interfaces.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextServices.h`

ScriptLanguageRecord

Identifies a specific script-language combination.

```
struct ScriptLanguageRecord {
    ScriptCode fScript;
    LangCode fLanguage;
};
typedef struct ScriptLanguageRecord ScriptLanguageRecord;
```

Fields

`fScript`
A `ScriptCode` value identifying a particular set of written characters (for example, Roman versus Cyrillic) and their encoding.

`fLanguage`
A `LangCode` value identifying a particular language (for example, English), as represented using a particular `ScriptCode` value.

Discussion
Structures of type ScriptLanguageRecord are used in the functions `SetDefaultInputMethod` (page 1601), `GetDefaultInputMethod` (page 1585), `SetTextServiceLanguage` (page 1603), and `GetTextServiceLanguage` (page 1590).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextServices.h`

ScriptLanguageSupport

Lists a component's supported scripts and languages.

```
struct ScriptLanguageSupport {
    short fScriptLanguageCount;
    ScriptLanguageRecord fScriptLanguageArray[1];
};
typedef struct ScriptLanguageSupport ScriptLanguageSupport;
typedef ScriptLanguageSupport * ScriptLanguageSupportPtr;
typedef ScriptLanguageSupportPtr * ScriptLanguageSupportHandle;
```

Fields

`fScriptLanguageCount`
An integer specifying the number of `ScriptLanguageRecord` structures provided in the `fScriptLanguageArray` field.

`fScriptLanguageArray`
A variable-length array of structures of type `ScriptLanguageRecord` (page 1614). Each of these structures identifies a specific script-language combination.

Discussion
A structure of type `ScriptLanguageSupport` is used in the function `GetScriptLanguageSupport` (page 1588) to list all of a component's supported scripts and languages. If you are a component developer filling out a `ScriptLanguageSupport` structure, you should start with the component's primary script and language as specified in the `componentFlags` field of its `ComponentDescription` structure.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextServices.h`

TextServiceInfo

Identifies a single text service component by name and `Component` value.

```
struct TextServiceInfo {
    Component fComponent;
    Str255 fItemName;
};
typedef struct TextServiceInfo TextServiceInfo;
typedef TextServiceInfo *TextServiceInfoPtr;
```

Fields

`fComponent`
A Component Manager value of type `Component`. A `Component` value is a pointer to an opaque structure called a `ComponentRecord` that describes a component. You must supply a `Component` value in the function `OpenTextService` (page 1597).

`fItemName`
A Pascal string with the name of a text service component. (The script system to use for displaying the string is specified in the `componentFlags` field of a `ComponentDescription` structure.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextServices.h`

TextServiceList

Lists one or more text service components by name and `Component` value.

```
struct TextServiceList {
    short fTextServiceCount;
    TextServiceInfo fServices[1];
};
typedef struct TextServiceList TextServiceList;
typedef TextServiceList * TextServiceListPtr;
typedef TextServiceListPtr * TextServiceListHandle;
```

Fields
`fTextServiceCount`
An integer specifying the number of `TextServiceInfo` structures in the text service component list provided in the `fServices` field.

`fServices`
A variable-length array of structures of type `TextServiceInfo` (page 1615). Each `TextServiceInfo` structure identifies a specific component by name and `Component` value.

Discussion
A structure of type `TextServiceInfo` is used in the function `GetServiceList` (page 1589) to list of all the text service components of a specified type that are currently available on a system.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextServices.h`

TextServicePropertyValue

Defines a data type for text service property values.

```
typedef SInt32 TextServicePropertyValue;
```

Discussion
The property values associated with this data type are "Text Services Property Values" (page 1641). Note that these values are declared as `CFStringRef` data types, so they require a cast to the `SInt32` data type before you can supply them as a `TextServicePropertyValue`.

Availability
Available in Mac OS X v10.3 and later.

Declared In
TextServices.h

TSMContext

A reference to an opaque object that specifies a TSM context.

```
typedef struct OpaqueTSMContext * TSMContext;
```

Availability
Available in Mac OS X v10.0 through Mac OS X v10.2.

Declared In
TextServices.h

TSMDocumentID

A reference to an opaque object that identifies a specific TSM document.

```
typedef struct OpaqueTSMDocumentID * TSMDocumentID;
```

Discussion
Each time a client application calls the function NewTSMDocument (page 1595), the Text Services Manager creates an opaque internal structure called a TSM Document and returns a pointer to the document's identification number.

Availability
Available in Mac OS X v10.0 and later.

Declared In
TextServices.h

TSMGlyphInfo

Describes one glyph embedded in a run of text.

```
struct TSMGlyphInfo {
    CFRange range;
    ATSFontRef fontRef;
    UInt16 collection;
    UInt16 glyphID;
};
typedef struct TSMGlyphInfo TSMGlyphInfo;
```

Fields

range
: A CFRange data structure that specifies, in UTF-16 offsets, a range within the text to which this TSMGlyphInfo data structure applies. I

fontRef
: An ATS font reference that specifies the font with which the glyph should be displayed. Note that the character collection ROS (Adobe Registry, Ordering, Supplement) is a property of the font.

`collection`

A glyph collection type that specifies how the `glyphID` parameter should be interpreted. When the value is `kGlyphCollectionID`, `glyphID` specifies the glyph's ID. When `collection` is a non-zero value, it specifies a character collection and `glyphID` specifies a CID. Note that `collection` must match the character collection of the font specified by the `fontRef` parameter.

When collections do not match, the `TSMGlyphInfo` data structure is invalid and should be ignored. You need to supply an ATSUI constant of type `GlyphCollection` to specify the character set you want to use. See *Inside Mac OS X: ATSUI Reference* for a list of the glyph collection constants you can specify.

`glyphID`

A glyph ID that specifies the glyph to use you to use in place of the current glyph. If you pass 0 instead of specifying a glyph, the `TSMGlyphInfo` data structure is used to attach a font to a range of text. In this case, the `fontRef` parameter specifies a font that should be used to display the range of text specified by the `range` parameter. This is useful when using characters in the Unicode private use area. Windings and other Windows based pi fonts are examples of such characters. When `glyphID` is zero, `collection` should also be zero and applications should ignore its value.

Discussion
The `TSMGlyphInfo` data structure is used as an item in the `TSMGlyphInfoArray` (page 1618) data structure. You use these structures to provide TSM with glyph and font information when you want to override the current glyph or font.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`TextServices.h`

TSMGlyphInfoArray

Contains an array of glyph information structures.

```
struct TSMGlyphInfoArray {
    ItemCount numGlyphInfo;
    TSMGlyphInfo glyphInfo[1];
};
typedef struct TSMGlyphInfoArray TSMGlyphInfoArray;
```

Fields
`numGlyphInfo`

The number of items in the `glyphInfo` array.

`glyphInfo`

An array of glyph information structures.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`TextServices.h`

Constants

Attribute Bits for TSM Document Access Carbon Events

Represents TSM document attributes.

```
enum {
    kTSMDocAccessFontSizeAttributeBit = 0,
    kTSMDocAccessEffectiveRangeAttributeBit = 1
};
```

Constants

`kTSMDocAccessFontSizeAttributeBit`

When this bit is set, indicates to obtain font size information; used in the Carbon event `kEventTSMDocumentAccessGetFont`.

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

`kTSMDocAccessEffectiveRangeAttributeBit`

When this bit is set, indicates to obtain effective range information used in the Carbon events `kEventTSMDocumentAccessGetFont` and `kEventTSMDocumentAccessGetGlyphInfo`.

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

Discussion

These bit assignments are used for the TSM document access attribute parameters. You can use these bits to specify desired (optional) attributes in the `kEventParamTSMDocAccessRequestedCharacterAttributes` parameter available for the events `kEventTSMDocumentAccessGetFont` and `kEventTSMDocumentAccessGetGlyphInfo`.

Availability

Not available in CarbonLib.

Available in Mac OS X v 10.3 and later.

Attribute Masks for TSM Document Access Carbon Events

Used to set or test for document-access attributes.

```
typedef UInt32 TSMDocAccessAttributes;
enum {
    kTSMDocAccessFontSizeAttribute = 1L << kTSMDocAccessFontSizeAttributeBit,
    kTSMDocAccessEffectiveRangeAttribute = 1L <<
kTSMDocAccessEffectiveRangeAttributeBit
};
```

Constants

`kTSMDocAccessFontSizeAttribute`

Use to set or test for the `kTSMDocAccessFontSizeAttributeBit` bit.

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

`kTSMDocAccessEffectiveRangeAttribute`
Use to set or test for the `kTSMDocAccessEffectiveRangeAttributeBit` bit.

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

Availability
Not available in CarbonLib.
Available in Mac OS X v 10.3 and later.

Carbon Event Class for TSM Document Access

Defines a constant for the Carbon event class used to allow TSM access to application documents content.

```
enum {
    kEventClassTSMDocumentAccess = 'tdac'
};
```

Constants
`kEventClassTSMDocumentAccess`
Used to request and deliver document content information. The events associated with this class provide text access, text attribute access, and transaction information. See "Carbon Events for TSM Document Access" (page 1620) for a list of the events defined for this class.

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

Discussion
The Text Services Manager (TSM) dispatches TSM document access events as Carbon events. You must install a Carbon event handler to access these events because they are not available through AppleEvent handlers.

Text Services dispatches these Carbon events through the function `SendTextInputEvent` (page 1600).

Availability
Not available in CarbonLib.
Available in Mac OS X v 10.3 and later.

Carbon Events for TSM Document Access

Define constants for the Carbon events associated with the TSM document access event class.

```
enum {
    kEventTSMDocumentAccessGetLength = 1,
    kEventTSMDocumentAccessGetSelectedRange = 2,
    kEventTSMDocumentAccessGetCharactersPtr = 3,
    kEventTSMDocumentAccessGetCharactersPtrForLargestBuffer = 4,
    kEventTSMDocumentAccessGetCharacters = 5,
    kEventTSMDocumentAccessGetFont = 6,
    kEventTSMDocumentAccessGetGlyphInfo = 7,
    kEventTSMDocumentAccessLockDocument = 8,
    kEventTSMDocumentAccessUnlockDocument = 9
};
```

Constants

`kEventTSMDocumentAccessGetLength`

Returns the number of 16-bit Unicode characters in the document.

You can obtain the following event parameters from this event:

- `kEventParamTSMDocAccessSendComponentInstance`. This parameter is provided by the text service originating the event.
- `kEventParamTSMDocAccessSendRefCon`. The TSM function `SendTextInputEvent` (page 1600), called by an input method, inserts this parameter before dispatching the event to the user focus.
- `kEventParamTSMDocAccessCharacterCount`. The size of the document in `UniChar` characters.

You can obtain the same information from this event as you can by calling the function `CFStringGetLength`, passing the document content formatted as a CFString.

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

`kEventTSMDocumentAccessGetSelectedRange`

Returns the selection range in the document.

You can obtain the following event parameters from this event:

- `kEventParamTSMDocAccessSendComponentInstance`. This parameter is provided by the text service originating the event. This can be `NULL` for input methods of the palette class, such as the typography panel.
- `kEventParamTSMDocAccessSendRefCon`. The TSM function `SendTextInputEvent` (page 1600), called by an input method, inserts this parameter before dispatching the event to the user focus.
- `kEventParamTSMDocAccessReplyCharacterRange`. The selection range as a CFRange in `UniChar` characters. If the selection is empty, the range identifies the insertion point and the range specifies a length of 0.

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

`kEventTSMDocumentAccessGetCharactersPtr`

Returns a Unicode pointer to the entire document content. Handle this event when your application has access to the entire document. If your application has access to a cache, use the event `kEventTSMDocumentAccessGetCharactersPtrForLargestBuffer`.

Some text engines may not support this event for reasons that are implementation-dependent. For example, a text engine backing store may consist of legacy encoding runs. It may also consist of unflattened Unicode, stored as a B-tree of text blocks. For such reasons, a text engine may reject a request for a pointer to a flattened Unicode buffer. Note that text access through this pointer is to be strictly read-only, so any changes to the document should be made through TSM text input events, such as `kEventTextInputUpdateActiveInputArea` or `kEventTextInputUnicodeText`. This pointer is valid only during a transaction surrounded by document lock/unlock events, or until an event causes the document to change, such as dispatching `kEventTextInputUpdateActiveInputArea` or `kEventTextInputUnicodeText` events, whichever occurs first.

You can obtain the following event parameters from this event:

- `kEventParamTSMDocAccessSendComponentInstance`. This parameter is provided by the input method originating the event.
- `kEventParamTSMDocAccessSendRefCon`. The TSM function `SendTextInputEvent` (page 1600), called by an input method, inserts this parameter before dispatching the event to the user focus.
- `kEventParamTSMDocAccessReplyCharactersPtr`. The `UniChar` pointer to the document.

You can obtain the same information from this event as you can by calling the function `CFStringGetCharactersPtr`, passing the document content formatted as a CFString.

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

`kEventTSMDocumentAccessGetCharactersPtrForLargestBuffer`

Returns a Unicode pointer to a portion of the document. Handle this event when your application has access to a cache. If your application has access to the entire document, use the event `kEventTSMDocumentAccessGetCharactersPtr`.

Some text engines keep text in unflattened Unicode—for example, stored as a B-tree of text blocks. Sometimes, especially for chunks of text near the insertion point, the text engine caches a chunk of text to which it can readily provide a pointer. But because the text is not flattened, the text engine might reject a request for such a pointer. See the Discussion for more information.

Note that text access through this pointer is strictly read-only, so any changes to the document should be made through TSM text input events, such as `kEventTextInputUpdateActiveInputArea` or `kEventTextInputUnicodeText`. This pointer is valid only during a transaction surrounded by document lock/unlock, or until an event causes the document to change, such as dispatching `kEventTextInputUpdateActiveInputArea` or `kEventTextInputUnicodeText` events.

You can obtain the following event parameters from this event:

- `kEventParamTSMDocAccessSendComponentInstance`. This parameter is provided by the input method originating the event.
- `kEventParamTSMDocAccessSendRefCon`. The TSM function `SendTextInputEvent`, called by an input method, inserts this parameter before dispatching the event to the user focus.
- `kEventParamTSMDocAccessSendCharacterIndex`. The location in the document for which the caller wants a pointer to a buffer of text that includes that location. This buffer could be available from a cache due to recent interaction near that location, such as the insertion point.
- `kEventParamTSMDocAccessReplyCharactersPtr`. The `UniChar` pointer to a portion of the document text.
- `kEventParamTSMDocAccessReplyCharacterRange`. A `CFRange` value for the text returned by the text pointer. The initial offset in the range is document-relative.

This event is similar to calling the function `CFStringGetCharactersPtr` on a portion of the document content formatted as a CFString, except that the substring is determined by the text engine.

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

`kEventTSMDocumentAccessGetCharacters`

This fills a caller provided buffer with Unicode characters in the specified range. This event is equivalent to calling the function `CFStringGetCharacters` on the document content treated as a CFString.

You can obtain the following event parameters from this event:

- `kEventParamTSMDocAccessSendComponentInstance`. This parameter is provided by the input method originating the event.
- `kEventParamTSMDocAccessSendRefCon`. The TSM function `SendTextInputEvent`, called by an input method, inserts this parameter before dispatching the event to the user focus.
- `kEventParamTSMDocAccessSendCharacterRange`. The range of text that should be copied into the buffer provided by the caller.
- `kEventParamTSMDocAccessSendCharactersPtr`. A buffer provided by the caller to contain the specified range of `UniChar` characters. This buffer is identical in usage to the one used in the function `CFStringGetCharacters`.

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

`kEventTSMDocumentAccessGetFont`

Returns font, font size, and the range over which these attributes are constant. Where the font/font size attributes span multiple characters, an effective range (over which requested attributes are constant) is returned by the text engine.

You can obtain the following event parameters from this event:

- `kEventParamTSMDocAccessSendComponentInstance`. This parameter is provided by the input method originating the event.
- `kEventParamTSMDocAccessSendRefCon`. The TSM function `SendTextInputEvent`, called by an input method, inserts this parameter before dispatching the event to the user focus.
- `kEventParamTSMDocAccessSendCharacterIndex`. The location in the document for which the caller would like font information.
- `kEventParamTSMDocAccessRequestedCharacterAttributes`. A `TSMDocAccessAttributes` bit field filled out with the desired attributes. Applicable values for this event are: `kTSMDocAccessFontSizeAttribute` which requests font size information through the `kEventParamTSMDocAccessReplyFontSize` parameter, and `kTSMDocAccessEffectiveRangeAttribute` which requests the text range over which font or font/size is constant.
- `kEventParamTSMDocAccessReplyATSFont`. The `ATSFontRef` for the location specified by the caller.
- `kEventParamTSMDocAccessReplyFontSize`. The font size for the requested location. This is an optional reply parameter. Return this information if `kTSMDocAccessFontSizeAttribute` is specified in the bit field passed as the `kEventParamTSMDocAccessRequestedCharacterAttributes` parameter.
- `kEventParamTSMDocAccessSendCharacterRange`. The maximum range of text the caller cares about. This is used to restrict the area of interest to the caller so the text engine doesn't process more characters than necessary in order to return an effective range.
- `kEventParamTSMDocAccessEffectiveRange`. The range of text over which both font and size are constant, within the bounds of the `kEventParamTSMDocAccessSendCharacterRange` parameter. This is an optional reply parameter. Return this information if `kTSMDocAccessEffectiveRangeAttribute` is specified in the bit field passed as the `kEventParamTSMDocAccessRequestedCharacterAttributes` parameter.

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

`kEventTSMDocumentAccessGetGlyphInfo`

Returns glyph info and the range covered by that glyph. Where a glyph spans multiple characters, the effective range, represented by the glyph, is returned by the application.

You can obtain the following event parameters from this event:

- `kEventParamTSMDocAccessSendComponentInstance`. This parameter is provided by the input method originating the event.
- `kEventParamTSMDocAccessSendRefCon`. The TSM function `SendTextInputEvent`, called by an input method, inserts this parameter before dispatching the event to the user focus.
- `kEventParamTSMDocAccessSendCharacterIndex`. The location in the document for which the caller would like glyph information.
- `kEventParamTSMDocAccessRequestedCharacterAttributes`. A `TSMDocAccessAttributes` bit field filled out with the information desired. The applicable value for this event is `kTSMDocAccessEffectiveRangeAttribute`, which requests the text range represented by a glyph.
- `kEventParamTSMDocAccessReplyATSUGlyphSelector`. The glyph used to display the range of text returned in the `kEventParamTSMDocAccessEffectiveRange` parameter. If the glyph used is the one that ATSUI would normally derive, this parameter can be omitted.
- `kEventParamTSMDocAccessEffectiveRange`. The range of text displayed as a glyph ID or CID. This is an optional reply parameter. Return this information if `kTSMDocAccessEffectiveRangeAttribute` is specified in the bit field passed as the `kEventParamTSMDocAccessRequestedCharacterAttributes` parameter.

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

`kEventTSMDocumentAccessLockDocument`

Notifies the application that it should not change its document's text content (on its own) while a text service is involved in a transaction. The application should not allow changes, for example, by its secondary threads. This type of event defines how a text service can obtain access to a document in a way that ensures data integrity during its transaction. The event can be used to prevent the application from letting its secondary threads modify the document while a text service is busy servicing an event, such as a key event, or some user interaction with text-service-provided user interface such as a menu selection. Also, while the document is locked, a text service is free to request pointer access to the document's text content (if this is supported by the application's text engine.) These lock-related events should be implemented using a retention counting scheme. Most applications will not support this kind of threading, so implementation of these events in the text engine are optional. In most text engines, the implementation of these events should be trivial, that is, just maintain a simple semaphore. TSM itself will implicitly lock/unlock around normal entry points into a text service, such as when it delivers key events to an input method, but there may be times when document changes can be driven by an input method without TSM involvement, such as the Carbon events involved when the user interacts with some user interface. In this case, the input method must manage locking, if the application supports it. However, the logic in an input method should not depend on whether TSM is in the call chain or not, and TSM should not depend on whether an input method performs correctly. This is why the lock mechanism needs to be some kind of retention counting scheme instead of a simple on and off mechanism. Document lock support is optional on the part of the text engine (if it is not threaded). TSM implicitly locks/unlocks the document around delivery of events to input methods, if the application supports it.You can obtain the following event parameters from this event:

- `kEventParamTSMDocAccessSendComponentInstance`. This parameter is provided by the input method originating the event.
- `kEventParamTSMDocAccessSendRefCon`. The TSM function `SendTextInputEvent` (page 1600), called by an input method, inserts this parameter before dispatching the event to the user focus.
- `kEventParamTSMDocAccessLockCount`. The resulting retention count of locks on the document.

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

`kEventTSMDocumentAccessUnlockDocument`

Unlock the document so the application text engine is free to initiate changes again. (See `kEventTSMDocumentAccessLockDocument`).

You can obtain the following event parameters from this event:

- `kEventParamTSMDocAccessSendComponentInstance`. This parameter is provided by the input method originating the event.
- `kEventParamTSMDocAccessSendRefCon`. The TSM function `SendTextInputEvent`, called by an input method, inserts this parameter before dispatching the event to the user focus.
- `kEventParamTSMDocAccessLockCount`. The resulting retention count of locks on the document.

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

Discussion

Text-access events are very similar in design to the CFString API. You can think of an entire document as a flattened Unicode string, and the events in this interface can access any portion of it. Just as the text is Unicode, the text offsets are also Unicode.

The event `kEventTSMDocumentAccessGetSelectedRange` allows a text service to obtain text near the insertion point (or selection), but access is by no means restricted to this vicinity. Use the event `kEventTSMDocumentAccessGetLength` to obtain the size of the document.

Supporting these events effectively provide hooks into the text engine, but it is understood that access to a document in this way is strictly read-only. Where direct access to document content cannot be provided through a pointer, the requested text can be copied instead. Situations where a pointer may not be available from the text engine include the following:

- The pointer requires conversion of text in Mac encodings to Unicode.
- The pointer requires sparse Unicode text blocks to be flattened into a single buffer.

The idea is to minimize copying and converting text encodings where possible. The text service typically begins by asking for a document pointer through the event `kEventTSMDocumentAccessGetCharactersPtr`. If this fails, it typically falls back to the event `kEventTSMDocumentAccessGetCharactersPtrForLargestBuffer`, specifying a location of interest. If this fails, it falls back to `kEventTSMDocumentAccessGetCharacters`, specifying a range of interest. Of course, when requesting small amounts of data with such a few characters on either side of the insertion point, there is no obligation to optimize in this way. It's valid to simply use `kEventTSMDocumentAccessGetCharacters`.

The text engine is entirely free to deny a request for a text pointer for these or any other implementation-specific reason.

Availability
Not available in CarbonLib.
Available in Mac OS X v 10.3 and later.

Carbon Event Parameters for General TSM Events

Define general parameters for TSM events.

```
enum {
    kEventParamTSMSendRefCon      = 'tsrc',
    kEventParamTSMSendComponentInstance = 'tsci'
};
```

Constants

`kEventParamTSMSendRefCon`
This parameter is equivalent to the text input parameter `kEventParamTextInputSendRefCon`; the parameter data type is `typeLongInteger`.
Available in Mac OS X v10.3 and later.
Declared in `CarbonEvents.h`.

`kEventParamTSMSendComponentInstance`
This parameter is equivalent to the text input parameter `kEventParamTextInputSendComponentInstance`; the parameter data type is `typeComponentInstance`.
Available in Mac OS X v10.3 and later.
Declared in `CarbonEvents.h`.

Availability
Not available in CarbonLib.
Available in Mac OS X v 10.3 and later.

Carbon Event Parameters for TSM Document Access

Define document access parameters for TSM events.

```
enum {
    kEventParamTSMDocAccessSendRefCon = kEventParamTSMSendRefCon,
    kEventParamTSMDocAccessSendComponentInstance =
kEventParamTSMSendComponentInstance,
    kEventParamTSMDocAccessCharacterCount = 'tdct',
    kEventParamTSMDocAccessReplyCharacterRange = 'tdrr',
    kEventParamTSMDocAccessReplyCharactersPtr = 'tdrp',
    kEventParamTSMDocAccessSendCharacterIndex = 'tdsi',
    kEventParamTSMDocAccessSendCharacterRange = 'tdsr',
    kEventParamTSMDocAccessSendCharactersPtr = 'tdsp',
    kEventParamTSMDocAccessRequestedCharacterAttributes = 'tdca',
    kEventParamTSMDocAccessReplyATSFont = 'tdaf',
    kEventParamTSMDocAccessReplyFontSize = 'tdrs',
    kEventParamTSMDocAccessEffectiveRange = 'tder',
    kEventParamTSMDocAccessReplyATSUGlyphSelector = 'tdrg',
    kEventParamTSMDocAccessLockCount = 'tdlc',
    typeATSFontRef                = 'atsf',
    typeGlyphSelector             = 'glfs'
};
```

Constants

`kEventParamTSMDocAccessSendRefCon`
The TSM function `SendTextInputEvent` (page 1600), called by an input method, inserts this parameter before dispatching the event to the user focus. The parameter data type is `typeLongInteger`.

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

`kEventParamTSMDocAccessSendComponentInstance`
The parameter data type is `typeComponentInstance`.

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

`kEventParamTSMDocAccessCharacterCount`
The parameter data type is `typeCFIndex`.

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

`kEventParamTSMDocAccessReplyCharacterRange`
The parameter data type is `typeCFRange`.

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

`kEventParamTSMDocAccessReplyCharactersPtr`
The parameter data type is `typePtr`.
Available in Mac OS X v10.3 and later.
Declared in `CarbonEvents.h`.

`kEventParamTSMDocAccessSendCharacterIndex`
The parameter data type is `typeCFIndex`.
Available in Mac OS X v10.3 and later.
Declared in `CarbonEvents.h`.

`kEventParamTSMDocAccessSendCharacterRange`
The parameter data type is `typeCFRange`.
Available in Mac OS X v10.3 and later.
Declared in `CarbonEvents.h`.

`kEventParamTSMDocAccessSendCharactersPtr`
The parameter data type is `typePtr`.
Available in Mac OS X v10.3 and later.
Declared in `CarbonEvents.h`.

`kEventParamTSMDocAccessRequestedCharacterAttributes`
The parameter data type is `typeUInt32`.
Available in Mac OS X v10.3 and later.
Declared in `CarbonEvents.h`.

`kEventParamTSMDocAccessReplyATSFont`
The parameter data type is `typeATSFontRef`.
Available in Mac OS X v10.3 and later.
Declared in `CarbonEvents.h`.

`kEventParamTSMDocAccessReplyFontSize`
The parameter data type is `typeFloat`.
Available in Mac OS X v10.3 and later.
Declared in `CarbonEvents.h`.

`kEventParamTSMDocAccessEffectiveRange`
The parameter data type is `typeRange`.
Available in Mac OS X v10.3 and later.
Declared in `CarbonEvents.h`.

`kEventParamTSMDocAccessReplyATSUGlyphSelector`
The parameter data type is `typeGlyphSelector`.
Available in Mac OS X v10.3 and later.
Declared in `CarbonEvents.h`.

`kEventParamTSMDocAccessLockCount`
The parameter data type is `typeCFIndex`.
Available in Mac OS X v10.3 and later.
Declared in `CarbonEvents.h`.

`typeATSFontRef`
The parameter data type is `ATSFontRef`.

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

`typeGlyphSelector`
The parameter data type is `ATSUGlyphSelector`.

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

Discussion
See "Carbon Events for TSM Document Access" (page 1620) for more information on these parameters and the information they contain for a specific event.

Availability
Not available in CarbonLib.
Available in Mac OS X v 10.3 and later.

Component Flags

Specify flags used for input method components.

```
enum {
    bTakeActiveEvent = 15,
    bHandleAERecording = 16,
    bScriptMask = 0x00007F00,
    bLanguageMask = 0x000000FF,
    bScriptLanguageMask = bScriptMask + bLanguageMask
};
```

Constants
`bTakeActiveEvent`
This bit is set if the component takes an active event,

Available in Mac OS X v10.0 and later.

Declared in `TextServices.h`.

`bHandleAERecording`
This bit is set if the component takes care of recording Apple Events.

Available beginning with version 2.0.

Declared in `TextServices.h`.

`bScriptMask`
Specifies bits 8 - 14.

Available in Mac OS X v10.0 and later.

Declared in `TextServices.h`.

`bLanguageMask`
Specifies bits 0 - 7.

Available in Mac OS X v10.0 and later.

Declared in `TextServices.h`.

`bScriptLanguageMask`
Specifies bits 0 - 14.

Available in Mac OS X v10.0 and later.

Declared in `TextServices.h`.

Document Property Tags

Specify property tags for a TSM document.

```
typedef OSType      TSMDocumentPropertyTag;
enum {

kTSMDocumentSupportGlyphInfoPropertyTag = 'dpgi',
kTSMDocumentUseFloatingWindowPropertyTag = 'uswm',
kTSMDocumentUnicodeInputWindowPropertyTag = 'dpub',
kTSMDocumentSupportDocumentAccessPropertyTag = 'dapy',
kTSMDocumentRefconPropertyTag = 'refc',
kTSMDocumentInputModePropertyTag = 'imim',
kTSMDocumentPropertySupportGlyphInfo =
        kTSMDocumentSupportGlyphInfoPropertyTag,
kTSMDocumentPropertyUnicodeInputWindow =
        kTSMDocumentUnicodeInputWindowPropertyTag,
kTSMDocumentTextServicePropertyTag = kTextServiceDocumentInterfaceType,
kTSMDocumentUnicodePropertyTag = kUnicodeDocumentInterfaceType,
kTSMDocumentTSMTEPropertyTag  = kTSMTEDocumentInterfaceType
};
```

Constants

`kTSMDocumentSupportGlyphInfoPropertyTag`
The existence of this property in a TSM document indicates that the event handlers associated with he TSM document are aware of the TSM `GlyhInfo` data structure. This structure allows the input source producing text to apply Glyph IDs, CIDs, or fonts to subranges of text produced. This is useful or characters in Unicode private use area, such as Windings. For more information, see Technical Note TN2079 Glyph Access Protocol. By convention, this value can be a `UInt32` with a value of 0, but this is arbitrary. Available in TSM 1.5, in Mac OS X 10.2 and later.

Available in Mac OS X v10.3 and later.

Declared in `TextServices.h`.

`kTSMDocumentUseFloatingWindowPropertyTag`
The presence of this property tag indicates that the TSM document should use the TSM floating input window to handle input from input methods. This form of input does not support Unicode input by default, unless the property `kTSMDocumentUnicodeInputWindowPropertyTag` is set.

Available in Mac OS X v10.3 and later.

Declared in `TextServices.h`.

`kTSMDocumentUnicodeInputWindowPropertyTag`
The presence of this property tag indicates that although the TSM document has been told to use the TSM floating input window to handle input from input methods, the floating window is to support Unicode input. This is useful when non input-related activity is to produce Unicode, such as keyboard navigation.

Available in Mac OS X v10.3 and later.

Declared in `TextServices.h`.

`kTSMDocumentSupportDocumentAccessPropertyTag`

The presence of this property tag indicates that the event handlers associated with this TSM document support the TSM document access event suite (see "Carbon Events for TSM Document Access" (page 1620).) This property also indicates that the handler for the TSMevent `kEventTextInputUpdateActiveInputArea` supports the `replaceRange` parameter and that the handler is a Carbon event handler, not an AppleEvent handler.

Available in Mac OS X v10.3 and later.

Declared in `TextServices.h`.

`kTSMDocumentRefconPropertyTag`

The property value initially contains the `refcon` value passed to the function `NewTSMDocument`. This property is useful for changing the `refcon` value after the TSM document has been created. The `refcon` value is a `long`, the same as that passed to `NewTSMDocument`. Property is value-dependent; see the Discussion for more information.

Available in Mac OS X v10.3 and later.

Declared in `TextServices.h`.

`kTSMDocumentInputModePropertyTag`

The property value indicates which input mode should be used by the current keyboard-class input method. It is useful for temporarily restricting text input to a subset of characters normally produced by an input method in a given script, such as Katakana for Japanese input. See "Text Service Properties" (page 1640) for more details. Also note that this property tag and value are passed unchanged to the function "SetTextServiceProperty" (page 1603), so it also serves as a text service property tag. See `kTextServiceInputModePropertyTag` for discussion on the values associated with this property.

The property value is a `CFStringRef` data type. With the function `TSMGetTextServiceProperty`, the behavior is that of a Copy function. The implementation of `SetTextServiceProperty` (in the component) retains or copies the CFString object. In either case the caller is responsible for releasing the reference. Property is value-dependent; see the Discussion for more information.

Available in Mac OS X v10.3 and later.

Declared in `TextServices.h`.

`kTSMDocumentPropertySupportGlyphInfo`

You should no longer use this property.

Available in Mac OS X v10.2 and later.

Declared in `TextServices.h`.

`kTSMDocumentPropertyUnicodeInputWindow`

You should no longer use this property.

Available in Mac OS X v10.3 and later.

Declared in `TextServices.h`.

`kTSMDocumentTextServicePropertyTag`

Specifies a non-Unicode savvy document. This property is equivalent to a pre-existing document interface type.

Available in Mac OS X v10.3 and later.

Declared in `TextServices.h`.

`kTSMDocumentUnicodePropertyTag`

This property is equivalent to the Unicode document interface type.

Available in Mac OS X v10.3 and later.

Declared in `TextServices.h`.

`kTSMDocumentTSMTEPropertyTag`
This property is equivalent to the TSMTE document interface type.

Available in Mac OS X v10.3 and later.

Declared in `TextServices.h`.

Discussion
You can use the functions `TSMSetDocumentProperty` (page 1611) and `TSMGetDocumentProperty` (page 1607) to set and get arbitrary property data needed by your application.

Unless otherwise noted, all properties are read-only, value-independent, and available in TSM version 2.2, which is the version available starting in Mac OS X version 10.3.

Value-independent properties are used where the existence of the property, and not its value, is sufficient. These properties can read by other clients, and are most often used by input methods. For example, input methods can query the current TSM document to see if supports unrestricted Unicode input, or if it supports the `GlyphInfo` protocol.

Value-dependent properties are used when the value associated with a property is meaningful.

Input Method Identifier

Specifies a keyboard input method text service.

```
enum {
    kInputMethodService = kKeyboardInputMethodClass
};
```

Constants
`kInputMethodService`
A four-character code identifying an input method text service. Specifies that the older constant name `kInputMethodService` is equivalent to the newer constant name `kKeyboardInputMethodClass`.

Available in Mac OS X v10.0 and later.

Declared in `TextServices.h`.

Input Mode Dictionary Key

Defines a string for the input mode dictionary key that you can use in the Component bundle info.plist.

```
#define kComponentBundleInputModeDictKey  CFSTR("ComponentInputModeDict")
```

Discussion
If you are developing an input method, you use this key in the component bundle info.plist to identify a dictionary of input mode information. The dictionary should contain keys to identify input modes—see "Individual Input Mode Keys" (page 1635)—and should have the form described in the Discussion section of the function `CopyTextServiceInputModeList` (page 1579). The function `CopyTextServiceInputModeList` returns an input mode dictionary.

Input Mode Palette Menu Definition Keys

Defines keys used to describe the items in a pull-down menu.

```
#define kTSInputModePaletteItemTitleKey   CFSTR("tsInputModePaletteItemTitleKey")
#define kTSInputModePaletteItemKeyEquivalentKey
CFSTR("tsInputModePaletteItemKeyEquivalentKey")
#define kTSInputModePaletteItemKeyEquivalentModifiersKey
CFSTR("tsInputModePaletteItemKeyEquivalentModifiersKey")
```

Constants

`kTSInputModePaletteItemTitleKey`
A CFString that specifies a menu item title. Use - for a separator.

`kTSInputModePaletteItemKeyEquivalentKey`
A CFString that specifies a menu item keyboard shortcut .

`kTSInputModePaletteItemKeyEquivalentModifiersKey`
A CFNumber that specifies a menu item keyboard shortcut modifier (from Events.h).

Discussion

These keys are returned by the function `GetInputModePaletteMenu` (page 1587), in the `outMenuItemsArray` parameter. For information on the structure of the CFDictionary, see the TextServices.h header file.

Input Mode Palette Control Keys

Defines keys used to describe controls for an input palette.

```
#define kTSInputModePaletteItemTypeKey  CFSTR("tsInputModePaletteItemTypeKey")
#define kTSInputModePaletteItemIconKey   CFSTR("tsInputModePaletteItemIconKey")
#define kTSInputModePaletteItemAltIconKey   CFSTR("tsInputModePaletteItemAltIconKey")
#define kTSInputModePaletteItemStateKey   CFSTR("tsInputModePaletteItemStateKey")
#define kTSInputModePaletteItemEnabledKey   CFSTR("tsInputModePaletteItemEnabledKey")
#define kTSInputModePaletteItemIDKey    CFSTR("tsInputModePaletteItemIDKey")
```

Constants

`kTSInputModePaletteItemTypeKey`
A CFNumber that specifies the type of control (0: push button, 1: toggle button, 2: pull-down menu),

`kTSInputModePaletteItemIconKey`
A CFString that specifies an icon file name. The file should be located in the input method bundle resource directory, so this is just the file name, not full path.

`kTSInputModePaletteItemAltIconKey`
A CFString that specifies an alternate icon file name. The file should be located in the input method bundle resource directory, so this is just the file name, not full path.

`kTSInputModePaletteItemStateKey`
A CFNumber that specifies the state of the control (0: clear or unpressed, 1: checked or pressed, 2: mixed).

`kTSInputModePaletteItemEnabledKey`
A CFBoolean that specifies the enabled state of the control.

`kTSInputModePaletteItemIDKey`
A CFNumber that specifies a `UInt32` tag ID for the control.

Discussion

You use these keys in a CFDictionary that contains control descriptions passed to the functions `TSMInputModePaletteLoadButtons` (page 1609) and `TSMInputModePaletteUpdateButtons` (page 1609). For information on the structure of the CFDictionary, see the TextServices.h header file.

Individual Input Mode Keys

Defines keys used to identify input modes in an input mode dictionary.

```
#define kTSInputModeListKey CFSTR("tsInputModeListKey")
#define kTSInputModeMenuIconFileKey CFSTR("tsInputModeMenuIconFileKey")
#define kTSInputModeAlternateMenuIconFileKey
        CFSTR("tsInputModeAlternateMenuIconFileKey")
#define kTSInputModePaletteIconFileKey
        CFSTR("tsInputModePaletteIconFileKey")
#define kTSInputModeDefaultStateKey CFSTR("tsInputModeDefaultStateKey")
#define kTSInputModeScriptKey CFSTR("tsInputModeScriptKey")
#define kTSInputModePrimaryInScriptKey
        CFSTR("tsInputModePrimaryInScriptKey")
#define kTSInputModeIsVisibleKey      CFSTR("tsInputModeIsVisibleKey")
#define kTSInputModeKeyEquivalentModifiersKey
        CFSTR("tsInputModeKeyEquivalentModifiersKey")
#define kTSInputModeKeyEquivalentKey
            CFSTR("tsInputModeKeyEquivalentKey")
#define kTSInputModeJISKeyboardShortcutKey
        CFSTR("tsInputModeJISKeyboardShortcutKey")
```

Discussion
If you are developing an input method, you use these keys in a dictionary of input mode information. The Component bundle info.plist should an input mode dictionary key that identifies the dictionary—see "Input Mode Dictionary Key" (page 1633). The dictionary should have the form described in the Discussion section of the function `CopyTextServiceInputModeList` (page 1579). The function `CopyTextServiceInputModeList` returns an input mode dictionary.

Interfaces

Specify types of text services interfaces.

```
enum {
    kTextService = 'tsvc'
};
```

Constants
`kTextService`
A four-character code identifying a text service of any kind (including input methods). This value is also used to identify non-Unicode TSM documents.

Available in Mac OS X v10.0 and later.

Declared in `TextServices.h`.

Discussion
This constant is used in arrays of type `InterfaceTypeList` (page 1614). In addition to this constants, the constant `kTSMTEInterfaceType` (`'tmTE'`), from TSMTE.h, is a supported interface type that allows TextEdit to provide automatic inline input support in TextEdit documents.

Language and Script Constants

Specify the language or script is not known or neutral.

```
enum {
    kUnknownLanguage = 0xFFFF,
    kUnknownScript = 0xFFFF,
    kNeutralScript = 0xFFFF
};
```

Constants

`kUnknownLanguage`
Specifies an unknown language.
Available in Mac OS X v10.0 and later.
Declared in `TextServices.h`.

`kUnknownScript`
Specifies an unknown script.
Available in Mac OS X v10.0 and later.
Declared in `TextServices.h`.

`kNeutralScript`
Specifies a neutral script.
Available in Mac OS X v10.0 and later.
Declared in `TextServices.h`.

Low-level Routine Selectors

Specify low level routines which are dispatched directly to the Component Manager.

```
enum {
    kCMGetScriptLangSupport = 0x0001,
    kCMInitiateTextService = 0x0002,
    kCMTerminateTextService = 0x0003,
    kCMActivateTextService = 0x0004,
    kCMDeactivateTextService = 0x0005,
    kCMTextServiceEvent = 0x0006,
    kCMGetTextServiceMenu = 0x0007,
    kCMTextServiceMenuSelect = 0x0008,
    kCMFixTextService = 0x0009,
    kCMSetTextServiceCursor = 0x000A,
    kCMHidePaletteWindows = 0x000B,
    kCMGetTextServiceProperty = 0x000C,
    kCMSetTextServiceProperty = 0x000D
};
```

Constants

`kCMGetScriptLangSupport`
Specifies the function `GetScriptLanguageSupport` (page 1588); Component Manager call selector 1.
Available in Mac OS X v10.0 and later.
Declared in `TextServices.h`.

`kCMInitiateTextService`
Specifies the function `InitiateTextService` (page 1593); Component Manager call selector 2.
Available in Mac OS X v10.0 and later.
Declared in `TextServices.h`.

`kCMTerminateTextService`
Specifies the function `TerminateTextService` (page 1604); Component Manager call selector 3.

Available in Mac OS X v10.0 and later.

Declared in `TextServices.h`.

`kCMActivateTextService`
Specifies the function `ActivateTextService` (page 1577); Component Manager call selector 4.

Available in Mac OS X v10.0 and later.

Declared in `TextServices.h`.

`kCMDeactivateTextService`
Specifies the function `DeactivateTextService` (page 1580); Component Manager call selector 5.

Available in Mac OS X v10.0 and later.

Declared in `TextServices.h`.

`kCMTextServiceEvent`
Specifies the function `TextServiceEventRef` (page 1605); Component Manager call selector 6.

Available in Mac OS X v10.0 and later.

Declared in `TextServices.h`.

`kCMGetTextServiceMenu`
Specifies the function `GetTextServiceMenu` (page 1590); Component Manager call selector 7.

Available in Mac OS X v10.0 and later.

Declared in `TextServices.h`.

`kCMTextServiceMenuSelect`
Component Manager call selector 8.

Available in Mac OS X v10.0 and later.

Declared in `TextServices.h`.

`kCMFixTextService`
Specifies the function `FixTextService` (page 1583); Component Manager call selector 9.

Available in Mac OS X v10.0 and later.

Declared in `TextServices.h`.

`kCMSetTextServiceCursor`
Component Manager call selector 10.

Available in Mac OS X v10.0 and later.

Declared in `TextServices.h`.

`kCMHidePaletteWindows`
Specifies the function `HidePaletteWindows` (page 1592); Component Manager call selector 11.

Available in Mac OS X v10.0 and later.

Declared in `TextServices.h`.

`kCMGetTextServiceProperty`
Specifies the function `GetTextServiceProperty` (page 1591); Component Manager call selector 12.

Available in Mac OS X v10.0 and later.

Declared in `TextServices.h`.

`kCMSetTextServiceProperty`
Specifies the function `SetTextServiceProperty` (page 1603); Component Manager call selector 13.

Available in Mac OS X v10.0 and later.

Declared in `TextServices.h`.

New Low-level Routine Selector

Specifies new low-level routine that are dispatched directly to the Component Manager.

```
enum {
    kCMUCTextServiceEvent = 0x000E
};
```

Constants

`kCMUCTextServiceEvent`
Component Manager call selector 14.

Available in Mac OS X v10.0 and later.

Declared in `TextServices.h`.

Text Service Classes

Specify text service classes supported by TSM.

```
enum {
    kKeyboardInputMethodClass = 'inpm',
    kInkInputMethodClass = 'ink ',
    kCharacterPaletteInputMethodClass = 'cplt',
    kSpeechInputMethodClass = 'voic',
    kOCRInputMethodClass = 'ocr '
};
typedef OSType TextServiceClass;
```

Constants

`kKeyboardInputMethodClass`
Specifies a text service class for keyboard input methods. Behavior is exclusive. Input methods in this class are normally associated with a Mac ScriptCode or Unicode, although they can be associated with several scripts by adopting the input mode protocol.

Available in Mac OS X v10.2 and later.

Declared in `TextServices.h`.

`kInkInputMethodClass`
Specifies a text service class for Ink input methods. Behavior is additive. Text services in the Ink class do not belong to any given script in the sense that those of the Keyboard class do. Once selected, this kind of text service remains active regardless of the current keyboard script. Although text services in this class are keyboard script agnostic, similar to input methods of the keyboard class they can still profess to produce only those Unicodes that are encoded in the Mac encoding specified in their component description record or their implementation of the `GetScriptLanguageSupport` component call.

Available in Mac OS X v10.2 and later.

Declared in `TextServices.h`.

`kCharacterPaletteInputMethodClass`
: Specifies a text service class for Character Palette input methods. Behavior is additive. Text services in the character palette class do not belong to any given script in the same sense that do those of the keyboard class. Once selected, this kind of text service remains active regardless of the current keyboard script. Although text services in this class are keyboard script agnostic, similar to input methods of the keyboard class, they can still produce only those Unicodes that are encoded in the Mac encoding specified in their component description record or their implementation of the `GetScriptLanguageSupport` component call. Unlike input methods in the keyboard class, multiple such text services can be activate in parallel. Mac OS X provides a System user interface to allow the user to both enable and select multiple such input methods.

  Available in Mac OS X v10.2 and later.

  Declared in `TextServices.h`.

`kSpeechInputMethodClass`
: Specifies a text service class for Speech input methods. Behavior is additive. Similar to Character palette class.

  Available in Mac OS X v10.3 and later.

  Declared in `TextServices.h`.

`kOCRInputMethodClass`
: Specifies a text service class for Optical Character Recognition input methods. Behavior is additive. Similar to Character palette class.

  Available in Mac OS X v10.3 and later.

  Declared in `TextServices.h`.

Discussion
Text service classes fall in two categories or behaviors. Text services that belong to some classes are exclusive of one another within a given Mac script code, such input methods of the keyboard class. Input Methods of other classes are additive in nature, regardless of the current keyboard script.

Within a given class and script, exclusive input methods can only be activated one at a time. Input methods in additive classes are keyboard script agnostic and can be active in parallel with other text services in the same class, such as multiple character palettes.

These are the same as the component subtype for the component description.

Text Service Version

Specifies the interface type for version 2.

```
enum {
    kTextServiceVersion2 = 'tsv2'
};
```

Constants
`kTextServiceVersion2`
: The interface type for V2 interfaces

  Available in Mac OS X v10.0 through Mac OS X v10.2.

  Declared in `TextServices.h`.

Text Service Properties

Specify a feature or functionality of a component.

```
typedef OSType TextServicePropertyTag;
enum {
    kTextServiceInputModePropertyTag = kTSMDocumentInputModePropertyTag,
    kIMJaTypingMethodRoman = 'roma',
    kIMJaTypingMethodKana = 'kana',
    kIMJaTypingMethodProperty = kTextServiceJaTypingMethodPropertyTag,
    kTextServiceJaTypingMethodPropertyTag = 'jtyp'
};
```

Constants

`kTextServiceInputModePropertyTag`
Specifies the input mode property for input methods. This property is a CFString object that uniquely identifies which input mode should be made current by a keyboard class input method, if possible. This property tag is identical to the tag `kTSMDocumentInputModePropertyTag` passed to the function `TSMDocumentProperty`. This allows the tag and value to be passed through without interpretation.

Available in Mac OS X v10.3 and later.

Declared in `TextServices.h`.

`kIMJaTypingMethodRoman`
Not recommended. Specify Japanese input in Roman script.

Available in Mac OS X v10.0 and later.

Declared in `TextServices.h`.

`kIMJaTypingMethodKana`
Not recommended. Specify Japanese input in Kana script.

Available in Mac OS X v10.0 and later.

Declared in `TextServices.h`.

`kIMJaTypingMethodProperty`
Deprecated. Specify the typing method as Japanese input. This property is deprecated. Use the tag `kTextServiceInputModePropertyTag` instead.

Available in Mac OS X v10.0 and later.

Declared in `TextServices.h`.

`kTextServiceJaTypingMethodPropertyTag`
Deprecated.Use the tag `kTextServiceInputModePropertyTag` instead.

Available in Mac OS X v10.3 and later.

Declared in `TextServices.h`.

Discussion

Text Service Property constants are used in `SetTextServiceProperty` (page 1603) and `GetTextServiceProperty` (page 1591). The only property that is recommend for you to use is the property `kTextServiceInputModePropertyTag`.

Input modes are either generic (pre-defined by TSM), or specific to an input method. An example of a generic input mode is Katakana input (Japanese) where input in a text field needs to be restricted to that character subset. Another is Roman input mode. This is useful to temporarily provide Roman input from an input method that normally allows text input in another script. The advantage to using Roman input mode over

forcing the keyboard script to Roman is that the same user interface for the input method continues to be available to the user, even though the input script changed. An example of a special input mode (input method specific) is Hanin input mode in Traditional Chinese input methods.

To temporarily change the current input mode from whatever it is to a generic one, use the function `GetTextServiceProperty` to obtain the current input mode, then call the function `SetTextServiceProperty` to switch to the generic mode. When done using the generic input mode, you can restore the original input mode.

You can find out what input modes are supported by an input method by calling the function `CopyTextServiceInputModeList`. If the input method does not support a specified input mode, the functions `GetTextServiceProperty` and `SetTextServiceProperty` return the result `tsmComponentPropertyUnsupportedErr`. The function `GetTextServiceProperty` returns the result `tsmComponentPropertyNotFoundErr`.

Text Services Property Values

Define values for the text services input mode property tags.

```
#define kTextServiceInputModeRoman     CFSTR("com.apple.inputmethod.Roman")
#define kTextServiceInputModePassword
        CFSTR("com.apple.inputmethod.Password")
#define kTextServiceInputModeJapaneseHiragana
    CFSTR("com.apple.inputmethod.Japanese.Hiragana")
#define kTextServiceInputModeJapaneseKatakana
    CFSTR("com.apple.inputmethod.Japanese.Katakana")
#define kTextServiceInputModeJapaneseFullWidthRoman
    CFSTR("com.apple.inputmethod.Japanese.FullWidthRoman")
#define kTextServiceInputModeJapaneseHalfWidthKana
    CFSTR("com.apple.inputmethod.Japanese.HalfWidthKana")
#define kTextServiceInputModeJapanesePlaceName
    CFSTR("com.apple.inputmethod.Japanese.PlaceName")
#define kTextServiceInputModeJapaneseFirstName
    CFSTR("com.apple.inputmethod.Japanese.FirstName")
#define kTextServiceInputModeJapaneseLastName
    CFSTR("com.apple.inputmethod.Japanese.LastName")
#define kTextServiceInputModeBopomofo
    CFSTR("com.apple.inputmethod.TradChinese.Bopomofo")
#define kTextServiceInputModeTradChinesePlaceName
    CFSTR("com.apple.inputmethod.TradChinese.PlaceName")
#define kTextServiceInputModeHangul
    CFSTR("com.apple.inputmethod.Korean.Hangul")
#define kTextServiceInputModeJapanese
    CFSTR("com.apple.inputmethod.Japanese")
#define kTextServiceInputModeTradChinese
    CFSTR("com.apple.inputmethod.TradChinese")
#define kTextServiceInputModeSimpChinese
    CFSTR("com.apple.inputmethod.SimpChinese")
#define kTextServiceInputModeKorean
    CFSTR("com.apple.inputmethod.Korean")
```

Constants

`kTextServiceInputModeRoman`
Specifies to restrict output to Roman characters only.

`kTextServiceInputModePassword`
`kTextServiceInputModeJapaneseHiragana`
Specifies to restrict output to Hiragana characters only (no conversion to Kanji, that is, yomi).

`kTextServiceInputModeJapaneseKatakana`
Specifies to restrict output to Katakana characters only (no conversion to Kanji).

`kTextServiceInputModeJapaneseFullWidthRoman`
`kTextServiceInputModeJapaneseHalfWidthKana`
`kTextServiceInputModeJapanesePlaceName`
`kTextServiceInputModeJapaneseFirstName`
`kTextServiceInputModeJapaneseLastName`
`kTextServiceInputModeBopomofo`
Specifies to restrict output to Bopomofo characters only (no conversion to Han).

`kTextServiceInputModeTradChinesePlaceName`
Specifies to restrict output to traditional chines place name.

`kTextServiceInputModeHangul`
Specifies to restrict output to Hangul syllables only (no conversion to Hanja).

`kTextServiceInputModeJapanese`
Specifies unrestricted Japanese output.

`kTextServiceInputModeTradChinese`
Specifies traditional Chinese generic (unrestricted) input mode.

`kTextServiceInputModeSimpChinese`
Specifies simplified Chinese generic (unrestricted) input mode.

`kTextServiceInputModeKorean`
Specifies Korean generic (unrestricted) output (Hanja possible).

Discussion
These values require a cast from the `CFStringRef` data type to an `SInt32` data type before they can be used in text services functions.

Text Services Object Attributes

Specify characteristics of text services.

```
#define kKeyboardInputMethodTypeName        "\pkeyboardinputmethod"
#define kHandwritingInputMethodTypeName     "\phandwritinginputmethod"
#define kSpeechInputMethodTypeName          "\pspeechinputmethod"
#define kTokenizeServiceTypeName            "\ptokenizetextservice"
#define kInteractiveTextServiceTypeName     "\pinteractivetextservice"
#define kInputMethodModeName                "\pinputmethodmode"
#define kInputMethodModeVariantName         "\pinputmethodvariantmode"
#define kTextServiceModeName                "\ptextservicemode"
#define kTextServiceNeedsInlineAppMode      "\ptextservicesneedsinlineapp"
#define kTextServiceNeedsGetProtocolMode "\ptextservicesneedsGetProtocol"
#define kTextServiceAnyAppMode              "\ptextservicesanyapp"
```

TSM Document Interfaces

Specify types of TSM document interfaces.

```
enum {
    kTextServiceDocumentInterfaceType = kTextService,
    kTSMTEDocumentInterfaceType   = 'tmTE',
    kUnicodeDocumentInterfaceType = 'udoc',
    };
```

Constants

`kTextServiceDocumentInterfaceType`

A four-character code identifying a TSM document type for traditional (non-Unicode) TSM documents. This is the traditional TSM document type. It does not support Unicode. TSM converts all Unicode produced by input methods to the Mac encoding represented by the current keyboard script (or the Mac encoding specified by the input method producing text.) Full Unicode input sources may not be selectable when this TSM document is active.

Available in Mac OS X v10.3 and later.

Declared in `TextServices.h`.

`kTSMTEDocumentInterfaceType`

Deprecated. Specifies a TSM document type for TSMTE document (see `kTSMTEInterfaceType` in TSMTE.h). This requests automatic management of inline input sessions by TextEdit (the text engine.) See *Technote TE27 - Inline Input for TextEdit with TSMTE*. This document interface type should no longer be used because TextEdit has been replaced by MLTE.

Available in Mac OS X v10.3 and later.

Declared in `TextServices.h`.

`kUnicodeDocumentInterfaceType`

Specifies a TSM document type for Unicode-savvy applications. TSM pass through all Unicode text unchanged. When this TSM document is active, the full range of input sources is available to the user, such as Unicode keyboard layouts.

Available in Mac OS X v10.3 and later.

Declared in `TextServices.h`.

Discussion

These constants are used in arrays of type `InterfaceTypeList` (page 1614). TSM Interface types, as of Mac OS X 10.3, are also stored as TSM document properties, so once a TSM document is created, you can easily find out its interface types at document creation.

Unicode Identifiers

Specify constants that identify Unicode components and documents.

```
enum {
    kUnicodeDocument = 'udoc',
    kUnicodeTextService = 'utsv'
};
```

Constants

`kUnicodeDocument`

A four-character code that identifies a Unicode TSM document, for use by Unicode-savvy applications.

Available in Mac OS X v10.0 and later.

Declared in `TextServices.h`.

`kUnicodeTextService`
Specifies a component type for a Unicode text service.

Available in Mac OS X v10.0 and later.

Declared in `TextServices.h`.

Collection Tags

Specify collection tags.

```
enum {
    kInteractiveServicesTag = 'tmin',
    kLocaleIDTag = 'loce',
    kTextInputObjectTag = 'tiot',
    kLocaleObjectRefTag = 'lobj',
    kLocaleRefTag = 'lref',
    kKeyboardInputMethodContextTag = 'kinp',
    kKeyboardLocaleObjectRefTag = 'kilo',
    kHandwritingInputMethodContextTag = 'hinp',
    kHandwritingLocaleObjectRefTag = 'hilo',
    kSpeechInputMethodContextTag = 'sinp',
    kSpeechLocaleObjectRefTag = 'silo',
    kPasswordModeTag = 'pwdm',
    kRefconTag = 'refc',
    kUseFloatingWindowTag = 'uswm',
    kReadOnlyDocumentTag = 'isro',
    kSupportsMultiInlineHolesTag = 'minl',
    kProtocolVersionTag = 'nprt',
    kTSMContextCollectionTag = 'tsmx'
};
```

Constants

`kUseFloatingWindowTag`
Specifies the use of a bottom-line floating window for an input method.

Available in Mac OS X v10.0 through Mac OS X v10.2.

Declared in `TextServices.h`.

Discussion

All the constants in this enumeration, except `kUseFloatingWindowTag`, are reserved for future use.

Input Mode Variants

Specify variant tags for input modes.

```
enum {
    kIM2ByteInputMode = '2byt',
    kIM1ByteInputMode = '1byt',
    kIMDirectInputMode = 'dinp'
};
```

Constants

`kIM2ByteInputMode`
Specifies a double-byte input mode.
Available in Mac OS X v10.0 through Mac OS X v10.2.
Declared in `TextServices.h`.

`kIM1ByteInputMode`
Specifies a single-byte input mode.
Available in Mac OS X v10.0 through Mac OS X v10.2.
Declared in `TextServices.h`.

`kIMDirectInputMode`
Specifies a direct input mode.
Available in Mac OS X v10.0 through Mac OS X v10.2.
Declared in `TextServices.h`.

Discussion
These constants are reserved for future use.

Input Mode - Standard Tags

Specify standard tags for input method modes.

```
enum {
    kIMRomanInputMode = 'romn',
    kIMPasswordInputMode = 'pasw',
    kIMXingInputMode = 'xing',
    kIMHuaInputMode = 'huam',
    kIMPinyinInputMode = 'piny',
    kIMQuweiInputMode = 'quwe',
    kIMCangjieInputMode = 'cgji',
    kIMJianyiInputMode = 'jnyi',
    kIMZhuyinInputMode = 'zhuy',
    kIMB5CodeInputMode = 'b5cd',
    kIMKatakanaInputMode = 'kata',
    kIMHiraganaInputMode = 'hira'
};
```

Discussion
These constants are reserved for future use.

Locale Object Attributes

Specify attributes of a locale object.

```
enum {
    kNeedsInputWindow = 1,
    kHandlesUpdateRegion = 2,
    kHandlesGetRegion = 3,
    kHandlesPos2Offset = 4,
    kHandlesOffset2Pos = 5,
    kInPasswordMode = 6,
    kHandleMultipleHoles = 7,
    kDocumentIsReadOnly = 8
};
```

Discussion
These constants are reserved for future use.

Version Constants

Specify versions of the Text Services Manager.

```
enum {
    kTSMVersion = 0x0150,
    kTSM15Version = kTSMVersion,
    kTSM20Version = 0x0200,
    kTSM22Version = 0x0220,
    kTSM23Version = 0x0230
};
```

Constants

`kTSMVersion`
Specifies the version of the Text Services Manager is 1.5
Available in Mac OS X v10.0 and later.
Declared in `TextServices.h`.

`kTSM15Version`
Specifies the version of the Text Services Manager is 1.5
Available in Mac OS X v10.3 and later.
Declared in `TextServices.h`.

`kTSM20Version`
Specifies the version of the Text Services Manager is 2.0 (Mac OS X v10.0).
Available in Mac OS X v10.3 and later.
Declared in `TextServices.h`.

`kTSM22Version`
Specifies the version of the Text Services Manager is 2.2 (Mac OS X 1v0.3).
Available in Mac OS X v10.3 and later.
Declared in `TextServices.h`.

`kTSM23Version`
Specifies the version of the Text Services Manager is 2.3 (Mac OS X v10.4).
Available in Mac OS X v10.4 and later.
Declared in `TextServices.h`.

Result Codes

The most common result codes returned by Text Services Manager are listed below.

Result Code	Value	Description
`tsmComponentNoErr`	0	Component result: no error Available in Mac OS X v10.0 and later.
`tsmUnsupScriptLanguageErr`	-2500	Specified script and language are not supported Available in Mac OS X v10.0 and later.
`tsmInputMethodNotFoundErr`	-2501	Specified input method cannot be found Available in Mac OS X v10.0 and later.
`tsmNotAnAppErr`	-2502	The caller was not an application Available in Mac OS X v10.0 and later.
`tsmAlreadyRegisteredErr`	-2503	The caller is already TSM-initialized Available in Mac OS X v10.0 and later.
`tsmNeverRegisteredErr`	-2504	The caller is not TSM-aware Available in Mac OS X v10.0 and later.
`tsmInvalidDocIDErr`	-2505	Invalid TSM document ID Available in Mac OS X v10.0 and later.
`tsmTSMDocBusyErr`	-2506	Document is still active Available in Mac OS X v10.0 and later.
`tsmDocNotActiveErr`	-2507	Document is not active Available in Mac OS X v10.0 and later.
`tsmNoOpenTSErr`	-2508	There is no open text service component Available in Mac OS X v10.0 and later.
`tsmCantOpenComponentErr`	-2509	Can't open the component Available in Mac OS X v10.0 and later.
`tsmTextServiceNotFoundErr`	-2510	No text service component found Available in Mac OS X v10.0 and later.
`tsmDocumentOpenErr`	-2511	There are open documents Available in Mac OS X v10.0 and later.
`tsmUseInputWindowErr`	-2512	An input window is being used Available in Mac OS X v10.0 and later.

Result Code	Value	Description
tsmTSHasNoMenuErr	-2513	The text service component has no menu Available in Mac OS X v10.0 and later.
tsmTSNotOpenErr	-2514	Text service component is not open Available in Mac OS X v10.0 and later.
tsmComponentAlreadyOpenErr	-2515	Text service component already open for document Available in Mac OS X v10.0 and later.
tsmInputMethodIsOldErr	-2516	The default input method is old-style Available in Mac OS X v10.0 and later.
tsmScriptHasNoIMErr	-2517	Script has no (or old) input method Available in Mac OS X v10.0 and later.
tsmUnsupportedTypeErr	-2518	Unsupported interface type Available in Mac OS X v10.0 and later.
tsmUnknownErr	-2519	Any other error not listed in this table Available in Mac OS X v10.0 and later.
tsmDefaultIsNotInputMethodErr	-2524	Current input source is a keyboard layout resource Available in Mac OS X v10.0 and later.
tsmDocPropertyNotFoundErr	-2528	Requested TSM document property not found Available in Mac OS X v10.2 and later.
tsmDocPropertyBufferTooSmallErr	-2529	Buffer passed for property value is too small Available in Mac OS X v10.2 and later.
tsmCantChangeForcedClassStateErr	-2530	Enabled state of a TextService class has been forced and cannot be changed Available in Mac OS X v10.2 and later.

Text Utilities Reference

Framework:	CoreServices/CoreServices.h, Carbon/Carbon.h
Declared in	TextUtils.h StringCompare.h NumberFormatting.h TypeSelect.h

Overview

The Text Utilities provide you with an integrated collection of routines for performing a variety of operations on textual information, ranging from modifying the contents of a string, to sorting strings from different languages, to converting times, dates, and numbers from internal representations to formatted strings and back. These routines work in conjunction with QuickDraw text drawing routines to help you display and modify text in applications that are distributed to an international audience.

The Text Utilities functions are used for numerous text-handling tasks, including

- defining strings–including functions for allocating strings in the heap and for loading strings from resources
- comparing and sorting strings–including functions for testing whether two strings are equal and functions for finding the sorting relationship between two strings
- modifying the contents of strings–including routines for converting the case of characters, stripping diacritical marks, replacing substrings, and truncating strings
- finding breaks and boundaries in text–including routines for finding word and line breaks, and for finding different script runs in a line of text
- converting and formatting date and time strings–including routines that convert numeric and string representations of dates and times into record format, and routines that convert numeric and record representations of dates and times into strings
- converting and formatting numeric strings–including routines that convert string representations of numbers into numeric representations

Carbon supports the majority of Text Utilities. However, Apple recommends that you use the comparison and word breaking utilities supplied by Unicode Utilities instead.

A number of obsolete Text Utilities functions-such as those prefixed with iu or IU-are not supported.

Functions by Task

Comparing Strings for Equality

`EqualString` (page 1658) Deprecated in Mac OS X v10.4
: Compares two Pascal strings for equality, using the comparison rules of the Macintosh file system. (Deprecated. Use `CFStringCompare` instead.)

`IdenticalString` (page 1666) Deprecated in Mac OS X v10.4
: Compares two Pascal strings for equality, making use of the string comparison information from a resource that you specify as a parameter. (Deprecated. Use `CFStringCompare` instead.)

`IdenticalText` (page 1666) Deprecated in Mac OS X v10.4
: Compares two text strings for equality, making use of the string comparison information from a resource that you specify as a parameter. (Deprecated. Use `CFStringCompare` instead.)

Converting Between Integers and Strings

`NumToString` (page 1672) Deprecated in Mac OS X v10.4
: Converts a long integer value into a Pascal string. (Deprecated. Use `CFStringCreateWithFormat` instead.)

`StringToNum` (page 1682) Deprecated in Mac OS X v10.4
: Converts the Pascal string representation of a base-10 number into a long integer value. (Deprecated. Use `CFStringGetIntValue` instead.)

Converting Between Strings and Floating-Point Numbers

`ExtendedToString` (page 1659) Deprecated in Mac OS X v10.4
: Converts an internal floating-point representation of a number into a string that can be presented to the user, using a `NumFormatStringRec` structure to specify how the output number string is formatted (Deprecated. Use `CFNumberFormatterCreateNumberFromString` instead.)

`StringToExtended` (page 1679) Deprecated in Mac OS X v10.4
: Converts a string representation of a number into a floating-point number, using a `NumFormatStringRec` structure to specify how the input number string is formatted. (Deprecated. Use `CFNumberFormatterCreateStringWithNumber` instead.)

Converting Between C and Pascal Strings

`c2pstr` (page 1654)
: Converts a C string to a Pascal string. (Deprecated. You should store strings as Core Foundation CFStrings instead. See *CFString Reference*.)

`C2PStr` (page 1654)
: Converts a C string to a Pascal string. (Deprecated. You should store strings as Core Foundation CFStrings instead. See *CFString Reference*.)

P2CStr (page 1673)
Converts a Pascal string to a C string. (Deprecated. You should store strings as Core Foundation CFStrings instead. See *CFString Reference*.)

c2pstrcpy (page 1654) Deprecated in Mac OS X v10.4
Converts a C string to a Pascal string. (Deprecated. You should store strings as Core Foundation CFStrings instead. See *CFString Reference*.)

CopyCStringToPascal (page 1657) Deprecated in Mac OS X v10.4
Converts a C string to a Pascal string. (Deprecated. You should store strings as Core Foundation CFStrings instead. See *CFString Reference*.)

CopyPascalStringToC (page 1657) Deprecated in Mac OS X v10.4
Converts a Pascal String to a C string. (Deprecated. You should store strings as Core Foundation CFStrings instead. See *CFString Reference*.)

p2cstr (page 1673) Deprecated in Mac OS X v10.4 Deprecated in Mac OS X v10.4 Deprecated in Mac OS X v10.5
Converts a Pascal string to a C string. (Deprecated. You should store strings as Core Foundation CFStrings instead. See *CFString Reference*.)

p2cstrcpy (page 1674) Deprecated in Mac OS X v10.4
Converts a Pascal string to a C string. (Deprecated. You should store strings as Core Foundation CFStrings instead. See *CFString Reference*.)

Defining and Specifying Strings

GetIndString (page 1664) Deprecated in Mac OS X v10.4
Loads a string from a string list ('STR#') resource into memory, given the resource ID of the string list and the index of the individual string. (Deprecated. Use CFBundleCopyLocalizedString instead.)

GetString (page 1665) Deprecated in Mac OS X v10.4
Loads a string from a string ('STR') resource into memory. (Deprecated. Use CFBundleCopyLocalizedString instead.)

NewString (page 1671) Deprecated in Mac OS X v10.4
Allocates memory in the heap for a string, copies its contents, and produces a handle for the heap version of the string. (Deprecated. Use CFStringCreateCopy instead.)

SetString (page 1677) Deprecated in Mac OS X v10.4
Changes the contents of a string referenced by a string handle, replacing the previous contents by copying the specified string. (Deprecated. Use CFStringCreateWithPascalString and CFStringReplaceAll.)

Determining Sorting Order for Strings in Different Languages

LanguageOrder (page 1668) Deprecated in Mac OS X v10.4
Determines the order in which strings in two different languages should be sorted. (Deprecated. Use CFStringCompare or UCCompareText instead.)

ScriptOrder (page 1677) Deprecated in Mac OS X v10.4
Determines the order in which strings in two different scripts should be sorted. (Deprecated. Use CFStringCompare or UCCompareText instead.)

`StringOrder` (page 1678) Deprecated in Mac OS X v10.4
Compares two Pascal strings, taking into account the script system and language for each of the strings. (Deprecated. Use `CFStringCompare` or `UCCompareText` instead.)

`TextOrder` (page 1684) Deprecated in Mac OS X v10.4
Compares two text strings, taking into account the script and language for each of the strings. (Deprecated. Use `CFStringCompare` or `UCCompareText` instead.)

Determining Sorting Order for Strings in the Same Language

`CompareString` (page 1655) Deprecated in Mac OS X v10.4
Compares two Pascal strings, making use of the string comparison information from a resource that you specify as a parameter. (Deprecated. Use `CFStringCompare` or `UCCompareText` instead.)

`CompareText` (page 1656) Deprecated in Mac OS X v10.4
Compares two text strings, making use of the string comparison information from a resource that you specify as a parameter. (Deprecated. Use `CFStringCompare` or `UCCompareText` instead.)

`RelString` (page 1674) Deprecated in Mac OS X v10.4
Compares two Pascal strings using the string comparison rules of the Macintosh file system and returns a value that indicates the sorting order of the first string relative to the second string. (Deprecated. Use `CFStringCompare` or `UCCompareText` instead.)

`relstring` (page 1675) Deprecated in Mac OS X v10.4
Compares two strings. (Deprecated. Use `CFStringCompare` or `UCCompareText` instead.)

Modifying Characters and Diacritical Marks

`LowercaseText` (page 1669) Deprecated in Mac OS X v10.4
Converts any uppercase characters in a text string into their lowercase equivalents. (Deprecated. Use `CFStringLowercase` instead.)

`StripDiacritics` (page 1683) Deprecated in Mac OS X v10.4
Strips any diacritical marks from a text string. (Deprecated. Use `CFStringTransform` instead.)

`UppercaseStripDiacritics` (page 1688) Deprecated in Mac OS X v10.4
Converts any lowercase characters in a text string into their uppercase equivalents and strips any diacritical marks from the text. (Deprecated. Use `CFStringTransform` instead.)

`UppercaseText` (page 1689) Deprecated in Mac OS X v10.4
Converts any lowercase characters in a text string into their uppercase equivalents. (Deprecated. Use `CFStringUppercase` instead.)

`UpperString` (page 1690) Deprecated in Mac OS X v10.4
Converts any lowercase letters in a Pascal string to their uppercase equivalents, using the Macintosh file system rules. (Deprecated. Use `CFStringUppercase` instead.)

`upperstring` (page 1691) Deprecated in Mac OS X v10.4
Converts any lowercase letters in a Pascal string to their uppercase equivalents. (Deprecated. Use `CFStringUppercase` instead.)

Searching for and Replacing Strings

`Munger` (page 1669)
Searches text for a specified string pattern and replaces it with another string.

`ReplaceText` (page 1676) Deprecated in Mac OS X v10.4
Searches text on a character-by-character basis, replacing all instances of a string in that text with another string. (Deprecated. Use `CFStringReplace` instead.)

Using Number Format Specification Strings for International Number Formatting

`FormatRecToString` (page 1663) Deprecated in Mac OS X v10.4
Converts an internal representation of number formatting information into a number format specification string, which can be displayed and modified. (Deprecated. Use `CFNumberFormatterGetFormat` instead.)

`StringToFormatRec` (page 1680) Deprecated in Mac OS X v10.4
Creates a number format specification string structure from a number format specification string that you supply in a Pascal string. (Deprecated. Use `CFNumberFormatterSetFormat` instead.)

Working With Word, Script, and Line Boundaries

`FindScriptRun` (page 1660) Deprecated in Mac OS X v10.4
Finds the next block of subscript text within a script run. (Deprecated. There is no replacement function because this capability is no longer needed in Mac OS X.)

`FindWordBreaks` (page 1661) Deprecated in Mac OS X v10.4
Determines the beginning and ending boundaries of a word in a text string. (Deprecated. Use `UCFindTextBreak` instead.)

Working With Universal Procedure Pointers

`DisposeIndexToStringUPP` (page 1658) Deprecated in Mac OS X v10.4
Disposes of a universal procedure pointer to an index-to-string callback.

`InvokeIndexToStringUPP` (page 1667) Deprecated in Mac OS X v10.4
Call an index-to-string callback.

`NewIndexToStringUPP` (page 1671) Deprecated in Mac OS X v10.4
Creates a new universal procedure pointer (UPP) to an index-to-string callback.

Working With Type Select Records

`TypeSelectClear` (page 1685) Deprecated in Mac OS X v10.4
Clears the key list and resets the type select record. (Deprecated. Use `UCTypeSelectFlushSelectorData` instead.)

`TypeSelectCompare` (page 1686) Deprecated in Mac OS X v10.4
Compares a text buffer to the keystroke buffer. (Deprecated. Use `UCTypeSelectCompare` instead.)

`TypeSelectFindItem` (page 1686) Deprecated in Mac OS X v10.4
: Finds the closest match between a specified list of characters and the keystrokes stored in the type select record. (Deprecated. Use `UCTypeSelectFindItem` instead.)

`TypeSelectNewKey` (page 1687) Deprecated in Mac OS X v10.4
: Creates a new type select record. (Deprecated. Use `UCTypeSelectCreateSelector` instead.)

Functions

c2pstr

Converts a C string to a Pascal string. (Deprecated in Mac OS X v10.4. You should store strings as Core Foundation CFStrings instead. See *CFString Reference*.)

```
StringPtr c2pstr (
   char *aStr
);
```

Availability
Available in Mac OS X v10.4 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`TextUtils.h`

C2PStr

Converts a C string to a Pascal string. (Deprecated in Mac OS X v10.4. You should store strings as Core Foundation CFStrings instead. See *CFString Reference*.)

```
StringPtr C2PStr (
    Ptr cString
);
```

Availability
Available in Mac OS X v10.4 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`TextUtils.h`

c2pstrcpy

Converts a C string to a Pascal string. (Deprecated in Mac OS X v10.4. You should store strings as Core Foundation CFStrings instead. See *CFString Reference*.)

```
void c2pstrcpy (
   Str255 dst,
   const char *src
);
```

Parameters

dst

On output, the Pascal string.

src

The C string you want to convert.

Discussion

This function allows in-place conversion. That is, the `src` and `dst` parameters can point to the same memory location.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Related Sample Code

SoftVDigX

Declared In

`TextUtils.h`

CompareString

Compares two Pascal strings, making use of the string comparison information from a resource that you specify as a parameter. (Deprecated in Mac OS X v10.4. Use `CFStringCompare` or `UCCompareText` instead.)

```
short CompareString (
    ConstStr255Param aStr,
    ConstStr255Param bStr,
    Handle itl2Handle
);
```

Parameters

aStr

One of the Pascal strings to be compared.

bStr

The other Pascal string to be compared.

itl2Handle

The handle to the string-manipulation resource that contains string comparison information. If the value of this parameter is `NULL`, `CompareString` makes use of the resource for the current script. The string-manipulation resource includes functions and tables for modifying string comparison and tables for case conversion and stripping of diacritical marks.

Return Value

Returns –1 if the first string is less than the second string, 0 if the first string is equal to the second string, and 1 if the first string is greater than the second string.

Discussion
This function takes both primary and secondary sorting orders into consideration and returns a value that indicates the sorting order of the first string relative to the second string.

Special Considerations

`CompareString` may move memory; your application should not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`StringCompare.h`

CompareText

Compares two text strings, making use of the string comparison information from a resource that you specify as a parameter. (Deprecated in Mac OS X v10.4. Use `CFStringCompare` or `UCCompareText` instead.)

```
short CompareText (
   const void *aPtr,
   const void *bPtr,
   short aLen,
   short bLen,
   Handle itl2Handle
);
```

Parameters

aPtr
A pointer to the first character of the first text string.

bPtr
A pointer to the first character of the second text string.

aLen
The length, in bytes, of the first text string.

bLen
The length, in bytes, of the second text string.

itl2Handle
A handle to a string-manipulation (`'itl2'`) resource that contains string comparison information. If the value of this parameter is `NULL`, `CompareText` makes use of the resource for the current script. The string-manipulation resource includes functions and tables for modifying string comparison and tables for case conversion and stripping of diacritical marks.

Return Value
Returns –1 if the first string is less than the second string, 0 if the first string is equal to the second string, and 1 if the first string is greater than the second string.

Discussion
This function takes both primary and secondary sorting orders into consideration and returns a value that indicates the sorting order of the first string relative to the second string.

Special Considerations

`CompareText` may move memory; your application should not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`StringCompare.h`

CopyCStringToPascal

Converts a C string to a Pascal string. (Deprecated in Mac OS X v10.4. You should store strings as Core Foundation CFStrings instead. See *CFString Reference*.)

```
void CopyCStringToPascal (
   const char *src,
   Str255 dst
);
```

Parameters

src

The C string you want to convert.

dst

On output, the Pascal string.

Discussion

This function allows in-place conversion. That is, the `src` and `dst` parameters can point to the same memory location.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

BSDLLCTest

Declared In

`TextUtils.h`

CopyPascalStringToC

Converts a Pascal String to a C string. (Deprecated in Mac OS X v10.4. You should store strings as Core Foundation CFStrings instead. See *CFString Reference*.)

```
void CopyPascalStringToC (
   ConstStr255Param src,
   char *dst
);
```

Parameters

src

The Pascal string you want to convert.

dst

On output, the C string.

Discussion

This function allows in-place conversion. That is, the `src` and `dst` parameters can point to the same memory location.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`TextUtils.h`

DisposeIndexToStringUPP

Disposes of a universal procedure pointer to an index-to-string callback. (Deprecated in Mac OS X v10.4.)

```
void DisposeIndexToStringUPP (
   IndexToStringUPP userUPP
);
```

Parameters

userUPP

The universal procedure pointer.

Discussion

See the callback `IndexToStringProcPtr` (page 1691) for more information.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`TypeSelect.h`

EqualString

Compares two Pascal strings for equality, using the comparison rules of the Macintosh file system. (Deprecated in Mac OS X v10.4. Use `CFStringCompare` instead.)

```
Boolean EqualString (
   ConstStr255Param str1,
   ConstStr255Param str2,
   Boolean caseSensitive,
   Boolean diacSensitive
);
```

Parameters

str1

One of the Pascal strings to be compared.

str2

The other Pascal string to be compared.

caseSensitive

A flag that indicates how to handle case-sensitive information during the comparison. If the value of `caseSens` is `TRUE`, uppercase characters are distinguished from the corresponding lowercase characters. If it is `FALSE`, case information is ignored.

diacSensitive

A flag that indicates how to handle information about diacritical marks during the string comparison. If the value of `diacSens` is `TRUE`, characters with diacritical marks are distinguished from the corresponding characters without diacritical marks during the comparison. If it is `FALSE`, diacritical marks are ignored.

Return Value

`TRUE` if the two strings are equal and `FALSE` if they are not equal. If its value is `TRUE`, `EqualString` distinguishes uppercase characters from the corresponding lowercase characters. If its value is `FALSE`, `EqualString` ignores diacritical marks during the comparison.

Discussion

The comparison is a simple, character-by-character value comparison. This function does not make use of any script or language information (i.e., is not localizable); it assumes the use of a Roman script system.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`StringCompare.h`

ExtendedToString

Converts an internal floating-point representation of a number into a string that can be presented to the user, using a `NumFormatStringRec` structure to specify how the output number string is formatted (Deprecated in Mac OS X v10.4. Use `CFNumberFormatterCreateNumberFromString` instead.)

```
FormatStatus ExtendedToString (
   const extended80 *x,
   const NumFormatString *myCanonical,
   const NumberParts *partsTable,
   Str255 outString
);
```

Parameters

x

A pointer to a floating-point value in 80-bit SANE representation.

myCanonical

A pointer to the internal representation of the formatting information for numbers, as produced by the `StringToFormatRec` function.

partsTable

A pointer to a structure, obtained from the tokens (`'itl4'`) resource, that shows the correspondence between generic number part separators (tokens) and their localized version (for example, a thousand separator is a comma in the United States and a decimal point in France).

outString

On output, contains the number formatted according to the information in `myFormatRec`.

Return Value

A value that denotes the confidence level for the conversion that it performed. The low byte of the `FormatStatus` value is of type `FormatResultType`. Be sure to cast the result of `ExtendedToString` to a type `FormatResultType` before working with it. See the description of the `FormatStatus` data type.

Discussion

`ExtendedToString` creates a string representation of a floating-point number, using the formatting information in the `myFormatRec` parameter (which was created by a previous call to `StringToFormatRec`) to determine how the number should be formatted for output. It uses the number parts table to determine the component parts of the number string.

To obtain a handle to the number parts table from a tokens resource, use the `GetIntlResourceTable` function.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`NumberFormatting.h`

FindScriptRun

Finds the next block of subscript text within a script run. (Deprecated in Mac OS X v10.4. There is no replacement function because this capability is no longer needed in Mac OS X.)

```
ScriptRunStatus FindScriptRun (
   Ptr textPtr,
   long textLen,
   long *lenUsed
);
```

Parameters

textPtr

A pointer to the text string to be analyzed.

textLen

The number of bytes in the text string.

lenUsed

On output, a pointer to the length, in bytes, of the script run that begins with the first character in the string; this length is always greater than or equal to 1, unless the string passed in is of length 0.

Return Value

Identifies the run as either native text, Roman, or one of the defined subscripts of the script system and returns a structure of type `ScriptRunStatus` (page 1698). See the description of the `ScriptRunStatus` data type.

Discussion

The `FindScriptRun` function is used to identify blocks of subscript text in a string, taking into account script and language considerations, making use of tables in the string-manipulation (`'itl2'`) resource in its computations. Some script systems include subscripts, which are character sets that are subsidiary to the main character set. One useful subscript is the set of all character codes that have the same meaning in Roman as they do in a non-Roman script. For other scripts such as Japanese, there are additional useful subscripts. For example, a Japanese script system might include some Hiragana characters that are useful for input methods.

`FindScriptRun` computes the length of the current run of subscript text in the text string specified by `textPtr` and `textLen`. It assigns the length, in bytes, to the `lenUsed` parameter and returns a status code. You can advance the text pointer by the value of `lenUsed` to make subsequent calls to this function. You can use this function to identify runs of subscript characters so that you can treat them separately.

Word processors and other applications can call `FindScriptRun` to separate style runs of native text from non-native text. You can use this capability to extract those characters and apply a different font to them.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`TextUtils.h`

FindWordBreaks

Determines the beginning and ending boundaries of a word in a text string. (Deprecated in Mac OS X v10.4. Use `UCFindTextBreak` instead.)

```
void FindWordBreaks (
   Ptr textPtr,
   short textLength,
   short offset,
   Boolean leadingEdge,
   BreakTablePtr breaks,
   OffsetTable offsets,
   ScriptCode script
);
```

Parameters

textPtr

A pointer to the text string to be examined.

textLength

The number of bytes in the text string.

offset

A byte offset into the text. This parameter plus the `leadingEdge` parameter determine the position of the character at which to start the search.

leadingEdge

A flag that specifies which character should be used to start the search. If `leadingEdge` is `TRUE`, the search starts with the character specified in the `offset` parameter; if it is `FALSE`, the search starts with the character preceding the offset.

breaks

A pointer to a word-break table of type `NBreakTable` or `BreakTable`. If the value of this pointer is 0, the default word-break table of the script system specified by the `script` parameter is used. If the value of this pointer is –1, the default line-break table of the specified script system is used.

offsets

On output, the values in this table indicate the boundaries of the word that has been found.

script

The script code for the script system whose tables are used to determine where word boundaries occur.

Discussion

`FindWordBreaks` searches for a word in a text string, taking into account script and language considerations, making use of tables in the string-manipulation (`'itl2'`) resource in its computations. The `textPtr` and `textLength` parameters specify the text string that you want searched. The `offset` parameter and `leadingEdge` parameter together indicate where the search begins.

`FindWordBreaks` searches backward through the text string for one of the word boundaries and forward through the text string for its other boundary. It uses the definitions in the table specified by `nbreaks` to determine what constitutes the boundaries of a word. Each script system's word-break table is part of its string-manipulation (`'itl2'`) resource.

`FindWordBreaks` returns its results in an `OffsetTable` structure. `FindWordBreaks` uses only the first element of this three-element table. Each element is a pair of integers: `offFirst` and `offSecond`.

`FindWordBreaks` places the offset from the beginning of the text string to just before the leading edge of the character of the word that it finds in the `offFirst` field.

`FindWordBreaks` places the offset from the beginning of the text string to just after the trailing edge of the last character of the word that it finds in the `offSecond` field. For example, if the text "This is it" is passed with `offset` set to 0 and `leadingEdge` set to `TRUE`, then `FindWordBreaks` returns the offset pair (0,4).

If `leadingEdge` is `TRUE` and the value of `offset` is 0, then `FindWordBreaks` returns the offset pair (0,0). If `leadingEdge` is `FALSE` and the value of `offset` equals the value of `textLength`, then `FindWordBreaks` returns the offset pair with values (`textLength`, `textLength`).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextUtils.h`

FormatRecToString

Converts an internal representation of number formatting information into a number format specification string, which can be displayed and modified. (Deprecated in Mac OS X v10.4. Use `CFNumberFormatterGetFormat` instead.)

```
FormatStatus FormatRecToString (
   const NumFormatString *myCanonical,
   const NumberParts *partsTable,
   Str255 outString,
   TripleInt positions
);
```

Parameters

myCanonical
A pointer to the internal representation of number formatting information, as created by a previous call to the `StringToFormatRec` function.

partsTable
A pointer to a structure, obtained from the tokens (`'itl4'`) resource, that shows the correspondence between generic number part separators (tokens) and their localized version (for example, a thousand separator is a comma in the United States and a decimal point in France).

outString
On output, contains the number format specification string.

positions
An array that specifies the starting position and length of each of the three possible format strings (positive, negative, or zero) in the number format specification string. Semicolons are used as separators in the string.

Return Value
A value that denotes the confidence level for the conversion that it performed. The low byte of the `FormatStatus` value is of type `FormatResultType`. Be sure to cast the result of `FormatRecToString` to a type `FormatResultType` before working with it. See the description of the `FormatStatus` data type.

Discussion
`FormatRecToString` is the inverse operation of `StringToFormatRec` (page 1680). The internal representation of the formatting information in `myFormatRec` must have been created by a prior call to the `StringToFormatRec` function. The information in the number parts table specifies how to build the string representation.

The output number format specification string in `outString` specifies how numbers appear. This string contains three parts, which are separated by semicolons. The first part is the positive number format, the second is the negative number format, and the third part is the zero number format.

The `positions` parameter is an array of three integers (a `TripleInt` value), which specifies the starting position in `outString` of each of three formatting specifications:

- `positions[fPositive]`. The index in `outString` of the first byte of the formatting specification for positive number values.
- `positions[fNegative]`. The index in `outString` of the first byte of the formatting specification for negative number values.
- `positions[fZero]`. The index in `outString` of the first byte of the formatting specification for zero number values.

To obtain a handle to the number parts table from a tokens resource, use the `GetIntlResourceTable` function.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`NumberFormatting.h`

GetIndString

Loads a string from a string list (`'STR#'`) resource into memory, given the resource ID of the string list and the index of the individual string. (Deprecated in Mac OS X v10.4. Use `CFBundleCopyLocalizedString` instead.)

```
void GetIndString (
   Str255 theString,
   short strListID,
   short index
);
```

Parameters

`theString`
On output, the Pascal string result; specifically, a copy of the string from a string list that has the resource ID provided in the `strListID` parameter. If the resource that you specify cannot be read or the index that you specify is out of range for the string list, `GetIndString` sets `theString` to an empty string.

`strListID`
The resource ID of the `'STR#'` resource that contains the string list.

`index`
The index of the string in the list. This is a value from 1 to the number of strings in the list that is referenced by the `strListID` parameter.

Discussion
If necessary, `GetIndString` reads the string list from the resource file by calling the Resource Manager function `GetResource`. `GetIndString` accesses the string specified by the `index` parameter and copies it into `theString`.

Special Considerations

`GetIndString` may move memory; your application should not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextUtils.h`

GetString

Loads a string from a string (`'STR'`) resource into memory. (Deprecated in Mac OS X v10.4. Use `CFBundleCopyLocalizedString` instead.)

```
StringHandle GetString (
   short stringID
);
```

Parameters

`stringID`
The resource ID of the string (`'STR '`) resource containing the string.

Return Value
A handle to a string with the specified resource ID. If necessary, `GetString` reads the handle form the resource file. If `GetString` cannot read the resource, it returns `NULL`.

Discussion
`GetString` calls the `GetResource` function of the Resource Manager to access the string. This means that if the specified resource is already in memory, `GetString` simply returns its handle.

Like the `NewString` (page 1671) function, `GetString` returns a handle whose size is based upon the actual length of the string.

If your application uses a large number of strings, it is more efficient to store them in a string list (`'STR#'`) resource than as individual resources in the resource file. You then use the `GetIndString` (page 1664) function to access each string in the list.

Special Considerations

`GetString` does not create a copy of the string.

`GetString` may move memory; your application should not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextUtils.h`

IdenticalString

Compares two Pascal strings for equality, making use of the string comparison information from a resource that you specify as a parameter. (Deprecated in Mac OS X v10.4. Use `CFStringCompare` instead.)

```
short IdenticalString (
   ConstStr255Param aStr,
   ConstStr255Param bStr,
   Handle itl2Handle
);
```

Parameters

aStr

One of the Pascal strings to be compared.

bStr

The other Pascal string to be compared.

itl2Handle

A handle to a string-manipulation (`'itl2'`) resource that contains string comparison information.

The `itl2Handle` parameter is used to specify a string-manipulation resource. If the value of this parameter is `NULL`, `IdenticalString` makes use of the resource for the current script. The string-manipulation resource includes tables for modifying string comparison and tables for case conversion and stripping of diacritical marks.

Return Value
Returns 0 if the two strings are equal; 1 if they are not equal. It compares the two strings without regard for secondary sorting order, the meaning of which depends on the language of the strings. For example, for the English language, using only primary differences means that `IdenticalString` ignores diacritical marks and does not distinguish between lowercase and uppercase. For example, if the two strings are `'Rose'` and `'rosé'`, `IdenticalString` considers them equal and returns 0.

Discussion
`IdenticalString` uses only primary differences in its comparison.

Special Considerations

`IdenticalString` may move memory; your application should not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`StringCompare.h`

IdenticalText

Compares two text strings for equality, making use of the string comparison information from a resource that you specify as a parameter. (Deprecated in Mac OS X v10.4. Use `CFStringCompare` instead.)

```
short IdenticalText (
   const void *aPtr,
   const void *bPtr,
   short aLen,
   short bLen,
   Handle itl2Handle
);
```

Parameters

aPtr

A pointer to the first character of the first text string.

bPtr

A pointer to the first character of the second text string.

aLen

The length, in bytes, of the first text string.

bLen

The length, in bytes, of the second text string.

itl2Handle

A handle to a string-manipulation (`'itl2'`) resource that contains string comparison information.

The `itl2Handle` parameter is used to specify a string-manipulation resource. If the value of this parameter is `NULL`, `IdenticalText` makes use of the resource for the current script. The string-manipulation resource includes functions and tables for modifying string comparison and tables for case conversion and stripping of diacritical marks.

Return Value

0 if the two text strings are equal; 1 if they are not equal. It compares the strings without regard for secondary sorting order, which means that it ignores diacritical marks and does not distinguish between lowercase and uppercase. For example, if the two text strings are `'Rose'` and `'rosé'`, `IdenticalText` considers them equal and returns 0.

Discussion

`IdenticalText` uses only primary sorting order in its comparison.

Special Considerations

`IdenticalText` may move memory; your application should not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`StringCompare.h`

InvokeIndexToStringUPP

Call an index-to-string callback. (Deprecated in Mac OS X v10.4.)

```
Boolean InvokeIndexToStringUPP (
   short item,
   ScriptCode *itemsScript,
   StringPtr *itemsStringPtr,
   void *yourDataPtr,
   IndexToStringUPP userUPP
);
```

Discussion
You should not need to use the function `InvokeIndexToStringUPP`, as the system calls your index-to-string callback function for you. See the callback `IndexToStringProcPtr` (page 1691) for more information.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TypeSelect.h`

LanguageOrder

Determines the order in which strings in two different languages should be sorted. (Deprecated in Mac OS X v10.4. Use `CFStringCompare` or `UCCompareText` instead.)

```
short LanguageOrder (
   LangCode language1,
   LangCode language2
);
```

Parameters

language1
The language code of the first language.

language2
The language code of the second language.

Return Value
A value that indicates the sorting order: –1 if strings in the first language should be sorted before sorting text in the second language, 1 if strings in the first language should be sorted after sorting strings in the second language, or 0 if the sorting order does not matter (that is, if the languages are the same).

Discussion
`LanguageOrder` takes a pair of language codes and determines in which order strings from the first language should be sorted relative to strings from the second language.

"Implicit Language Codes" (page 1702) are listed in the Constants section. The implicit language codes `scriptCurLang` and `scriptDefLang` are not valid for `LanguageOrder` because the script system being used is not specified as a parameter to this function.

Special Considerations

`LanguageOrder` may move memory; your application should not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`StringCompare.h`

LowercaseText

Converts any uppercase characters in a text string into their lowercase equivalents. (Deprecated in Mac OS X v10.4. Use `CFStringLowercase` instead.)

```
void LowercaseText (
   Ptr textPtr,
   short len,
   ScriptCode script
);
```

Parameters

`textPtr`

A pointer to the text string to be converted.

`len`

The number of bytes in the text string. The text string can be up to 32 KB in length.

`script`

The script code for the script system whose resources are used to determine the results of converting characters.

The conversion uses tables in the string-manipulation (`'itl2'`) resource of the script specified by the value of the `script` parameter. You can specify `smSystemScript` to use the system script and `smCurrentScript` to use the script of the current font in the current graphics port.

Discussion
`LowercaseText` traverses the characters starting at the address specified by `textPtr` and continues for the number of characters specified in `len`. It converts any uppercase characters in the text into lowercase.

If `LowercaseText` cannot access the specified resource, it generates an error code and does not modify the string. You need to call the `ResError` function to determine which, if any, error occurred.

Special Considerations

`LowercaseText` may move memory; your application should not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextUtils.h`

Munger

Searches text for a specified string pattern and replaces it with another string.

```
long Munger (
   Handle h,
   long offset,
   const void *ptr1,
   long len1,
   const void *ptr2,
   long len2
);
```

Parameters

h

A handle to the text string that is being manipulated.

offset

The byte offset in the destination string at which `Munger` begins its operation.

ptr1

A pointer to the first character in the string for which `Munger` is searching.

len1

The number of bytes in the string for which `Munger` is searching.

ptr2

A pointer to the first character in the substitution string.

len2

The number of bytes in the substitution string.

Return Value

A negative value if `Munger` cannot find the designated string.

Discussion

`Munger` manipulates bytes in a string to which you specify a handle in the `h` parameter. The manipulation begins at a byte offset, specified in `offset`, in the string. `Munger` searches for the string specified by `ptr1` and `len1`; when it finds an instance of that string, it replaces it with the substitution string, which is specified by `ptr2` and `len2`.

`Munger` operates on a byte-by-byte basis, which can produce inappropriate results for 2-byte script systems. The `ReplaceText` (page 1676) function works properly for all languages. You are encouraged to use `ReplaceText` instead of `Munger` whenever possible.

`Munger` takes special action if either of the specified pointer values is `NULL` or if either of the length values is `0`.

- If `ptr1` is `NULL`, `Munger` replaces characters without searching. It replaces `len1` characters starting at the `offset` location with the substitution string.
- If `ptr1` is `NULL` and `len1` is negative, `Munger` replaces all of the characters from the `offset` location to the end of the string with the substitution string.
- If `len1` is 0, `Munger` inserts the substitution string without replacing anything. `Munger` inserts the string at the `offset` location and returns the offset of the first byte past where the insertion occurred.
- If `ptr2` is `NULL`, `Munger` searches but does not replace. In this case, `Munger` returns the offset at which the string was found.
- If `len2` is 0 and `ptr2` is not `NULL`, `Munger` searches and deletes. In this case, `Munger` returns the offset at which it deleted.

- If the portion of the string from the `offset` location to its end matches the beginning of the string that `Munger` is searching for, `Munger` replaces that portion with the substitution string.

Be careful not to specify an offset with a value that is greater than the length of the destination string. Unpredictable results may occur.

`Munger` calls the `GetHandleSize` and `SetHandleSize` functions to access or modify the length of the string it is manipulating.

Special Considerations

`Munger` may move memory; your application should not call this function at interrupt time.

The destination string must be in a relocatable block that was allocated by the Memory Manager.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextUtils.h`

NewIndexToStringUPP

Creates a new universal procedure pointer (UPP) to an index-to-string callback. (Deprecated in Mac OS X v10.4.)

```
IndexToStringUPP NewIndexToStringUPP (
   IndexToStringProcPtr userRoutine
);
```

Parameters

`userRoutine`
A pointer to your index-to-string callback.

Return Value
On return, a UPP to the index-to-string callback.

Discussion
See the callback `IndexToStringProcPtr` (page 1691) for more information.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TypeSelect.h`

NewString

Allocates memory in the heap for a string, copies its contents, and produces a handle for the heap version of the string. (Deprecated in Mac OS X v10.4. Use `CFStringCreateCopy` instead.)

```
StringHandle NewString (
   ConstStr255Param theString
);
```

Parameters

theString

A Pascal string that you want copied onto the heap.

Return Value

A handle to the newly allocated string. If the string cannot be allocated, `NewString` returns `NULL`. The size of the allocated string is based on the actual length of `theString`, which may not be 255 bytes.

Discussion

Before using Pascal string functions that can change the length of the string, it is a good idea to maximize the size of the string object on the heap. You can call either the `SetString` (page 1677) function or the Memory Manager function `SetHandleSize` to modify the string's size.

Special Considerations

`NewString` may move memory; your application should not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`TextUtils.h`

NumToString

Converts a long integer value into a Pascal string. (Deprecated in Mac OS X v10.4. Use `CFStringCreateWithFormat` instead.)

```
void NumToString (
   long theNum,
   Str255 theString
);
```

Parameters

theNum

A long integer value. If the value of the number in the parameter `theNum` is negative, the string begins with a minus sign; otherwise, the sign is omitted.

theString

On output, contains the Pascal string representation of the number. Leading zeros are suppressed, except that a value of 0 produces the string "0". `NumToString` does not include thousand separators or decimal points in its formatted output.

Discussion

`NumToString` creates a string representation of `theNum` as a base-10 value and returns the result in `theString`.

Unless patched by a script system with different rules, this function assumes that you are using standard numeric token processing, meaning that the Roman script system number processing rules are used.

For functions that make use of the token-processing information that is found in the tokens (`'itl4'`) resource of script systems for converting numbers, see the sections "Using Number Format Specification Strings for International Number Formatting" and "Converting Between Strings and Floating-Point Numbers".

Special Considerations

`NumToString` may move memory; your application should not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`NumberFormatting.h`

p2cstr

Converts a Pascal string to a C string. (Deprecated in Mac OS X v10.4. You should store strings as Core Foundation CFStrings instead. See *CFString Reference*.)

```
char * p2cstr (
   StringPtr aStr
);
```

Availability
Available in Mac OS X v10.4 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextUtils.h`

P2CStr

Converts a Pascal string to a C string. (Deprecated in Mac OS X v10.4. You should store strings as Core Foundation CFStrings instead. See *CFString Reference*.)

```
Ptr P2CStr (
    StringPtr pString
);
```

Availability
Available in Mac OS X v10.4 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextUtils.h`

p2cstrcpy

Converts a Pascal string to a C string. (Deprecated in Mac OS X v10.4. You should store strings as Core Foundation CFStrings instead. See *CFString Reference*.)

```
void p2cstrcpy (
   char *dst,
   ConstStr255Param src
);
```

Parameters

dst

On output, the C string.

src

The Pascal string you want to convert.

Discussion

This function allows in-place conversion. That is, the `src` and `dst` parameters can point to the same memory location.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`TextUtils.h`

RelString

Compares two Pascal strings using the string comparison rules of the Macintosh file system and returns a value that indicates the sorting order of the first string relative to the second string. (Deprecated in Mac OS X v10.4. Use `CFStringCompare` or `UCCompareText` instead.)

```
short RelString (
   ConstStr255Param str1,
   ConstStr255Param str2,
   Boolean caseSensitive,
   Boolean diacSensitive
);
```

Parameters

str1

One of the Pascal strings to be compared.

str2

The other Pascal string to be compared.

caseSensitive

A flag that indicates how to handle case-sensitive information during the comparison. If the value of `caseSens` is `TRUE`, uppercase characters are distinguished from the corresponding lowercase characters. If it is `FALSE`, case information is ignored.

diacSensitive
A flag that indicates how to handle information about diacritical marks during the string comparison. If the value of `diacSensitive` is `TRUE`, characters with diacritical marks are distinguished from the corresponding characters without diacritical marks during the comparison. If it is `FALSE`, diacritical marks are ignored.

Return Value
Returns –1 if the first string is less than the second string, 0 if the two strings are equal, and 1 if the first string is greater than the second string. It compares the two strings in the same manner as does the `EqualString` function, by simply looking at the ASCII values of their characters. However, `RelString` provides more information about the two strings—it indicates their relationship to each other, rather than determining if they are exactly equal.

Discussion
This function does not make use of any script or language information; it assumes the original Macintosh character set only.

Special Considerations

The `RelString` function is not localizable and does not work properly with non-Roman script systems.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`StringCompare.h`

relstring

Compares two strings. (Deprecated in Mac OS X v10.4. Use `CFStringCompare` or `UCCompareText` instead.)

Not recommended

```
short relstring (
   const char *str1,
   const char *str2,
   Boolean caseSensitive,
   Boolean diacSensitive
);
```

Parameters
str1
The string to be compared to `str2`.
str2
The string to be compared to `str1`.
caseSensitive
A flag that indicates how to handle case-sensitive information during the comparison.
diacSensitive
A flag that indicates how to handle information about diacritical marks during the string comparison.

Return Value
Returns –1 if the first string is less than the second string, 0 if the two strings are equal, and 1 if the first string is greater than the second string.

Discussion
This function is not recommended. Instead, see the function `RelString` (page 1674).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`StringCompare.h`

ReplaceText

Searches text on a character-by-character basis, replacing all instances of a string in that text with another string. (Deprecated in Mac OS X v10.4. Use `CFStringReplace` instead.)

```
short ReplaceText (
    Handle baseText,
    Handle substitutionText,
    Str15 key
);
```

Parameters

baseText
A handle to the string in which `ReplaceText` is to substitute text.

substitutionText
A handle to the string that `ReplaceText` uses as substitute text.

key
A Pascal string of less than 16 bytes that `ReplaceText` searches for.

Return Value
An integer value; if positive, it indicates the number of substitutions performed; if negative, it indicates an error. The constant `noErr` is returned if there was no error and no substitutions were performed.

Discussion
`ReplaceText` searches the text specified by the `baseText` parameter for instances of the string in the `key` parameter and replaces each instance with the text specified by the `substitutionText` parameter. `ReplaceText` searches on a character-by-character basis (as opposed to byte-by-byte), so it works properly for all script systems, including 2-byte script systems. It recognizes 2-byte characters in script systems that contain them and advances the search appropriately after encountering a 2-byte character.

Special Considerations

`ReplaceText` may move memory; your application should not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`StringCompare.h`

ScriptOrder

Determines the order in which strings in two different scripts should be sorted. (Deprecated in Mac OS X v10.4. Use `CFStringCompare` or `UCCompareText` instead.)

```
short ScriptOrder (
   ScriptCode script1,
   ScriptCode script2
);
```

Parameters

script1
The script code of the first script.

script2
The script code of the second script.

Return Value
A value that indicates the sorting order: –1 if strings in the first script should be sorted before strings in the second script are sorted, 1 if strings in the first script should be sorted after strings in the second script are sorted, or 0 if the sorting order does not matter (that is, if the scripts are the same).

Discussion
Text of the system script is always first in a sorted list, regardless of the result returned by this function. When determining the order in which text from two different script systems should be sorted, the system script always sorts first, and scripts that are not enabled and installed always sort last. Invalid script or language codes always sort after valid ones.

Special Considerations

`ScriptOrder` may move memory; your application should not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`StringCompare.h`

SetString

Changes the contents of a string referenced by a string handle, replacing the previous contents by copying the specified string. (Deprecated in Mac OS X v10.4. Use `CFStringCreateWithPascalString` and `CFStringReplaceAll`.)

```
void SetString (
   StringHandle theString,
   ConstStr255Param strNew
);
```

Parameters

theString

A Pascal string.

strNew

A handle to the string in memory whose contents you are replacing. If the new string (`theString`) is larger than the string originally referenced by `strNew`, `SetString` automatically resizes the handle and copies in the contents of the specified string.

Special Considerations

`SetString` may move memory; your application should not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`TextUtils.h`

StringOrder

Compares two Pascal strings, taking into account the script system and language for each of the strings. (Deprecated in Mac OS X v10.4. Use `CFStringCompare` or `UCCompareText` instead.)

```
short StringOrder (
   ConstStr255Param aStr,
   ConstStr255Param bStr,
   ScriptCode aScript,
   ScriptCode bScript,
   LangCode aLang,
   LangCode bLang
);
```

Parameters

aStr

One of the Pascal strings to be compared.

bStr

The other Pascal string to be compared.

aScript

The script code for the second string.

bScript

The script code for the first string.

aLang

The language code for the first string.

bLang

The language code for the second string.

Return Value
–1 if the first string is less than the second string, 0 if the first string is equal to the second string, and 1 if the first string is greater than the second string. The ordering of script and language codes, which is based on information in the script-sorting resource, is considered in determining the relationship of the two strings.

Discussion
This function takes both primary and secondary sorting orders into consideration and returns a value that indicates whether the first string is less than, equal to, or greater than the second string.

"Implicit Language Codes" (page 1702) are listed in the Constants section. Most applications specify the language code `scriptCurLang` for both the `aLang` and `bLang` values.

`StringOrder` first calls `ScriptOrder` (page 1677); if the result of `ScriptOrder` is not 0 (that is, if the strings use different scripts), `StringOrder` returns the same result.

`StringOrder` next calls `LanguageOrder` (page 1668); if the result of `LanguageOrder` is not 0 (that is, if the strings use different languages), `StringOrder` returns the same result.

At this point, `StringOrder` has two strings that are in the same script and language, so it compares them by using the sorting rules for that script and language, applying both the primary and secondary sorting orders. If that script is not installed and enabled, it uses the sorting rules specified by the system script or the font script, depending on the state of the international resources selection flag.

The `StringOrder` function is primarily used to insert Pascal strings in a sorted list; for sorting, rather than using this function, it may be faster to sort first by script and language by using the `ScriptOrder` and `LanguageOrder` functions, and then to call the `CompareString` (page 1655) function, to sort strings within a script or language group.

Special Considerations

`StringOrder` may move memory; your application should not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`StringCompare.h`

StringToExtended

Converts a string representation of a number into a floating-point number, using a `NumFormatStringRec` structure to specify how the input number string is formatted. (Deprecated in Mac OS X v10.4. Use `CFNumberFormatterCreateStringWithNumber` instead.)

```
FormatStatus StringToExtended (
   ConstStr255Param source,
   const NumFormatString *myCanonical,
   const NumberParts *partsTable,
   extended80 *x
);
```

Parameters

source

A Pascal string that contains the string representation of a number.

myCanonical

A pointer to the internal representation of the formatting information for numbers, as produced by the `StringToFormatRec` function.

partsTable

A pointer to a structure, obtained from the tokens (`'itl4'`) resource, that shows the correspondence between generic number part separators (tokens) and their localized version (for example, a thousand separator is a comma in the United States and a decimal point in France).

x

On output, contains a pointer to the 80-bit SANE representation of the floating-point number.

Return Value

A value that denotes the confidence level for the conversion that it performed. The low byte of the `FormatStatus` value is of type `FormatResultType`. Be sure to cast the result of `StringToExtended` to a type `FormatResultType` before working with it. `StringToExtended` returns an 80-bit, not a 96-bit, representation. See the description of the `FormatStatus` data type.

Discussion

`StringToExtended` uses the internal representation of number formatting information that was created by a prior call to `StringToFormatRec` to parse the input number string. It uses the number parts table to determine the components of the number string that is being converted. `StringToExtended` parses the string and then converts the string to a simple form, stripping nondigits and replacing the decimal point before converting it into a floating-point number. If the input string does not match any of the patterns, then `StringToExtended` parses the string as well as it can and returns a confidence level result that indicates the parsing difficulties.

To obtain a handle to the number parts table from a tokens resource, use the `GetIntlResourceTable` function.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`NumberFormatting.h`

StringToFormatRec

Creates a number format specification string structure from a number format specification string that you supply in a Pascal string. (Deprecated in Mac OS X v10.4. Use `CFNumberFormatterSetFormat` instead.)

```
FormatStatus StringToFormatRec (
   ConstStr255Param inString,
   const NumberParts *partsTable,
   NumFormatString *outString
);
```

Parameters

inString

A Pascal string that contains the number formatting specification.

The `inString` parameter contains a number format specification string that specifies how numbers appear. This string contains up to three specifications, separated by semicolons. The positive number format is specified first, the negative number format is second, and the zero number format is last. If the string contains only one part, that is the format of all three types of numbers. If the string contains two parts, the first part is the format for positive and zero number values, and the second part is the format for negative numbers.

partsTable

A pointer to a structure, usually obtained from the tokens (`'itl4'`) resource, that shows the correspondence between generic number part separators (tokens) and their localized version (for example, a thousand separator is a comma in the United States and a decimal point in France).

outString

On output, a pointer to a `NumFormatStringRec` structure that contains the values that form the internal representation of the format specification. The format of the data in this structure is private.

Return Value

A value that denotes the confidence level for the conversion that was performed. The low byte of the value is of type `FormatResultType`. Be sure to cast the result of `StringToFormatRec` to a type `FormatResultType` before working with it. See the description of the `FormatStatus` data type.

Discussion

`StringToFormatRec` converts a number format specification string into the internal representation contained in a number format string structure. It uses information in the current script's tokens resource to determine the components of the number. `StringToFormatRec` checks the validity both of the input format string and of the number parts table (since this table can be programmed by the application). `StringToFormatRec` ignores spurious characters.

To obtain a handle to the number parts table from a tokens resource, use the `GetIntlResourceTable` function.

Special Considerations

`StringToFormatRec` may move memory; your application should not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`NumberFormatting.h`

StringToNum

Converts the Pascal string representation of a base-10 number into a long integer value. (Deprecated in Mac OS X v10.4. Use `CFStringGetIntValue` instead.)

```
void StringToNum (
   ConstStr255Param theString,
   long *theNum
);
```

Parameters

theString

A Pascal string representation of a base-10 number. The numeric string can be padded with leading zeros or with a sign.

theNum

On output, contains a pointer to the numeric value.

Discussion

Unless patched by a script system with different rules, this function assumes that you are using standard numeric token processing, meaning that the Roman script system number processing rules are used.

For functions that make use of the token-processing information that is found in the tokens (`'itl4'`) resource of script systems for converting numbers, see the sections "Using Number Format Specification Strings for International Number Formatting" and "Converting Between Strings and Floating-Point Numbers".

The 32-bit result is negated if the string begins with a minus sign. Integer overflow occurs if the magnitude is greater than or equal to 2 raised to the 31st power. `StringToNum` performs the negation using the two's complement method: the state of each bit is reversed and then 1 is added to the result. For example, here are possible results produced by `StringToNum`:

- The value of `theString` is "-23". `StringToNum` returns the value -23 in `theNum`.
- The value of `theString` is "-0". `StringToNum` returns the value 0 in `theNum`.
- The value of `theString` is "055". `StringToNum` returns the value 55 in `theNum`.
- The value of `theString` is "2147483648" (magnitude is 2^31). `StringToNum` returns the value –2147483648 in `theNum`.
- The value of `theString` is "–2147483648". `StringToNum` returns the value –2147483648 in `theNum`.
- The value of `theString` is "4294967295" (magnitude is 2^32–1). `StringToNum` returns the value -1 in `theNum`.
- The value of `theString` is "–4294967295". `StringToNum` returns the value 1 in `theNum`.

`StringToNum` does not check whether the characters in the string are between 0 and 9; instead, it takes advantage of the fact that the ASCII values for these characters are $30 through $39, and masks the last four bits for use as a digit. For example, `StringToNum` converts 2: to the number 30 since the character code for the colon (:) is $3A. Because `StringToNum` operates this way, spaces are treated as zeros (the character code for a space is $20), and other characters do get converted into numbers. For example, the character codes for 'C', 'A', and 'T' are $43, $41, and $54 respectively. Hence, the strings 'CAT', '+CAT', and '-CAT' would produce the results 314, 314, and -314.

One consequence of this conversion method is that `StringToNum` does not ignore thousand separators (the "," character in the United States), which can lead to improper conversions. It is a good idea to ensure that all characters in `theString` are valid digits before you call `StringToNum`.

Special Considerations

`StringToNum` may move memory; your application should not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`NumberFormatting.h`

StripDiacritics

Strips any diacritical marks from a text string. (Deprecated in Mac OS X v10.4. Use `CFStringTransform` instead.)

```
void StripDiacritics (
   Ptr textPtr,
   short len,
   ScriptCode script
);
```

Parameters

`textPtr`

A pointer to the text string to be stripped.

`len`

The length, in bytes, of the text string. The text string can be up to 32 KB in length.

`script`

The script code for the script system whose rules are used for determining which character results from stripping a diacritical mark.

The conversion uses tables in the string-manipulation (`'itl2'`) resource of the script specified by the value of the `script` parameter. You can specify `smSystemScript` to use the system script and `smCurrentScript` to use the script of the current font in the current graphics port.

Discussion

`StripDiacritics` traverses the characters starting at the address specified by `textPtr` and continues for the number of characters specified in `len`. It strips any diacritical marks from the text.

If `StripDiacritics` cannot access the specified resource, it generates an error code and does not modify the string. You need to call the `ResError` function to determine which, if any, error occurred.

Special Considerations

`StripDiacritics` may move memory; your application should not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`TextUtils.h`

TextOrder

Compares two text strings, taking into account the script and language for each of the strings. (Deprecated in Mac OS X v10.4. Use `CFStringCompare` or `UCCompareText` instead.)

```
short TextOrder (
   const void *aPtr,
   const void *bPtr,
   short aLen,
   short bLen,
   ScriptCode aScript,
   ScriptCode bScript,
   LangCode aLang,
   LangCode bLang
);
```

Parameters

aPtr
A pointer to the first character of the first text string.

bPtr
A pointer to the first character of the second text string.

aLen
The length, in bytes, of the first text string.

bLen
The length, in bytes, of the second text string.

aScript
The script code for the first text string.

bScript
The script code for the second text string.

aLang
The language code for the first text string.

bLang
The language code for the second text string.

Return Value

Returns –1 if the first string is less than the second string, 0 if the first string is equal to the second string, and 1 if the first string is greater than the second string. The ordering of script and language codes, which is based on information in the script-sorting resource, is considered in determining the relationship of the two strings.

Discussion

This function takes both primary and secondary sorting orders into consideration and returns a value that indicates whether the first string is less than, equal to, or greater than the second string.

"Implicit Language Codes" (page 1702) are listed in the Constants section. Most applications specify the language code `scriptCurLang` for both the `aLang` and `bLang` values.

`TextOrder` first calls `ScriptOrder` (page 1677); if the result of `ScriptOrder` is not 0 (that is, if the strings use different scripts), `TextOrder` returns the same result.

`TextOrder` next calls `LanguageOrder` (page 1668); if the result of `LanguageOrder` is not 0 (that is, if the strings use different languages), `TextOrder` returns the same result.

At this point, `TextOrder` has two strings that are in the same script and language, so it compares them by using the sorting rules for that script and language, applying both the primary and secondary sorting orders. If that script is not installed and enabled, it uses the sorting rules specified by the system script or the font script, depending on the state of the international resources selection flag.

The `TextOrder` function is primarily used to insert text strings in a sorted list; for sorting, rather than using this function, it may be faster to sort first by script and language by using the `ScriptOrder` and `LanguageOrder` functions, and then to call the `CompareText` (page 1656) function, to sort strings within a script or language group.

Special Considerations

`TextOrder` may move memory; your application should not call this function at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`StringCompare.h`

TypeSelectClear

Clears the key list and resets the type select record. (Deprecated in Mac OS X v10.4. Use `UCTypeSelectFlushSelectorData` instead.)

Not recommended.

```
void TypeSelectClear (
   TypeSelectRecord *tsr
);
```

Parameters

tsr

A pointer to the type-select record you want to clear.

Discussion
The use of this function is not recommended in a Unicode-based application. If you want to use this function in an application that uses the Unicode character set, you must first convert Unicode text strings to Macintosh encoded Pascal text strings. You must also provide the encoding type or be able to determine it by extracting it from the text or by examining the system or keyboard script.

Special Considerations

For Unicode-based applications, you should use the UCTypeSelect functions, which manipulate a `UCTypeSelectRef` object. For more detalis, see Unicode Utilities (`UnicodeUtilities.h`).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TypeSelect.h`

TypeSelectCompare

Compares a text buffer to the keystroke buffer. (Deprecated in Mac OS X v10.4. Use `UCTypeSelectCompare` instead.)

Not recommended.

```
short TypeSelectCompare (
   const TypeSelectRecord *tsr,
   ScriptCode testStringScript,
   StringPtr testStringPtr
);
```

Parameters

tsr

A type select record that contains the keystroke buffer.

testStringScript

The script code of the test string.

testStringPtr

A pointer to the text you want to compare to the keystroke buffer.

Return Value

A numerical value that represents the ordering of the characters in the keystroke buffer with respect to the test string buffer. The value -1 is returned if characters in the keystroke buffer sort before those in `testStringPtr`; 0 if characters in the keystroke buffer are the same as those in `testStringPtr`, and 1 if the characters in the keystroke buffer sort after those in `testStringPtr`.

Discussion

The use of this function is not recommended in a Unicode-based application. If you want to use this function in an application that uses the Unicode character set, you must first convert Unicode text strings to Macintosh encoded Pascal text strings. You must also provide the encoding type or be able to determine it by extracting it from the text or by examining the system or keyboard script.

Special Considerations

For Unicode-based applications, you should use the UCTypeSelect functions, which manipulate a `UCTypeSelectRef` object. For more detalis, see Unicode Utilities (`UnicodeUtilities.h`).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`TypeSelect.h`

TypeSelectFindItem

Finds the closest match between a specified list of characters and the keystrokes stored in the type select record. (Deprecated in Mac OS X v10.4. Use `UCTypeSelectFindItem` instead.)

Not recommended.

```
short TypeSelectFindItem (
   const TypeSelectRecord *tsr,
   short listSize,
   TSCode selectMode,
   IndexToStringUPP getStringProc,
   void *yourDataPtr
);
```

Parameters

tsr

A pointer to the type select record that contains the keystrokes you want to compare.

listSize

The size of the list to search through.

selectMode

The select mode. See `Type Select Modes` (page 1703)for a list of the constants you can supply.

getStringProc

A pointer to your index-to-string callback function. See `IndexToStringProcPtr` (page 1691) for more information.

yourDataPtr

A pointer to your data structure. This is passed to your index-to-string callback, and can be `NULL`, depending on how you implement your callback function.

Return Value

Discussion

The use of this function is not recommended in a Unicode-based application. If you want to use this function in an application that uses the Unicode character set, you must first convert Unicode text strings to Macintosh encoded Pascal text strings. You must also provide the encoding type or be able to determine it by extracting it from the text or by examining the system or keyboard script.

Special Considerations

For Unicode-based applications, you should use the UCTypeSelect functions, which manipulate a `UCTypeSelectRef` object. For more detalis, see Unicode Utilities (`UnicodeUtilities.h`).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`TypeSelect.h`

TypeSelectNewKey

Creates a new type select record. (Deprecated in Mac OS X v10.4. Use `UCTypeSelectCreateSelector` instead.)

Not recommended.

```
Boolean TypeSelectNewKey (
   const EventRecord *theEvent,
   TypeSelectRecord *tsr
);
```

Parameters

theEvent

A pointer to an event record.

tsr

A pointer to a type select record.

Return Value

Returns `true` if the function executed successfully; `false` otherwise.

Discussion

The use of this function is not recommended in a Unicode-based application. If you want to use this function in an application that uses the Unicode character set, you must first convert Unicode text strings to Macintosh encoded Pascal text strings. You must also provide the encoding type or be able to determine it by extracting it from the text or by examining the system or keyboard script.

Special Considerations

For Unicode-based applications, you should use the UCTypeSelect functions, which manipulate a `UCTypeSelectRef` object. For more detalis, see Unicode Utilities (`UnicodeUtilities.h`).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`TypeSelect.h`

UppercaseStripDiacritics

Converts any lowercase characters in a text string into their uppercase equivalents and strips any diacritical marks from the text. (Deprecated in Mac OS X v10.4. Use `CFStringTransform` instead.)

```
void UppercaseStripDiacritics (
   Ptr textPtr,
   short len,
   ScriptCode script
);
```

Parameters

textPtr

A pointer to the text string to be converted.

len

The length, in bytes, of the text string. The text string can be up to 32 KB in length.

script

The script code of the script system whose resources are used to determine the results of converting characters.

The conversion uses tables in the string-manipulation (`'itl2'`) resource of the script specified by the value of the `script` parameter. You can specify `smSystemScript` to use the system script and `smCurrentScript` to use the script of the current font in the current graphics port.

Discussion

`UppercaseStripDiacritics` traverses the characters starting at the address specified by `textPtr` and continues for the number of characters specified in `len`. It converts lowercase characters in the text into their uppercase equivalents and also strips diacritical marks from the text string. This function combines the effects of the `UppercaseText` (page 1689) and `StripDiacritics` (page 1683) functions.

If `UppercaseStripDiacritics` cannot access the specified resource, it generates an error code and does not modify the string. You need to call the `ResError` function to determine which, if any, error occurred.

Special Considerations

`UppercaseStripDiacritics` may move memory; your application should not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`TextUtils.h`

UppercaseText

Converts any lowercase characters in a text string into their uppercase equivalents. (Deprecated in Mac OS X v10.4. Use `CFStringUppercase` instead.)

```
void UppercaseText (
   Ptr textPtr,
   short len,
   ScriptCode script
);
```

Parameters

textPtr

A pointer to the text string to be converted.

len

The length, in bytes, of the text string. The text string can be up to 32 KB in length.

script

The script code of the script system whose case conversion rules are used for determining uppercase character equivalents.

The conversion uses tables in the string-manipulation (`'itl2'`) resource of the specified `script`. You can specify `smSystemScript` to use the system script and `smCurrentScript` to use the script of the current font in the current graphics port.

Discussion

`UppercaseText` traverses the characters starting at the address specified by `textPtr` and continues for the number of characters specified in `len`. It converts any lowercase characters in the text into uppercase.

If `UppercaseText` cannot access the specified resource, it generates an error code and does not modify the string. You need to call the `ResError` function to determine which, if any, error occurred.

Special Considerations

`UppercaseText` may move memory; your application should not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`TextUtils.h`

UpperString

Converts any lowercase letters in a Pascal string to their uppercase equivalents, using the Macintosh file system rules. (Deprecated in Mac OS X v10.4. Use `CFStringUppercase` instead.)

```
void UpperString (
   Str255 theString,
   Boolean diacSensitive
);
```

Parameters

theString

On input, this is the Pascal string to be converted. On output, this contains the string resulting from the conversion. `UpperString` traverses the characters in `theString` and converts any lowercase characters with character codes in the range 0x00 through 0xD8 into their uppercase equivalents. `UpperString` places the converted characters in `theString`.

diacSensitive

A flag that indicates whether the case conversion is to strip diacritical marks. If the value of this parameter is `TRUE`, diacritical marks are considered in the conversion; if it is `FALSE`, any diacritical marks are stripped.

Discussion

Only a subset of the Roman character set (character codes with values through $D8) are converted. Use this function to emulate the behavior of the Macintosh file system.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`TextUtils.h`

upperstring

Converts any lowercase letters in a Pascal string to their uppercase equivalents. (Deprecated in Mac OS X v10.4. Use `CFStringUppercase` instead.)

Not recommended

```
void upperstring (
   char *theString,
   Boolean diacSensitive
);
```

Parameters

`theString`

On input, this is the Pascal string to be converted. On output, this contains the string resulting from the conversion.

`diacSensitive`

A flag that indicates whether the case conversion is to strip diacritical marks. If the value of this parameter is `TRUE`, diacritical marks are considered in the conversion; if it is `FALSE`, any diacritical marks are stripped.

Discussion
You should use the function `CFStringUppercase` instead of this one.

Carbon Porting Notes

Use `UpperString` instead.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextUtils.h`

Callbacks

IndexToStringProcPtr

Defines a pointer to your index-to-string callback function that retrieves the string associated with an index value.

Not recommended.

```
typedef Boolean (*IndexToStringProcPtr)
(
    short item,
    ScriptCode * itemsScript,
    StringPtr * itemsStringPtr,
    void * yourDataPtr
);
```

If you name your function `MyIndexToStringProc`, you would declare it like this:

```
Boolean MyIndexToStringProcPtr (
    short item,
    ScriptCode * itemsScript,
    StringPtr * itemsStringPtr,
    void * yourDataPtr
);
```

Parameters

item
The index value for which the `TypeSelect` function requests a string.

itemsScript
The script code of the string specified by `itemsStringPtr`.

itemsStringPtr
On return, points to the string that matches the index specify by the `item` parameter.

yourDataPtr
A pointer to your data structure. This is passed to your index-to-string callback, and can be `NULL`, depending on how you implement your callback function.

Return Value
Returns `true` if a string matching that index value was found; `false` otherwise.

Discussion
The use of this function is not recommended in a Unicode-based application. If you want to use this function in an application that uses the Unicode character set, you must first convert Unicode text strings to Macintosh encoded Pascal text strings. You must also provide the encoding type or be able to determine it by extracting it from the text or by examining the system or keyboard script.

Availability
Not recommended. Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`TypeSelect.h`

Data Types

BreakTable

Contains information used to determine the boundaries of a word.

```
struct BreakTable {
    char charTypes[256];
    short tripleLength;
    short triples[1];
};
typedef struct BreakTable BreakTable;
typedef BreakTable * BreakTablePtr;
```

Discussion
You can supply a `BreakTable` as a parameter to the function `FindWordBreaks` (page 1661).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`TextUtils.h`

FormatClass

Defines a data type used to access entries in a triple integer array.

```
typedef SInt8 FormatClass;
```

Discussion
Each of the three `FVector` entries in a triple integer array is accessed by one of the values of the `FormatClass` type. See `FVector` (page 1693) for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NumberFormatting.h`

FormatStatus

Defines a data type used to denote the confidence level for a conversion.

```
typedef short FormatStatus;
```

Discussion
A `FormatStatus` value is returned by the functions `ExtendedToString` (page 1659), `StringToExtended` (page 1679), `FormatRecToString` (page 1663), and `StringToFormatRec` (page 1680).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NumberFormatting.h`

FVector

Contains position and length information for one portion of a formatted numeric string.

```
struct FVector {
    short start;
    short length;
};
typedef struct FVector FVector;
typedef FVector TripleInt[3];
```

Fields

`start`

The starting byte position in the string of the specification information.

`length`

The number of bytes used in the string for the specification information.

Discussion

The `FVector` data structure is used in the `TripleInt` (page 1698) array.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NumberFormatting.h`

IndexToStringUPP

Defines a universal procedure pointer to an index-to-string callback.

```
typedef IndexToStringProcPtr IndexToStringUPP;
```

Discussion

For more information, see the description of the `IndexToStringProcPtr` (page 1691) callback function.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`TypeSelect.h`

NBreakTable

Contains information used by the `FindWordBreaks` function to determine word boundaries.

```
struct NBreakTable {
    SInt8 flags1;
    SInt8 flags2;
    short version;
    short classTableOff;
    short auxCTableOff;
    short backwdTableOff;
    short forwdTableOff;
    short doBackup;
    short length;
    char charTypes[256];
    short tables[1];
};
typedef struct NBreakTable NBreakTable;
typedef NBreakTable * NBreakTablePtr;
```

Fields

`flags1`
: The high-order byte of the break table format flags. If the high-order bit of this byte is set to 1, this break table is in the format used by `FindWordBreaks`.

`flags2`
: The low-order byte of the break table format flags. If the value in this byte is 0, the break table belongs to a 1-byte script system; in this case `FindWordBreaks` does not check for 2-byte characters.

`version`
: The version of this break table.

`classTableOff`
: The offset in bytes from the beginning of the break table to the beginning of the class table.

`auxCTableOff`
: The offset in bytes from the beginning of the break table to the beginning of the auxiliary class table.

`backwdTableOff`
: The offset in bytes from the beginning of the break table to the beginning of the backward-processing table.

`forwdTableOff`
: The offset in bytes from the beginning of the break table to the beginning of the forward-processing table.

`doBackup`
: The minimum byte offset into the buffer for doing backward processing. If the selected character for `FindWordBreaks` has a byte offset less than `doBackup`, `FindWordBreaks` skips backward processing altogether and starts from the beginning of the buffer.

`length`
: The length in bytes of the entire break table, including the individuals tables.

`charTypes`
: The class table.

`tables`
: The data of the auxiliary class table, backward table, and forward table.

Discussion

The tables have this format and content:

- The class table is an array of 256 signed bytes. Offsets into the table represent byte values; if the entry at a given offset in the table is positive, it means that a byte whose value equals that offset is a single-byte character, and the entry at that offset is the class number for the character. If the entry is negative, it means that the byte is the first byte of a 2-byte character code, and the auxiliary class table must be used to determine the character class. Odd negative numbers are handled differently from even negative numbers.
- The auxiliary class table assigns character classes to 2-byte characters. It is used when the class table determines that a byte value represents the first byte of a 2-byte character.
  - The auxiliary class table handles odd negative values from the class table as follows. If the first word of the auxiliary class table is equal to or greater than zero, it represents the default class number for 2-byte character codes—the class assigned to every odd negative value from the class table. If the first word is less than zero, it is the negative of the offset from the beginning of the auxiliary class table to a first-byte class table (a table of 2-byte character classes that can be determined from just the first byte). The value from the class table is negated, 1 is subtracted from it to obtain an even offset, and the value at that offset into the first-byte class table is the class to be assigned.
  - The auxiliary class table handles even negative values from the class table as follows. The auxiliary class table begins with a variable-length word array. The words that follow the first word are offsets to row tables. Row tables have the same format as the class table, but are used to map the second byte of a 2-byte character code to a class number. If the entry in the class table for a given byte is an even negative number, `FindWordBreaks` negates this value to obtain the offset from the beginning of the auxiliary class table to the appropriate word, which in turn contains an offset to the appropriate row table. That row table is then used to map the second byte of the character to a class number.
- The backward-processing table is a state table used by `FindWordBreaks` for backward searching. Using the backward-processing table, `FindWordBreaks` starts at a specified character, moving backward as necessary until it encounters a word boundary.
- The forward-processing table is a state table used by `FindWordBreaks` for forward searching. Using the forward-processing table, `FindWordBreaks` starts at one word boundary and moves forward until it encounters another word boundary.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`TextUtils.h`

NumFormatString

Contains data that represents the internal number formatting specification.

```
struct NumFormatString {
    UInt8 fLength;
    UInt8 fVersion;
    char data[254];
};
typedef struct NumFormatString NumFormatString;
typedef NumFormatString NumFormatStringRec;
```

Fields

`fLength`
The number of bytes in the data actually used for this number formatting specification.

`fVersion`
The version number of the number formatting specification.

`data`
The data that comprises the number formatting specification.

Discussion

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NumberFormatting.h`

NumFormatStringRec

Defines an internal numeric representation that is independent of region, language, and other multicultural consideration.

```
typedef NumFormatString NumFormatStringRec;
```

Discussion
To allow for all of the international variations in numeric presentation styles, you need to include in your function calls a number parts table from a tokens (`'itl4'`) resource. You can usually use the number parts table in the standard tokens resource that is supplied with the system. You also need to define the format of input and output numeric strings, including which characters (if any) to use as thousand separators, whether to indicate negative values with a minus sign or by enclosing the number in parentheses, and how to display zero values.

To make it possible to map a number that was formatted for one specification into another format, the Mac OS defines an internal numeric representation that is independent of region, language, and other multicultural considerations: the `NumFormatStringRec` structure. This structure is created from a number format specification string that defines the appearance of numeric strings.

Four of the numeric string functions use the number formatting specification, defined by the `NumFormatStringRec` data type: `StringToFormatRec` (page 1680), `FormatRecToString` (page 1663), `StringToExtended` (page 1679), and `ExtendedToString` (page 1659). The number format specification structure contains the data that represents the internal number formatting specification information. This data is stored in a private format.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`NumberFormatting.h`

ScriptRunStatus

Contains script-specific information for a script run.

```
struct ScriptRunStatus {
    SInt8 script;
    SInt8 runVariant;
};
typedef struct ScriptRunStatus ScriptRunStatus;
```

Fields

`script`

The script code of the subscript run. Zero indicates the Roman script system.

`runVariant`

Script-specific information about the run, in the same format as that returned by the `CharacterType` function. This information includes the type of subscript—for example, Kanji, Katakana, or Hiragana for a Japanese script system.

Discussion

The `FindScriptRun` (page 1660) function returns the script run status structure, defined by the `ScriptRunStatus` data type, when it completes its processing, which is to find a run of subscript text in a string.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`TextUtils.h`

TripleInt

Defines a data type used to return the position and length information for three different portions of a formatted numeric string.

```
typedef FVector TripleInt[3];
```

Discussion

The `FormatRecToString` (page 1663) function uses the triple-integer array, defined by the `TripleInt` data type, to return the starting position and length in a string of three different portions of a formatted numeric string: the positive value string, the negative value string, and the zero value string. Each element of the triple integer array is an `FVector` structure. Each of the three `FVector` entries in the triple integer array is accessed by one of the values of the `FormatClass` type.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`NumberFormatting.h`

TypeSelectRecord

Contains a buffer of keystrokes, the script code associated with the keystrokes, and timer information.

```
struct TypeSelectRecord {
    unsigned long tsrLastKeyTime;
    ScriptCode tsrScript;
    Str63 tsrKeyStrokes;
};
typedef struct TypeSelectRecord TypeSelectRecord;
```

Fields

`tsrLastKeyTime`
A value that indicates timeout information.

`tsrScript`
A script code.

`tsrKeyStrokes`
The keystroke buffer.

Discussion

The `TypeSelectRecord` data structure is passed as a parameter to the functions `TypeSelectNewKey` (page 1687), `TypeSelectFindItem` (page 1686), `TypeSelectCompare` (page 1686), and `TypeSelectClear` (page 1685).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`TypeSelect.h`

Constants

Format Result Types

Specify values that can be returned in the low byte of a format status (`FormatStatus`) value.

```
enum {
    fFormatOK = 0,
    fBestGuess = 1,
    fOutOfSynch = 2,
    fSpuriousChars = 3,
    fMissingDelimiter = 4,
    fExtraDecimal = 5,
    fMissingLiteral = 6,
    fExtraExp = 7,
    fFormatOverflow = 8,
    fFormStrIsNAN = 9,
    fBadPartsTable = 10,
    fExtraPercent = 11,
    fExtraSeparator = 12,
    fEmptyFormatString = 13
};
typedef SInt8 FormatResultType;
```

Constants

`fFormatOK`
Specifies format is okay.
Available in Mac OS X v10.0 and later.
Declared in `NumberFormatting.h`.

`fBestGuess`
Specifies the format is the best guess.
Available in Mac OS X v10.0 and later.
Declared in `NumberFormatting.h`.

`fOutOfSynch`
Specifies the format is out of sync.
Available in Mac OS X v10.0 and later.
Declared in `NumberFormatting.h`.

`fSpuriousChars`
Specifies the format contains spurious characters.
Available in Mac OS X v10.0 and later.
Declared in `NumberFormatting.h`.

`fMissingDelimiter`
Specifies a missing delimiter.
Available in Mac OS X v10.0 and later.
Declared in `NumberFormatting.h`.

`fExtraDecimal`
Specifies the format contains an extra decimal sign.
Available in Mac OS X v10.0 and later.
Declared in `NumberFormatting.h`.

`fMissingLiteral`
Specifies the format is missing a literal.
Available in Mac OS X v10.0 and later.
Declared in `NumberFormatting.h`.

`fExtraExp`
Available in Mac OS X v10.0 and later.
Declared in `NumberFormatting.h`.

`fFormatOverflow`
Specifies a format overflow.
Available in Mac OS X v10.0 and later.
Declared in `NumberFormatting.h`.

`fFormStrIsNAN`
Available in Mac OS X v10.0 and later.
Declared in `NumberFormatting.h`.

`fBadPartsTable`
Specifies the parts table is bad.
Available in Mac OS X v10.0 and later.
Declared in `NumberFormatting.h`.

`fExtraPercent`
Specifies the format contains an extra percent sign.
Available in Mac OS X v10.0 and later.
Declared in `NumberFormatting.h`.

`fExtraSeparator`
Specifies an extra separator.
Available in Mac OS X v10.0 and later.
Declared in `NumberFormatting.h`.

`fEmptyFormatString`
Specifies the format string is empty.
Available in Mac OS X v10.0 and later.
Declared in `NumberFormatting.h`.

Discussion
A format result type is returned in the low byte of a format status (`FormatStatus`) value. A `FormatStatus` (page 1693) value is returned by the functions `ExtendedToString` (page 1659), `StringToExtended` (page 1679), `FormatRecToString` (page 1663), and `StringToFormatRec` (page 1680). A format status value denotes the confidence level for a conversion.

TripleInt Index Values

Specify an index for a `TripleInt` array.

```
enum {
    fPositive = 0,
    fNegative = 1,
    fZero = 2
};
```

Constants

`fPositive`

Specifies the positive value string.

Available in Mac OS X v10.0 and later.

Declared in `NumberFormatting.h`.

`fNegative`

Specifies the negative value string.

Available in Mac OS X v10.0 and later.

Declared in `NumberFormatting.h`.

`fZero`

Specifies the zero value string.

Available in Mac OS X v10.0 and later.

Declared in `NumberFormatting.h`.

Discussion

See `TripleInt` (page 1698) for more information.

NumFormatString Version

Specifies the first version of the `NumFormatString` data structure.

```
enum {
    fVNumber = 0
};
```

Discussion

See `NumFormatString` (page 1696) for more information.

Implicit Language Codes

Specify implicit language codes.

```
enum {
    systemCurLang = -2,
    systemDefLang = -3,
    currentCurLang = -4,
    currentDefLang = -5,
    scriptCurLang = -6,
    scriptDefLang = -7
};
```

Constants

`systemCurLang`
Specifies the current language for system script (from `'itlb'`).
Available in Mac OS X v10.0 and later.
Declared in `StringCompare.h`.

`systemDefLang`
Specifies the default language for system script (from `'itlm'`).
Available in Mac OS X v10.0 and later.
Declared in `StringCompare.h`.

`currentCurLang`
Specifies the current language for current script (from `'itlb'`).
Available in Mac OS X v10.0 and later.
Declared in `StringCompare.h`.

`currentDefLang`
Specifies the default language for current script (from `'itlm'`).
Available in Mac OS X v10.0 and later.
Declared in `StringCompare.h`.

`scriptCurLang`
Specifies the current language for specified script (from `'itlb'`)
Available in Mac OS X v10.0 and later.
Declared in `StringCompare.h`.

`scriptDefLang`
Specifies the default language for specified script (from `'itlm'`)
Available in Mac OS X v10.0 and later.
Declared in `StringCompare.h`.

Discussion
The functions `LanguageOrder` (page 1668), `StringOrder` (page 1678), and `TextOrder` (page 1684) accept as parameters implicit language codes listed here, as well as explicit language codes.

Type Select Modes

Contains type-select code information.

```
typedef SInt16 TSCode;
enum {
    tsPreviousSelectMode = -1,
    tsNormalSelectMode = 0,
    tsNextSelectMode = 1
};
```

Constants

`tsPreviousSelectMode`
Specifies previous-select mode.
Available in Mac OS X v10.0 and later.
Declared in `TypeSelect.h`.

`tsNormalSelectMode`
Specifies normal-select mode.
Available in Mac OS X v10.0 and later.
Declared in `TypeSelect.h`.

`tsNextSelectMode`
Specifies next-select mode.
Available in Mac OS X v10.0 and later.
Declared in `TypeSelect.h`.

Discussion
This structure is passed as a parameter to the function `TypeSelectFindItem` (page 1686).

Obsolete Language Code Values

Specify language code values that are no longer used.

```
enum {
    iuSystemCurLang = systemCurLang,
    iuSystemDefLang = systemDefLang,
    iuCurrentCurLang = currentCurLang,
    iuCurrentDefLang = currentDefLang,
    iuScriptCurLang = scriptCurLang,
    iuScriptDefLang = scriptDefLang
};
```

Translation Manager Reference

Framework:	Carbon/Carbon.h
Declared in	Translation.h TranslationExtensions.h

Overview

You can use the Translation Manager to direct the translation of documents from one format to another. For example, Macintosh Easy Open uses the Translation Manager to provide

- automatic translation of a document, if the application that created the document is not available
- automatic translation of documents drop-launched onto an application
- enhanced file-opening dialog boxes and (when necessary) automatic translation of documents the user selects in those dialog boxes
- batch desktop translation of documents
- automatic translation of data pasted from the clipboard

These services allow your application to open documents created by other applications (possibly running on other operating systems) and to import data from other applications with better fidelity than previously possible.

Macintosh Easy Open does not do any translating itself, and it does not have any knowledge of translation data models. Instead, it delegates these functions to translation extensions or to applications with built-in translation capability. Translation extensions and application translation capabilities operate as "black boxes" to Macintosh Easy Open. At system startup (or whenever new translation extensions become available), Macintosh Easy Open catalogs the translation capability of each translation extension and each application, and then invokes each as needed. Macintosh Easy Open can support multiple translation systems.

Carbon supports the Translation Manager in Mac OS 9, with the exception of the functions declared in `TranslationExtensions.h`.

Important: The Translation Manager was deprecated in Mac OS X v10.3. In Mac OS X, Carbon includes the Translation Manager headers but does not implement any of the functionality. If you call the functions declared in the API, they do nothing. You should use Translation Services instead.

Functions

CanDocBeOpened

Determines whether a specified application can open a particular document. (Deprecated in Mac OS X v10.3. Use Launch Services to determine whether a document can be opened. See *Launch Services Programming Guide*.)

Not Recommended

```
OSErr CanDocBeOpened (
   const FSSpec *targetDocument,
   short appVRefNumHint,
   OSType appSignature,
   const FileType *nativeTypes,
   Boolean onlyNative,
   DocOpenMethod *howToOpen,
   FileTranslationSpec *howToTranslate
);
```

Parameters

targetDocument

A pointer to the document to check.

appVRefNumHint

The volume reference number of the volume containing the application. The search for the specified application begins on this volume if the application isn't found there, the search continues to other mounted volumes.

appSignature

The signature of the application.

nativeTypes

A pointer to the zero-terminated list of file types that the application can open without translation; if this parameter contains `NULL`, the default list of file types returned by the `GetFileTypesThatAppCanNativelyOpen` (page 1710) function is used.

onlyNative

If `TRUE`, determine only whether the application can open the document without translation; otherwise, determine whether the application can open the document after translation.

howToOpen

On return, a pointer to a constant indicating the method of opening the document. This field contains a meaningful value only if the function returns `noErr` (indicating that the specified document can be opened). See "DocOpenMethod" (page 1731) for a description of the values you can use here.

howToTranslate

On return, if the document needs to be translated before it can be opened, a pointer to a buffer of information (in a private format) indicating how to translate the document. You pass the information returned in this parameter to the `TranslateFile` (page 1714) function.

Return Value
A result code. If the application can open the document, the function returns `noErr`.

Discussion
A preference must have already been set (using the Document Converter tool) on how to open the document.

Special Considerations

This function might cause memory to be moved or purged; you should not call it at interrupt time.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.3.

Not available to 64-bit applications.

Declared In
`Translation.h`

DisposeGetScrapDataUPP

Disposes of a universal procedure pointer (UPP) to a source-data fetcher callback. (Deprecated in Mac OS X v10.3. There is no replacement function. You should adopt Translation Services instead.)

```
void DisposeGetScrapDataUPP (
   GetScrapDataUPP userUPP
);
```

Parameters

userUPP

The universal procedure pointer.

Discussion
See the callback `GetScrapDataProcPtr` (page 1726) for more information.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.3.

Declared In
`Translation.h`

ExtendFileTypeList

Creates a list of file types that can be translated into a type in a given list. (Deprecated in Mac OS X v10.3. Use the Translation Services function `TranslationCreateWithSourceArray` instead.)

Not Recommended

```
OSErr ExtendFileTypeList (
   const FileType *originalTypeList,
   short numberOriginalTypes,
   FileType *extendedTypeList,
   short *numberExtendedTypes
);
```

Parameters

originalTypeList

A pointer to a list of file types that can be opened.

numberOriginalTypes

The number of file types in the `originalTypeList` parameter.

extendedTypeList

On return, a pointer to a buffer filled with file types that can be translated into the types in `originalTypeList`.

numberExtendedTypes

On input, a pointer to the maximum number of file types that can be put into the buffer passed in the `extendedTypeList` parameter. On return, a pointer to the actual number of file types put into the extended type list.

Return Value

A result code. See "Translation Manager Result Codes" (page 1732).

Discussion

Note that the number of types specified in the parameters `numberOriginalTypes` and `numberExtendedTypes` is limited only by available memory.

The Standard File Package calls this function internally your application probably won't need to use it.

Special Considerations

This function might cause memory to be moved or purged; you should not call it at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.3.

Not available to 64-bit applications.

Declared In

`Translation.h`

GetDocumentKindString

Allows you to get a document kind string. (Deprecated in Mac OS X v10.3. There is no replacement function, but you can use Launch Services to obtain similar information. See *Launch Services Programming Guide*.)

Not Recommended

```
OSErr GetDocumentKindString (
   short docVRefNum,
   OSType docType,
   OSType docCreator,
   Str63 kindString
);
```

Parameters

docVRefNum

The volume containing the document. This is a hint to the Translation Manager. If it doesn't find the string on that volume, it will use an internal search path to look on other volumes for the string.

docType

The type code of the document you want to query.

docCreator

The creator code of the document you want to query.

kindString

Upon return, contains the kind string to display for the specified document type and creator.

Return Value
A result code. See "Translation Manager Result Codes" (page 1732).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.3.
Not available to 64-bit applications.

Declared In
`Translation.h`

GetFileTranslationPaths

A low-level routine that allows you to get all the translation capabilities of the Translation Manager. (Deprecated in Mac OS X v10.3. Use the Translation Services function `TranslationCreateWithSourceArray` instead.)

Not Recommended

```
short GetFileTranslationPaths (
   const FSSpec *srcDocument,
   FileType dstDocType,
   unsigned short maxResultCount,
   FileTranslationSpecArrayPtr resultBuffer
);
```

Parameters

srcDocument

A source document (optional), or `NULL`.

dstDocType

The desired document type to which you would like `srcDocument` translated.

resultBuffer

The requested translation information.

Return Value
Returns the number of translation paths, or a result code if the value is negative.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.3.
Not available to 64-bit applications.

Declared In
`Translation.h`

GetFileTypesThatAppCanNativelyOpen

Obtains a list of file types that an application can open by itself. (Deprecated in Mac OS X v10.3. There is no replacement function. Applications should use Translation Services instead.)

Not Recommended

```
OSErr GetFileTypesThatAppCanNativelyOpen (
   short appVRefNumHint,
   OSType appSignature,
   FileType *nativeTypes
);
```

Parameters

appVRefNumHint
The volume reference number of the volume containing the application. The search for the specified application begins on this volume if the application isn't found there, the search continues to other mounted volumes.

appSignature
The signature of the application.

nativeTypes
On return, a pointer to an array of file types that the application can open without translation. If successful, the array contains up to 64 file types. If fewer than 64 types are returned, the end of the list is indicated by an entry whose value is 0.

Return Value
A result code. See "Translation Manager Result Codes" (page 1732).

Special Considerations
This function might cause memory to be moved or purged; you should not call it at interrupt time.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.3.
Not available to 64-bit applications.

Declared In
`Translation.h`

GetPathFromTranslationDialog

Displays the Translation Dialog, which attempts to generate a list of translation paths resulting in a document readable by the target application. (Deprecated in Mac OS X v10.3. There is no replacement function. However, applications can obtain this information using Launch Services, Translation Services, and uniform type identifiers.)

Not Recommended

```
OSErr GetPathFromTranslationDialog (
   const FSSpec *theDocument,
   const FSSpec *theApplication,
   TypesBlockPtr typeList,
   DocOpenMethod *howToOpen,
   FileTranslationSpec *howToTranslate
);
```

Parameters

theDocument
The target file.

theApplication
The target application.

typeList
Specifies a list of file types into which to translate the target document.

howToOpen
Upon return, contains the translation open method.

howToTranslate
Upon return, contains the translation specification.

Return Value

A result code. See "Translation Manager Result Codes" (page 1732).

Special Considerations

For information about using Launch Services and uniform type identifiers, see *Launch Services Programming Guide* and *Uniform Type Identifiers Overview*.

Availability

Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.3.
Not available to 64-bit applications.

Declared In

`Translation.h`

GetTranslationExtensionName

Finds the name of the extension performing the translation. (Deprecated in Mac OS X v10.3. There is no replacement function. However, you can obtain useful user-level information by calling the Translation Manager function `TranslationCopyDestinationType` and the uniform type identifiers function `UTTypeCopyDescription`.)

Not Recommended

```
OSErr GetTranslationExtensionName (
   const FileTranslationSpec *translationMethod,
   Str31 extensionName
);
```

Parameters

translationMethod

A file translation method obtained by calling `CanDocBeOpened` or `GetFileTranslationPaths`.

extensionName

Upon return, contains the name of the extension performing the translation.

Return Value

A result code. See "Translation Manager Result Codes" (page 1732).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.3.

Not available to 64-bit applications.

Declared In

`Translation.h`

InvokeGetScrapDataUPP

Calls a source-data fetcher callback. (Deprecated in Mac OS X v10.3. There is no replacement function. You should adopt Translation Services instead.)

```
OSErr InvokeGetScrapDataUPP (
   ScrapType requestedFormat,
   Handle dataH,
   void *srcDataGetterRefCon,
   GetScrapDataUPP userUPP
);
```

Discussion

You should not need to use the function `InvokeGetScrapDataUPP`, as the system calls your source-data fetcher callback for you. See the callback `GetScrapDataProcPtr` (page 1726) for more information.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.3.

Declared In

`Translation.h`

NewGetScrapDataUPP

Creates a new universal procedure pointer (UPP) to a source-data fetcher callback. (Deprecated in Mac OS X v10.3. There is no replacement function. You should adopt Translation Services instead.)

```
GetScrapDataUPP NewGetScrapDataUPP (
   GetScrapDataProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your source-data fetcher callback.

Return Value

On return, a UPP to the source-data fetcher callback.

Discussion

See the callback `GetScrapDataProcPtr` (page 1726) for more information.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.3.

Declared In

`Translation.h`

SetTranslationAdvertisement

Allows your translation extension to install an advertisement into the upper portion of the progress dialog box. (Deprecated in Mac OS X v10.3. There is no replacement function. You should adopt Translation Services instead.)

Unsupported

```
OSErr SetTranslationAdvertisement (
   TranslationRefNum refNum,
   PicHandle advertisement
);
```

Parameters

refNum

A translation reference number. You should set this parameter to the translation reference number passed to your `DoTranslateFileProcPtr` (page 1723) or `DoTranslateScrapProcPtr` (page 1724) callback functions. The Translation Manager uses that number internally.

advertisement

A handle to a picture to display in the upper portion of the dialog box. If this parameter is `NULL`, no advertisement is displayed and the upper portion of the dialog box is removed before the box is displayed to the user. After the function installs the specified advertisement, it then displays the dialog box.

Your translation extension can read the picture data from its resource fork, but it should detach the resource from the resource fork (by calling the `DetachResource` function) and make the handle unpurgeable before calling this function. Because you'll usually load the picture data into the temporary heap provided for the translation extension, the picture data is automatically disposed of when that heap is destroyed. If your translation extension loads the picture data elsewhere in memory, you are responsible for disposing of it before returning from your `DoTranslateFile` or `DoTranslateScrap` callback function.

The size of the picture to display can be no larger than 280 by 50 pixels. If the picture you specify is smaller than that, it is automatically centered (both vertically and horizontally) in the available space.

Return Value
A result code. See "Translation Manager Result Codes" (page 1732).

Discussion
Your translation extension should call this function only in response to the `kTranslateTranslateFile` or `kTranslateTranslateScrap` request code (that is, you should only call this function in your `DoTranslateFile` or `DoTranslateScrap` callback function). Do not call this function in response to any other request code or from any code that isn't a translation extension.

You must call this function before you call the `UpdateTranslationProgress` (page 1716) function for the first time.

Special Considerations

This function might cause memory to be moved or purged; you should not call it at interrupt time.

Carbon Porting Notes

The functions contained in TranslationExtensions.h were originally written to be used only by someone implementing a Mac Easy Open translation component. Carbon, however, is for applications and not extensions. Therefore, this function is not supported.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.3.
Not available to 64-bit applications.

Declared In
`TranslationExtensions.h`

TranslateFile

Translates a document from one format to another. (Deprecated in Mac OS X v10.3. Use the Translation Services function `TranslationPerformForFile` or `TranslationPerformForURL` instead.)

Not Recommended

```
OSErr TranslateFile (
   const FSSpec *sourceDocument,
   const FSSpec *destinationDocument,
   const FileTranslationSpec *howToTranslate
);
```

Parameters

sourceDocument

A pointer to the document to translate.

destinationDocument

A pointer to the file to put the translated document into. Note that your application only specifies the name and location for the file; the function creates the file and puts the translated data into it. The destination file must not exist before you call this function.

howToTranslate

A pointer to a buffer of information indicating how to translate the document. Usually, you'll get this information by calling the `CanDocBeOpened` (page 1706) function.

Return Value

A result code. See "Translation Manager Result Codes" (page 1732).

Special Considerations

This function might cause memory to be moved or purged; you should not call it at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.3.

Not available to 64-bit applications.

Declared In

`Translation.h`

TranslateScrap

Uses a client-specified callback function to get the source data to translate. (Deprecated in Mac OS X v10.3. Use the Translation Manager function `TranslationPerformForData` instead.)

Not Recommended

```
OSErr TranslateScrap (
   GetScrapDataUPP sourceDataGetter,
   void *sourceDataGetterRefCon,
   ScrapType destinationFormat,
   Handle destinationData,
   short progressDialogID
);
```

Parameters

sourceDataGetter

The callback that provides the data to translate.

sourceDataGetterRefCon

A generic pointer to private information for your callback.

destinationFormat
The desired translation format.

destinationData
A handle you provide. The Translation Extension will automatically re-size it as necessary during translation. Upon exit, if the routine successfully executes, it will contain the translated information.

progressDialogID
This parameter should always be assigned the value `TranslationScrapProgressDialogID`.

Return Value
A result code. See "Translation Manager Result Codes" (page 1732).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.3.
Not available to 64-bit applications.

Declared In
`Translation.h`

UpdateTranslationProgress

Allows your translation extension to update the progress dialog box that is displayed during file and scrap translation and give the user a chance to cancel. (Deprecated in Mac OS X v10.3. There is no replacement function. You should adopt Translation Services instead.)

Unsupported

```
OSErr UpdateTranslationProgress (
   TranslationRefNum refNum,
   short percentDone,
   Boolean *canceled
);
```

Parameters

refNum
A translation reference number. You should set this parameter to the translation reference number passed to your `DoTranslateFileProcPtr` (page 1723) or `DoTranslateScrapProcPtr` (page 1724) callback function. The Translation Manager uses that number internally.

percentDone
A value in the range 0–100 that indicates the percentage of the translation that has been completed (the approximate percentage of time elapsed until completion). When the translation is complete, you should call this function with this parameter set to 100 so that the user can see that the translation is complete.

canceled
On return, a pointer to a value which indicates whether or not the user canceled the translation. `TRUE` if the user clicked the Cancel button in the progress dialog box, or typed Command-period while the box is displayed; otherwise, `FALSE`. When `TRUE`, you should stop the translation, and your `DoTranslateFile` or `DoTranslateScrap` callback function should return the result code `userCancelledErr`.

Return Value
A result code. See "Translation Manager Result Codes" (page 1732).

Discussion
Your translation extension should call this function only in response to the `kTranslateTranslateFile` or `kTranslateTranslateScrap` request code (that is, you should only call this function in your `DoTranslateFile` or `DoTranslateScrap` callback function). Do not call this function in response to any other request code or from any code that isn't a translation extension.

You should already have called `SetTranslationAdvertisement` before calling `UpdateTranslationProgress`.

Special Considerations

This function might cause memory to be moved or purged; you should not call it at interrupt time.

Carbon Porting Notes

The functions contained in TranslationExtensions.h were originally written to be used only by someone implementing a Mac Easy Open translation component. Carbon, however, is for applications and not extensions. Therefore, this function is not supported.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.3.
Not available to 64-bit applications.

Declared In
`TranslationExtensions.h`

Callbacks

DoGetFileTranslationListProcPtr

Defines a pointer to a get file translation list callback function that returns a list of the file types which your extension can translate.

Unsupported

```
typedef ComponentResult (*DoGetFileTranslationListProcPtr)
(
    ComponentInstance self,
    FileTranslationListHandle translationList
);
```

If you name your function `MyDoGetFileTranslationListProc`, you would declare it like this:

```
ComponentResult DoGetFileTranslationListProcPtr
(
    ComponentInstance self,
    FileTranslationListHandle translationList
);
```

Parameters

self
A component instance that identifies the component containing the translation extension.

translationList

On entry to your function, this parameter contains a handle to a structure of type `FileTranslationList` (page 1727). If your translation extension can translate any files at all, your function should resize that handle and fill the block with a list of the file types it can translate. If the translation list whose handle you return in this parameter has the `groupCount` field set to 0, Macintosh Easy Open assumes that your extension cannot translate any file types.

For improved performance, Macintosh Easy Open remembers each translation extension's most recently returned file translation list and passes that list to your get file translation list callback function in this parameter. If you determine that the list hasn't changed, you should simply return the same handle to Macintosh Easy Open.

Return Value
If successful, your function should return `noErr`. Otherwise, your function should return an appropriate result code. The Component Manager requires this function to return a value of type `ComponentResult` to simplify dispatching. See the Component Manager documentation for a description of the `ComponentResult` data type.

Discussion
A file translation extension must respond to the `kTranslateGetFileTranslationList` request code. Whenever it first notices the extension, Macintosh Easy Open calls your extension with this request code to obtain a list of the file types that the extension can translate. You can handle this request by calling the Component Manager function `CallComponentFunctionWithStorage` and passing it a pointer to a your get file translation list callback function.

Carbon Porting Notes

The functions contained in TranslationExtensions.h were originally written to be used only by someone implementing a Mac Easy Open translation component. Carbon, however, is for applications and not extensions. Therefore, this function is not supported.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TranslationExtensions.h`

DoGetScrapTranslationListProcPtr

Defines a pointer to a get-scrap-translation-list callback function that returns a list of the scrap types that your extension can translate.

Unsupported

```
typedef ComponentResult (*DoGetScrapTranslationListProcPtr)
(
    ComponentInstance self,
    ScrapTranslationListHandle list
);
```

If you name your function `MyDoGetScrapTranslationListProc`, you would declare it like this:

```
ComponentResult DoGetScrapTranslationListProcPtr
(
    ComponentInstance self,
    ScrapTranslationListHandle list
```

```
);
```

Parameters

self

A component instance that identifies the component containing the translation extension.

list

A handle to a `ScrapTranslationList` (page 1729). Your function should return, through this parameter, a handle to a list of the scrap types from and into which your translation extension can translate. If your translation extension can translate any scrap types at all, your function should resize this handle and fill the block with a list of the scrap types it can translate. If the translation list whose handle you return in this parameter has the `groupCount` field set to 0, Macintosh Easy Open assumes that your extension cannot translate any scrap types.

On entry to your function, this parameter contains a handle to a structure of type `ScrapTranslationList`. When it first becomes aware of your extension, Macintosh Easy Open calls your translation extension's get scrap translation list function. For improved performance, Macintosh Easy Open remembers each translation extension's most recently returned scrap translation list and passes that list to your function in this parameter. If you determine that the list hasn't changed, you should simply return the same handle to Macintosh Easy Open.

Return Value

If successful, your function should return `noErr`. Otherwise, your function should return an appropriate result code. The Component Manager requires this function to return a value of type `ComponentResult` to simplify dispatching. See the Component Manager documentation for a description of the `ComponentResult` data type.

Discussion

A scrap translation extension must respond to the `kTranslateGetScrapTranslationList` request code. At system startup time, the Translation Manager calls your extension with this code. You can handle this request by calling the Component Manager function `CallComponentFunctionWithStorage` and passing it a pointer to your get scrap translation list callback function.

Carbon Porting Notes

The functions contained in TranslationExtensions.h were originally written to be used only by someone implementing a Mac Easy Open translation component. Carbon, however, is for applications and not extensions. Therefore, this function is not supported.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`TranslationExtensions.h`

DoGetTranslatedFilenameProcPtr

Defines a pointer to a get-translated-filename callback function.

Unsupported

```
typedef ComponentResult (*DoGetTranslatedFilenameProcPtr)
(
    ComponentInstance self,
    FileType dstType,
    long dstTypeHint,
    FSSpec * theDocument
);
```

If you name your function `MyDoGetTranslatedFilenameProc`, you would declare it like this:

```
ComponentResult DoGetTranslatedFilenameProcPtr
(
    ComponentInstance self,
    FileType dstType,
    long dstTypeHint,
    FSSpec * theDocument
);
```

Parameters

self

dstType

theDocument

Return Value

See the Component Manager documentation for a description of the `ComponentResult` data type.

Carbon Porting Notes

The functions contained in TranslationExtensions.h were originally written to be used only by someone implementing a Mac Easy Open translation component. Carbon, however, is for applications and not extensions. Therefore, this function is not supported.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`TranslationExtensions.h`

DoIdentifyFileProcPtr

Defines a pointer to a file identification callback function that identifies a file as having a format which your extension can translate.

Unsupported

```
typedef ComponentResult (*DoIdentifyFileProcPtr)
(
    ComponentInstance self,
    const FSSpec * theDocument,
    FileType * docType
);
```

If you name your function `MyDoIdentifyFileProc`, you would declare it like this:

```
ComponentResult DoIdentifyFileProcPtr (
    ComponentInstance self,
```

```
    const FSSpec * theDocument,
    FileType * docType
);
```

Parameters

self

A component instance that identifies the component containing the translation extension.

theDocument

A pointer to a file system specification structure that specifies the document that the translation extension must identify.

docType

Your function should return, in this parameter, the file format type of the file specified in the `theDocument` parameter.

Your function should not return `'TEXT'` as a file type unless you determine that the document consists solely of a plain, unformatted stream of ASCII characters.

Return Value

If successful, your function should return `noErr`. Otherwise, your function should return an appropriate result code. If your translation extension does not recognize the type of the specified file, your function should return the result code `noTypeErr`. The Component Manager requires this function to return a value of type `ComponentResult` to simplify dispatching. See the Component Manager documentation for a description of the `ComponentResult` data type.

Discussion

A file translation extension must respond to the `kTranslateIdentifyFile` request code. The Translation Manager uses this request code to allow the translation extension to identify a file as having a format that the extension can translate. You can handle this request by calling the Component Manager function `CallComponentFunctionWithStorage` and passing it a pointer to your file identification callback function.

Carbon Porting Notes

The functions contained in TranslationExtensions.h were originally written to be used only by someone implementing a Mac Easy Open translation component. Carbon, however, is for applications and not extensions. Therefore, this function is not supported.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`TranslationExtensions.h`

DoIdentifyScrapProcPtr

Defines a pointer to a scrap identification callback function that identifies a scrap as one that your scrap translation extension can translate.

Unsupported

```
typedef ComponentResult (*DoIdentifyScrapProcPtr)
(
    ComponentInstance self,
    const void * dataPtr,
    Size dataLength,
    ScrapType * dataFormat
);
```

If you name your function `MyDoIdentifyScrapProc`, you would declare it like this:

```
ComponentResult DoIdentifyScrapProcPtr
(
    ComponentInstance self,
    const void * dataPtr,
    Size dataLength,
    ScrapType * dataFormat
);
```

Parameters

self

A component instance that identifies the component containing the translation extension.

dataPtr

A pointer to the scrap to translate.

dataLength

The size of the scrap to translate.

dataFormat

On entry, the type of the scrap format. Your function returns, through this parameter, the type of the scrap format of the scrap specified by the `dataPtr` parameter, as recognized by your translation extension.

In general, the scrap that your `DoIdentifyScrap` function is asked to identify is always in one of the formats listed among the source formats in the translation groups contained in your extension's scrap translation list. Your scrap translation extension therefore needs only to verify that the indicated scrap is of the specified format.

Return Value

If successful, your function should return `noErr`. Otherwise, your function should return an appropriate result code. If your translation extension does not recognize the type of the specified scrap, your function should return the result code `noTypeErr`. The Component Manager requires this function to return a value of type `ComponentResult` to simplify dispatching. See the Component Manager documentation for a description of the `ComponentResult` data type.

Discussion

A scrap translation extension must respond to the `kTranslateIdentifyScrap` request code. You can handle this request by calling the Component Manager function `CallComponentFunctionWithStorage` and passing it a pointer to a your scrap identification callback function.

Carbon Porting Notes

The functions contained in TranslationExtensions.h were originally written to be used only by someone implementing a Mac Easy Open translation component. Carbon, however, is for applications and not extensions. Therefore, this function is not supported.

Availability

Available in Mac OS X v10.0 and later.

Declared In
`TranslationExtensions.h`

DoTranslateFileProcPtr

Defines a pointer to a file translation callback function that translates a document from one format into another.

Unsupported

```
typedef ComponentResult (*DoTranslateFileProcPtr)
(
    ComponentInstance self,
    TranslationRefNum refNum,
    const FSSpec * sourceDocument,
    FileType srcType,
    long srcTypeHint,
    const FSSpec * dstDoc,
    FileType dstType,
    long dstTypeHint
);
```

If you name your function `MyDoTranslateFileProc`, you would declare it like this:

```
ComponentResult DoTranslateFileProcPtr
(
    ComponentInstance self,
    TranslationRefNum refNum,
    const FSSpec * sourceDocument,
    FileType srcType,
    long srcTypeHint,
    const FSSpec * dstDoc,
    FileType dstType,
    long dstTypeHint
);
```

Parameters

self
: A component instance that identifies the component containing your translation extension.

refNum
: The translation reference number for this translation.

  Macintosh Easy Open assigns this reference number to the translation. Each translation is assigned a unique number to distinguish the translation from any other translations that might occur. You need to pass this reference number to any Macintosh Easy Open functions you call from within the file translation extension; for instance, if by calling the `SetTranslationAdvertisement` function you display the progress dialog box, you'll pass that reference number in the `refNum` parameter.

sourceDocument
: A file system specification structure that specifies the document to translate.

srcType
: The format of the file to be translated.

srcTypeHint
: The value in the `hint` field of the source document's file type specification.

dstDoc

A file system specification structure that specifies the destination document.

Your function should put the translated document into the file specified by this parameter. The data fork of the destination file already exists by the time your function is called. In addition, if the `flags` field in the appropriate destination file type specification in your extension's file translation list has the `taDstDocNeedsResourceFork` bit set, the destination file already contains a resource fork. Your function should open the destination file and fill its data or resource fork (or both) with the appropriate translated data.

dstType

The format into which to translate the source document.

dstTypeHint

The value in the `hint` field of the destination document's file type specification.

Return Value

If successful, your function should return `noErr`. Otherwise, your function should return an appropriate result code. If it cannot translate the source file, your function should return a result code different from `noErr`. In that case, Macintosh Easy Open will automatically delete the destination file. The Component Manager requires this function to return a value of type `ComponentResult` to simplify dispatching. See the Component Manager documentation for a description of the `ComponentResult` data type.

Discussion

A file translation extension must respond to the `kTranslateTranslateFile` request code. You can handle this request by calling the Component Manager function `CallComponentFunctionWithStorage` and passing it a pointer to your file translation function.

Your file translation function can translate the source file itself or rely upon external translators.

Your translation extension should call the `SetTranslationAdvertisement` (page 1713) function to display the progress dialog box and the `UpdateTranslationProgress` (page 1716) function to update the dialog box periodically.

Carbon Porting Notes

The functions contained in TranslationExtensions.h were originally written to be used only by someone implementing a Mac Easy Open translation component. Carbon, however, is for applications and not extensions. Therefore, this function is not supported.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`TranslationExtensions.h`

DoTranslateScrapProcPtr

Defines a pointer to a scrap translation callback function that translates a scrap from one format into another.

Unsupported

```
typedef ComponentResult (*DoTranslateScrapProcPtr)
(
    ComponentInstance self,
    TranslationRefNum refNum,
    const void * srcDataPtr,
    Size srcDataLength,
    ScrapType srcType,
    long srcTypeHint,
    Handle dstData,
    ScrapType dstType,
    long dstTypeHint
);
```

If you name your function `MyDoTranslateScrapProc`, you would declare it like this:

```
ComponentResult DoTranslateScrapProcPtr
(
    ComponentInstance self,
    TranslationRefNum refNum,
    const void * srcDataPtr,
    Size srcDataLength,
    ScrapType srcType,
    long srcTypeHint,
    Handle dstData,
    ScrapType dstType,
    long dstTypeHint
);
```

Parameters

self

A component instance that identifies the component containing the translation extension.

refNum

The translation reference number for this translation.

Macintosh Easy Open assigns this reference number to the translation. Each translation is assigned a unique number to distinguish the translation from any other translations that might be occurring. You need to pass this reference number to any Macintosh Easy Open functions you call from within the scrap translation extension; for instance, if you display the progress dialog box by calling the `SetTranslationAdvertisement` function, you'll pass that reference number in the `refNum` parameter.

srcDataPtr

A pointer to the scrap to translate.

srcDataLength

The size of the scrap to translate.

srcType

The format of the scrap to translate.

srcTypeHint

The value in the `hint` field of the source document's scrap type specification.

dstData

A handle to the destination to be filled in. Your function should put the translated data into the block specified here, resizing it as necessary.

dstType
The format into which to translate the source scrap.

dstTypeHint
The value in the `hint` field of the destination document's scrap type specification.

Return Value
If successful, your function should return `noErr`. Otherwise, your function should return an appropriate result code. The Component Manager requires this function to return a value of type `ComponentResult` to simplify dispatching. See the Component Manager documentation for a description of the `ComponentResult` data type.

Discussion
A scrap translation extension must respond to the `kTranslateTranslateScrap` request code. You can handle this request by calling the Component Manager function `CallComponentFunctionWithStorage` and passing it a pointer to your function. Your scrap translation callback function can translate the source file itself or rely upon external translators.

Your translation extension should call the `SetTranslationAdvertisement` (page 1713) function to display the progress dialog box and the `UpdateTranslationProgress` (page 1716) function to update the dialog box periodically.

Carbon Porting Notes

The functions contained in TranslationExtensions.h were originally written to be used only by someone implementing a Mac Easy Open translation component. Carbon, however, is for applications and not extensions. Therefore, this function is not supported.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TranslationExtensions.h`

GetScrapDataProcPtr

Defines a pointer to a source-data fetching callback.

```
typedef OSErr (*GetScrapDataProcPtr)
(
    ScrapType requestedFormat,
    Handle dataH,
    void * srcDataGetterRefCon
);
```

If you name your function `MyGetScrapDataProc`, you would declare it like this:

```
OSErr GetScrapDataProcPtr (
    ScrapType requestedFormat,
    Handle dataH,
    void * srcDataGetterRefCon
);
```

Parameters

requestedFormat

Format of data that `TranslateScrap` (page 1715) needs.

dataH

The handle in which to put the requested data.

Return Value

A result code. See "Translation Manager Result Codes" (page 1732).

Discussion

The first time this function is call ed, you should resize and fill in the handle with a list all the formats that you have available to be translated, and the length of each. When called again, you should supply the data in one of the formats in the list.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Translation.h`

Data Types

FileTranslationList

Defines a list of file formats an extension can translate.

```
struct FileTranslationList {
  unsigned long modDate;
  unsigned long groupCount;
};
typedef struct FileTranslationList  FileTranslationList;
typedef FileTranslationList *       FileTranslationListPtr;
typedef FileTranslationListPtr *    FileTranslationListHandle;
```

Fields

`modDate`

The creation date of the file translation list. If your extension uses external translators, you might set this field to the modification date of a folder containing those translators.

`groupCount`

The number of translation groups that follow.

Discussion

The Translation Manager uses the file translation list that it gets from each translation system to create a master database of format translations it can direct. A file translation list consists of a field indicating the modification date of the list and a count of the number of groups that follow those two fields.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`TranslationExtensions.h`

FileTranslationSpec

Defines a file translation method supported by the Translation Manager.

```
struct FileTranslationSpec {
  OSType          componentSignature;
  const void *    translationSystemInfo;
  FileTypeSpec    src;
  FileTypeSpec    dst;
};
typedef struct FileTranslationSpec      FileTranslationSpec;
typedef FileTranslationSpec *           FileTranslationSpecArrayPtr;
typedef FileTranslationSpecArrayPtr *   FileTranslationSpecArrayHandle;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Translation.h`

FileType

Defines the translation file type of a document.

```
typedef OSType FileType;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TranslationExtensions.h`

FileTypeSpec

Defines a descriptor for the source or destination file type used in a translation method.

```
struct FileTypeSpec {
    FileType format;
    long hint;
    TranslationAttributes flags;
    OSType catInfoType;
    OSType catInfoCreator;
};
typedef struct FileTypeSpec FileTypeSpec;
```

Fields

`format`
: The translation file type of the document. Macintosh Easy Open uses this field as the canonical way to describe the format of a file for translation purposes.

`hint`
: A 4-byte value reserved for use by your translation extension.

`flags`
: A 4-byte value consisting of bit flags that specify how to control the translation. This field is used only for destination file types; you should set it to 0 for all source file type specifications. Currently 2 bits are defined; all other bits should be cleared to 0.

`catInfoType`
: The type of the file as contained in the volume's catalog file.

`catInfoCreator`
: The creator of the file as contained in the volume's catalog file.

Discussion
The `FileTranslationList` (page 1727) structure uses file type specifications to describe document formats. A file type specification is defined by the `FileTypeSpec` data structure.

The interpretation of some of the fields of a file type specification depends on whether the specification occurs in the list of source document types or in the list of destination document types:

In file type specifications occurring in the list of source document types in a file translation list, Macintosh Easy Open uses the `format` and `catInfoCreator` fields to determine the kind string displayed in the "From" format specification of the translation progress dialog box.

In file type specifications occurring in the list of destination document types in a file translation list, Macintosh Easy Open uses the `format` and `catInfoCreator` fields to determine the kind string displayed in the "To" format specification in the translation progress dialog box. The `format` and `catInfoCreator` fields are also used to get the information displayed in the Document Converter dialog box. However, Macintosh Easy Open uses the `catInfoType` and `catInfoCreator` fields to set the catalog type and creator of the destination file.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TranslationExtensions.h`

ScrapTranslationList

Defines the scrap formats an extension can translate.

```
struct ScrapTranslationList {
  unsigned long   modDate;
  unsigned long   groupCount;
};
typedef struct ScrapTranslationList     ScrapTranslationList;
typedef ScrapTranslationList *          ScrapTranslationListPtr;
typedef ScrapTranslationListPtr *       ScrapTranslationListHandle;
```

Fields
`modDate`
: The creation date of the scrap translation list. If your extension uses external translators, you might set this field to the modification date of a folder containing those translators.

`groupCount`
: The number of translation groups that follow. The size of the translation list prepared by an extension is variable, depending upon the number of groups, the scrap specification structure size, and the number of scrap types that the extension knows about.

Discussion
The Translation Manager uses the scrap translation list that it gets from each translation system to create a master database of its translation capability. A scrap translation list consists of a field indicating the modification date of the list and a count of the number of groups that follow those two fields.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TranslationExtensions.h`

ScrapType

Defines the scrap type in a Translation Manager scrap format.

```
typedef ResType ScrapType;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TranslationExtensions.h`

ScrapTypeSpec

Describes a specific scrap format.

```
struct ScrapTypeSpec {
    ScrapType format;
    long hint;
};
typedef struct ScrapTypeSpec ScrapTypeSpec;
```

Fields
`format`
The type of the specified scrap.
`hint`
A 4-byte value reserved for use by your translation extension.

Discussion
The `ScrapTypeSpec` data structure is used by the `ScrapTranslationList` (page 1729) structure.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TranslationExtensions.h`

TypesBlock

Defines a null-terminated array of `OSType` or `FileType` elements.

```
typedef OSType      TypesBlock[64];
typedef OSType *    TypesBlockPtr;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Translation.h`

Constants

DocOpenMethod

Specifies the ways a document can be opened.

```
enum {
  domCannot = 0,
  domNative = 1,
  domTranslateFirst = 2,
  domWildcard = 3
};
typedef short DocOpenMethod;
```

Constants

`domCannot`
Indicates that the application cannot open the document.
Available in Mac OS X v10.0 and later.
Declared in `Translation.h`.

`domNative`
Indicates that the application can open the document natively.
Available in Mac OS X v10.0 and later.
Declared in `Translation.h`.

`domTranslateFirst`
Indicates that the application can open the document only after it's been translated.
Available in Mac OS X v10.0 and later.
Declared in `Translation.h`.

`domWildcard`
Indicates that the application has the file type '****' in its list of the file types that it can open and hence can open any type of document.
Available in Mac OS X v10.0 and later.
Declared in `Translation.h`.

Discussion
The `CanDocBeOpened` (page 1706) function uses the following constants to specify the method for opening a given document.

Result Codes

The most common result codes returned by the Translation Manager are listed in the table below.

Result Code	Value	Description
`invalidTranslationPathErr`	-3025	Source type to destination type not a valid path. Available in Mac OS X v10.0 and later.
`couldNotParseSourceFileErr`	-3026	Source document does not contain source type. Available in Mac OS X v10.0 and later.
`noTranslationPathErr`	-3030	Application cannot open document. Available in Mac OS X v10.0 and later.
`badTranslationSpecErr`	-3031	Translation path is invalid. Available in Mac OS X v10.0 and later.
`noPrefAppErr`	-3032	No translation preference available. Available in Mac OS X v10.0 and later.

Gestalt Constants

You can check for version and feature availability information by using the Translation Manager selectors defined in the Gestalt Manager. For more information, see *Inside Mac OS X: Gestalt Manager Reference*.

URL Access Manager Reference (Not Recommended)

Framework: Carbon/Carbon.h

Declared in URLAccess.h

Overview

Important: URL Access Manager is deprecated as of Mac OS X v10.4. You should use CFNetwork instead (as described in *CFNetwork Programming Guide*).

CFNetwork provides better reliability and performance and is used by Apple's own applications. URL Access Manager is no longer being enhanced or improved.

The URL Access Manager is an API that you can use to perform data transfer to and from a URL from within your application. It includes support for automatic decompression of compressed files and for automatic file extraction from Stuffit archives (with version 5.0 of Stuffit).

The URL Access Manager allows you to use any of the following protocols during download operations: File Transfer Protocol (FTP), Hypertext Transfer Protocol (HTTP), secure Hypertext Transfer Protocol (HTTPS), or a URL representing a local file (begins with `file://`). You might use the latter to test your application on a computer that does not have access to an HTTP or FTP server. For upload operations, you must use an FTP URL.

This document describes the URL Access Manager API through version 2.0.3.

Functions by Task

Getting Information About the URL Access Manager

`URLGetURLAccessVersion` (page 1749) Deprecated in Mac OS X v10.4

Determines the version of URL Access Manager installed on the user's system. (Deprecated. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

Creating and Disposing of a URL Reference

`URLDisposeReference` (page 1741) Deprecated in Mac OS X v10.4

Disposes of the memory associated with a URL reference. (Deprecated. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

URLNewReference (page 1750) Deprecated in Mac OS X v10.4
Creates a URL reference. (Deprecated. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

Getting and Setting Information About a URL

URLGetProperty (page 1747) Deprecated in Mac OS X v10.4
Obtains the value of a URL property. (Deprecated. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

URLGetPropertySize (page 1748) Deprecated in Mac OS X v10.4
Determines the size of a URL property. (Deprecated. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

URLSetProperty (page 1753) Deprecated in Mac OS X v10.4
Sets the value of a URL property. (Deprecated. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

Performing Simple Data Transfer

URLDownload (page 1741) Deprecated in Mac OS X v10.4
Downloads data from a URL specified by a URL reference. (Deprecated. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

URLSimpleDownload (page 1754) Deprecated in Mac OS X v10.4
Downloads data from a URL specified by a character string. (Deprecated. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

URLSimpleUpload (page 1756) Deprecated in Mac OS X v10.4
Uploads a file or directory to an FTP URL specified by a character string. (Deprecated. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

URLUpload (page 1757) Deprecated in Mac OS X v10.4
Uploads a file or directory to an FTP URL specified by a URL reference. (Deprecated. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

Getting More Control Over Data Transfer Operations

URLGetBuffer (page 1743) Deprecated in Mac OS X v10.4
Obtains the next buffer of data in a download operation. (Deprecated. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

URLGetDataAvailable (page 1745) Deprecated in Mac OS X v10.4
Determines the amount of data currently available for retrieval in a download operation. (Deprecated. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

URLOpen (page 1751) Deprecated in Mac OS X v10.4
Opens a URL and starts an asynchronous download or upload operation. (Deprecated. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

URLReleaseBuffer (page 1752) Deprecated in Mac OS X v10.4
Releases a buffer. (Deprecated. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

Terminating Data Transfer Operations

`URLAbort` (page 1740) Deprecated in Mac OS X v10.4
: Terminates a data transfer operation. (Deprecated. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

Getting Data Transfer Information

`URLGetCurrentState` (page 1744) Deprecated in Mac OS X v10.4
: Determines the status of a data transfer operation.

`URLGetError` (page 1746) Deprecated in Mac OS X v10.4
: Determines the error code of a failed data transfer operation. (Deprecated. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

`URLGetFileInfo` (page 1746) Deprecated in Mac OS X v10.4
: Obtains the file type and creator of a file. (Deprecated. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

`URLIdle` (page 1749) Deprecated in Mac OS X v10.4
: Gives the URL Access Manager time to refill its buffers during download operations. (Deprecated. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

Working With URL Access Manager Callbacks

`DisposeURLNotifyUPP` (page 1736) Deprecated in Mac OS X v10.4
: Disposes of a UPP to your data transfer event notification callback. (Deprecated. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

`DisposeURLSystemEventUPP` (page 1736) Deprecated in Mac OS X v10.4
: Disposes of a UPP to your system event notification callback. (Deprecated. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

`InvokeURLNotifyUPP` (page 1737) Deprecated in Mac OS X v10.4
: Invokes your data transfer event notification callback. (Deprecated. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

`InvokeURLSystemEventUPP` (page 1738) Deprecated in Mac OS X v10.4
: Invokes your system event notification callback. (Deprecated. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

`NewURLNotifyUPP` (page 1738) Deprecated in Mac OS X v10.4
: Creates a UPP to your data transfer event notification callback. (Deprecated. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

`NewURLSystemEventUPP` (page 1739) Deprecated in Mac OS X v10.4
: Creates a UPP to your system event notification callback. (Deprecated. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

Functions

DisposeURLNotifyUPP

Disposes of a UPP to your data transfer event notification callback. (Deprecated in Mac OS X v10.4. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

```
void DisposeURLNotifyUPP (
   URLNotifyUPP userUPP
);
```

Parameters

userUPP

A Universal Procedure Pointer (UPP) to your notification callback function.

Discussion

When you are finished with a UPP to your notification callback function, you should dispose of it by calling the `DisposeURLNotifyUPP` function.

Special Considerations

CFNetwork provides better reliability and performance and is used by Apple's own applications. URL Access Manager is no longer being enhanced or improved.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`URLAccess.h`

DisposeURLSystemEventUPP

Disposes of a UPP to your system event notification callback. (Deprecated in Mac OS X v10.4. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

```
void DisposeURLSystemEventUPP (
   URLSystemEventUPP userUPP
);
```

Parameters

userUPP

A UPP to your system event callback function.

Discussion

When you are finished with a UPP to your system event callback function, you should dispose of it by calling the `DisposeURLSystemEventUPP` function.

Special Considerations

CFNetwork provides better reliability and performance and is used by Apple's own applications. URL Access Manager is no longer being enhanced or improved.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In
URLAccess.h

InvokeURLNotifyUPP

Invokes your data transfer event notification callback. (Deprecated in Mac OS X v10.4. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

```
OSStatus InvokeURLNotifyUPP (
   void *userContext,
   URLEvent event,
   URLCallbackInfo *callbackInfo,
   URLNotifyUPP userUPP
);
```

Parameters

userContext

A pointer to application-defined storage. The URL Access Manager passes this value in the `userContext` parameter of your notification callback function. Your application can use this to set up its context when your data transfer event notification callback is called.

event

The data transfer events you want your application to receive. See "Data Transfer Event Constants" (page 1764) for a description of possible values. The URL Access Manager tests the bitmask you pass in the `eventRegister` parameter of the function `URLOpen` (page 1751) to determine which events to pass to your callback function. See "Data Transfer Event Mask Constants" (page 1766) for a description of this bitmask.

callbackInfo

A pointer to a structure of type `URLCallbackInfo` (page 1762) that provides information about the data transfer event to your callback function. The URL Access Manager passes a pointer to this structure in the `callbackInfo` parameter of your notification callback function.

userUPP

A Universal Procedure Pointer to your data transfer notification callback. For information on how to write this function, see `URLNotifyProcPtr` (page 1759).

Return Value
A result code. See "URL Access Manager Result Codes" (page 1779).

Discussion
The URL Access Manager calls the `InvokeURLNotifyUPP` function when you pass a UPP to your callback function in the `notifyProc` parameter of the function `URLOpen` (page 1751), and the data transfer event that you specified in the `eventRegister` parameter occurs.

Special Considerations

CFNetwork provides better reliability and performance and is used by Apple's own applications. URL Access Manager is no longer being enhanced or improved.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
URLAccess.h

InvokeURLSystemEventUPP

Invokes your system event notification callback. (Deprecated in Mac OS X v10.4. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

```
OSStatus InvokeURLSystemEventUPP (
   void *userContext,
   EventRecord *event,
   URLSystemEventUPP userUPP
);
```

Parameters

userContext

A pointer to application-defined storage. The URL Access Manager passes this value in the `userContext` parameter of your system event callback function. Your application can use this to set up its context when your system event notification callback is called.

event

A pointer to an event record that provides information about the system event to your callback function.

userUPP

A Universal Procedure Pointer to your system event notification callback. For information on how to write this function, see `URLSystemEventProcPtr` (page 1760).

Return Value
A result code. See "URL Access Manager Result Codes" (page 1779).

Discussion
The URL Access Manager calls the `InvokeURLSystemEventUPP` function when you pass a UPP to your callback function in the eventProc parameter of the functions `URLSimpleDownload` (page 1754), `URLSimpleUpload` (page 1756), `URLDownload` (page 1741), or `URLUpload` (page 1757), and a system event occurs while a progress indicator or authentication dialog box is being displayed.

Special Considerations

CFNetwork provides better reliability and performance and is used by Apple's own applications. URL Access Manager is no longer being enhanced or improved.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
URLAccess.h

NewURLNotifyUPP

Creates a UPP to your data transfer event notification callback. (Deprecated in Mac OS X v10.4. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

```
URLNotifyUPP NewURLNotifyUPP (
   URLNotifyProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your data transfer event notification callback. For information on how to write your callback, see URLNotifyProcPtr (page 1759).

Return Value

A UPP to your data transfer event notification callback. You can register your callback by passing this UPP in the notifyProc parameter of the function URLOpen (page 1751). See the description of the URLNotifyUPP data type.

Discussion

The NewURLNotifyUPP function creates a pointer to your data transfer event notification callback. You pass a pointer to your callback in the notifyProc parameter of the function URLOpen (page 1751) if you want your application to receive data transfer events. Pass a bitmask in the eventRegister parameter of URLOpen (page 1751) indicating which data transfer events you want to receive.

Special Considerations

CFNetwork provides better reliability and performance and is used by Apple's own applications. URL Access Manager is no longer being enhanced or improved.

When you are finished with your data transfer event notification callback, you should dispose of the UPP by calling the function DisposeURLNotifyUPP (page 1736).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

URLAccess.h

NewURLSystemEventUPP

Creates a UPP to your system event notification callback. (Deprecated in Mac OS X v10.4. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

```
URLSystemEventUPP NewURLSystemEventUPP (
   URLSystemEventProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your system event notification callback. For information on how to write your callback, see URLSystemEventProcPtr (page 1760).

Return Value

A UPP to your system event notification callback. You can register your callback by passing this UPP in the eventProc parameter of the function URLSimpleDownload (page 1754), URLSimpleUpload (page 1756), URLDownload (page 1741), or URLUpload (page 1757). See the description of the URLSystemEventUPP data type.

Discussion

The `NewURLSystemEventUPP` function creates a pointer to your system event callback function. You pass a pointer to your callback function in the `eventProc` parameter of the functions `URLSimpleDownload` (page 1754), `URLSimpleUpload` (page 1756), `URLDownload` (page 1741), and `URLUpload` (page 1757) if you want update events to be passed to your application while a dialog box is displayed. (In Mac OS X, this is not necessary, since all dialog boxes are moveable). In order for these functions to display a dialog box, you must set the mask constant `kURLDisplayProgressFlag` or `kURLDisplayAuthFlag` in the bitmask passed in the `openFlags` parameter.

Special Considerations

CFNetwork provides better reliability and performance and is used by Apple's own applications. URL Access Manager is no longer being enhanced or improved.

When you are finished with your system event notification callback, you should dispose of the UPP by calling the function `DisposeURLNotifyUPP` (page 1736).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`URLAccess.h`

URLAbort

Terminates a data transfer operation. (Deprecated in Mac OS X v10.4. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

```
OSStatus URLAbort (
   URLReference urlRef
);
```

Parameters

urlRef

A reference to the URL whose data transfer operation you wish to terminate.

Return Value

A result code. See "URL Access Manager Result Codes" (page 1779).

Discussion

The `URLAbort` function terminates any data transfer operation started by the functions `URLSimpleDownload` (page 1754), `URLDownload` (page 1741), `URLSimpleUpload` (page 1756), `URLUpload` (page 1757), or `URLOpen` (page 1751). When your application calls `URLAbort`, the URL Access Manager changes the state returned by the function `URLGetCurrentState` (page 1744) to `kURLAbortingState` and passes the constant `kURLAbortInitiatedEvent` to your notification callback function. When data transfer is terminated, the URL Access Manager changes the state returned by `URLGetCurrentState` (page 1744) to `kURLCompletedState` and passes the constant `kURLCompletedEvent` in the `event` parameter of your notification callback function.

Special Considerations

CFNetwork provides better reliability and performance and is used by Apple's own applications. URL Access Manager is no longer being enhanced or improved.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`URLAccess.h`

URLDisposeReference

Disposes of the memory associated with a URL reference. (Deprecated in Mac OS X v10.4. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

```
OSStatus URLDisposeReference (
   URLReference urlRef
);
```

Parameters

urlRef

A reference to the URL whose associated memory you wish to dispose of. You should call the `URLDisposeReference` function to release the memory occupied by a URL reference when you are finished with it.

Return Value
A result code. See "URL Access Manager Result Codes" (page 1779).

Special Considerations

CFNetwork provides better reliability and performance and is used by Apple's own applications. URL Access Manager is no longer being enhanced or improved.

You must call the `URLDisposeReference` function to dispose of the reference associated with a URL reference even if the data transfer operation fails. Failure to call `URLDisposeReference` may result in thread or memory leaks.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`URLAccess.h`

URLDownload

Downloads data from a URL specified by a URL reference. (Deprecated in Mac OS X v10.4. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

```
OSStatus URLDownload (
   URLReference urlRef,
   FSSpec *destination,
   Handle destinationHandle,
   URLOpenFlags openFlags,
   URLSystemEventUPP eventProc,
   void *userContext
);
```

Parameters

urlRef

A reference to the URL from which data is to be downloaded. Once you call `URLDownload`, you cannot use the same reference if you call `URLDownload` again. Instead, you must create a new URL reference by calling the function `URLNewReference` (page 1750).

destination

A pointer to a file specification structure that identifies the file or directory into which data is to be downloaded. If you wish to download data into memory, pass `NULL` in this parameter and a valid handle in the `destinationHandle` parameter. If you pass a file specification that does not identify a file or directory, the name of the file or directory specified by the pathname in the `urlRef` parameter is used. If you pass a file or directory that already exists, and do not specify `kURLReplaceExistingFlag` in the `openFlags` parameter, `URLDownload` creates a new file or directory whose name has a number appended before the extension. For example, if the URL specifies a file named `file.txt`, `URLDownload` changes the filename to `file1.txt`.

destinationHandle

A handle to the destination in memory where you want the data downloaded. Before calling `URLDownload`, create a zero-sized handle. If you wish to download data into a file or directory, pass `NULL` in this parameter and a valid file specification in the `destination` parameter.

openFlags

A bitmask that indicates the data transfer options to use. You can specify any of the following masks for downloading options: `kURLReplaceExistingFlag`, `kURLExpandFileFlag`, `kURLExpandAndVerifyFlag`, `kURLDisplayProgressFlag`, `kURLDisplayAuthFlag`, `kURLIsDirectoryHintFlag`, `kURLDoNotTryAnonymousFlag`, `kURLDebinhexOnlyFlag`, `kURLNoAutoRedirect`, and `kURLDirectoryListingFlag`. See "Data Transfer Options Mask Constants" (page 1770) for a description of possible values.

eventProc

A Universal Procedure Pointer (UPP) to your system event callback function, if one exists. For information on how to write a system event callback, see `URLSystemEventProcPtr` (page 1760). If you want to handle events that occur while a progress indicator or authentication dialog box is being displayed, specify the appropriate mask (either `kURLDisplayProgressFlag` or `kURLDisplayAuthFlag`) in the `openFlags` parameter and pass a UPP to your callback function in this parameter. Pass `NULL` if you do not want to receive notification of these events. In this case, the URL Access Manager displays a nonmovable modal progress indicator or authentication dialog box.

userContext

A pointer to application-defined storage that will be passed to your system event callback function, if one exists. Your application can use this to set up its context when your system event callback function is called.

Return Value

A result code. See "URL Access Manager Result Codes" (page 1779). If your application is multi-threaded, and more than one thread calls `URLDownload` simultaneously, `URLDownload` returns the result code `kURLProgessAlreadyDisplayedError` if you specify `kURLDisplayProgressFlag` in the `openFlags` parameter and the URL Access Manager is already displaying a progress indicator.

Discussion
The `URLDownload` function downloads data from a URL specified by a URL reference to a file, directory, or memory. It does not return until the download is complete. If you want to download data from a URL identified by a URL string rather than a reference, call the function `URLSimpleDownload` (page 1754). The difference between the two functions is that URLDownload allows you to access other URL Access Manager functions before, after, or during the download. If you want more control over a data transfer operation, call the function `URLOpen` (page 1751).

If you wish to download data to a file or directory, pass a valid file specification in the `destination` parameter. If you instead wish to download data to memory, pass a valid handle in the `destinationHandle` parameter. If the URL specified in the `urlRef` parameter points to a file, the file is downloaded regardless of whether the bit specified by the mask constant `kURLDirectoryListingFlag` or `KURLIsDirectoryHintFlag` is set in the `openFlags` parameter.

When `URLDownload` downloads data from a URL that represents a local file (that is, a URL that begins with `file://`), the data fork is downloaded but the resource fork is not.

Special Considerations

CFNetwork provides better reliability and performance and is used by Apple's own applications. URL Access Manager is no longer being enhanced or improved.

`URLDownload` yields time to other threads. Your application should call `URLDownload` from a thread other than the main thread so that other processes have time to run.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`URLAccess.h`

URLGetBuffer

Obtains the next buffer of data in a download operation. (Deprecated in Mac OS X v10.4. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

```
OSStatus URLGetBuffer (
   URLReference urlRef,
   void **buffer,
   Size *bufferSize
);
```

Parameters

urlRef
A reference to the URL whose next buffer you wish to obtain.

buffer
On return, a handle to a buffer containing the downloaded data.

bufferSize
On return, a pointer to the number of bytes of data in the buffer.

Return Value
A result code. See "URL Access Manager Result Codes" (page 1779).

Discussion
The `URLGetBuffer` function obtains the next buffer of data in a download operation. `URLGetBuffer` does not enable you to retain or modify the transferred data. If you pass `NULL` in the `fileSpec` parameter of the function `URLOpen` (page 1751), you should call `URLGetBuffer` to retrieve data as it is downloaded.

You should call `URLGetBuffer` repeatedly until URL Access Manager passes the event constant `kURLCompletedEvent` or `kURLAbortInitiatedEvent` in the `event` parameter of your notification callback function, or until the function `URLGetCurrentState` (page 1744) returns the state constant `kURLTransactionComplete` or `kURLAbortingState`. Between calls to `URLGetBuffer`, you should call the function `URLIdle` (page 1749) to allow time for the URL Access Manager to refill its buffers.

To determine the number of bytes remaining in the buffer, call the function `URLGetDataAvailable` (page 1745). The size returned by `URLGetDataAvailable` (page 1745) does not include the number of bytes in transit to a buffer, nor does it include the amount of data not yet transferred from the URL.

Special Considerations

CFNetwork provides better reliability and performance and is used by Apple's own applications. URL Access Manager is no longer being enhanced or improved.

You should release the returned buffer as soon as possible after a call to `URLGetBuffer` by calling the function `URLReleaseBuffer` (page 1752). This prevents the URL Access Manager from running out of buffers.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`URLAccess.h`

URLGetCurrentState

Determines the status of a data transfer operation. (Deprecated in Mac OS X v10.4.)

```
OSStatus URLGetCurrentState (
   URLReference urlRef,
   URLState *state
);
```

Parameters

urlRef
A reference to the URL whose data transfer state you want to determine.

state
On return, a pointer to the state of data transfer. See "Data Transfer State Constants" (page 1773) for a description of possible values.

Return Value
A result code. See "URL Access Manager Result Codes" (page 1779).

Discussion
The `URLGetCurrentState` function determines the current status of a data transfer operation. You may wish to call `URLGetCurrentState` periodically to monitor the status of a download or upload operation.

Special Considerations

CFNetwork provides better reliability and performance and is used by Apple's own applications. URL Access Manager is no longer being enhanced or improved.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

URLAccess.h

URLGetDataAvailable

Determines the amount of data currently available for retrieval in a download operation. (Deprecated in Mac OS X v10.4. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

```
OSStatus URLGetDataAvailable (
   URLReference urlRef,
   Size *dataSize
);
```

Parameters

urlRef

A reference to the URL for which you wish to determine the amount od data currently available for retrieval in a download operation.

dataSize

On return, a pointer to the size (in bytes) of data available for retrieval in a download operation.

Return Value

A result code. See "URL Access Manager Result Codes" (page 1779).

Discussion

The URLGetDataAvailable (page 1745) function determines the amount of data remaining in the buffer of the URL Access Manager that you will obtain from a call to the function URLGetBuffer (page 1743). You should only call this function if you passed an invalid destination file to the function URLOpen (page 1751). This does not include the number of bytes in transit to your buffer, nor does it include the amount of data not yet transferred from the URL Access Manager. To calculate the amount of data remaining to be downloaded, pass the name constant kURLResourceSize in the property parameter of the function URLGetProperty (page 1747) and subtract the amount of data copied.

Special Considerations

CFNetwork provides better reliability and performance and is used by Apple's own applications. URL Access Manager is no longer being enhanced or improved.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

URLAccess.h

URLGetError

Determines the error code of a failed data transfer operation. (Deprecated in Mac OS X v10.4. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

```
OSStatus URLGetError (
   URLReference urlRef,
   OSStatus *urlError
);
```

Parameters

urlRef

A reference to the URL whose data transfer operation failed.

urlError

A pointer to a C string representing the name of the error code returned by the failed operation.

Return Value

A result code. See "URL Access Manager Result Codes" (page 1779).

Discussion

The `URLGetError` function determines the error code returned when a data transfer operation fails. The error code may be a system error code, a protocol-specific error code, or one of the error codes listed in "URL Access Manager Result Codes" (page 1779).

Special Considerations

CFNetwork provides better reliability and performance and is used by Apple's own applications. URL Access Manager is no longer being enhanced or improved.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`URLAccess.h`

URLGetFileInfo

Obtains the file type and creator of a file. (Deprecated in Mac OS X v10.4. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

```
OSStatus URLGetFileInfo (
   StringPtr fName,
   OSType *fType,
   OSType *fCreator
);
```

Parameters

fName

A pointer to a Pascal string representing the name of the file for which you want information.

fType

On return, a pointer to the file type code of the specified filename.

fCreator

On return, a pointer to the file creator code of the specified filename.

Return Value
A result code. See "URL Access Manager Result Codes" (page 1779).

Discussion
The `URLGetFileInfo` function obtains the file type and creator codes for a specified filename. The type and creator codes are determined by the Internet configuration mapping table and are based on the filename extension. For example, if you pass the filename `"jane.txt"`, `URLGetFileInfo` will return `'TEXT'` in the `type` parameter and `'ttxt'` in the `creator` parameter.

Special Considerations

CFNetwork provides better reliability and performance and is used by Apple's own applications. URL Access Manager is no longer being enhanced or improved.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`URLAccess.h`

URLGetProperty

Obtains the value of a URL property. (Deprecated in Mac OS X v10.4. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

```
OSStatus URLGetProperty (
   URLReference urlRef,
   const char *property,
   void *propertyBuffer,
   Size bufferSize
);
```

Parameters

urlRef

A reference to the URL whose property value you want to determine.

property

A pointer to a C string representing the name of the property value you want to determine. For a description of property name constants and their corresponding data types, see "Universal URL Property Name Constants" (page 1776) and "HTTP and HTTPS URL Property Name Constants" (page 1775).

propertyBuffer

A pointer to a buffer containing the property value you want to obtain. You must also pass the correct data type of the property value you wish to obtain. Before calling `URLGetProperty`, allocate enough memory in this buffer to contain the property value you wish to obtain. On return, a pointer to a buffer containing the property value. If you do not allocate enough memory for the buffer, `URLGetProperty` does not pass back the property value in this parameter and returns the result code `kURLPropertyBufferTooSmallError`.

bufferSize

The size (in bytes) of the buffer pointed to by `propertyBuffer`. To determine the buffer size, call the function `URLGetPropertySize` (page 1748). If the buffer size is too small, `URLGetProperty` returns the result code `kURLPropertyBufferTooSmallError` and does not pass back the property value in the `propertyBuffer` parameter.

Return Value
A result code. See "URL Access Manager Result Codes" (page 1779). The result code `kURLPropertyBufferTooSmallError` indicates that you did not allocate enough memory for the buffer in the `propertyBuffer` parameter. The result code `kURLPropertyNotYetKnownError` indicates that the value of the property is not yet available.

Discussion
The `URLGetProperty` function obtains the value of a URL property identified by the property name constant specified in the property parameter.

Special Considerations

CFNetwork provides better reliability and performance and is used by Apple's own applications. URL Access Manager is no longer being enhanced or improved.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`URLAccess.h`

URLGetPropertySize

Determines the size of a URL property. (Deprecated in Mac OS X v10.4. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

```
OSStatus URLGetPropertySize (
   URLReference urlRef,
   const char *property,
   Size *propertySize
);
```

Parameters

urlRef

A reference to the URL whose property size you want to determine.

property

A pointer to a C string representing the name of the property value whose size you want to determine. For a description of property name constants, see "Universal URL Property Name Constants" (page 1776) and "HTTP and HTTPS URL Property Name Constants" (page 1775).

propertySize

On return, a pointer to the size (in bytes) of the specified property value. If the size is not available, `URLGetPropertySize` passes back `-1` in this parameter and returns the result code `kURLPropertyNotYetKnownError`.

Return Value
A result code. See "URL Access Manager Result Codes" (page 1779).

Discussion
The `URLGetProperty` function obtains the size of the property value identified by the property name constant passed in the property parameter. For a description of property name constants and data types of the corresponding property values, see "Universal URL Property Name Constants" (page 1776) and "HTTP and HTTPS URL Property Name Constants" (page 1775).

You should call the `URLGetPropertySize` function before calling the function `URLGetProperty` (page 1747) to determine the size of the buffer containing the property value you wish to obtain. Pass the value passed back in the `propertySize` parameter in the `bufferSize` parameter of `URLGetProperty` (page 1747).

Special Considerations

CFNetwork provides better reliability and performance and is used by Apple's own applications. URL Access Manager is no longer being enhanced or improved.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`URLAccess.h`

URLGetURLAccessVersion

Determines the version of URL Access Manager installed on the user's system. (Deprecated in Mac OS X v10.4. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

```
OSStatus URLGetURLAccessVersion (
   UInt32 *returnVers
);
```

Parameters

returnVers
On return, a pointer to the version number of the URL Access Manager installed on the user's system.

Return Value
A result code. See "URL Access Manager Result Codes" (page 1779).

Special Considerations

CFNetwork provides better reliability and performance and is used by Apple's own applications. URL Access Manager is no longer being enhanced or improved.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`URLAccess.h`

URLIdle

Gives the URL Access Manager time to refill its buffers during download operations. (Deprecated in Mac OS X v10.4. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

```
OSStatus URLIdle (
   void
);
```

Return Value
A result code. See "URL Access Manager Result Codes" (page 1779).

Discussion
The `URLIdle` function gives the URL Access Manager time to refill its buffers during download operations. You should call URLIdle periodically after you call the function `URLOpen` (page 1751) to allow time for the URL Access Manager to refill its buffers.

Special Considerations

CFNetwork provides better reliability and performance and is used by Apple's own applications. URL Access Manager is no longer being enhanced or improved.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`URLAccess.h`

URLNewReference

Creates a URL reference. (Deprecated in Mac OS X v10.4. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

```
OSStatus URLNewReference (
   const char *url,
   URLReference *urlRef
);
```

Parameters

url

A pointer to a C string representing the name of the URL you want to create.

urlRef

On return, a pointer to the newly-created URL reference.

Return Value
A result code. See "URL Access Manager Result Codes" (page 1779).

Discussion
The `URLNewReference` function creates a URL reference that you can use in subsequent calls to the URL Access Manager. When you no longer need a URL reference, you should dispose of its memory by calling the function `URLDisposeReference` (page 1741).

Special Considerations

CFNetwork provides better reliability and performance and is used by Apple's own applications. URL Access Manager is no longer being enhanced or improved.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
URLAccess.h

URLOpen

Opens a URL and starts an asynchronous download or upload operation. (Deprecated in Mac OS X v10.4. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

```
OSStatus URLOpen (
   URLReference urlRef,
   FSSpec *fileSpec,
   URLOpenFlags openFlags,
   URLNotifyUPP notifyProc,
   URLEventMask eventRegister,
   void *userContext
);
```

Parameters

urlRef

A reference to the URL to or from which you wish to transfer data. You cannot use the same reference if you call URLOpen again. Instead, you must create a new URL reference by calling the function URLNewReference (page 1750). If the URL refers to a file, the file is downloaded regardless of whether you specify kURLDirectoryListingFlag or KURLIsDirectoryHintFlag in the openFlags parameter. See "Naming Your Destination File" for more information.

fileSpec

A pointer to a file specification that identifies the file or directory from which data is to be uploaded or downloaded. For upload operations, you must pass a valid file specification. For download operations, you can pass NULL. In this case, you must call the function URLGetBuffer (page 1743) to retrieve the data as it is downloaded. For more information, see the function discussion.

openFlags

A bitmask that indicates the data transfer options to use. You can specify any of the following masks for upload operations: kURLUploadFlag, kURLReplaceExistingFlag, kURLBinHexFileFlag, and kURLDoNotTryAnonymousFlag. You can specify any of the following masks for download operations: kURLReplaceExistingFlag, kURLIsDirectoryHintFlag, kURLDoNotTryAnonymousFlag, kURLDebinhexOnlyFlag, kURLNoAutoRedirect, and kURLDirectoryListingFlag. See "Data Transfer Options Mask Constants" (page 1770) for a description of possible values.

notifyProc

A Universal Procedure Pointer (UPP) to a data transfer event notification callback, as described in URLNotifyProcPtr (page 1759). You should create a notification callback function if you wish to receive notification of certain data transfer events. In this case, you should also pass a bitmask of the events you wish to receive in the eventRegister parameter. The data transfer events that you receive will vary depending upon whether the destination file you specify is valid. Pass NULL if you do not want to receive notification of data transfer events.

eventRegister

A bitmask that URLOpen will test to determine the data transfer events that you wish to receive notification of. To receive data transfer events, you should also pass a UPP to your callback in the notifyProc parameter. See "Data Transfer Event Mask Constants" (page 1766) for a description of this mask.

userContext
A pointer to application-defined storage that will be passed to your notification callback function. Your application can use this to set up its context when your notification callback function is called.

Return Value
A result code. See "URL Access Manager Result Codes" (page 1779).

Discussion
The `URLOpen` function starts a download or upload operation and returns control to your application immediately. For download operations, you do not have to specify a valid destination file. In this case, you should call the function `URLGetBuffer` (page 1743) repeatedly to get the next buffer of data. Between calls to `URLGetBuffer` (page 1743), you should call the function `URLIdle` (page 1749) to allow time for the URL Access Manager to refill its buffers during download operations. After each call to `URLGetBuffer` (page 1743), you call the function `URLReleaseBuffer` (page 1752) to prevent the URL Access Manager from running out of buffers. You can call the function `URLGetDataAvailable` (page 1745) to determine the amount of data remaining in the buffer of the URL Access Manager that you will obtain from a call to the function `URLGetBuffer` (page 1743).

If you pass a valid destination file, you should not call the functions `URLGetBuffer` (page 1743), `URLReleaseBuffer` (page 1752), or `URLGetDataAvailable` (page 1745).

If you wish to be notified of certain data transfer events, you can specify a data transfer event callback and pass a pointer to it in the `URLEventMask` parameter of URLOpen. The data transfer events that you receive will vary depending upon whether the destination file you specify is valid. In addition, you should pass a bitmask representing the events you wish to be notified of in the `eventRegister` parameter.

When `URLOpen` downloads data from a URL that represents a local file (that is, a URL that begins with `file://`), the data fork is downloaded but the resource fork is not.

Special Considerations

CFNetwork provides better reliability and performance and is used by Apple's own applications. URL Access Manager is no longer being enhanced or improved.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`URLAccess.h`

URLReleaseBuffer

Releases a buffer. (Deprecated in Mac OS X v10.4. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

```
OSStatus URLReleaseBuffer (
   URLReference urlRef,
   void *buffer
);
```

Parameters

urlRef
A reference to the URL whose buffer you want to release.

buffer
A pointer to the buffer you want to release.

Return Value
A result code. See "URL Access Manager Result Codes" (page 1779).

Discussion
The `URLReleaseBuffer` function releases the buffer obtained by calling the function `URLGetBuffer` (page 1743). To prevent the URL Access Manager from running out of buffers, you should call `URLReleaseBuffer` after each call to `URLGetBuffer` (page 1743).

Special Considerations

CFNetwork provides better reliability and performance and is used by Apple's own applications. URL Access Manager is no longer being enhanced or improved.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`URLAccess.h`

URLSetProperty

Sets the value of a URL property. (Deprecated in Mac OS X v10.4. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

```
OSStatus URLSetProperty (
   URLReference urlRef,
   const char *property,
   void *propertyBuffer,
   Size bufferSize
);
```

Parameters

urlRef
A reference to the URL whose property value you want to set.

property
A pointer to a C string representing the name of the property value you want to set. You can only set property values identified by the constants `kURLPassword`, `kURLUserName`, `kURLHTTPRequestMethod`, `kURLHTTPRequestHeader`, `kURLHTTPRequestBody`, and `kURLHTTPUserAgent`. For a description of these property name constants and their corresponding data types, see "Universal URL Property Name Constants" (page 1776) and "HTTP and HTTPS URL Property Name Constants" (page 1775).

propertyBuffer
A pointer to a buffer containing the data you would like the property to be set to. The data must be of the correct type.

bufferSize
The size (in bytes) of the data you want to set.

Return Value
A result code. See "URL Access Manager Result Codes" (page 1779). The result code `kURLUnsettablePropertyError` indicates that a property value cannot be set.

Discussion

The `URLSetProperty` function enables you to set those property values identified by the following constants: `kURLPassword`, `kURLUserName`, `kURLPassword`, `kURLHTTPRequestMethod`, `kURLHTTPRequestHeader`, `kURLHTTPRequestBody`, and `kURLHTTPUserAgent`. For a description of these property name constants and their corresponding data types, see "Universal URL Property Name Constants" (page 1776) and "HTTP and HTTPS URL Property Name Constants" (page 1775).

You may wish to call `URLSetProperty` before calling the function `URLDownload` (page 1741) or `URLUpload` (page 1757) to set a URL property before a data transfer operation.

Special Considerations

CFNetwork provides better reliability and performance and is used by Apple's own applications. URL Access Manager is no longer being enhanced or improved.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`URLAccess.h`

URLSimpleDownload

Downloads data from a URL specified by a character string. (Deprecated in Mac OS X v10.4. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

```
OSStatus URLSimpleDownload (
   const char *url,
   FSSpec *destination,
   Handle destinationHandle,
   URLOpenFlags openFlags,
   URLSystemEventUPP eventProc,
   void *userContext
);
```

Parameters

url

A pointer to a C string representing the pathname of the URL from which data is to be downloaded. If the pathname specifies a file, the file is downloaded regardless of whether you specify `kURLDirectoryListingFlag` or `KURLIsDirectoryHintFlag` in the `openFlags` parameter.

destination

A pointer to a file specification structure that identifies the file or directory into which data is to be downloaded. If you wish to download data into memory, pass `NULL` in this parameter and a valid handle in the `destinationHandle` parameter. If you pass a file specification that does not identify a file or directory, the name of the file or directory specified by the pathname in the `url` parameter is used. If you pass a file or directory that already exists, and do not specify `kURLReplaceExistingFlag` in the `openFlags` parameter, `URLSimpleDownload` creates a new file or directory whose name has a number appended before the extension. For example, if the URL specifies a file named `file.txt`, `URLSimpleDownload` changes the filename to `file1.txt`.

destinationHandle

A handle to the destination in memory where you want the data downloaded. Before calling `URLDownload`, create a zero-sized handle. If you wish to download data into a file or directory, pass `NULL` in this parameter and a valid file specification in the `destination` parameter.

openFlags

A bitmask that indicates the data transfer options to use. You can specify any of the following masks for downloading options: `kURLReplaceExistingFlag`, `kURLExpandFileFlag`, `kURLExpandAndVerifyFlag`, `kURLDisplayProgressFlag`, `kURLDisplayAuthFlag`, `kURLIsDirectoryHintFlag`, `kURLDoNotTryAnonymousFlag`, `kURLDebinhexOnlyFlag`, `kURLNoAutoRedirect`, and `kURLDirectoryListingFlag`. See "Data Transfer Options Mask Constants" (page 1770) for a description of possible values.

eventProc

A Universal Procedure Pointer (UPP) to your system event callback function, if one exists. For information on how to write a system event callback, see `URLSystemEventProcPtr` (page 1760). If you want to handle events that occur while a progress indicator or authentication dialog box is being displayed, specify the appropriate mask (either `kURLDisplayProgressFlag` or `kURLDisplayAuthFlag`) in the `openFlags` parameter and pass a UPP to your callback function in this parameter. Pass `NULL` if you do not want to receive notification of these events. In this case, the URL Access Manager displays a nonmovable modal progress indicator or authentication dialog box.

userContext

A pointer to application-defined storage that will be passed to your system event callback function, if one exists. Your application can use this to set up its context when your system event callback function is called.

Return Value

A result code. See "URL Access Manager Result Codes" (page 1779). If your application is multi-threaded, and more than one thread calls `URLSimpleDownload` simultaneously, `URLSimpleDownload` returns the result code `kURLProgressAlreadyDisplayedError` if you specify `kURLDisplayProgressFlag` in the `openFlags` parameter and the URL Access Manager is already displaying a progress indicator.

Discussion

The `URLSimpleDownload` function downloads data from a URL specified by a pathname to a specified file, directory, or memory. It does not return until the download is complete. If you want to download data from a URL identified by a reference rather than a pathname, call the function `URLDownload` (page 1741). The difference between the two functions is that `URLDownload` (page 1741) allows you to access other URL Access Manager functions before, after, or during the download. If you want more control over a data transfer operation, call the function `URLOpen` (page 1751).

If you wish to download data to a file or directory, pass a valid file specification in the `destination` parameter. If you instead wish to download data to memory, pass a valid handle in the `destinationHandle` parameter.

When `URLSimpleDownload` downloads data from a URL that represents a local file (that is, a URL that begins with `file://`), the data fork is downloaded but the resource fork is not.

Special Considerations

CFNetwork provides better reliability and performance and is used by Apple's own applications. URL Access Manager is no longer being enhanced or improved.

`URLSimpleDownload` yields time to other threads. Your application should call URLSimpleDownload from a thread other than the main thread so that other processes have time to run.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In
URLAccess.h

URLSimpleUpload

Uploads a file or directory to an FTP URL specified by a character string. (Deprecated in Mac OS X v10.4. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

```
OSStatus URLSimpleUpload (
   const char *url,
   const FSSpec *source,
   URLOpenFlags openFlags,
   URLSystemEventUPP eventProc,
   void *userContext
);
```

Parameters

url

A pointer to a C string representing the URL to which a file or directory is to be uploaded. If you wish to replace the destination directory of this URL with the file or directory that you pass in the source parameter, terminate the string with a slash character (/), and set the mask constant kURLReplaceExistingFlag in the openFlags parameter. If you specify a name that already exists on the server and do not specify kURLReplaceExistingFlag, URLSimpleUpload returns the result code kURLDestinationExistsError. If you do not specify a name, do not specify kURLReplaceExistingFlag in the openFlags parameter, and the name already exists on the server, the URL Access Manager creates a unique name by appending a number to the original name before the extension, if any. For example, if the URL specifies a file named file.txt, URLSimpleUpload changes the filename to file1.txt. See "Naming Your Destination File" for more information.

source

A pointer to a file specification structure that describes the file or directory you want to upload.

openFlags

A bitmask that indicates the data transfer options to use. You can specify any of the following masks for uploading options: kURLReplaceExistingFlag, kURLBinHexFileFlag, kURLDisplayProgressFlag, kURLDisplayAuthFlag, and kURLDoNotTryAnonymousFlag. See "Data Transfer Options Mask Constants" (page 1770) for a description of possible values.

eventProc

A Universal Procedure Pointer (UPP) to your system event callback function, if one exists. For information on how to write a system event callback, see URLSystemEventProcPtr (page 1760). If you want to handle events that occur while a progress indicator or authentication dialog box is being displayed, specify the appropriate mask (either kURLDisplayProgressFlag or kURLDisplayAuthFlag) in the openFlags parameter and pass a UPP to your callback function in this parameter. Pass NULL if you do not want to receive notification of these events. In this case, the URL Access Manager displays a nonmovable modal progress indicator or authentication dialog box.

userContext

A pointer to application-defined storage that will be passed to your system event callback function, if one exists. Your application can use this to set up its context when your system event callback function is called.

Return Value
A result code. See "URL Access Manager Result Codes" (page 1779). The result code `kURLDestinationExistsError` indicates that you specified a pathname that already exists on the server but did not set the bit specified by the mask constant `kURLReplaceExistingFlag` in the `openFlags` parameter. If your application is multi-threaded, and more than one thread calls `URLSimpleUpload` simultaneously, `URLSimpleUpload` returns the result code `kURLProgessAlreadyDisplayedError` if you specify `kURLDisplayProgressFlag` in the `openFlags` parameter and the URL Access Manager is already displaying a progress indicator.

Discussion
The `URLSimpleUpload` function uploads a file or directory to an FTP URL specified by a pathname. It does not return until the upload is complete. If you want to upload data from a URL identified by a reference rather than a pathname, call the function `URLUpload` (page 1757). The difference between the two functions is that `URLUpload` (page 1757) allows you to access other URL Access Manager functions before, after, or during the download. If you want more control over a data transfer operation, call the function `URLOpen` (page 1751).

Special Considerations

CFNetwork provides better reliability and performance and is used by Apple's own applications. URL Access Manager is no longer being enhanced or improved.

`URLSimpleUpload` yields time to other threads. Your application should call `URLSimpleUpload` from a thread other than the main thread so that other processes have time to run.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`URLAccess.h`

URLUpload

Uploads a file or directory to an FTP URL specified by a URL reference. (Deprecated in Mac OS X v10.4. Use CFNetwork instead; see *CFNetwork Programming Guide*.)

```
OSStatus URLUpload (
   URLReference urlRef,
   const FSSpec *source,
   URLOpenFlags openFlags,
   URLSystemEventUPP eventProc,
   void *userContext
);
```

Parameters

urlRef

A reference to the URL to which a file or directory is to be uploaded. Once you have called `URLUpload`, you cannot use the same reference again. If you wish to replace the destination directory of this URL with the file or directory that you pass in the source parameter, set the mask constant `kURLReplaceExistingFlag` in the `openFlags` parameter. If you specify a name that already exists on the server and do not specify `kURLReplaceExistingFlag`, `URLUpload` returns the result code `kURLDestinationExistsError`. If you do not specify a name, do not specify `kURLReplaceExistingFlag` in the `openFlags` parameter, and the name already exists on the server, the URL Access Manager creates a unique name by appending a number to the original name before the extension, if any. For example, if the URL specifies a file named `file.txt`, `URLUpload` changes the filename to `file1.txt`. See "Naming Your Destination File" for more information.

source

A pointer to a file specification structure that describes the file or directory you want to upload.

openFlags

A bitmask that indicates the data transfer options you want used. You can specify any of the following masks for uploading options: `kURLReplaceExistingFlag`, `kURLBinHexFileFlag`, `kURLDisplayProgressFlag`, `kURLDisplayAuthFlag`, and `kURLDoNotTryAnonymousFlag`. See "URL Access Manager Reference" (page 1736) for a description of possible values.

eventProc

A Universal Procedure Pointer (UPP) to your system event callback function, if one exists. For information on how to write a system event callback, see `URLSystemEventProcPtr` (page 1760). If you want to handle events that occur while a progress indicator or authentication dialog box is being displayed, specify the appropriate mask (either `kURLDisplayProgressFlag` or `kURLDisplayAuthFlag`) in the `openFlags` parameter and pass a UPP to your callback function in this parameter. Pass `NULL` if you do not want to receive notification of these events. In this case, the URL Access Manager displays a nonmovable modal progress indicator or authentication dialog box.

userContext

A pointer to application-defined storage that will be passed to your system event callback function, if one exists. Your application can use this to set up its context when your system event callback function is called.

Return Value

A result code. See "URL Access Manager Result Codes" (page 1779). The result code `kURLDestinationExistsError` indicates that you specified a pathname that already exists on the server but did not specify `kURLReplaceExistingFlag` in the `openFlags` parameter. If your application is multi-threaded, and more than one thread calls `URLUpload` simultaneously, `URLUpload` returns the result code `kURLProgessAlreadyDisplayedError` if you specify `kURLDisplayProgressFlag` in the `openFlags` parameter and the URL Access Manager is already displaying a progress indicator.

Discussion
The `URLUpload` function uploads a file or directory to an FTP URL specified by a URL reference. It does not return until the upload is complete. If you want to upload data from a URL identified by a pathname rather than a reference, call the function `URLSimpleUpload` (page 1756). The difference between the two functions is that URLUpload allows you to access other URL Access Manager functions before, after, or during the download. If you want more control over a data transfer operation, call the function `URLOpen` (page 1751).

Special Considerations

CFNetwork provides better reliability and performance and is used by Apple's own applications. URL Access Manager is no longer being enhanced or improved.

`URLUpload` yields time to other threads. Your application should call `URLUpload` from a thread other than the main thread so that other processes have time to run.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`URLAccess.h`

Callbacks

URLNotifyProcPtr

Defines a pointer to your notification callback function that handles certain data transfer events that occur during data transfer operations.

```
typedef OSStatus (*URLNotifyProcPtr)
(
    void * userContext,
    URLEvent event,
    URLCallbackInfo * callbackInfo
);
```

If you name your function `MyURLNotifyProc`, you would declare it like this:

```
OSStatus MyURLNotifyProc (
    void * userContext,
    URLEvent event,
    URLCallbackInfo * callbackInfo
);
```

Parameters

`userContext`

A pointer to application-defined storage that your application previously passed to the function `URLOpen` (page 1751). Your application can use this to set up its context when your notification callback function is called.

event

The data transfer event that your application wishes to be notified of. See "Data Transfer Event Constants" (page 1764) for a description of possible values. The type of event that can trigger your callback depends on the event mask you passed in the `eventRegister` parameter of the function `URLOpen` (page 1751), and whether you pass a valid file specification in the `fileSpec` parameter of `URLOpen` (page 1751). For more information, see the discussion.

callbackInfo

A pointer to a structure of type `URLCallbackInfo` (page 1762). On return, the structure contains information about the data transfer event that occurred. The URL Access Manager passes this information to your callback function via the `callbackInfo` parameter of the function `InvokeURLNotifyUPP` (page 1737).

Return Value

A result code. See "URL Access Manager Result Codes" (page 1779). Your notification callback function should process the data transfer event and return `noErr`.

Discussion

Your notification callback function handles certain data transfer events that occur during data transfer operations performed by the function `URLOpen` (page 1751). You can define an event notification function and the events for which you want to receive notification only if you do not specify a file in which to store the data for download operations. In order to be notified of these events, you must pass a UPP to your notification callback function in the `notifyProc` parameter. You indicate the type of data transfer events you want to receive via a bitmask in the `eventRegister` parameter.

Note that if you pass a valid file specification to `URLOpen` (page 1751), your callback function will not be notified of data available and transaction completed events as identified by the constants `kURLDataAvailableEvent` and `kURLTransactionCompleteEvent`. If you pass a valid file specification to `URLOpen` (page 1751), your callback function notified if any of the following events occur: `kURLPercentEvent`, `kURLPeriodicEvent`, `kURLPropertyChangedEvent`, `kURLSystemEvent`, `kURLInitiatedEvent`, `kURLResourceFoundEvent`, `kURLDownloadingEvent`, `kURLUploadingEvent`, `kURLAbortInitiatedEvent`, `kURLCompletedEvent`, and `kURLErrorOccurredEvent`.

When your callback is called, it should process the event immediately and return 0. You may wish your callback function to update its user interface, allocate and deallocate memory, or call the Thread Manager function `NewThread`.

Special Considerations

Do not call the function `URLDisposeReference` (page 1741) from your notification callback function. Doing so may cause your application to stop working.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`URLAccess.h`

URLSystemEventProcPtr

Defines a pointer to your system event notification callback that handles update events that occur while a dialog box is displayed during a data transfer operation.

```
typedef OSStatus (*URLSystemEventProcPtr)
(
    void * userContext,
    EventRecord * event
);
```

If you name your function `MyURLSystemEventProc`, you would declare it like this:

```
OSStatus MyURLSystemEventProc (
    void * userContext,
    EventRecord * event
);
```

Parameters

userContext

A pointer to application-defined storage that your application previously passed to the function `URLSimpleDownload` (page 1754), `URLDownload` (page 1741), `URLSimpleUpload` (page 1756), or `URLUpload` (page 1757). Your application can use this value to set up its context when the system event callback function is called.

event

A pointer to an event record containing information about the system event that occurred during the data transfer operation.

Return Value

A result code. See "URL Access Manager Result Codes" (page 1779). Your system event callback function should process the system event and return `noErr`.

Discussion

You pass a pointer to your callback function in the `eventProc` parameter of the function `URLSimpleDownload` (page 1754), `URLSimpleUpload` (page 1756), `URLDownload` (page 1741), or `URLUpload` (page 1757) if you want update events to be passed to your application while a dialog box is displayed by these functions. (In Mac OS X, this is not necessary, since all dialog boxes are moveable). In order for these functions to display a dialog box, you must set the mask constant `kURLDisplayProgressFlag` or `kURLDisplayAuthFlag` in the bitmask passed in the `openFlags` parameter. Call the function `NewURLSystemEventUPP` (page 1739) to create a UPP to your system event notification callback. If you do not write your own system event notification callback, these functions will display a nonmovable modal dialog box.

When your callback is called, it should process the event immediately and return 0. You may wish your callback function to update its user interface, allocate and deallocate memory, or call the Thread Manager function `NewThread`.

Special Considerations

Do not call the function `URLDisposeReference` (page 1741) from your callback function. Doing so may cause your application to stop working.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`URLAccess.h`

Data Types

URLCallbackInfo

Contains information about a data transfer event.

```
struct URLCallbackInfo {
    UInt32 version;
    URLReference urlRef;
    const char * property;
    UInt32 currentSize;
    EventRecord * systemEvent;
};
typedef struct URLCallbackInfo URLCallbackInfo;
```

Fields

`version`
The version of this structure. This value is currently 0.

`urlRef`
A reference to the URL associated with the data transfer event.

`property`
A pointer to a C string representing the name of the URL property that has changed, if relevant. This field is only valid if a property change event occurs as identified by the event constant `kURLPropertyChangedEvent`, described in "Data Transfer Event Constants" (page 1764). or a description of name constants and data types of the corresponding property values, see "Universal URL Property Name Constants" (page 1776) and "HTTP and HTTPS URL Property Name Constants" (page 1775). You should specify this field if the event involves a change in a property value.

`currentSize`
The current total size (in bytes) of the data that has been downloaded and processed by the client.

`systemEvent`
A pointer to an event record containing information about the system event that occurred, if relevant. If the event is not a system event, as identified by the event constant `kURLSystemEvent`, described in "Data Transfer Event Constants" (page 1764), this field is not valid.

Discussion

The `URLCallbackInfo` type represents a structure that contains information about the data transfer event that you want notification of. The URL Access Manager passes a pointer to this structure in the `callbackInfo` parameter of your notification callback function. For information on how to write a notification callback function, see `URLNotifyProcPtr` (page 1759).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`URLAccess.h`

URLNotifyUPP

```
typedef URLNotifyProcPtr URLNotifyUPP;
```

Discussion
For more information, see the description of the callback function `URLNotifyProcPtr` (page 1759).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`URLAccess.h`

URLReference

Represents a reference to a URL.

```
typedef struct OpaqueURLReference * URLReference;
```

Discussion
The `URLReference` type represents a reference to an opaque structure that identifies a URL. You should call the function `URLNewReference` (page 1750) to create a URL reference. The function `URLDisposeReference` (page 1741) disposes of a URL reference when no longer needed. You pass a reference of this type to URL Access Manager functions that operate on a URL in some way.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`URLAccess.h`

URLSystemEventUPP

```
typedef URLSystemEventProcPtr URLSystemEventUPP;
```

Discussion
For more information, see the description of the callback function `URLSystemEventProcPtr` (page 1760).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`URLAccess.h`

Constants

Authentication Type Constant

Represents the default value of the property value identified by the property name constant `kURLAuthType`.

```
enum {
    kUserNameAndPasswordFlag = 0x00000001
};
```

Constants

`kUserNameAndPasswordFlag`

Represents the default value of the property value identified by the property name constant `kURLAuthType`, described in "Universal URL Property Name Constants" (page 1776). This value indicates that both the user name and password are used for authentication.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

Discussion

This constant represents the default value of the authentication type property value. The authentication type property value is identified by the property name constant `kURLAuthType`, described in "Universal URL Property Name Constants" (page 1776). If you do not set the `kURLAuthType` property, the default value will be used for the authentication type. In this case, both the user name and password are used for authentication purposes.

Data Transfer Event Constants

Identify data transfer events that occur during a data transfer operation.

```
typedef UInt32 URLEvent;
enum {
    kURLInitiatedEvent = kURLInitiatingState,
    kURLResourceFoundEvent = kURLResourceFoundState,
    kURLDownloadingEvent = kURLDownloadingState,
    kURLAbortInitiatedEvent = kURLAbortingState,
    kURLCompletedEvent = kURLCompletedState,
    kURLErrorOccurredEvent = kURLErrorOccurredState,
    kURLDataAvailableEvent = kURLDataAvailableState,
    kURLTransactionCompleteEvent = kURLTransactionCompleteState,
    kURLUploadingEvent = kURLUploadingState,
    kURLSystemEvent = 29,
    kURLPercentEvent = 30,
    kURLPeriodicEvent = 31,
    kURLPropertyChangedEvent = 32
};
```

Constants

`kURLInitiatedEvent`

Indicates the function `URLOpen` (page 1751) has been called but the location specified by the URL reference has not yet been accessed.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLResourceFoundEvent`

Indicates that the location specified by the URL reference has been accessed and is valid.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLDownloadingEvent`
Indicates that a download operation is in progress.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLAbortInitiatedEvent`
Indicates that a data transfer operation has been aborted. When your application calls the function `URLAbort` (page 1740), the URL Access Manager changes the state returned by the function `URLGetCurrentState` (page 1744) to `kURLAbortingState` and passes the constant `kURLAbortInitiatedEvent` to your notification callback function. When data transfer is terminated, the URL Access Manager changes the state returned by `URLGetCurrentState` (page 1744) to `kURLCompletedState` and passes the constant `kURLCompletedEvent` in the `event` parameter of your notification callback function.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLCompletedEvent`
Indicates that all operations associated with a call to `URLOpen` (page 1751) have been completed. This includes the successful completion of a download or upload operation or the completion of cleanup work after aborting a download or upload operation. For example, when a data transfer operation is aborted, the URL Access Manager changes the state returned by the function `URLGetCurrentState` (page 1744) to `kURLCompletedState` and passes the constant `kURLCompletedEvent` in the `event` parameter of your notification callback function.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLErrorOccurredEvent`
Indicates that an error occurred during data transfer. If you receive this event, you may wish to call the function `URLGetError` (page 1746) to determine the nature of the error.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLDataAvailableEvent`
Indicates that data is available in buffers. If you receive this event, you can call the function `URLGetBuffer` (page 1743) to obtain the next buffer of data. You may wish to call the function `URLGetDataAvailable` (page 1745) to determine the amount of data available for retrieval in a download operation. Note that if you pass a valid file specification in the `fileSpec` parameter of `URLOpen` (page 1751), your notification callback function will not be called for data available events.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLTransactionCompleteEvent`
Indicates that a download operation is complete because there is no more data to retrieve from buffers. Note that if you pass a valid file specification in the `fileSpec` parameter of `URLOpen` (page 1751), your notification callback function will not be called for transaction completed events.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLUploadingEvent`
Indicates that an upload operation is in progress.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLSystemEvent`
: Indicates that a system event has occurred.

  Available in Mac OS X v10.0 and later.

  Declared in `URLAccess.h`.

`kURLPercentEvent`
: Indicates that the size of the data being downloaded is known. In this case, an increment of one percent of the data was transferred into buffers.

  Available in Mac OS X v10.0 and later.

  Declared in `URLAccess.h`.

`kURLPeriodicEvent`
: Indicates that a time interval of approximately one quarter of a second has passed.

  Available in Mac OS X v10.0 and later.

  Declared in `URLAccess.h`.

`kURLPropertyChangedEvent`
: Indicates that a property such as a filename has become known or changed. In this case, the name of the changed property will be passed to your notification function via the `property` field of the `callbackInfo` structure.

  Available in Mac OS X v10.0 and later.

  Declared in `URLAccess.h`.

Discussion
The `URLEvent` enumeration defines constants that identify data transfer events that occur during a data transfer operation performed by `URLOpen` (page 1751). In order to be notified of these events, you must pass a UPP to your data transfer notification callback in the `notifyProc` parameter. You indicate the type of data transfer events you want to receive via a bitmask in the `eventRegister` parameter. For a description of this bitmask, see "Data Transfer Event Mask Constants" (page 1766).

Data Transfer Event Mask Constants

Represent a mask that identifies the data transfer events occurring during a data transfer operation that your application wants notification of.

```
typedef unsigned long URLEventMask;
enum {
    kURLInitiatedEventMask = 1 << (kURLInitiatedEvent - 1),
    kURLResourceFoundEventMask = 1 << (kURLResourceFoundEvent
- 1),
    kURLDownloadingMask = 1 << (kURLDownloadingEvent - 1),
    kURLUploadingMask = 1 << (kURLUploadingEvent - 1),
    kURLAbortInitiatedMask = 1 << (kURLAbortInitiatedEvent
- 1),
    kURLCompletedEventMask = 1 << (kURLCompletedEvent - 1),
    kURLErrorOccurredEventMask = 1 << (kURLErrorOccurredEvent
- 1),
    kURLDataAvailableEventMask = 1 << (kURLDataAvailableEvent
- 1),
    kURLTransactionCompleteEventMask = 1 << (kURLTransactionCompleteEvent
- 1),
    kURLSystemEventMask = 1 << (kURLSystemEvent - 1),
    kURLPercentEventMask = 1 << (kURLPercentEvent - 1),
    kURLPeriodicEventMask = 1 << (kURLPeriodicEvent - 1),
    kURLPropertyChangedEventMask = 1 << (kURLPropertyChangedEvent
- 1),
    kURLAllBufferEventsMask = kURLDataAvailableEventMask +
kURLTransactionCompleteEventMask,
    kURLAllNonBufferEventsMask = kURLInitiatedEventMask + kURLDownloadingMask
+ kURLUploadingMask + kURLAbortInitiatedMask + kURLCompletedEventMask
+ kURLErrorOccurredEventMask + kURLPercentEventMask + kURLPeriodicEventMask
+ kURLPropertyChangedEventMask,
    kURLAllEventsMask = 0xFFFFFFFF
};
```

Constants

`kURLInitiatedEventMask`

If the bit specified by this mask is set, your notification callback function will be notified when the function `URLOpen` (page 1751) has been called but the location specified by the URL reference has not yet been accessed.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLResourceFoundEventMask`

If the bit specified by this mask is set, your notification callback function will be notified when the location specified by a URL reference has been accessed and is valid.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLDownloadingMask`

If the bit specified by this mask is set, your notification callback function will be notified when a download operation is in progress.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLUploadingMask`

If the bit specified by this mask is set, your notification callback function will be notified when an upload operation is in progress.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLAbortInitiatedMask`

If the bit specified by this mask is set, your notification callback function will be notified when a download or upload operation has been aborted. When your application calls the function `URLAbort` (page 1740), the URL Access Manager changes the state returned by the function `URLGetCurrentState` (page 1744) to `kURLAbortingState` and passes the constant `kURLAbortInitiatedEvent` to your notification callback function. When data transfer is terminated, the URL Access Manager changes the state returned by `URLGetCurrentState` (page 1744) to `kURLCompletedState` and passes the constant `kURLCompletedEvent` in the `event` parameter of your notification callback function.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLCompletedEventMask`

If the bit specified by this mask is set, your notification callback function will be notified when all operations associated with a call to the function `URLOpen` (page 1751) have been completed. This indicates either the successful completion of an operation or the completion of cleanup work after aborting the operation. For example, when a data transfer operation is aborted, the URL Access Manager changes the state returned by the function `URLGetCurrentState` (page 1744) to `kURLCompletedState` and passes the constant `kURLCompletedEvent` in the `event` parameter of your notification callback function.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLErrorOccurredEventMask`

If the bit specified by this mask is set, your notification callback function will be notified when an error has occurred. If you receive this event, you may wish to call the function `URLGetError` (page 1746) to determine the nature of the error.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLDataAvailableEventMask`

If the bit specified by this mask is set, your notification callback function will be notified when data is available in buffers. If you receive this event, you may wish to call the function `URLGetDataAvailable` (page 1745) to determine the amount of data available for retrieval in a download operation. Note that if you pass a valid file specification in the `fileSpec` parameter of the function `URLOpen` (page 1751), your notification callback function will not be called for data available events.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLTransactionCompleteEventMask`

If the bit specified by this mask is set, your notification callback function will be notified when the operation is complete because there is no more data to retrieve from buffers. Note that if you pass a valid file specification in the `fileSpec` parameter of the function `URLOpen` (page 1751), your notification callback function will not be called for transaction completed events.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLSystemEventMask`

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLPercentEventMask`
: If the bit specified by this mask is set, your notification callback function will be notified when an increment of one percent of the data has been transferred into buffers. This occurs only when the size of the data being transferred is known. This information is useful if you want the URL Access Manager to display a progress indicator.

  Available in Mac OS X v10.0 and later.

  Declared in `URLAccess.h`.

`kURLPeriodicEventMask`
: If the bit specified by this mask is set, your notification callback function will be notified when a time interval of approximately one quarter of a second has passed. You can use this event to report the progress of the download operation when the size of the data is unknown or for other processing that you wish to perform at regular intervals.

  Available in Mac OS X v10.0 and later.

  Declared in `URLAccess.h`.

`kURLPropertyChangedEventMask`
: If the bit specified by this mask is set, your notification callback function will be notified when the value of a URL property, such as a filename or user name, has become known or changes.

  Available in Mac OS X v10.0 and later.

  Declared in `URLAccess.h`.

`kURLAllBufferEventsMask`
: If the bit specified by this mask is set, your notification callback function will be notified when a buffer-related event indicated by the event constants `kURLDataAvailableEvent` or `kURLTransactionCompleteEvent` occurred. If you pass a file specification in the `fileSpec` parameter of the function `URLOpen` (page 1751), your notification callback function will not be called for buffer-related events.

  Available in Mac OS X v10.0 and later.

  Declared in `URLAccess.h`.

`kURLAllNonBufferEventsMask`
: If the bit specified by this mask is set, your notification callback function will be notified when an event unrelated to a buffer occurred. This includes all events except those represented by the constants `kURLDataAvailableEvent` and `kURLTransactionCompleteEvent`.

  Available in Mac OS X v10.0 and later.

  Declared in `URLAccess.h`.

`kURLAllEventsMask`
: If the bit specified by this mask is set, your notification callback function will be notified when any of the above data transfer events occur. If you pass a file specification in the `fileSpec` parameter of the function `URLOpen` (page 1751), your notification callback function will not be called for buffer-related events.

  Available in Mac OS X v10.0 and later.

  Declared in `URLAccess.h`.

Discussion

The `URLEventMask` enumeration defines masks that identify the data transfer events occurring during a call to the function `URLOpen` (page 1751) that your application wants notification of. For a description of data transfer events, see "Data Transfer Event Constants" (page 1764). You can define an event notification function and the events for which you want to receive notification only if you do not specify a file in which to store the data for downloads. You can indicate which events you want to receive notification of via a bitmask in the `eventRegister` parameter of `URLOpen` (page 1751).

Data Transfer Options Mask Constants

Represent a mask that identifies the data transfer options to use when uploading or downloading data.

```
typedef UInt32 URLOpenFlags;
enum {
    kURLReplaceExistingFlag = 1 << 0,
    kURLBinHexFileFlag = 1 << 1,
    kURLExpandFileFlag = 1 << 2,
    kURLDisplayProgressFlag = 1 << 3,
    kURLDisplayAuthFlag = 1 << 4,
    kURLUploadFlag = 1 << 5,
    kURLIsDirectoryHintFlag = 1 << 6,
    kURLDoNotTryAnonymousFlag = 1 << 7,
    kURLDirectoryListingFlag = 1 << 8,
    kURLExpandAndVerifyFlag = 1 << 9,
    kURLNoAutoRedirectFlag = 1 << 10,
    kURLDebinhexOnlyFlag = 1 << 11,
    kURLDoNotDeleteOnErrorFlag = 1 << 12,
    kURLResumeDownloadFlag = 1 << 13,
    kURLReservedFlag = (unsigned long) 1 << 31
};
```

Constants

`kURLReplaceExistingFlag`

If the bit specified by this mask is set and the destination file or directory exists, the file or directory contents are replaced by the newly downloaded or uploaded data. If this bit is not set and the name of the file is specified and does exist, the URL Access Manager returns the result code `kURLDestinationExistsError`. If the name of the file or directory is not specified, the file or directory already exists, and the bit specified by this mask is not set, a number is appended to the name before any extension until a unique name is created, and the data is transferred to the new file or directory name without notifying the calling application that the name has changed. In the case of a download operation, your application can check the `destination` parameter of the functions `URLSimpleDownload` (page 1754) and `URLDownload` (page 1741) to obtain the new filename.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLBinHexFileFlag`

If the bit specified by this mask is set, the URL Access Manager converts a nontext file that has a resource fork to `BinHex` format before uploading it.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLExpandFileFlag`

If the bit specified by this mask is set, files in `BinHex` format are decoded. If version 5.0 of the Stuffit Engine is installed in the System Folder, the URL Access Manager uses it to expand the file.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLDisplayProgressFlag`

If the bit specified by this mask is set, the URL Access Manager displays a nonmovable modal progress indicator during data transfer operations only if you have not provided a system event notification callback. On Mac OS X, dialog boxes will always be moveable. To handle data transfer events that occur while a progress indicator is being displayed, pass a UPP to your data transfer event notification callback in the `eventProc` parameter of the functions `URLSimpleDownload` (page 1754), `URLDownload` (page 1741), `URLSimpleUpload` (page 1756), and `URLUpload` (page 1757).

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLDisplayAuthFlag`

If the bit specified by this mask is set, the URL Access Manager displays a nonmovable modal authentication dialog box when user authentication is required only if you have not provided a system event notification callback. On Mac OS X, dialog boxes will always be moveable. To handle data transfer events that occur while an authentication dialog box is being displayed, pass a UPP to your data transfer event notification callback in the `eventProc` parameter of the functions `URLSimpleDownload` (page 1754), `URLDownload` (page 1741), `URLSimpleUpload` (page 1756), and `URLUpload` (page 1757). If the bit specified by this mask is clear, the user name and password properties of the URL are used for authentication purposes. If these are not set, the URL Access Manager returns the result code `kURLAuthenticationError`.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLUploadFlag`

If the bit specified by this mask is set, the function `URLOpen` (page 1751) will upload the file or directory to the specified URL.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLIsDirectoryHintFlag`

If the bit specified by this mask is set, download operations assume that the URL points to a directory. Note that if you pass a pathname that specifies a file in the `url` parameter of the function `URLSimpleDownload` (page 1754), the file is downloaded regardless of whether you specify `kURLDirectoryListingFlag` or `KURLIsDirectoryHintFlag` in the `openFlags` parameter.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLDoNotTryAnonymousFlag`

If the bits specified by this mask is set, when FTP authentication occurs, the functions `URLSimpleDownload` (page 1754), `URLDownload` (page 1741), `URLSimpleUpload` (page 1756), `URLUpload` (page 1757), and `URLOpen` (page 1751) will not try to log on anonymously. Instead, they will rely on the setting of the mask constant `kURLDisplayAuthFlag`. If the bit specified by the `kURLDoNotTryAnonymousFlag` mask is not set, these functions will first attempt to log on anonymously.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLDirectoryListingFlag`
If the bit specified by this mask is set, a listing of the directory, rather than the entire directory, is downloaded. If the URL points to a file instead of a directory, the file is downloaded. Note that if you pass a pathname that specifies a file in the `url` parameter of the function `URLSimpleDownload` (page 1754), the file is downloaded regardless of whether you specify `kURLDirectoryListingFlag` or `KURLIsDirectoryHintFlag` in the `openFlags` parameter.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLExpandAndVerifyFlag`
If this flag is available (that is, the File Signing shared library is available) and the bit specified by this mask is set, the signature attached to the file is verified. Success indicates that the file was signed by the certificate authority, but the certificate will not be displayed until after the file is downloaded.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLNoAutoRedirectFlag`
If the bit specified by this mask is set, if an HTTP request returns a "redirect" status (300, 301, or 302), the transfer will complete without attempting to redirect to the next URL. Otherwise, redirects are followed until actual data is encountered or an error is returned.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLDebinhexOnlyFlag`
If the bit specified by this mask is set, the internal engine is used to decode files, rather than the external Stuffit Engine, even if Stuffit is installed. This prevents the display of the Stuffit progress user interface. If you set this bit, you must also set the `kURLExpandFileFlag` mask.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLDoNotDeleteOnErrorFlag`
Do not delete the downloaded file if an error or abort occurs. This flag applies to downloading only and should be used if interested in later resuming the download.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLResumeDownloadFlag`
The passed in file is partially downloaded, attempt to resume it. Currently works for HTTP only. If no `FSSpec` passed in, this flag will be ignored. Overridden by `kURLReplaceExistingFlag`.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLReservedFlag`
Reserved for internal use.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

Discussion
The `URLOpenFlags` enumeration defines masks you can use to identify the data transfer options you want used when performing data transfer operations. You pass this mask in the `openFlags` parameter of the functions `URLSimpleDownload` (page 1754), `URLDownload` (page 1741), `URLSimpleUpload` (page 1756),

URLUpload (page 1757), and URLOpen (page 1751). The options that you can specify for upload and download operations differ, as do those that you can specify for the low-level function URLOpen (page 1751). For a description of the options you can specify in each case, see the appropriate function discussions.

Data Transfer State Constants

Identifies the current state of a data transfer operation.

```
typedef UInt32 URLState;
enum {
    kURLNullState = 0,
    kURLInitiatingState = 1,
    kURLLookingUpHostState = 2,
    kURLConnectingState = 3,
    kURLResourceFoundState = 4,
    kURLDownloadingState = 5,
    kURLDataAvailableState = 0x10 + kURLDownloadingState,
    kURLTransactionCompleteState = 6,
    kURLErrorOccurredState = 7,
    kURLAbortingState = 8,
    kURLCompletedState = 9,
    kURLUploadingState = 10
};
```

Constants

kURLNullState
: Indicates that the function URLOpen (page 1751) has not yet been called.

  Available in Mac OS X v10.0 and later.

  Declared in URLAccess.h.

kURLInitiatingState
: Indicates that the function URLOpen (page 1751) has been called, but the location specified by the URL reference has not yet been accessed. The stream enters this state from the kURLNullState state.

  Available in Mac OS X v10.0 and later.

  Declared in URLAccess.h.

kURLLookingUpHostState
: Indicates that the function URLOpen (page 1751) has been called, and that the host is being looked up. The stream enters this state from the kURLInitiatingState state.

  Available in Mac OS X v10.0 and later.

  Declared in URLAccess.h.

kURLConnectingState
: Indicates that the function URLOpen (page 1751) has been called, and a connection is being made. The stream enters this state from the kURLLookingUpHostState state.

  Available in Mac OS X v10.0 and later.

  Declared in URLAccess.h.

kURLResourceFoundState
: Indicates that the location specified by the URL reference has been accessed and is valid. The stream enters this state from the kURLConnectingState state.

  Available in Mac OS X v10.0 and later.

  Declared in URLAccess.h.

`kURLDownloadingState`
Indicates that the download operation is in progress but there is currently no data in the buffers. The stream enters this state initially from the `kURLResourceFoundState` state. During a download operation, the stream's state may alternate between the `kURLDownloadingState` and the `kURLDataAvailableState` states.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLDataAvailableState`
Indicates that the download operation is in progress and data is available in the buffers. The stream initially enters this state from the `kURLDownloadingState` state. During a download operation, the stream's state may alternate between the `kURLDownloadingState` and the `kURLDataAvailableState` states. If the stream is in the data available state, you may want to call the function `URLGetDataAvailable` (page 1745) to determine the amount of data available for download. If you pass `NULL` in the `fileSpec` parameter of the function `URLOpen` (page 1751), you will need to call the function `URLGetBuffer` (page 1743) to obtain the next buffer of data.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLTransactionCompleteState`
Indicates that a download or upload operation is complete. The stream can enter this state from the `kURLDownloadingState` state.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLErrorOccurredState`
Indicates that an error occurred during data transfer. The stream can enter this state from any state except the `kURLAbortingState` state. If the stream is in this state, you may wish to call the function `URLGetError` (page 1746) to determine the nature of the error.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLAbortingState`
Indicates that a download or upload operation is aborting. The stream enters this state from the `kURLErrorOccurredState` state or as a result of calling the function `URLOpen` (page 1751) when the stream is in any other state. When your application calls the function `URLAbort` (page 1740), the URL Access Manager changes the state returned by the function `URLGetCurrentState` (page 1744) to `kURLAbortingState` and passes the constant `kURLAbortInitiatedEvent` to your notification callback function.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLCompletedState`
Indicates that there is no more activity to be performed on this stream. In this case, the data transfer has either completed successfully or been aborted. The stream enters this state from the `kURLTransactionCompleteState` or the `kURLAbortingState` state. When data transfer is terminated after a data transfer operation is aborted, the URL Access Manager changes the state returned by `URLGetCurrentState` (page 1744) to `kURLCompletedState` and passes the constant `kURLCompletedEvent` in the `event` parameter of your notification callback function.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLUploadingState`
Indicates that an upload operation is in progress.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

Discussion
The `URLState` enumeration defines constants that identify the status of a data transfer operation with respect to a URL. The function `URLGetCurrentState` (page 1744) passes back one of these constants in the `state` parameter to indicate the status of a data transfer operation. All constants except `kURLDataAvailableState` and `kURLCompletedState` can be returned at any time. If you pass a valid file specification in the `fileSpec` parameter of the function `URLOpen` (page 1751), your notification callback function will not be notified of data available and transaction completed states as identified by the constants `kURLDataAvailableState` and `kURLTransactionCompleteState`.

HTTP and HTTPS URL Property Name Constants

Identify property values specific to HTTP and HTTPS URLs.

```
#define kURLHTTPRequestMethod "URLHTTPRequestMethod"
#define kURLHTTPRequestHeader "URLHTTPRequestHeader"
#define kURLHTTPRequestBody "URLHTTPRequestBody"
#define kURLHTTPRespHeader "URLHTTPRespHeader"
#define kURLHTTPUserAgent "URLHTTPUserAgent"
#define kURLHTTPRedirectedURL "URLHTTPRedirectedURL"
#define kURLSSLCipherSuite "URLSSLCipherSuite"
```

Constants
`kURLHTTPRequestMethod`
Identifies the HTTP request method property value. You use this name constant to set or obtain a C string that represents the HTTP method to be used in the request. If you are posting a form, you must set this property to the string "POST".

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLHTTPRequestHeader`
Identifies the HTTP request header property value. You use this name constant to set or obtain a C string that represents the HTTP header to be used in the request. You may set this property to contain all headers needed for the request. If you are posting a form and have set the properties identified by the name constants `kURLHTTPRequestMethod` and `kURLHTTPRequestBody`, you do not need to set the property identified by this tag.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLHTTPRequestBody`
Identifies the HTTP request body property value. You use this name constant to set or obtain a buffer of data that represents the HTTP body to be provided in the request. If you set the property identified by this tag but not that identified by the name constant `kURLHTTPHeader`, a body-length header is automatically added to the request. If you are posting a form, you must set this property to the form data you want sent.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLHTTPRespHeader`
: Identifies the HTTP response header property value. You use this name constant to obtain a C string that represents the HTTP response header that was received.

  Available in Mac OS X v10.0 and later.

  Declared in `URLAccess.h`.

`kURLHTTPUserAgent`
: Identifies the user agent property value. You use this name constant to set or obtain a C string that represents the HTTP user agent string that is embedded in HTTP requests. By default, the URL Access Manager sets the user agent string to "URL Access 1.0 (Macintosh; PPC)".

  Available in Mac OS X v10.0 and later.

  Declared in `URLAccess.h`.

`kURLHTTPRedirectedURL`
: Identifies the redirected URL property value. You use this name constant to obtain a C string that represents the URL that you were redirected to.

  Available in Mac OS X v10.0 and later.

  Declared in `URLAccess.h`.

`kURLSSLCipherSuite`
: Identifies the SSL cipher suite property value.

  Available in Mac OS X v10.0 and later.

  Declared in `URLAccess.h`.

Discussion
These constants represent Apple-defined name constants that identify property values specific to HTTP and HTTPS URLs. For a description of the name constants that identify property values universal to all URLs, see `Universal URL Property Name Constants` (page 1776).

You pass one of these name constants in the property parameter of the functions `URLSetProperty` (page 1753) and `URLGetProperty` (page 1747), respectively, to set or obtain a particular property value. Note that you can only set HTTP and HTTPS property values identified by the constants `kURLHTTPRequestMethod`, `kURLHTTPRequestHeader`, `kURLHTTPRequestBody`, and `kURLHTTPUserAgent`. You must also pass the correct data type corresponding to the property value in the `propertyBuffer` parameter of these functions.

Version Notes
Prior to version 2.0.3 of the URL Access Manager, the data type of the property value identified by the name constant `kURLHTTPRequestBody` was a C string. In 2.0.3 and later, the data type is a buffer of data.

Universal URL Property Name Constants

Identify property values universal to all URLs.

```
#define kURLURL "URLString"
#define kURLResourceSize "URLResourceSize"
#define kURLLastModifiedTime "URLLastModifiedTime"
#define kURLMIMEType "URLMIMEType"
#define kURLFileType "URLFileType"
#define kURLFileCreator "URLFileCreator"
#define kURLCharacterSet "URLCharacterSet"
#define kURLResourceName "URLResourceName"
#define kURLHost "URLHost"
#define kURLAuthType "URLAuthType"
#define kURLUserName "URLUserName"
#define kURLPassword "URLPassword"
#define kURLStatusString "URLStatusString"
#define kURLIsSecure "URLIsSecure"
#define kURLCertificate "URLCertificate"
#define kURLTotalItems "URLTotalItems"
#define kURLConnectTimeout "URLConnectTimeout"
```

Constants

`kURLURL`

Identifies the name string property value. You use this name constant to obtain a C string that represents the URL.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLResourceSize`

Identifies the resource size property value. You use this name constant to obtain a value of type `Size` that represents the total size of the data at the location specified by the URL.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLLastModifiedTime`

Identifies the modification time property value. You use this name constant to obtain a value of type `UInt32` that represents the last time the data was modified.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLMIMEType`

Identifies the MIME type property value. You use this name constant to obtain a Pascal string that represents the MIME type of the URL.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLFileType`

Identifies the file type property value. You use this name constant to set or obtain a value of type `OSType` that represents the file type as specified in a call to the function `URLOpen` (page 1751). If the file type was not specified, `kURLFileType` obtains the file type compatible with the MIME type.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLFileCreator`
Identifies the file creator property value. You use this name constant to set or obtain a value of type `OSType` that represents the file creator as specified in a call to the function `URLOpen` (page 1751). If the file creator was not specified, `kURLFileType` obtains the file type compatible with the MIME type.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLCharacterSet`
Identifies the character set property value. You use this name constant to obtain a Pascal string that represents the character set used by the URL, as returned by the HTTP server.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLResourceName`
Identifies the resource name property value. You use this name constant to obtain a Pascal string that represents the name associated with the data to be downloaded.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLHost`
Identifies the host property value. You use this name constant to obtain a Pascal string that represents the host on which the data is located.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLAuthType`
Identifies the authentication type property value. You use this name constant to obtain a value that represents the type of authentication that the download operation requires. The default authentication type is `kUserNameAndPasswordFlag`, described in `Authentication Type Constant` (page 1763).

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLUserName`
Identifies the user name property value. You use this name constant to set or obtain a Pascal string that represents the user name used for authentication.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLPassword`
Identifies the password property value. You use this name constant to set or obtain a Pascal string that represents the password used for authentication.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLStatusString`
Identifies the status property value. You use this name constant to obtain a Pascal string that represents the current status of the data stream. You can use this property to display the status of the data transfer operation.

Available in Mac OS X v10.0 and later.

Declared in `URLAccess.h`.

`kURLIsSecure`
: Identifies the security property value. You use this name constant to get a Boolean value that indicates whether the download operation is secure.

  Available in Mac OS X v10.0 and later.

  Declared in `URLAccess.h`.

`kURLCertificate`
: Identifies the certificate property value. You use this name constant to obtain a buffer of data that represents the certificate provided by a remote server.

  Available in Mac OS X v10.0 and later.

  Declared in `URLAccess.h`.

`kURLTotalItems`
: Identifies the total items property value. You use this name constant to obtain a value of type `UInt32` that represents the total number of items being uploaded or downloaded.

  Available in Mac OS X v10.0 and later.

  Declared in `URLAccess.h`.

`kURLConnectTimeout`
: Identifies the connection timeout property value.

  Available in Mac OS X v10.0 and later.

  Declared in `URLAccess.h`.

Discussion
These constants represent Apple-defined name constants that identify property values universal to all URLs. For a description of the name constants that identify property values specific to HTTP and HTTPS URLs, see `HTTP and HTTPS URL Property Name Constants` (page 1775).

You pass one of these name constants in the property parameter of the functions `URLSetProperty` (page 1753) and `URLGetProperty` (page 1747), respectively, to set or obtain a particular property value. Note that you can only set the universal property values identified by the constants `kURLPassword` and `kURLUserName`. You must also pass the correct data type corresponding to the property value in the `propertyBuffer` parameter of these functions.

Result Codes

The most common result codes returned by URL Access Manager are listed in the table below. The following result codes may also be returned; `noErr` (0), `nsvErr` (-35), `fnfErr` (-43), `paramErr` (-50), and `dirNFErr` (-120).

Result Code	Value	Description
`kURLInvalidURLReferenceError`	-30770	Returned by functions that operate on URL references to indicate that a reference is invalid. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
kURLProgressAlreadyDisplayedError	-30771	Returned by the functions URLSimpleDownload, URLDownload, URLSimpleUpload, and URLUpload to indicate that a progress indicator is already displayed. Available in Mac OS X v10.0 and later.
kURLDestinationExistsError	-30772	Returned by the functions URLSimpleUpload and URLUpload to indicate that the destination file already exists. Available in Mac OS X v10.0 and later.
kURLInvalidURLError	-30773	Returned by functions that operate on URL strings to indicate that the format of the URL is invalid. Available in Mac OS X v10.0 and later.
kURLUnsupportedSchemeError	-30774	Returned by functions that operate on URL strings to indicate that the transfer protocol is not supported. Available in Mac OS X v10.0 and later.
kURLServerBusyError	-30775	Indicates a failed data transfer operation. Available in Mac OS X v10.0 and later.
kURLAuthenticationError	-30776	Returned by URLSimpleDownload, URLDownload, URLSimpleUpload, and URLUpload functions if no authentication dialog box is allowed and the user name and password properties of the URL are set incorrectly or don't exist. Available in Mac OS X v10.0 and later.
kURLPropertyNotYetKnownError	-30777	Returned by the functions URLGetProperty and URLGetPropertySize to indicate that the value or size of a URL property is not available. Available in Mac OS X v10.0 and later.
kURLUnknownPropertyError	-30778	Returned by functions URLSetProperty, URLGetProperty, and URLGetPropertySize to indicate that the property is invalid or undefined. Available in Mac OS X v10.0 and later.
kURLPropertyBufferTooSmallError	-30779	Returned by the function URLGetProperty to indicate that the buffer is too small to receive the requested property. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
kURLUnsettablePropertyError	-30780	Returned by the function URLSetProperty to indicate that the property cannot be set. Available in Mac OS X v10.0 and later.
kURLInvalidCallError	-30781	Returned by the functions URLGetDataAvailable, URLGetBuffer, and URLReleaseBuffer to indicate that the call is invalid. Available in Mac OS X v10.0 and later.
kURLFileEmptyError	-30783	Indicates a failed data transfer operation. Available in Mac OS X v10.0 and later.
kURLExtensionFailureError	-30785	Indicates that your extension failed to load. Available in Mac OS 9 and earlier.
kURLInvalidConfigurationError	-30786	Indicates a failed data transfer operation. This is returned when you attempt to upload through an HTTP proxy, since upload through proxies is not supported. Available in Mac OS X v10.0 and later.
kURLAccessNotAvailableError	-30787	Returned by the function URLGetURLAccessVersion to indicate that the URL Access Manager is not available. Available in Mac OS X v10.0 and later.
kURL68kNotSupportedError	-30788	Indicates that URL Access Manager was called from within a 68K context. Available in Mac OS 9 and earlier.

Window Manager Reference

Framework: Carbon/Carbon.h

Declared in MacWindows.h

Overview

Your application uses the Window Manager to create and manage windows. For example, your application uses the Window Manager to create and display a new window when the user creates a new document or opens an existing document. When the user clicks or holds down the mouse button while the cursor is in a window created by your application, you use the Window Manager to determine the location of the mouse action and to alter the window display as appropriate. When the user closes a window, you use the Window Manager to remove the window from the screen.

A Macintosh application uses windows for most communication with the user, from discrete interactions such as presenting and acknowledging alert boxes to open-ended interactions such as creating and editing documents. Users generally type words and formulas, draw pictures, or otherwise enter data in a window on the screen. Your application typically lets the user save this data in a file, open saved files, and view the saved data in a window.

A window can be any size or shape, and the user can display any number of windows, within the limits of available memory, on the screen at once.

The Window Manager defines a set of standard windows and provides a set of routines for managing them. The Window Manager helps your application display windows that are consistent with the Macintosh user interface.

Note: Historically, the Window Manager has offered different successive methods for creating and manipulating windows. Many of the older functions have been deprecated and, in most cases, this reference provides a recommended replacement. For the most up-to-date information about creating windows, see the document *Handling Carbon Windows and Controls*.

Carbon supports the Window Manager. Be aware, however, that if you use custom window definition procedures (also known as WDEFs), you must move them out of resources and compile them into your application. In addition:

- Your application must use the functions defined by the Window Manager whenever it creates and disposes of Window Manager data structures. For example, instead of directly creating and disposing of window records, applications must call Window Manager functions such as `CreateNewWindow` and `DisposeWindow`.
- You must revise your application so that it accesses Window Manager data structures only through accessor functions.

- You are encouraged to adopt the standard Mac OS window definition procedures in your application. Applications that use the standard Mac OS window definition procedures inherit the Mac OS human interface appearance on Mac OS 9 and Mac OS X. Applications that use custom window definition procedures work correctly, but because custom definition procedures invoke their own drawing routines, the Mac OS can't draw these applications with the current appearance (unless you specifically use Appearance Manager drawing primitives).

Functions by Task

Accessing Information About a Window

`IsValidWindowPtr` (page 1902)
Reports whether a pointer is a valid window pointer.

`GetWindowGreatestAreaDevice` (page 1848)
Returns the graphics device with the greatest area of intersection with a specified window region.

`HIWindowGetGreatestAreaDisplay` (page 1887)
Finds the display with the greatest area of intersection with a window region.

`HIWindowCopyShape` (page 1879)
Retrieves a shape that describes a region of a window.

`HIWindowGetScaleMode` (page 1889)
Obtains the window's scale mode and the application's display scale factor.

`GetWindowList` (page 1856)
Obtains the first window in a window list.

`GetWindowWidgetHilite` (page 1868)
Obtains the window part code of the window widget that is currently highlighted.

`IsWindowModified` (page 1907)
Obtains the modification state of the specified window.

`SetWindowModified` (page 1946)
Sets the modification state of the specified window.

`HIWindowGetCGWindowID` (page 1886)
Returns the Quartz window ID assigned to a window.

`HIWindowFromCGWindowID` (page 1884)
Returns the window in the current process with a specified Quartz window ID.

`GetWindowRegion` (page 1864) Deprecated in Mac OS X v10.5
Obtains a handle to a specific window region.

Activating Window Path Pop-Up Menus

`IsWindowPathSelectEvent` (page 1908)
Determines whether a Carbon event describing a click on a window's title should cause a path selection menu to be displayed.

`WindowPathSelect` (page 1970)
Displays a window path pop-up menu.

`IsWindowPathSelectClick` (page 1907) Deprecated in Mac OS X v10.5
Reports whether a mouse click should activate the window path pop-up menu. (Deprecated. Use `IsWindowPathSelectEvent` (page 1908) instead.)

Associating Data With Windows

`GetWindowProperty` (page 1859)
Obtains a piece of data that is associated with a window.

`SetWindowProperty` (page 1948)
Associates an arbitrary piece of data with a window.

`GetWindowPropertySize` (page 1861)
Obtains the size of a piece of data that is associated with a window.

`RemoveWindowProperty` (page 1923)
Removes a piece of data that is associated with a window.

`ChangeWindowPropertyAttributes` (page 1806)
Changes attributes associated with a window property.

`GetWindowPropertyAttributes` (page 1860)
Obtains the attributes of a window property.

Collapsing Windows

`CollapseWindow` (page 1810)
Collapses or expands a window to the dock.

`CollapseAllWindows` (page 1810)
Collapses or expands all collapsable windows in an application.

`IsWindowCollapsed` (page 1904)
Determines whether a window is currently collapsed.

`IsWindowCollapsable` (page 1903)
Determines whether a window can be collapsed.

Creating, Storing, and Closing Windows

`CreateNewWindow` (page 1815)
Creates a window from parameter data.

`CreateCustomWindow` (page 1814)
Creates a custom window based on a registered toolbox object class or a custom window root view.

`HIWindowCreate` (page 1880)
Creates a standard or custom window.

`DisposeWindow` (page 1820)
Removes a window.

`CreateWindowFromCollection` (page 1817) Deprecated in Mac OS X v10.5
Creates a window from collection data. (Deprecated. Use `HIArchiveCopyDecodedCFType` (page 2310) to decode a window from an archive instead.)

`CreateWindowFromResource` (page 1818) Deprecated in Mac OS X v10.5
Creates a window from `'wind'` resource data. (Deprecated. Use nib files and `CreateWindowFromNib` (page 1059) instead.)

`StoreWindowIntoCollection` (page 1960) Deprecated in Mac OS X v10.5
Stores data describing a window into a collection. (Deprecated. Use `HIArchiveEncodeCFType` (page 2314) to encode a window to an archive instead.)

Displaying Floating Windows and Window Animations

`AreFloatingWindowsVisible` (page 1801)
Indicates whether an application's floating windows are currently visible.

`HideFloatingWindows` (page 1871)
Hides an application's floating windows.

`ShowFloatingWindows` (page 1956)
Shows an application's floating windows.

Displaying Windows

`ActivateWindow` (page 1800)
Activates or deactivates a window.

`IsWindowActive` (page 1902)
Indicates whether the specified window is active.

`HiliteWindow` (page 1873)
Sets a window's highlighting status.

`SelectWindow` (page 1929)
Makes a window active.

`ShowWindow` (page 1959)
Makes an invisible window visible.

`HideWindow` (page 1872)
Makes a window invisible.

`ShowHide` (page 1957)
Sets a window's visibility.

`BringToFront` (page 1803)
Brings a window to the front.

`SendBehind` (page 1929)
Moves one window behind another.

`HIWindowInvalidateShadow` (page 1890)
Recalculates a window's shadow.

Dragging Proxy Icons

`BeginWindowProxyDrag` (page 1802)
Creates the drag reference and the drag image when the user drags a proxy icon.

`EndWindowProxyDrag` (page 1826)
Disposes of the drag reference when the user completes the drag of a proxy icon.

`HiliteWindowFrameForDrag` (page 1874)
Sets the highlight state of the window's structure region to reflect the window's validity as a drag-and-drop destination.

`TrackWindowProxyDrag` (page 1963)
Handles all aspects of the drag process when the user drags a proxy icon.

`TrackWindowProxyFromExistingDrag` (page 1964)
Allows custom handling of the drag process when the user drags a proxy icon.

`HIWindowTrackProxyDrag` (page 1897)
Tracks the drag of a window proxy icon.

Establishing Proxy Icons

`GetWindowProxyAlias` (page 1862)
Obtains an alias for the file that is associated with a window.

`SetWindowProxyAlias` (page 1949)
Associates a file with a window.

`GetWindowProxyIcon` (page 1863)
Obtains a window's proxy icon.

`SetWindowProxyIcon` (page 1951)
Overrides the default proxy icon for a window.

`RemoveWindowProxy` (page 1923)
Dissociates a file from a window.

`SetWindowProxyCreatorAndType` (page 1950)
Sets the proxy icon for a window that lacks an associated file.

`HIWindowGetProxyFSRef` (page 1888)
Obtains the `FSRef` used to determine the proxy icon for a window.

`HIWindowSetProxyFSRef` (page 1894)
Sets the proxy icon for a window using an `FSRef` to a file system object.

Getting and Setting Window Structure Fields

`GetNextWindow` (page 1839)
Returns the next window in a window list.

`GetWindowKind` (page 1856)
Returns a window's window kind.

`SetWindowKind` (page 1945)
Sets a window's window kind.

`GetWindowPort` (page 1858)
Gets the window's color graphics port.

`SetPortWindowPort` (page 1932)
Sets the current graphics port to the window's port.

`GetWindowPortBounds` (page 1859)
Obtains the bounds of the window port.

`GetWindowStandardState` (page 1866)
Obtains a window's standard zoom rectangle.

`SetWindowStandardState` (page 1953)
Sets a window's standard zoom rectangle.

`GetWindowUserState` (page 1868)
Returns a window's user zoom rectangle.

`SetWindowUserState` (page 1954)
Sets a window's user zoom rectangle.

`IsWindowHilited` (page 1905)
Indicates whether the window frame is currently highlighted.

`IsWindowLatentVisible` (page 1906)
Indicates whether a window is visible onscreen or is latently visible but not currently onscreen.

`IsWindowVisible` (page 1910)
Indicates whether the window frame is currently visible.

`GetWindowStructurePort` (page 1866)
Obtains a graphics port that is used when drawing a window's structure.

`GetWindowStructureWidths` (page 1867)
Obtains the width of the structure region on each edge of a window.

Handling Mouse Events in Windows

`DragWindow` (page 1824)
Moves a window on the screen when the user drags it by its drag region.

`MoveWindow` (page 1910)
Moves a window on the desktop.

`PinRect` (page 1919)
Returns the point within the specified rectangle that is closest to the specified point.

`SizeWindow` (page 1959)
Sets the size of a window.

`TrackBox` (page 1961)
Tracks clicks in the collapse, close, size, and zoom boxes, and clicks of the toolbar button.

`TrackGoAway` (page 1962)
Tracks the cursor when the user presses the mouse button while the cursor is in the close box.

`ZoomWindow` (page 1971)
Zooms the window when the user has pressed and released the mouse button with the cursor in the zoom box.

Locating Windows

`ActiveNonFloatingWindow` (page 1800)
Returns the currently active nonfloating window.

`FrontNonFloatingWindow` (page 1829)
Returns to the application the frontmost visible window that is not a floating window.

`FindWindow` (page 1827)
Maps the location of the cursor to a part of the screen or a region of a window when your application receives a mouse-down event.

`FindWindowOfClass` (page 1828)
Finds a window of a specific class at the specified point onscreen.

`HIWindowFindAtLocation` (page 1882)
Finds a window in the current process at a specified location.

`GetFrontWindowOfClass` (page 1834)
Obtains the frontmost window of a given class.

`GetNextWindowOfClass` (page 1839)
Obtains the next window in a given window group.

`GetPreviousWindow` (page 1840)
Returns the window above the specified window in the window list.

`FrontWindow` (page 1830) Deprecated in Mac OS X v10.5
Identifies the frontmost visible window. (Deprecated. Use `ActiveNonFloatingWindow` (page 1800), `FrontNonFloatingWindow` (page 1829), or `GetFrontWindowOfClass` (page 1834) instead.)

Maintaining the Update Region

`BeginUpdate` (page 1801)
Starts updating a window when you receive an update event for that window.

`EndUpdate` (page 1826)
Finishes updating a window.

`InvalWindowRect` (page 1898)
Adds a rectangle to a window's update region.

`InvalWindowRgn` (page 1899)
Adds a region to a window's update region.

`IsWindowUpdatePending` (page 1909)
Determines whether a window update is pending.

`ValidWindowRect` (page 1969)
Removes a rectangle from a window's update region.

`ValidWindowRgn` (page 1969)
Removes a region from a window's update region.

Managing Activation Scope

`GetWindowActivationScope` (page 1841)
Obtains a window's activation scope.

`SetWindowActivationScope` (page 1935)
Sets a window's activation scope.

Managing Dock Tiles

`HIWindowCreateCollapsedDockTileContext` (page 1881)
Creates a Quartz graphics context for drawing a collapsed window's Dock tile.

`HIWindowReleaseCollapsedDockTileContext` (page 1892)
Releases a Quartz graphics context for drawing a collapsed window's Dock tile.

`GetWindowDockTileMenu` (page 1847)
Returns the menu to be displayed by a window's dock tile.

`SetWindowDockTileMenu` (page 1940)
Associates a pop-up menu with a window.

`UpdateCollapsedWindowDockTile` (page 1968)
Updates the image of a window in the dock to the current contents of the window.

`CreateQDContextForCollapsedWindowDockTile` (page 1816) Deprecated in Mac OS X v10.5
Obtains a `CGrafPtr` for a collapsed window's tile in the dock. (Deprecated. Use `HIWindowCreateCollapsedDockTileContext` (page 1881) instead.)

`ReleaseQDContextForCollapsedWindowDockTile` (page 1921) Deprecated in Mac OS X v10.5
Releases a port and other state created by `CreateQDContextForCollapsedWindowDockTile`. (Deprecated. Use `HIWindowReleaseCollapsedDockTileContext` (page 1892) instead.)

Managing Modality

`GetWindowModality` (page 1857)
Obtains the modality of a window.

`SetWindowModality` (page 1946)
Sets the modality of a window.

`HIWindowIsDocumentModalTarget` (page 1891)
Determines if a window is currently the target window of another document modal window, such as a sheet.

Managing Themes

`SetThemeWindowBackground` (page 1933)
Sets a window's background theme.

`SetThemeTextColorForWindow` (page 1933)
Sets a text color that contrasts with a theme brush.

`HIWindowGetThemeBackground` (page 1889) Deprecated in Mac OS X v10.4 Deprecated in Mac OS X v10.5
Gets the theme background brush for a window.

Managing Toolbars

`GetWindowToolbar` (page 1867)
Obtains the toolbar associated with a window.

`SetWindowToolbar` (page 1954)
Associates a toolbar with a window.

`ShowHideWindowToolbar` (page 1957)
Shows or hides the toolbar.

`IsWindowToolbarVisible` (page 1909)
Determines whether a window's toolbar is visible.

`HIWindowSetToolbarView` (page 1895) Deprecated in Mac OS X v10.4 Deprecated in Mac OS X v10.5
Sets a custom toolbar view for a window.

Managing Transitions

`TransitionWindow` (page 1965)
Shows, hides, moves, or resizes a window with appropriate animation and sound.

`TransitionWindowAndParent` (page 1966)
Shows or hides a window, potentially also moving a second window, with animation and sound.

`TransitionWindowWithOptions` (page 1967)
Transitions a window from one state to another with appropriate animation and sound.

Managing Transparency

`GetWindowAlpha` (page 1842)
Returns the current alpha channel value for the window.

`SetWindowAlpha` (page 1935)
Sets the window's alpha channel value.

Managing UPPs

`DisposeWindowDefUPP` (page 1821) Deprecated in Mac OS X v10.5
Disposes of the UPP for your window definition. (Deprecated. The WDEF interface is deprecated; use a custom HIView to draw your custom window frame instead.)

`DisposeWindowPaintUPP` (page 1822) Deprecated in Mac OS X v10.5
Disposes of the UPP to your region painting callback function. (Deprecated. The window content painting interface is deprecated; use a `kEventControlDraw` Carbon event handler on a compositing window's content view instead.)

`InvokeWindowDefUPP` (page 1900) Deprecated in Mac OS X v10.5
Invokes the UPP for a window definition. (Deprecated. The WDEF interface is deprecated; use a custom HIView to draw your custom window frame instead.)

`InvokeWindowPaintUPP` (page 1901) Deprecated in Mac OS X v10.5
Invokes the UPP for the specified painting region. (Deprecated. The window content painting interface is deprecated; use a `kEventControlDraw` Carbon event handler on a compositing window's content view instead.)

`NewWindowDefUPP` (page 1917) Deprecated in Mac OS X v10.5
Creates a new UPP for a window definition. (Deprecated. The WDEF interface is deprecated; use a custom HIView to draw your custom window frame instead.)

`NewWindowPaintUPP` (page 1917) Deprecated in Mac OS X v10.5
Creates a new UPP for a painting region. (Deprecated. The window content painting interface is deprecated; use a `kEventControlDraw` Carbon event handler on a compositing window's content view instead.)

Managing Window Attributes

`GetWindowAttributes` (page 1842)
Obtains the attributes of a window.

`GetAvailableWindowAttributes` (page 1830)
Returns the window attributes that are valid for a window class

`ChangeWindowAttributes` (page 1805)
Changes a window's attributes.

`HIWindowTestAttribute` (page 1896)
Returns a Boolean value indicating whether a window has a specified attribute.

`HIWindowChangeAttributes` (page 1874)
Changes the attributes of a window.

`HIWindowIsAttributeAvailable` (page 1890)
Returns a Boolean value indicating whether a window attribute is valid for a specified window class.

Managing Window Availability

`HIWindowChangeAvailability` (page 1875)
Changes the availability of a window during Exposé or in Spaces.

`HIWindowGetAvailability` (page 1884)
Obtains the availability of a window during Exposé or in Spaces.

Managing Window Classes

`GetWindowClass` (page 1844)
Obtains the class of a window.

`HIWindowChangeClass` (page 1876)
Changes the appearance and behavior of a window.

`IsValidWindowClass` (page 1901)
Determines whether a given window class is valid.

`SetWindowClass` (page 1938) Deprecated in Mac OS X v10.5
Sets the class of a window. (Deprecated. Use `HIWindowChangeClass` (page 1876), `SetWindowGroup` (page 1941), or `HIWindowChangeAttributes` (page 1874) instead.)

Managing Window Features

`GetWindowFeatures` (page 1847)
Obtains the features that a window supports.

`HIWindowChangeFeatures` (page 1877)
Changes a window's features.

Managing Window Focus

`SetUserFocusWindow` (page 1934)
Designates a window to receive user focus.

`GetUserFocusWindow` (page 1841)
Returns the current user focus window.

`HIWindowShowsFocus` (page 1896) Deprecated in Mac OS X v10.4 Deprecated in Mac OS X v10.4
Returns a Boolean value indicating whether a window's content should show focus indicators such as focus rings.

Managing Window Groups

`ChangeWindowGroupAttributes` (page 1806)
Changes the attributes of a window group.

`CopyWindowGroupName` (page 1812)
Obtains a copy of the window group name.

`CountWindowGroupContents` (page 1813)
Counts the number of members of a window group.

`CreateWindowGroup` (page 1818)
Creates a window group.

`DebugPrintAllWindowGroups` (page 1819)
Debugging utility function listing all window groups.

`DebugPrintWindowGroup` (page 1819)
Debugging utility functions for use with window groups.

`GetIndexedWindow` (page 1836)
Obtains the window at the given index in the window group.

`GetWindowGroup` (page 1849)
Obtains the window group associated with a window.

`GetWindowGroupAttributes` (page 1849)
Obtains the attributes of a window group.

`GetWindowGroupContents` (page 1850)
Obtains the contents of a window group.

`GetWindowGroupLevel` (page 1851)
Obtains the level of the group in the window class hierarchy.

`GetWindowGroupLevelOfType` (page 1851)
Obtains the Core Graphics window level of a window group.

`GetWindowGroupOfClass` (page 1852)
Obtains the window group corresponding to a given window class.

`GetWindowGroupOwner` (page 1853)
Obtains the window that owns a window group. (if any)

`GetWindowGroupParent` (page 1853)
Obtains the parent group of a window group.

`GetWindowGroupRetainCount` (page 1853)
Determines the current reference count for a window group.

`GetWindowGroupSibling` (page 1854)
Obtains the next or previous group of a window group.

`GetWindowIndex` (page 1855)
Obtains the index number of a specified window in a group.

`IsWindowContainedInGroup` (page 1904)
Determines if a window is a member of a window group or any of its subgroups.

`ReleaseWindowGroup` (page 1922)
Decrements the reference count for a window group.

`RetainWindowGroup` (page 1927)
Increments the reference count for a window group.

`SendWindowGroupBehind` (page 1930)
Orders one window group behind another.

`SetWindowGroup` (page 1941)
Assigns a window to a window group.

`SetWindowGroupLevel` (page 1942)
Sets the level of group in the window class hierarchy.

`SetWindowGroupLevelOfType` (page 1942)
Sets the window level of a window group.

`SetWindowGroupName` (page 1943)
Assigns a name to a window group.

`SetWindowGroupOwner` (page 1944)
Sets a window as the owner of a window group.

`SetWindowGroupParent` (page 1944)
Sets a window group to be the parent of another window group.

Managing Window Titles

`CopyWindowAlternateTitle` (page 1812)
Obtains a copy of the alternate window title.

`SetWindowAlternateTitle` (page 1936)
Sets an alternate window title.

`CopyWindowTitleAsCFString` (page 1813)
Copies the window title into a Core Foundation string.

`SetWindowTitleWithCFString` (page 1953)
Sets the window title to the contents of a Core Foundation string.

Manipulating Drawers

`OpenDrawer` (page 1917)
Opens a drawer.

`CloseDrawer` (page 1809)
Closes a drawer.

`GetDrawerCurrentEdge` (page 1832)
Obtains the current window edge from which the drawer appears.

`GetDrawerPreferredEdge` (page 1833)
Obtains the preferred opening edge for a drawer.

`SetDrawerPreferredEdge` (page 1932)
Set the preferred window edge from which the drawer should appear.

`GetDrawerOffsets` (page 1833)
Obtains the positioning offsets of a drawer.

`SetDrawerOffsets` (page 1931)
Sets the positioning offsets for the drawer with respect to its parent window.

`GetDrawerParent` (page 1833)
Obtains the parent window of a drawer.

`SetDrawerParent` (page 1931)
Sets the parent window for a drawer.

`GetDrawerState` (page 1834)
Determines the current state of the drawer.

`ToggleDrawer` (page 1961)
Toggles the drawer state.

`HIWindowCopyDrawers` (page 1879) Deprecated in Mac OS X v10.4
Obtains an array of the drawers that are attached to a window.

Manipulating Sheets

`GetSheetWindowParent` (page 1841)
Obtains the parent window of a sheet.

`ShowSheetWindow` (page 1958)
Shows a sheet window using appropriate visual effects.

`HideSheetWindow` (page 1872)
Hides a sheet window using appropriate visual effects.

`DetachSheetWindow` (page 1819)
Detaches a sheet window from its parent window.

Manipulating Window Color Information

`GetWindowContentColor` (page 1845)
Obtains the color to which a window's content region is redrawn.

`GetWindowContentPattern` (page 1846)
Obtains the pattern to which a window's content region is redrawn.

`SetWindowContentColor` (page 1938)
Sets the color to which a window's content region is redrawn.

`GetWRefCon` (page 1869)
Returns the reference constant from a window.

`SetWindowContentPattern` (page 1939)
Sets the pattern to which a window's content region is redrawn.

`SetWRefCon` (page 1955)
Sets the `refCon` field of a window.

`GetWindowPic` (page 1858) Deprecated in Mac OS X v10.5
Returns a handle to a window's picture. (Deprecated. Use an HIImageView object to draw a window's content and ask the view for its image instead.)

`SetWindowPic` (page 1947) Deprecated in Mac OS X v10.5
Sets a picture for the Window Manager to draw in a window's content region. (Deprecated. Use an HIImageView object to draw a window's content instead.)

Referencing Windows

`CloneWindow` (page 1808) Deprecated in Mac OS X v10.5
Increments the number of references to a window. (Deprecated. Use `CFRetain` instead.)

`GetWindowOwnerCount` (page 1857) Deprecated in Mac OS X v10.5
Obtains the number of existing references to a window. (Deprecated. Use `CFGetRetainCount` instead.)

`GetWindowRetainCount` (page 1865) Deprecated in Mac OS X v10.5
Returns the retain count of a window. (Deprecated. Use `CFGetRetainCount` instead.)

`ReleaseWindow` (page 1922) Deprecated in Mac OS X v10.5
Decrements the retain count of a window, and destroys the window if the retain count falls to zero. (Deprecated. Use `CFRelease` instead.)

`RetainWindow` (page 1926) Deprecated in Mac OS X v10.5
Increments the retain count of a window. (Deprecated. Use `CFRetain` instead.)

Scrolling

`ScrollWindowRect` (page 1927)
Scroll any area of a window.

`ScrollWindowRegion` (page 1928)
Scrolls a window's region.

Sizing and Positioning Windows

`GetWindowBounds` (page 1843)
Obtains the size and position of the bounding rectangle of the specified window region.

`HIWindowGetBounds` (page 1885)
Gets the bounds of a specified region of a window.

`SetWindowBounds` (page 1936)
Sets a window's size and position from the bounding rectangle of the specified window region.

`HIWindowSetBounds` (page 1893)
Sets the bounds of a window based on either the structure or content region.

`MoveWindowStructure` (page 1911)
Positions a window relative to its structure region.

`RepositionWindow` (page 1924)
Positions a window relative to another window or a display screen.

`ResizeWindow` (page 1925)
Handles all user interaction while a window is being resized.

`GetAvailableWindowPositioningBounds` (page 1831)
Obtains the available window positioning bounds.

`HIWindowGetAvailablePositioningBounds` (page 1885)
Gets the available window positioning bounds on a display.

`GetAvailableWindowPositioningRegion` (page 1832)
Obtains the available window positioning region.

`HIWindowCopyAvailablePositioningShape` (page 1878)
Copies the available window positioning shape on a display.

`HIWindowConstrain` (page 1877)
Moves and resizes a window to be within a specified bounding rectangle.

`GetWindowResizeLimits` (page 1865)
Returns the minimum and maximum content sizes for a window.

`SetWindowResizeLimits` (page 1952)
Sets the maximum and minimum resize limits for windows.

`ConstrainWindowToScreen` (page 1811) Deprecated in Mac OS X v10.4
Moves and resizes a window so that it's contained entirely on a single screen.

Updating the Screen

`EnableScreenUpdates` (page 1825)
Enables screen updates for changes to the current application's windows.

`DisableScreenUpdates` (page 1820)
Disables updates for changes to the current application's windows.

Using Default and Cancel Buttons

You can use these functions to add dialog-like button controls to normal windows.

`SetWindowDefaultButton` (page 1940)
Specifies a default button for a window.

`GetWindowDefaultButton` (page 1846)
Returns the current default button for a window.

`SetWindowCancelButton` (page 1937)
Specifies a Cancel button for a window.

`GetWindowCancelButton` (page 1844)
Returns the current Cancel button for a window.

Zooming Windows

`HIWindowGetIdealUserState` (page 1887)
Gets the bounds of a window's content region in its user state.

`IsWindowInStandardState` (page 1905)
Determines whether a window is currently zoomed in to the user state or zoomed out to the standard state.

`HIWindowIsInStandardState` (page 1891)
Returns a Boolean value indicating whether a window is zoomed out to its standard state.

`HIWindowSetIdealUserState` (page 1894)
Sets the bounds of a window's content region in its user state.

`ZoomWindowIdeal` (page 1972)
Zooms a window in accordance with human interface guidelines.

`GetWindowIdealUserState` (page 1854) Deprecated in Mac OS X v10.4
Obtains the size and position of a window in its user state.

`SetWindowIdealUserState` (page 1945) Deprecated in Mac OS X v10.4
Sets the size and position of a window in its user state.

Miscellaneous

`CreateStandardWindowMenu` (page 1816)
Creates a standard window menu for your application.

`GetWindowFromPort` (page 1848)
Gets a window reference from a `CGrafPtr` data type.

`HIWindowFlush` (page 1883)
Flushes any dirty areas a window might have.

`RegisterWindowDefinition` (page 1920)
Registers a binding between a resource ID and a window definition function.

`ReshapeCustomWindow` (page 1924)
Notifies the Window Manager that a custom window's shape has changed.

`InstallWindowContentPaintProc` (page 1898) Deprecated in Mac OS X v10.5
Installs a window content painting callback. (Deprecated. Use a `kEventControlDraw` Carbon event handler on a window's content view instead.)

Legacy Functions

`CalcVis` (page 1804) Deprecated in Mac OS X v10.5
Calculates the visible region of a window. (Deprecated. There is no replacement function.)

`CalcVisBehind` (page 1804) Deprecated in Mac OS X v10.5
Calculates the visible regions of a series of windows. (Deprecated. There is no replacement function.)

`CheckUpdate` (page 1807) Deprecated in Mac OS X v10.5
Scans the window list for windows that need updating. (Deprecated. Use `FindSpecificEventInQueue` (page 258) or `AcquireFirstMatchingEventInQueue` (page 245) instead.)

`ClipAbove` (page 1808) Deprecated in Mac OS X v10.5
Determines the clip region of the Window Manager port. (Deprecated. There is no replacement function.)

`DragGrayRgn` (page 1822) Deprecated in Mac OS X v10.5
Moves a gray outline of a region on the screen, following the movements of the cursor, until the mouse button is released. (Deprecated. Use an overlay window or other custom drawing instead.)

`DragTheRgn` (page 1824) Deprecated in Mac OS X v10.5
Tracks the mouse as the user drags the outline of a region. (Deprecated. Use an overlay window or other custom drawing instead.)

`GetGrayRgn` (page 1835) Deprecated in Mac OS X v10.5
Returns a region that covers the desktop area of all active displays. (Deprecated. To determine the area in which a window may be positioned, use `HIWindowGetAvailablePositioningBounds` (page 1885) or `HIWindowCopyAvailablePositioningShape` (page 1878).)

`GetNewCWindow` (page 1836) Deprecated in Mac OS X v10.5
Creates a color window from a window resource. (Deprecated. Use nib files and `CreateWindowFromNib` (page 1059) instead.)

`GetNewWindow` (page 1838) Deprecated in Mac OS X v10.5
Creates a window from a window resource. (Deprecated. Use nib files and `CreateWindowFromNib` (page 1059) instead.)

`GetWindowProxyFSSpec` (page 1862) Deprecated in Mac OS X v10.5
Obtains a file system specification structure for the file that is associated with a window. (Deprecated. Use `HIWindowGetProxyFSRef` (page 1888) instead.)

`GetWTitle` (page 1869) Deprecated in Mac OS X v10.5
Retrieves the title of a window as a Pascal string. (Deprecated. Use `CopyWindowTitleAsCFString` (page 1813) instead.)

`GetWVariant` (page 1870) Deprecated in Mac OS X v10.5
Returns a window's variation code. (Deprecated. Use `GetWindowAttributes` (page 1842) to determine aspects of a window's appearance or behavior.)

`GrowWindow` (page 1870) Deprecated in Mac OS X v10.5
Allows the user to change the size of a window. (Deprecated. Use `ResizeWindow` (page 1925) instead.)

`NewCWindow` (page 1912) Deprecated in Mac OS X v10.5
Creates a window with a specified list of characteristics. (Deprecated. Use `CreateNewWindow` (page 1815) instead.)

`NewWindow` (page 1914) Deprecated in Mac OS X v10.5
Creates a window from a parameter list. (Deprecated. Use `CreateNewWindow` (page 1815) instead.)

`PaintBehind` (page 1918) Deprecated in Mac OS X v10.5
Redraws a series of windows in the window list. (Deprecated. Use `InvalWindowRect` (page 1898), `InvalWindowRgn` (page 1899), or `HIViewSetNeedsDisplay` (page 2485) to invalidate a portion of a window.)

`PaintOne` (page 1919) Deprecated in Mac OS X v10.5
: Redraws the invalid, exposed portions of one window on the desktop. (Deprecated. Use `InvalWindowRect` (page 1898), `InvalWindowRgn` (page 1899), or `HIViewSetNeedsDisplay` (page 2485) to invalidate a portion of a window.)

`SetWindowProxyFSSpec` (page 1950) Deprecated in Mac OS X v10.5
: Associates a file with a window. (Deprecated. Use `HIWindowSetProxyFSRef` (page 1894) instead.)

`SetWTitle` (page 1956) Deprecated in Mac OS X v10.5
: Specifies a window's title. (Deprecated. Use `SetWindowTitleWithCFString` (page 1953) instead.)

`DrawGrowIcon` (page 1825) Deprecated in Mac OS X v10.4 Deprecated in Mac OS X v10.5
: Draws a grow icon in the window frame. (Deprecated. There is no replacement function.)

Functions

ActivateWindow

Activates or deactivates a window.

```
OSStatus ActivateWindow (
   WindowRef inWindow,
   Boolean inActivate
);
```

Parameters

inWindow
: The window to activate or deactivate.

inActivate
: Pass `true` to activate the window, `false` otherwise.

Return Value

A result code. See "Window Manager Result Codes" (page 2051).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Related Sample Code

BSDLLCTest

Declared In

`MacWindows.h`

ActiveNonFloatingWindow

Returns the currently active nonfloating window.

```
WindowRef ActiveNonFloatingWindow (
   void
);
```

Return Value
A reference to the active window.

Discussion
Note that the active window is not necessarily the frontmost window, and it is not necessarily the window with user focus. Call `GetUserFocusWindow` (page 1841) to get the window that has user focus.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

AreFloatingWindowsVisible

Indicates whether an application's floating windows are currently visible.

```
Boolean AreFloatingWindowsVisible (
   void
);
```

Return Value
A Boolean whose value is `true` if the application's floating windows are currently shown or `false` if the application's floating windows are currently hidden.

Discussion
This function checks the visibility state of an application's floating windows, which are hidden automatically when the application receives a suspend event and are made visible automatically when the application receives a resume event.

Special Considerations

The `AreFloatingWindowsVisible` function operates only upon windows created with the `kFloatingWindowClass` constant; see "Window Class Constants" (page 1988) for more details on this constant.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

BeginUpdate

Starts updating a window when you receive an update event for that window.

```
void BeginUpdate (
   WindowRef window
);
```

Parameters

window

The window that is to be updated when an update event is received. Your application gets this information from the `message` field in the update event structure.

Discussion

The `BeginUpdate` function limits the visible region of the window's graphics port to the intersection of the visible region and the update region it then sets the window's update region to an empty region. After calling `BeginUpdate`, your application redraws either the entire content region or only the visible region. In either case, only the parts of the window that require updating are actually redrawn on the screen.

Every call to `BeginUpdate` must be matched with a subsequent call to `EndUpdate` (page 1826) after your application redraws the content region. `BeginUpdate` and `EndUpdate` can't be nested. That is, you must call `EndUpdate` before the next call to `BeginUpdate`.

In Mac OS X, you only receive one update event. If you don't call `BeginUpdate`, you won't receive any further update events until the window is invalidated again.

Special Considerations

This function should not be used on composited windows. Modifying a composited window's update region does not affect the area of the window to be drawn. A composited window does not use its window update region to control drawing. Instead, a composited window determines what to draw by looking at the invalid regions of the views contained in the window.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

HideMenuBar

Simple DrawSprocket

Declared In

`MacWindows.h`

BeginWindowProxyDrag

Creates the drag reference and the drag image when the user drags a proxy icon.

```
OSStatus BeginWindowProxyDrag (
   WindowRef window,
   DragRef *outNewDrag,
   RgnHandle outDragOutlineRgn
);
```

Parameters

window

The window whose proxy icon is being dragged.

outNewDrag

On input, a pointer to a value of type `DragRef`. On return, the value refers to the current drag process.

outDragOutlineRgn

On input, a value of type `RgnHandle`. Your application can create this handle with a call to the QuickDraw function `NewRgn`. On return, this region is set to the outline of the icon being dragged.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
Typically, if the proxy icon represents a type of object (currently, file system entities such as files, folders, and volumes) supported by the Window Manager, the Window Manager can handle all aspects of the drag process itself, and your application should call the function `TrackWindowProxyDrag` (page 1963). However, if the proxy icon represents a type of data that the Window Manager does not support, or if you want to implement custom dragging behavior, your application should call the function `TrackWindowProxyFromExistingDrag` (page 1964).

The `TrackWindowProxyFromExistingDrag` (page 1964) function accepts an existing drag reference and adds file data if the window contains a file proxy. If your application uses `TrackWindowProxyFromExistingDrag`, you then have the choice of using this function in conjunction with the functions `BeginWindowProxyDrag` and `EndWindowProxyDrag` (page 1826) or simply calling `TrackWindowProxyFromExistingDrag` and handling all aspects of creating and disposing of the drag yourself.

Specifically, your application can call `BeginWindowProxyDrag` to set up the drag image and drag reference. Your application must then track the drag, using `TrackWindowProxyFromExistingDrag`, and do any required moving of data and, finally, call `EndWindowProxyDrag` (page 1826) to dispose of the drag reference. `BeginWindowProxyDrag` should not be used for types handled by the Window Manager unless the application wants to implement custom dragging behavior for those types.

Your application detects a drag when the function `FindWindow` (page 1827) returns the `inProxyIcon` result code.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

BringToFront

Brings a window to the front.

```
void BringToFront (
   WindowRef window
);
```

Parameters

window

The window that is to be brought to the front.

Discussion
The `BringToFront` function puts the specified window at the beginning of the window list and redraws the window in front of all others on the screen. It does not change the window's highlighting or make it active.

Your application does not ordinarily call `BringToFront`. The user interface guidelines specify that the frontmost window should be the active window. To bring a window to the front and make it active, call the function `SelectWindow` (page 1929).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
BSDLLCTest

Declared In
`MacWindows.h`

CalcVis

Calculates the visible region of a window. (Deprecated in Mac OS X v10.5. There is no replacement function.)

```
void CalcVis (
   WindowRef window
);
```

Parameters
window
On input, a pointer to the window's complete window structure.

Discussion
The Window Manager calls the `CalcVis` function; your application does not normally need to. `CalcVis` calculates the visible region of the specified window by starting with its content region and subtracting the structure region of each window in front of it.

Special Considerations
In Mac OS X, the visible region of a window is managed by the window server. Applications never need to call this function.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

CalcVisBehind

Calculates the visible regions of a series of windows. (Deprecated in Mac OS X v10.5. There is no replacement function.)

```
void CalcVisBehind (
   WindowRef startWindow,
   RgnHandle clobberedRgn
);
```

Parameters

startWindow

On input, a pointer to a window structure.

clobberedRgn

On input, a handle to the desktop region that has become invalid.

Discussion

The Window Manager calls the `CalcVisBehind` function; your application does not normally need to. `CalcVisBehind` calculates the visible regions of the window specified by the `startWindow` parameter and all windows behind `startWindow` that intersect `clobberedRgn`. It is called after `PaintBehind`.

Special Considerations

In Mac OS X, the visible region of a window is managed by the window server. Applications never need to call this function.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

ChangeWindowAttributes

Changes a window's attributes.

```
OSStatus ChangeWindowAttributes (
   WindowRef window,
   WindowAttributes setTheseAttributes,
   WindowAttributes clearTheseAttributes
);
```

Parameters

window

The window whose attributes you want to change.

setTheseAttributes

The attributes you want to set. Pass `kWindowNoAttributes` if you do not want to set any attributes. See "Window Attributes" (page 1998) for a list of window attributes.

clearTheseAttributes

The attributes you want to clear (if any). Pass `kWindowNoAttributes` if you do not want to clear any attributes. See "Window Attributes" (page 1998) for a list of window attributes.

Return Value

A result code. See "Window Manager Result Codes" (page 2051).

Discussion
If the changed attributes affect the visible window's frame, the window regions are recalculated and the window is redrawn.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
QTCarbonShell

Declared In
`MacWindows.h`

ChangeWindowGroupAttributes

Changes the attributes of a window group.

```
OSStatus ChangeWindowGroupAttributes (
   WindowGroupRef inGroup,
   WindowGroupAttributes setTheseAttributes,
   WindowGroupAttributes clearTheseAttributes
);
```

Parameters

inGroup
The window group whose attributes you want to set.

setTheseAttributes
The attributes you want to set. See "Window Group Attributes" (page 2031) for a list of possible attributes.

clearTheseAttributes
The attributes you want to clear (if any). See "Window Group Attributes" (page 2031) for a list of possible attributes.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

ChangeWindowPropertyAttributes

Changes attributes associated with a window property.

```
OSStatus ChangeWindowPropertyAttributes (
   WindowRef window,
   OSType propertyCreator,
   OSType propertyTag,
   OptionBits attributesToSet,
   OptionBits attributesToClear
);
```

Parameters

window
The window whose property attributes are to be changed.

propertyCreator
The property creator.

propertyTag
The property tag.

attributesToSet
The attributes to set. For a possible value, see "Window Property Persistent Constant" (page 2024).

attributesToClear
The attributes to clear. For a possible value, see "Window Property Persistent Constant" (page 2024).

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

CheckUpdate

Scans the window list for windows that need updating. (Deprecated in Mac OS X v10.5. Use `FindSpecificEventInQueue` (page 258) or `AcquireFirstMatchingEventInQueue` (page 245) instead.)

```
Boolean CheckUpdate (
   EventRecord *theEvent
);
```

Parameters

theEvent
On input, a pointer to an event structure to be filled in if a window needs updating.

Return Value
A Boolean value. If `CheckUpdate` finds a window structure whose update region is not empty and whose window structure does not contain a picture handle, it stores an update event in the event structure referenced through the parameter `theEvent` and returns `true`. If it finds no such window, it returns `false`.

Discussion
The Event Manager calls the `CheckUpdate` function; your application does not normally need to. `CheckUpdate` scans the window list from front to back, checking for a visible window that needs updating (that is, a visible window whose update region is not empty). If it finds one whose window structure contains a picture handle, it redraws the window itself and continues through the list.

Special Considerations

If you are using a compositing window, the Window Manager never generates update events for the window and you will never find update events in the event queue.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

ClipAbove

Determines the clip region of the Window Manager port. (Deprecated in Mac OS X v10.5. There is no replacement function.)

```
void ClipAbove (
   WindowRef window
);
```

Parameters

window

On input, a pointer to the window.

Discussion

The Window Manager calls the `ClipAbove` function; your application does not normally need to. `ClipAbove` sets the clip region of the Window Manager port to be the area of the desktop that intersects the current clip region, minus the structure regions of all the windows in front of the specified window.

`ClipAbove` retrieves the desktop region from the global variable `GrayRgn`.

Special Considerations

Mac OS X applications never need to call this function.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

CloneWindow

Increments the number of references to a window. (Deprecated in Mac OS X v10.5. Use `CFRetain` instead.)

```
OSStatus CloneWindow (
   WindowRef window
);
```

Parameters

window

The window whose reference count is to be incremented.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
You should call `CloneWindow` if you are using a window and want to ensure that it is not disposed while you are using it. With the Window Manager in Mac OS 8.5 and later, all windows are created with a reference count (owner count) of one. The function `CloneWindow` increments the number of references to a window, and the earlier function `DisposeWindow` decrements the number of references. When the reference count reaches zero, `DisposeWindow` disposes of the window.

In Mac OS X v10.2 and later, you can also call `CFRetain` to increment the reference count of a window.

Special Considerations

To maintain an accurate reference count, you must follow every call to the `CloneWindow` function with a matching call to the `DisposeWindow` function when your application is ready to release its reference to the window.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

CloseDrawer

Closes a drawer.

```
OSStatus CloseDrawer (
   WindowRef inDrawerWindow,
   Boolean inAsync
);
```

Parameters

inDrawerWindow

The drawer window that is to be closed.

inAsync

Pass `true` for asynchronous closing; otherwise, pass `false`.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
`CloseDrawer` may close the drawer either synchronously or asynchronously, depending on the value of the `inAsync` parameter. If `inAsync` is true, `CloseDrawer` installs an event loop timer that closes the drawer after `CloseDrawer` returns to the caller; therefore, the caller must be running its event loop for the drawer to close. If `inAsync` is false, `CloseDrawer` closes the drawer completely before returning to the caller. `CloseDrawer` retains the drawer window while the drawer is closing, and releases it when the drawer is fully closed. `CloseDrawer` sends the `kEventWindowDrawerClosing` event to the drawer, the drawer's parent, and the application before closing the drawer. If an event handler for this event returns `userCanceledErr`, `CloseDrawer` will return immediately without closing the drawer. `CloseDrawer` sends the `kEventWindowDrawerClosed` event to the drawer, the drawer's parent, and the application after the drawer has finished closing.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

CollapseAllWindows

Collapses or expands all collapsable windows in an application.

```
OSStatus CollapseAllWindows (
   Boolean collapse
);
```

Parameters
collapse
Set to `true` to collapse all windows in the application. Set to `false` to expand all windows in the application.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
In Mac OS X, this function works with any window that has the `kWindowCollapseBoxAttribute`. If that attribute is not present, the Window Manager checks for the `kWindowCanCollapse` feature bit.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

CollapseWindow

Collapses or expands a window to the dock.

```
OSStatus CollapseWindow (
   WindowRef window,
   Boolean collapse
);
```

Parameters

window

The window that is to be collapsed or expanded.

collapse

Indicates whether the window should be collapsed or expanded.

Return Value

A result code. See "Window Manager Result Codes" (page 2051).

Discussion

The `CollapseWindow` function tells the Window Manager to collapse or expand a window depending upon the value passed in the `collapse` parameter. In Mac OS X, any window that has the `kWindowCollapseBoxAttribute` can be collapsed. If that attribute is not present, the Window Manager checks for the `kWindowCanCollapse` feature bit.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

ConstrainWindowToScreen

Moves and resizes a window so that it's contained entirely on a single screen.

```
OSStatus ConstrainWindowToScreen (
    WindowRef inWindowRef,
    WindowRegionCode inRegionCode,
    WindowConstrainOptions inOptions,
    const Rect *inScreenRect,
    Rect *outStructure
);
```

Parameters

inWindowRef

The window to constrain.

inRegionCode

The window region to constrain. See "Window Region Constants" (page 2021) for a list of possible constants to pass.

inOptions

Flags controlling how the window is constrained.

inScreenRect

A rectangle, in global coordinates, in which to constrain the window. May be `NULL`. If `NULL`, the window is constrained to the screen with the greatest intersection with the specified window region.

outStructure

On exit, contains the new structure bounds of the window, in global coordinates. May be `NULL`.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

See Also
`HIWindowConstrain` (page 1877)

Declared In
`MacWindows.h`

CopyWindowAlternateTitle

Obtains a copy of the alternate window title.

```
OSStatus CopyWindowAlternateTitle (
   WindowRef inWindow,
   CFStringRef *outTitle
);
```

Parameters

`inWindow`
The window to get the alternate title from.

`outTitle`
Receives the alternate title for the window. If the window does not have an alternate title, `NULL` will be returned in `outTitle`.

Return Value
A result code. See "Window Manager Result Codes" (page 2051). An operating system status code.

Discussion
See the discussion of `SetWindowAlternateTitle` (page 1936) for more information about alternate window titles.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

CopyWindowGroupName

Obtains a copy of the window group name.

```
OSStatus CopyWindowGroupName (
   WindowGroupRef inGroup,
   CFStringRef *outName
);
```

Parameters

inGroup

The window group to query. For information on this data type,

outName

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
MacWindows.h

CopyWindowTitleAsCFString

Copies the window title into a Core Foundation string.

```
OSStatus CopyWindowTitleAsCFString (
   WindowRef inWindow,
   CFStringRef *outString
);
```

Parameters

inWindow

The window whose title is to be copied.

outString

On output, the window's title.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

MacWindows.h

CountWindowGroupContents

Counts the number of members of a window group.

```
ItemCount CountWindowGroupContents (
   WindowGroupRef inGroup,
   WindowGroupContentOptions inOptions
);
```

Parameters

inGroup

The window group whose members are to be counted.

inOptions

Counting options. See "Window Group Content Options" (page 2032) for possible constants to pass.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
MacWindows.h

CreateCustomWindow

Creates a custom window based on a registered toolbox object class or a custom window root view.

```
OSStatus CreateCustomWindow (
   const WindowDefSpec *def,
   WindowClass windowClass,
   WindowAttributes attributes,
   const Rect *contentBounds,
   WindowRef *outWindow
);
```

Parameters

def

For information on this data type, see `WindowDefSpec` (page 1985).

windowClass

The class the custom window should belong to. This value determines the layer ordering of the custom window.

attributes

Attributes for the window. See "Window Attributes" (page 1998) for a list of possible attributes.

contentBounds

Pointer to a `Rect` structure in global coordinates indicating the dimensions of the window's content region.

outWindow

On return, the newly-created window.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

See Also
`HIWindowCreate` (page 1880)

Declared In
MacWindows.h

CreateNewWindow

Creates a window from parameter data.

```
OSStatus CreateNewWindow (
   WindowClass windowClass,
   WindowAttributes attributes,
   const Rect *contentBounds,
   WindowRef *outWindow
);
```

Parameters

windowClass
A constant that categorizes the class of window to be created. For certain classes, the window class can be altered after the window is created by calling HIWindowChangeClass (page 1876). See "Window Class Constants" (page 1988) for a description of possible values for this parameter.

attributes
Attributes for the window. See "Window Attributes" (page 1998) for a list of possible attributes.

contentBounds
Pointer to a Rect structure in global coordinates indicating the dimensions of the window's content region.

outWindow
On input, a pointer to a value of type WindowRef. On return, the window pointer points to the newly created window.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
The CreateNewWindow function creates a window based on the attributes and class you specify in the attributes and windowClass parameters. CreateNewWindow sets the new window's content region to the size and location specified by the rectangle passed in the bounds parameter, which in turn determines the dimensions of the entire window. The Window Manager creates the window invisibly and places it at the front of the window's window group. After calling CreateNewWindow, you should set any desired associated data—using Window Manager or Control Manager accessor functions—then call the function TransitionWindow (page 1965) or ShowWindow (page 1959) to display the window.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

MacWindows.h

CreateQDContextForCollapsedWindowDockTile

Obtains a `CGrafPtr` for a collapsed window's tile in the dock. (Deprecated in Mac OS X v10.5. Use `HIWindowCreateCollapsedDockTileContext` (page 1881) instead.)

```
OSStatus CreateQDContextForCollapsedWindowDockTile (
   WindowRef inWindow,
   CGrafPtr *outContext
);
```

Parameters

inWindow

The window whose `CGrafPtr` is to be obtained.

outContext

On output, a pointer to the window's `CGrafPtr`.

Return Value

A result code. See "Window Manager Result Codes" (page 2051).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

QTCarbonShell

Declared In

`MacWindows.h`

CreateStandardWindowMenu

Creates a standard window menu for your application.

```
OSStatus CreateStandardWindowMenu (
   OptionBits inOptions,
   MenuRef *outMenu
);
```

Parameters

inOptions

Option bits. Pass 0 or `kWindowMenuIncludeRotate`. For information on the `kWindowMenuIncludeRotate` constant, see "Window Menu Item Property Constants" (page 2042).

outMenu

On output, a new menu reference that contains the standard window menu items and commands.

Return Value

A result code. See "Window Manager Result Codes" (page 2051). An operating system status code.

Discussion

You can call this function to create a window menu for your application. To register a window to be tracked by this menu, you either create your window with `CreateNewWindow` (page 1815), passing the `kWindowInWindowMenuAttribute`, or you can use `ChangeWindowAttributes` (page 1805) after the window

is created. The Toolbox takes care of acting on the standard items such as zoom and minimize, as well as bringing selected windows to the front. All you need to do is insert the menu in your menu bar (typically at the end of your menu list) and register your windows, and the Toolbox does the rest.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

CreateWindowFromCollection

Creates a window from collection data. (Deprecated in Mac OS X v10.5. Use `HIArchiveCopyDecodedCFType` (page 2310) to decode a window from an archive instead.)

```
OSStatus CreateWindowFromCollection (
   Collection collection,
   WindowRef *outWindow
);
```

Parameters

collection

A reference to the collection to be used in creating the window. You pass a reference to a previously created collection, such as that returned by the Collection Manager function `NewCollection`. The collection used to create the window must contain the required items for a resource of type `'wind'` or window creation fails.

outWindow

On input, a pointer to a value of type `WindowRef`. On return, the window pointer points to the newly created window.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
This function creates a window invisibly and places it at the front of the window's window group. After calling `CreateWindowFromCollection`, you should set any desired associated data—using Window Manager or Control Manager accessor functions—then call the function `TransitionWindow` (page 1965) or `ShowWindow` (page 1959) to display the window. The number of references to the collection (that is, its owner count) is incremented by a minimum of one for the duration of this call.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

CreateWindowFromResource

Creates a window from `'wind'` resource data. (Deprecated in Mac OS X v10.5. Use nib files and `CreateWindowFromNib` (page 1059) instead.)

```
OSStatus CreateWindowFromResource (
   SInt16 resID,
   WindowRef *outWindow
);
```

Parameters

resID

The resource ID of a resource of type `'wind'`. Pass in the ID of the `'wind'` resource to be used to create the window.

outWindow

On input, a pointer to a value of type `WindowRef`. On return, the window pointer points to the newly created window.

Return Value

A result code. See "Window Manager Result Codes" (page 2051).

Discussion

The `CreateWindowFromResource` function loads a window from a `'wind'` resource. The Window Manager creates the window invisibly and places it at the front of the window's window group. After calling `CreateWindowFromResource`, you should set any desired associated data—using Window Manager or Control Manager accessor functions—then call the function `TransitionWindow` (page 1965) or `ShowWindow` (page 1959) to display the window.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

DebugPrintWindowGroup

Debugging utility functions for use with window groups.

```
void DebugPrintWindowGroup (
   WindowGroupRef inGroup
);
```

Parameters

inGroup
The window group. For information on this data type,

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`HIToolboxDebugging.h`

DetachSheetWindow

Detaches a sheet window from its parent window.

```
OSStatus DetachSheetWindow (
   WindowRef inSheet
);
```

Parameters

inSheet

The window sheet that is to be detached from its parent window.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
This function detaches a sheet window from its parent window without affecting the visibility or position of the sheet or its parent. This function is useful for hiding a sheet window without an animation effect. To do so, call `DetachSheetWindow` to detach the sheet from the parent, and then call `HideWindow` (page 1872) to hide the sheet. Call `DisposeWindow` (page 1820) to destroy the sheet.

Availability
Available in Mac OS X v10.3 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

DisableScreenUpdates

Disables updates for changes to the current application's windows.

```
OSStatus DisableScreenUpdates (
   void
);
```

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

DisposeWindow

Removes a window.

```
void DisposeWindow (
   WindowRef window
);
```

Parameters

window

On input, the window to be closed.

Discussion
The `DisposeWindow` function reduces a window's reference count by one. If the resulting reference count is zero, then `DisposeWindow` removes the window from the screen and deletes it from the window list, then releases the memory occupied by all structures associated with the window, including the window structure.

Note that `DisposeWindow` assumes that any picture pointed to by the window structure field `windowPic` is data, not a resource, and it calls the QuickDraw function `KillPicture` to delete it. If your application uses a picture stored as a resource, you must release the resource or release the memory it occupies with the `ReleaseResource` function and set the `windowPic` field to `NULL` before closing the window.

Any pending update events for the window are discarded. If the window being removed is the frontmost window, the window behind it, if any, becomes the active window.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

DisposeWindowDefUPP

Disposes of the UPP for your window definition. (Deprecated in Mac OS X v10.5. The WDEF interface is deprecated; use a custom HIView to draw your custom window frame instead.)

```
void DisposeWindowDefUPP (
   WindowDefUPP userUPP
);
```

Parameters
`userUPP`
The UPP that is to be disposed of.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

DisposeWindowPaintUPP

Disposes of the UPP to your region painting callback function. (Deprecated in Mac OS X v10.5. The window content painting interface is deprecated; use a `kEventControlDraw` Carbon event handler on a compositing window's content view instead.)

```
void DisposeWindowPaintUPP (
   WindowPaintUPP userUPP
);
```

Parameters

userUPP

The UPP that is to be disposed of.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Declared In

`MacWindows.h`

DragGrayRgn

Moves a gray outline of a region on the screen, following the movements of the cursor, until the mouse button is released. (Deprecated in Mac OS X v10.5. Use an overlay window or other custom drawing instead.)

```
long DragGrayRgn (
   RgnHandle theRgn,
   Point startPt,
   const Rect *limitRect,
   const Rect *slopRect,
   short axis,
   DragGrayRgnUPP actionProc
);
```

Parameters

theRgn

On input, a handle to the region to be dragged.

startPt

On input, the location, in the local coordinates of the current graphics port, of the cursor when the mouse button was pressed.

limitRect

On input, a pointer to a rectangle, given in the local coordinates of the current graphics port, that limits where the region can be dragged. This parameter works with the `slopRect` parameter.

slopRect

On input, a pointer to a rectangle, given in the local coordinates of the current graphics port, that gives the user some leeway in moving the mouse without violating the limits of the `limitRect` parameter. The `slopRect` rectangle should be larger than the `limitRect` rectangle.

axis

On input, a constant that constrains the region's motion. The `axis` parameter can have one of three values: `noConstraint` (0), `hAxisOnly` (1), or `vAxisOnly` (2).

If an axis constraint is in effect, the outline follows the cursor's movements along only the specified axis, ignoring motion along the other axis. With or without an axis constraint, the outline appears only when the mouse is inside the `slopRect` rectangle.

actionProc

On input, a pointer to a function that defines an action to be performed repeatedly as long as the user holds down the mouse button. The function can have no parameters. If the value of `actionProc` is `null`, `DragGrayRgn` simply retains control until the mouse button is released.

Return Value
A long integer that specifies the difference between the point where the mouse button was pressed and the offset point.

Discussion
The `DragGrayRgn` function is called by `DragWindow` to move an outline of a window around the screen as the user drags a window. It returns the difference between the point where the mouse button was pressed and the offset point (the point in the region whose horizontal and vertical offsets from the upper-left corner of the region's enclosing rectangle are the same as the offsets of the starting point when the user pressed the mouse button. `DragGrayRgn` stores the vertical difference between the starting point and the offset point in the high-order word of the return value and the horizontal difference in the low-order word.

It limits the movement of the region according to constraints set by the `limitRect` and `slopRect` parameters:

- As long as the cursor is inside the `limitRect` rectangle, the region's outline follows it normally. If the mouse button is released while the cursor is within this rectangle, the return value reflects the simple distance that the cursor moved in each dimension.
- When the cursor moves outside the `limitRect` rectangle, the offset point stops at the edge of the `limitRect` rectangle. If the mouse button is released while the cursor is outside the `limitRect` rectangle but inside the `slopRect` rectangle, the return value reflects only the difference between the starting point and the offset point, regardless of how far outside of the `limitRect` rectangle the cursor may have moved. (Note that part of the region can fall outside the `limitRect` rectangle, but not the offset point.)
- When the cursor moves outside the `slopRect` rectangle, the region's outline disappears from the screen. The `DragGrayRgn` function continues to track the cursor, however, and if the cursor moves back into the `slopRect` rectangle, the outline reappears. If the mouse button is released while the cursor is outside the `slopRect` rectangle, both words of the return value are set to `0x8000`. In this case, the Window Manager does not move the window from its original location.
- To accommodate systems with multiple monitors, QuickDraw recognizes a port rectangle of `screenBits.bounds` as a special case and allows drawing on all parts of the desktop.

The region stops moving when the offset point reaches the edge of the `limitRect` rectangle. The cursor continues to move, but the region does not.

If the mouse button is released while the cursor is anywhere inside the `slopRect` rectangle, the Window Manager redraws the window in its new location, which is calculated from the value returned by `DragGrayRgn`.

Carbon Porting Notes

Can't be used for live dragging. If you are implementing your own window dragging, use `DragWindow` instead. If you need to override window positioning during a drag, register a Carbon event handler for `kEventWindowBoundsChanging`. Okay to use if you're dragging objects within a window.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

DragTheRgn

Tracks the mouse as the user drags the outline of a region. (Deprecated in Mac OS X v10.5. Use an overlay window or other custom drawing instead.)

```
long DragTheRgn (
   RgnHandle theRgn,
   Point startPt,
   const Rect *limitRect,
   const Rect *slopRect,
   short axis,
   DragGrayRgnUPP actionProc
);
```

Carbon Porting Notes

Can't be used for live dragging. If you are implementing your own window dragging, use `DragWindow` instead. If you need to override window positioning during a drag, register a Carbon event handler for `kEventWindowBoundsChanging`. Okay to use if you're dragging objects within a window.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

DragWindow

Moves a window on the screen when the user drags it by its drag region.

```
void DragWindow (
   WindowRef window,
   Point startPt,
   const Rect *boundsRect
);
```

Parameters

window
The window that is to be dragged.

startPt
On input, the location, in global coordinates, of the cursor at the time the user pressed the mouse button. Your application retrieves this point from the `where` field of the event structure.

boundsRect

On input, a pointer to a rectangle, given in global coordinates, that limits the region to which a window can be dragged. If the mouse button is released when the cursor is outside the limits of `boundsRect`, `DragWindow` returns without moving the window (or, if it was inactive, without making it the active window).

In CarbonLib and Mac OS X, this parameter can be `NULL` to indicate that there are no restrictions on window movement. This parameter is ignored by CarbonLib and Mac OS X v10.0 through v10.2; it is obeyed in Mac OX v10.3 and later.

Discussion
The `DragWindow` function moves the window around the screen, following the movement of the cursor until the user releases the mouse button. If the Command key was not pressed when the mouse button was pressed, `DragWindow` calls `SelectWindow` to make the window active before it drags the window. If the Command key was pressed when the mouse button was pressed, `DragWindow` moves the window without making it active.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

EnableScreenUpdates

Enables screen updates for changes to the current application's windows.

```
OSStatus EnableScreenUpdates (
   void
);
```

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

EndUpdate

Finishes updating a window.

```
void EndUpdate (
   WindowRef window
);
```

Parameters
window
The window for which updating is to be finished.

Discussion
The `EndUpdate` function restores the normal visible region of a window's graphics port. When you receive an update event for a window, you call `BeginUpdate` (page 1801), redraw the update region, and then call `EndUpdate`. Each call to `BeginUpdate` must be balanced by a subsequent call to `EndUpdate`.

Special Considerations

This function should not be used on composited windows. Modifying a composited window's update region does not affect the area of the window to be drawn. A composited window does not use its window update region to control drawing. Instead, a composited window determines what to draw by looking at the invalid regions of the views contained in the window.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

HideMenuBar
Simple DrawSprocket

Declared In
`MacWindows.h`

EndWindowProxyDrag

Disposes of the drag reference when the user completes the drag of a proxy icon.

```
OSStatus EndWindowProxyDrag (
   WindowRef window,
   DragRef theDrag
);
```

Parameters

window

The window whose proxy icon is being dragged.

theDrag

A value that refers to the current drag process. Pass in the value produced in the `outNewDrag` parameter of `BeginWindowProxyDrag`.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
Typically, if the proxy icon represents a type of object (currently, file system entities such as files, folders, and volumes) supported by the Window Manager, the Window Manager can handle all aspects of the drag process itself, and your application should call the function `TrackWindowProxyDrag` (page 1963). However, if the proxy icon represents a type of data that the Window Manager does not support, or if you want to implement custom dragging behavior, your application should call the function `TrackWindowProxyFromExistingDrag` (page 1964).

The `TrackWindowProxyFromExistingDrag` (page 1964) function accepts an existing drag reference and adds file data if the window contains a file proxy. If your application uses `TrackWindowProxyFromExistingDrag`, you then have the choice of using this function in conjunction with the functions `BeginWindowProxyDrag` (page 1802) and `EndWindowProxyDrag` or simply calling `TrackWindowProxyFromExistingDrag` and handling all aspects of creating and disposing of the drag yourself.

Specifically, your application can call `BeginWindowProxyDrag` to set up the drag image and drag reference. Your application must then track the drag, using `TrackWindowProxyFromExistingDrag`, and do any required moving of data and, finally, call `EndWindowProxyDrag` to dispose of the drag reference and its associated image data. The `EndWindowProxyDrag` function does not dispose of the region created for use by `BeginWindowProxyDrag`, however, so this remains the application's responsibility to dispose. The `EndWindowProxyDrag` function should not be used for types handled by the Window Manager unless you want to implement custom dragging behavior for those types.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

FindWindow

Maps the location of the cursor to a part of the screen or a region of a window when your application receives a mouse-down event.

```
WindowPartCode FindWindow (
    Point thePoint,
    WindowRef *window
);
```

Parameters

thePoint

The point, in global coordinates, where the mouse-down event occurred. Your application retrieves this information from the `where` field of the event structure.

window

A pointer to the window in which the mouse-down event occurred. `FindWindow` produces `NULL` if the mouse-down event occurred outside a window.

Return Value

The location of the cursor when the user pressed the mouse button; see "Window Part Code Constants" (page 2013).

Discussion

You typically call the function `FindWindow` whenever you receive a mouse-down event. The `FindWindow` function helps you dispatch the event by reporting whether the cursor was in the menu bar or in a window when the mouse button was pressed. If the cursor was in a window, the function will produce both a pointer to the window and a constant that identifies the region of the window in which the event occurred.

If you are using the Carbon event handlers to handle events, a faster way of getting the window and part that received a mouse-down event is to get the `kEventParamWindowRef` and `kEventParamWindowPartCode` parameters from the event.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

FindWindowOfClass

Finds a window of a specific class at the specified point onscreen.

```
OSStatus FindWindowOfClass (
   const Point *where,
   WindowClass inWindowClass,
   WindowRef *outWindow,
   WindowPartCode *outWindowPart
);
```

Parameters

where

The point, in global coordinates, at which to search for a window.

inWindowClass

The class of window for which to search. Passing `kAllWindowClasses` returns any window found at `where`.

outWindow

On return, a pointer to the window, if it is of the specified class. If no window was found, this value is `NULL`. Note that you can pass `NULL` for this parameter.

outWindowPart

On return, the part code of the window part under the mouse. If no window was found, this value is `inDesk`. Note that you can pass `NULL` for this parameter.

Return Value

A result code. If no window of the specified class is found at the specified point, this function returns `errWindowNotFound`. For other possible return values, see "Window Manager Result Codes" (page 2051).

Discussion

This function is similar to `FindWindow` (page 1827), but lets you restrict the search to windows of a particular class.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

See Also

`HIWindowFindAtLocation` (page 1882)

Declared In

`MacWindows.h`

FrontNonFloatingWindow

Returns to the application the frontmost visible window that is not a floating window.

```
WindowRef FrontNonFloatingWindow (
   void
);
```

Return Value

The first visible window in the window list that is of a nonfloating class. See "Window Class Constants" (page 1988) for a description of window classes.

Discussion
Your application should call the `FrontNonFloatingWindow` function when you want to identify the frontmost visible window that is not a floating window. If you want to identify the frontmost visible window, whether floating or not, your application should call the function `FrontWindow`.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
CarbonSketch
QTCarbonShell

Declared In
`MacWindows.h`

FrontWindow

Identifies the frontmost visible window. (Deprecated in Mac OS X v10.5. Use `ActiveNonFloatingWindow` (page 1800), `FrontNonFloatingWindow` (page 1829), or `GetFrontWindowOfClass` (page 1834) instead.)

```
WindowRef FrontWindow (
   void
);
```

Return Value
The first visible window in the window list. If there are no visible windows, `FrontWindow` returns `NULL`.

Discussion
Most applications should call `ActiveNonFloatingWindow` (page 1800) or `FrontNonFloatingWindow` (page 1829) instead of `FrontWindow` because `ActiveNonFloatingWindow` and `FrontNonFloatingWindow` return the active and frontmost document window, respectively, skipping over other types of windows that may be in front of the active document, such as the menubar window, floating windows, help tags and toolbars.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Related Sample Code
HideMenuBar

Declared In
`MacWindows.h`

GetAvailableWindowAttributes

Returns the window attributes that are valid for a window class

```
WindowAttributes GetAvailableWindowAttributes (
   WindowClass inClass
);
```

Parameters

inClass

The window class to query.

Return Value

The window attributes that are valid for the window class specified by `inClass`. See "Window Attributes" (page 1998) for a list of possible attributes.

Discussion

Some window classes support different attributes on different platforms. For example, floating windows can have collapse boxes in Mac OS 9, but not in Mac OS X. The Window Manager returns an error if you attempt to create a window with attributes that aren't supported for the requested window class.

You can use this API to determine those attributes that are supported by the current platform and remove those attributes that are not supported by the current platform before calling `CreateNewWindow` (page 1815).

Availability

Available in Mac OS X v10.1 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

GetAvailableWindowPositioningBounds

Obtains the available window positioning bounds.

```
OSStatus GetAvailableWindowPositioningBounds (
   GDHandle inDevice,
   Rect *outAvailableRect
);
```

Parameters

inDevice

The screen for which the available window positioning bounds are to be obtained.

outAvailableRect

On return, a pointer to the available bounds for the device specified by `inDevice`.

Return Value

A result code. See "Window Manager Result Codes" (page 2051).

Discussion

The available window positioning bounds is that area on the screen inside which a window may be positioned without intersecting or overlapping the menu bar, Dock, or other UI provided by the operating system.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

GetAvailableWindowPositioningRegion

Obtains the available window positioning region.

```
OSStatus GetAvailableWindowPositioningRegion (
   GDHandle inDevice,
   RgnHandle ioRgn
);
```

Parameters

inDevice

The screen for which the available window positioning region is to be obtained.

ioRgn

On input, contains a preallocated `RgnHandle`. On return, the `RgnHandle` has been modified to contain the available region for the given screen.

Return Value

A result code. See "Window Manager Result Codes" (page 2051).

Discussion

The available window positioning region is that area on the screen inside which a window may be positioned without intersecting or overlapping the menu bar, Dock, or other UI provided by the operating system. This function differs from `GetAvailableWindowPositioningBounds` (page 1831) in that the bounds version removes the entire area that may theoretically be covered by the Dock, even if the Dock does not currently reach from edge to edge of the device on which it is positioned. The region version includes the area at the sides of the Dock that is not covered by the Dock in the available region.

Availability

Available in Mac OS X v10.2 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

GetDrawerCurrentEdge

Obtains the current window edge from which the drawer appears.

```
OptionBits GetDrawerCurrentEdge (
   WindowRef inDrawerWindow
);
```

Parameters

inDrawerWindow

The drawer window whose window edge is to be obtained.

Return Value

The current window edge. See "Window Edge Constants" (page 2041) for a list of possible return values.

Availability

Available in Mac OS X v10.2 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

GetDrawerOffsets

Obtains the positioning offsets of a drawer.

```
OSStatus GetDrawerOffsets (
   WindowRef inDrawerWindow,
   CGFloat *outLeadingOffset,
   CGFloat *outTrailingOffset
);
```

Parameters

inDrawerWindow

The drawer window whose positioning offsets are to be obtained.

outLeadingOffset

On exit, a pointer to the drawer's leading offset. Pass `NULL` if you don't need this information.

outTrailingOffset

On exit, a pointer to the drawer's trailing offset. Pass `NULL` if you don't need this information.

Return Value

A result code. See "Window Manager Result Codes" (page 2051).

Availability

Available in Mac OS X v10.2 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

GetDrawerParent

Obtains the parent window of a drawer.

```
WindowRef GetDrawerParent (
   WindowRef inDrawerWindow
);
```

Parameters

inDrawerWindow

The drawer window whose parent window is to be obtained.

Return Value

The window that is the parent of the drawer specified by `inDrawerWindow`.

Availability

Available in Mac OS X v10.2 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

GetDrawerPreferredEdge

Obtains the preferred opening edge for a drawer.

```
OptionBits GetDrawerPreferredEdge (
   WindowRef inDrawerWindow
);
```

Parameters

inDrawerWindow

The drawer window whose preferred opening edge is to be obtained.

Return Value

See "Window Edge Constants" (page 2041) for a list of possible values.

Discussion

Note that the preferred edge may not be the same as the current edge, due to window positioning. For example, the right edge may be the preferred edge, but if the window is placed such that the right edge is offscreen, the drawer will appear on the left edge instead.

Availability

Available in Mac OS X v10.2 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

GetDrawerState

Determines the current state of the drawer.

```
WindowDrawerState GetDrawerState (
   WindowRef inDrawerWindow
);
```

Parameters

inDrawerWindow

The drawer window whose state is to be determined.

Return Value

See "Drawer State Constants" (page 2040) for a list of possible values.

Availability

Available in Mac OS X v10.2 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

GetFrontWindowOfClass

Obtains the frontmost window of a given class.

```
WindowRef GetFrontWindowOfClass (
   WindowClass inWindowClass,
   Boolean mustBeVisible
);
```

Parameters

inWindowClass

The class of the window you want to obtain. If you pass `kAllWindowClasses`, the function returns the frontmost window in the window list.

mustBeVisible

If set to `true`, the function returns the frontmost visible window. If set to `false`, the function returns the frontmost window of the specified class, regardless of whether the window is visible.

Return Value
A reference to the frontmost window of the class specified by `inWindowClass`.

Carbon Porting Notes

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
HID Config Save
QTCarbonShell
QTMetaData

Declared In
`MacWindows.h`

GetGrayRgn

Returns a region that covers the desktop area of all active displays. (Deprecated in Mac OS X v10.5. To determine the area in which a window may be positioned, use `HIWindowGetAvailablePositioningBounds` (page 1885) or `HIWindowCopyAvailablePositioningShape` (page 1878).)

```
RgnHandle GetGrayRgn (
    void
);
```

Return Value
A handle to the current desktop region from the global variable `GrayRgn`.

Discussion
When your application calls `DragWindow` to let the user drag a window, it can use `GetGrayRgn` to set the limiting rectangle to the entire desktop area. The desktop region represents all available screen space, that is, the desktop area displayed by all monitors attached to the computer.

Special Considerations

Your application should not modify the desktop region.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Related Sample Code
HideMenuBar

Declared In
`MacWindows.h`

GetIndexedWindow

Obtains the window at the given index in the window group.

```
OSStatus GetIndexedWindow (
   WindowGroupRef inGroup,
   ItemCount inIndex,
   WindowGroupContentOptions inOptions,
   WindowRef *outWindow
);
```

Parameters

inGroup
The window group. For information on this data type,

inIndex
The index of the window. This parameter may range from `1` to the value returned by `CountWindowGroupContents`.

inOptions
Options for determining the number of windows. See "Window Group Content Options" (page 2032) for possible values.

outWindow
The window at the index specified by `inIndex` in the group specified by `inGroup`.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

GetNewCWindow

Creates a color window from a window resource. (Deprecated in Mac OS X v10.5. Use nib files and `CreateWindowFromNib` (page 1059) instead.)

```
WindowRef GetNewCWindow (
   short windowID,
   void *wStorage,
   WindowRef behind
);
```

Parameters

windowID

On input, the resource ID of the 'WIND' resource that defines the properties of the window.

wStorage

On input, a pointer to memory space for the window structure. If you specify a value of null for wStorage, the GetNewCWindow function allocates the window structure as a nonrelocatable object in the heap. You can reduce the chances of heap fragmentation by allocating the memory your application needs for window structures early in your initialization code. Whenever you need to create a window, you can allocate memory from your own block and pass a pointer to it in the wStorage parameter.

behind

On input, a pointer to the window that appears immediately in front of the new window on the desktop. To place a new window in front of all other windows on the desktop, specify a value of (WindowRef)-1L. When you place a window in front of all others, GetNewCWindow removes the highlighting from the previously active window, highlights the newly created window, and generates the appropriate activate events. Note that if you create an invisible window in front of all others on the desktop, the user sees no active window until you make the new window visible (or make another window active).

To place a new window behind all other windows, specify a value of null.

Return Value

A pointer to the newly created window structure.

Discussion

The GetNewCWindow function creates a new color window from the specified window resource and returns a pointer to the newly created window structure. You can use the returned window pointer to refer to this window in most Window Manager functions. If GetNewCWindow is unable to read the window or window definition function from the resource file, it returns null.

The GetNewCWindow function looks for a 'wctb' resource with the same resource ID as that of the 'WIND ' resource. If it finds one, it uses the window color information in the 'wctb' resource for coloring the window content area.

If the window's definition function (specified in the window resource) is not already in memory, GetNewCWindow reads it into memory and stores a handle to it in the window structure.

To create the window, GetNewCWindow retrieves the window characteristics from the window resource and then calls the NewCWindow function, passing the characteristics as parameters.

The GetNewCWindow function creates a window in a color graphics port. Your application typically sets up its own global variables reflecting the system setup during initialization by calling the Gestalt function.

Special Considerations

If you must get your window definition from a resource, use CreateWindowFromResource. Otherwise, use CreateWindowFromNib or CreateNewWindow.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

GetNewWindow

Creates a window from a window resource. (Deprecated in Mac OS X v10.5. Use nib files and `CreateWindowFromNib` (page 1059) instead.)

```
WindowRef GetNewWindow (
   short windowID,
   void *wStorage,
   WindowRef behind
);
```

Parameters

windowID

On input, the resource ID of the '`WIND`' resource that defines the properties of the window.

wStorage

On input, a pointer to memory space for the window structure. If you specify a value of `null` for `wStorage`, the `GetNewWindow` function allocates the window structure as a nonrelocatable object in the heap. You can reduce the chances of heap fragmentation by allocating the memory your application needs for window structures early in your initialization code. Whenever you need to create a window, you can allocate memory from your own block and pass a pointer to it in the `wStorage` parameter.

behind

On input, a pointer to the window that appears immediately in front of the new window on the desktop. To place a new window in front of all other windows on the desktop, specify a value of (`WindowRef`)-1l. When you place a window in front of all others, `GetNewWindow` removes the highlighting from the previously active window, highlights the newly created window, and generates the appropriate activate events. Note that if you create an invisible window in front of all others on the desktop, the user sees no active window until you make the new window visible (or make another window active). To place a new window behind all other windows, specify a value of `null`.

Return Value
A pointer to the newly created color window structure.

Discussion
The `GetNewWindow` function takes the same parameters as `GetNewCWindow` (page 1836) and returns a value of type `WindowRef`. The only difference is that it creates a monochrome graphics port, not a color graphics port, regardless of the presence of a corresponding '`wctb `' resource (it loads the resource but doesn't use it). The window structure and graphics port structure that describe monochrome and color graphics ports are the same size and can be used interchangeably in most Window Manager functions.

The `GetNewWindow` function creates a new window from the specified window resource and returns a pointer to the newly created window structure. You can use the returned window pointer to refer to this window in most Window Manager functions. If `GetNewWindow` is unable to read the window or window definition function from the resource file, it returns `null`.

If the window's definition function (specified in the window resource) is not already in memory, `GetNewWindow` reads it into memory and stores a handle to it in the window structure. It allocates space in the application heap for the structure and content regions of the window.

To create the window, `GetNewWindow` retrieves the window characteristics from the window resource and then calls the function `NewWindow`, passing the characteristics as parameters.

Special Considerations

If you must get your window definition from a resource, use `CreateWindowFromResource`. Otherwise, use `CreateWindowFromNib` or `CreateNewWindow`.

Version Notes

The `GetNewWindow` function was originally implemented prior to Color QuickDraw. In Mac OS 8, you should call the Color QuickDraw function `GetNewCWindow` instead of `GetNewWindow` to programmatically create a window, because Color QuickDraw is always available in Mac OS 8. Use of this function is not recommended with Mac OS 8 and later. `GetNewWindow` is described here only for completeness.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

GetNextWindow

Returns the next window in a window list.

```
WindowRef GetNextWindow (
    WindowRef window
);
```

Parameters

window

The window to start from.

Return Value

The next window in a window list.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

GetNextWindowOfClass

Obtains the next window in a given window group.

```
WindowRef GetNextWindowOfClass (
   WindowRef inWindow,
   WindowClass inWindowClass,
   Boolean mustBeVisible
);
```

Parameters

inWindow

The window at which to start.

inWindowClass

The class of window to obtain. If you pass `kAllWindowClasses`, the function returns the window directly behind the input window. If no windows exist behind the front window, the function returns `NULL`.

mustBeVisible

If set to `true`, this function returns the next visible window of the specified window class. If set to `false`, this function returns the next window of the specified window class, regardless of whether it is visible.

Return Value
A reference for the next window of the specified class after the window specified by `inWindow`.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
QTCarbonShell

Declared In
`MacWindows.h`

GetPreviousWindow

Returns the window above the specified window in the window list.

```
WindowRef GetPreviousWindow (
   WindowRef inWindow
);
```

Parameters

inWindow

The window at which to start.

Return Value
A reference for the previous window of the specified class.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

GetSheetWindowParent

Obtains the parent window of a sheet.

```
OSStatus GetSheetWindowParent (
   WindowRef inSheet,
   WindowRef *outParentWindow
);
```

Parameters

inSheet

The window sheet whose parent is to be obtained.

outParentWindow

A pointer to the reference for the parent of the window sheet specified by `inSheet`.

Return Value

A result code. See "Window Manager Result Codes" (page 2051).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

GetUserFocusWindow

Returns the current user focus window.

```
WindowRef GetUserFocusWindow (
    void
);
```

Return Value

The window receiving user focus.

Discussion

This function returns the window that receives menu commands and keyboard input as part of the standard event dispatching.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

GetWindowActivationScope

Obtains a window's activation scope.

```
OSStatus GetWindowActivationScope (
   WindowRef inWindow,
   WindowActivationScope *outScope
);
```

Parameters

inWindow

The window whose activation scope is to be obtained.

outScope

On return, a pointer to the window's activation scope.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
MacWindows.h

GetWindowAlpha

Returns the current alpha channel value for the window.

```
OSStatus GetWindowAlpha (
   WindowRef inWindow,
   CGFloat *outAlpha
);
```

Parameters

inWindow

The window for which the value of the alpha channel is to be obtained.

outAlpha

The current alpha value. This value can range from 0.0 (completely transparent) to 1.0 (opaque).

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
MacWindows.h

GetWindowAttributes

Obtains the attributes of a window.

```
OSStatus GetWindowAttributes (
   WindowRef window,
   WindowAttributes *outAttributes
);
```

Parameters

window

The window whose attributes you want to obtain.

outAttributes

On input, a pointer to an unsigned 32-bit value of type `WindowAttributes`. On return, the bits are set to the attributes of the specified window. See "Window Attributes" (page 1998) for a description of possible attributes.

Return Value

A result code. See "Window Manager Result Codes" (page 2051).

Discussion

Window attributes specify a window's features (such as whether the window has a close box) and logical attributes (such as whether the window receives update and activate events).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

GetWindowBounds

Obtains the size and position of the bounding rectangle of the specified window region.

```
OSStatus GetWindowBounds (
   WindowRef window,
   WindowRegionCode regionCode,
   Rect *globalBounds
);
```

Parameters

window

The window whose bounds you want to obtain.

regionCode

A constant identifying the window region whose bounds you want to obtain. See "Window Region Constants" (page 2021) for a list of possible values.

globalBounds

A pointer to a structure of type `Rect`. On return, the rectangle contains the dimensions and position, in global coordinates, of the window region specified in the `regionCode` parameter.

Return Value

A result code. See "Window Manager Result Codes" (page 2051).

Discussion

Use the `GetWindowBounds` function to obtain the bounding rectangle for the specified window region for the specified window.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

See Also
`HIWindowGetBounds` (page 1885)

Related Sample Code
QTCarbonShell

Declared In
`MacWindows.h`

GetWindowCancelButton

Returns the current Cancel button for a window.

```
OSStatus GetWindowCancelButton (
    WindowRef inWindow,
    ControlRef *outControl
);
```

Parameters

inWindow
The window whose Cancel button you want to obtain.

outControl
A pointer to a control. On output, the control is the Cancel button.

Return Value
A result code.

Discussion
You can use this function to determine which button or control is the specified Cancel button for a given window. This button would be considered to have been clicked if the user instead presses Command-period or the Escape key.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

GetWindowClass

Obtains the class of a window.

```
OSStatus GetWindowClass (
   WindowRef window,
   WindowClass *outClass
);
```

Parameters

window

The window whose class you want to obtain.

outClass

On input, a pointer to a value of type `WindowClass`. On return, this value identifies the class of the specified window. See "Window Class Constants" (page 1988) for a list of possible window classes. In Mac OS 8 and Mac OS 9, for windows not originally created by `CreateNewWindow` (page 1815), the class pointed to by the `outClass` parameter is always identified by the constant `kDocumentWindowClass`.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

GetWindowContentColor

Obtains the color to which a window's content region is redrawn.

```
OSStatus GetWindowContentColor (
   WindowRef window,
   RGBColor *color
);
```

Parameters

window

The window whose content color is being retrieved.

color

On input, a pointer to an `RGBColor` structure. On return, the structure contains the content color for the specified window.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
The `GetWindowContentColor` function obtains the color to which the window's content region is redrawn.

See also the function `SetWindowContentColor` (page 1938).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
MacWindows.h

GetWindowContentPattern

Obtains the pattern to which a window's content region is redrawn.

```
OSStatus GetWindowContentPattern (
   WindowRef window,
   PixPatHandle outPixPat
);
```

Parameters

window
The window whose content pattern is being retrieved.

outPixPat
On input, a handle to a structure of type PixPat. On return, the structure contains a copy of the content pattern data for the specified window, which your application is responsible for disposing.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
The GetWindowContentPattern function obtains the pattern to which the window's content region is redrawn.

See also the function SetWindowContentPattern (page 1939).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
MacWindows.h

GetWindowDefaultButton

Returns the current default button for a window.

```
OSStatus GetWindowDefaultButton (
    WindowRef inWindow,
    ControlRef *outControl
);
```

Parameters

inWindow
The window whose default button you want to obtain.

outControl
A pointer to a control. On output, the control is the default button.

Return Value
A result code.

Discussion
You can use this function to determine which button or control is the default for a given window. This button would be considered to have been clicked if the user instead presses the Return or Enter keys on the keyboard.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

GetWindowDockTileMenu

Returns the menu to be displayed by a window's dock tile.

```
MenuRef GetWindowDockTileMenu (
   WindowRef inWindow
);
```

Parameters

`inWindow`
The window whose menu is to be obtained.

Return Value
The menu reference for the window specified by `inWindow`. See the Menu Manager documentation for a description of the `MenuRef` data type.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

GetWindowFeatures

Obtains the features that a window supports.

```
OSStatus GetWindowFeatures (
   WindowRef window,
   UInt32 *outFeatures
);
```

Parameters

`window`
A pointer to the window to be examined.

`outFeatures`
On input, a pointer to an unsigned 32-bit value. On return, the bits of the value specify the features the window supports; see "Window Feature Bits" (page 2011).

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
The `GetWindowFeatures` function produces a window definition function's features in response to a `kWindowMsgGetFeatures` message.

Instead of calling this function, most applications should call `GetWindowAttributes` (page 1842) to check for specific attributes, such as `kWindowCollapseBoxAttribute` and `kWindowResizableAttribute`.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

GetWindowFromPort

Gets a window reference from a `CGrafPtr` data type.

```
WindowRef GetWindowFromPort (
   CGrafPtr port
);
```

Parameters

port
The port to query.

Return Value
The window reference obtained from the port specified by `port`, or `NULL` if the `port` parameter is not actually attached to a window.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

GetWindowGreatestAreaDevice

Returns the graphics device with the greatest area of intersection with a specified window region.

```
OSStatus GetWindowGreatestAreaDevice (
   WindowRef inWindow,
   WindowRegionCode inRegion,
   GDHandle *outGreatestDevice,
   Rect *outGreatestDeviceRect
);
```

Parameters

inWindow
The window to compare against.

inRegion

The window region to compare against. See "Window Region Constants" (page 2021) for a list of possible values.

outGreatestDevice

On return, the graphics device with the greatest intersection. May be `NULL`.

outGreatestDeviceRect

On return, the bounds of the graphics device with the greatest intersection. May be `NULL`. If the device with the greatest intersection also contains the menu bar, the device rect will exclude the menu bar area.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

GetWindowGroup

Obtains the window group associated with a window.

```
WindowGroupRef GetWindowGroup (
   WindowRef inWindow
);
```

Parameters

inWindow

The window whose window group is to be obtained.

Return Value
The window group reference for the window specified by `inWindow`. For information on this data type, see `WindowGroupRef` (page 1986).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

GetWindowGroupAttributes

Obtains the attributes of a window group.

```
OSStatus GetWindowGroupAttributes (
   WindowGroupRef inGroup,
   WindowGroupAttributes *outAttributes
);
```

Parameters

inGroup

The window group whose attributes are to be changed. For information on this data type,

outAttributes

On return, the attributes of the group. See "Window Group Attributes" (page 2031) for a list of possible values.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

GetWindowGroupContents

Obtains the contents of a window group.

```
OSStatus GetWindowGroupContents (
   WindowGroupRef inGroup,
   WindowGroupContentOptions inOptions,
   ItemCount inAllowedItems,
   ItemCount *outNumItems,
   void **outItems
);
```

Parameters

inGroup

The window group whose contents you want to obtain. For information on this data type, see `WindowGroupRef` (page 1986).

inOptions

Options for determining how to count the group members. See "Window Group Content Options" (page 2032) for a list of possible values.

inAllowedItems

The number of items that will fit in `outItems`.

outNumItems

On return, the number of items in the group.

outItems

On entry, this parameter must be a pointer to a pre-allocated buffer in which the window group contents (either window references or window group references) are to be placed. On return, the buffer pointed to by this parameter contains the requested window references or window group references.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

GetWindowGroupLevel

Obtains the level of the group in the window class hierarchy.

```
OSStatus GetWindowGroupLevel (
   WindowGroupRef inGroup,
   SInt32 *outLevel
);
```

Parameters

inGroup
The window group. For information on this data type,

outLevel
On exit, the window level of the windows in this group.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
The window group's level is only used to set the level of its windows if the window group is a child of the root group. If there is another group in the group hierarchy between this group and the root group, this group's level is ignored.

See the Core Graphics frameworks header `CGWindowLevel.h` for a listing of window levels.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

GetWindowGroupLevelOfType

Obtains the Core Graphics window level of a window group.

```
OSStatus GetWindowGroupLevelOfType (
   WindowGroupRef inGroup,
   UInt32 inLevelType,
   CGWindowLevel *outLevel
);
```

Parameters

inGroup
The window group whose Core Graphics window level is to be obtained.

inLevelType

The level type to obtain. Specify `kWindowGroupLevelActive`, `kWindowGroupLevelInactive`, or `kWindowGroupLevelPromoted`. For details, see "Window Group Level Constants" (page 2048).

outLevel

On output, the Core Graphics window level for the windows in this group.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
In Mac OS X v10.4 and later, multiple Core Graphics window levels may be associated with a window group: one level for when the application is active and another for when the application is inactive. The Window Manager automatically switches each group's Core Graphics window level as the application becomes active or inactive. Use `GetWindowGroupLevelOfType` to get each Core Graphics window level associated with a window group, including the promoted window level that is actually in use for windows in the group when the application is active.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

GetWindowGroupOfClass

Obtains the window group corresponding to a given window class.

```
WindowGroupRef GetWindowGroupOfClass (
   WindowClass windowClass
);
```

Parameters

windowClass

The window class to query.

Return Value
For information on this data type, see `WindowGroupRef` (page 1986).

Discussion
Each window class has an associated pre-defined window group. This function returns the window group reference for the window group that is associated with `windowClass`. Note that all windows in a group do not have to be of the same window class.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

GetWindowGroupOwner

Obtains the window that owns a window group. (if any)

```
WindowRef GetWindowGroupOwner (
   WindowGroupRef inGroup
);
```

Parameters

inGroup

The window group to query. For information on this data type,

Return Value

The window reference for the window that owns the group specified by `inGroup`.

Discussion

You call `SetWindowGroupOwner` (page 1944) to associate a window group with a particular window.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

GetWindowGroupParent

Obtains the parent group of a window group.

```
WindowGroupRef GetWindowGroupParent (
   WindowGroupRef inGroup
);
```

Parameters

inGroup

The window group whose parent is to be obtained.

Return Value

The parent of the window group specified by `inGroup`.

Discussion

You can nest window groups within each other.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

GetWindowGroupRetainCount

Determines the current reference count for a window group.

```
ItemCount GetWindowGroupRetainCount (
   WindowGroupRef inGroup
);
```

Parameters

inGroup

The window group for which the current reference count is to be obtained. For information on this data type, see `WindowGroupRef` (page 1986).

Availability
Available in Mac OS X v10.1 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

GetWindowGroupSibling

Obtains the next or previous group of a window group.

```
WindowGroupRef GetWindowGroupSibling (
   WindowGroupRef inGroup,
   Boolean inNextGroup
);
```

Parameters

inGroup

The window group for which the next or previous group is to be obtained. For information on this data type, see `WindowGroupRef` (page 1986).

inNextGroup

Pass `true` to obtain the next sibling; `false` to obtain the previous sibling.

Return Value
The next or previous group. For information on this data type, see `WindowGroupRef` (page 1986).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

GetWindowIdealUserState

Obtains the size and position of a window in its user state.

```
OSStatus GetWindowIdealUserState (
    WindowRef inWindow,
    Rect *outUserState
);
```

Parameters

inWindow

The window for which you want to obtain the user state.

outUserState

On input, a pointer to a structure of type `Rect`. On return, this rectangle specifies the current size and position of the window's user state, in global coordinates.

Return Value

A result code. See "Window Manager Result Codes" (page 2051).

Discussion

Because the window definition function relies upon the `WStateData` structure, it is unaware of the ideal standard state, and this causes the user state data that it stores in the `WStateData` structure to be unreliable. While the Window Manager is reliably aware of the window's zoom state, it cannot record the current user state in the `WStateData` structure, because the window definition function can overwrite that data. Therefore, the function `ZoomWindowIdeal` (page 1972) maintains the window's user state independently of the `WStateData` structure. The `GetWindowIdealUserState` function gives your application access to the user state data maintained by `ZoomWindowIdeal`. However, your application should not typically need to use this function; it is supplied for completeness.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

See Also

`HIWindowGetIdealUserState` (page 1887)

Declared In

`MacWindows.h`

GetWindowIndex

Obtains the index number of a specified window in a group.

```
OSStatus GetWindowIndex (
   WindowRef inWindow,
   WindowGroupRef inStartGroup,
   WindowGroupContentOptions inOptions,
   ItemCount *outIndex
);
```

Parameters

inWindow

The window whose window group index number is to be obtained.

inStartGroup

The window group to query.

inOptions

Specifies how to enumerate the specified window; `kWindowGroupContentsReturnWindows` is implied and does not need to be specified explicitly.

outIndex

A pointer to a variable that, on return, contains the window's z-order index. The frontmost window in a window group has an index of 1. Window indexes increase as the window gets lower in z-order (that is, visually further from the top of the window list and closer to the desktop.)

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

GetWindowKind

Returns a window's window kind.

```
short GetWindowKind (
   WindowRef window
);
```

Parameters

window

The window whose window kind is to be returned.

Return Value
An integer representing the window kind; see "Window Kinds" (page 2029).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

GetWindowList

Obtains the first window in a window list.

```
WindowRef GetWindowList (
   void
);
```

Return Value
A window reference for the first window in the list.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
MacWindows.h

GetWindowModality

Obtains the modality of a window.

```
OSStatus GetWindowModality (
   WindowRef inWindow,
   WindowModality *outModalKind,
   WindowRef *outUnavailableWindow
);
```

Parameters

inWindow
The window whose modality is to be obtained.

outModalKind
On return, contains the modality of the window.

outUnavailableWindow
On return, if the window is window-modal, contains the target window of the specified window's modality.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
MacWindows.h

GetWindowOwnerCount

Obtains the number of existing references to a window. (Deprecated in Mac OS X v10.5. Use `CFGetRetainCount` instead.)

```
OSStatus GetWindowOwnerCount (
   WindowRef window,
   ItemCount *outCount
);
```

Parameters

window
The window whose reference (owner) count is to be determined.

outCount
A pointer to a value that, on return, contains the current number of references to the window.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
All windows are created with a reference count (owner count) of one. The function `CloneWindow` (page 1808) increments the number of references to a window, and the earlier function `DisposeWindow` decrements the number of references. When the reference count reaches zero, `DisposeWindow` disposes of the window.

In Mac OS X v10.2 and later, you can also call `CFGetRetainCount` to get the number of existing references to a window.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

GetWindowPic

Returns a handle to a window's picture. (Deprecated in Mac OS X v10.5. Use an HIImageView object to draw a window's content and ask the view for its image instead.)

```
PicHandle GetWindowPic (
   WindowRef window
);
```

Parameters
window
The window whose picture handle is to be returned.

Return Value
A handle to the picture to be drawn in a specified window's content region. The handle must have been stored previously with the function `SetWindowPic` (page 1947).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

GetWindowPort

Gets the window's color graphics port.

```
CGrafPtr GetWindowPort (
   WindowRef window
);
```

Parameters
window
The window whose color graphics port is to be obtained.

Return Value
A pointer to the window's color graphics port. See the QuickDraw Manager documentation for a description of the `CGrafPtr` data type.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
CarbonSketch
QTCarbonShell

Declared In
`MacWindows.h`

GetWindowPortBounds

Obtains the bounds of the window port.

```
Rect * GetWindowPortBounds (
   WindowRef window,
   Rect *bounds
);
```

Parameters

window
The window whose port bounds you want.

bounds
A pointer to a `Rect` structure. On return, the `Rect` structure contains the bounds of the window port.

Return Value
The same value (pointer to a `Rect` structure) that was passed to `GetWindowPortBounds` in the `bounds` parameter.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
CarbonSketch
HID Explorer

Declared In
`MacWindows.h`

GetWindowProperty

Obtains a piece of data that is associated with a window.

```
OSStatus GetWindowProperty (
   WindowRef window,
   PropertyCreator propertyCreator,
   PropertyTag propertyTag,
   ByteCount bufferSize,
   ByteCount *actualSize,
   void *propertyBuffer
);
```

Parameters

window

The window to be examined for associated data.

propertyCreator

The creator code (typically, the application's signature) of the associated data to be obtained.

propertyTag

The application-defined code identifying the associated data to be obtained.

bufferSize

The size of the associated data to be obtained. If the size of the data is unknown, use the function `GetWindowPropertySize` (page 1861) to get the data's size. If the size specified does not match the actual size of the property, `GetWindowProperty` only retrieves data up to the size specified or up to the actual size of the property, whichever is smaller, and an error is returned.

actualSize

On input, a pointer to a value. On return, the value specifies the actual size of the obtained data. You may pass `NULL` for the `actualSize` parameter if you are not interested in this information.

propertyBuffer

On input, a pointer to a buffer. On return, this buffer contains a copy of the data that is associated with the specified window.

Return Value

A result code. See "Window Manager Result Codes" (page 2051).

Discussion

The data retrieved by the `GetWindowProperty` function must have been previously associated with the window with the function `SetWindowProperty` (page 1948).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Related Sample Code

QTMetaData

Declared In

`MacWindows.h`

GetWindowPropertyAttributes

Obtains the attributes of a window property.

```
OSStatus GetWindowPropertyAttributes (
   WindowRef window,
   OSType propertyCreator,
   OSType propertyTag,
   OptionBits *attributes
);
```

Parameters

window

The window having a property whose attributes are to be obtained.

propertyCreator

The property creator.

propertyTag

The property tag.

attributes

On return, the property's attributes. Currently, the only valid property is `kWindowPropertyPersistent`. For a description of this property, see "Window Property Persistent Constant" (page 2024).

Return Value

A result code. See "Window Manager Result Codes" (page 2051).

Carbon Porting Notes

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

GetWindowPropertySize

Obtains the size of a piece of data that is associated with a window.

```
OSStatus GetWindowPropertySize (
   WindowRef window,
   PropertyCreator creator,
   PropertyTag tag,
   ByteCount *size
);
```

Parameters

window

The window to be examined for associated data.

creator

The creator code (typically, the application's signature) of the associated data whose size is to be obtained.

tag

The application-defined code identifying the associated data whose size is to be obtained.

size

A pointer to a value that, on return, specifies the size of the associated data.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
If you want to retrieve a piece of associated data with the `GetWindowProperty` (page 1859) function, you typically need to use the `GetWindowPropertySize` function to determine the size of the data beforehand.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

GetWindowProxyAlias

Obtains an alias for the file that is associated with a window.

```
OSStatus GetWindowProxyAlias (
   WindowRef window,
   AliasHandle *alias
);
```

Parameters

window
The window for which you want to determine the associated file.

alias
On input, a pointer to a value of type `AliasHandle`. On return, the `AliasRecord` structure referenced by the alias handle contains a copy of the alias data for the file associated with the specified window. Your application must dispose of this handle.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
Your application can call the `GetWindowProxyAlias` function to retrieve alias data for the file associated with a window.

See also the function `SetWindowProxyAlias` (page 1949).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

GetWindowProxyFSSpec

Obtains a file system specification structure for the file that is associated with a window. (Deprecated in Mac OS X v10.5. Use `HIWindowGetProxyFSRef` (page 1888) instead.)

```
OSStatus GetWindowProxyFSSpec (
   WindowRef window,
   FSSpec *outFile
);
```

Parameters

window

A pointer to the window for which you wish to determine the associated file.

outFile

On input, a pointer to an `FSSpec` structure. On return, this structure contains a copy of the file system specification data for the file associated with the specified window.

Return Value

A result code. See "Window Manager Result Codes" (page 2051).

Discussion

You can use the `GetWindowProxyFSSpec` function to obtain identifying information about a proxy file: its volume reference number, directory ID, and file name.

See also the function `SetWindowProxyFSSpec`.

Special Considerations

The use of file specification structures is no longer recommended.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Related Sample Code

QTCarbonShell

Declared In

`MacWindows.h`

GetWindowProxyIcon

Obtains a window's proxy icon.

```
OSStatus GetWindowProxyIcon (
   WindowRef window,
   IconRef *outIcon
);
```

Parameters

window

The window for which you want to obtain the proxy icon.

outIcon

A pointer to a variable of type `IconRef` that, on return, identifies the window's proxy icon. Your application must not dispose of this icon.

Return Value

A result code. If no proxy icon is found, this function returns `errWindowDoesNotHaveProxy`. For other possible return values, see "Window Manager Result Codes" (page 2051).

Discussion
There are several different ways to associate a proxy icon with a window:

- If you use the function `SetWindowProxyIcon` (page 1951), `GetWindowProxyIcon` returns the proxy icon you set.
- If you use the function `SetWindowProxyCreatorAndType` (page 1950), that function uses Icon Services to find and set the proxy icon corresponding to the creator and type. `GetWindowProxyIcon` returns that icon.
- If you use `SetWindowProxyAlias` (page 1949), `SetWindowProxyFSSpec` (page 1950), or `HIWindowSetProxyFSRef` (page 1894), then `GetWindowProxyIcon` attempts to resolve the alias (if available) and returns the icon associated with the specified file.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

GetWindowRegion

Obtains a handle to a specific window region. (Deprecated in Mac OS X v10.5.)

```
OSStatus GetWindowRegion (
   WindowRef window,
   WindowRegionCode inRegionCode,
   RgnHandle ioWinRgn
);
```

Parameters

window
The window for which a window region handle is to be obtained.

inRegionCode
A constant representing the window region whose handle you want to obtain; see "Window Region Constants" (page 2021) for a list of possible values.

ioWinRgn
On input, a handle to a region created by your application. On return, the handle is set to the specified window region.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
The `GetWindowRegion` function produces a handle to a window definition function's window region in response to a `kWindowMsgGetRegion` message. The visibility of the window is unimportant for `GetWindowRegion` to work correctly.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

See Also
HIWindowCopyShape (page 1879)

Declared In
MacWindows.h

GetWindowResizeLimits

Returns the minimum and maximum content sizes for a window.

```
OSStatus GetWindowResizeLimits (
   WindowRef inWindow,
   HISize *outMinLimits,
   HISize *outMaxLimits
);
```

Parameters

inWindow
The window whose minimum and maximum content sizes are to be obtained.

outMinLimits
On return, the window's minimum content size. Pass NULL if you don't want this information. For information on the HISize data type, see HIGeometry.h.

outMaxLimits
On return, the window's maximum content size. Pass NULL if you don't want this information. For information on the HISize data type, see HIGeometry.h.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
MacWindows.h

GetWindowRetainCount

Returns the retain count of a window. (Deprecated in Mac OS X v10.5. Use CFGetRetainCount instead.)

```
ItemCount GetWindowRetainCount (
   WindowRef inWindow
);
```

Parameters

inWindow
The window whose retain count to retrieve.

Discussion
This API is equivalent to GetWindowOwnerCount (page 1857). For consistency with Core Foundation and Carbon Events, it is preferred over GetWindowOwnerCount. Both APIs will continue to be supported.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

GetWindowStandardState

Obtains a window's standard zoom rectangle.

```
Rect * GetWindowStandardState (
   WindowRef window,
   Rect *rect
);
```

Parameters

window
The window whose standard zoom rectangle is to be obtained.

rect
On input, a pointer to a `Rect` structure. On return, the `Rect` structure contains the window's standard zoom rectangle, in global coordinates. A window's standard zoom rectangle is the window content bounds when the window is zoomed out to its greatest extent.

Return Value
The same value (pointer to a `Rect` structure) that was passed to `GetWindowStandardState` in the `rect` parameter.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

GetWindowStructurePort

Obtains a graphics port that is used when drawing a window's structure.

```
CGrafPtr GetWindowStructurePort (
   WindowRef inWindow
);
```

Parameters

inWindow
The window to query.

Return Value
The CGrafPtr that is used when drawing the window's structure (window frame).

Availability
Available in Mac OS X v10.1 and later.

Not available to 64-bit applications.

Declared In
MacWindows.h

GetWindowStructureWidths

Obtains the width of the structure region on each edge of a window.

```
OSStatus GetWindowStructureWidths (
   WindowRef inWindow,
   Rect *outRect
);
```

Parameters

inWindow
The window to query.

outRect
On return, the `Rect` structure is filled in with the widths of the structure.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
MacWindows.h

GetWindowToolbar

Obtains the toolbar associated with a window.

```
OSStatus GetWindowToolbar (
   WindowRef inWindow,
   HIToolbarRef *outToolbar
);
```

Parameters

inWindow
The window whose toolbar is to be obtained.

outToolbar
On return, the toolbar that is attached to the window, or `NULL` if the window has no toolbar.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
MacWindows.h

GetWindowUserState

Returns a window's user zoom rectangle.

```
Rect * GetWindowUserState (
   WindowRef window,
   Rect *rect
);
```

Parameters

window
The window whose user zoom rectangle is to be returned.

rect
On input, a pointer to a `Rect` structure. On return, the `Rect` structure contains the window's user zoom rectangle, in global coordinates. A window's user zoom rectangle is the window content bounds when the window is zoomed back in.

Return Value
The same value (pointer to a `Rect` structure) that was passed to `GetWindowUserState` in the `rect` parameter.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
MacWindows.h

GetWindowWidgetHilite

Obtains the window part code of the window widget that is currently highlighted.

```
OSStatus GetWindowWidgetHilite (
   WindowRef inWindow,
   WindowDefPartCode *outHilite
);
```

Parameters

inWindow
The window to query.

outHilite
The highlight.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
MacWindows.h

GetWRefCon

Returns the reference constant from a window.

```
SRefCon GetWRefCon (
   WindowRef window
);
```

Parameters

window
The window whose reference constant is to be returned.

Return Value
The long integer data stored in the `refCon` field of the window structure specified in the `window` parameter.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
CarbonSketch
QTCarbonShell

Declared In
MacWindows.h

GetWTitle

Retrieves the title of a window as a Pascal string. (Deprecated in Mac OS X v10.5. Use `CopyWindowTitleAsCFString` (page 1813) instead.)

```
void GetWTitle (
   WindowRef window,
   Str255 title
);
```

Parameters

window
On input, a pointer to the window structure.

title
A Pascal string. On output, the string contains the window title.

Discussion
The `GetWTitle` function returns the title of the window in the `title` parameter.

When you need to retrieve a window's title, you should always use `GetWTitle` instead of reading the title from a window structure.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
MacWindows.h

GetWVariant

Returns a window's variation code. (Deprecated in Mac OS X v10.5. Use `GetWindowAttributes` (page 1842) to determine aspects of a window's appearance or behavior.)

```
short GetWVariant (
    WindowRef window
);
```

Parameters

window
On input, a pointer to the window structure.

Return Value
A short integer that specifies the variation code of the specified window. Depending on the window definition function, the result of `GetWVariant` can represent one of the standard variation codes or a variation code defined by your own window definition function.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
MacWindows.h

GrowWindow

Allows the user to change the size of a window. (Deprecated in Mac OS X v10.5. Use `ResizeWindow` (page 1925) instead.)

```
long GrowWindow (
   WindowRef window,
   Point startPt,
   const Rect *bBox
);
```

Parameters

window
On input, a pointer to the window structure of the window to drag.

startPt
On input, the location of the cursor at the time the mouse button was first pressed, in global coordinates. Your application retrieves this point from the `where` field of the event structure.

bBox

On input, a pointer to a rectangle structure that specifies the limits on the vertical and horizontal measurements of the port rectangle, in pixels.

Although the `bBox` parameter gives the address of a structure which is in the form of the `Rect` data type, the four numbers in the structure represent lengths, not screen coordinates. The `top`, `left`, `bottom`, and `right` fields of the `bBox` parameter specify the minimum vertical measurement (`top`), the minimum horizontal measurement (`left`), the maximum vertical measurement (`bottom`), and the maximum horizontal measurement (`right`).

The minimum measurements must be large enough to allow a manageable rectangle 64 pixels on a side is typical. Because the user cannot ordinarily move the cursor off the screen, you can safely set the upper bounds to the largest possible length (65,535 pixels) when you're using `GrowWindow` to follow cursor movements.

Return Value
A long integer that specifies the new dimensions, in pixels, of the resulting window: the height in the high-order word of the returned long-integer value and the width in the low-order word. A return value of 0 means that the new size is the same as the size of the current port rectangle.

Discussion
The `GrowWindow` function displays an outline (grow image) of the window as the user moves the cursor to make the window larger or smaller; it handles all user interaction until the user releases the mouse button. After calling `GrowWindow`, you call the function `SizeWindow` to change the size of the window.

The `GrowWindow` function moves a dotted-line image of the window's right and lower edges around the screen, following the movements of the cursor until the mouse button is released. You can use the functions `HiWord` and `LoWord`, described in the *Mathematical and Logical Utilities Reference*, to retrieve only the high-order and low-order words, respectively.

Special Considerations

In non-Carbon implementations of `GrowWindow` on Mac OS 8 and 9, the maximum size that the specified window is allowed to grow to is actually one less than the values specified in the `bBox` parameter. For example, if you pass the values 500 in the `bBox.bottom` field and 600 in the `bBox.right` field, the maximum height and width of the window would actually be 499 and 599, respectively.

However, in Carbon, the maximum height and width allowed for the specified window is equal to the values passed in the `bBox.bottom` and `bBox.right` fields, respectively.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

HideFloatingWindows

Hides an application's floating windows.

```
OSStatus HideFloatingWindows (
   void
);
```

Return Value
A result code. For details, see "Window Manager Result Codes" (page 2051).

Discussion
When an application receives a suspend event, its floating windows are hidden automatically. When the application receives a resume event, the floating windows are made visible automatically. Call this function if you want to hide your floating windows manually.

See also the function `ShowFloatingWindows` (page 1956).

Special Considerations

The `HideFloatingWindows` function operates only upon windows created with the `kFloatingWindowClass` constant; see "Window Class Constants" (page 1988) for more details on this constant.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

HideSheetWindow

Hides a sheet window using appropriate visual effects.

```
OSStatus HideSheetWindow (
   WindowRef inSheet
);
```

Parameters

inSheet
The window sheet that is to be hidden.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

HideWindow

Makes a window invisible.

```
void HideWindow (
   WindowRef window
);
```

Parameters

window

The window that is to be made invisible.

Discussion

The `HideWindow` function make a visible window invisible. If you hide the frontmost window, `HideWindow` removes the highlighting, brings the window behind it to the front, highlights the new frontmost window, and generates the appropriate activate events.

To reverse the actions of `HideWindow`, you must call both `ShowWindow` (page 1959), to make the window visible, and `SelectWindow` (page 1929), to select it.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

HiliteWindow

Sets a window's highlighting status.

```
void HiliteWindow (
   WindowRef window,
   Boolean fHilite
);
```

Parameters

window

On input, a pointer to the window structure.

fHilite

On input, a Boolean value that specifies the highlighting status: `true` highlights a window; `false` removes highlighting.

Discussion

The `HiliteWindow` function sets a window's highlighting status to the specified state. If the value of the `fHilite` parameter is `true`, `HiliteWindow` highlights the specified window; if the specified window is already highlighted, the function has no effect. If the value of `fHilite` is `false`, `HiliteWindow` removes highlighting from the specified window; if the window is not already highlighted, the function has no effect.

Your application doesn't normally need to call `HiliteWindow`. To make a window active, you can call `SelectWindow` or `ActivateWindow`, which handle highlighting for you.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

HiliteWindowFrameForDrag

Sets the highlight state of the window's structure region to reflect the window's validity as a drag-and-drop destination.

```
OSStatus HiliteWindowFrameForDrag (
   WindowRef window,
   Boolean hilited
);
```

Parameters

window

The window for which you want to set the highlight state.

hilited

Pass `true` if the window's frame should be highlighted otherwise, pass `false`.

Return Value

A result code. See "Window Manager Result Codes" (page 2051).

Discussion

Applications typically call the Drag Manager functions `ShowDragHilite` and `HideDragHilite` to indicate that a window is a valid drag-and-drop destination. If your application does not do this—that is, if your application implements any type of custom drag highlighting, such as highlighting more than one area of a window at a time—it must call the `HiliteWindowFrameForDrag` function.

The `HiliteWindowFrameForDrag` function highlights a window's proxy icon when the user drags content inside the window that is a valid content type for that destination. The default behavior of system-defined windows is to highlight the proxy icon along with the window's content area when the window is a valid drag-and-drop destination. If you call the Drag Manager functions `ShowDragHilite` and `HideDragHilite`, you don't need to use `HiliteWindowFrameForDrag`.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

HIWindowChangeAttributes

Changes the attributes of a window.

```
OSStatus HIWindowChangeAttributes (
   WindowRef inWindow,
   const int *inAttrToSet,
   const int *inAttrToClear
);
```

Parameters

inWindow

The window to change.

inAttrToSet

A zero-terminated array of window attribute constants. Possible values are described in "Window Attribute Identifiers" (page 1992). Each array entry specifies an attribute of the window to set. You may pass NULL if you do not wish to set any attributes.

inAttrToClear

A zero-terminated array of window attribute constants. Possible values are described in "Window Attribute Identifiers" (page 1992). Each array entry specifies an attribute of the window to clear. You may pass NULL if you do not wish to clear any attributes.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
This function takes two arrays of window attribute constants, as described in "Window Attribute Identifiers" (page 1992). The first array specifies the attributes to set, and the second specifies the attributes to clear. For example, you might call this function as follows:

```
int setAttr[] = { kHIWindowBitCloseBox, kHIWindowBitZoomBox, 0 };
int clearAttr[] = { kHIWindowBitNoTitleBar, 0 };
HIWindowChangeAttributes (window, setAttr, clearAttr);
```

Special Considerations

In Mac OS X v10.4 or earlier, you can use the function ChangeWindowAttributes (page 1805) to achieve similar results.

Availability
Available in Mac OS X v10.5 and later.
Not available to 64-bit applications.

Declared In
MacWindows.h

HIWindowChangeAvailability

Changes the availability of a window during Exposé or in Spaces.

```
OSStatus HIWindowChangeAvailability (
   WindowRef inWindow,
   HIWindowAvailability inSetAvailability,
   HIWindowAvailability inClearAvailability
);
```

Parameters

inWindow

The window whose availability is to be changed.

inSetAvailability

The availability bits to set. For details, see "Window Availability Constants" (page 2046).

inClearAvailability

The availability bits to clear. For details, see "Window Availability Constants" (page 2046).

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
This function overrides the default behavior of the Window Manager in determining whether a window is visible during Exposé or in all Spaces workspaces. Most applications should not override the default behavior; these options should only be used in special cases. For example, accessibility assistance applications may need to create windows that are visible in all workspaces.

By default, newly created windows of class `kDocumentWindowClass` are given an availability of `0` (meaning that they are available during Exposé), and windows from all other window classes are given an availability of `kHIWindowExposeHidden`.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

HIWindowChangeClass

Changes the appearance and behavior of a window.

```
OSStatus HIWindowChangeClass (
   WindowRef inWindow,
   WindowClass inWindowClass
);
```

Parameters

window
The window whose class you want to change.

inClass
The new class that is to be applied to the window. See "Window Class Constants" (page 1988) for a list of possible window classes.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
This function changes the class of a window. Unlike `SetWindowClass` (page 1938), `HIWindowChangeClass` effectively changes both the appearance and behavior of the window.

This function can convert a window between `kDocumentWindowClass`, `kFloatingWindowClass`, `kUtilityWindowClass`, and `kMovableModalWindowClass` only. It cannot, for example, change a document window into a plain window.

The attributes of the window are adjusted to contain only those that are allowed for the new class. It is the caller's responsibility to adjust them further, as necessary, after `HIWindowChangeClass` returns.

Availability
Available in Mac OS X v10.3 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

HIWindowChangeFeatures

Changes a window's features.

```
OSStatus HIWindowChangeFeatures (
   WindowRef inWindow,
   UInt64 inSetThese,
   UInt64 inClearThese
);
```

Parameters

inWindow

The window whose features are to be changed.

inSetThese

The feature bits to set. For details, see "Window Feature Bits" (page 2011).

inClearThese

The feature bits to clear. For details, see "Window Feature Bits" (page 2011).

Return Value

A result code. See "Window Manager Result Codes" (page 2051).

Discussion

`HIWindowChangeFeatures` changes the features of a window on the fly. This function should only be used by custom window definitions or window frame views.

Availability

Available in Mac OS X v10.3 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

HIWindowConstrain

Moves and resizes a window to be within a specified bounding rectangle.

```
OSStatus HIWindowConstrain (
   WindowRef inWindowRef,
   WindowRegionCode inRegionCode,
   WindowConstrainOptions inOptions,
    HICoordinateSpace inSpace,
   const HIRect *inScreenBounds,
    const HISize *inMinimumSize,
   HIRect *ioBounds
);
```

Parameters

inWindowRef

The window to constrain.

inRegionCode

The window region to constrain. For a list of possible values, see "Window Region Constants" (page 2021).

inOptions

Flags controlling how the window is constrained. For a list of possible options, see "Window Constrain Options" (page 2028).

inSpace

The coordinate space in which the `inScreenBounds`, `inMinimumSize`, and `ioBounds` parameters are expressed. This parameter must be either `kHICoordSpaceScreenPixels` or `kHICoordSpace72DPIGlobal`.

inScreenBounds

A rectangle within which to constrain the window. You may pass `NULL` if you don't need to specify a screen bounds. If `NULL`, the window is constrained to the screen that has the greatest intersection with the specified window region.

inMinimumSize

A minimum size that should be kept within the specified screen bounds. This parameter is ignored if the `kWindowConstrainMoveMinimum` option is not set. Even if that option is set, you may still pass `NULL` if you don't need to customize the minimum dimensions.

ioBounds

If the `inOptions` parameter contains `kWindowConstrainUseSpecifiedBounds`, then this parameter should be a bounding rectangle of the specified window region. The bounding rectangle does not have to match the actual current bounds of the specified region; it may be a hypothetical bounds that you would like to constrain without actually moving the window to that location. On output, contains the new structure bounds of the window. You may pass `NULL` if you don't need the window bounds returned.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Availability
Available in Mac OS X v10.5 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

HIWindowCopyAvailablePositioningShape

Copies the available window positioning shape on a display.

```
OSStatus HIWindowCopyAvailablePositioningShape (
   CGDirectDisplayID inDisplay,
   HICoordinateSpace inSpace,
   HIShapeRef *outShape
);
```

Parameters

inDisplay

The display for which to find the available shape. May be `kCGNullDirectDisplay` to request the shape of the main display.

inSpace

The coordinate space in which the positioning shape should be returned. This parameter must be either `kHICoordSpaceScreenPixel` or `kHICoordSpace72DPIGlobal`.

outShape

A pointer to a shape (an HIShape object). On output, the shape describes the available bounds for the specified display. This shape is returned in the specified coordinate space. You should release the shape when you no longer need it.

Discussion

This function finds the area on the display in which a window may be positioned without intersecting or overlapping the menu bar, Dock, or other UI provided by the operating system. This function differs from `HIWindowGetAvailablePositioningBounds` (page 1885) in that the bounds version removes the entire area that may theoretically be covered by the Dock, even if the Dock does not currently reach from edge to edge of the display on which it is positioned. The shape version includes the area at the sides of the Dock that is not covered by the Dock.

Availability

Available in Mac OS X v10.5 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

HIWindowCopyDrawers

Obtains an array of the drawers that are attached to a window.

```
OSStatus HIWindowCopyDrawers (
    WindowRef inWindow,
    CFArrayRef *outDrawers
);
```

Parameters

inWindow

The parent window to access.

outDrawers

A pointer to a Core Foundation array. On output, each array entry is a drawer window attached to the parent window specified in the `inWindow` parameter. The array will be valid, but empty, if the parent window has no drawers. You should release the array when you no longer need it.

Return Value

A result code. See "Window Manager Result Codes" (page 2051).

Availability

Available in Mac OS X v10.5 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

HIWindowCopyShape

Retrieves a shape that describes a region of a window.

```
OSStatus HIWindowCopyShape (
    WindowRef inWindow,
    WindowRegionCode inRegion,
    HICoordinateSpace inSpace,
    HIShapeRef *outShape
);
```

Parameters

inWindow

The window to access.

inRegion

The window region whose shape you want to obtain. For a list of possible values, see "Window Region Constants" (page 2021).

inSpace

The coordinate space in which the shape should be returned. This parameter must be `kHICoordSpaceWindow`, `kHICoordSpaceScreenPixel`, or `kHICoordSpace72DPIGlobal`.

outShape

A pointer to a shape (an HIShape object). On output, the shape describes the specified window region. The shape is returned in the specified coordinate space. You should release the shape when you no longer need it. If the window does not support the specified window region, no shape is returned.

Return Value

A result code. If the window does not support the specified window region, the result returned is `errWindowRegionCodeInvalid`. For other possible values, see "Window Manager Result Codes" (page 2051).

Availability

Available in Mac OS X v10.5 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

HIWindowCreate

Creates a standard or custom window.

```
OSStatus HIWindowCreate (
    WindowClass inClass,
    const int *inAttributes,
    const WindowDefSpec *inDefSpec,
    HICoordinateSpace inSpace,
    const HIRect *inBounds,
    WindowRef *outWindow
);
```

Parameters

inClass

The class of window to be created. For a list of possible classes, see "Window Class Constants" (page 1988).

inAttributes

A zero-terminated array of window attribute constants. Each array entry specifies an attribute of the window to set. You may pass `NULL` if you don't need to set any attributes. For a list of possible attributes, see "Window Attribute Identifiers" (page 1992).

inDefSpec

A pointer to a custom window proc ID or root view for the window. You may pass `NULL` if you don't need to customize the window.

inSpace

The coordinate space in which the content bounds is expressed. This parameter must be either `kHICoordSpaceScreenPixels` or `kHICoordSpace72DPIGlobal`.

inBounds

A pointer to the bounds of the content area of the window in the coordinate space specified by the `inSpace` parameter. If you specify non-integral coordinates, they will be rounded to the nearest integral value in screen pixel space when the window is actually positioned or sized.

outWindow

A pointer to a window variable. On output, the variable contains the new window.

Return Value

A result code. See "Window Manager Result Codes" (page 2051).

Discussion

This function makes it possible to create windows with content bounds expressed in different coordinate spaces. In Mac OS X v10.5 and later, you can use this function in place of `CreateNewWindow` (page 1815) or `CreateCustomWindow` (page 1814) to create a window from a set of parameters.

Most developers will want to work primarily in the 72 DPI coordinate space. Doing so makes your code independent of the current user interface scale factor, and eases source compatibility with earlier versions of Mac OS X that do not support resolution independence. However, there are also certain cases where your application must express your window's bounds in pixel coordinates; primarily when you need to position your windows so they exactly align with each other or with some other fixed location, such as the edge of the display. For these cases, you should use the screen pixel coordinate space.

Availability

Available in Mac OS X v10.5 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

HIWindowCreateCollapsedDockTileContext

Creates a Quartz graphics context for drawing a collapsed window's Dock tile.

```
OSStatus HIWindowCreateCollapsedDockTileContext (
   WindowRef inWindow,
   CGContextRef *outContext,
   HISize *outContextSize
);
```

Parameters

inWindow

The collapsed window.

outContext

A pointer to a `CGContextRef` variable. On output, the variable contains the graphics context for drawing the window's Dock tile.

outContextSize

A pointer to a `HISize` structure. On output, the structure contains the width and height of the area in which to draw.

Return Value

A result code. If the window is not collapsed, the result code is `windowWrongStateErr`. For other possible values, see "Window Manager Result Codes" (page 2051).

Discussion

When you are finished drawing in the graphics context, you should:

1. Call `CGContextFlush` to ensure that your drawing appears onscreen.
2. Call `HIWindowReleaseCollapsedDockTileContext` (page 1892) to release the context. Do not call `CFRelease` or `CGContextRelease` to release the context, or you may leak system resources.

Availability

Available in Mac OS X v10.5 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

HIWindowFindAtLocation

Finds a window in the current process at a specified location.

```
OSStatus HIWindowFindAtLocation (
    const HIPoint *inLocation,
    HICoordinateSpace inSpace,
    WindowRef inStartWindow,
    OptionBits inOptions,
    WindowRef *outWindow,
    WindowPartCode *outWindowPart,
    HIPoint *outWindowLocation
);
```

Parameters

inLocation

The location, in global coordinates, at which to search for a window.

inSpace

The coordinate space in which the location is expressed. This parameter must be either `kHICoordSpaceScreenPixel` or `kHICoordSpace72DPIGlobal`.

inStartWindow

The window at which to start the search, inclusive. Pass `kFirstWindowOfClass` to start the search at the beginning of the window list. Passing `NULL` will cause the search to start at the end of the window list, and therefore no window will be found.

inOptions

Reserved. Pass zero.

outWindow

A pointer to a window variable. On output, the variable contains the window in the current process at the specified location, if any, or `NULL` if no window is found.

outWindowPart

A pointer to a window part code variable. On output, the variable contains the window part that was hit. You may pass `NULL` if you don't need this information.

outWindowLocation

A pointer to a point variable. On output, the variable contains the specified location transformed into window-relative coordinates, taking into account any window transform or magnification. You may pass `NULL` if you don't need this information.

Return Value
A result code. If no window is found that satisfies the search criteria, this function returns `errWindowNotFound`. For other possible return values, see "Window Manager Result Codes" (page 2051).

Discussion
This function searches the window list of the current process for a window that contains the specified location. If you need to determine whether the window is of a particular class, you can use the function `GetWindowClass` (page 1844) and compare the result to the desired class.

Availability
Available in Mac OS X v10.5 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

HIWindowFlush

Flushes any dirty areas a window might have.

```
OSStatus HIWindowFlush (
   WindowRef inWindow
);
```

Parameters

window

The window to flush.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
This function allows you to manually flush dirty areas of a window to the screen. This is the preferred way to flush window buffers in Mac OS X v10.3 and later. If called for a composited window, this function also renders any views in the window that are invalid.

Availability
Available in Mac OS X v10.3 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

HIWindowFromCGWindowID

Returns the window in the current process with a specified Quartz window ID.

```
WindowRef HIWindowFromCGWindowID (
    CGWindowID inWindowID
);
```

Parameters

inWindowID

The window ID, as returned by `HIWindowGetCGWindowID` (page 1886) or `CGWindowListCopyWindowInfo`.

Return Value

The window to which the window ID is assigned. This function returns `NULL` if the window ID is invalid or if it refers to a window in another process.

Discussion

This function returns the window in the current process to which the specified window ID is assigned by the window server when the window is created.

Availability

Available in Mac OS X v10.5 and later.

Not available to 64-bit applications.

See Also

`HIWindowGetCGWindowID` (page 1886)

Declared In

`MacWindows.h`

HIWindowGetAvailability

Obtains the availability of a window during Exposé or in Spaces.

```
OSStatus HIWindowGetAvailability (
   WindowRef inWindow,
   HIWindowAvailability *outAvailability
);
```

Parameters

inWindow

The window whose availability is to be obtained.

outAvailability

On exit, the current setting of the window's availability bits. For details, see "Window Availability Constants" (page 2046).

Return Value

A result code. See "Window Manager Result Codes" (page 2051).

Availability

Available in Mac OS X v10.4 and later.

Not available to 64-bit applications.

Declared In
MacWindows.h

HIWindowGetAvailablePositioningBounds

Gets the available window positioning bounds on a display.

```
OSStatus HIWindowGetAvailablePositioningBounds (
   CGDirectDisplayID inDisplay,
   HICoordinateSpace inSpace,
   HIRect *outAvailableRect
);
```

Parameters

inDisplay

The display for which to find the available bounds. May be `kCGNullDirectDisplay` to request the bounds of the main display.

inSpace

The coordinate space in which the positioning bounds should be returned. This must be either `kHICoordSpaceScreenPixel` or `kHICoordSpace72DPIGlobal`.

outAvailableRect

A pointer to a rectangle provided by the caller. On output, the rectangle contains the available bounds for the specified display. This rectangle is returned in the specified coordinate space.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
This function gets the bounds of the display not including the menu bar and Dock, if located on that display.

Availability
Available in Mac OS X v10.5 and later.
Not available to 64-bit applications.

Declared In
MacWindows.h

HIWindowGetBounds

Gets the bounds of a specified region of a window.

```
OSStatus HIWindowGetBounds (
    WindowRef inWindow,
    WindowRegionCode inRegion,
    HICoordinateSpace inSpace,
    HIRect *outBounds
);
```

Parameters

inWindow

The window to access.

inRegion

The window region. For a list of possible values, see "Window Region Constants" (page 2021).

inSpace

The coordinate space in which the bounds should be returned. This parameter must be `kHICoordSpaceWindow`, `kHICoordSpaceScreenPixel`, or `kHICoordSpace72DPIGlobal`.

outBounds

A pointer to an `HIRect` (page 2324) structure. On output, the structure contains the origin and size of the bounding rectangle of the specified window region. If the window does not support the region, the structure is not modified.

Return Value

A result code. If the window does not support the specified window region, the result returned is `errWindowRegionCodeInvalid`.

Availability

Available in Mac OS X v10.5 and later.

Not available to 64-bit applications.

See Also

`HIWindowSetBounds` (page 1893)

Declared In

`MacWindows.h`

HIWindowGetCGWindowID

Returns the Quartz window ID assigned to a window.

```
CGWindowID HIWindowGetCGWindowID (
   WindowRef inWindow
);
```

Parameters

inWindow

The window to access.

Return Value

The window ID of the specified window, or zero if the window is invalid.

Discussion

This function returns the window ID assigned by the window server when a window is created. The window ID is not generally useful with any other Carbon function, but may be used with other Mac OS X functions that require a window ID, such as functions in OpenGL.

Availability

Available in Mac OS X v10.5 and later.

Not available to 64-bit applications.

See Also

`HIWindowFromCGWindowID` (page 1884)

Declared In

`MacWindows.h`

HIWindowGetGreatestAreaDisplay

Finds the display with the greatest area of intersection with a window region.

```
OSStatus HIWindowGetGreatestAreaDisplay (
   WindowRef inWindow,
   WindowRegionCode inRegion,
   HICoordinateSpace inSpace,
   CGDirectDisplayID *outGreatestDisplay,
   HIRect *outGreatestDisplayRect
);
```

Parameters

inWindow

The window to compare against.

inRegion

The window region to compare against. See "Window Region Constants" (page 2021) for a list of possible values.

inSpace

The coordinate space in which the display bounds should be returned. This must be either `kHICoordSpaceScreenPixel` or `kHICoordSpace72DPIGlobal`.

outGreatestDisplay

A pointer to a display ID provided by the caller, or `NULL` if you don't need this information. On output, the display ID contains the display with the greatest intersection.

outGreatestDisplayRect

A pointer to a rectangle provided by the caller, or `NULL` if you don't need this information. On output, the rectangle contains the bounds of the display with the greatest intersection. If the display with the greatest intersection also contains the menu bar, the rectangle excludes the menu bar area. This rectangle is returned in the specified coordinate space.

Return Value

A result code. See "Window Manager Result Codes" (page 2051).

Availability

Available in Mac OS X v10.5 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

HIWindowGetIdealUserState

Gets the bounds of a window's content region in its user state.

```
OSStatus HIWindowGetIdealUserState (
   WindowRef inWindow,
   HICoordinateSpace inSpace,
   HIRect *outUserState
);
```

Parameters

inWindow

The window to access.

inSpace

The coordinate space in which the user state bounds should be returned. This parameter must be `kHICoordSpaceScreenPixel` or `kHICoordSpace72DPIGlobal`.

outUserState

A pointer to a structure of type `HIRect`. On return, this rectangle contains the global coordinates of the window's content region when zoomed in. If the window has not yet been zoomed, this rectangle contains the window's current content bounds.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
This function returns information about the window's user state most recently recorded by the function `ZoomWindowIdeal` (page 1972).

Availability
Available in Mac OS X v10.5 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

HIWindowGetProxyFSRef

Obtains the `FSRef` used to determine the proxy icon for a window.

```
OSStatus HIWindowGetProxyFSRef (
   WindowRef window,
   FSRef *outRef
);
```

Parameters

inWindow

The window whose proxy `FSRef` is to be obtained.

outRef

On exit, the `FSRef` for the window's proxy icon.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
If the specified window's proxy icon has been specified using `HIWindowSetProxyFSRef` (page 1894) or `SetWindowProxyAlias` (page 1949), `HIWindowGetProxyFSRef` returns `noErr` and a valid `FSRef` for the window's proxy icon. If the window has no proxy icon, or if the icon was specified by calling `SetWindowProxyCreatorAndType` or `SetWindowProxyIcon`, this function returns an error.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

HIWindowGetScaleMode

Obtains the window's scale mode and the application's display scale factor.

```
OSStatus HIWindowGetScaleMode (
   WindowRef inWindow,
   HIWindowScaleMode *outMode,
   CGFloat *outScaleFactor
);
```

Parameters

inWindow

The window whose scale mode is to be obtained.

outMode

On exit, an `HIWindowScaleMode` indicating the window's scale mode. For details, see "Window Scale Mode Constants" (page 2047).

outScaleFactor

On exit, a float indicating the display scale factor for the application. Pass `NULL` if you are not interested in acquiring the scale factor.

Return Value

A result code. See "Window Manager Result Codes" (page 2051).

Discussion

The window's scale mode is based on the application's display scale factor and any resolution-independent attributes specified at window creation time. Applications and the views within the window can use the scale mode and display scale factor to draw properly the content of a window for a particular scale mode.

Availability

Available in Mac OS X v10.4 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

HIWindowGetThemeBackground

Gets the theme background brush for a window.

```
OSStatus HIWindowGetThemeBackground (
    WindowRef inWindow,
    ThemeBrush *outThemeBrush
);
```

Parameters

inWindow

The window from which to get the brush.

outThemeBrush

A pointer to a theme brush. On output, the brush is the window's theme background brush.

Return Value

A result code. If no brush is found, `themeNoAppropriateBrushErr` is returned.

Discussion
This function gets the theme background brush previously set by calling the function `SetThemeWindowBackground` (page 1933).

Availability
Available in Mac OS X v10.5 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

HIWindowInvalidateShadow

Recalculates a window's shadow.

```
OSStatus HIWindowInvalidateShadow (
   WindowRef inWindow
);
```

Parameters
inWindow
The window whose shadow is to be recalculated.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
`HIWindowInvalidateShadow` is not typically used by applications. It is useful if your application has customized window frames that change shape dynamically. After you have drawn the new window shape, you should call `HIWindowInvalidateShadow` to recalculate the shadow so that it follows the new window shape.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

HIWindowIsAttributeAvailable

Returns a Boolean value indicating whether a window attribute is valid for a specified window class.

```
Boolean HIWindowIsAttributeAvailable (
   WindowClass inClass,
   int inAttr
);
```

Parameters
inClass
The window class to test.

inAttr

The window attribute to test. You must specify one of the window attributes described in "Window Attribute Identifiers" (page 1992).

Return Value
If `true`, the window class supports the specified attribute. Otherwise, `false`.

Availability
Available in Mac OS X v10.5 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

HIWindowIsDocumentModalTarget

Determines if a window is currently the target window of another document modal window, such as a sheet.

```
Boolean HIWindowIsDocumentModalTarget (
   WindowRef inWindow,
   WindowRef *outOwner
);
```

Parameters

inWindow

The window to query.

outOwner

If this function returns `true`, `inWindow` is the target of a document modal window and `outOwner` is set to the document modal window. If this function does not return `true`, `outOwner` is undefined. Pass `NULL` if you don't want the owner's window reference.

Return Value
A Boolean whose value is `true` if the window specified by `inWindow` is currently the target of a document modal window; otherwise, `false`.

Availability
Available in Mac OS X v10.3 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

HIWindowIsInStandardState

Returns a Boolean value indicating whether a window is zoomed out to its standard state.

```
Boolean HIWindowIsInStandardState (
   WindowRef inWindow,
   const HISize *inIdealSize,
    HICoordinateSpace inSpace,
   HIRect *outIdealStandardState
);
```

Parameters

inWindow

The window whose zoom state is to be determined.

inIdealSize

The ideal width and height of the window's content region, regardless of the actual screen device dimensions. If you set `inIdealSize` to `NULL`, this function examines the dimensions stored in the `stdState` field of the `WStateData` structure.

inSpace

The coordinate space in which the ideal size is expressed and in which the standard state bounds should be returned. This parameter must be either `kHICoordSpaceScreenPixel` or `kHICoordSpace72DPIGlobal`.

outIdealStandardState

A pointer to an `HIRect` variable. On return, the variable contains the bounds of the content region of the window in its standard state, based on the data supplied in the `inIdealSize` parameter. You may pass `NULL` if you do not need this information.

Return Value

If `true`, the window is currently in its standard state. If `false`, the window is currently in its user state.

Discussion

This function compares the window's current dimensions to those in the `inIdealSize` parameter to determine if the window is currently in its standard state. You can use this function to decide whether a user's click in the zoom box is a request to zoom to the user state or the standard state, as described in the function `ZoomWindowIdeal` (page 1972). You can also use this function to determine the size and position of the standard state that the Window Manager would calculate for a window, given a specified ideal size; this value is returned in the `outIdealStandardState` parameter.

Availability

Available in Mac OS X v10.5 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

HIWindowReleaseCollapsedDockTileContext

Releases a Quartz graphics context for drawing a collapsed window's Dock tile.

```
OSStatus HIWindowReleaseCollapsedDockTileContext (
   WindowRef inWindow,
   CGContextRef inContext
);
```

Parameters

inWindow

The collapsed window.

inContext

The graphics context to release. On return, the context is invalid and should no longer be used.

Return Value
A result code. If the window is not collapsed, the result code is `windowWrongStateErr`. For other possible values, see "Window Manager Result Codes" (page 2051).

Discussion
To ensure that your drawing appears onscreen, you should call `CGContextFlush` before calling this function to release the context. Do not call `CFRelease` or `CGContextRelease` to release the context, or you may leak system resources.

Availability
Available in Mac OS X v10.5 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

HIWindowSetBounds

Sets the bounds of a window based on either the structure or content region.

```
OSStatus HIWindowSetBounds (
    WindowRef inWindow,
    WindowRegionCode inRegion,
    HICoordinateSpace inSpace,
    HIRect *inBounds
);
```

Parameters

inWindow

The window to access.

inRegion

The window region on which to base the window's new bounds. This parameter must be either `kWindowStructureRgn` or `kWindowContentRgn`.

inSpace

The coordinate space in which the bounds are expressed. This parameter must be `kHICoordSpaceWindow`, `kHICoordSpaceScreenPixel`, or `kHICoordSpace72DPIGlobal`.

inBounds

A pointer to an `HIRect` (page 2324) structure that specifies the origin and size of the bounding rectangle of the specified window region. If the coordinate space is `kHICoordSpaceWindow`, then the origin of the bounds is a window-relative value. Therefore, you can use this coordinate space to resize a window without first getting its current bounds by setting the origin to (0,0), or you can offset a window from its current position by setting the origin to the offset amount and the size to the window's current size.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Availability
Available in Mac OS X v10.5 and later.
Not available to 64-bit applications.

See Also
HIWindowGetBounds (page 1885)

Declared In
MacWindows.h

HIWindowSetIdealUserState

Sets the bounds of a window's content region in its user state.

```
OSStatus HIWindowSetIdealUserState (
    WindowRef inWindow,
    HICoordinateSpace inSpace,
    const HIRect *inUserState
);
```

Parameters

inWindow
The window to access.

inSpace
The coordinate space in which the user state bounds are expressed. This parameter must be either kHICoordSpaceScreenPixel or kHICoordSpace72DPIGlobal.

inUserState
The new bounds (position and size) of the window's content region in its user state.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
A window's ideal user state is used by the function ZoomWindowIdeal (page 1972) when zooming in.

Availability
Available in Mac OS X v10.5 and later.
Not available to 64-bit applications.

Declared In
MacWindows.h

HIWindowSetProxyFSRef

Sets the proxy icon for a window using an FSRef to a file system object.

```
OSStatus HIWindowSetProxyFSRef (
   WindowRef window,
   const FSRef *inRef
);
```

Parameters

inWindow
The window whose proxy icon is to be set.

inRef
The file system object the window represents.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
This function determines the window's proxy icon by asking Icon Services for the icon for the object specified by `inRef`.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

HIWindowSetToolbarView

Sets a custom toolbar view for a window.

```
OSStatus HIWindowSetToolbarView (
    WindowRef inWindow,
    HIViewRef inView
);
```

Parameters

`inWindow`
The window whose toolbar view to set.

`inView`
The custom toolbar view for the window. You may pass `NULL` to remove the custom view from the window. Setting a custom view will also remove any HIToolbar that is associated with the window.

After a custom toolbar view has been set, the window owns the view and will release it automatically when the window is destroyed, or when a different custom view or standard HIToolbar is set for the window.

Return Value
A result code.

Discussion
This function is provided for use by applications that cannot use the HIToolbar API. For best compatibility with future versions of Mac OS X, you should use HIToolbar if possible. However, if HIToolbar is not sufficient for your needs, you can use this function to provide a custom toolbar view that will be placed at the standard location inside the window frame.

You are responsible for defining the appearance and behavior of the view. You cannot use this function to customize the view that is associated with an HIToolbar; a window with an HIToolbar uses a standard view that cannot be customized. When using a custom toolbar view, no function that takes an HIToolbar will work with that window. For more information about custom toolbar views, see `MacWindows.h`.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

HIWindowShowsFocus

Returns a Boolean value indicating whether a window's content should show focus indicators such as focus rings.

```
Boolean HIWindowShowsFocus (
    WindowRef inWindow
);
```

Parameters

inWindow
The window to access.

Return Value

If `true`, a window's content should show focus indicators; otherwise `false`.

Discussion

This function returns `true` if the window is either the modeless focus or the effective focus.

Availability

Available in Mac OS X v10.5 and later.
Not available to 64-bit applications.

Declared In

`MacWindows.h`

HIWindowTestAttribute

Returns a Boolean value indicating whether a window has a specified attribute.

```
Boolean HIWindowTestAttribute (
   WindowRef inWindow,
   int inAttr
);
```

Parameters

inWindow
The window to test.

inAttr
The window attribute to test. You must specify one of the window attributes described in "Window Attribute Identifiers" (page 1992).

Return Value

If `true`, the window has the specified attribute. Otherwise, `false`.

Availability

Available in Mac OS X v10.5 and later.
Not available to 64-bit applications.

Declared In

`MacWindows.h`

HIWindowTrackProxyDrag

Tracks the drag of a window proxy icon.

```
OSStatus HIWindowTrackProxyDrag (
    WindowRef inWindow,
    EventRef inEvent,
    DragRef inDrag
);
```

Parameters

inWindow

The window whose proxy icon to drag.

inEvent

The event that resulted in starting a drag. This will most commonly be `kEventControlTrack`, but any event with `kEventParamMouseLocation` and `kEventParamKeyModifiers` parameters is all that is required.

inDrag

The proxy icon drag reference. You may pass `NULL` if you want the Window Manager to create and populate the drag reference. The Window Manager will add its own drag flavors to the drag even if you pass a pre-created drag reference.

Discussion

You can use this function to manage the dragging of the proxy icon in your application's windows. If you use the standard window event handler and you do not need to customize the proxy icon drag process, you may rely on the standard handler to call this function.

If you want to allow the Window Manager to create the drag reference and populate it with drag flavors, you should pass `NULL` in the `inDrag` parameter. If you want to create the drag reference yourself and add your own drag flavors, you should call `BeginWindowProxyDrag` (page 1802) to create the drag reference, add your own flavors, call `HIWindowTrackProxyDrag` to track the proxy icon drag, and then call `EndWindowProxyDrag` (page 1826) to release the drag reference.

A proxy icon may only be dragged if the window represented by the proxy icon is not modified, as indicated by the `IsWindowModified` (page 1907) function. This restriction exists because a proxy icon is a representation of a physical file system object, and dragging the proxy icon may result in the Finder making a copy of the file system object. If the window is modified, then it contains user data that has not yet been saved to disk; making a copy of the file system object would result in a stale copy that did not contain the user's current data.

By default, all newly created windows are considered to be dirty. The application must pass false to `SetWindowModified` (page 1946) before the proxy icon will be draggable. In Mac OS X v10.3 and later, the proxy icon is also draggable in dirty windows if the proxy icon was provided using the `SetWindowProxyIcon` (page 1951) or `SetWindowProxyCreatorAndType` (page 1950) functions. Dragging is allowed in this case because the window does not represent an actual file system object, and therefore there is no risk of user data loss.

Availability

Available in Mac OS X v10.5 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

InstallWindowContentPaintProc

Installs a window content painting callback. (Deprecated in Mac OS X v10.5. Use a `kEventControlDraw` Carbon event handler on a window's content view instead.)

```
OSStatus InstallWindowContentPaintProc (
   WindowRef window,
   WindowPaintUPP paintProc,
   WindowPaintProcOptions options,
   void *refCon
);
```

Parameters

window

The window whose default content painting function you want to override.

paintProc

A UPP to your window painting callback function. See `WindowPaintProcPtr` (page 1978) for more information about the format of this function.

options

The options that are to be set. See "Window Paint Callback Options" (page 2043) for a list of possible values.

refCon

Application-defined data. This data is passed to your callback when it is called.

Return Value

A result code. See "Window Manager Result Codes" (page 2051).

Discussion

To remove a previously-installed paint proc (returning to the standard window manager erase-to-white content painting), pass `NULL` in the `paintProc` and `refCon` parameters.

Special Considerations

Instead of using this function, you should install a Carbon event handler for the `kEventControlDraw` event on a window's content view.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

InvalWindowRect

Adds a rectangle to a window's update region.

```
OSStatus InvalWindowRect (
   WindowRef window,
   const Rect *bounds
);
```

Parameters

window

The window containing the rectangle you want to be updated.

bounds

Set this structure to specify, in local coordinates, a rectangle to be added to the window's update region.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
The `InvalWindowRect` function informs the Window Manager that an area of a window should be redrawn.

See also the functions `ValidWindowRect` (page 1969) and `InvalWindowRgn` (page 1899).

Special Considerations

This function should not be used on composited windows. Modifying a composited window's update region does not affect the area of the window to be drawn. A composited window does not use its window update region to control drawing. Instead, a composited window determines what to draw by looking at the invalid regions of the views contained in the window.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
CarbonSketch
HID Explorer

Declared In
`MacWindows.h`

InvalWindowRgn

Adds a region to a window's update region.

```
OSStatus InvalWindowRgn (
   WindowRef window,
   RgnHandle region
);
```

Parameters

window

The window containing the region that you want to update.

region

Set this region to specify, in local coordinates, the area to be added to the window's update region.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
The `InvalWindowRgn` function informs the Window Manager that an area of a window should be redrawn.

See also the functions `InvalWindowRect` (page 1898) and `ValidWindowRgn` (page 1969).

Special Considerations

This function should not be used on composited windows. Modifying a composited window's update region does not affect the area of the window to be drawn. A composited window does not use its window update region to control drawing. Instead, a composited window determines what to draw by looking at the invalid regions of the views contained in the window.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

InvokeWindowDefUPP

Invokes the UPP for a window definition. (Deprecated in Mac OS X v10.5. The WDEF interface is deprecated; use a custom HIView to draw your custom window frame instead.)

```
long InvokeWindowDefUPP (
   short varCode,
   WindowRef window,
   short message,
   long param,
   WindowDefUPP userUPP
);
```

Parameters

varCode
The window's variation code.

window
The window whose UPP is to be invoked.

message
The message.

param
The parameter.

userUPP
The UPP to invoke.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

InvokeWindowPaintUPP

Invokes the UPP for the specified painting region. (Deprecated in Mac OS X v10.5. The window content painting interface is deprecated; use a `kEventControlDraw` Carbon event handler on a compositing window's content view instead.)

```
OSStatus InvokeWindowPaintUPP (
   GDHandle device,
   GrafPtr qdContext,
   WindowRef window,
   RgnHandle inClientPaintRgn,
   RgnHandle outSystemPaintRgn,
   void *refCon,
   WindowPaintUPP userUPP
);
```

Parameters

device

The graphics device on which the window background should be painted.

qdContext

The QuickDraw port in which the window background should be painted.

window

The window whose UPP is to be invoked.

inClientPaintRgn

The region of the window background that needs to be painted, in local coordinates.

outSystemPaintRgn

On return, the region of the window background that the paint proc requests the Window Manager to paint.

refCon

Application-defined data.

userUPP

The UPP to invoke. For more information on this data type, see `WindowPaintUPP` (page 1987).

Return Value

A result code. See "Window Manager Result Codes" (page 2051).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Declared In

`MacWindows.h`

IsValidWindowClass

Determines whether a given window class is valid.

```
Boolean IsValidWindowClass (
   WindowClass inClass
);
```

Parameters

inClass

The window class to query.

Return Value

A Boolean whose value is `true` if the window class is valid; otherwise, `false`.

Availability

Available in Mac OS X v10.1 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

IsValidWindowPtr

Reports whether a pointer is a valid window pointer.

```
Boolean IsValidWindowPtr (
   WindowRef possibleWindow
);
```

Parameters

possibleWindow

The window to query.

Return Value

A Boolean whose value is `true` if the specified pointer is a valid window pointer; otherwise, `false`.

Discussion

This function is primarily intended for use with debugging your application.

Special Considerations

The `IsValidWindowPtr` function is a processor-intensive call.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

IsWindowActive

Indicates whether the specified window is active.

```
Boolean IsWindowActive (
   WindowRef inWindow
);
```

Parameters

inWindow

The window to query.

Return Value

Returns `true` if the window is active, `false` otherwise.

Discussion

Whether a window is considered active is determined by its activation scope, highlighting, and z-order. For windows that have an activation scope of `kWindowActivationScopeAll`, a window is active if it is the window returned by the `ActiveNonFloatingWindow` (page 1800) function or if it is in the same window group as the window returned by `ActiveNonFloatingWindow` and the window group has the `kWindowGroupAttrSharedActivation` attribute. For windows that have some other activation scope, the window is active if its window frame is highlighted and the window is the frontmost window in its window group.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

IsWindowCollapsable

Determines whether a window can be collapsed.

```
Boolean IsWindowCollapsable (
   WindowRef window
);
```

Parameters

window

The window to be examined.

Return Value

If `true`, the window can be collapsed; otherwise, `false`.

Discussion

You can call the `IsWindowCollapsable` function to determine if a given window can be collapsed by the `CollapseWindow` (page 1810) function. In Mac OS X, the presence or absence of the `kWindowCollapseBoxAttribute` is the primary way of determining whether a window can be collapsed. If that attribute is not present, the Window Manager checks for the `kWindowCanCollapse` feature bit.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

IsWindowCollapsed

Determines whether a window is currently collapsed.

```
Boolean IsWindowCollapsed (
   WindowRef window
);
```

Parameters

window
The window to be examined.

Return Value

If `true`, the window is collapsed. If `false`, the window is expanded.

Discussion

On Mac OS 9, only window definition functions that return the feature bit `kWindowCanCollapse` in response to a `kWindowGetFeatures` message support this function; for more information, see `GetWindowFeatures` (page 1847). Typically, a window's content region is empty in a collapsed state. In Mac OS X, the presence or absence of the `kWindowCollapseBoxAttribute` attribute determines whether a window can be collapsed.

Availability

Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In

`MacWindows.h`

IsWindowContainedInGroup

Determines if a window is a member of a window group or any of its subgroups.

```
Boolean IsWindowContainedInGroup (
   WindowRef inWindow,
   WindowGroupRef inGroup
);
```

Parameters

inWindow
The window to query.

inGroup
The window group to query.

Return Value

A Boolean whose value is `true` if `inWindow` is a member of the window group specified by `inGroup`, or if `inWindow` is a member of a window group that is a member of the window group specified by `inGroup`. Otherwise, this function returns `false`.

Discussion

This function returns `true` if group A contains window A. It also returns `true` if group A contains group B and group B contains window A.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In
MacWindows.h

IsWindowHilited

Indicates whether the window frame is currently highlighted.

```
Boolean IsWindowHilited (
   WindowRef window
);
```

Parameters

window
The window to query.

Return Value
A Boolean value indicating whether or not the window frame is highlighted. If `true`, the window is visible. If `false`, the window frame is not highlighted.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
MacWindows.h

IsWindowInStandardState

Determines whether a window is currently zoomed in to the user state or zoomed out to the standard state.

```
Boolean IsWindowInStandardState (
    WindowRef inWindow,
    const Point *inIdealSize,
    Rect *outIdealStandardState
);
```

Parameters

inWindow
The window whose zoom state is to be determined.

inIdealSize
Set the `Point` structure to contain the ideal width and height of the window's content region, regardless of the actual screen device dimensions. If you set `inIdealSize` to `NULL`, `IsWindowInStandardState` examines the dimensions stored in the `stdState` field of the `WStateData` structure.

outIdealStandardState
On input, a pointer to a structure of type `Rect`. On return, the rectangle contains the global coordinates for the content region of the window in its standard state, based on the data supplied in the `inIdealSize` parameter. You may pass `NULL` if you do not want to receive this data.

Return Value
A Boolean whose value is `true` if the window is currently in its standard state; `false` if the window is currently in the user state.

Discussion
The `IsWindowInStandardState` function compares the window's current dimensions to those referred to by the `inIdealSize` parameter to determine if the window is currently in the standard state. Your application may use `IsWindowInStandardState` to decide whether a user's click of the zoom box is a request to zoom to the user state or the standard state, as described in the function `ZoomWindowIdeal` (page 1972). Your application may also use `IsWindowInStandardState` to determine the size and position of the standard state that the Window Manager would calculate for a window, given a specified ideal size; this value is produced in the `outIdealStandardState` parameter.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

`HIWindowIsInStandardState` (page 1891)

Declared In
`MacWindows.h`

IsWindowLatentVisible

Indicates whether a window is visible onscreen or is latently visible but not currently onscreen.

```
Boolean IsWindowLatentVisible (
   WindowRef inWindow,
   WindowLatentVisibility *outLatentVisible
);
```

Parameters

inWindow
The window to query.

outLatentVisible
If the window is onscreen, the latent visibility is zero. If the window is offscreen, this parameter returns the latent visibility flags of the window. If any of the flags are set, the window is latently visible.

Return Value
A Boolean whose value is `true` if the window is currently onscreen; otherwise, `false`.

Discussion
All windows are either onscreen or offscreen. A window that is offscreen may still be latently visible. This occurs, for example, when a floating window is hidden as an application is suspended. The floating window is not visible onscreen, but it is latently visible and is only hidden due to the suspended state of the application. When the application becomes active again, the floating window will be placed back onscreen.

Availability
Available in Mac OS X v10.1 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

IsWindowModified

Obtains the modification state of the specified window.

```
Boolean IsWindowModified (
   WindowRef window
);
```

Parameters

window

The window whose modification state is to be obtained.

Return Value

`true` if the content of the window has been modified; otherwise, `false`. Newly created windows start out with their modification state automatically set to `true`.

Discussion

Your application can use the functions `IsWindowModified` and `SetWindowModified` (page 1946) instead of maintaining its own separate record of the modification state of the content of a window.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Related Sample Code

QTCarbonShell

Declared In

`MacWindows.h`

IsWindowPathSelectClick

Reports whether a mouse click should activate the window path pop-up menu. (Deprecated in Mac OS X v10.5. Use `IsWindowPathSelectEvent` (page 1908) instead.)

```
Boolean IsWindowPathSelectClick (
   WindowRef window,
   const EventRecord *event
);
```

Parameters

window

The window in which the mouse-down event occurred.

event

A pointer to the `EventRecord` structure containing the mouse-down event that `IsWindowPathSelectClick` is to examine.

Return Value

A Boolean whose value is `true` f the mouse click should activate the window path pop-up menu; otherwise `false`.

Discussion
The Window Manager provides system support for your application to display window path pop-up menus, such as those used in Finder windows. When the user presses the Command key and clicks on the window's title, the window displays a pop-up menu containing a standard file system path, informing the user of the location of the document displayed in the window and allowing the user to open windows for folders along the path.

Because the window title includes both the proxy icon region and part of the drag region of the window, your application must be prepared to respond to a click in either region by displaying a window path pop-up menu. Therefore, when the `FindWindow` (page 1827) function returns either the `inDrag` or the `inProxyIcon` result code—you should pass the event to the `IsWindowPathSelectClick` function to determine whether the mouse-down event should activate the window path pop-up menu. If `IsWindowPathSelectClick` returns a value of `true`, your application should then call the function `WindowPathSelect` (page 1970) to display the menu.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

IsWindowPathSelectEvent

Determines whether a Carbon event describing a click on a window's title should cause a path selection menu to be displayed.

```
Boolean IsWindowPathSelectEvent (
   WindowRef window,
   EventRef inEvent
);
```

Parameters

window
The window to query.

inEvent
The event. In CarbonLib and in Mac OS X v10.2 and earlier, the function only returns `true` for `kEventClassMouse`/`kEventMouseDown` events. In Mac OS X v10.3 and later, this function returns `true` for any event that has suitable `kEventParamMouseLocation` and `kEventParamModifiers` parameters.

Return Value
A Boolean whose value is `true` if the click should cause a path selection menu to be displayed; otherwise, `false`. If this function returns `true`, the application should call `WindowPathSelect` (page 1970).

Discussion
Windows that have a proxy icon provided using an `FSRef` or alias can support a path selection menu, which displays the file system path to the object, one menu item per directory. Making a selection from this item automatically opens the corresponding object in the Finder.

Availability
Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In
MacWindows.h

IsWindowToolbarVisible

Determines whether a window's toolbar is visible.

```
Boolean IsWindowToolbarVisible (
   WindowRef inWindow
);
```

Parameters

inWindow
The window to query.

Return Value
A Boolean whose value is `true` if the window's toolbar is visible; otherwise, `false`.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
MacWindows.h

IsWindowUpdatePending

Determines whether a window update is pending.

```
Boolean IsWindowUpdatePending (
   WindowRef window
);
```

Parameters

window
The non-composited window to query.

Return Value
A Boolean whose value is `true` if an update is pending; otherwise, `false`.

Special Considerations

Modifying a composited window's update region does not affect the area of the window to be drawn. A composited window does not use its window update region to control drawing. Instead, a composited window determines what to draw by looking at the invalid regions of the views contained in the window.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
MacWindows.h

IsWindowVisible

Indicates whether the window frame is currently visible.

```
Boolean IsWindowVisible (
    WindowRef window
);
```

Parameters

window

The window to query.

Return Value

A Boolean value indicating whether or not the window is visible. If `true`, the window is visible. If `false`, the window is invisible.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

MoveWindow

Moves a window on the desktop.

```
void MoveWindow (
    WindowRef window,
    short hGlobal,
    short vGlobal,
    Boolean front
);
```

Parameters

window

The window that is to be moved on the desktop.

hGlobal

On input, the new location, in global coordinates, of the left edge of the window's port rectangle.

vGlobal

On input, the new location, in global coordinates, of the top edge of the window's port rectangle.

front

On input, a Boolean value specifying whether the window is to become the frontmost, active window. If the value of the front parameter is `false`, `MoveWindow` does not change its plane or status. If the value of the front parameter is `true` and the window isn't active, `MoveWindow` makes it active by calling the `SelectWindow` (page 1929) function.

Discussion

The `MoveWindow` function moves the specified window to the location specified by the `hGlobal` and `vGlobal` parameters, without changing the window's size. The upper-left corner of the window's port rectangle is placed at the point (`vGlobal`, `hGlobal`). The local coordinates of the upper-left corner are unaffected.

Your application doesn't normally call `MoveWindow`. When the user drags a window by dragging its title bar, you can call `DragWindow` (page 1824) which in turn calls `MoveWindow` when the user releases the mouse button.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
HID Calibrator

Declared In
`MacWindows.h`

MoveWindowStructure

Positions a window relative to its structure region.

```
OSStatus MoveWindowStructure (
   WindowRef window,
   short hGlobal,
   short vGlobal
);
```

Parameters

window
The window that is to be moved.

hGlobal
A value specifying the horizontal position, in global coordinates, to which the left edge of the window's structure region is to be moved.

vGlobal
A value specifying the vertical position, in global coordinates, to which the top edge of the window's structure region is to be moved.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
The `MoveWindowStructure` function moves the specified window, but does not change the window's size. When your application calls `MoveWindowStructure`, the positioning of the specified window is determined by the positioning of its structure region. This is in contrast to the `MoveWindow` function, where the positioning of the window's content region determines the positioning of the window. After moving the window, `MoveWindowStructure` displays the window in its new position.

Note that your application should not call the `MoveWindowStructure` function to position a window when the user drags the window by its drag region. When the user drags the window, your application should call the pre–Mac OS 8.5 Window Manager function `DragWindow`.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
QTCarbonShell

Declared In
MacWindows.h

NewCWindow

Creates a window with a specified list of characteristics. (Deprecated in Mac OS X v10.5. Use CreateNewWindow (page 1815) instead.)

```
WindowRef NewCWindow (
   void *wStorage,
   const Rect *boundsRect,
   ConstStr255Param title,
   Boolean visible,
   short procID,
   WindowRef behind,
   Boolean goAwayFlag,
   SRefCon refCon
);
```

Parameters

wStorage

On input, a pointer to the window structure. If you specify null as the value of wStorage, NewCWindow allocates the window structure as a nonrelocatable object in the application heap. You can reduce the chances of heap fragmentation by allocating memory from a block of memory reserved for this purpose by your application and passing a pointer to it in the wStorage parameter.

boundsRect

On input, a pointer to a rectangle, given in global coordinates, that specifies the window's initial size and location. This rectangle becomes the port rectangle of the window's graphics port. For the standard window types, the boundsRect field defines the content region of the window. The NewCWindow function places the origin of the local coordinate system at the upper-left corner of the port rectangle. NewCWindow calls the QuickDraw function OpenCPort to create the graphics port. The bitmap, pen pattern, and other characteristics of the window's graphics port are the same as the default values set by OpenCPort, except for the character font, which is set to the application font instead of the system font.

title

On input, a pascal string that specifies the window's title. If the title is too long to fit in the title bar, the title is truncated. To suppress the title in a window with a title bar, pass an empty string, not null, in the title parameter. null is an invalid value and may cause runtime errors.

visible

On input, a Boolean value indicating visibility status: `true` means that the Window Manager displays the window; `false` means it does not. If the value of the `visible` parameter is `true`, the Window Manager draws a new window as soon as the window exists. The Window Manager first calls the window definition function to draw the window frame. If the value of the `goAwayFlag` parameter is also `true` and the window is frontmost (that is, if the value of the behind parameter is (`WindowRef`)–`1L`), the Window Manager instructs the window definition function to draw a close box in the window frame. After drawing the frame, the Window Manager generates an update event to trigger your application's drawing of the content region.

When you create a window, you typically specify `false` as the value of the `visible` parameter. When you're ready to display the window, call `ShowWindow`.

procID

On input, the window's definition ID, a value that specifies both the window definition function and the variation code within that definition function. For a list of possible values, see "Pre-Appearance Window Definition IDs" (page 2048).

behind

On input, a pointer to the window that appears immediately in front of the new window on the desktop. To place a new window in front of all other windows on the desktop, specify a value of (`WindowRef`)–`1L`. When you place a new window in front of all others, `NewCWindow` removes highlighting from the previously active window, highlights the newly created window, and generates activate events that trigger your application's updating of both windows. Note that if you create an invisible window in front of all others on the desktop, the user sees no active window until you make the new window visible (or make another window active).

To place a new window behind all other windows, specify a value of `null`.

goAwayFlag

On input, a Boolean value that determines whether the window has a close box. If the value of `goAwayFlag` is `true` and the window type supports a close box, the Window Manager draws a close box in the title bar and recognizes mouse clicks in the close region; if the value of `goAwayFlag` is `false` or the window type does not support a close box, it does not.

refCon

On input, a window's reference constant, set and used only by your application.

Return Value
A pointer to the newly created window structure.

Discussion
The `NewCWindow` function creates a window as specified by its parameters, adds it to the window list, and returns a pointer to the newly created window structure. You can use the returned window pointer to refer to this window in most Window Manager functions. If `NewCWindow` is unable to read the window definition function from the resource file, it returns `null`.

The `NewCWindow` function looks for a `'wctb '` resource with the same resource ID as the `'WIND '` resource. If it finds one, it uses the window color information in the `'wctb '` resource for coloring the window content region.

If the window's definition function is not already in memory, `NewCWindow` reads it into memory and stores a handle to it in the window structure. It allocates space for the structure and content regions of the window.

Storing the characteristics of your windows as resources, especially window titles and window items, makes your application easier to localize.

The `NewCWindow` function creates a window in a color graphics port. Creating color windows whenever possible ensures that your windows appear on color monitors with whatever color options the user has selected. Your application typically sets up its own set of global variables reflecting the system setup during initialization by calling the `Gestalt` function.

Special Considerations

If you let the Window Manager create the window structure in your application's heap, call `DisposeWindow` to close the window and dispose of its window structure. If you allocated the memory for the window structure yourself and passed a pointer to `NewCWindow`, use the function `CloseWindow` to close the window and the appropriate disposal function (determined by how you have allocated memory) to dispose of the window structure.

Carbon Porting Notes

In Carbon, you cannot pass your own storage in to the `wStorage` parameter.

Carbon does not support custom window definitions stored in 'WDEF' resources. If you want to specify a custom window definition for `NewCWindow`, you must compile your definition function directly in your application and then register the function by calling `RegisterWindowDefinition`. When `NewCWindow` gets a `procID` value that doesn't recognize, it checks a special mapping table to find the pointer that's registered for the resource ID embedded in the `procID` parameter. It then calls that function to implement your window.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

NewWindow

Creates a window from a parameter list. (Deprecated in Mac OS X v10.5. Use `CreateNewWindow` (page 1815) instead.)

```
WindowRef NewWindow (
   void *wStorage,
   const Rect *boundsRect,
   ConstStr255Param title,
   Boolean visible,
   short theProc,
   WindowRef behind,
   Boolean goAwayFlag,
   SRefCon refCon
);
```

Parameters

wStorage

On input, a pointer to the window structure. If you specify `null` as the value of `wStorage`, `NewWindow` allocates the window structure as a nonrelocatable object in the heap. You can reduce the chances of heap fragmentation by allocating the storage from a block of memory reserved for this purpose by your application and passing a pointer to it in the `wStorage` parameter.

boundsRect

On input, a pointer to a rectangle, given in global coordinates, which specifies the window's initial size and location. This rectangle becomes the port rectangle of the window's graphics port. For the standard window types, `boundsRect` defines the content region of the window. The `NewWindow` function places the origin of the local coordinate system at the upper-left corner of the port rectangle. `NewWindow` calls the QuickDraw function `OpenPort` to create the graphics port. The bitmap, pen pattern, and other characteristics of the window's graphics port are the same as the default values set by `OpenPort`, except for the character font, which is set to the application font instead of the system font. The coordinates of the graphics port's port boundaries and visible region are changed along with its port rectangle.

title

On input, a pascal string that specifies the window's title. If the title is too long to fit in the title bar, the title is truncated. To suppress the title in a window with a title bar, pass an empty string, not `null`. `null` is an invalid value and may cause runtime errors.

visible

On input, a Boolean value indicating visibility status: `true` means that the Window Manager displays the window; `false` means it does not.

If the value of the `visible` parameter is `true`, the Window Manager draws a new window as soon as the window exists. The Window Manager first calls the window definition function to draw the window frame. If the value of the `goAwayFlag` parameter (described below) is also `true` and the window is frontmost (that is, if the value of the behind parameter is (`WindowRef`(–`1L`), the Window Manager instructs the window definition function to draw a close box in the window frame. After drawing the frame, the Window Manager generates an update event to trigger your application's drawing of the content region.

When you create a window, you typically specify `false` as the value of the `visible` parameter. When you're ready to display the window, you call the function `ShowWindow`.

theProc

On input, the window's definition ID, which specifies both the window definition function and the variation code for that definition function. For a list of possible values, see "`Pre-Appearance Window Definition IDs`" (page 2048).

behind

On input, a pointer to the window that appears immediately in front of the new window on the desktop. To place a new window in front of all other windows on the desktop, specify a value of (`WindowRef`)–`1L`. When you place a new window in front of all others, `NewWindow` removes highlighting from the previously active window, highlights the newly created window, and generates activate events that trigger your application's updating of both windows. Note that if you create an invisible window in front of all others on the desktop, the user sees no active window until you make the new window visible (or make another window active).

To place a new window behind all other windows, specify a value of `null`.

goAwayFlag

On input, a Boolean value that determines whether or not the window has a close box. If the value of `goAwayFlag` is `true` and the window type supports a close box, the Window Manager draws a close box in the title bar and recognizes mouse clicks in the close region; if the value of `goAwayFlag` is `false` or the window type does not support a close box, it does not. The `goAwayFlag` parameter is ignored for movable modal or modal dialog boxes which do not support a close box.

refCon

On input, the window's reference constant, set and used only by your application.

Discussion

The `NewWindow` function takes the same parameters as `NewCWindow` and returns a `WindowRef` as its function result. The only difference is that `NewWindow` creates a window in a monochrome graphics port, not a color graphics port. The window structure and graphics port structure that describe monochrome and color graphics ports are the same size and can be used interchangeably in most Window Manager functions.

The `NewWindow` function creates a window as specified by its parameters, adds it to the window list, and returns a pointer to the newly created window structure. You can use the returned window pointer to refer to this window in most Window Manager functions. If `NewWindow` is unable to read the window definition function from the resource file, it returns `null`.

If the window's definition function is not already in memory, `NewWindow` reads it into memory and stores a handle to it in the window structure. It allocates space for the structure and content regions of the window.

Storing the characteristics of your windows as resources, especially window titles and window items, makes your application easier to localize.

Special Considerations

If you let the Window Manager create the window structure in your application's heap, call `DisposeWindow` to close the window and dispose of its window structure. If you allocated the memory for the window structure yourself and passed a pointer to `NewWindow`, use the function `CloseWindow` to close the window and the appropriate disposal function (determined by how you have allocated memory) to dispose of the window structure.

Version Notes

The `NewWindow` function was originally implemented prior to Color QuickDraw. In Mac OS 8, you should call the Color QuickDraw function `NewCWindow` instead of `NewWindow` to programmatically create a window, because Color QuickDraw is always available in Mac OS 8. Use of this function is not recommended with Mac OS 8 and later. `NewWindow` is described here only for completeness.

Carbon Porting Notes

In Carbon, you cannot pass your own storage in to the `wStorage` parameter.

In Carbon, `NewWindow` is functionally equivalent to the `NewCWindow`, in that `NewWindow` returns a color window instead of a monochrome window.

Carbon does not support custom window definitions stored in 'WDEF' resources. If you want to specify a custom window definition for `NewWindow`, you must compile your definition function directly in your application and then register the function by calling `RegisterWindowDefinition`. When `NewWindow` gets a `procID` value that doesn't recognize, it checks a special mapping table to find the pointer that's registered for the resource ID embedded in the `procID` parameter. It then calls that function to implement your window.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

NewWindowDefUPP

Creates a new UPP for a window definition. (Deprecated in Mac OS X v10.5. The WDEF interface is deprecated; use a custom HIView to draw your custom window frame instead.)

```
WindowDefUPP NewWindowDefUPP (
   WindowDefProcPtr userRoutine
);
```

Parameters

userRoutine

For information, see `WindowDefProcPtr` (page 1973).

Return Value

For a description of the `WindowDefUPP` data type, see `WindowDefUPP` (page 1986).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

NewWindowPaintUPP

Creates a new UPP for a painting region. (Deprecated in Mac OS X v10.5. The window content painting interface is deprecated; use a `kEventControlDraw` Carbon event handler on a compositing window's content view instead.)

```
WindowPaintUPP NewWindowPaintUPP (
   WindowPaintProcPtr userRoutine
);
```

Parameters

userRoutine

For information, see `WindowPaintProcPtr` (page 1978).

Return Value

A UPP to the window paint function.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Declared In

`MacWindows.h`

OpenDrawer

Opens a drawer.

```
OSStatus OpenDrawer (
   WindowRef inDrawerWindow,
   OptionBits inEdge,
   Boolean inAsync
);
```

Parameters

inDrawerWindow

The drawer window to open.

inEdge

The parent window edge on which to open the drawer. Pass `kWindowEdgeDefault` to use the drawer's preferred edge. If there is not enough room on the preferred edge, `OpenDrawer` tries the opposite edge. If there is insufficient room on both edges, the drawer will open on the preferred edge but may extend offscreen, under the Dock, or under the menu bar.

inAsync

Indicates whether to open the drawer synchronously (the drawer is entirely opened before the function call returns) or asynchronously (the drawer opens using an event loop timer after the function call returns). Specify `true` for asynchronous and `false` for synchronous.

Return Value

A result code. See "Window Manager Result Codes" (page 2051).

Availability

Available in Mac OS X v10.2 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

PaintBehind

Redraws a series of windows in the window list. (Deprecated in Mac OS X v10.5. Use `InvalWindowRect` (page 1898), `InvalWindowRgn` (page 1899), or `HIViewSetNeedsDisplay` (page 2485) to invalidate a portion of a window.)

```
void PaintBehind (
   WindowRef startWindow,
   RgnHandle clobberedRgn
);
```

Parameters

startWindow

On input, a pointer to the window's complete window structure.

clobberedRgn

On input, a handle to the region that has become invalid.

Discussion

The Window Manager calls the `PaintBehind` function; your application does not normally need to. `PaintBehind` calls `PaintOne` for `startWindow` and all the windows behind `startWindow`, clipped to `clobberedRgn`.

Special Considerations

Mac OS X applications never need to call this function.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

PaintOne

Redraws the invalid, exposed portions of one window on the desktop. (Deprecated in Mac OS X v10.5. Use `InvalWindowRect` (page 1898), `InvalWindowRgn` (page 1899), or `HIViewSetNeedsDisplay` (page 2485) to invalidate a portion of a window.)

```
void PaintOne (
   WindowRef window,
   RgnHandle clobberedRgn
);
```

Parameters

window
On input, a pointer to the window structure.

clobberedRgn
On input, a handle to the region that has become invalid.

Discussion
The Window Manager calls the `PaintOne` function; your application does not normally need to. `PaintOne` "paints" the invalid portion of the specified window and all windows above it. `PaintOne` draws as much of the window frame as is in `clobberedRgn` and, if some content region is exposed, erases the exposed area (paints it with the content pattern rather than the background pattern using `SetWinColor` or `SetThemeWindowBackground`) and adds it to the window's update region.

If the value of the `window` parameter is `null`, the window is the desktop, and `PaintOne` paints it with the desktop pattern.

Special Considerations

Mac OS X applications never need to call this function.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

PinRect

Returns the point within the specified rectangle that is closest to the specified point.

```
long PinRect (
   const Rect *theRect,
   Point thePt
);
```

Parameters

theRect

On input, a pointer to a rectangle in which the point is to be contained.

thePt

On input, a pointer to the point to be contained.

Return Value

A long integer that specifies a point within the specified rectangle that is as close as possible to the specified point. (The high-order word of the returned long integer is the vertical coordinate; the low-order word is the horizontal coordinate.

Discussion

`DragGrayRgn` uses the `PinRect` function to contain a point within a specified rectangle. If the specified point is within the rectangle, `PinRect` returns the point itself. If not, then

- if the horizontal position is to the left of the rectangle, `PinRect` returns the left edge as the horizontal coordinate
- if the horizontal position is to the right of the rectangle, `PinRect` returns the right edge minus 1 as the horizontal coordinate
- if the vertical position is above the rectangle, `PinRect` returns the top edge as the vertical coordinate
- if the vertical position is below the rectangle, `PinRect` returns the bottom edge minus 1 as the vertical coordinate

The 1 is subtracted when the point is below or to the right of the rectangle so that a pixel drawn at that point lies within the rectangle.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

RegisterWindowDefinition

Registers a binding between a resource ID and a window definition function.

```
OSStatus RegisterWindowDefinition (
   SInt16 inResID,
   const WindowDefSpec *inDefSpec
);
```

Parameters

inResID

A WDEF proc ID, as used in a `'WIND'` resource.

inDefSpec

Specifies the `WindowDefUPP` that should be used for windows with the given WDEF proc ID. Pass `NULL` to unregister a given WDEF proc ID.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
In the Mac OS 8.x Window Manager, a `'WIND'` resource can contain an embedded WDEF procID that is used by the Window Manager as the resource ID of a `'WDEF'` resource to lay out and draw the window. The `'WDEF'` resource is loaded by the Window Manager when you load the window with `GetNewWindow`. Since WDEFs can no longer be packaged as code resources on Carbon, the procID can no longer refer directly to a WDEF resource. However, using `RegisterWindowDefinition` you can instead specify a UniversalProcPtr pointing to code in your application code fragment.

To unregister a window definition, pass `NULL` in the `inDefSpec` parameter for a given WDEF proc ID.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

ReleaseQDContextForCollapsedWindowDockTile

Releases a port and other state created by `CreateQDContextForCollapsedWindowDockTile`. (Deprecated in Mac OS X v10.5. Use `HIWindowReleaseCollapsedDockTileContext` (page 1892) instead.)

```
OSStatus ReleaseQDContextForCollapsedWindowDockTile (
   WindowRef inWindow,
   CGrafPtr inContext
);
```

Parameters

inWindow

The window whose port is to be released.

inContext

The port that is to be released.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
You must call this function instead of calling `DisposePort` directly, or you may leak system resources.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
MacWindows.h

ReleaseWindow

Decrements the retain count of a window, and destroys the window if the retain count falls to zero. (Deprecated in Mac OS X v10.5. Use `CFRelease` instead.)

```
OSStatus ReleaseWindow (
   WindowRef inWindow
);
```

Parameters

inWindow
The window whose retain count is to be decremented.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
This API is equivalent to `DisposeWindow` (page 1820). For consistency with Core Foundation and Carbon Events, it is preferred over `DisposeWindow`. Both APIs will continue to be supported.

In Mac OS X v10.2 and later, you can also call `CFRelease` to decrement the retain count of a window.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
MacWindows.h

ReleaseWindowGroup

Decrements the reference count for a window group.

```
OSStatus ReleaseWindowGroup (
   WindowGroupRef inGroup
);
```

Parameters

inGroup
The window group whose reference count is to be queried.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
MacWindows.h

RemoveWindowProperty

Removes a piece of data that is associated with a window.

```
OSStatus RemoveWindowProperty (
   WindowRef window,
   PropertyCreator propertyCreator,
   PropertyTag propertyTag
);
```

Parameters

window

The window whose data is to be removed.

propertyCreator

The creator code (typically, the application's signature) of the associated data to be removed.

propertyTag

The application-defined code identifying the associated data to be removed.

Return Value

A result code. See "Window Manager Result Codes" (page 2051).

Discussion

The data removed by the `RemoveWindowProperty` function must have been previously associated with the window with the function `SetWindowProperty` (page 1948).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

RemoveWindowProxy

Dissociates a file from a window.

```
OSStatus RemoveWindowProxy (
   WindowRef window
);
```

Parameters

window

The window for which you want to remove the associated file.

Return Value

A result code. See "Window Manager Result Codes" (page 2051).

Discussion

The `RemoveWindowProxy` function redraws the window title bar after removing all data associated with a given file, including the proxy icon, path menu, and file data.

Special Considerations

On Mac OS 8.x and Mac OS 9.x, you must save and restore the current graphics port—by calling the QuickDraw functions `GetPort` and `SetPort`—around each call to the `RemoveWindowProxy` function.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
QTCarbonShell

Declared In
`MacWindows.h`

RepositionWindow

Positions a window relative to another window or a display screen.

```
OSStatus RepositionWindow (
   WindowRef window,
   WindowRef parentWindow,
   WindowPositionMethod method
);
```

Parameters

`window`
The window whose position you want to set.

`parentWindow`
A pointer to the "parent" window, as defined by your application. In cases where the window positioning method does not require a parent window, you should set the `parentWindow` parameter to `NULL`.

`method`
A constant specifying the window positioning method to be used; see "Window Position Constants" (page 2017) for descriptions of possible values.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
Your application may call the `RepositionWindow` function to position any window, relative to another window or to a display screen. After positioning the window, `RepositionWindow` displays the window in its new position.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
BSDLLCTest

Declared In
`MacWindows.h`

ReshapeCustomWindow

Notifies the Window Manager that a custom window's shape has changed.

```
OSStatus ReshapeCustomWindow (
   WindowRef window
);
```

Parameters

window

The window whose shape has changed.

Return Value

A result code. See "Window Manager Result Codes" (page 2051).

Discussion

If the shape of a custom window needs to change dynamically, outside of the context of normal Window Manager operations, you must use `ReshapeCustomWindow` to notify the Window Manager so that it can recalculate the window regions and update the screen. The Window Manager queries your custom window definition for the new structure and content regions and updates the screen with the new window shape.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

ResizeWindow

Handles all user interaction while a window is being resized.

```
Boolean ResizeWindow (
   WindowRef inWindow,
   Point inStartPoint,
   const Rect *inSizeConstraints,
   Rect *outNewContentRect
);
```

Parameters

window

The window that is to be resized.

inStartPoint

Set the `Point` structure to contain the location, specified in global coordinates, where the mouse-down event occurred. Your application may retrieve this value from the `where` field of the `EventRecord` structure.

inSizeConstraints

Set the rectangle to specify the limits on the vertical and horizontal measurements of the content rectangle, in pixels. Although this parameter gives the address of a structure that is in the form of the `Rect` data type, the four numbers in the structure represent limits, not screen coordinates. The `top`, `left`, `bottom`, and `right` fields of the structure specify the minimum vertical measurement (`top`), the minimum horizontal measurement (`left`), the maximum vertical measurement (`bottom`), and the maximum horizontal measurement (`right`). The minimum dimensions should be large enough to allow a manageable rectangle; 64 pixels on a side is typical. The maximum dimensions can be no greater than 32,767. You can pass `NULL` to allow the user to resize the window to any size that is contained onscreen.

outNewContentRect
On input, a pointer to a structure of type `Rect`. On return, the structure contains the new dimensions of the window's content region, in global coordinates.

Return Value
`true` if the window was successfully resized; otherwise, `false`.

Discussion
The `ResizeWindow` function moves either an outline of the window's edges (Mac OS 9.x and earlier) or the actual window (Mac OS X) around the screen, following the user's cursor movements, and handles all user interaction until the mouse button is released. Unlike with the function `GrowWindow`, there is no need to follow this call with a call to the function `SizeWindow`, because once the mouse button is released, `ResizeWindow` resizes the window if the user has changed the window size. Once the resizing is complete, `ResizeWindow` draws the window in the new size.

Your application should call `ResizeWindow` instead of the earlier Window Manager functions `SizeWindow` and `GrowWindow`. The `ResizeWindow` function informs your application of the new window bounds, so that your application can respond to any changes in the window's position.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

RetainWindow

Increments the retain count of a window. (Deprecated in Mac OS X v10.5. Use `CFRetain` instead.)

```
OSStatus RetainWindow (
   WindowRef inWindow
);
```

Parameters
inWindow
The window whose retain count is to be incremented.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
This API is equivalent to `CloneWindow` (page 1808). For consistency with Core Foundation and Carbon Events, it is preferred over `CloneWindow`. Both APIs will continue to be supported.

In Mac OS X v10.2 and later, you can also call `CFRetain` to increment the retain count of a window.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

RetainWindowGroup

Increments the reference count for a window group.

```
OSStatus RetainWindowGroup (
   WindowGroupRef inGroup
);
```

Parameters

inGroup

The window group whose reference count is to be incremented. For information on this data type, see `WindowGroupRef` (page 1986).

Return Value

A result code. See "Window Manager Result Codes" (page 2051).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

ScrollWindowRect

Scroll any area of a window.

```
OSStatus ScrollWindowRect (
   WindowRef inWindow,
   const Rect *inScrollRect,
   SInt16 inHPixels,
   SInt16 inVPixels,
   ScrollWindowOptions inOptions,
   RgnHandle outExposedRgn
);
```

Parameters

inWindow

The window to scroll in.

inScrollRect

The rectangle to scroll, in local coordinates.

inHPixels

The number of pixels to scroll horizontally.

inVPixels

The number of pixels to scroll vertically.

inOptions

Options for the scroll. See "Window Scrolling Options" (page 2044) for a list of possible options.

outExposedRgn

A valid region handle for the area newly revealed by the scroll (can be `NULL`). If `NULL`, the exposed region is added to the window's update region, regardless of the state of the `kScrollWindowInvalidate` option. This prevents updates from being lost in multiple monitor situations where the Window Manager can't copy the entire region due to differing color tables.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
Scrolls pixels that are inside the specified region of the input window. No other pixels or the bits they represent are affected. The pixels are shifted a distance of `inHPixels` horizontally and `inVPixels` vertically. The positive directions are to the right and down. The pixels that are shifted out of the specified window are not displayed, and the bits they represent are not saved. The exposed empty area created by the scrolling is returned in the update region parameter and optionally added to the window's update region.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

ScrollWindowRegion

Scrolls a window's region.

```
OSStatus ScrollWindowRegion (
   WindowRef inWindow,
   RgnHandle inScrollRgn,
   SInt16 inHPixels,
   SInt16 inVPixels,
   ScrollWindowOptions inOptions,
   RgnHandle outExposedRgn
);
```

Parameters

inWindow
The window to scroll in.

inScrollRgn
The region to scroll, in local coordinates.

inHPixels
The number of pixels to scroll horizontally.

inVPixels
The number of pixels to scroll vertically.

inOptions
Options for the scroll. See "Window Scrolling Options" (page 2044) for a list of possible options.

outExposedRgn
A valid region handle for the area newly revealed by the scroll (can be `NULL`). If `NULL`, the exposed region is added to the window's update region, regardless of the state of the `kScrollWindowInvalidate` option. This prevents updates from being lost in multiple monitor situations where the Window Manager can't copy the entire region due to differing color tables.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
Scrolls pixels that are inside the specified region of the input window. No other pixels or the bits they represent are affected. The pixels are shifted a distance of `inHPixels` horizontally and `inVPixels` vertically. The positive directions are to the right and down. The pixels that are shifted out of the specified window are not displayed, and the bits they represent are not saved. The exposed empty area created by the scrolling is returned in the update region parameter and optionally added to the window's update region

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

SelectWindow

Makes a window active.

```
void SelectWindow (
   WindowRef window
);
```

Parameters
window
The window that is to be made active.

Discussion
The `SelectWindow` function removes highlighting from the previously active window, brings the specified window to the front, highlights it, and generates the activate events to deactivate the previously active window and activate the specified window. If the specified window is already active, `SelectWindow` has no effect. Call `SelectWindow` when the user presses the mouse button while the cursor is in the content region of an inactive window.

Even if the specified window is invisible, `SelectWindow` brings the window to the front, activates the window, and deactivates the previously active window. Note that in this case, no active window is visible on the screen. If you do select an invisible window, be sure to call `ShowWindow` (page 1959) immediately to make the window visible (and accessible to the user).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
HideMenuBar
QTCarbonShell

Declared In
`MacWindows.h`

SendBehind

Moves one window behind another.

```
void SendBehind (
   WindowRef window,
   WindowRef behindWindow
);
```

Parameters

window

The window to be moved.

behindWindow

On input, a pointer to the window that is to be in front of the moved window.

Discussion

The `SendBehind` function moves the window pointed to by the parameter `window` behind the window pointed to by the parameter `behindWindow`. If the move exposes previously obscured windows or parts of windows, `SendBehind` redraws the frames as necessary and generates the appropriate update events to have any newly exposed content areas redrawn.

If the value of `behindWindow` is `NULL`, `SendBehind` sends the window to be moved behind all other windows on the desktop. If the window to be moved is the active window, `SendBehind` removes its highlighting, highlights the newly exposed frontmost window, and generates the appropriate activate events.

Do not use `SendBehind` to deactivate a window after you've made a new window active with the function `SelectWindow` (page 1929). The `SelectWindow` function automatically deactivates the previously active window.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

SendWindowGroupBehind

Orders one window group behind another.

```
OSStatus SendWindowGroupBehind (
   WindowGroupRef inGroup,
   WindowGroupRef behindGroup
);
```

Parameters

inGroup

The window group.

behindGroup

The "behind" window group.

Return Value

A result code. See "Window Manager Result Codes" (page 2051).

Discussion

A window group can contain multiple window groups. You can use this function to order nested groups.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

SetDrawerOffsets

Sets the positioning offsets for the drawer with respect to its parent window.

```
OSStatus SetDrawerOffsets (
   WindowRef inDrawerWindow,
   CGFloat inLeadingOffset,
   CGFloat inTrailingOffset
);
```

Parameters

inDrawerWindow
The drawer window whose positioning offsets are to be set.

inLeadingOffset
The new leading offset, in pixels. Pass `kWindowOffsetUnchanged` if you don't want to change the leading offset.

inTrailingOffset
The new trailing offset, in pixels. Pass `kWindowOffsetUnchanged` if you don't want to change the trailing offset.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

SetDrawerParent

Sets the parent window for a drawer.

```
OSStatus SetDrawerParent (
   WindowRef inDrawerWindow,
   WindowRef inParent
);
```

Parameters

inDrawerWindow
The drawer window whose parent window is to be set.

inParent
The window that is to be set as the parent of the window specified by `inDrawerWindow`.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

SetDrawerPreferredEdge

Set the preferred window edge from which the drawer should appear.

```
OSStatus SetDrawerPreferredEdge (
   WindowRef inDrawerWindow,
   OptionBits inEdge
);
```

Parameters

inDrawerWindow
The drawer window whose preferred window edge is to be set.

inEdge
The preferred edge. See "Window Edge Constants" (page 2041) for a list of possible values.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

SetPortWindowPort

Sets the current graphics port to the window's port.

```
void SetPortWindowPort (
   WindowRef window
);
```

Parameters

window
The window whose graphics port is to be set.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
HID Explorer

QTCarbonShell

Declared In
MacWindows.h

SetThemeTextColorForWindow

Sets a text color that contrasts with a theme brush.

```
OSStatus SetThemeTextColorForWindow (
   WindowRef inWindow,
   Boolean inActive,
   SInt16 inDepth,
   Boolean inColorDev
);
```

Parameters

inWindow
The window whose text color is to be set.

inActive
A Boolean whose value is `true` to indicate an active state or `false` to indicate an inactive state.

inDepth
The bit depth of the window's port. In Mac OS X, this parameter is ignored and should always be set to `32`.

inColorDev
A Boolean whose value is `true` to indicate that the window's port is color or `false` to indicate that the port is black and white. In Mac OS X, this parameter is ignored and should always be set to `true`.

Return Value
A result code. See "Window Manager Result Codes" (page 2051) for a list of possible values.

Discussion
`SetThemeTextColorForWindow` sets a text color in the specified window's port that contrasts with the brush specified by `SetThemeWindowBackground` (page 1933) and also matches the `inActive` parameter.

Only a subset of the theme brushes have theme text colors. As of Mac OS 9 and Mac OS X v10.4 and later, the Alert, Dialog, Modeless Dialog, and Notification brushes have corresponding text colors. For any other brush, `SetThemeTextColorForWindow` returns `themeNoAppropriateBrushErr` and does not modify the text color.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
MacWindows.h

SetThemeWindowBackground

Sets a window's background theme.

```
OSStatus SetThemeWindowBackground (
   WindowRef inWindow,
   ThemeBrush inBrush,
   Boolean inUpdate
);
```

Parameters

inWindow

The window whose background theme is to be set.

inBrush

The theme brush that determines how the window background is painted. For information on theme brushes, see the Appearance Manager documentation.

inUpdate

A Boolean whose value is `true` if you want the window to be redrawn immediately using the new background brush; otherwise, `false`.

Return Value
A result code. See "Window Manager Result Codes" (page 2051) for a list of possible values.

Availability
Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In
`MacWindows.h`

SetUserFocusWindow

Designates a window to receive user focus.

```
OSStatus SetUserFocusWindow (
    WindowRef inWindow
);
```

Return Value
A result code.

Discussion
You can use this function to assign user focus to a specified window. This tells the Carbon Event Manager to route events that should go to the user focus (for example, commands and keyboard events) to the specified window. This can be used, for example, to route keyboard events to a floating palette, since floating palettes do not normally receive user focus.

Setting focus automatically defocuses whatever element formerly had user focus. If the focus changes to a new window, the `kEventWindowFocusAcquired` Carbon event will be sent to the newly focused window, and the `kEventWindowFocusRelinquish` Carbon event will be sent to the previously focused window.

If you pass `kUserFocusAuto` in the `inWindow` parameter, the system picks the best candidate for user focus (typically, this will be the active window). If you temporarily change the focus to a special window, you should use this option to restore the focus rather than setting the focus to an explicit window.

Availability
Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In
MacWindows.h

SetWindowActivationScope

Sets a window's activation scope.

```
OSStatus SetWindowActivationScope (
   WindowRef inWindow,
   WindowActivationScope inScope
);
```

Parameters

inWindow
The window whose activation scope is to be set.

inScope
The new activation scope.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
MacWindows.h

SetWindowAlpha

Sets the window's alpha channel value.

```
OSStatus SetWindowAlpha (
   WindowRef inWindow,
   CGFloat inAlpha
);
```

Parameters

inWindow
The window whose alpha channel value is to be set.

inAlpha
The alpha value to set. This value can range from 0.0 (completely transparent) to 1.0 (opaque).

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
MacWindows.h

SetWindowAlternateTitle

Sets an alternate window title.

```
OSStatus SetWindowAlternateTitle (
   WindowRef inWindow,
   CFStringRef inTitle
);
```

Parameters

inWindow

The window for which to set the alternate title.

inTitle

The alternate title for the window. Passing `NULL` for this parameter will remove any alternate title that might be present.

Return Value

A result code. See "Window Manager Result Codes" (page 2051). An operating system status code.

Discussion

This API sets an alternate title for a window. The alternate title overrides what is displayed in the Window menu. If you do not set an alternate title, the normal window title is used. You would normally use this if the window title was not expressive enough to be used in the Window menu (or similar text-only situation).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

SetWindowBounds

Sets a window's size and position from the bounding rectangle of the specified window region.

```
OSStatus SetWindowBounds (
   WindowRef window,
   WindowRegionCode regionCode,
   const Rect *globalBounds
);
```

Parameters

window

The window whose bounds are to be set.

regionCode

A constant specifying the region to be used in determining the window's size and position. The only region codes allowed for this parameter are `kWindowStructureRgn` and `kWindowContentRgn`.

globalBounds

Set the rectangle to specify the dimensions and position, in global coordinates, of the window region specified in the `regionCode` parameter.

Return Value

A result code. See "Window Manager Result Codes" (page 2051).

Discussion
The `SetWindowBounds` function sets a window's size and position to that specified by the rectangle that your application passes in the `globalBounds` parameter. After doing so, `SetWindowBounds` redraws the window, if the window is visible.

When you call the `SetWindowBounds` function, your application specifies whether the window's content region or its structure region is more important in determining the window's ultimate size and position. This distinction can be important with versions of the Mac OS running the Appearance Manager, since the total dimensions of a window—and, therefore, its spatial relationship to the rest of the screen—may vary from appearance to appearance. In general, you should specify `kWindowStructureRgn` for the `regionCode` parameter if how the window as a whole relates to a given monitor is more important than the exact positioning of its content on the screen. On the other hand, if you specify `kWindowContentRgn` for the `regionCode` parameter because the positioning of your application's content is of greatest concern, then it is important to note that with some appearances some part of the window's structure region or "frame" may extend past the edge of a monitor and not be displayed.

See also the function `GetWindowBounds` (page 1843).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

See Also
`HIWindowSetBounds` (page 1893)

Declared In
`MacWindows.h`

SetWindowCancelButton

Specifies a Cancel button for a window.

```
OSStatus SetWindowCancelButton (
    WindowRef inWindow,
    ControlRef inControl
);
```

Parameters

inWindow
The window whose Cancel button you want to set.

inControl
The control to designate as the Cancel button.

Return Value
A result code.

Discussion
You can use this function to specify a control (normally a button) to be the Cancel button for a given window. This button would be considered to have been clicked if the user instead presses Command-period or the Escape key.

The standard window event handler looks for keystrokes that correspond to the cancel button and generates events of type `kEventControlHit` when it detects the correct key being pressed. This is similar to the way the Dialog Manager responds to cancel buttons, except that instead of returning an item index for which button is pressed, the Carbon Event Manager generates a control hit event.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

SetWindowClass

Sets the class of a window. (Deprecated in Mac OS X v10.5. Use `HIWindowChangeClass` (page 1876), `SetWindowGroup` (page 1941), or `HIWindowChangeAttributes` (page 1874) instead.)

```
OSStatus SetWindowClass (
   WindowRef inWindow,
   WindowClass inWindowClass
);
```

Parameters

window
The window whose class you want to set.

inClass
The class that is to be set. See "Window Class Constants" (page 1988) for a list of possible window classes.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
This function changes the class of a window. It also changes the window's z-order so that it is grouped with other windows of the same class. It does not change the visual appearance of the window.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

SetWindowContentColor

Sets the color to which a window's content region is redrawn.

```
OSStatus SetWindowContentColor (
   WindowRef window,
   const RGBColor *color
);
```

Parameters

window

The window whose content color is to be set.

color

Set this structure to specify the content color to be used.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
If your application uses the `SetWindowContentColor` function, the window's content region is redrawn to the color you specify, without affecting the value specified in the window's `CGrafPort` structure for the current background color.

See also the function `GetWindowContentColor` (page 1845).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

SetWindowContentPattern

Sets the pattern to which a window's content region is redrawn.

```
OSStatus SetWindowContentPattern (
   WindowRef window,
   PixPatHandle pixPat
);
```

Parameters

window

A pointer to the window whose content pattern is being set.

pixPat

Set this structure to specify the content pattern to be used. This handle is copied by the Window Manager, and your application continues to own the original. Therefore there may be higher RAM requirements for applications with numerous identically patterned windows.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
If your application uses the `SetWindowContentPattern` function, the window's content region is redrawn to the pattern you specify, without affecting the value specified in the window's `CGrafPort` structure for the current background pattern.

See also the function `GetWindowContentPattern` (page 1846).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

SetWindowDefaultButton

Specifies a default button for a window.

```
OSStatus SetWindowDefaultButton (
    WindowRef inWindow,
    ControlRef inControl
);
```

Parameters

inWindow
The window whose default button you want to set.

inControl
The control to designate as the default.

Return Value
A result code.

Discussion
You can use this function to specify a control (normally a button) to be the default for a given window. This button would be considered to have been clicked if the user instead presses the Return or Enter keys on the keyboard.

The standard window event handler looks for keystrokes that correspond to the default button and generates events of type `kEventControlHit` when it detects the correct key being pressed. This is similar to the way the Dialog Manager responds to default buttons, except that instead of returning an item index for which button is pressed, the Carbon Event Manager generates a control hit event.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
BSDLLCTest
CarbonCocoa_PictureCursor

Declared In
`MacWindows.h`

SetWindowDockTileMenu

Associates a pop-up menu with a window.

```
OSStatus SetWindowDockTileMenu (
   WindowRef inWindow,
   MenuRef inMenu
);
```

Parameters

inWindow

The window with which a pop-up menu is to be associated.

inMenu

The pop-up menu that is to be associated with the window specified by `inWindow`

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
You specify a dock tile menu if you want to be able to present special selections when the user activates the pop-up menu associated with the window's minimized dock tile.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

QTCarbonShell

Declared In
`MacWindows.h`

SetWindowGroup

Assigns a window to a window group.

```
OSStatus SetWindowGroup (
   WindowRef inWindow,
   WindowGroupRef inNewGroup
);
```

Parameters

inWindow

The window that is to be assigned to a window group.

inNewGroup

The window group. For information on this data type, see `WindowGroupRef` (page 1986).

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

SetWindowGroupLevel

Sets the level of group in the window class hierarchy.

```
OSStatus SetWindowGroupLevel (
   WindowGroupRef inGroup,
   SInt32 inLevel
);
```

Parameters

inGroup

The window group.

inLevel

The new level for the windows in this group.

Return Value

A result code. See "Window Manager Result Codes" (page 2051).

Discussion

The window group's level is only used to set the level of its windows if the window group is a child of the root group. If there is another group in the group hierarchy between this group and the root group, this group's level is ignored.

In Mac OS X v10.4 and later, `SetWindowGroupLevel` sets all three window levels associated with a window group: active, inactive, and promoted. It then immediately determines if the active level needs to be promoted to a larger value, and if so, sets the promoted level to that value.

See the Core Graphics frameworks header `CGWindowLevel.h` for a listing of window levels.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

SetWindowGroupLevelOfType

Sets the window level of a window group.

```
OSStatus SetWindowGroupLevelOfType (
   WindowGroupRef inGroup,
   UInt32 inLevelType,
   CGWindowLevel inLevel
);
```

Parameters

inGroup

The window group whose Core Graphics window level is to be set.

inLevelType

The level type to set. Specify `kWindowGroupLevelActive` or `kWindowGroupLevelInactive`. For details, see "Window Group Level Constants" (page 2048).

inLevel

The new level that is to be set for the windows in this group.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
In Mac OS X v10.4 and later, multiple window levels may be associated with a window group: one level for when the application is active and another for when the application is inactive. The Window Manager automatically switches each group's level as the application becomes active or inactive. Call `SetWindowGroupLevelOfType` to set the active and inactive window level for a window group. The window group's level is only used to set the level of its windows if the window group is a child of the root group. If there is another group in the group hierarchy between this group and the root group, this group's level is ignored.

You can also use `SetWindowGroupLevelOfType` to set the promoted window level that is actually used for windows in the group. Doing so is not recommended, however, because the promoted window level is reset by the Window Manager whenever the window group hierarchy structure changes. Any changes that you make to the promoted level may, therefore, be overwritten. In general, you should only use `SetWindowGroupLevelOfType` to set the active and inactive window levels. When setting the active level of a group with the fixed-level window group attribute, this function also automatically sets the promoted level to the same value and updates the promoted level of any non-fixed-level groups above the group being modified.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

SetWindowGroupName

Assigns a name to a window group.

```
OSStatus SetWindowGroupName (
   WindowGroupRef inGroup,
   CFStringRef inName
);
```

Parameters

inGroup
The window group. For information on this data type, see `WindowGroupRef` (page 1986).

inName

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Carbon Porting Notes

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

SetWindowGroupOwner

Sets a window as the owner of a window group.

```
OSStatus SetWindowGroupOwner (
   WindowGroupRef inGroup,
   WindowRef inWindow
);
```

Parameters

inGroup

The window group that is to be set as the owner of the window group specified by `inWindow`.

inWindow

The window group whose owner is to be set.

Return Value

A result code. See "Window Manager Result Codes" (page 2051).

Discussion

This function is rarely needed and is known to be problematic, so calling this function is not recommended.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

SetWindowGroupParent

Sets a window group to be the parent of another window group.

```
OSStatus SetWindowGroupParent (
   WindowGroupRef inGroup,
   WindowGroupRef inNewGroup
);
```

Parameters

inGroup

The window group whose parent window group is to be set. The specified window group cannot contain any windows at the time of this call.

inNewGroup

The window group that is to be the parent of `inGroup`. For information on this data type, see `WindowGroupRef` (page 1986).

Return Value

A result code. See "Window Manager Result Codes" (page 2051).

Discussion

You can nest groups within each other using this function.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In
MacWindows.h

SetWindowIdealUserState

Sets the size and position of a window in its user state.

```
OSStatus SetWindowIdealUserState (
    WindowRef inWindow,
    const Rect *inUserState
);
```

Parameters

inWindow
The window whose size and position in its user state is to be set.

inUserState
Set this rectangle to specify the new size and position of the window's user state, in global coordinates.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
Because the window definition function relies upon the `WStateData` structure, it is unaware of the ideal standard state, and this causes the user state data that it stores in the `WStateData` structure to be unreliable. While the Window Manager is reliably aware of the window's zoom state, it cannot record the current user state in the `WStateData` structure, because the window definition function can overwrite that data. Therefore, the function `SetWindowIdealUserState` maintains the window's user state independently of the `WStateData` structure. The `SetWindowIdealUserState` function gives your application access to the user state data maintained by `ZoomWindowIdeal` (page 1972). However, your application does not typically need to use this function; it is supplied for completeness.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

`HIWindowSetIdealUserState` (page 1894)

Declared In
MacWindows.h

SetWindowKind

Sets a window's window kind.

```
void SetWindowKind (
   WindowRef window,
   short kind
);
```

Parameters

window
The window whose window kind is to be set.

kind

An integer representing the window kind.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

SetWindowModality

Sets the modality of a window.

```
OSStatus SetWindowModality (
   WindowRef inWindow,
   WindowModality inModalKind,
   WindowRef inUnavailableWindow
);
```

Parameters

inWindow

The window whose modality to set.

inModalKind

The new modality for the window. See "Window Modality Options" (page 2016) for a list of possible options.

inUnavailableWindow

If the window is becoming document-modal, this parameter specifies the window to which the `inWindow` parameter is modal. The window specified by this parameter will not be available while `inWindow` is in window-modal state.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
The modality of a window is used by the Carbon event manager to automatically determine appropriate event handling.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

SetWindowModified

Sets the modification state of the specified window.

```
OSStatus SetWindowModified (
   WindowRef window,
   Boolean modified
);
```

Parameters

window

The window whose modification state is to be set.

modified

Pass `true` if the content of the window has been modified; otherwise, pass `false`.

Return Value

A result code. See "Window Manager Result Codes" (page 2051).

Discussion

Your application can use the functions `SetWindowModified` and `IsWindowModified` (page 1907) instead of maintaining its own separate record of the modification state of the content of a window. The modification state of a window is visually represented by a dot in the window's close box. If the dot is present, the window is modified; if the dot is absent, the window is not modified.

Your application should distinguish between the modification state of the window and the modification state of the window's contents, typically a document. The modification state of the window contents are what should affect `SetWindowModified`. For example, in the case of a word processing document, you call `SetWindowModified` (passing `true` in the `modified` parameter) whenever the user types new characters into the document. However, you do not call `SetWindowModified` when the user moves the window, because that change does not affect the document contents. If you need to track whether the window position has changed, you need to do this with your own flag.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Related Sample Code

QTCarbonShell

Declared In

`MacWindows.h`

SetWindowPic

Sets a picture for the Window Manager to draw in a window's content region. (Deprecated in Mac OS X v10.5. Use an HIImageView object to draw a window's content instead.)

```
void SetWindowPic (
   WindowRef window,
   PicHandle pic
);
```

Parameters

window

The window whose picture is to be set.

pic

On input, a handle to the picture to be drawn in the window.

Discussion
The `SetWindowPic` function stores in a window structure a handle to a picture to be drawn in the window. When the window's content region must be updated, the Window Manager then draws the picture or part of the picture, as necessary, instead of generating an update event.

The `DisposeWindow` (page 1820) function assumes that any picture pointed to by the window structure field `windowPic` is stored as data, not as a resource. If your application uses a picture stored as a resource, you must release the memory it occupies by calling the Resource Manager's `ReleaseResource` function and set the `WindowPic` field to `NULL` before you close the window.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

SetWindowProperty

Associates an arbitrary piece of data with a window.

```
OSStatus SetWindowProperty (
   WindowRef window,
   PropertyCreator propertyCreator,
   PropertyTag propertyTag,
   ByteCount propertySize,
   const void *propertyBuffer
);
```

Parameters

window
The window with which data is to be associated.

propertyCreator
The creator code (typically, the application's signature) of the data to be associated.

propertyTag
A value identifying the data to be associated. You define the tag your application uses to identify the data; this code is not to be confused with the file type for the data.

propertySize
The size of the data to be associated.

propertyBuffer
A pointer to the data to be associated.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
Data set with the `SetWindowProperty` function may be obtained with the function `GetWindowProperty` (page 1859) and removed with the function `RemoveWindowProperty` (page 1923).

Availability
Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

HID Calibrator
QTMetaData

Declared In
`MacWindows.h`

SetWindowProxyAlias

Associates a file with a window.

```
OSStatus SetWindowProxyAlias (
   WindowRef inWindow,
   AliasHandle inAlias
);
```

Parameters

inWindow
The window with which the specified file is to be associated.

inAlias
A handle to a structure of type `AliasRecord` for the file to associate with the specified window. You can obtain an alias handle by calling the function `GetWindowProxyAlias` (page 1862). The Window Manager copies the alias data, so you can dispose of the alias after `SetWindowProxyAlias` returns.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
Your application should call the `SetWindowProxyAlias` function to establish a proxy icon for a given window. The creator code and file type of the file associated with a window determine the proxy icon that is displayed for the window.

Because the `SetWindowProxyAlias` function won't work without a saved file, you must establish the initial proxy icon for a new, untitled window with the function `SetWindowProxyCreatorAndType` (page 1950), which requires that you know the file type and creator code for the file, but does not require that the file have been saved.

Special Considerations

On Mac OS 8.x and Mac OS 9.x, you must save and restore the current graphics port—by calling the QuickDraw functions `GetPort` and `SetPort`—around each call to the `SetWindowProxyAlias` function.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

SetWindowProxyCreatorAndType

Sets the proxy icon for a window that lacks an associated file.

```
OSStatus SetWindowProxyCreatorAndType (
   WindowRef window,
   OSType fileCreator,
   OSType fileType,
   SInt16 vRefNum
);
```

Parameters

window

The window for which you want to set the proxy icon.

fileCreator

A code that is to be used, together with the `fileType` parameter, to determine the proxy icon. This typically is the creator code of the file that would be created, were the user to save the contents of the window.

fileType

A code that is to be used, together with the `fileCreator` parameter, to determine the proxy icon. This typically is the file type of the file that would be created, were the user to save the contents of the window.

vRefNum

A value identifying the volume containing the default desktop database to search for the icon associated with the file type and creator code specified in the `fileCreator` and `fileType` parameters. Pass `kOnSystemDisk` if the volume is unknown.

Return Value

A result code. See "Window Manager Result Codes" (page 2051).

Special Considerations

On Mac OS 8.x and Mac OS 9.x, you must save and restore the current graphics port—by calling the QuickDraw functions `GetPort` and `SetPort`—around each call to the `SetWindowProxyCreatorAndType` function.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

SetWindowProxyFSSpec

Associates a file with a window. (Deprecated in Mac OS X v10.5. Use `HIWindowSetProxyFSRef` (page 1894) instead.)

```
OSStatus SetWindowProxyFSSpec (
   WindowRef window,
   const FSSpec *inFile
);
```

Parameters

window

A pointer to the window with which the specified file is to be associated.

inFile

Set the file system specification structure to contain the data for the file to associate with the specified window. You can obtain an `FSSpec` structure by calling the function `GetWindowProxyFSSpec` (page 1862).

Return Value

A result code. See "Window Manager Result Codes" (page 2051).

Discussion

Your application should call the `SetWindowProxyFSSpec` function to establish a proxy icon for a given window. The creator code and file type of the file associated with a window determine the proxy icon that is displayed for the window.

Because the `SetWindowProxyFSSpec` function won't work without a saved file, you must establish the initial proxy icon for a new, untitled window with the function `SetWindowProxyCreatorAndType`, which requires that you know the file type and creator code for the file, but does not require that the file have been saved.

You must save and restore the current graphics port—by calling the QuickDraw functions `GetPort` and `SetPort`—around each call to the `SetWindowProxyFSSpec` function.

See also the function `SetWindowProxyAlias`.

Special Considerations

The use of file specifications is no longer recommended.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Related Sample Code

QTCarbonShell

Declared In

`MacWindows.h`

SetWindowProxyIcon

Overrides the default proxy icon for a window.

```
OSStatus SetWindowProxyIcon (
   WindowRef window,
   IconRef icon
);
```

Parameters

window

The window for which you want to set the proxy icon.

icon

An icon reference identifying the icon to be used for the window's proxy icon. If there is already a proxy icon in use of the type desired, an `IconRef` value may be obtained for that icon by calling the function `GetWindowProxyIcon` (page 1863). Otherwise, your application must call the Icon Services function `GetIconRefFromFile` to get a value of type `IconRef`. The Window Manager retains the `IconRef`, so you can release `icon` after `SetWindowProxyIcon` returns. See the Icon Services and Utilities documentation for a description of the `IconRef` data type.

Return Value

A result code. See "Window Manager Result Codes" (page 2051).

Discussion

If you want to override the proxy icon that the Window Manager displays by default for a given file, your application should call the `SetWindowProxyIcon` function.

More typically, when you do not want to override a window's default proxy icon, your application would call one of the following functions: `HIWindowSetProxyFSRef` (page 1894), `SetWindowProxyAlias` (page 1949), or `SetWindowProxyCreatorAndType` (page 1950).

On Mac OS 8.x and Mac OS 9.x, you must save and restore the current graphics port—by calling the QuickDraw functions `GetPort` and `SetPort`—around each call to the `SetWindowProxyIcon` function.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

SetWindowResizeLimits

Sets the maximum and minimum resize limits for windows.

```
OSStatus SetWindowResizeLimits (
   WindowRef inWindow,
   const HISize *inMinLimits,
   const HISize *inMaxLimits
);
```

Parameters

inWindow

The window whose maximum and minimum resize limits are to be set.

inMinLimits

The minimum limits. Pass `NULL` if you don't want to set this limit. For information on the `HISize` data type, see HIGeometry.h.

inMaxLimits

The maximum limits. Pass `NULL` if you don't want to set this limit. For information on the `HISize` data type, see HIGeometry.h.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

SetWindowStandardState

Sets a window's standard zoom rectangle.

```
void SetWindowStandardState (
   WindowRef window,
   const Rect *rect
);
```

Parameters

window

The window whose standard zoom rectangle is to be set.

rect

On input, a rectangle (in global coordinates) representing the window's standard zoom rectangle. A window's standard zoom rectangle is the window content bounds when the window is zoomed out to its largest extent.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

SetWindowTitleWithCFString

Sets the window title to the contents of a Core Foundation string.

```
OSStatus SetWindowTitleWithCFString (
   WindowRef inWindow,
   CFStringRef inString
);
```

Parameters

inWindow

The window whose title is to be set.

inString
The title to set.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

SetWindowToolbar

Associates a toolbar with a window.

```
OSStatus SetWindowToolbar (
   WindowRef inWindow,
   HIToolbarRef inToolbar
);
```

Parameters
inWindow
The window with which the toolbar specified by `inToolbar` is to be associated.
inToolbar
The toolbar that is to be associated with the window specified by `inWindow`.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

SetWindowUserState

Sets a window's user zoom rectangle.

```
void SetWindowUserState (
   WindowRef window,
   const Rect *rect
);
```

Parameters

window

The window whose user zoom rectangle is to be set.

rect

On input, a pointer to a rectangle (in global coordinates) representing the user zoom rectangle that is to be set. The window's user zoom rectangle is the window content bounds when the window is zoomed back in.

Availability
Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In
`MacWindows.h`

SetWRefCon

Sets the `refCon` field of a window.

```
void SetWRefCon (
   WindowRef window,
   SRefCon data
);
```

Parameters

window

The window whose `refCon` field is to be set.

data

On input, the data to be placed in the `refCon` field.

Discussion
The `SetWRefCon` function places the specified data in the `refCon` field of the specified window structure. The `refCon` field is available to your application for any window-related data it needs to store.

Availability
Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Related Sample Code
CarbonSketch

QTCarbonShell

Declared In
`MacWindows.h`

SetWTitle

Specifies a window's title. (Deprecated in Mac OS X v10.5. Use `SetWindowTitleWithCFString` (page 1953) instead.)

```
void SetWTitle (
   WindowRef window,
   ConstStr255Param title
);
```

Parameters

window

On input, a pointer to the window structure.

title

On input, a Pascal string containing the window title. To suppress the title in a window with a title bar, pass an empty string, not `null`.

Discussion

The `SetWTitle` function changes a window's title to the specified string, both in the window structure and on the screen, and redraws the window's frame as necessary. Always use `SetWTitle` instead of changing the title in a window structure.

When the user opens a previously saved document, you typically create a new (invisible) window with the title "untitled" and then call `SetWTitle` to give the window the document's name before displaying it. You also call `SetWTitle` when the user saves a document under a new name.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

ShowFloatingWindows

Shows an application's floating windows.

```
OSStatus ShowFloatingWindows (
   void
);
```

Return Value

A result code. For details, see "Window Manager Result Codes" (page 2051).

Discussion

When an application receives a suspend event, its floating windows are hidden automatically. When the application receives a resume event, the floating windows are made visible automatically. Call this function if you want to make your floating windows visible manually.

See also the function `HideFloatingWindows` (page 1871).

Special Considerations

The `ShowFloatingWindows` function operates only upon windows created with the `kFloatingWindowClass` constant; see "Window Class Constants" (page 1988) for more details on this constant.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

ShowHide

Sets a window's visibility.

```
void ShowHide (
   WindowRef window,
   Boolean showFlag
);
```

Parameters

window
On input, a pointer to the window structure.

showFlag
On input, a Boolean value that specifies its visibility: `true` makes a window visible; `false` makes it invisible.

Discussion
The `ShowHide` function sets a window's visibility to the status specified by the `showFlag` parameter. If the value of `showFlag` is `true`, `ShowHide` makes the window visible if it's not already visible and has no effect if it's already visible. If the value of `showFlag` is `false`, `ShowHide` makes the window invisible if it's not already invisible and has no effect if it's already invisible.

The `ShowHide` function never changes the highlighting or front-to-back ordering of windows and generates no activate events.

Use `ShowHide` only where you need to manually control window activation. Otherwise, use `ShowWindow` or `HideWindow` instead.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

ShowHideWindowToolbar

Shows or hides the toolbar.

```
OSStatus ShowHideWindowToolbar (
   WindowRef inWindow,
   Boolean inShow,
   Boolean inAnimate
);
```

Parameters

inWindow

The window whose toolbar is to be shown or hidden.

inShow

Pass `true` to show the toolbar, `false` otherwise.

inAnimate

Pass `true` to animate the transition, pass `false` for no animation.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In

ShowSheetWindow

Shows a sheet window using appropriate visual effects.

```
OSStatus ShowSheetWindow (
   WindowRef inSheet,
   WindowRef inParentWindow
);
```

Parameters

inSheet

The window sheet that is to be shown.

inParentWindow

The parent of the window specified by `inSheet`.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
QTCarbonShell

Declared In
`MacWindows.h`

ShowWindow

Makes an invisible window visible.

```
void ShowWindow (
    WindowRef window
);
```

Parameters

window

The window that is to be made visible.

Discussion

The `ShowWindow` function makes an invisible window visible. If the specified window is already visible, `ShowWindow` has no effect. Your application typically creates a new window in an invisible state, performs any necessary setup of the content region, and then calls `ShowWindow` to make the window visible.

When you call `ShowWindow` to display a window that is invisible, the Window Manager draws the window frame and sends an event to request the application to draw the content region before the window becomes visible. For compositing windows, the Window Manager sends a `kEventControlDraw` event to each HIView in the window. For non-compositing windows, the Window Manager sends a `kEventWindowDrawContent` event. If a non-compositing window does not handle the `kEventWindowDrawContent`, the Window Manager shows the window and generates an update event to request your application to draw the content region.

If the newly visible window is the frontmost window, `ShowWindow` highlights it if it's not already highlighted and generates an activate event to make it active. The `ShowWindow` function does not activate a window that is not frontmost on the desktop.

Because `ShowWindow` does not change the front-to-back ordering of windows, it is not the inverse of `HideWindow` (page 1872). If you make the frontmost window invisible with `HideWindow`, and`HideWindow` has activated another window, you must call both `ShowWindow` and `SelectWindow` (page 1929) to bring the original window back to the front.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

SizeWindow

Sets the size of a window.

```
void SizeWindow (
   WindowRef window,
   short w,
   short h,
   Boolean fUpdate
);
```

Parameters

window

The window whose size is to be set.

w

On input, the new window width, in pixels.

h

On input, the new window height, in pixels.

fUpdate

On input, a Boolean value that specifies whether any newly created area of the content region is to be accumulated into the update region (`true`) or not (`false`). You ordinarily pass a value of `true` to ensure that the area is updated. If you pass `false`, you're responsible for maintaining the update region yourself. For a composited window, this parameter is ignored, and any views that intersect the newly exposed area of the window are automatically invalidated. For more information on adding rectangles to and removing rectangles from the update region, see `InvalWindowRect` (page 1898) and `ValidWindowRect` (page 1969).

Discussion

The `SizeWindow` function changes the size of the window's graphics port rectangle to the dimensions specified by the w and h parameters, or does nothing if the values of `w` and `h` are both `0`. The Window Manager redraws the window in the new size, recentering the title and truncating it if necessary.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Related Sample Code

QTCarbonShell

Declared In

`MacWindows.h`

StoreWindowIntoCollection

Stores data describing a window into a collection. (Deprecated in Mac OS X v10.5. Use `HIArchiveEncodeCFType` (page 2314) to encode a window to an archive instead.)

```
OSStatus StoreWindowIntoCollection (
   WindowRef window,
   Collection collection
);
```

Parameters

window

The window to be stored.

collection

A reference to the collection into which the window is to be stored. You pass a reference to a previously created collection, such as that returned by the Collection Manager function `NewCollection`.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
The `StoreWindowIntoCollection` function stores any window—including those not created by the Window Manager calls—into the specified collection. The Window Manager does not empty the collection beforehand, so any existing items in the collection remain.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

ToggleDrawer

Toggles the drawer state.

```
OSStatus ToggleDrawer (
   WindowRef inDrawerWindow
);
```

Parameters

inDrawerWindow

The drawer window whose drawer state is to be toggled.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
If the drawer is currently open or opening, this function closes the drawer. If the drawer is currently closed or closing, this function opens the drawer.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

TrackBox

Tracks clicks in the collapse, close, size, and zoom boxes, and clicks of the toolbar button.

```
Boolean TrackBox (
   WindowRef window,
   Point thePt,
   WindowPartCode partCode
);
```

Parameters

window

The window in which the mouse button was pressed.

thePt

On input, the location of the cursor when the mouse button was pressed. Your application receives this point from the `where` field in the event structure.

partCode

On input, the part code (`inZoomIn`, `inZoomOut`, `inGoAway`, `inGrow`, `inCollapseBox`, or `inToolbarButton`) returned by `FindWindow` (page 1827); see "Part Identifier Constants" (page 2043).

Return Value

A Boolean whose value is `true` if the specified part was clicked; otherwise, `false`. If `TrackBox` returns `true`, it also removes highlighting from the specified part.

Discussion

The `TrackBox` function tracks the cursor when the user presses the mouse button while the cursor is in the specified part, retaining control until the mouse button is released. While the button is down, `TrackBox` highlights the part while the cursor is in the part's region.

When the mouse button is released, `TrackBox` removes the highlighting from the part and returns `true` if the cursor is within the part's region and `false` if it is not.

If `TrackBox` returns `true` after tracking the close box, your application should close the window. If `TrackBox` returns `true` after tracking the grow box, your application should call `ResizeWindow` (page 1925). If `TrackBox` returns `true` after tracking the collapse box, your application should call `CollapseWindow` (page 1810). When tracking the toolbar button, your application should call `ShowHideWindowToolbar` (page 1957).

Your application calls the `TrackBox` function when it receives a result code of `inZoomIn` or `inZoomOut` from the function `FindWindow` (page 1827). If `TrackBox` returns `true`, your application calculates the standard state, if necessary, and calls the function `ZoomWindow` (page 1971) to zoom the window. If `TrackBox` returns `false`, your application does nothing.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

TrackGoAway

Tracks the cursor when the user presses the mouse button while the cursor is in the close box.

```
Boolean TrackGoAway (
   WindowRef window,
   Point thePt
);
```

Parameters

window

On input, the window in which the mouse-down event occurred.

thePt

On input, the location of the cursor at the time the mouse button was pressed. Your application receives this point from the `where` field of the event structure.

Return Value

When the mouse button is released, `TrackGoAway` removes the highlighting from the close box and returns `true` if the cursor is within the close region and `false` if it is not.

Discussion

The `TrackGoAway` function tracks cursor activity when the user presses the mouse button while the cursor is in the close box, retaining control until the user releases the mouse button. While the button is down, `TrackGoAway` highlights the close box as long as the cursor is in the close region.

Your application calls the `TrackGoAway` function when it receives a result code of `inGoAway` from `FindWindow` (page 1827). If `TrackGoAway` returns `true`, your application calls its own function for closing a window, which can call `DisposeWindow` (page 1820) to remove the window from the screen. If `TrackGoAway` returns `false`, your application does nothing.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Related Sample Code

HideMenuBar

Declared In

`MacWindows.h`

TrackWindowProxyDrag

Handles all aspects of the drag process when the user drags a proxy icon.

```
OSStatus TrackWindowProxyDrag (
   WindowRef window,
   Point startPt
);
```

Parameters

window

The window whose proxy icon is being dragged.

startPt

Set the `Point` structure to contain the point, specified in global coordinates, where the mouse-down event that began the drag occurred. Your application may retrieve this value from the `where` field of the `event` structure.

Return Value
A result code. See "Window Manager Result Codes" (page 2051). If you receive the error `errUserWantsToDragWindow` (–5607), your application should respond by calling the Window Manager function `DragWindow`. Errors are also returned from the Drag Manager, including `userCanceledErr` (–128).

Discussion
If your application uses proxy icons to represent a type of object (currently, file system entities such as files, folders, and volumes) supported by the Window Manager, your application should call the `TrackWindowProxyDrag` function, and the Window Manager can handle all aspects of the drag process for you. If your application calls the `TrackWindowProxyDrag` function, it does not have to call the Drag Manager function `WaitMouseMoved` before starting to track the drag, as the Window Manager handles this automatically. However, if a proxy icon represents a type of data that the Window Manager does not support, or if you want to implement custom dragging behavior, your application should call the function `TrackWindowProxyFromExistingDrag` (page 1964).

Your application detects that a user is dragging one of its proxy icons when the function `FindWindow` (page 1827) returns the `inProxyIcon` result code; see "Window Part Code Constants" (page 2013) for more details.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

See Also
`HIWindowTrackProxyDrag` (page 1897)

Declared In
`MacWindows.h`

TrackWindowProxyFromExistingDrag

Allows custom handling of the drag process when the user drags a proxy icon.

```
OSStatus TrackWindowProxyFromExistingDrag (
   WindowRef window,
   Point startPt,
   DragRef drag,
   RgnHandle inDragOutlineRgn
);
```

Parameters

window
The window whose proxy icon is being dragged.

startPt
Set the `Point` structure to contain the point, specified in global coordinates, where the mouse-down event that began the drag occurred. Your application may retrieve this value from the `where` field of the `event` structure.

drag
A value that refers to the current drag process. Pass in the value produced in the `outNewDrag` parameter of the function `BeginWindowProxyDrag` (page 1802). If you are not using `BeginWindowProxyDrag` in conjunction with `TrackWindowProxyFromExistingDrag`, you must create the drag reference yourself with the Drag Manager function `NewDrag`.

inDragOutlineRgn

A region handle representing an outline of the icon being dragged. You may obtain a handle to this region from the `outDragOutlineRgn` parameter of `BeginWindowProxyDrag`. If you are not using `BeginWindowProxyDrag` in conjunction with `TrackWindowProxyFromExistingDrag`, you must create the region yourself.

Return Value
A result code. See "Window Manager Result Codes" (page 2051). Errors are also returned from the Drag Manager, including `userCanceledErr` (-128).

Discussion
Typically, if the proxy icon represents a type of object (currently, file system entities such as files, folders, and volumes) supported by the Window Manager, the Window Manager can handle all aspects of the drag process itself, and your application should call the function `TrackWindowProxyDrag` (page 1963). However, if the proxy icon represents a type of data that the Window Manager does not support, or if you want to implement custom dragging behavior, your application should call the `TrackWindowProxyFromExistingDrag` function.

The `TrackWindowProxyFromExistingDrag` function accepts an existing drag reference and adds file data if the window contains a file proxy. If your application uses `TrackWindowProxyFromExistingDrag`, you then have the choice of using this function in conjunction with the functions `BeginWindowProxyDrag` (page 1802) and `EndWindowProxyDrag` (page 1826) or simply calling `TrackWindowProxyFromExistingDrag` and handling all aspects of creating and disposing of the drag yourself.

Your application detects a drag when the function `FindWindow` (page 1827) returns the `inProxyIcon` result code; see "Window Part Code Constants" (page 2013) for more details.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

TransitionWindow

Shows, hides, moves, or resizes a window with appropriate animation and sound.

```
OSStatus TransitionWindow (
   WindowRef inWindow,
   WindowTransitionEffect inEffect,
   WindowTransitionAction inAction,
   const Rect *inRect
);
```

Parameters
inWindow

The window on which to act.

inEffect

The type of visual effect to use. `TransitionWindow` supports the Zoom, Slide, Fade, and Genie transition effects. The Slide effect is supported in Mac OS X and in CarbonLib 1.5 and later. The Fade and Genie effects are supported in Mac OS X v10.3 and later. See "Window Transition Effect Constants" (page 2027) for constants and descriptions of these effects.

inAction

The action to take. `TransitionWindow` supports the Show, Hide, Move, and Resize actions. The Move and Resize actions are supported in Mac OS X and in CarbonLib 1.5 and later. See "Window Transition Action Constants" (page 2026) for possible values.

inRect

A screen rect in global coordinates, or `NULL` for some transition actions. The interpretation of the rect is dependent on the transition action. For details, see the documentation for each action.

If you pass `kWindowShowTransitionAction` in the `action` parameter then, before calling `TransitionWindow`, set the rectangle to specify the dimensions and position, in global coordinates, of the area from which the zoom is to start. If you pass `NULL`, `TransitionWindow` uses the center of the display screen as the source rectangle.

If you pass `kWindowHideTransitionAction` in the `action` parameter then, before calling `TransitionWindow`, set the rectangle to specify the dimensions and position, in global coordinates, of the area at which the zoom is to end.

If you pass `NULL`, `TransitionWindow` uses the center of the display screen as the destination rectangle.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
The `TransitionWindow` function displays an animation of a window's transition between the open and closed states, such as that displayed by the Finder. `TransitionWindow` uses the rectangle specified in the `rect` parameter for one end of the animation (the source or the destination of the zoom, depending upon whether the window is being shown or hidden, respectively) and the window's current size and position for the other end of the animation. `TransitionWindow` also plays sounds appropriate to the current theme for the opening and closing actions.

Your application may use `TransitionWindow` instead of the functions `ShowWindow` and `HideWindow`. Like these pre–Mac OS 8.5 Window Manager functions, `TransitionWindow` generates the appropriate update and active events when it shows and hides windows.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

TransitionWindowAndParent

Shows or hides a window, potentially also moving a second window, with animation and sound.

```
OSStatus TransitionWindowAndParent (
   WindowRef inWindow,
   WindowRef inParentWindow,
   WindowTransitionEffect inEffect,
   WindowTransitionAction inAction,
   const Rect *inRect
);
```

Parameters

inWindow

The window that is to be shown or hidden.

inParentWindow

The window to which inWindow is related. For the Sheet effect, this parameter must be a valid window reference; for other effects, this parameter should be `NULL`.

inEffect

The type of visual effect to use. This function is most commonly used to perform the Sheet transition effect, but it also supports the Zoom, Slide, Fade, and Genie effects. See "Window Transition Effect Constants" (page 2027) for constants and descriptions of these effects.

inAction

The action to take on the window. The Show, Hide, Move, and Resize actions are supported. See "Window Transition Action Constants" (page 2026) for the appropriate constants.

inRect

A screen rect in global coordinates. The interpretation of the rect is dependent on the transition action; see the documentation for each action for details. May be `NULL` for some transition actions.

Return Value

A result code. See "Window Manager Result Codes" (page 2051).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`MacWindows.h`

TransitionWindowWithOptions

Transitions a window from one state to another with appropriate animation and sound.

```
OSStatus TransitionWindowWithOptions (
   WindowRef inWindow,
   WindowTransitionEffect inEffect,
   WindowTransitionAction inAction,
   const HIRect *inBounds,
   Boolean inAsync,
   TransitionWindowOptions *inOptions
);
```

Parameters

inWindow

The window to transition.

inEffect

The type of visual effect to use. For possible values, see "Window Transition Effect Constants" (page 2027) for a description of this value.

inAction

The action to take. For possible values, see "Window Transition Action Constants" (page 2026).

inBounds

A screen rect in global coordinates. The interpretation of the rect is dependent on the transition action; see "Window Transition Action Constants" (page 2026) for the details of each action. This parameter may be `NULL` for the Show and Hide actions for the Zoom and Sheet effects. This parameter is ignored and must be `NULL` for the Show and Hide actions for the Fade effect.

inAsync

A Boolean whose value indicates whether the transition should run synchronously or asynchronously. If `inAsync` is `true`, this function returns immediately, and the transition runs using an event loop timer. You must run your event loop for the transition to occur. If `inAsync` is `false`, this function blocks until the transition completes. In either case, the `kEventWindowTransitionStarted` and `kEventWindowTransitionCompleted` Carbon events are sent to the transitioning window at the start and end of the transition.

inOptions

Extra information that are required for some transitions. This parameter may be `NULL` if the specified transition effect does not require extra information.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Availability
Available in Mac OS X v10.3 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

UpdateCollapsedWindowDockTile

Updates the image of a window in the dock to the current contents of the window.

```
OSStatus UpdateCollapsedWindowDockTile (
   WindowRef inWindow
);
```

Parameters

inWindow

The window whose image is to be updated.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
Use this function for periodic updates, not for animation purposes. If you want animation, use `CreateQDContextForCollapsedWindowDockTile` (page 1816).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
MacWindows.h

ValidWindowRect

Removes a rectangle from a window's update region.

```
OSStatus ValidWindowRect (
   WindowRef window,
   const Rect *bounds
);
```

Parameters

window

The window containing the rectangle you want to remove from the update region.

bounds

Set this structure to specify, in local coordinates, a rectangle to be removed from the window's update region.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
The `ValidWindowRect` function informs the Window Manager that an area of a window no longer needs to be redrawn. The `ValidWindowRect` function is similar to the `ValidRect` function, but `ValidWindowRect` allows the window that it operates upon to be explicitly specified, instead of operating on the current graphics port, so `ValidWindowRect` does not require the graphics port to be set before its use.

See also the functions `InvalWindowRect` (page 1898) and `ValidWindowRgn` (page 1969).

Special Considerations

This function should not be used on composited windows. Modifying a composited window's update region does not affect the area of the window to be drawn. A composited window does not use its window update region to control drawing. Instead, a composited window determines what to draw by looking at the invalid regions of the views contained in the window.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
MacWindows.h

ValidWindowRgn

Removes a region from a window's update region.

```
OSStatus ValidWindowRgn (
   WindowRef window,
   RgnHandle region
);
```

Parameters

window

The window containing the region you want to remove from the update region.

region

Set this region to specify, in local coordinates, the area to be removed from the window's update region.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
The `ValidWindowRgn` function informs the Window Manager that an area of a window no longer needs to be redrawn. The `ValidWindowRgn` function is similar to the `ValidRgn` function, but `ValidWindowRgn` allows the window that it operates upon to be explicitly specified, instead of operating on the current graphics port, so `ValidWindowRgn` does not require the graphics port to be set before its use.

See also the functions `InvalWindowRgn` (page 1899) and `ValidWindowRect` (page 1969).

Special Considerations

This function should not be used on composited windows. Modifying a composited window's update region does not affect the area of the window to be drawn. A composited window does not use its window update region to control drawing. Instead, a composited window determines what to draw by looking at the invalid regions of the views contained in the window.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

WindowPathSelect

Displays a window path pop-up menu.

```
OSStatus WindowPathSelect (
   WindowRef window,
   MenuRef menu,
   SInt32 *outMenuResult
);
```

Parameters

window

The window for which a window path pop-up menu is to be displayed.

menu

The menu to be displayed for the specified window or `NULL`. If you pass `NULL` in this parameter, the Window Manager provides a default menu and sends a Reveal Object Apple event to the Finder if a menu item is selected. Note that in order to pass `NULL`, a file must currently be associated with the window [call `HIWindowSetProxyFSRef` (page 1894) to associate a file with the window]. If you pass a menu, this menu supersedes the default window path pop-up menu. There does not have to be a file currently associated with the window if you pass in your own menu.

outMenuResult

A pointer to a value that, on return, contains the menu and menu item the user chose. The high-order word of the value produced contains the menu ID, and the low-order word contains the item number of the menu item. If the user does not select a menu item, 0 is produced in the high-order word, and the low-order word is undefined. For file menus that have not been overridden, 0 is always produced in this parameter. Pass `NULL` in this parameter if you do not want this information.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
Your application should call the `WindowPathSelect` function when it detects a Command-click in the title of a window, that is, when the `IsWindowPathSelectClick` (page 1907) or `IsWindowPathSelectEvent` (page 1908) function returns a value of `true`. Calling `WindowPathSelect` causes the Window Manager to display a window path pop-up menu for your window.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

ZoomWindow

Zooms the window when the user has pressed and released the mouse button with the cursor in the zoom box.

```
void ZoomWindow (
   WindowRef window,
   WindowPartCode partCode,
   Boolean front
);
```

Parameters

window

The window that is to be zoomed.

partCode

On input, the part code (either `inZoomIn` or `inZoomOut`) returned by the `FindWindow` function; see "Part Identifier Constants" (page 2043).

front

On return, a Boolean value that determines whether the window is to be brought to the front. If the value of `front` is `true`, the window necessarily becomes the frontmost, active window. If the value of `front` is `false`, the window's position in the window list does not change. Note that if a window was active before it was zoomed, it remains active even if the value of `front` is `false`.

Discussion
The `ZoomWindow` function zooms a window in or out, depending on the value of the `partCode` parameter. Your application calls `ZoomWindow`, passing it the part code returned by `FindWindow` (page 1827), when it receives a result of `true` from `TrackBox`. The `ZoomWindow` function then changes the window's port rectangle to either the user state (if the part code is `inZoomIn`) or the standard state (if the part code is `inZoomOut`), as stored in the window state structure, described in the section `WStateData` (page 1987).

If the part code is `inZoomOut`, your application ordinarily calculates and sets the standard state before calling `ZoomWindow`.

For best results, call the QuickDraw function `EraseRect`, passing the window's graphics port as the port rectangle, before calling `ZoomWindow`.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

ZoomWindowIdeal

Zooms a window in accordance with human interface guidelines.

```
OSStatus ZoomWindowIdeal (
   WindowRef inWindow,
   WindowPartCode inPartCode,
   Point *ioIdealSize
);
```

Parameters

inWindow
The window that is to be zoomed.

inPartCode
A value specifying the direction of the zoom being requested. Your application passes in the relevant value (either the `inZoomIn` or the `inZoomOut` constant).

ioIdealSize
When you specify `inZoomIn` in the `partCode` parameter, you pass a pointer to the `Point` structure, but do not fill the structure with data. On return, the `Point` structure contains the new height and width of the window's content region, and `ZoomWindowIdeal` restores the previous user state.

When you specify `inZoomOut` in the `partCode` parameter, you pass the ideal height and width of the window's content region in the `Point` structure. On return, the `Point` structure contains the new height and width of the window's content region. `ZoomWindowIdeal` saves the user state of the window and zooms the window to its ideal size for the standard state.

Return Value
A result code. See "Window Manager Result Codes" (page 2051).

Discussion
Applications should use the `ZoomWindowIdeal` function instead of the older function `ZoomWindow`. When your application calls `ZoomWindowIdeal`, it automatically conforms to the human interface guidelines for determining a window's standard state.

The `ZoomWindowIdeal` function calculates a window's ideal standard state and updates a window's ideal user state independently of the `WStateData` structure. Previously, the window definition function was responsible for updating the user state, but because it relies upon the `WStateData` structure, the window definition function is unaware of the ideal standard state and can no longer track the window's zoom state reliably.

While the Window Manager is reliably aware of the window's zoom state, it cannot record the current user state in the `WStateData` structure, because the window definition function can overwrite that data. Therefore, if your application uses `ZoomWindowIdeal`, the `WStateData` structure is superseded, and the result of the `FindWindow` (page 1827) function should be ignored when determining whether a particular user click of the zoom box is a request to zoom in or out. When you adopt `ZoomWindowIdeal` and your application receives a result of either `inZoomIn` or `inZoomOut` from `FindWindow`, your application must use the function `IsWindowInStandardState` (page 1905) to determine the appropriate part code to pass in the `partCode` parameter.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Callbacks

WindowDefProcPtr

Defines a pointer to a window definition callback function. Your window definition callback function determines how a window looks and behaves.

```
typedef long (*WindowDefProcPtr) (
    short varCode,
    WindowRef window,
    short message,
    long param
);
```

If you name your function `MyWindowDefProc`, you would declare it like this:

```
long MyWindowDefProc (
    short varCode,
    WindowRef window,
    short message,
    long param
);
```

Parameters

varCode
The window's variation code.

window
A pointer to the window's window structure.

message
A value indicating the task to be performed. The `message` parameter contains one of the values defined in "Window Definition Message Constants" (page 2036). Other messages are reserved for internal use by the system. The list in the discussion section that follows explains each of these tasks in detail.

param
Data associated with the task specified by the `message` parameter. If the task requires no data, this parameter is ignored.

Return Value
Your window definition function should perform whatever task is specified by the `message` parameter and return a function result, if appropriate. If the task performed requires no result code, return 0.

Discussion
Various Window Manager functions call a window definition function whenever they need to perform a window-dependent action, such as drawing the window on the screen. If you want to define new, nonstandard windows for your application, you must write a window definition function, compile it in your application, and either use `RegisterWindowDefinition` (page 1920) to register it with the system or call `CreateCustomWindow` (page 1814) to create the custom window directly.

Note that Carbon does not allow you to store custom window definitions in a `'WDEF'` resource file as you could in pre-Carbon systems.

If you use `RegisterWindowDefinition` (page 1920), the Window Manager calls the Resource Manager to access your window definition function with the given resource ID; see "Pre-Appearance Window Definition IDs" in*Window Manager Legacy Reference* for a description of how window definition IDs are derived from resource IDs and variation codes.

The Resource Manager reads your window definition function into memory and returns a handle to it. The Window Manager stores this handle in the `windowDefProc` field of the window structure. Later, when it needs to perform an action on the window, the Window Manager calls the window definition function and passes it the variation code as a parameter.

Your window definition function is responsible for

- drawing the window frame
- reporting the region where mouse-down events occur
- calculating the window's structure region and content region
- drawing the size box
- resizing the window frame when the user drags the size box
- reporting the window's features or the location of a specific window region
- performing any customized initialization or disposal tasks

The Window Manager defines the data type `WindowDefUPP` to identify the universal procedure pointer for this application-defined function:

```
typedef UniversalProcPtr WindowDefUPP;
```

You typically use the `NewWindowDefProc` macro like this:

```
WindowDefUPP myWindowDefUPP;
myWindowDefUPP = NewWindowDefProc(MyWindow);
```

You typically use the `CallWindowDefProc` macro like this:

```
CallWindowDefProc (myWindowDefUPP, varCode, theWindow, message,  param);
```

The `message` parameter contains a value specifying the task to be performed by your window definition function. These tasks are:

- *Drawing the Window Frame*

  When the Window Manager passes `wDraw` in the `message` parameter, your window definition function should respond by drawing the window frame in the current graphics port (which is the Window Manager port). The window part code to be drawn will be passed in the `param` parameter of your window definition function. Your window definition function should perform the following steps:

  - Change the current port from the `WMgrPort` to the `WMgrCPort` to allow the system to draw in the full range of RGB colors.
  - Update the pen attributes, text attributes, and `bkPat` fields in the `WMgrCPort` to the values of the corresponding fields in the `WMgrPort`. The Window Manager automatically transfers the `vis` and `clip` regions.

  The parallelism of the `WMgrPort` and the `WMgrCPort` is maintained only by the window definition functions. All window definition functions that draw in the `WMgrPort` should follow the steps listed above even if the changed fields do not affect their operation.

  You must make certain checks to determine exactly how to draw the frame. If the value of the `visible` field in the window structure is `false`, you should do nothing; otherwise, you should examine the `param` parameter and the status flags in the window structure:

  - If the value of `param` is 0, draw the entire window frame (including the size box, if your window definition function incorporates the size box into the frame).
  - If the value of `param` is 0 and the `hilited` field in the window structure is `true`, highlight the frame to show that the window is active. If the value of the `goAwayFlag` field in the window structure is also `true`, draw a close box in the window frame. If the value of the `spareFlag` field in the window structure is also `true`, draw a zoom box in the window frame.
  - If the value of the `param` parameter is `wInGoAway`, redraw the window's close box, with or without highlighting as appropriate.
  - If the value of the `param` parameter is `wInZoom`, redraw the window's zoom box, with or without highlighting as appropriate.
  - If the value of the `param` parameter is `wInCollapseBox`, redraw the window's collapse box, with or without highlighting as appropriate.

  You can call `GetWindowWidgetHilite` (page 1868) to determine whether the close, zoom, or collapse box is currently highlighted. This function returns the part code of the currently highlighted part, or zero if no part is highlighted. You should draw the indicated part with highlighting, and draw other parts with no highlighting.

  The window frame typically, but not necessarily, includes the window's title, which should be displayed in the system font and system font size. The Window Manager port is already set to use the system font and system font size.

  Nothing drawn outside the window's structure region will be visible.

Your window definition function should return 0 as the function result for this message.

- *Reporting the Region of a Mouse-Down Event*

  When the Window Manager passes `wHit` in the `message` parameter, your window definition function should respond by reporting the region of the specified mouse-down event. The mouse location (in global coordinates) of the window frame will be passed into the `param` parameter of your window definition function. The vertical coordinate is in the high-order word of the parameter, and the horizontal coordinate is in the low-order word.

  In response to the `wHit` message, your window definition function should return one of the constants defined in "Window Definition Hit Test Result Code Constants" (page 2034).

  In Mac OS 9, return the constants `wInGrow`, `wInGoAway`, `wInZoomIn`, `wInZoomOut`, and `wInCollapseBox` only if the window is active—by convention, the size box, close box, zoom box, and collapse box aren't drawn if the window is inactive. In an inactive document window, for example, a mouse-down event in the part of the title bar that would contain the close box if the window were active is reported as `wInDrag`. In Mac OS X, your WDEF can return these part codes for inactive windows because these boxes are drawn even if the window is inactive.

- *Calculating Regions*

  When the Window Manager passes `wCalcRgns` in the `message` parameter, your window definition function should respond by calculating the window's structure and content regions based on the current graphics port's port rectangle. These regions, whose handles are in the `strucRgn` and `contRgn` fields of the window structure, are in global coordinates. The Window Manager requests this operation only if the window is visible. The mouse location (in global coordinates) of the window frame will be passed into the `param` parameter of your window definition function.

  Your window definition function should call `IsWindowCollapsed` (page 1904) to determine its collapse state. Then your window definition function can modify its structure and content regions as appropriate. Typically, a window's content region is empty in a collapsed state.

  When you calculate regions for your own type of window, do not alter the clip region or the visible region of the Window Manager port. The Window Manager and QuickDraw take care of this for you. Altering the Window Manager port's clip region or visible region may damage other windows.

  Your window definition function should return 0 as the function result for this message.

- *Performing Additional Window Initialization*

  When the Window Manager passes `wNew` in the `message` parameter, your window definition function should respond by performing any initialization that it may require. If the content region has an unusual shape, for example, you might allocate memory for the region and store the region handle in the `dataHandle` field of the window structure. The initialization function for a standard document window creates the `wStateData` structure for storing zooming data.

  Your window definition function should ignore the `param` parameter and return 0 as the function result for this message.

- *Performing Additional Window Disposal Actions*

  When the Window Manager passes `wDispose` in the `message` parameter, your window definition function should respond by performing any additional tasks necessary for disposing of a window. You might, for example, release memory that was allocated by the initialization function. The dispose function for a standard document window disposes of the `wStateData` structure.

  Your window definition function should ignore the `param` parameter and return 0 as the function result for this message.

- *Drawing the Window's Grow Image*

When the Window Manager passes `wGrow` in the `message` parameter, your window definition function should respond to being resized by drawing a dotted outline of the window in the current graphics port in the pen pattern and mode. (The pen pattern and mode are set up—as `gray` and `notPatXor`—to conform to Appearance-compliant human interface guidelines.)

A rectangle (in global coordinates) whose upper-left corner is aligned with the port rectangle of the window's graphics port is passed into the `param` parameter of your window definition function. Your grow image should be sized appropriately for the specified rectangle. As the user drags the mouse, the Window Manager sends repeated `wGrow` messages, so that you can change your grow image to match the changing mouse location.

Your window definition function should return 0 as the function result for this message.

- *Drawing the Size Box*

  When the Window Manager passes `wDrawGIcon` in the `message` parameter, your window definition function should respond by drawing the size box in the content region if the window is active. If the window is inactive, your window definition function should draw whatever is appropriate to show that the window cannot currently be sized. Your window definition function may also draw scroll bar delimiter lines. Your window definition function should ignore the `param` parameter.

  If the size box is located in the window frame, draw the size box in response to a `wDraw` message, not a `wDrawGIcon` message.

  Your window definition function should return 0 as the function result for this message.

- *Reporting Window Features*

  When the Window Manager passes `kWindowMsgGetFeatures` in the `message` parameter, your window definition function should respond by setting the `param` parameter to reflect the features that your window supports. The value passed back in the `param` parameter should be comprised of one or more of the values defined in "Window Feature Bits" (page 2011).

  Your window definition function should return 1 as the function result for this message.

- *Returning the Location of Window Regions*

  When the Window Manager passes `kWindowMsgGetRegion` in the `message` parameter, your window definition function should respond by returning the location (in global coordinates) of the specified window region. A pointer to a window region structure will be passed in the `param` parameter.

  The window region structure is a structure of type `GetWindowRegionRec` (page 1981). Your window definition function should return an operating system status (`OSStatus`) message as the function result for this message. The result code `errWindowRegionCodeInvalid` indicates that the window region passed in was not valid.

  Application-defined window definition functions are changed with Appearance Manager 1.0 to support collapse boxes and feature reporting.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacWindows.h`

WindowPaintProcPtr

Defines a pointer to a custom content region painting function.

```
typedef OSStatus (*WindowPaintProcPtr) (
    GDHandle device,
    GrafPtr qdContext,
    WindowRef window,
    RgnHandle inClientPaintRgn,
    RgnHandle outSystemPaintRgn,
    void * refCon
);
```

If you name your function `MyWindowPaintProc`, you would declare it like this:

```
OSStatus MyWindowPaintProc (
    GDHandle device,
    GrafPtr qdContext,
    WindowRef window,
    RgnHandle inClientPaintRgn,
    RgnHandle outSystemPaintRgn,
    void * refCon
);
```

Parameters

device

The current graphics device (`GDevice`).

qdContext

The graphics port to draw into. Note that you should draw into this port, not the one associated with the window; the painting region `inClientPaintRgn` is defined relative to this port. The port may be an offscreen graphics world.

window

The window to paint in.

inClientPaintRgn

The region to be painted. Treat as a const. This region is clipped to the intersection of the current graphics device and the `clobberedRgn` parameter passed to `PaintBehind`.

outSystemPaintRgn

The region for the system to paint. Initially empty. If your paint procedure sets this region before returning, the Window Manager will erase this region using the system's window content paint function.

refCon

Application-defined data that you passed to `InstallWindowContentPaintProc` (page 1898).

Return Value

A result code. See "Window Manager Result Codes" (page 2051).

Discussion

Each window in the system contains a reference to a content paint proc. This proc is called to erase the window's content region during `PaintBehind` or `PaintOne` operations. The client application can override the system paint proc by calling `InstallWindowContentPaintProc` (page 1898). A window may only have one paint proc installed at any one time, and the paint proc cannot be retrieved by the client application.

If your content region painting callback returns any value other than noErr, `outSystemPaintRgn` is ignored and the entire area of `inClientPaintRgn` is painted using the system paint proc.

When a previously obscured portion of a window is exposed, the window manager will iterate over active displays and call the window's content paint proc once for each device intersecting the region.

Availability
Available in Mac OS X v10.0 and later.

Data Types

BasicWindowDescription

Describes basic window characteristics for use in a collection item.

```
struct BasicWindowDescription {
    UInt32 descriptionSize
    Rect windowContentRect
    Rect windowZoomRect
    UInt32 windowRefCon
    UInt32 windowStateFlags
    WindowPositionMethod windowPositionMethod
    UInt32 windowDefinitionVersion
    union {
        struct {
            SInt16 windowDefProc;
            Boolean windowHasCloseBox;
        } versionOne;
        struct {
            WindowClass windowClass;
            WindowAttributes windowAttributes;
        } versionTwo;
    } windowDefinition;
};
typedef struct BasicWindowDescription BasicWindowDescription;
```

Fields

`descriptionSize`
A value specifying the size of the entire `BasicWindowDescription` structure.

`windowContentRect`
A structure of type `Rect`, specifying the initial size and screen location of the window's content area.

`windowZoomRect`
Reserved.

`windowRefCon`
The window's reference value field, which is simply storage space available to your application for any purpose. The value contained in this field persists when the `'WIND'` resource is stored, so you should avoid saving pointers in this field, as they may become stale.

`windowStateFlags`

A 32-bit value whose bits you set to indicate the status of transient window states. See "Basic Window Description State Constant" (page 2010) for possible values.

`windowPositionMethod`

The specification last used in the function `RepositionWindow` (page 1924) to position this window, if any. See "Window Position Constants" (page 2017) for a description of possible values for this field.

`windowDefinitionVersion`

The version of the window definition used for the window. Set this field to a value of 1 if your application is creating a pre–Mac OS 8.5 window, that is, a window lacking class and attribute information. Set this field to a value of 2 if your application is creating a window using class and attribute information. See "Basic Window Description Version Constants" (page 2023) for descriptions of these values.

`windowDefinition`

A union of the `versionOne` and `versionTwo` structures. Your application must either specify the window's class and attributes, or it must supply a window definition ID and specify whether or not the window has a close box. See "Window Class Constants" (page 1988) and "Window Attributes" (page 1998) for descriptions of class and attribute values.

Discussion

The `BasicWindowDescription` structure is a default collection item for a resource of type `'wind'`. You use the `BasicWindowDescription` structure to describe the statically-sized base characteristics of a window.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`MacWindows.h`

GetGrowImageRegionRec

Defines a region to be XOR'd during a window grow or resize operation.

```
struct GetGrowImageRegionRec {
    Rect growRect;
    RgnHandle growImageRegion;
};
typedef struct GetGrowImageRegionRec GetGrowImageRegionRec;
```

Fields

`growRect`

The window's new bounds in global coordinates.

`growImageRegion`

The grow image region.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`MacWindows.h`

GetWindowRegionRec

Passed to window definitions in the `kWindowMsgGetRegion` message.

```
struct GetWindowRegionRec {
    RgnHandle winRgn;
    WindowRegionCode regionCode;
};
typedef struct GetWindowRegionRec GetWindowRegionRec;
typedef GetWindowRegionRec * GetWindowRegionPtr;
```

Fields

`winRgn`

A handle to a window region based on the value specified in the `regionCode` field. Modify this region.

`regionCode`

A value representing a given window region; see "Window Region Constants" (page 2021).

Special Considerations

Availability

Available in Mac OS X v10.0 and later.

Declared In

`MacWindows.h`

HIWindowRef

Represents a window.

```
typedef WindowRef HIWindowRef;
```

Availability

Available in Mac OS X v10.3 and later.

Declared In

`MacWindows.h`

MeasureWindowTitleRec

Defines specifications of the window title.

```
struct MeasureWindowTitleRec {
    SInt16 fullTitleWidth;
    SInt16 titleTextWidth;
    Boolean isUnicodeTitle;
    Boolean unused;
};
typedef struct MeasureWindowTitleRec MeasureWindowTitleRec;
typedef MeasureWindowTitleRec * MeasureWindowTitleRecPtr;
```

Fields

`fullTitleWidth`

Your window definition function sets this field to a value specifying the total width in pixels of the window title text and any proxy icon that may be present, ignoring any compression or truncation that might be required when the title is actually drawn. That is, the specified width should be the ideal width that would be used if the window were sufficiently wide to draw the entire title along with a proxy icon. You should measure the title width using the current system font. If no proxy icon is present, this field should have the same value as the `titleTextWidth` field.

`titleTextWidth`

Your window definition function sets this field to a value specifying the width in pixels of the window title text, ignoring any compression or truncation that might be required when the title is actually drawn. That is, the specified width should be the ideal width that would be used if the window were sufficiently wide to draw the entire title. You should measure the title width using the current system font.

`isUnicodeTitle`

Your window definition function may ignore this field; it is reserved for future use.

`unused`

Your window definition function may ignore this field; it is reserved for future use.

Discussion

If you implement a custom window definition function, when the Window Manager passes the message `kWindowMsgMeasureTitle` in your window definition function's `message` parameter it also passes a pointer to a structure of type `MeasureWindowTitleRec` in the `param` parameter. Your window definition function is responsible for setting the contents of the `MeasureWindowTitleRec` structure to contain data describing the ideal title width.

See "Window Definition Message Constants" (page 2036) and "Window Feature Bits" (page 2011) for more details on the `kWindowMsgMeasureTitle` message and the corresponding `kWindowCanMeasureTitle` feature flag.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`MacWindows.h`

PropertyCreator

Defines the creator of a window property.

```
typedef OSType PropertyCreator;
```

Availability

Available in Mac OS X v10.0 and later.

Declared In
MacWindows.h

PropertyTag

Defines a window property tag.

```
typedef OSType PropertyTag;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
MacWindows.h

PicHandle

Defines a picture handle.

```
typedef PicPtr * PicPatHandle;
```

PixPatHandle

Pixel pattern handle.

```
typedef PixPatPtr * PixPatHandle;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
QuickdrawTypes.h

RGBColor

RGB color.

```
struct RGBColor {
    unsigned short red;
    unsigned short green;
    unsigned short blue;
};
typedef struct RGBColor;
typedef RGBColor * RGBColorPtr;
```

Fields
red
An unsigned short integer specifying the red value of the color.
green
An unsigned short integer specifying the green value of the color.

`blue`
An unsigned short integer specifying the red value of the color.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`IOMacOSTypes.h`

RgnHandle

Region handle.

```
typedef struct OpaqueRgnHandle * RgnHandle;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`QuickdrawTypes.h`

SetupWindowProxyDragImageRec

Defines a window proxy drag image.

```
struct SetupWindowProxyDragImageRec {
    GWorldPtr imageGWorld;
    RgnHandle imageRgn;
    RgnHandle outlineRgn;
};
typedef struct SetupWindowProxyDragImageRec SetupWindowProxyDragImageRec;
```

Fields
`imageGWorld`
A pointer to the offscreen graphics world containing the drag image. The window definition function must allocate the offscreen graphics world, since the Window Manager has no way of knowing the appropriate size for the drag image. The Window Manager disposes of the offscreen graphics world.

`imageRgn`
A handle to a region containing the drag image. Only this portion of the offscreen graphics world referred to by the `imageGWorld` field is actually drawn. The Window Manager allocates and disposes of this region.

`outlineRgn`
A handle to a region containing an outline of the drag image, for use on monitors incapable of displaying the drag image itself. The Window Manager allocates and disposes of this region.

Discussion
If you implement a custom window definition function, when the function `TrackWindowProxyDrag` (page 1963) is called, the Window Manager passes the message `kWindowMsgSetupProxyDragImage` in your window definition function's `message` parameter and passes a pointer to a structure of type `SetupWindowProxyDragImageRec` in the `param` parameter. Your window definition function is responsible for setting the contents of the `SetupWindowProxyDragImageRec` structure to contain data describing the proxy icon's drag image.

See "Window Definition Message Constants" (page 2036)and "Window Feature Bits" (page 2011) for more details on the `kWindowMsgSetupProxyDragImage` message and the corresponding `kWindowCanSetupProxyDragImage` feature flag.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MacWindows.h`

TransitionWindowOptions

Defines transition options used when calling `TransitionWindowWithOptions`.

```
struct TransitionWindowOptions {
    UInt32 version;
    EventTime duration;
    WindowRef window;
    void * userData;
};
typedef struct TransitionWindowOptions TransitionWindowOptions;
```

Fields

`version`
The structure version. You must put `0` in this field.

`duration`
The duration of the fade, in seconds. For use with the Sheet, Slide, Fade, and Genie transition effects; ignored for other effects. You may pass 0 to use the default duration. The effect is not guaranteed to last precisely this long, but should be a close approximation.

`window`
The parent window of the sheet; for use with `kWindowSheetTransitionEffect`.

`userData`
A value that is sent as the `kEventParamUserData` parameter for the `kEventWindowTransitionStarted` and `kEventWindowTransitionCompleted` events.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`MacWindows.h`

WindowDefSpec

Defines a window definition.

```
struct WindowDefSpec {
    WindowDefType defType
    union {
        WindowDefUPP defProc;
        void * classRef;
        short procID;
        void * rootView;
    } u;
};
typedef struct WindowDefSpec WindowDefSpec;
typedef WindowDefSpec * WindowDefSpecPtr;
```

Fields

`defType`

The window definition type. See "Window Definition Type Constants" (page 2033) for a list of possible values.

`u`

A pointer to the window definition, depending on the constant passed into the `defType` field.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MacWindows.h`

WindowDefUPP

Defines a UPP to a specified window definition.

```
typedef WindowDefProcPtr WindowDefUPP;
```

Discussion
For more information, see `WindowDefProcPtr` (page 1973).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MacWindows.h`

WindowGroupRef

Represents a window group.

```
typedef struct OpaqueWindowGroupRef * WindowGroupRef;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MacWindows.h`

WindowPaintUPP

Defines a UPP to the specified region painting callback.

```
typedef WindowPaintProcPtr WindowPaintUPP;
```

Discussion
For more information, see `WindowPaintProcPtr` (page 1978).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MacWindows.h`

WindowRef

An opaque type that represents a window.

```
typedef WindowPtr WindowRef;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`QuickdrawTypes.h`

WStateData

Stores the user state and the standard state of a window.

```
struct WStateData {
    Rect userState;
    Rect stdState;
};
typedef struct WStateData WStateData;
typedef WStateData * WStateDataPtr;
```

Fields

`userState`

A rectangle that describes the window size and location established by the user.

The Window Manager initializes the user state to the size and location of the window when it is first displayed, and then updates the `userState` field whenever the user resizes a window. Although the user state specifies both the size and location of the window, the Window Manager updates the window state data structure only when the user resizes a window—not when the user merely moves a window.

`stdState`

The rectangle describing the window size and location that your application considers the most convenient, considering the function and contents of the document, the screen space available, and the position of the window in its user state. If your application does not define a standard state, the Window Manager automatically sets the standard state to the entire gray region on the main screen, minus a three-pixel border on all sides. The user cannot change a window's standard state.

Discussion
When the Appearance Manager is available, you should not extend the window state data structure. Instead use the `refCon` field of the color window structure or extend the window record structure.

The zoom box allows the user to alternate quickly between two window positions and sizes: the user state and the standard state. The Window Manager stores the user state and your application stores the standard state in the window state data structure of type `WStateData`. The handle to this structure appears in the `dataHandle` field of the window structure.

The `ZoomWindow` (page 1971) function changes the size of a window according to the values in the window state data structure.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MacWindows.h`

Constants

Window Class Constants

Constants that specify the standard window classes.

```
typedef UInt32 WindowClass;
enum {
    kAlertWindowClass = 1,
    kMovableAlertWindowClass = 2,
    kModalWindowClass = 3,
    kMovableModalWindowClass = 4,
    kFloatingWindowClass = 5,
    kDocumentWindowClass = 6,
    kUtilityWindowClass = 8,
    kHelpWindowClass = 10,
    kSheetWindowClass = 11,
    kToolbarWindowClass = 12,
    kPlainWindowClass = 13,
    kOverlayWindowClass = 14,
    kSheetAlertWindowClass = 15,
    kAltPlainWindowClass = 16,
    kDrawerWindowClass = 20,
    kAllWindowClasses = 0xFFFFFFFF
};
```

Constants

`kAlertWindowClass`

Identifies an alert box window. An alert window is used when the application needs the user's attention immediately. On Mac OS 9 and earlier, a visible alert window will prevent the user from switching to any other application. Use `kThemeBrushAlertBackgroundActive` to draw the background of alert windows. Alert windows are initially placed in the modal window group, given a modality of `kWindowModalityAppModal`, and given an activation scope of `kWindowActivationScopeAll`.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kMovableAlertWindowClass`

Identifies a movable alert box window. Generally, you should use this window class rather than `kAlertWindowClass`. Use `kThemeBrushAlertBackgroundActive` to draw the background of alert windows. Alert windows are initially placed in the modal window group, given a modality of `kWindowModalityAppModal`, and given an activation scope of `kWindowActivationScopeAll`.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kModalWindowClass`

Identifies a modal dialog box window. Use `kThemeBrushDialogBackgroundActive` to draw the background of modal dialog windows. Modal dialog windows are initially placed in the modal window group, given a modality of `kWindowModalityAppModal`, and given an activation scope of `kWindowActivationScopeAll`.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kMovableModalWindowClass`

Identifies a movable modal dialog box window. In Mac OS X and CarbonLib 1.3 and later, use `kThemeBrushMovableModalBackground` to draw the background of alert windows. Alert windows are initially placed in the modal window group, given a modality of `kWindowModalityAppModal`, and given an activation scope of `kWindowActivationScopeAll`.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kFloatingWindowClass`

Identifies a window that floats above all document windows. If your application assigns this constant to a window, the Window Manager ensures that the window has the proper floating behavior. Use `kThemeBrushUtilityWindowBackgroundActive` or `kThemeBrushDocumentWindowBackground` to draw the background of floating windows. Floating windows are initially placed in the floating window group, given a modality of `kWindowModalityNone`, and given an activation scope of `kWindowActivationScopeIndependent`.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kDocumentWindowClass`

Identifies a document window or modeless dialog box window. Use `kThemeBrushDocumentWindowBackground` or your own custom drawing to draw the background of a document window. Document windows are initially placed in the document window group, given a modality of `kWindowModalityNone`, and given an activation scope of `kWindowActivationScopeAll`.The Window Manager assigns this class to pre–Mac OS 8.5 Window Manager windows.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kUtilityWindowClass`

Identifies a utility window. A utility window is similar to a floating window, but it floats above the windows of all applications rather than just above the windows of the application that creates it. Use `kThemeBrushUtilityWindowBackgroundActive` or `kThemeBrushDocumentWindowBackground` to draw the background of utility windows. Utility windows are initially placed in the utility window group, given a modality of `kWindowModalityNone`, and given an activation scope of `kWindowActivationScopeIndependent`.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kHelpWindowClass`

Identifies a window used for help tags. It has no window frame. Typically you should use the Help Manager to display help tags, rather than creating a help tag window yourself. Help windows are initially placed in the help window group, given a modality of `kWindowModalityNone`, and given an activation scope of `kWindowActivationScopeNone`.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kSheetWindowClass`

Identifies a sheet. (Mac OS X only.) Use `kThemeBrushSheetBackgroundOpaque` to draw an opaque background for sheet windows, or `kThemeBrushSheetBackgroundTransparent` to draw a transparent background. Sheet windows are initially placed in the document window group, given a modality of `kWindowModalityNone`, and given an activation scope of `kWindowActivationScopeAll`.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kToolbarWindowClass`

Identifies a toolbar window, which is used to display a palette of controls. A toolbar window is similar to a floating window, and like a floating window, is layered above all application windows except for alert and modal windows, but is layered beneath floating windows. Toolbar windows are initially placed in the toolbar window group, given a modality of `kWindowModalityNone`, and given an activation scope of `kWindowActivationScopeNone`.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kPlainWindowClass`

Identifies a plain window, which has a single-pixel window frame. Plain windows are initially placed in the document window group, given a modality of `kWindowModalityNone`, and given an activation scope of `kWindowActivationScopeAll`.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kOverlayWindowClass`

Identifies an overlay window, which is a completely transparent window. Overlay windows are positioned by default above all other windows, but you can group an overlay window with any other window, at any z-order. Overlay windows are intended as a replacement for the pre-Carbon practice of drawing directly into the Window Manager port. By creating a full-screen overlay window and drawing into it, you can draw over any window in any application without disturbing the contents of the windows beneath your drawing. Overlay windows have a default handler for `kEventWindowPaint` that uses `CGContextClearRect` to clear the overlay window's alpha channel to zero. This ensures the initial transparency of the window. You can install your own `kEventWindowPaint` handler to do your own drawing; typically, you would call through to the default handler with `CallNextEventHandler` first, and then use `QDBeginCGContext` to create your own context for drawing. You can use either QuickDraw or Core Graphics to draw into an overlay window, but you must use Core Graphics to draw if you need any of your drawing to be non-opaque, since QuickDraw always sets the alpha channel of any pixels that it touches to 1.0. (QuickDraw is also deprecated in Mac OS X v10.4 and later.) You can also use the standard window event handler together with regular controls in an overlay window. When using the standard window event handler, you will probably want your `kEventWindowPaint` handler to return `eventNotHandledErr` (after calling the default handler with `CallNextEventHandler` first) so that after the Paint handler returns, the Window Manager will send a `kEventWindowDrawContent` event which the standard window event handler can respond to by drawing the controls in the window. Overlay windows are initially placed in the overlay window group, given a modality of `kWindowModalityNone`, and given an activation scope of `kWindowActivationScopeNone`.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kSheetAlertWindowClass`

Identifies an alert sheet. Use `kThemeBrushSheetBackgroundOpaque` to draw an opaque background for sheet alert windows, or `kThemeBrushSheetBackgroundTransparent` to draw a transparent background. Sheet alert windows are initially placed in the document window group, given a modality of `kWindowModalityNone`, and given an activation scope of `kWindowActivationScopeAll`.

Available in Mac OS X v10.1 and later.

Declared in `MacWindows.h`.

`kAltPlainWindowClass`
: Identifies an alternate plain window, which is similar to a plain window but has a solid black shadow on its right and bottom sides. It is rarely used in modern Mac OS applications. Alternate plain windows are initially placed in the document window group, given a modality of `kWindowModalityNone`, and given an activation scope of `kWindowActivationScopeAll`.

  Available in Mac OS X v10.1 and later.

  Declared in `MacWindows.h`.

`kDrawerWindowClass`
: Identifies a drawer. Use `kThemeBrushDrawerBackground` or `kThemeBrushDocumentWindowBackground` to draw the background of drawer windows. Drawer windows are initially placed in the document window group, given a modality of `kWindowModalityNone`, and given an activation scope of `kWindowActivationScopeAll`. Drawer windows should always be created using the compositing window attribute.

  Available in Mac OS X v10.2 and later.

  Declared in `MacWindows.h`.

`kAllWindowClasses`
: Specifier used to designate all window classes. Used with `GetFrontWindowOfClass`, `FindWindowOfClass`, and `GetNextWindowOfClass` to indicate that there should be no restriction on the class of the returned window. Also used with `GetWindowGroupOfClass` to get the root window group.

  Available in Mac OS X v10.0 and later.

  Declared in `MacWindows.h`.

Discussion
The `WindowClass` constants categorize windows into groups of like types. The grouping of windows facilitates the appropriate display (that is, both the look and the front-to-back ordering) and tracking of windows.

You can define a window's class using the function `CreateNewWindow` (page 1815) and obtain a window's class using the function `GetWindowClass` (page 1844). You can change the class of certain windows by calling `HIWindowChangeClass` (page 1876).

Window Attribute Identifiers

Constants that specify standard window attributes.

```
enum {
    kHIWindowBitCloseBox = 1,
    kHIWindowBitZoomBox = 2,
    kHIWindowBitCollapseBox = 4,
    kHIWindowBitResizable = 5,
    kHIWindowBitSideTitlebar = 6,
    kHIWindowBitToolbarButton = 7,
    kHIWindowBitUnifiedTitleAndToolbar = 8,
    kHIWindowBitTextured = 9,
    kHIWindowBitNoTitleBar = 10,
    kHIWindowBitTexturedSquareCorners = 11,
    kHIWindowBitNoTexturedContentSeparator = 12,
    kHIWindowBitDoesNotCycle = 16,
    kHIWindowBitNoUpdates = 17,
    kHIWindowBitNoActivates = 18,
    kHIWindowBitOpaqueForEvents = 19,
    kHIWindowBitCompositing = 20,
    kHIWindowBitFrameworkScaled = 21,
    kHIWindowBitNoShadow = 22,
    kHIWindowBitCanBeVisibleWithoutLogin = 23,
    kHIWindowBitAsyncDrag = 24,
    kHIWindowBitHideOnSuspend = 25,
    kHIWindowBitStandardHandler = 26,
    kHIWindowBitHideOnFullScreen = 27,
    kHIWindowBitInWindowMenu = 28,
    kHIWindowBitLiveResize = 29,
    kHIWindowBitIgnoreClicks = 30,
    kHIWindowBitNoConstrain = 32,
    kHIWindowBitDoesNotHide = 33,
    kHIWindowBitAutoViewDragTracking = 34,
    kHIWindowBitDoesNotShowBadgeInDock = 35
};
```

Constants

`kHIWindowBitCloseBox`

The window has a close box. This attribute is available for windows of class `kDocumentWindowClass` (page 1990), `kFloatingWindowClass` (page 1990), and `kUtilityWindowClass` (page 1990).

Available in Mac OS X v10.5 and later.

Declared in `MacWindows.h`.

`kHIWindowBitZoomBox`

The window has a zoom box. This attribute is available for windows of class `kDocumentWindowClass` (page 1990), `kFloatingWindowClass` (page 1990), and `kUtilityWindowClass` (page 1990). When this attribute is set on a window, both the `kWindowHorizontalZoomAttribute` and `kWindowVerticalZoomAttribute` bits are set automatically.

Available in Mac OS X v10.5 and later.

Declared in `MacWindows.h`.

`kHIWindowBitCollapseBox`
The window has a collapse box. This attribute is available for windows of class `kDocumentWindowClass` (page 1990), `kFloatingWindowClass` (page 1990), and `kUtilityWindowClass` (page 1990). For floating and utility window classes, this attribute must be added to the window after the window is created; it may not be added to the window at creation time.

Available in Mac OS X v10.5 and later.

Declared in `MacWindows.h`.

`kHIWindowBitResizable`
The window has a resize tab or box and is resizable. This attribute is available for windows of class `kDocumentWindowClass` (page 1990), `kMovableModalWindowClass` (page 1989), `kFloatingWindowClass` (page 1990), `kUtilityWindowClass` (page 1990), and `kSheetWindowClass` (page 1990).

Available in Mac OS X v10.5 and later.

Declared in `MacWindows.h`.

`kHIWindowBitSideTitlebar`
The window has a vertical title bar on the side of the window. This attribute is available for windows of the `kFloatingWindowClass` (page 1990) and `kUtilityWindowClass` (page 1990) class.

Available in Mac OS X v10.5 and later.

Declared in `MacWindows.h`.

`kHIWindowBitToolbarButton`
The window has a toolbar button. This oblong clear button shows and hides the toolbar. This attribute is available for windows of class `kDocumentWindowClass` (page 1990).

Available in Mac OS X v10.5 and later.

Declared in `MacWindows.h`.

`kHIWindowBitUnifiedTitleAndToolbar`
The window draws its window title and toolbar using a unified appearance that has no separator between the two areas. A window may not have both this attribute and the `kHIWindowBitTextured` attribute.

Available in Mac OS X v10.5 and later.

Declared in `MacWindows.h`.

`kHIWindowBitTextured`
The window uses the textured or brushed-metal appearance. Drawers can also be textured, but dynamically adjust their appearance based on their parent window's appearance; it is not necessary to specify this attribute for a textured drawer. This attribute is available for windows of class `kDocumentWindowClass` (page 1990) and `kFloatingWindowClass` (page 1990).

Available in Mac OS X v10.5 and later.

Declared in `MacWindows.h`.

`kHIWindowBitNoTitleBar`
The window's title bar can be hidden. This attribute is available for windows of class `kDocumentWindowClass` (page 1990), `kFloatingWindowClass` (page 1990), and `kUtilityWindowClass` (page 1990).

Available in Mac OS X v10.5 and later.

Declared in `MacWindows.h`.

`kHIWindowBitTexturedSquareCorners`
Indicates that a textured window should have square corners. By default, a textured window has round corners. When this attribute is set on a window, the window frame view automatically makes the grow box view opaque, and when this attribute is cleared, the window frame view automatically makes the grow box view transparent. You can change the grow box view transparency after modifying this attribute with the function `HIGrowBoxViewSetTransparent` (page 2416). Relevant only for textured windows; ignored in non-textured windows.

Available in Mac OS X v10.5 and later.

Declared in `MacWindows.h`.

`kHIWindowBitNoTexturedContentSeparator`
Indicates that no border is drawn between the toolbar and window content. This attribute is relevant only in textured windows; it is ignored in non-textured windows.

Available in Mac OS X v10.5 and later.

Declared in `MacWindows.h`.

`kHIWindowBitDoesNotCycle`
The window does not participate in window cycling invoked by Command-~ or keyboard shortcuts defined in the Keyboard & Mouse preference pane.

Available in Mac OS X v10.5 and later.

Declared in `MacWindows.h`.

`kHIWindowBitNoUpdates`
The window does not receive update events. This attribute is available for all windows.

Available in Mac OS X v10.5 and later.

Declared in `MacWindows.h`.

`kHIWindowBitNoActivates`
The window does not receive activate events. This attribute is available for all windows.

Available in Mac OS X v10.5 and later.

Declared in `MacWindows.h`.

`kHIWindowBitOpaqueForEvents`
The window receives mouse events even for areas of the window that are transparent (that is, have an alpha channel component of zero).

Available in Mac OS X v10.5 and later.

Declared in `MacWindows.h`.

`kHIWindowBitCompositing`
The window uses HIView-based compositing, which means that the entire window is comprised of HIViews, and can be treated thusly. This attribute must be specified at window creation; you may not add this attribute after the window has been created.

Available in Mac OS X v10.5 and later.

Declared in `MacWindows.h`.

`kHIWindowBitFrameworkScaled`
The window's content is scaled to match the display scale factor. This attribute can only be used when `kHIWindowBitCompositing` is also enabled. When this attribute is enabled, you may not draw with QuickDraw in the window. If this attribute is enabled and if the scale factor is something other than 1.0, the window's scale mode is `kHIWindowScaleModeFrameworkScaled`. If you specify this attribute and `kHIWindowBitApplicationScaled`, the `kHIWindowBitApplicationScaled` attribute is ignored. You may only specify this attribute at window creation time.

Available in Mac OS X v10.5 and later.

Declared in `MacWindows.h`.

`kHIWindowBitNoShadow`
The window has no shadow. This attribute is available for all windows, and is given automatically to windows of class `kOverlayWindowClass` (page 1991).

Available in Mac OS X v10.5 and later.

Declared in `MacWindows.h`.

`kHIWindowBitCanBeVisibleWithoutLogin`
The window can be made visible prior to user login. By default, in Mac OS X 10.5 and later no windows can be visible before a user logs into the system; this protects the user against certain types of malicious use of insecure applications. However, some software, such as input methods or other accessibility software, may need to deliberately make windows available prior to user login. Such software should add this window attribute to its windows.

Available in Mac OS X v10.5 and later.

Declared in `MacWindows.h`.

`kHIWindowBitAsyncDrag`
The window server drags the window automatically. Your application should not call `DragWindow` (page 1824) for this window because this function would fight with the Window Server for control. This attribute is ignored if the window is grouped with other windows in a window group that has the `kWindowGroupAttrMoveTogether` attribute.

Available in Mac OS X v10.5 and later.

Declared in `MacWindows.h`.

`kHIWindowBitHideOnSuspend`
The window is hidden automatically on suspend and shown on resume. This attribute available for all windows and is given automatically to windows of class `kFloatingWindowClass` (page 1990), `kHelpWindowClass` (page 1990), and `kToolbarWindowClass` (page 1991).

Available in Mac OS X v10.5 and later.

Declared in `MacWindows.h`.

`kHIWindowBitStandardHandler`
The window supports the standard window event handler. The standard event handler provides standard actions for common window events. See *Carbon Event Manager Programming Guide* for details. This attribute is available for all windows.

Available in Mac OS X v10.5 and later.

Declared in `MacWindows.h`.

`kHIWindowBitHideOnFullScreen`
The window is automatically hidden during full-screen mode (when the menubar is invisible) and shown afterwards. Available for all windows. This attribute is automatically given to windows of class `kUtilityWindowClass` (page 1990).

Available in Mac OS X v10.5 and later.

Declared in `MacWindows.h`.

`kHIWindowBitInWindowMenu`
The window title appears in the system-generated Window menu. This attribute is only available for windows of class `kDocumentWindowClass` (page 1990) and is automatically given to windows of that class.

Available in Mac OS X v10.5 and later.

Declared in `MacWindows.h`.

`kHIWindowBitLiveResize`
The window supports live resizing. This attribute is available for all windows.

Available in Mac OS X v10.5 and later.

Declared in `MacWindows.h`.

`kHIWindowBitIgnoreClicks`
The window never receives mouse events, even in areas that are opaque. Instead, clicks on the window are passed through to windows beneath it.

Available in Mac OS X v10.5 and later.

Declared in `MacWindows.h`.

`kHIWindowBitNoConstrain`
The window is not repositioned by the default `kEventWindowConstrain` handler in response to changes in monitor size, Dock position, and so on.

Available in Mac OS X v10.5 and later.

Declared in `MacWindows.h`.

`kHIWindowBitDoesNotHide`
The window does not hide when the application is hidden.

Available in Mac OS X v10.5 and later.

Declared in `MacWindows.h`.

`kHIWindowBitAutoViewDragTracking`
The window automatically installs Drag Manager callbacks to detect drag actions, and automatically sends HIView drag Carbon events. Setting this attribute is equivalent to calling the function `SetAutomaticControlDragTrackingEnabledForWindow` (page 643) (and calling that function will set this attribute).

Available in Mac OS X v10.5 and later.

Declared in `MacWindows.h`.

`kHIWindowBitDoesNotShowBadgeInDock`
Indicates that the Dock should not add a badge to this window's icon when the window is minimized to the Dock.

Discussion
In Mac OS X version 10.5 and later, you may use these constants to set or test the attributes of a window. For example, you may use them with the function `HIWindowCreate` (page 1880) to define the attributes of a new window, the function `HIWindowChangeAttributes` (page 1874) to change a window's attributes, and the function `HIWindowTestAttribute` (page 1896) to test whether a window has a specific attribute.

Window Attributes

Bit masks that specify standard window attributes. In Mac OS X v10.5 and later, you may use "Window Attribute Identifiers" (page 1992) instead.

```
typedef UInt32 WindowAttributes;
enum {
    kWindowNoAttributes = 0,
    kWindowCloseBoxAttribute = (1L << 0),
    kWindowHorizontalZoomAttribute = (1L << 1),
    kWindowVerticalZoomAttribute = (1L << 2),
    kWindowFullZoomAttribute = (kWindowVerticalZoomAttribute |
kWindowHorizontalZoomAttribute),
    kWindowCollapseBoxAttribute = (1L << 3),
    kWindowResizableAttribute = (1L << 4),
    kWindowSideTitlebarAttribute = (1L << 5),
    kWindowToolbarButtonAttribute = (1L << 6),
    kWindowUnifiedTitleAndToolbarAttribute = (1L << 7),
    kWindowMetalAttribute = (1L << 8),
    kWindowNoTitleBarAttribute = (1L << 9),
    kWindowTexturedSquareCornersAttribute = (1L << 10),
    kWindowMetalNoContentSeparatorAttribute = (1L << 11),
    kWindowDoesNotCycleAttribute = (1L << 15),
    kWindowNoUpdatesAttribute = (1L << 16),
    kWindowNoActivatesAttribute = (1L << 17),
    kWindowOpaqueForEventsAttribute = (1L << 18),
    kWindowCompositingAttribute = (1L << 19),
    kWindowFrameworkScaledAttribute = (1L << 20),
    kWindowNoShadowAttribute = (1L << 21),
    kWindowCanBeVisibleWithoutLoginAttribute = (1L << 22),
    kWindowAsyncDragAttribute = (1L << 23),
    kWindowHideOnSuspendAttribute = (1L << 24),
    kWindowStandardHandlerAttribute = (1L << 25),
    kWindowHideOnFullScreenAttribute = (1L << 26),
    kWindowInWindowMenuAttribute = (1L << 27),
    kWindowLiveResizeAttribute = (1L << 28),
    kWindowIgnoreClicksAttribute = (1L << 29),
    kWindowNoConstrainAttribute = (1L << 31),
    kWindowStandardDocumentAttributes = (kWindowCloseBoxAttribute |
kWindowFullZoomAttribute | kWindowCollapseBoxAttribute | kWindowResizableAttribute),
    kWindowStandardFloatingAttributes = (kWindowCloseBoxAttribute |
kWindowCollapseBoxAttribute)
};
```

Constants

`kWindowNoAttributes`

If no bits are set, the window has none of the standard attributes.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowCloseBoxAttribute`

If the bit specified by this mask is set, the window has a close box. See `kHIWindowBitCloseBox` (page 1993).

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowHorizontalZoomAttribute`
If the bit specified by this mask is set, the window changes width when zooming. See `kHIWindowBitZoomBox` (page 1993).

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowVerticalZoomAttribute`
If the bit specified by this mask is set, the window changes height when zooming. See `kHIWindowBitZoomBox` (page 1993).

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowFullZoomAttribute`
If the bits specified by this mask are set, the window changes both width and height when zooming. See `kHIWindowBitZoomBox` (page 1993).

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowCollapseBoxAttribute`
If the bit specified by this mask is set, the window has a collapse box. See `kHIWindowBitCollapseBox` (page 1994).

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowResizableAttribute`
If the bit specified by this mask is set, the window has a resize tab or box and is resizable. See `kHIWindowBitResizable` (page 1994).

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowSideTitlebarAttribute`
If the bit specified by this mask is set, the window has a side title bar. See `kHIWindowBitSideTitlebar` (page 1994).

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowToolbarButtonAttribute`
If the bit specified by this mask is set, the window has a toolbar button. See `kHIWindowBitToolbarButton` (page 1994).

Available in Mac OS X v10.1 and later.

Declared in `MacWindows.h`.

`kWindowUnifiedTitleAndToolbarAttribute`
If the bit specified by this mask is set, the window draws its window title and toolbar using a unified appearance that has no separator between the two areas. A window may not have both this attribute and the `kWindowMetalAttribute` attribute.

Available in Mac OS X v10.5 and later.

Declared in `MacWindows.h`.

`kWindowMetalAttribute`
If the bit specified by this mask is set, the window has a textured or brushed-metal appearance. See `kHIWindowBitTextured` (page 1994).

Available in Mac OS X v10.2 and later.

Declared in `MacWindows.h`.

`kWindowNoTitleBarAttribute`
If the bit specified by this mask is set, the window's title bar can be hidden. See `kHIWindowBitNoTitleBar` (page 1994).

Available in Mac OS X v10.4 and later.

Declared in `MacWindows.h`.

`kWindowTexturedSquareCornersAttribute`
See `kHIWindowBitTexturedSquareCorners` (page 1995).

Available in Mac OS X v10.5 and later.

Declared in `MacWindows.h`.

`kWindowMetalNoContentSeparatorAttribute`
If the bit specified by this mask is set, no border is drawn between the toolbar and window content. See `kHIWindowBitNoTexturedContentSeparator` (page 1995).

Available in Mac OS X v10.4 and later.

Declared in `MacWindows.h`.

`kWindowDoesNotCycleAttribute`
If the bit specified by this mask is set, the window does not participate in window cycling. See `kHIWindowBitDoesNotCycle` (page 1995).

Available in Mac OS X v10.3 and later.

Declared in `MacWindows.h`.

`kWindowNoUpdatesAttribute`
If the bit specified by this mask is set, the window does not receive update events. See `kHIWindowBitNoUpdates` (page 1995).

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowNoActivatesAttribute`
If the bit specified by this mask is set, the window does not receive activate events. See `kHIWindowBitNoActivates` (page 1995).

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowOpaqueForEventsAttribute`
If the bit specified by this mask is set, the window receives mouse events even for areas of the window that are transparent. See `kHIWindowBitOpaqueForEvents` (page 1995).

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowCompositingAttribute`
If the bit specified by this mask is set, the window uses HIView-based compositing. See `kHIWindowBitCompositing` (page 1995).

Available in Mac OS X v10.2 and later.

Declared in `MacWindows.h`.

`kWindowFrameworkScaledAttribute`
If the bit specified by this mask is set, this window's content is scaled to match the display scale factor. See `kHIWindowBitFrameworkScaled` (page 1996).

Available in Mac OS X v10.4 and later.

Declared in `MacWindows.h`.

`kWindowNoShadowAttribute`
If the bit specified by this mask is set, the window has no shadow. See `kHIWindowBitNoShadow` (page 1996).

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowCanBeVisibleWithoutLoginAttribute`
If the bit specified by this mask is set, the window can be made visible prior to user login. See `kHIWindowBitCanBeVisibleWithoutLogin` (page 1996).

Available in Mac OS X v10.5 and later.

Declared in `MacWindows.h`.

`kWindowAsyncDragAttribute`
If the bit specified by this mask is set, the window server drags the window automatically. See `kHIWindowBitAsyncDrag` (page 1996).

Available in Mac OS X v10.3 and later.

Declared in `MacWindows.h`.

`kWindowHideOnSuspendAttribute`
If the bit specified by this mask is set, the window is hidden automatically on suspend and shown on resume. See `kHIWindowBitHideOnSuspend` (page 1996).

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowStandardHandlerAttribute`
If the bit specified by this mask is set, the window supports the standard window event handler. See `kHIWindowBitStandardHandler` (page 1996).

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowHideOnFullScreenAttribute`
If the bit specified by this mask is set, the window is automatically hidden during fullscreen mode (when the menubar is invisible) and shown afterwards. See `kHIWindowBitHideOnFullScreen` (page 1997).

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowInWindowMenuAttribute`
If the bit specified by this mask is set, the window title appears in the system-generated Window menu. See `kHIWindowBitInWindowMenu` (page 1997).

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowLiveResizeAttribute`
If the bit specified by this mask is set, the window supports live resizing. See `kHIWindowBitLiveResize` (page 1997).

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowIgnoreClicksAttribute`
If the bit specified by this mask is set, the window never receives mouse events, even in areas that are opaque. See `kHIWindowBitIgnoreClicks` (page 1997).

Available in Mac OS X v10.2 and later.

Declared in `MacWindows.h`.

`kWindowNoConstrainAttribute`
If the bit specified by this mask is set, the window is not repositioned by the default `kEventWindowConstrain` handler. See `kHIWindowBitNoConstrain` (page 1997).

Available in Mac OS X v10.1 and later.

Declared in `MacWindows.h`.

`kWindowStandardDocumentAttributes`
If the bits specified by this mask are set, the window has the attributes of a standard document window—that is, a close box, full zoom box, collapse box, and size box.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowStandardFloatingAttributes`
If the bits specified by this mask are set, the window has the attributes of a standard floating window—that is, a close box and collapse box.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

Discussion
The `WindowAttributes` enumeration defines masks your application can use to set or test the bits in a window attributes parameter. You can use these masks with the function `CreateNewWindow` (page 1815) to define a window's attributes, and with the function `ChangeWindowAttributes` (page 1805) to change a window's attributes. You can also use these masks to test the attributes parameter produced by the function `GetWindowAttributes` (page 1842), thereby obtaining a window's attributes.

User Focus Auto-Select Constant

Defines a constant that tells the system to pick the best user focus window.

```
#define kUserFocusAuto  ((WindowRef)(-1))
```

Constants
`kUserFocusAuto`
Pass this constant to the function `SetUserFocusWindow` (page 1934) to have the system choose the most appropriate window for user focus.

Available in Mac OS X v10.2 and later.

Declared in `MacWindows.h`.

Appearance-Compliant Window Resource IDs

Define window resources for Appearance-compliant applications.

```
enum {
    kWindowDocumentDefProcResID = 64,
    kWindowDialogDefProcResID = 65,
    kWindowUtilityDefProcResID = 66,
    kWindowUtilitySideTitleDefProcResID = 67,
    kWindowSheetDefProcResID = 68,
    kWindowSimpleDefProcResID = 69,
    kWindowSheetAlertDefProcResID = 70
};
```

Constants

`kWindowDocumentDefProcResID`

Defines Appearance-compliant standard document windows with a size box. Standard document windows created with this resource ID can use variation codes to create windows with vertical and horizontal zoom boxes.

Available with Appearance 1.0 and later.

Declared in `MacWindows.h`.

`kWindowDialogDefProcResID`

Defines Appearance-compliant dialog and alert boxes. Modal and movable modal dialog boxes created with this resource ID are displayed with no space between their content and structure region. Alert boxes created with this resource ID are displayed with a red-tinged border.

Declared in `MacWindows.h`.

Available with Appearance 1.0 and later.

`kWindowUtilityDefProcResID`

Defines Appearance-compliant utility (floating) windows with a top title bar and a size box.

Available with Appearance 1.0 and later.

Declared in `MacWindows.h`.

`kWindowUtilitySideTitleDefProcResID`

Defines Appearance-compliant utility (floating) windows with a side title bar and a size box.

Available with Appearance 1.0 and later.

Declared in `MacWindows.h`.

`kWindowSheetDefProcResID`

Defines a window sheet.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowSimpleDefProcResID`

Defines a simple window with no window frame.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowSheetAlertDefProcResID`

Defines a sheet window that is displayed as an alert (rather than a dialog) on Mac OS 9.

Available in Mac OS X v10.1 and later.

Declared in `MacWindows.h`.

Discussion
Window resource IDs are changed with Appearance Manager 1.0. The Window Manager now provides many new standard, Appearance-compliant window resource IDs for your application.

You can use a window resource ID constant to create a window definition ID; see "Pre-Appearance Window Definition IDs" in*Window Manager Legacy Reference* for more details.

Note that the standard Appearance-compliant resource ID constants `kWindowDocumentDefProcResID`, `kWindowUtilityDefProcResID`, and `kWindowUtilitySideTitleDefProcResID` specify windows with collapse boxes.

Resource IDs 0 through 127 are reserved for use by the system.

Appearance-Compliant Window Definition ID Constants

Define different window kinds.

```
enum {
    kWindowDocumentProc = 1024,
    kWindowGrowDocumentProc = 1025,
    kWindowVertZoomDocumentProc = 1026,
    kWindowVertZoomGrowDocumentProc = 1027,
    kWindowHorizZoomDocumentProc = 1028,
    kWindowHorizZoomGrowDocumentProc = 1029,
    kWindowFullZoomDocumentProc = 1030,
    kWindowFullZoomGrowDocumentProc = 1031
};
enum {
    kWindowPlainDialogProc = 1040,
    kWindowShadowDialogProc = 1041,
    kWindowModalDialogProc = 1042,
    kWindowMovableModalDialogProc = 1043,
    kWindowAlertProc = 1044,
    kWindowMovableAlertProc = 1045
};
enum {
    kWindowMovableModalGrowProc = 1046
};
enum {
    kWindowFloatProc = 1057,
    kWindowFloatGrowProc = 1059,
    kWindowFloatVertZoomProc = 1061,
    kWindowFloatVertZoomGrowProc = 1063,
    kWindowFloatHorizZoomProc = 1065,
    kWindowFloatHorizZoomGrowProc = 1067,
    kWindowFloatFullZoomProc = 1069,
    kWindowFloatFullZoomGrowProc = 1071
};
enum {
    kWindowFloatSideProc = 1073,
    kWindowFloatSideGrowProc = 1075,
    kWindowFloatSideVertZoomProc = 1077,
    kWindowFloatSideVertZoomGrowProc = 1079,
    kWindowFloatSideHorizZoomProc = 1081,
    kWindowFloatSideHorizZoomGrowProc = 1083,
    kWindowFloatSideFullZoomProc = 1085,
    kWindowFloatSideFullZoomGrowProc = 1087
};
enum {
    kWindowSheetProc = 1088,
    kWindowSheetAlertProc = 1120
};
enum {
    kWindowSimpleProc = 1104,
    kWindowSimpleFrameProc = 1105
};
```

Constants

`kWindowDocumentProc`

Appearance-compliant movable window with no size box or zoom box. Available with Appearance 1.0 and later. The corresponding pre-Appearance window definition ID is `noGrowDocProc`.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowGrowDocumentProc`
: Appearance-compliant standard document window (movable window with size box). Available with Appearance 1.0 and later. The corresponding pre-Appearance window definition ID is `documentProc`.

  Available in Mac OS X v10.0 and later.

  Declared in `MacWindows.h`.

`kWindowVertZoomDocumentProc`
: Appearance-compliant window with vertical zoom box and no size box. Available with Appearance 1.0 and later. There is no corresponding pre-Appearance window definition ID.

  Available in Mac OS X v10.0 and later.

  Declared in `MacWindows.h`.

`kWindowVertZoomGrowDocumentProc`
: Appearance-compliant window with vertical zoom box and size box. Available with Appearance 1.0 and later. There is no corresponding pre-Appearance window definition ID.

  Available in Mac OS X v10.0 and later.

  Declared in `MacWindows.h`.

`kWindowHorizZoomDocumentProc`
: Appearance-compliant window with horizontal zoom box and no size box. Available with Appearance 1.0 and later. There is no corresponding pre-Appearance window definition ID.

  Available in Mac OS X v10.0 and later.

  Declared in `MacWindows.h`.

`kWindowHorizZoomGrowDocumentProc`
: Appearance-compliant window with horizontal zoom box and size box. Available with Appearance 1.0 and later. There is no corresponding pre-Appearance window definition ID.

  Available in Mac OS X v10.0 and later.

  Declared in `MacWindows.h`.

`kWindowFullZoomDocumentProc`
: Appearance-compliant window with full zoom box and no size box. Available with Appearance 1.0 and later. The corresponding pre-Appearance window definition ID is `zoomNoGrow`.

  Available in Mac OS X v10.0 and later.

  Declared in `MacWindows.h`.

`kWindowFullZoomGrowDocumentProc`
: Appearance-compliant window with full zoom box and size box. Available with Appearance 1.0 and later. The corresponding pre-Appearance window definition ID is `zoomDocProc`.

  Available in Mac OS X v10.0 and later.

  Declared in `MacWindows.h`.

`kWindowPlainDialogProc`
: Appearance-compliant modeless dialog box. Available with Appearance 1.0 and later. The corresponding pre-Appearance window definition ID is `plainDBox`.

  Available in Mac OS X v10.0 and later.

  Declared in `MacWindows.h`.

`kWindowShadowDialogProc`
Appearance-compliant modeless dialog box with shadow. Available with Appearance 1.0 and later. The corresponding pre-Appearance window definition ID is `altDBoxProc`.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowModalDialogProc`
Appearance-compliant modal dialog box. Available with Appearance 1.0 and later. The corresponding pre-Appearance window definition ID is `dBoxProc`.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowMovableModalDialogProc`
Appearance-compliant movable modal dialog box. Available with Appearance 1.0 and later. The corresponding pre-Appearance window definition ID is `movableDBoxProc`.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowAlertProc`
Appearance-compliant alert box. Available with Appearance 1.0 and later. There is no corresponding pre-Appearance window definition ID.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowMovableAlertProc`
Appearance-compliant movable alert box. Available with Appearance 1.0 and later. There is no corresponding pre-Appearance window definition ID.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowMovableModalGrowProc`
Appearance-compliant movable modal dialog box with size box. Available with Appearance 1.0.1 and later. There is no corresponding pre-Appearance window definition ID.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowFloatProc`
Appearance-compliant utility (floating) window with no size box or zoom box. Available with Appearance 1.0 and later. The corresponding pre-Appearance window definition ID is `floatProc`.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowFloatGrowProc`
Appearance-compliant utility (floating) window with a size box. Available with Appearance 1.0 and later. The corresponding pre-Appearance window definition ID is `floatGrowProc`.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowFloatVertZoomProc`
: Appearance-compliant utility (floating) window with a vertical zoom box. Available with Appearance 1.0 and later. There is no corresponding pre-Appearance window definition ID.

  Available in Mac OS X v10.0 and later.

  Declared in `MacWindows.h`.

`kWindowFloatVertZoomGrowProc`
: Appearance-compliant utility (floating) window with a vertical zoom box and size box. Available with Appearance 1.0 and later. There is no corresponding pre-Appearance window definition ID.

  Available in Mac OS X v10.0 and later.

  Declared in `MacWindows.h`.

`kWindowFloatHorizZoomProc`
: Appearance-compliant utility (floating) window with a horizontal zoom box. Available with Appearance 1.0 and later. There is no corresponding pre-Appearance window definition ID.

  Available in Mac OS X v10.0 and later.

  Declared in `MacWindows.h`.

`kWindowFloatHorizZoomGrowProc`
: Appearance-compliant utility (floating) window with a horizontal zoom box and size box. Available with Appearance 1.0 and later. There is no corresponding pre-Appearance window definition ID.

  Available in Mac OS X v10.0 and later.

  Declared in `MacWindows.h`.

`kWindowFloatFullZoomProc`
: Appearance-compliant utility (floating) window with full zoom box. Available with Appearance 1.0 and later. The corresponding pre-Appearance window definition ID is `floatZoomProc`.

  Available in Mac OS X v10.0 and later.

  Declared in `MacWindows.h`.

`kWindowFloatFullZoomGrowProc`
: Appearance-compliant utility (floating) window with full zoom box and size box. Available with Appearance 1.0 and later. The corresponding pre-Appearance window definition ID is `floatZoomGrowProc`.

  Available in Mac OS X v10.0 and later.

  Declared in `MacWindows.h`.

`kWindowFloatSideProc`
: Appearance-compliant utility (floating) window with side title bar. Available with Appearance 1.0 and later. The corresponding pre-Appearance window definition ID is `floatSideProc`.

  Available in Mac OS X v10.0 and later.

  Declared in `MacWindows.h`.

`kWindowFloatSideGrowProc`
: Appearance-compliant utility (floating) window with side title bar and size box. Available with Appearance 1.0 and later. The corresponding pre-Appearance window definition ID is `floatSideGrowProc`.

  Available in Mac OS X v10.0 and later.

  Declared in `MacWindows.h`.

`kWindowFloatSideVertZoomProc`
: Appearance-compliant utility (floating) window with side title bar and vertical zoom box. Available with Appearance 1.0 and later. There is no corresponding pre-Appearance window definition ID.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowFloatSideVertZoomGrowProc`
: Appearance-compliant utility (floating) window with side title bar, vertical zoom box, and size box. Available with Appearance 1.0 and later. There is no corresponding pre-Appearance window definition ID.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowFloatSideHorizZoomProc`
: Appearance-compliant utility (floating) window with side title bar and horizontal zoom box. Available with Appearance 1.0 and later. There is no corresponding pre-Appearance window definition ID.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowFloatSideHorizZoomGrowProc`
: Appearance-compliant utility (floating) window with side title bar, horizontal zoom box, and size box. Available with Appearance 1.0 and later. There is no corresponding pre-Appearance window definition ID.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowFloatSideFullZoomProc`
: Appearance-compliant utility (floating) window with side title bar and full zoom box. Available with Appearance 1.0 and later. The corresponding pre-Appearance window definition ID is `floatSideZoomProc`.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowFloatSideFullZoomGrowProc`
: Appearance-compliant utility (floating) window with side title bar, full zoom box, and size box. Available with Appearance 1.0 and later. The corresponding pre-Appearance window definition ID is `floatSideZoomGrowProc`.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowSheetProc`
: A standard document sheet.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowSheetAlertProc`
: An alert sheet.

Available in Mac OS X v10.1 and later.

Declared in `MacWindows.h`.

`kWindowSimpleProc`
A window that has no structure region; the content covers the entire window.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowSimpleFrameProc`
A window that has a 1-pixel black frame as its structure.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

Basic Window Description State Constant

Define the window description state constant.

```
enum {
    kWindowIsCollapsedState = (1 << 0L)
};
```

Constants

`kWindowIsCollapsedState`
If the bit specified by this mask is set, the window is currently collapsed.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

Discussion

You can use this mask to set a bit in the `windowStateFlags` field of a structure of type `BasicWindowDescription` (page 1979), thereby specifying a transient window state.

Window Frame View Part Codes

HIView part codes used by window frame views.

```
enum {
    kHIWindowTitleBarPart = 2,
    kHIWindowDragPart = 3,
    kHIWindowTitleProxyIconPart = 2
};
```

Constants

`kHIWindowTitleBarPart`
Identifies the title bar part of a window frame view. This part code is used by the functions `GetWindowBounds` (page 1843) and `GetWindowRegion` (page 1864) when called with `kWindowTitleBarRgn`.

Available in Mac OS X v10.5 and later.

Declared in `HIWindowViews.h`.

`kHIWindowDragPart`
Identifies the draggable part of a window frame view. This part code is used by `GetWindowBounds` (page 1843) and `GetWindowRegion` (page 1864) when called with `kWindowDragRgn`.

Available in Mac OS X v10.5 and later.

Declared in `HIWindowViews.h`.

`kHIWindowTitleProxyIconPart`
Identifies the proxy icon part of a window frame title view. The title view is a subview of the window frame view and is identified by an HIViewID of `kHIViewWindowTitleID`. This part code is not used by the window frame view itself, but only by the title view. This part code is used by `GetWindowBounds` (page 1843) and `GetWindowRegion` (page 1864) when called with `kWindowTitleProxyIconRgn`.

Available in Mac OS X v10.5 and later.

Declared in `HIWindowViews.h`.

Discussion
These part codes are used by an HIView that implements the frame of a window. They may be used with the standard document windows provided by the Window Manager. A custom window frame view may optionally (but is not required to) implement these part codes in its event handlers for `kEventControlGetPartRegion` and `kEventControlGetPartBounds`.

Window Feature Bits

Specify features available in a window.

```
enum {
    kWindowCanGrow = (1 << 0),
    kWindowCanZoom = (1 << 1),
    kWindowCanCollapse = (1 << 2),
    kWindowIsModal = (1 << 3),
    kWindowCanGetWindowRegion = (1 << 4),
    kWindowIsAlert = (1 << 5),
    kWindowHasTitleBar = (1 << 6),
    kWindowSupportsDragHilite = (1 << 7),
    kWindowSupportsModifiedBit = (1 << 8),
    kWindowCanDrawInCurrentPort = (1 << 9),
    kWindowCanSetupProxyDragImage = (1 << 10),
    kWindowCanMeasureTitle = (1 << 11),
    kWindowWantsDisposeAtProcessDeath = (1 << 12),
    kWindowSupportsGetGrowImageRegion = (1 << 13),
    kWindowIsOpaque = (1 << 14),
    kWindowDefSupportsColorGrafPort = 0x40000002
};
```

Constants
`kWindowCanGrow`
If this bit (bit 0) is set, the window has a grow box (may not be visible).

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowCanZoom`
If this bit (bit 1) is set, the window has a zoom box (may not be visible).

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowCanCollapse`
If this bit (bit 2) is set, the window has a collapse box.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowIsModal`
If this bit (bit 3) is set, the window should behave as modal.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowCanGetWindowRegion`
If this bit (bit 4) is set, the window supports a call to `GetWindowRegion` (page 1864).

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowIsAlert`
If this bit (bit 5) is set, the window is an alert box (may be movable or not). When this constant is added to `kWindowIsModal`, the user should be able to switch out of the application and move the alert box.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowHasTitleBar`
If this bit (bit 6) is set, the window has a title bar.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowSupportsDragHilite`
If the bit specified by this mask is set, the window supports the `kWindowMsgDragHilite` message. (Mac OS 8.5 and later.)

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowSupportsModifiedBit`
If the bit specified by this mask is set, the window supports the `kWindowMsgModified` message. (Mac OS 8.5 and later.)

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowCanDrawInCurrentPort`
If the bit specified by this mask is set, the window supports the `kWindowMsgDrawInCurrentPort` message. (Mac OS 8.5 and later.)

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowCanSetupProxyDragImage`
If the bit specified by this mask is set, the window supports the `kWindowMsgSetupProxyDragImage` message. (Mac OS 8.5 and later.)

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowCanMeasureTitle`
If the bit specified by this mask is set, the window supports the `kWindowMsgMeasureTitle` message. (Mac OS 8.5 and later.)

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowWantsDisposeAtProcessDeath`

If the bit specified by this mask is set, the window definition function wants to receive a `wDispose` message for the window if it still exists when the application quits.

Previously, the Window Manager would send a `wDispose` message only if the application explicitly closed the window with calls to the `CloseWindow` or `DisposeWindow` functions. The Window Manager would delete a window that still existed when the application called `ExitToShell` without notifying the window definition function, as part of the destruction of the process.

Note that if a window has the `kWindowWantsDisposeAtProcessDeath` feature bit set, the Window Manager sends your window definition function a `wDispose` message for the window when the application exits for any cause, including if your application crashes.

A window might want to set this feature flag if it allocates data when it is initialized that lives outside of the application heap and that is not automatically disposed when the application quits. The `wDispose` message is sent very early in the termination process, so it is still safe for the window definition function to call the system back (for example, you may want to do this in order to dispose of any auxiliary data). However, to ensure compatibility and to create the minimum performance impact, the window definition function should try to do as little as possible after receiving a `wDispose` message sent during the termination process. (Mac OS 8.5 and later.)

This feature is only available in Mac OS 8 and 9. It is not supported in Mac OS X.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowSupportsGetGrowImageRegion`

(Mac OS 8.5 and later.)

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowIsOpaque`

Indicates that the window is entirely opaque. If this feature bit is set, the window will use less memory because no alpha channel information will be stored for the window's pixels.

Available in Mac OS X v10.1 and later.

Declared in `MacWindows.h`.

`kWindowDefSupportsColorGrafPort`

Indicates that the window definition does not require that the current port be the classic Window Manager port. Not supported in Mac OS X.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

Discussion

For descriptions of the messages that correspond to these feature flags, see "Window Definition Message Constants" (page 2036).

Window Part Code Constants

Indicate which part of the window was hit.

```
typedef SInt16 WindowPartCode;
enum {
    inDesk = 0,
    inNoWindow = 0,
    inMenuBar = 1,
    inSysWindow = 2,
    inContent = 3,
    inDrag = 4,
    inGrow = 5,
    inGoAway = 6,
    inZoomIn = 7,
    inZoomOut = 8,
    inCollapseBox = 11,
    inProxyIcon = 12,
    inToolbarButton = 13,
    inStructure = 15
};
```

Constants

`inDesk`

The cursor is in the desktop region, not in the menu bar, a driver window, or any window that belongs to your application. When `FindWindow` (page 1827) returns `inDesk`, your application doesn't need to do anything.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`inNoWindow`

The cursor is not in a window.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`inMenuBar`

The user has pressed the mouse button while the cursor is in the menu bar. When `FindWindow` returns `inMenuBar`, your application typically adjusts its menus and then calls the Menu Manager function `MenuSelect` to let the user choose menu items.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`inSysWindow`

Not supported by Carbon.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`inContent`

The user has pressed the mouse button while the cursor is in the content area (excluding the size box in an active window) of one of your application's windows. When `FindWindow` returns `inContent`, your application determines how to handle clicks in the content region.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`inDrag`

The user has pressed the mouse button while the cursor is in the drag region of a window. When `FindWindow` returns `inDrag`, your application typically calls `DragWindow` to let the user drag the window to a new location.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`inGrow`

The user has pressed the mouse button while the cursor is in an active window's size box. When `FindWindow` returns `inGrow`, your application typically calls `ResizeWindow` (page 1925).

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`inGoAway`

The user has pressed the mouse button while the cursor is in an active window's close box. When `FindWindow` returns `inGoAway`, your application typically calls`TrackGoAway` (page 1962) to track mouse activity while the button is down and then calls its own function for closing a window if the user releases the button while the cursor is in the close box.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`inZoomIn`

The user has pressed the mouse button while the cursor is in the zoom box of an active window that is currently in the standard state. When `FindWindow` returns `inZoomIn`, your application typically calls `TrackBox` to track mouse activity while the button is down and then calls its own function for zooming a window if the user releases the button while the cursor is in the zoom box.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`inZoomOut`

The user has pressed the mouse button while the cursor is in the zoom box of an active window that is currently in the user state. When `FindWindow` returns `inZoomOut`, your application typically calls the function `TrackBox` to track mouse activity while the button is down. Your application then calls its own function for zooming a window if the user releases the button while the cursor is in the zoom box.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`inCollapseBox`

The user has pressed the mouse button while the cursor is in an active window's collapse box. When `FindWindow` returns `inCollapseBox`, your application typically does nothing, because the system will collapse your window for you.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`inProxyIcon`

The user has pressed the mouse button while the cursor is in the proxy icon of a window. When `FindWindow` returns `inProxyIcon`, your application typically calls the function `TrackWindowProxyDrag` (page 1963).

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`inToolbarButton`
The user has pressed the mouse button while the cursor is in the toolbar button. (Mac OS X only.)

Available in Mac OS X v10.1 and later.

Declared in `MacWindows.h`.

`inStructure`
The user has pressed the mouse button while the cursor is in the window's structure region.

Available in Mac OS X v10.1 and later.

Declared in `MacWindows.h`.

Discussion
When your application receives a mouse-down event, you typically call `FindWindow` (page 1827), which returns an integer that specifies the location, in global coordinates, of the cursor at the time the user pressed the mouse button.

Window Modality Options

Specify the modality of a window.

```
typedef UInt32 WindowModality;
enum {
    kWindowModalityNone = 0,
    kWindowModalitySystemModal = 1,
    kWindowModalityAppModal = 2,
    kWindowModalityWindowModal = 3
};
```

Constants
`kWindowModalityNone`
A window does not prevent interaction with any other window in the system.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowModalitySystemModal`
The window is system-modal. In Mac OS 9 and earlier, the user cannot perform any other action until the window is dismissed. In Mac OS X, this constant produces the same behavior as `kWindowModalityAppModal`, so there is no way to prevent the user from interacting with windows from other applications.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowModalityAppModal`
The window is application-modal; that is the user cannot perform any other action within the application until the window is dismissed. The user can switch to other applications, however.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowModalityWindowModal`
The window is document-modal; the user cannot perform any other action within the current document window until the modal window associated with it is dismissed. The user can switch to other windows or applications, however. Sheets are document-modal.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

Window Position Constants

Define where to place a window.

```
typedef UInt32 WindowPositionMethod;
enum {
    kWindowCenterOnMainScreen = 1,
    kWindowCenterOnParentWindow = 2,
    kWindowCenterOnParentWindowScreen = 3,
    kWindowCascadeOnMainScreen = 4,
    kWindowCascadeOnParentWindow = 5,
    kWindowCascadeOnParentWindowScreen = 6,
    kWindowCascadeStartAtParentWindowScreen = 10,
    kWindowAlertPositionOnMainScreen = 7,
    kWindowAlertPositionOnParentWindow = 8,
    kWindowAlertPositionOnParentWindowScreen = 9
};
```

Constants

`kWindowCenterOnMainScreen`
Center the window, both horizontally and vertically, on the screen that contains the menu bar.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowCenterOnParentWindow`
Center the window, both horizontally and vertically, on the parent window. If the window to be centered is wider than the parent window, its left edge is aligned with the parent window's left edge.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowCenterOnParentWindowScreen`
Center the window, both horizontally and vertically, on the screen containing the parent window. In Mac OS X v10.3 and later, the parent window may be the same as the positioned window. In CarbonLib and earlier versions of Mac OS X, the parent window must be different from the positioned window.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowCascadeOnMainScreen`
Place the window just below the menu bar at the left edge of the main screen. Subsequent windows are placed on the screen relative to the first window, such that the frame of the preceding window remains visible behind the current window. The exact amount by which windows are offset depends upon the dimensions of the window frame under a given appearance.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowCascadeOnParentWindow`
: Place the window a distance below and to the right of the upper-left corner of the parent window such that the frame of the parent window remains visible behind the current window. The exact amount by which windows are offset depends upon the dimensions of the window frame under a given appearance.

  Available in Mac OS X v10.0 and later.

  Declared in `MacWindows.h`.

`kWindowCascadeOnParentWindowScreen`
: Place the window just below the menu bar at the left edge of the screen containing the parent window. Subsequent windows are placed on the screen relative to the first window, such that the frame of the preceding window remains visible behind the current window. The exact amount by which windows are offset depends upon the dimensions of the window frame under a given appearance. In Mac OS X v10.3 and later, the parent window may be the same as the positioned window. In CarbonLib and earlier versions of Mac OS X, the parent window must be different from the positioned window.

  Available in Mac OS X v10.0 and later.

  Declared in `MacWindows.h`.

`kWindowCascadeStartAtParentWindowScreen`
: Cascade the window on the screen containing the largest portion of its parent window, starting below and to the right of its parent window. The parent window must be different from the positioned window. (Available in Mac OS X v10.2 and CarbonLib 1.6 and later.)

  Available in Mac OS X v10.2 and later.

  Declared in `MacWindows.h`.

`kWindowAlertPositionOnMainScreen`
: Center the window horizontally and position it vertically on the screen that contains the menu bar, such that about one-fifth of the screen is above it. In Mac OS X v10.3 and later, the parent window may be the same as the positioned window. In CarbonLib and earlier versions of Mac OS X, the parent window must be different from the positioned window.

  Available in Mac OS X v10.0 and later.

  Declared in `MacWindows.h`.

`kWindowAlertPositionOnParentWindow`
: Center the window horizontally and position it vertically such that about one-fifth of the parent window is above it.

  Available in Mac OS X v10.0 and later.

  Declared in `MacWindows.h`.

`kWindowAlertPositionOnParentWindowScreen`
: Center the window horizontally and position it vertically such that about one-fifth of the screen containing the parent window is above it.

  Available in Mac OS X v10.0 and later.

  Declared in `MacWindows.h`.

Discussion
To specify the factors that determine how a window should be positioned, you supply one of these `WindowPositionMethod` constants to the function `RepositionWindow` (page 1924) or in the `BasicWindowDescription` structure of a resource of type `'wind'`. Do not confuse the `WindowPositionMethod` constants with the pre–Mac OS 8.5 Window Manager window positioning constants or use the `WindowPositionMethod` constants where the older constants are required (such as in the `StandardAlert` function or in `'WIND'`, `'DLOG'`, or `'ALRT'` resources).

System 7 Window Positioning Constants

Define window positioning constants used in `'WIND'`, `'DLOG'`, or `'ALRT'` resources, as well as the `StandardAlert` function.

```
enum {
    kWindowNoPosition = 0x0000,
    kWindowDefaultPosition = 0x0000,
    kWindowCenterMainScreen = 0x280A,
    kWindowAlertPositionMainScreen = 0x300A,
    kWindowStaggerMainScreen = 0x380A,
    kWindowCenterParentWindow = 0xA80A,
    kWindowAlertPositionParentWindow = 0xB00A,
    kWindowStaggerParentWindow = 0xB80A,
    kWindowCenterParentWindowScreen = 0x680A,
    kWindowAlertPositionParentWindowScreen = 0x700A,
    kWindowStaggerParentWindowScreen = 0x780A
};
```

Constants

`kWindowNoPosition`
No position.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowDefaultPosition`
Use the initial location.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowCenterMainScreen`
Center the window on the main screen.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowAlertPositionMainScreen`
Place the window in the alert position on the main screen.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowStaggerMainScreen`
Stagger the window on the main screen.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowCenterParentWindow`
Center the window on the parent window.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowAlertPositionParentWindow`
Place the window in the alert position on the parent window.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowStaggerParentWindow`
Stagger the window relative to the parent window.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowCenterParentWindowScreen`
Center the window on the parent window screen.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowAlertPositionParentWindowScreen`
Place the window in the alert position on the parent window screen.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowStaggerParentWindowScreen`
Stagger the window on the parent window screen.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

Discussion
You can use these constants in the optional positioning specification field of the window resource and in the dialog resource to override the window position established by the rectangle specified for the window or dialog. These positioning constants are convenient when the user is creating new documents or when you are handling your own dialog boxes and alert boxes.

These constants are passed into the `StandardAlert` function and are used in' `WIND` ', 'DLOG', and 'ALRT' templates. `StandardAlert` uses zero to specify the default position. Other calls use zero to specify “no position”.

Do not pass these constants to the`RepositionWindow` function or store these constants in the `BasicWindowDescription` structure of a 'WIND' resource.

The meaning of the terms used in the window positioning constant descriptions are as follows:

- center

  Centered both horizontally and vertically, relative either to a screen or to another window (if a window to be centered relative to another window is wider than the window that preceded it, it is pinned to the left edge; a narrower window is centered)

- stagger

  Located 20 pixels to the right and 20 pixels below the upper-left corner of the last window (in the case of staggering relative to a screen, the first window is placed just below the menu bar at the left edge of the screen, and subsequent windows are placed on that screen relative to the first window)

- alert position

  Centered horizontally and placed in the “alert position” vertically, that is, with about one-fifth of the window or screen above the new window and the rest below

- parent window

  Place in the position of the window in which the user was last working based on the frontmost window before the new window comes up.

Window Region Constants

Define various window regions.

```
typedef UInt16 WindowRegionCode;
enum {
    kWindowTitleBarRgn = 0,
    kWindowTitleTextRgn = 1,
    kWindowCloseBoxRgn = 2,
    kWindowZoomBoxRgn = 3,
    kWindowDragRgn = 5,
    kWindowGrowRgn = 6,
    kWindowCollapseBoxRgn = 7,
    kWindowTitleProxyIconRgn = 8,
    kWindowStructureRgn = 32,
    kWindowContentRgn = 33,
    kWindowUpdateRgn = 34,
    kWindowOpaqueRgn = 35,
    kWindowGlobalPortRgn = 40,
    kWindowToolbarButtonRgn = 41
};
```

Constants

`kWindowTitleBarRgn`
The entire area occupied by a window's title bar, including the title text region.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowTitleTextRgn`
That portion of a window's title bar that is occupied by the name of the window.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowCloseBoxRgn`
The area occupied by a window's close box.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowZoomBoxRgn`
The area occupied by a window's zoom box.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowDragRgn`
The draggable area of the window frame; this area includes the title bar and window outline and excludes the size box, close box, zoom box, and collapse box.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowGrowRgn`
The area occupied by a window's size box.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowCollapseBoxRgn`
The area occupied by a window's collapse box.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowTitleProxyIconRgn`
Specifies the region in the window's title area that contains the proxy icon. The proxy icon region is always located within the window's title text region.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowStructureRgn`
The entire area occupied by a window, including the frame and content region; the window may be partially off-screen but its structure region does not change.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowContentRgn`
The window's content region—the part of a window in which your application displays the contents of the window or dialog, including the size box and any controls.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowUpdateRgn`
The window's update region––the part of the window that needs to be redrawn.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowOpaqueRgn`
Area of window considered to be opaque. Only valid for windows with alpha channels. (Mac OS X only)

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowGlobalPortRgn`
Bounds of the window's port in global coordinates; not affected by `CollapseWindow` (page 1810).

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowToolbarButtonRgn`
Bounds of the toolbar button area.

Available in Mac OS X v10.4 and later.

Declared in `MacWindows.h`.

Discussion
You can pass constants of type `WindowRegionCode` in the `inRegionCode` parameter of `GetWindowRegion` (page 1864) to obtain a handle to a specific window region. The `WindowRegionCode` constants are available with Appearance Manager 1.0 and later.

Version Notes
With the Window Manager in Mac OS 8.5 and later, you may pass the `kWindowTitleProxyIconRgn`, `kWindowStructureRgn`, and `kWindowContentRgn` constants to the function `GetWindowRegion` (page 1864).

Window Latent Visibility Constants

Defines window latent visibility constants.

```
typedef UInt32 WindowLatentVisibility;
enum {
    kWindowLatentVisibleFloater = 1 << 0,
    kWindowLatentVisibleSuspend = 1 << 1,
    kWindowLatentVisibleFullScreen = 1 << 2,
    kWindowLatentVisibleAppHidden = 1 << 3,
    kWindowLatentVisibleCollapsedOwner = 1 << 4,
    kWindowLatentVisibleCollapsedGroup = 1 << 5
};
```

Constants

`kWindowLatentVisibleFloater`
The window is a floating window, and floating windows are hidden.

Available in Mac OS X v10.1 and later.

Declared in `MacWindows.h`.

`kWindowLatentVisibleSuspend`
The window has `kWindowHideOnSuspendAttribute` set and the application is suspended.

Available in Mac OS X v10.1 and later.

Declared in `MacWindows.h`.

`kWindowLatentVisibleFullScreen`
The window has `kWindowHideOnFullScreenAttribute` set and the mode is full-screen.

Available in Mac OS X v10.1 and later.

Declared in `MacWindows.h`.

`kWindowLatentVisibleAppHidden`
The window's process is hidden.

Available in Mac OS X v10.1 and later.

Declared in `MacWindows.h`.

`kWindowLatentVisibleCollapsedOwner`
The window is in an owned group, and the owner was collapsed.

Available in Mac OS X v10.1 and later.

Declared in `MacWindows.h`.

`kWindowLatentVisibleCollapsedGroup`
The window is in a group for which `kWindowGroupAttrHideOnCollapse` is set, and another window in the group was collapsed.

Available in Mac OS X v10.1 and later.

Declared in `MacWindows.h`.

Basic Window Description Version Constants

Describe different Mac OS window versions.

```
enum {
    kWindowDefinitionVersionOne = 1,
    kWindowDefinitionVersionTwo = 2
};
```

Constants

`kWindowDefinitionVersionOne`

Specifies a pre–Mac OS 8.5 Window Manager window. Windows of this version are created using a window definition ID and a Boolean value indicating whether or not the window has a close box.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowDefinitionVersionTwo`

Specifies a Mac OS 8.5 Window Manager window. Windows of this version are created using class and attribute information. For details on classes and attributes, see "Window Class Constants" (page 1988) and "Window Attributes" (page 1998) respectively.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

Discussion

You may supply one of these values in the `windowDefinitionVersion` field of a structure of type `BasicWindowDescription` (page 1979) to specify the version of the window definition used for a window.

Window Property Persistent Constant

Define the window property persistent constant.

```
enum {
    kWindowPropertyPersistent = 0x00000001
};
```

Constants

`kWindowPropertyPersistent`

Indicates this property gets saved when the window is archived. Note, however, that window properties are not archived at all in Mac OS X v10.4.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

Window Variant Constants

Specify window variants.

```
enum {
    kDocumentWindowVariantCode = 0,
    kModalDialogVariantCode = 1,
    kPlainDialogVariantCode = 2,
    kShadowDialogVariantCode = 3,
    kMovableModalDialogVariantCode = 5,
    kAlertVariantCode = 7,
    kMovableAlertVariantCode = 9,
    kSideFloaterVariantCode = 8
};
```

Constants

`kDocumentWindowVariantCode`
Variation code for a document window.
Available in Mac OS X v10.0 and later.
Declared in `MacWindows.h`.

`kModalDialogVariantCode`
Variation code for modal dialog boxes. The code can be added to 16 x the resource ID constant `kStandardWindowDefinition` to create a standard, pre-Appearance modal dialog box window.
Available in Mac OS X v10.0 and later.
Declared in `MacWindows.h`.

`kPlainDialogVariantCode`
Variation code for a plain dialog box.
Available in Mac OS X v10.0 and later.
Declared in `MacWindows.h`.

`kShadowDialogVariantCode`
Variation code for a shadow dialog box.
Available in Mac OS X v10.0 and later.
Declared in `MacWindows.h`.

`kMovableModalDialogVariantCode`
Variation code for movable modal dialog boxes. The code can be added to 16 x the resource ID constant `kStandardWindowDefinition` to create a standard, pre-Appearance movable modal dialog box.
Available in Mac OS X v10.0 and later.
Declared in `MacWindows.h`.

`kAlertVariantCode`
Variation code for a standard alert box.
Available in Mac OS X v10.0 and later.
Declared in `MacWindows.h`.

`kMovableAlertVariantCode`
Variation code for a movable alert box.
Available in Mac OS X v10.0 and later.
Declared in `MacWindows.h`.

`kSideFloaterVariantCode`
Variation code for utility (floating) windows with a side title bar. The code can be added to 16 x the resource ID constant `kFloatingWindowDefinition` to create a standard, pre-Appearance utility (floating) window with a side title bar.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

Window Transition Action Constants

Specify the type of window action taking place.

```
typedef UInt32 WindowTransitionAction;
enum {
    kWindowShowTransitionAction = 1,
    kWindowHideTransitionAction = 2,
    kWindowMoveTransitionAction = 3,
    kWindowResizeTransitionAction = 4
};
```

Constants

`kWindowShowTransitionAction`
Specifies that the animation display the window opening, that is, transitioning from a closed to an open state.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowHideTransitionAction`
Specifies that the animation display the window closing, that is, transitioning from an open to a closed state.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowMoveTransitionAction`
Moves the window. Use with the Slide transition effect. The `inRect` parameter contains the global coordinates of the window's new structure bounds and cannot be `NULL`. (Available in Mac OS X, and in CarbonLib 1.5 and later.)

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowResizeTransitionAction`
Resizes the window. Use with the Slide transition effect. The `inRect` parameter contains the global coordinates of the window's new structure bounds and cannot be `NULL`. (Available in Mac OS X and in CarbonLib 1.5 and later.)

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

Discussion

You may pass these `WindowTransitionAction` constants to the function `TransitionWindow` (page 1965) to specify the direction of the animation effect that is to be performed for a window.

Window Transition Effect Constants

Designate the type of transition effect to use to show or hide the window.

```
typedef UInt32 WindowTransitionEffect;
enum {
    kWindowZoomTransitionEffect = 1,
    kWindowSheetTransitionEffect = 2,
    kWindowSlideTransitionEffect = 3,
    kWindowFadeTransitionEffect = 4,
    kWindowGenieTransitionEffect = 5
};
```

Constants

`kWindowZoomTransitionEffect`
Specifies an animation that displays the window zooming between the open and closed states. The direction of the animation, whether from open to closed, or closed to open, depends upon the `WindowTransitionAction` constant specified in conjunction with the `WindowTransitionEffect` constant; see"Window Transition Action Constants" (page 2026) for descriptions of possible values.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowSheetTransitionEffect`
Zoom in or out from the parent window. Use with `TransitionWindowAndParent` (page 1966) and Show or Hide transition actions. (Available in Mac OS X, and in CarbonLib 1.5 and later.)

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowSlideTransitionEffect`
Slide the window into its new position. Use with `TransitionWindow` (page 1965) and Move or Resize transition actions. (Available in Mac OS X and in CarbonLib 1.5 and later.)

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowFadeTransitionEffect`
Fade the window into or out of visibility. Use with the Show or Hide transition action. (Available in Mac OS X v10.3 and later.)

Available in Mac OS X v10.3 and later.

Declared in `MacWindows.h`.

`kWindowGenieTransitionEffect`
Use the Genie effect that the Dock uses to minimize or maximize a window to show or hide the window. Use with the Show or Hide transition action. (Available in Mac OS X v10.3 and later.)

Available in Mac OS X v10.3 and later.

Declared in `MacWindows.h`.

Discussion

You may pass this `WindowTransitionEffect` constant to the function `TransitionWindow` (page 1965) to specify the type of animation effect that is to be performed for a window.

Window Activation Scope Constants

Defines window activation scope constants.

```
typedef UInt32 WindowActivationScope;
enum {
    kWindowActivationScopeNone = 0,
    kWindowActivationScopeIndependent = 1,
    kWindowActivationScopeAll = 2
};
```

Constants

`kWindowActivationScopeNone`
Windows with this scope are never activated by the Window Manager. Use `kWindowActivationScopeNone` when the window's visual state does not change based on activation (for example, tooltip windows), or when the client wants to manually control all activation. The window owner is free to explicitly activate or deactivate a window by calling `ActivateWindow` (page 1800).

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowActivationScopeIndependent`
Windows with this scope are always active if visible and are unaffected by the activation state of other windows. This activation scope is automatically used by floating windows.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowActivationScopeAll`
Windows with this scope are activated relative to other windows with the same scope in the current process. Only one window with this scope can be active in the entire process. This activation scope is automatically used by document and dialog windows.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

Window Constrain Options

Constrain options for window resize, growing, and so on.

```
typedef UInt32 WindowConstrainOptions;
enum {
    kWindowConstrainMayResize = (1L << 0),
    kWindowConstrainMoveRegardlessOfFit = (1L << 1),
    kWindowConstrainAllowPartial = (1L << 2),
    kWindowConstrainCalcOnly = (1L << 3),
    kWindowConstrainUseTransitionWindow = (1L << 4),
    kWindowConstrainMoveMinimum = 1 << 6,
    kWindowConstrainUseSpecifiedBounds = 1 << 8,
    kWindowConstrainStandardOptions = kWindowConstrainMoveRegardlessOfFit
};
```

Constants

`kWindowConstrainMayResize`
The window may be resized if necessary to make it fit onscreen.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowConstrainMoveRegardlessOfFit`
The window may be moved even if it doesn't fit entirely onscreen.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowConstrainAllowPartial`
Allow partial intersection of the specified window region with the screen instead of requiring total intersection.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowConstrainCalcOnly`
Calculate the new window bounds but don't actually move the window.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowConstrainUseTransitionWindow`
Use `TransitionWindow` (page 1965) with `kWindowSlideTransitionEffect` to move windows onscreen.

Available in Mac OS X v10.2 and later.

Declared in `MacWindows.h`.

`kWindowConstrainMoveMinimum`
Move the window the minimum amount necessary to be onscreen. This option is only supported by the function `HIWindowConstrain` (page 1877). This option applies if a partial fit is not allowed (`kWindowConstrainAllowPartial` is not specified) or a partial fit is allowed, but the window is not even partially visible. In either case, the window will be moved just enough to be slightly onscreen. You may customize the minimum amount that is required to be visible by passing the desired dimensions in the `inMinimumSize` parameter to `HIWindowConstrain`.

Available in Mac OS X v10.5 and later.

Declared in `MacWindows.h`.

`kWindowConstrainUseSpecifiedBounds`
Use the specified bounds of the window region to be constrained. This option is only supported by the function `HIWindowConstrain` (page 1877). The bounds are specified using the `ioBounds` parameter, allowing you to constrain a window to a hypothetical location. For example, if you plan to move your window such that its content region is at a certain location, and you want to know in advance before moving the window whether the window would be offscreen at that location, you can use this option.

Available in Mac OS X v10.5 and later.

Declared in `MacWindows.h`.

`kWindowConstrainStandardOptions`
Use the most common options: don't resize the window, move the window regardless of fit to the screen, require total intersection of the specified window region with the screen, and move the window.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

Window Kinds

Identify how a window was created.

```
enum {
    dialogKind = 2,
    userKind = 8,
    kDialogWindowKind = 2,
    kApplicationWindowKind = 8
};
```

Constants

`dialogKind`
Obsolete equivalent to `kDialogWindowKind`.
Available in Mac OS X v10.0 and later.
Declared in `MacWindows.h`.

`userKind`
Obsolete equivalent to `kApplicationWindowKind`.
Available in Mac OS X v10.0 and later.
Declared in `MacWindows.h`.

`kDialogWindowKind`
Identifies all dialog or alert windows, whether created by system software or, indirectly through the Dialog Manager, by your application. The Dialog Manager uses this field to track dialog and alert windows.
Available in Mac OS X v10.0 and later.
Declared in `MacWindows.h`.

`kApplicationWindowKind`
Identifies a window created directly by your application.
Available in Mac OS X v10.0 and later.
Declared in `MacWindows.h`.

Discussion

The Window Manager uses these constants in the `windowKind` field of a color window structure or window structure. Your application can use any value greater than 7.

Window Group Selection Constants

Indicate which window group to select.

```
enum {
    kNextWindowGroup = true,
    kPreviousWindowGroup = false
};
```

Constants

`kNextWindowGroup`
Move to the next window group (in the z-order).
Available in Mac OS X v10.0 and later.
Declared in `MacWindows.h`.

`kPreviousWindowGroup`
Move to the previous window group (in the z-order).
Available in Mac OS X v10.0 and later.
Declared in `MacWindows.h`.

Window Group Attributes

Define attributes for window groups.

```
typedef UInt32 WindowGroupAttributes;
enum {
    kWindowGroupAttrSelectAsLayer = 1 << 0,
    kWindowGroupAttrMoveTogether = 1 << 1,
    kWindowGroupAttrLayerTogether = 1 << 2,
    kWindowGroupAttrSharedActivation = 1 << 3,
    kWindowGroupAttrHideOnCollapse = 1 << 4,
    kWindowGroupAttrFixedLevel = 1 << 5
};
```

Constants

`kWindowGroupAttrSelectAsLayer`

Makes the group behave somewhat as a layer of windows that move together. When any window in the group is brought to the front of the group, the entire group will also be brought to the front of the containing group's child hierarchy. Use of this constant is not recommended; its behavior is rarely useful.

Available in Mac OS X v10.1 and later.

Declared in `MacWindows.h`.

`kWindowGroupAttrMoveTogether`

The positions of the contents of this group with respect to each other cannot be changed. When one item moves, all other items are moved simultaneously. Note that if one window's position is changed by calling a Window Manager function in Mac OS X v10.4 and later, the positions of the other windows in the group are updated asynchronously—that is, their bounds are not necessarily updated during the function call itself, even though visually the windows move together.

Available in Mac OS X v10.1 and later.

Declared in `MacWindows.h`.

`kWindowGroupAttrLayerTogether`

The z-order of the contents of this group with respect to each other cannot be changed. When one item changes z-order, all other items are moved simultaneously. For purposes of z-ordering, the group and all its subgroups are effectively treated as if they were a single window in the parent group of this group.

Available in Mac OS X v10.1 and later.

Declared in `MacWindows.h`.

`kWindowGroupAttrSharedActivation`

The active state of the windows in this group is shared. The windows in the group are activated or deactivated according to the activation scope of the group, but when any window in the group changes activation, all other windows change to match.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowGroupAttrHideOnCollapse`

When any window in this group is collapsed, all other windows in this group are hidden. All subgroups of this group are also examined for this attribute, and any the windows of any subgroup with this attribute are also hidden. All windows will be shown again when the collapsed window is expanded.

Available in Mac OS X v10.1 and later.

Declared in `MacWindows.h`.

`kWindowGroupAttrFixedLevel`
If this attribute is specified, this window group's window level should be left unchanged. If this attribute is not specified, this window group's window level will be promoted to a value equal to the level of the next fixed-level window group beneath it in the window group hierarchy. (Available in Mac OS X v10.4 and later.)

Available in Mac OS X v10.4 and later.

Declared in `MacWindows.h`.

Version Notes
In Mac OS X v10.2.4 and later, the HIToolbox framework improved its use of the window group API so that showing a sheet on a window that was already grouped with another window would not break the existing grouping. To make this change work properly, applications that create their own window groups using the `kWindowGroupAttrMoveTogether` and `kWindowGroupAttrLayerTogether` attributes should also specify the `kWindowGroupAttrHideOnCollapse` and `kWindowGroupAttrSharedActivation` attributes.

Obsolete Window Group Attributes

Define obsolete window group attribute names.

```
enum {
    kWindowGroupAttrSelectable = kWindowGroupAttrSelectAsLayer,
    kWindowGroupAttrPositionFixed = kWindowGroupAttrMoveTogether,
    kWindowGroupAttrZOrderFixed = kWindowGroupAttrLayerTogether
};
```

Constants
`kWindowGroupAttrSelectable`
Obsolete name for `kWindowGroupAttrSelectAsLayer`.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowGroupAttrPositionFixed`
Obsolete name; use `kWindowGroupAttrMoveTogether` instead.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowGroupAttrZOrderFixed`
Obsolete name; use `kWindowGroupAttrLayerTogether` instead.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

Window Group Content Options

Window group counting options.

```
typedef UInt32 WindowGroupContentOptions;
enum {
    kWindowGroupContentsReturnWindows = 1 << 0,
    kWindowGroupContentsRecurse = 1 << 1,
    kWindowGroupContentsVisible = 1 << 2
};
```

Constants

`kWindowGroupContentsReturnWindows`
Count only windows in the window group.
Available in Mac OS X v10.0 and later.
Declared in `MacWindows.h`.

`kWindowGroupContentsRecurse`
Recursively count windows of any subgroups of windows in the specified window group.
Available in Mac OS X v10.0 and later.
Declared in `MacWindows.h`.

`kWindowGroupContentsVisible`
Counts only visible windows.
Available in Mac OS X v10.0 and later.
Declared in `MacWindows.h`.

Discussion
You use these constants with the `CountWindowGroupContents` (page 1813) function.

Window Class Position Constants

Specify which window in the class to select.

```
enum {
    kFirstWindowOfClass = -1,
    kLastWindowOfClass = 0
};
```

Constants

`kFirstWindowOfClass`
Select the first window in the class.

`kLastWindowOfClass`
Select the last window in the class.

Discussion
These constants describe special cases for the “behind” parameter in window creation calls.

Window Definition Type Constants

Defines the type of custom window definition.

```
typedef UInt32 WindowDefType;
enum {
    kWindowDefProcPtr = 0,
    kWindowDefObjectClass = 1,
    kWindowDefProcID = 2,
    kWindowDefHIView = 3
};
```

Constants

`kWindowDefProcPtr`
The definition is procedure pointer–based.
Available in Mac OS X v10.0 and later.
Declared in `MacWindows.h`.

`kWindowDefObjectClass`
The definition is a toolbox object.
Available in Mac OS X v10.0 and later.
Declared in `MacWindows.h`.

`kWindowDefProcID`
An ID that identifies a particular `'WDEF'` and would typically be one of the constants described in "Appearance-Compliant Window Definition ID Constants" (page 2004).
Available in Mac OS X v10.0 and later.
Declared in `MacWindows.h`.

`kWindowDefHIView`
The definition is an HIView-based object.
Available in Mac OS X v10.2 and later.
Declared in `MacWindows.h`.

Window Definition Procedure Constant

Define the window definition procedure constant.

```
enum {
    kWindowDefProcType = 'WDEF'
};
```

Constants

`kWindowDefProcType`
Window definition type.
Available in Mac OS X v10.0 and later.
Declared in `MacWindows.h`.

Window Definition Hit Test Result Code Constants

Defines result constants to be used by window definition hit testing.

```
typedef SInt16 WindowDefPartCode;
enum {
    wNoHit = 0,
    wInContent = 1,
    wInDrag = 2,
    wInGrow = 3,
    wInGoAway = 4,
    wInZoomIn = 5,
    wInZoomOut = 6,
    wInCollapseBox = 9,
    wInProxyIcon = 10,
    wInToolbarButton = 11,
    wInStructure = 13
};
```

Constants

`wNoHit`

The mouse-down event did not occur in the content region or the drag region of any active or inactive window or in the close, size, zoom, or collapse box of an active window. The return value `wNoHit` might also mean that the point isn't in the window. The standard window definition functions, for example, return `wNoHit` if the point is in the window frame but not in the title bar.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`wInContent`

The mouse-down event occurred in the content region of an active or inactive window (with the exception of the size box).

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`wInDrag`

The mouse-down event occurred in the drag region of an active or inactive window.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`wInGrow`

The mouse-down occurred in the size box of an active window.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`wInGoAway`

The mouse-down event occurred in the close box of an active window.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`wInZoomIn`

The mouse-down event occurred in the zoom box of an active window that is currently in the standard state.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`wInZoomOut`
: The mouse-down event occurred in the zoom box of an active window that is currently in the user state.

  Available in Mac OS X v10.0 and later.

  Declared in `MacWindows.h`.

`wInCollapseBox`
: The mouse-down event occurred in the collapse box of an active window.

  Available with Appearance Manager 1.0 and later.

  Declared in `MacWindows.h`.

`wInProxyIcon`
: The mouse-down event occurred in the proxy icon of a window.

  Available in Mac OS X v10.0 and later.

  Declared in `MacWindows.h`.

`wInToolbarButton`
: The mouse-down event occurred in the toolbar button.

  Available in Mac OS X v10.1 and later.

  Declared in `MacWindows.h`.

`wInStructure`
: The mouse-down event occurred in the window's structure region.

  Available in Mac OS X v10.1 and later.

  Declared in `MacWindows.h`.

Discussion
In response to the `wHit` message, your window definition function should return one of these constants.

Return the constants `wInGrow`, `wInGoAway`, `wInZoomIn`, `wInZoomOut`, and `wInCollapseBox` only if the window is active—by convention, the size box, close box, zoom box, and collapse box aren't drawn if the window is inactive. In an inactive document window, for example, a mouse-down event in the part of the title bar that would contain the close box if the window were active is reported as `wInDrag`.

With the Mac OS 8.5 Window Manager and later, your window definition function may return the `wInProxyIcon` constant to report that a mouse-down event occurred in your window's proxy icon.

Window Definition Message Constants

Defines messages sent to non Carbon Event–based window definitions.

```
enum {
    kWindowMsgDraw = 0,
    kWindowMsgHitTest = 1,
    kWindowMsgCalculateShape = 2,
    kWindowMsgInitialize = 3,
    kWindowMsgCleanUp = 4,
    kWindowMsgDrawGrowOutline = 5,
    kWindowMsgDrawGrowBox = 6
};
enum {
    kWindowMsgGetFeatures = 7,
    kWindowMsgGetRegion = 8
};
enum {
    kWindowMsgDragHilite = 9,
    kWindowMsgModified = 10,
    kWindowMsgDrawInCurrentPort = 11,
    kWindowMsgSetupProxyDragImage = 12,
    kWindowMsgStateChanged = 13,
    kWindowMsgMeasureTitle = 14
};
enum {
    kWindowMsgGetGrowImageRegion = 19
};
```

Constants

`kWindowMsgDraw`
Draw the window's frame.
Available in Mac OS X v10.0 and later.
Declared in `MacWindows.h`.

`kWindowMsgHitTest`
Report the location of a mouse-down event.
Available in Mac OS X v10.0 and later.
Declared in `MacWindows.h`.

`kWindowMsgCalculateShape`
Calculate the structure region and the content region.
Available in Mac OS X v10.0 and later.
Declared in `MacWindows.h`.

`kWindowMsgInitialize`
Perform additional initialization.
Available in Mac OS X v10.0 and later.
Declared in `MacWindows.h`.

`kWindowMsgCleanUp`
Perform additional disposal.
Available in Mac OS X v10.0 and later.
Declared in `MacWindows.h`.

`kWindowMsgDrawGrowOutline`
Draw the dotted outline of the window that you see during a resizing operation.
Available in Mac OS X v10.0 and later.
Declared in `MacWindows.h`.

`kWindowMsgDrawGrowBox`
: Draw the outlines for the size box and the scroll bar.

  Available in Mac OS X v10.0 and later.

  Declared in `MacWindows.h`.

`kWindowMsgGetFeatures`
: Report the window's features.

  Available with Appearance Manager 1.0 and later.

  Declared in `MacWindows.h`.

`kWindowMsgGetRegion`
: Report the location of a specific window region.

  Available with Appearance Manager 1.0 and later.

  Declared in `MacWindows.h`.

`kWindowMsgDragHilite`
: Redraw the window's structure region to reflect the window's validity as a drag-and-drop destination. The Window Manager passes an accompanying Boolean value in your window definition function's `param` parameter. If the value passed is `true`, this indicates that the window's structure region should be highlighted. If the value passed is `false`, the structure region should be unhighlighted. Your window definition function should return 0 as the function result. (Mac OS 8.5 and later.)

  Available in Mac OS X v10.0 and later.

  Declared in `MacWindows.h`.

`kWindowMsgModified`
: Track the window's modification state. The Window Manager sends this message when the function `SetWindowModified` (page 1946) is called. The Window Manager passes an accompanying Boolean value in your window definition function's `param` parameter. If the value passed is `true`, the document contained in the window has been modified. If the value passed is `false`, the document has been saved to disk. You should redraw the window's structure region to reflect the new modification state, if appropriate. For example, system-defined document windows dim the proxy icon to indicate that the document has been modified by the user and cannot be moved at that time. Your window definition function should return 0 as the function result. (Mac OS 8.5 and later.)

  Available in Mac OS X v10.0 and later.

  Declared in `MacWindows.h`.

`kWindowMsgDrawInCurrentPort`
: Draw the window's frame in the current graphics port. Other than restricting drawing to the current port, this message is similar to the pre–Mac OS 8.5 Window Manager window definition message constant `wDraw`. (Mac OS 8.5 and later.)

  Available in Mac OS X v10.0 and later.

  Declared in `MacWindows.h`.

`kWindowMsgSetupProxyDragImage`

Create the image of the window's proxy icon that the Drag Manager uses to represent the icon while it is being dragged. When your application calls the function `TrackWindowProxyDrag` (page 1963), the Window Manager passes this message in your window definition function's `message` parameter and an accompanying pointer to a structure of type `SetupWindowProxyDragImageRec` (page 1984) in the `param` parameter. Your window definition function is responsible for setting the contents of the structure to contain the data describing the proxy icon's drag image. Your window definition function should return 0 as the function result. (Mac OS 8.5 and later.)

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowMsgStateChanged`

Be informed that some aspect of the window's public state has changed. The Window Manager passes this message in your window definition function's `message` parameter and an accompanying flag in the `param` parameter that indicates what part of the window's state has been altered. This message is simply a notification message—no response by the window definition function is required. Your window definition function should return 0 as the function result. The `kWindowMsgStateChanged` message is sent after the window's internal data has been updated, but before any redraw occurs onscreen. A window definition function should not redraw the window frame in response to this message. If it is necessary to redraw the window frame, the Window Manager notifies the window definition function with a `wDraw` message. See "Window Definition State-Changed Constant" (page 2039) for descriptions of the values that the Window Manager can pass to specify the state change that has occurred. (Mac OS 8.5 and later.)

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowMsgMeasureTitle`

Measure and return the ideal title width. The Window Manager passes this message in the window definition function's `message` parameter and an accompanying pointer to a structure of type `MeasureWindowTitleRec` (page 1981) in the `param` parameter. Your window definition function is responsible for setting the contents of the structure to contain data describing the title width. You should return 0 as the function result. (Mac OS 8.5 and later.)

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kWindowMsgGetGrowImageRegion`

Obtain a region to XOR with window during grow or resize. Alter the `GetGrowImageRegionRec` structure passed with the message to the region to be XOR'd. (

Available in Carbon only.)

Declared in `MacWindows.h`.

Discussion
The Window Manager may pass one of these constants in the `message` parameter of your window definition function to specify the action that your function must perform. For descriptions of the feature bits that correspond to these messages, see "Window Feature Bits" (page 2011). Other messages are reserved for internal use by the system.

Window Definition State-Changed Constant

Define the window definition state-changed constant.

```
enum {
    kWindowStateTitleChanged = (1 << 0)
};
```

Constants

`kWindowStateTitleChanged`

If the bit specified by this mask is set, the window's title has changed.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

Discussion

If you implement a custom window definition function, when the Window Manager passes the `kWindowMsgStateChanged` message in your window definition function's `message` parameter it may also pass a value in the `param` parameter with one or more bits set to indicate what part of the window's state has changed. You may use this mask to test this value. For a description of the `kWindowMsgStateChanged` message, see "Window Definition Message Constants" (page 2036).

Special Considerations

Drawer State Constants

Define constants that indicate the current drawer state.

```
typedef UInt32 WindowDrawerState;
enum {
    kWindowDrawerOpening = 1,
    kWindowDrawerOpen = 2,
    kWindowDrawerClosing = 3,
    kWindowDrawerClosed = 4
};
```

Constants

`kWindowDrawerOpening`

The drawer is opening.

Available in Mac OS X v10.2 and later.

Declared in `MacWindows.h`.

`kWindowDrawerOpen`

The drawer is open.

Available in Mac OS X v10.2 and later.

Declared in `MacWindows.h`.

`kWindowDrawerClosing`

The drawer is closing.

Available in Mac OS X v10.2 and later.

Declared in `MacWindows.h`.

`kWindowDrawerClosed`

The drawer is closed.

Available in Mac OS X v10.2 and later.

Declared in `MacWindows.h`.

Version Notes

Introduced in Mac OS X v10.2.

Window Edge Constants

Specify the edge from which a drawer should appear.

```
enum {
    kWindowEdgeDefault = 0,
    kWindowEdgeTop = 1 << 0,
    kWindowEdgeLeft = 1 << 1,
    kWindowEdgeBottom = 1 << 2,
    kWindowEdgeRight = 1 << 3
};
```

Constants

`kWindowEdgeDefault`
The drawer should be opened on whatever edge of the parent window has previously been set as the drawer's preferred edge.

Available in Mac OS X v10.2 and later.

Declared in `MacWindows.h`.

`kWindowEdgeTop`
The drawer should slide out from the top edge.

Available in Mac OS X v10.2 and later.

Declared in `MacWindows.h`.

`kWindowEdgeLeft`
The drawer should slide out from the left edge.

Available in Mac OS X v10.2 and later.

Declared in `MacWindows.h`.

`kWindowEdgeBottom`
The drawer should slide out from the bottom edge.

Available in Mac OS X v10.2 and later.

Declared in `MacWindows.h`.

`kWindowEdgeRight`
The drawer should slide out from the right edge.

Available in Mac OS X v10.2 and later.

Declared in `MacWindows.h`.

Rotating Window Menu Item Constant

Indicates whether to add the rotating window item to the Window menu.

```
enum {
    kWindowMenuIncludeRotate = 1 << 0
};
```

Constants

`kWindowMenuIncludeRotate`
Requests that the standard window menu include a Rotate Windows menu item.

Available in Mac OS X v10.2 and later.

Declared in `MacWindows.h`.

Discussion
This constant is used with the function `CreateStandardWindowMenu` (page 1816).

Window Menu Item Property Constants

Constants used to access property data of items in the standard window menu.

```
enum {
    kHIWindowMenuCreator = 'wind',
    kHIWindowMenuWindowTag = 'wind'
};
```

Constants

`kHIWindowMenuCreator`
The property creator for accessing standard window menu item properties.
Available in Mac OS X v10.5 and later.
Declared in `MacWindows.h`.

`kHIWindowMenuWindowTag`
The property tag for accessing standard window menu item properties that hold windows (values of type `WindowRef`). Menu items with the `kHICommandSelectWindow` command ID will have a property with this tag that contains the window to be activated when that item is selected.
Available in Mac OS X v10.5 and later.
Declared in `MacWindows.h`.

Discussion
These constants are used with the Menu Manager functions `GetMenuItemProperty` (page 1281) and `SetMenuItemProperty` (page 1341).

Toolbar View Background Tag

A tag used to inform a custom toolbar view whether to draw its background or leave its background transparent.

```
enum {
    kHIToolbarViewDrawBackgroundTag = 'back'
};
```

Constants

`kHIToolbarViewDrawBackgroundTag`
A `SetControlData` (page 652) tag that is used by the standard window frame view to inform the toolbar view whether the view should draw its background or leave its background transparent. The data for this tag is a Boolean. If the data value is true, the toolbar view should draw its background as it desires. If the data value is false, the toolbar view should leave its background transparent so that the window's root view can show through the toolbar view. Currently, the toolbar view will be asked to leave its background transparent for windows with the textured or unified appearance.
Available in Mac OS X v10.4 and later.
Declared in `MacWindows.h`.

Window Paint Callback Options

Define options to use with the window paint callback function.

```
typedef OptionBits WindowPaintProcOptions;
enum {
    kWindowPaintProcOptionsNone = 0
};
```

Constants

`kWindowPaintProcOptionsNone`
No options.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

Part Identifier Constants

Used in the `value` field of the `ColorSpec` structure, define which part of the window the color affects.

```
enum {
    wContentColor = 0,
    wFrameColor = 1,
    wTextColor = 2,
    wHiliteColor = 3,
    wTitleBarColor = 4
};
```

Constants

`wContentColor`
Produces background color for content region of window.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`wFrameColor`
Produces color of window's outline.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`wTextColor`
Produces color of window's title and button text.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`wHiliteColor`
Reserved.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`wTitleBarColor`
Reserved.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

Discussion
When the Appearance Manager is available and you are using standard windows, all the fields of the window color table structure are ignored except the part identifier constant `wContentColor` in the `value` field of the `ColorSpec` structure, which produces the background color for the window's content region.

If you are creating your own custom windows, the window color table structure and all its part identifier constants can still be used.

Desk Pattern Resource ID

The resource ID of the desktop pattern.

```
enum {
    deskPatID = 16
};
```

Constants
`deskPatID`
The resource ID of the desktop pattern.
Available in Mac OS X v10.0 and later.
Declared in `MacWindows.h`.

Discussion
The Window Manager provides the desk pattern resource ID constants, which is the ID of `Pattern` and `PixPat` resources that the operating system uses to draw the desktop. The operating system uses the `deskPatID` constant while the desktop is being drawn. It looks for a resource with this ID and uses the contents of the resource to draw the desktop.

Window Scrolling Options

Options for scrolling windows.

```
typedef UInt32 ScrollWindowOptions;
enum {
    kScrollWindowNoOptions = 0,
    kScrollWindowInvalidate = (1L << 0),
    kScrollWindowEraseToPortBackground = (1L << 1)
};
```

Constants
`kScrollWindowNoOptions`
No options.
Available in Mac OS X v10.0 and later.
Declared in `MacWindows.h`.

`kScrollWindowInvalidate`
Add the exposed area to the window's update region.
Available in Mac OS X v10.0 and later.
Declared in `MacWindows.h`.

`kScrollWindowEraseToPortBackground`
Erase the exposed area using the background color/pattern of the window's graphics port.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

Discussion
Use these constants with the `ScrollWindowRect` (page 1927) and `ScrollWindowRegion` (page 1928) functions.

Availability
Available in Mac OS 8.1 and later.

'wind' Resource Default Collection Item Constants

Specify default collection items in a window (`'wind'`) resource.

```
enum {
    kStoredWindowSystemTag = 'appl',
    kStoredBasicWindowDescriptionID = 'sbas',
    kStoredWindowPascalTitleID = 's255',
    kStoredWindowTitleCFStringID = 'cfst'
};
```

Constants
`kStoredWindowSystemTag`
This item tag specifies a system-defined collection item. Note that the `'appl'` collection item tag is reserved for use by Apple Computer, Inc. Do not define new collection items using this tag.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kStoredBasicWindowDescriptionID`
In combination with `kStoredWindowSystemTag`, this item ID specifies an item of type `BasicWindowDescription`. See `BasicWindowDescription` (page 1979) for details on this type.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kStoredWindowPascalTitleID`
In combination with `kStoredWindowSystemTag`, this item ID specifies a Pascal title string.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kStoredWindowTitleCFStringID`
This item tag specifies the CFString title string.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

Discussion
These constants specify the tag and the IDs that identify the default collection items contained in a resource of type `'wind'`.

Window Resource IDs

Define standard resource IDs for windows.

```
enum {
    kStandardWindowDefinition = 0,
    kRoundWindowDefinition = 1,
    kFloatingWindowDefinition = 124
};
```

Constants

`kStandardWindowDefinition`

Defines pre-Appearance standard document windows and dialog boxes. When mapping is enabled, this resource ID is mapped to `kWindowDocumentDefProcResID` or `kWindowDialogDefProcResID`. When mapped to `kWindowDocumentDefProcResID`, this produces an Appearance-compliant standard document window with no size box and no vertical or horizontal zoom box. When mapped to `kWindowDialogDefProcResID`, this produces an Appearance-compliant dialog box with no size box and a 3-pixel space between the dialog box's content and structure region.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kRoundWindowDefinition`

Defines pre-Appearance standard desk-accessory style windows. This resource ID is not mapped to any Appearance-compliant resource ID when mapping is enabled.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`kFloatingWindowDefinition`

Defines pre-Appearance utility (floating) windows. When mapping is enabled, this resource ID is mapped to `kWindowUtilityDefProcResID` or `kWindowUtilitySideTitleDefProcResID`. When mapped to `kWindowUtilityDefProcResID`, this produces an Appearance-compliant utility window. When mapped to `kWindowUtilitySideTitleDefProcResID`, it produces an Appearance-compliant utility window with a side title bar.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

Discussion

Window resource IDs are changed with Appearance Manager 1.0. The Window Manager now provides many new standard, Appearance-compliant window resource IDs for your program. For a description of the Appearance-compliant window resource IDs, see "Appearance-Compliant Window Resource IDs" (page 2003).

You can use a window resource ID constant to create a window definition ID; see "Pre-Appearance Window Definition IDs" in *Window Manager Legacy Reference* for more details.

Resource IDs 0 through 127 are reserved for use by the system.

Window Availability Constants

Define window availability constants for Exposé and Spaces.

```
typedef OptionBits HIWindowAvailability;
enum {
    kHIWindowExposeHidden = 1 << 0,
    kHIWindowVisibleInAllSpaces = 1 << 8
};
```

Constants

`kHIWindowExposeHidden`

If this bit is set, the window is hidden during the "All Windows" and "Application windows" modes of Exposé. If this bit is not set, the window is visible during those modes.

Available in Mac OS X v10.4 and later.

Declared in `MacWindows.h`.

`kHIWindowVisibleInAllSpaces`

If this bit is set, the window is visible in all Spaces workspaces. If this bit is not set, the window is only visible in the workspace in which it was created.

Available in Mac OS X v10.5 and later.

Declared in `MacWindows.h`.

Discussion

These mask bits are used with the function `HIWindowChangeAvailability` (page 1875) to override the default behavior of the Window Manager in determining whether a window is visible during Exposé or in all Spaces workspaces. By default, newly created windows of class `kDocumentWindowClass` are given an availability of `0` (meaning that they are available during Exposé), and windows from all other window classes are given an availability of `kHIWindowExposeHidden`.

Window Scale Mode Constants

Define window scale mode constants.

```
typedef UInt32 HIWindowScaleMode;
enum {
    kHIWindowScaleModeUnscaled = 0,
    kHIWindowScaleModeMagnified = 1,
    kHIWindowScaleModeFrameworkScaled = 2
};
```

Constants

`kHIWindowScaleModeUnscaled`

The window is not scaled at all because the display scale factor is 1.0.

Available in Mac OS X v10.4 and later.

Declared in `MacWindows.h`.

`kHIWindowScaleModeMagnified`

The window's backing store is being magnified by the Window Server because the display scale factor is not equal to 1.0 and because the window was not created with the `kWindowFrameworkScaledAttribute`.

Available in Mac OS X v10.4 and later.

Declared in `MacWindows.h`.

`kHIWindowScaleModeFrameworkScaled`
The window's contents are scaled to match the display scale factor because the display scale factor is not equal to 1.0 and because the window was created with `kWindowFrameworkScaledAttribute`.

Available in Mac OS X v10.4 and later.

Declared in `MacWindows.h`.

Discussion
A window's scale mode indicates in which resolution-independent scale mode it is operating.

Window Group Level Constants

Define window group level constants.

```
enum {
kWindowGroupLevelActive = 1,
kWindowGroupLevelInactive = 2,
kWindowGroupLevelPromoted = 3,
};
```

Constants
`kWindowGroupLevelActive`
The window level that is nominally used for windows in the group when the application is active. However, if a group with a higher window level is positioned below this group in the window group hierarchy, this group's active level will be promoted to match the level of the group in front of it. Use `kWindowGroupLevelPromoted` to determine the actual window level in use for a group.

Available in Mac OS X v10.4 and later.

Declared in `MacWindows.h`.

`kWindowGroupLevelInactive`
The window level for windows in the group when the application is inactive.

Available in Mac OS X v10.4 and later.

Declared in `MacWindows.h`.

`kWindowGroupLevelPromoted`
The window level that is actually used for windows in the group when the application is active. This level is the same as the Active window level or is a larger value to match the level of a group below this group. Setting the promoted window level explicitly is not recommended because the promoted level is reset by the Window Manager whenever the window group hierarchy structure changes. Therefore any changes that you make to the promoted level can be overwritten.

Available in Mac OS X v10.4 and later.

Declared in `MacWindows.h`.

Discussion
These constants are used when calling `GetWindowGroupLevelOfType` (page 1851) and `SetWindowGroupLevelOfType` (page 1942).

Pre-Appearance Window Definition IDs

Older window definition IDs used before the introduction of the Appearance Manager.

```
enum {
    documentProc = 0,
    dBoxProc = 1,
    plainDBox = 2,
    altDBoxProc = 3,
    noGrowDocProc = 4,
    movableDBoxProc = 5,
    zoomDocProc = 8,
    zoomNoGrow = 12,
    rDocProc = 16,
    floatProc = 1985,
    floatGrowProc = 1987,
    floatZoomProc = 1989,
    floatZoomGrowProc = 1991,
    floatSideProc = 1993,
    floatSideGrowProc = 1995,
    floatSideZoomProc = 1997,
    floatSideZoomGrowProc = 1999
};
```

Constants

`documentProc`

Pre-Appearance document window (movable window with size box).

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`dBoxProc`

Pre-Appearance modal dialog box.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`plainDBox`

Pre-Appearance modeless dialog box.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`altDBoxProc`

Pre-Appearance modeless dialog box with shadow.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`noGrowDocProc`

Pre-Appearance movable window with no size box or zoom box.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`movableDBoxProc`

Pre-Appearance movable modal dialog box.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`zoomDocProc`
: Pre-Appearance movable window with size box and full zoom box.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`zoomNoGrow`
: Pre-Appearance window with full zoom box and no size box.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`rDocProc`
: Pre-Appearance rounded-corner window. You can control the diameter of curvature of a rounded-corner window (window type `rDocProc`) by adding one of these integers to the `rDocProc` constant:

`rDocProc` (diameters of curvature: 16, 16)

`rDocProc` + 2 (diameters of curvature: 4, 4)

`rDocProc` + 4 (diameters of curvature: 6, 6)

`rDocProc` + 6 (diameters of curvature: 10, 10)

Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared in `MacWindows.h`.

`floatProc`
: Pre-Appearance utility (floating) window with no size box or zoom box.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`floatGrowProc`
: Pre-Appearance utility (floating) window with size box.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`floatZoomProc`
: Pre-Appearance utility (floating) window with zoom box.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`floatZoomGrowProc`
: Pre-Appearance utility (floating) window with size box and zoom box.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`floatSideProc`
: Pre-Appearance utility (floating) window with side title bar and no size or zoom box.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`floatSideGrowProc`
: Pre-Appearance utility (floating) window with side title bar and size box.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`floatSideZoomProc`

Pre-Appearance utility (floating) window with side title bar and zoom box.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

`floatSideZoomGrowProc`

Pre-Appearance utility (floating) window with side title bar, size box, and zoom box.

Available in Mac OS X v10.0 and later.

Declared in `MacWindows.h`.

Discussion
Note that window definition IDs are changed with Appearance Manager 1.0. The Window Manager now provides many new, standard, Appearance-compliant window types.

Your application typically supplies a window definition ID to a resource of type `'WIND'` or to a window-creation function to specify which window definition function to use in creating the window. A variation code may also be used to describe variations of the same basic window.

The window definition ID is an integer that contains the resource ID of the window definition function in its upper 12 bits and a variation code in its lower 4 bits. For a given resource ID and variation code, the window definition ID is derived as follows: window definition ID = (16 x resource ID) + variation code.

The window definition IDs for dialog boxes and utility (floating) windows pertain to the appearances of these windows only, not their behaviors. For example, if you want a utility window to have the proper behavior, that is, float, your application must provide for it.

When mapping is enabled, standard pre-Appearance window definition function IDs will be mapped to their Appearance-compliant equivalents.

Result Codes

The table below lists result codes defined for the Window Manager.

Result Code	Value	Description
`errInvalidWindowRef`	-5600	The window is not valid. Available in Mac OS X v10.0 and later.
`errUnsupportedWindowAttributesForClass`	-5601	Attribute bits are inappropriate for the specified window class. Available in Mac OS X v10.0 and later.
`errWindowDoesNotHaveProxy`	-5602	No proxy attached to window. Available in Mac OS X v10.0 and later.
`errInvalidWindowProperty`	-5603	`'appl'` creator code not allowed. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
errWindowPropertyNotFound	-5604	The window property does not exist. Available in Mac OS X v10.0 and later.
errUnrecognizedWindowClass	-5605	Unknown window class. Available in Mac OS X v10.0 and later.
errCorruptWindowDescription	-5606	Incorrect size or version supplied in the BasicWindowDescription structure. Available in Mac OS X v10.0 and later.
errUserWantsToDragWindow	-5607	Entire window is being dragged, not proxy icon. Available in Mac OS X v10.0 and later.
errWindowsAlreadyInitialized	-5608	Called InitFloatingWindows twice, or called InitWindows and then InitFloatingWindows. Available in Mac OS X v10.0 and later.
errFloatingWindowsNotInitialized	-5609	Called HideFloatingWindows or ShowFloatingWindows without calling InitFloatingWindows. Available in Mac OS X v10.0 and later.
errWindowNotFound	-5610	No window was found that satisfies the search criteria. Available in Mac OS X v10.0 and later.
errWindowDoesNotFitOnscreen	-5611	The window does not fit on a single screen. Available in Mac OS X v10.0 and later.
windowAttributeImmutableErr	-5612	Tried to change a window attribute that can't be changed after the window is created. Available in Mac OS X v10.0 and later.
windowAttributesConflictErr	-5613	Passed two window attributes that are mutually exclusive. Available in Mac OS X v10.0 and later.
windowManagerInternalErr	-5614	Internal error in the Window Manager. Available in Mac OS X v10.0 and later.
windowWrongStateErr	-5615	The window state makes the current action invalid. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
windowGroupInvalidErr	-5616	The window group is not valid. Available in Mac OS X v10.0 and later.
windowAppModalStateAlreadyExistsErr	-5617	The window is already application modal. Available in Mac OS X v10.1 and later.
windowNoAppModalStateErr	-5618	The window is not currently application modal. Available in Mac OS X v10.1 and later.
errWindowDoesntSupportFocus	-30583	Not used. Available in Mac OS X v10.0 and later.
errWindowRegionCodeInvalid	-30593	The window region code is not valid. Available in Mac OS X v10.0 and later.

Other References

Apple Help Reference

Framework: Carbon/Carbon.h

Declared in AppleHelp.h

Overview

Apple Help is an update and enhancement to previous versions of the Mac OS help system. It is available in Mac OS 8.6 and later, including Mac OS X.

This reference describes the application programming interface (API) for registering help books and calling the Help Viewer application.

Functions

AHGotoMainTOC

Tells the Help Viewer to load the specified main table-of-contents page. (Deprecated in Mac OS X v10.4. Use `AHGotoPage` (page 2058) to jump to different books or anchors.)

```
OSStatus AHGotoMainTOC (
   AHTOCType toctype
);
```

Parameters

toctype

A value specifying which Help Center page should be loaded. If you pass the `kAHTOCTypeUser` constant, for example, the Help Viewer loads the Help Center page.

Return Value

A result code. See "Apple Help Result Codes" (page 2061).

Discussion

This function is synchronous. Calling this function opens the Help Viewer application, if required, and loads the specified Help Center page.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`AppleHelp.h`

AHGotoPage

Tells the Help Viewer to load the specified HTML page.

```
OSStatus AHGotoPage (
   CFStringRef bookname,
   CFStringRef path,
   CFStringRef anchor
);
```

Parameters

bookname

A string specifying the name of the help book that contains the page to be loaded. If the name of the help book (as specified by the `AppleTitle` meta tag) is SurfWriter Help, for example, you pass a string containing the value `SurfWriter Help`. You may pass `NULL` in this parameter.

path

A string specifying a path for the page to be loaded. Specify the path relative to the help book given in the `bookname` parameter. If you pass `NULL` in this parameter, the Help Viewer opens to your help book's title page. If you pass `NULL` in the `bookname` parameter, you must specify the value passed in the `path` parameter as a full URL in the form `file://`.

anchor

An optional string specifying an anchor to which the Help Viewer scrolls after loading the specified page. If you do not specify an anchor, the Help Viewer scrolls to the top of the page.

Return Value

A result code. See "Apple Help Result Codes" (page 2061).

Discussion

This function is synchronous. Calling this function opens the Help Viewer application, if required, and loads the specified HTML page.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`AppleHelp.h`

AHLookupAnchor

Tells the Help Viewer to search for a specified anchor and load it.

```
OSStatus AHLookupAnchor (
   CFStringRef bookname,
   CFStringRef anchor
);
```

Parameters

bookname

A string specifying the name of the help book to search for the desired anchor. If the name of the help book (as specified by the `AppleTitle` meta tag) is SurfWriter Help, for example, you pass a string containing the value `SurfWriter Help`. If you do not specify a value in this parameter, the Help Viewer searches all available help books for the specified anchor.

anchor

A string specifying an anchor to load. You should ensure that each anchor name in your help book is unique. If you specify an anchor name that is not unique, the Help Viewer displays a list of links to all the anchors with that name.

Return Value
A result code. See "Apple Help Result Codes" (page 2061).

Discussion
This function is synchronous. Calling this function opens the Help Viewer application, if required, and loads the specified anchor or the list of links to multiple anchors, as appropriate. You must specify anchor indexing when you index your help book to perform anchor lookup.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AppleHelp.h`

AHRegisterHelpBook

Registers a help book.

```
OSStatus AHRegisterHelpBook (
   const FSRef *appBundleRef
);
```

Parameters

appBundleRef

A file system reference for the bundle containing the help book you wish to register.

Return Value
A result code. See "Apple Help Result Codes" (page 2061).

Discussion
Carbon applications must call this function in order to register a help book. If your Cocoa application provides appropriate key/value pairs specifying a single help book in your application's property list, as described in *Providing User Assistance with Apple Help*, you only need to call `AHRegisterHelpBook` if you wish to call the Apple Help functions to access your help content yourself. If you install an additional help book that is not described in your property list, you must call the `AHRegisterHelpBook` function in order to have the new book appear in the Help Center. If you call this function and specify a help book that is already registered, the `AHRegisterHelpBook` function returns a result of `noErr`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AppleHelp.h`

AHSearch

Tells the Help Viewer to search for a specified string in a given help book.

```
OSStatus AHSearch (
   CFStringRef bookname,
   CFStringRef query
);
```

Parameters

bookname

A string specifying the name of the help book to be searched. If the name of the help book (as specified by the `AppleTitle` meta tag) is SurfWriter Help, for example, you pass a string containing the value `SurfWriter Help`. If you pass `NULL` in this parameter, the Help Viewer searches all available help books.

query

A string containing the text to search for.

Return Value
A result code. See "Apple Help Result Codes" (page 2061).

Discussion
This function is synchronous. Calling this function opens the Help Viewer application, if required, and displays the results of the search.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AppleHelp.h`

Constants

TOC Specification Constants

Passed to the `AHGotoMainTOC` function to identify the table of contents page to open.

```
typedef SInt16 AHTOCType;
enum {
    kAHTOCTypeUser = 0,
    kAHTOCTypeDeveloper = 1
};
```

Constants

`kAHTOCTypeUser`

Opens the Help Center.

Available in Mac OS X v10.0 and later.

Declared in `AppleHelp.h`.

`kAHTOCTypeDeveloper`

Opens the Developer Help Center.

Available in Mac OS X v10.0 and later.

Declared in `AppleHelp.h`.

Result Codes

The most common result codes returned by Apple Help are listed below.

Result Code	Value	Description
`kAHInternalErr`	-10790	The requested operation could not be completed. Available in Mac OS X v10.0 and later.
`kAHInternetConfigPrefErr`	-10791	There was an error while attempting to read Internet Config settings. Available in Mac OS X v10.0 and later.

Carbon Printing Reference

Framework:	Carbon/Carbon.h
Declared in	PMApplication.h PMApplicationDeprecated.h
Companion guide	Supporting Printing in Your Carbon Application

Overview

Carbon Printing is a C API used by Carbon applications to display a user interface for printing. Carbon Printing provides functions to:

- Display the Page Setup dialog, which allows a user to modify the page format of a document to be printed
- Display the Print dialog, which allows a user to modify the default settings for a print job
- Execute a print loop that displays a printing status dialog

Carbon applications also need to use Core Printing to fully implement their printing features. For information about Core Printing, see *Core Printing Reference*.

Note: Carbon Printing and the Carbon Human Interface Toolbox are not available to 64-bit applications. To build a 64-bit application with a user interface, you must use Cocoa. For information about printing in Cocoa applications, see *Printing Programming Topics for Cocoa*.

Functions by Task

Displaying the Page Setup and Print Dialogs

`PMSessionUseSheets` (page 2093)
Specifies that a printing dialog should be displayed as a sheet and specifies a function to call when the user dismisses the printing dialog.

`PMSessionPageSetupDialog` (page 2088)
Displays the Page Setup dialog and records the user's selections in a page format object.

`PMSessionPrintDialog` (page 2091)
Displays the Print dialog and records the user's selections in a print settings object.

PMShowPageSetupDialogAsSheet (page 2097)
Displays a Page Setup dialog as a sheet attached to a window.

PMShowPrintDialogWithOptions (page 2098)
Displays a Print dialog with a specified set of controls.

PMShowPrintDialogWithOptionsAsSheet (page 2099)
Displays a Print dialog with a specified set of controls as a sheet attached to a window.

PMSessionEnablePrinterPresets (page 2086)
Enables the use of printer presets in the Print dialog.

PMSessionDisablePrinterPresets (page 2086)
Disables the use of printer presets in the Print dialog.

Print Loop Functions

PMSessionBeginCGDocument (page 2082)
Begins a print job in which all drawing is to a Quartz graphics context. A printing status dialog informs the user of the job's progress.

PMSessionEndDocument (page 2087)
Ends a print job started by calling the function PMSessionBeginCGDocument (page 2082) or PMSessionBeginDocument (page 2083).

PMSessionBeginPage (page 2084)
Starts a new page for printing in the specified printing session.

PMSessionEndPage (page 2087)
Indicates the end of drawing the current page for the specified printing session.

PMSessionBeginDocument (page 2083) Deprecated in Mac OS X v10.5
Begins a print job in which, by default, all drawing is to a QuickDraw graphics port. A printing status dialog informs the user of the job's progress. (Deprecated. Use PMSessionBeginCGDocument (page 2082) instead.)

Creating, Calling, and Deleting Universal Procedure Pointers

NewPMSheetDoneUPP (page 2072)
Creates a new universal procedure pointer (UPP) to a sheet-done callback.

InvokePMSheetDoneUPP (page 2070)
Calls a sheet-done callback.

DisposePMSheetDoneUPP (page 2068)
Disposes of a universal procedure pointer (UPP) to a sheet-done callback.

DisposePMItemUPP (page 2067) Deprecated in Mac OS X v10.4
Disposes of a universal procedure pointer (UPP) to a dialog item event handling callback. (Deprecated. Use a printing dialog extension instead.)

DisposePMPageSetupDialogInitUPP (page 2067) Deprecated in Mac OS X v10.4
Disposes of a universal procedure pointer (UPP) to a Page Setup dialog initialization callback. (Deprecated. Use a printing dialog extension instead.)

DisposePMPrintDialogInitUPP (page 2068) Deprecated in Mac OS X v10.4
: Disposes of a universal procedure pointer (UPP) to a Print dialog initialization callback function. (Deprecated. Use a printing dialog extension instead.)

InvokePMItemUPP (page 2068) Deprecated in Mac OS X v10.4
: Calls a dialog item event handling callback. (Deprecated. Use a printing dialog extension instead.)

InvokePMPageSetupDialogInitUPP (page 2069) Deprecated in Mac OS X v10.4
: Calls a Page Setup dialog initialization callback. (Deprecated. Use a printing dialog extension instead.)

InvokePMPrintDialogInitUPP (page 2069) Deprecated in Mac OS X v10.4
: Calls a Print dialog initialization callback. (Deprecated. Use a printing dialog extension instead.)

NewPMItemUPP (page 2070) Deprecated in Mac OS X v10.4
: Creates a new universal procedure pointer (UPP) to a dialog item event handling callback. (Deprecated. Use a printing dialog extension instead.)

NewPMPageSetupDialogInitUPP (page 2071) Deprecated in Mac OS X v10.4
: Creates a new universal procedure pointer (UPP) to a Page Setup dialog initialization callback. (Deprecated. Use a printing dialog extension instead.)

NewPMPrintDialogInitUPP (page 2071) Deprecated in Mac OS X v10.4
: Creates a new universal procedure pointer (UPP) to a Print dialog initialization callback. (Deprecated. Use a printing dialog extension instead.)

Customizing the Page Setup and Print Dialogs

The functions in this section make it possible to extend a printing dialog using the so-called AppendDITL method. Instead of using these functions, you should create a printing dialog extension. If you use these functions to extend a printing dialog, you cannot use sheets.

PMGetDialogAccepted (page 2075) Deprecated in Mac OS X v10.4
: Determines whether the user has confirmed a printing dialog. (Deprecated. Use a printing dialog extension instead.)

PMGetDialogDone (page 2075) Deprecated in Mac OS X v10.4
: Determines whether the user has finished with a dialog. (Deprecated. Use a printing dialog extension instead.)

PMGetDialogPtr (page 2076) Deprecated in Mac OS X v10.4
: Obtains the dialog reference for a dialog. (Deprecated. Use a printing dialog extension instead.)

PMGetItemProc (page 2076) Deprecated in Mac OS X v10.4
: Obtains the item proc callback function for a custom dialog. (Deprecated. Use a printing dialog extension instead.)

PMGetModalFilterProc (page 2077) Deprecated in Mac OS X v10.4
: Obtains the event handling callback function for a modal dialog. (Deprecated. Use a printing dialog extension instead.)

PMSessionPageSetupDialogInit (page 2089) Deprecated in Mac OS X v10.4
: Initializes a custom Page Setup dialog. (Deprecated. Use a printing dialog extension instead.)

PMSessionPageSetupDialogMain (page 2090) Deprecated in Mac OS X v10.4
: Displays your application's custom Page Setup dialog. (Deprecated. Use a printing dialog extension instead.)

PMSessionPrintDialogInit (page 2091) Deprecated in Mac OS X v10.4
: Initializes a custom Print dialog. (Deprecated. Use a printing dialog extension instead.)

`PMSessionPrintDialogMain` (page 2092) Deprecated in Mac OS X v10.4
Displays your application's custom Print dialog. (Deprecated. Use a printing dialog extension instead.)

`PMSetDialogAccepted` (page 2094) Deprecated in Mac OS X v10.4
Indicates that the user confirmed a custom dialog. (Deprecated. Use a printing dialog extension instead.)

`PMSetDialogDone` (page 2095) Deprecated in Mac OS X v10.4
Indicates that the user finished with a custom dialog. (Deprecated. Use a printing dialog extension instead.)

`PMSetItemProc` (page 2096) Deprecated in Mac OS X v10.4
Installs an item proc callback function for items in a custom dialog. (Deprecated. Use a printing dialog extension instead.)

`PMSetModalFilterProc` (page 2096) Deprecated in Mac OS X v10.4
Installs an event handling callback function for a modal dialog. (Deprecated. Use a printing dialog extension instead.)

Legacy Carbon Printing Functions

The functions in this section are deprecated and have been replaced by session-based functions that take a `PMPrintSession` object. In some cases, the replacement function is also deprecated.

`PMBeginDocument` (page 2072) Deprecated in Mac OS X v10.4
Establishes a graphics context for imaging a document. This context is an opaque `grafPort`. (Deprecated. Use `PMSessionBeginCGDocument` (page 2082) instead.)

`PMBeginPage` (page 2073) Deprecated in Mac OS X v10.4
Initializes a scaling rectangle for printing a page. (Deprecated. Use `PMSessionBeginPage` (page 2084) instead.)

`PMEndDocument` (page 2074) Deprecated in Mac OS X v10.4
Closes the context created for imaging a document. (Deprecated. Use `PMSessionEndDocument` (page 2087) instead.)

`PMEndPage` (page 2074) Deprecated in Mac OS X v10.4
Finishes printing the current page. (Deprecated. Use `PMSessionEndPage` (page 2087) instead.)

`PMPageSetupDialog` (page 2078) Deprecated in Mac OS X v10.4
Displays the Page Setup dialog and records the user's selections in a `PMPageFormat` object. (Deprecated. Use `PMSessionPageSetupDialog` (page 2088) or `PMShowPageSetupDialogAsSheet` (page 2097) instead.)

`PMPageSetupDialogInit` (page 2078) Deprecated in Mac OS X v10.4
Initializes a custom Page Setup dialog. (Deprecated. Use a printing dialog extension instead.)

`PMPageSetupDialogMain` (page 2079) Deprecated in Mac OS X v10.4
Displays your application's customized Page Setup dialog. (Deprecated. Use a printing dialog extension instead.)

`PMPrintDialog` (page 2080) Deprecated in Mac OS X v10.4
Displays the Print dialog and records the user's selections in a `PMPrintSettings` object. (Deprecated. Use `PMSessionPrintDialog` (page 2091), `PMShowPrintDialogWithOptions` (page 2098), or `PMShowPrintDialogWithOptionsAsSheet` (page 2099) instead.)

`PMPrintDialogInit` (page 2080) Deprecated in Mac OS X v10.4
Initializes a custom Print dialog. (Deprecated. Use a printing dialog extension instead.)

`PMPrintDialogInitWithPageFormat` (page 2081) Deprecated in Mac OS X v10.4
Initializes a custom Print dialog. (Deprecated. Use a printing dialog extension instead.)

`PMPrintDialogMain` (page 2082) Deprecated in Mac OS X v10.4
Displays your application's custom Print dialog. (Deprecated. Use a printing dialog extension instead.)

Functions

DisposePMItemUPP

Disposes of a universal procedure pointer (UPP) to a dialog item event handling callback. (Deprecated in Mac OS X v10.4. Use a printing dialog extension instead.)

```
void DisposePMItemUPP (
   PMItemUPP userUPP
);
```

Parameters

userUPP
The universal procedure pointer.

Discussion

See the `PMItemProcPtr` (page 2100) callback function.

Availability

Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In

`PMApplicationDeprecated.h`

DisposePMPageSetupDialogInitUPP

Disposes of a universal procedure pointer (UPP) to a Page Setup dialog initialization callback. (Deprecated in Mac OS X v10.4. Use a printing dialog extension instead.)

```
void DisposePMPageSetupDialogInitUPP (
   PMPageSetupDialogInitUPP userUPP
);
```

Parameters

userUPP
The universal procedure pointer.

Discussion

See the `PMPageSetupDialogInitProcPtr` (page 2101) callback function.

Availability

Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
PMApplicationDeprecated.h

DisposePMPrintDialogInitUPP

Disposes of a universal procedure pointer (UPP) to a Print dialog initialization callback function. (Deprecated in Mac OS X v10.4. Use a printing dialog extension instead.)

```
void DisposePMPrintDialogInitUPP (
   PMPrintDialogInitUPP userUPP
);
```

Parameters

userUPP

The universal procedure pointer.

Discussion
See the PMPrintDialogInitProcPtr (page 2102) callback function.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
PMApplicationDeprecated.h

DisposePMSheetDoneUPP

Disposes of a universal procedure pointer (UPP) to a sheet-done callback.

```
void DisposePMSheetDoneUPP (
   PMSheetDoneUPP userUPP
);
```

Parameters

userUPP

A UPP to your sheet-done callback.

Discussion
See the callback PMSheetDoneProcPtr (page 2103) for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
PMApplication.h

InvokePMItemUPP

Calls a dialog item event handling callback. (Deprecated in Mac OS X v10.4. Use a printing dialog extension instead.)

```
void InvokePMItemUPP (
   DialogRef theDialog,
   short item,
   PMItemUPP userUPP
);
```

Discussion
You should not need to use the function `InvokePMInvokeUPP`, as the printing system calls your item event handling callback function for you. See the `PMItemProcPtr` (page 2100) callback function.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`PMApplicationDeprecated.h`

InvokePMPageSetupDialogInitUPP

Calls a Page Setup dialog initialization callback. (Deprecated in Mac OS X v10.4. Use a printing dialog extension instead.)

```
void InvokePMPageSetupDialogInitUPP (
   PMPageFormat pageFormat,
   PMDialog *theDialog,
   PMPageSetupDialogInitUPP userUPP
);
```

Discussion
You should not need to use the function `InvokePMPageSetupDialogInitUPP`, as the printing system calls your Page Setup dialog initialization callback function for you. See the `PMPageSetupDialogInitProcPtr` (page 2101) callback function.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`PMApplicationDeprecated.h`

InvokePMPrintDialogInitUPP

Calls a Print dialog initialization callback. (Deprecated in Mac OS X v10.4. Use a printing dialog extension instead.)

```
void InvokePMPrintDialogInitUPP (
   PMPrintSettings printSettings,
   PMDialog *theDialog,
   PMPrintDialogInitUPP userUPP
);
```

Discussion
You should not need to use the function `InvokePMPrintDialogInitUPP`, as the printing system calls your Print dialog initialization callback function for you. See the `PMPrintDialogInitProcPtr` (page 2102) callback function.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`PMApplicationDeprecated.h`

InvokePMSheetDoneUPP

Calls a sheet-done callback.

```
void InvokePMSheetDoneUPP (
   PMPrintSession printSession,
   WindowRef documentWindow,
   Boolean accepted,
   PMSheetDoneUPP userUPP
);
```

Discussion
You should not need to use the function `InvokePMSheetDoneUPP`, as the printing system calls your sheet-done callback function for you. See the callback `PMSheetDoneProcPtr` (page 2103) for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`PMApplication.h`

NewPMItemUPP

Creates a new universal procedure pointer (UPP) to a dialog item event handling callback. (Deprecated in Mac OS X v10.4. Use a printing dialog extension instead.)

```
PMItemUPP NewPMItemUPP (
   PMItemProcPtr userRoutine
);
```

Parameters
userRoutine
A pointer to your dialog item event handling callback.

Return Value
On return, a UPP to the dialog item event handling callback.

Discussion
See the `PMItemProcPtr` (page 2100) callback function.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`PMApplicationDeprecated.h`

NewPMPageSetupDialogInitUPP

Creates a new universal procedure pointer (UPP) to a Page Setup dialog initialization callback. (Deprecated in Mac OS X v10.4. Use a printing dialog extension instead.)

```
PMPageSetupDialogInitUPP NewPMPageSetupDialogInitUPP (
   PMPageSetupDialogInitProcPtr userRoutine
);
```

Parameters
userRoutine
A pointer to your Page Setup dialog initialization callback.

Return Value
On return, a UPP to the Page Setup dialog initialization callback.

Discussion
See the `PMPageSetupDialogInitProcPtr` (page 2101) callback function.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`PMApplicationDeprecated.h`

NewPMPrintDialogInitUPP

Creates a new universal procedure pointer (UPP) to a Print dialog initialization callback. (Deprecated in Mac OS X v10.4. Use a printing dialog extension instead.)

```
PMPrintDialogInitUPP NewPMPrintDialogInitUPP (
   PMPrintDialogInitProcPtr userRoutine
);
```

Parameters
userRoutine
A pointer to your Print dialog initialization callback.

Return Value
On return, a UPP to the Print dialog initialization callback.

Discussion
See the `PMPrintDialogInitProcPtr` (page 2102) callback function.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`PMApplicationDeprecated.h`

NewPMSheetDoneUPP

Creates a new universal procedure pointer (UPP) to a sheet-done callback.

```
PMSheetDoneUPP NewPMSheetDoneUPP (
   PMSheetDoneProcPtr userRoutine
);
```

Parameters
`userRoutine`
A pointer to your sheet-done callback.

Return Value
On return, a UPP to the sheet-done callback.

Discussion
See the callback `PMSheetDoneProcPtr` (page 2103) for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`PMApplication.h`

PMBeginDocument

Establishes a graphics context for imaging a document. This context is an opaque `grafPort`. (Deprecated in Mac OS X v10.4. Use `PMSessionBeginCGDocument` (page 2082) instead.)

```
OSStatus PMBeginDocument (
    PMPrintSettings printSettings,
    PMPageFormat pageFormat,
    PMPrintContext *printContext
);
```

Parameters
`printSettings`
A `PMPrintSettings` object.

pageFormat
A PMPageFormat object.

printContext
On return, an initialized PMPrintContext object.

Return Value
A result code. See Core Printing Result Codes.

Discussion
Valid within a PMBegin/PMEnd block. You must balance a call to PMBeginDocument with a call to PMEndDocument.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
PMApplicationDeprecated.h

PMBeginPage

Initializes a scaling rectangle for printing a page. (Deprecated in Mac OS X v10.4. Use PMSessionBeginPage (page 2084) instead.)

```
OSStatus PMBeginPage (
    PMPrintContext printContext,
    const PMRect *pageFrame
);
```

Parameters

printContext
A PMPrintContext object.

pageFrame
A pointer to a bounding rectangle for drawing the page. This value is usually obtained from the function PMGetAdjustedRect, but if no scaling is needed, pass NULL. In Mac OS X, this parameter is ignored.

Return Value
A result code. See Core Printing Result Codes.

Discussion
Valid after calling PMBegin and PMBeginDocument.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
PMApplicationDeprecated.h

PMEndDocument

Closes the context created for imaging a document. (Deprecated in Mac OS X v10.4. Use `PMSessionEndDocument` (page 2087) instead.)

```
OSStatus PMEndDocument (
    PMPrintContext printContext
);
```

Parameters

printContext

On return, an invalidated `PMPrintContext` object.

Return Value

A result code. See Core Printing Result Codes.

Discussion

Valid after calling `PMBegin` and `PMBeginDocument`.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`PMApplicationDeprecated.h`

PMEndPage

Finishes printing the current page. (Deprecated in Mac OS X v10.4. Use `PMSessionEndPage` (page 2087) instead.)

```
OSStatus PMEndPage (
    PMPrintContext printContext
);
```

Parameters

printContext

A `PMPrintContext` object.

Return Value

A result code. See Core Printing Result Codes.

Discussion

Valid after calling `PMBegin`, `PMBeginDocument`, and `PMBeginPage`.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`PMApplicationDeprecated.h`

PMGetDialogAccepted

Determines whether the user has confirmed a printing dialog. (Deprecated in Mac OS X v10.4. Use a printing dialog extension instead.)

```
OSStatus PMGetDialogAccepted (
   PMDialog pmDialog,
   Boolean *process
);
```

Parameters

pmDialog

A `PMDialog` object representing your customized Page Setup or Print dialog.

process

Returns `true` if the user confirms the dialog. In the case of the Page Setup dialog, this means the user clicked the OK button; in the case of the Print dialog, this means the user clicked the Print or Preview button. Returns `false` if the user clicks the Cancel button.

Return Value

A result code. See Core Printing Result Codes.

Discussion

The function `PMGetDialogAccepted` is valid between the creation and release of a printing session and while displaying your custom Page Setup or Print dialog.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`PMApplicationDeprecated.h`

PMGetDialogDone

Determines whether the user has finished with a dialog. (Deprecated in Mac OS X v10.4. Use a printing dialog extension instead.)

```
OSStatus PMGetDialogDone (
   PMDialog pmDialog,
   Boolean *done
);
```

Parameters

pmDialog

A `PMDialog` object representing your customized Page Setup or Print dialog.

done

Returns `true` if the user clicked the OK, Print, or Cancel button; `false` if the user did not click any of these buttons.

Return Value

A result code. See Core Printing Result Codes.

Discussion
The function `PMGetDialogDone` is valid between the creation and release of a printing session and while displaying your Page Setup or Print dialog.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`PMApplicationDeprecated.h`

PMGetDialogPtr

Obtains the dialog reference for a dialog. (Deprecated in Mac OS X v10.4. Use a printing dialog extension instead.)

```
OSStatus PMGetDialogPtr (
   PMDialog pmDialog,
   DialogRef *theDialog
);
```

Parameters

pmDialog
The `PMDialog` object from which you wish to extract the `DialogRecord` structure.

theDialog
On return, a pointer to a Dialog Manager `DialogRef` object.

Return Value
A result code. See Core Printing Result Codes.

Discussion
The function `PMGetDialogPtr` is valid between the creation and release of a printing session and after calling `PMSessionPageSetupDialogInit` to initialize a Page Setup dialog, or calling `PMSessionPrintDialogInit` to initialize a Print dialog.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`PMApplicationDeprecated.h`

PMGetItemProc

Obtains the item proc callback function for a custom dialog. (Deprecated in Mac OS X v10.4. Use a printing dialog extension instead.)

```
OSStatus PMGetItemProc (
   PMDialog pmDialog,
   PMItemUPP *itemProc
);
```

Parameters

pmDialog

A `PMDialog` object representing the Page Setup or Print dialog for which you want to obtain the item proc function.

itemProc

On return, a pointer to the current dialog item proc function.

Return Value
A result code. See Core Printing Result Codes.

Discussion
The function `PMGetItemProc` is valid only between the creation and release of a printing session. You can call `PMGetItemProc` to get the existing item proc function before you replace it with a call to the function `PMSetItemProc`. You should call this function only if you need to handle events in a custom dialog you create using the `AppendDITL` method. In Mac OS X, you should create a custom dialog by writing a printing dialog extension. If you use this function to extend a printing dialog in Mac OS X, you cannot use sheets.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`PMApplicationDeprecated.h`

PMGetModalFilterProc

Obtains the event handling callback function for a modal dialog. (Deprecated in Mac OS X v10.4. Use a printing dialog extension instead.)

```
OSStatus PMGetModalFilterProc (
   PMDialog pmDialog,
   ModalFilterUPP *filterProc
);
```

Parameters

pmDialog

A `PMDialog` object representing the Page Setup or Print dialog for which you want to obtain the event handling function.

filterProc

On return, a pointer to the current dialog event handling function.

Return Value
A result code. See Core Printing Result Codes.

Discussion
The function `PMGetModalFilterProc` is valid only between the creation and release of a printing session. You can call `PMGetModalFilterProc` to get the existing event handling function before you replace it with a call to the function `PMSetModalFilterProc`. The event handling function is not called in Mac OS X.

You should call the function `PMGetModalFilterProc` only if you create a custom dialog using the `AppendDITL` method. In Mac OS X, you should create a custom dialog by writing a printing dialog extension. If you use this function to extend a printing dialog in Mac OS X, you cannot use sheets.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`PMApplicationDeprecated.h`

PMPageSetupDialog

Displays the Page Setup dialog and records the user's selections in a `PMPageFormat` object. (Deprecated in Mac OS X v10.4. Use `PMSessionPageSetupDialog` (page 2088) or `PMShowPageSetupDialogAsSheet` (page 2097) instead.)

```
OSStatus PMPageSetupDialog (
    PMPageFormat pageFormat,
    Boolean *accepted
);
```

Parameters

pageFormat
A `PMPageFormat` object.

accepted
Returns `true` if the user clicks the OK button, or `false` if the user clicks Cancel.

Return Value
A result code. See Core Printing Result Codes.

Discussion
Valid after calling `PMBegin` and creating a page format object. Never call `PMPageSetupDialog` between the pages of a document.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`PMApplicationDeprecated.h`

PMPageSetupDialogInit

Initializes a custom Page Setup dialog. (Deprecated in Mac OS X v10.4. Use a printing dialog extension instead.)

```
OSStatus PMPageSetupDialogInit (
    PMPageFormat pageFormat,
    PMDialog *newDialog
);
```

Parameters

pageFormat

A `PMPageFormat` object.

newDialog

On return, a pointer to an initialized `PMDialog` object, ready for customization by your application. Because the `PMPageSetupDialogMain` function does not include a parameter for passing this `PMDialog` object to your dialog initialization callback function, your application should store this pointer in a global variable or as extended data in the `PMPageFormat` object. See the discussion of the `PMPageSetupDialogInitProcPtr` callback function for more information.

Return Value
A result code. See Core Printing Result Codes.

Discussion
Valid after calling `PMBegin` and creating a page format object.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`PMApplicationDeprecated.h`

PMPageSetupDialogMain

Displays your application's customized Page Setup dialog. (Deprecated in Mac OS X v10.4. Use a printing dialog extension instead.)

```
OSStatus PMPageSetupDialogMain (
    PMPageFormat pageFormat,
    Boolean *accepted,
    PMPageSetupDialogInitUPP myInitProc
);
```

Parameters

pageFormat

A `PMPageFormat` object.

accepted

Returns `true` if the user clicks the OK button, or `false` if the user clicks Cancel.

myInitProc

A universal procedure pointer to your dialog initialization function. Your initialization function is defined by the callback `PMPageSetupDialogInitProcPtr`.

Return Value
A result code. See Core Printing Result Codes.

Discussion
Valid after calling `PMBegin` and creating a page format object

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`PMApplicationDeprecated.h`

PMPrintDialog

Displays the Print dialog and records the user's selections in a `PMPrintSettings` object. (Deprecated in Mac OS X v10.4. Use `PMSessionPrintDialog` (page 2091), `PMShowPrintDialogWithOptions` (page 2098), or `PMShowPrintDialogWithOptionsAsSheet` (page 2099) instead.)

```
OSStatus PMPrintDialog (
    PMPrintSettings printSettings,
    PMPageFormat constPageFormat,
    Boolean *accepted
);
```

Parameters

printSettings
A `PMPrintSettings` object.

constPageFormat
A `PMPageFormat` object.

accepted
Returns `true` if the user clicks the OK button, or `false` if the user clicks Cancel.

Return Value
A result code. See Core Printing Result Codes.

Discussion
Valid after calling `PMBegin` and creating a page format and print settings object.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`PMApplicationDeprecated.h`

PMPrintDialogInit

Initializes a custom Print dialog. (Deprecated in Mac OS X v10.4. Use a printing dialog extension instead.)

```
OSStatus PMPrintDialogInit (
    PMPrintSettings printSettings,
    PMDialog *newDialog
);
```

Parameters

printSettings
A `PMPrintSettings` object.

newDialog

On return, a pointer to an initialized `PMDialog` object, ready for customization by your application. Because the `PMPrintDialogMain` function does not include a parameter for passing this `PMDialog` object to your dialog initialization callback function, your application should store this pointer in a global variable or as extended data in the `PMPrintSettings` object. See the discussion of the `PMPrintDialogInitProcPtr` callback function for more information.

Return Value
A result code. See Core Printing Result Codes.

Discussion
Valid after calling `PMBegin` and creating a page format and print settings object.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`PMApplicationDeprecated.h`

PMPrintDialogInitWithPageFormat

Initializes a custom Print dialog. (Deprecated in Mac OS X v10.4. Use a printing dialog extension instead.)

```
OSStatus PMPrintDialogInitWithPageFormat (
    PMPrintSettings printSettings,
    PMPageFormat constPageFormat,
    PMDialog *newDialog
);
```

Parameters

printSettings

A `PMPrintSettings` object.

constPageFormat

A `PMPageFormat` object.

newDialog

On return, a pointer to an initialized `PMDialog` object, ready for customization by your application. Because the `PMPrintDialogMain` function does not include a parameter for passing this `PMDialog` object to your dialog initialization callback function, your application should store this pointer in a global variable or as extended data in the `PMPrintSettings` object. See the discussion of the `PMPrintDialogInitProcPtr` callback function for more information.

Return Value
A result code. See Core Printing Result Codes.

Discussion
Valid after calling `PMBegin` and creating a page format and print settings object.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`PMApplicationDeprecated.h`

PMPrintDialogMain

Displays your application's custom Print dialog. (Deprecated in Mac OS X v10.4. Use a printing dialog extension instead.)

```
OSStatus PMPrintDialogMain (
    PMPrintSettings printSettings,
    PMPageFormat constPageFormat,
    Boolean *accepted,
    PMPrintDialogInitUPP myInitProc
);
```

Parameters

printSettings

A `PMPrintSettings` object.

constPageFormat

A `PMPageFormat` object.

accepted

Returns `true` if the user clicks the OK button, or `false` if the user clicks Cancel.

myInitProc

A universal procedure pointer to your dialog initialization function. Your initialization function is defined by the callback `PMPrintDialogIinitProcPtr`.

Return Value

A result code. See Core Printing Result Codes.

Discussion

Valid after calling `PMBegin` and creating a page format and print settings object.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`PMApplicationDeprecated.h`

PMSessionBeginCGDocument

Begins a print job in which all drawing is to a Quartz graphics context. A printing status dialog informs the user of the job's progress.

```
OSStatus PMSessionBeginCGDocument (
   PMPrintSession printSession,
   PMPrintSettings printSettings,
   PMPageFormat pageFormat
);
```

Parameters

printSession

The printing session for the new print job.

printSettings

The print settings for the new print job.

pageFormat
The page format for the new print job.

Return Value
A result code. See Core Printing Result Codes.

Discussion
This function starts a print job in which your application draws in a Quartz graphics context, and should be called within your application's print loop. This function is similar to the function `PMSessionBeginCGDocumentNoDialog` except that the printing status dialog is displayed.

You must call this function between the creation and release of a printing session. See the function `PMCreateSession`. If you present a printing dialog before you call this function, when calling this function you should use the same `PMPrintSession` object you used to present the dialog.

Before you call `PMSessionBeginCGDocument`, you should call `PMSessionValidatePrintSettings` and `PMSessionValidatePageFormat` to make sure the specified print settings and page format objects are updated and valid. After you call `PMSessionBeginCGDocument`, if you call a function that changes the specified print settings or page format object, the change is ignored for the current print job.

This function must be called before its corresponding `End` function (`PMSessionEndDocument` (page 2087)). If the function `PMSessionBeginCGDocument` returns `noErr`, you must later call the `End` function, even if errors occur within the scope of the `Begin` and `End` functions.

The printing system automatically handles printing multiple copies. Your application does not need to perform any tasks other than specifying the number of copies in the printing session.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

See Also
`PMSessionBeginCGDocumentNoDialog`

Declared In
`PMApplication.h`

PMSessionBeginDocument

Begins a print job in which, by default, all drawing is to a QuickDraw graphics port. A printing status dialog informs the user of the job's progress. (Deprecated in Mac OS X v10.5. Use `PMSessionBeginCGDocument` (page 2082) instead.)

```
OSStatus PMSessionBeginDocument (
   PMPrintSession printSession,
   PMPrintSettings printSettings,
   PMPageFormat pageFormat
);
```

Parameters
printSession
The printing session for the new print job.

printSettings
The print settings for the new print job.

pageFormat
The page format for the new print job.

Return Value
A result code. See Core Printing Result Codes.

Discussion
The function `PMSessionBeginDocument` starts a print job and should be called within your application's print loop. This function is similar to the function `PMSessionBeginDocumentNoDialog` except that the printing status dialog is displayed.

You must call this function between the creation and release of a printing session. See the function `PMCreateSession`. If you present a printing dialog before you call `PMSessionBeginDocument`, you should use the same `PMPrintSession` object you used to present the dialog.

Before you call `PMSessionBeginDocument`, you should call `PMSessionValidatePrintSettings` and `PMSessionValidatePageFormat` to make sure the specified print settings and page format objects are updated and valid. After you call `PMSessionBeginDocument`, if you call a function that changes the specified print settings or page format object, the change is ignored for the current print job.

This function must be called before its corresponding `End` function (`PMSessionEndDocument` (page 2087)). If the function `PMSessionBeginDocument` function returns `noErr`, you must later call the `End` function, even if errors occur within the scope of the `Begin` and `End` functions.

The printing system automatically handles printing multiple copies. Your application does not need to perform any tasks other than specifying the number of copies in the printing session.

Special Considerations

In Mac OS X v10.4 and later, Apple recommends using the function `PMSessionBeginCGDocument` (page 2082) instead of this function. QuickDraw is deprecated and your application should be using Quartz 2D for its rendering.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Related Sample Code
CarbonSketch

Declared In
`PMApplicationDeprecated.h`

PMSessionBeginPage

Starts a new page for printing in the specified printing session.

```
OSStatus PMSessionBeginPage (
    PMPrintSession printSession,
    PMPageFormat pageFormat,
    const PMRect *pageFrame
);
```

Parameters

printSession

The printing session for the print job.

pageFormat

The page format for the new page. If you pass `NULL`, the printing system uses the page format you passed to `PMSessionBeginCGDocument` (page 2082).

pageFrame

You should pass `NULL`, as this parameter is currently unsupported.

Return Value

A result code. If the user cancels the print job, this function returns `kPMCancel`.

Discussion

You must call this function between the creation and release of a printing session. See the function `PMCreateSession`. You must call the functions `PMSessionBeginPage` and `PMSessionEndPage` (page 2087) within the scope of calls to the `Begin` print job function (`PMSessionBeginCGDocument` (page 2082)) and the `End` print job function (`PMSessionEndDocument` (page 2087)).

You should call the function `PMSessionError` immediately before you call `PMSessionBeginPage`. If `PMSessionError` returns an error, then you should not call the function `PMSessionBeginPage`. Because `PMSessionBeginPage` also initializes the printing graphics context, your application should not make assumptions about the state of the context (for example, the current font) between successive pages. After each call to `PMSessionBeginPage`, your application should call `PMSessionGetCGGraphicsContext` to obtain the current printing context.

If the function `PMSessionBeginPage` returns `noErr`, you must later call the function `PMSessionEndPage`, even if errors occur within the scope of `PMSessionBeginPage` and `PMSessionEndPage`.

The printing system automatically handles printing multiple copies. Your application does not need to perform any tasks other than specifying the number of copies in the printing session.

Special Considerations

Prior to Mac OS X v10.5, the *pageFormat* parameter is ignored. In Mac OS X v10.5 and later, the printing system supports multiple orientations within a print job. When you call this function and supply a page format, the orientation specified in the page format is used for the current page. Other settings in the page format, such as paper size or scaling, are ignored.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Related Sample Code

CarbonSketch

Declared In

`PMApplication.h`

PMSessionDisablePrinterPresets

Disables the use of printer presets in the Print dialog.

```
OSStatus PMSessionDisablePrinterPresets (
    PMPrintSession session
);
```

Parameters

session

The printing session you use to present the Print dialog.

Return Value

A result code. See Core Printing Result Codes.

Discussion

When you call this function with the specified printing session, the Print dialog for that session does not show any printer presets. Presets are disabled by default.

Availability

Available in Mac OS X v10.2 and later.

Not available to 64-bit applications.

See Also

`PMSessionEnablePrinterPresets` (page 2086)

Declared In

`PMApplication.h`

PMSessionEnablePrinterPresets

Enables the use of printer presets in the Print dialog.

```
OSStatus PMSessionEnablePrinterPresets (
    PMPrintSession session,
    CFStringRef graphicsType
);
```

Parameters

session

The printing session you use to present the Print dialog.

graphicsType

The printer presets in the dialog should be suitable for rendering this type of graphic. Currently, the only defined graphics type is `"Photo"`.

Return Value

A result code. See Core Printing Result Codes.

Discussion

When you call this function with the specified printing session, the Print dialog shows the presets available for the specified graphics type.

Availability

Available in Mac OS X v10.2 and later.

Not available to 64-bit applications.

See Also
PMSessionDisablePrinterPresets (page 2086)

Declared In
PMApplication.h

PMSessionEndDocument

Ends a print job started by calling the function PMSessionBeginCGDocument (page 2082) or PMSessionBeginDocument (page 2083).

```
OSStatus PMSessionEndDocument (
   PMPrintSession printSession
);
```

Parameters

printSession

The current printing session. On return, the printing session is no longer valid; however, you must still call the function PMRelease to release the object.

Return Value
A result code. See Core Printing Result Codes.

Discussion
You must call this function between the creation and release of a printing session. See the function PMCreateSession. The function PMSessionEndDocument is used to end a print job, and it should be called within your application's print loop after the call to PMSessionEndPage and before releasing the printing session.

This function must be called after its corresponding Begin function (PMSessionBeginCGDocument (page 2082) or PMSessionBeginDocument (page 2083)). If the Begin function returns noErr, the function PMSessionEndDocument must be called, even if errors occur within the scope of the Begin and End functions. You should not call PMSessionEndDocument if the Begin function returns an error.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
CarbonSketch

Declared In
PMApplication.h

PMSessionEndPage

Indicates the end of drawing the current page for the specified printing session.

```
OSStatus PMSessionEndPage (
   PMPrintSession printSession
);
```

Parameters

printSession

The printing session for the print job.

Return Value

A result code. See Core Printing Result Codes.

Discussion

You must call this function between the creation and release of a printing session. See the function `PMCreateSession`. You must call the functions `PMSessionBeginPage` (page 2084) and `PMSessionEndPage` within the scope of calls to the `Begin` print job function (`PMSessionBeginCGDocument` (page 2082)) and the `End` print job function (`PMSessionEndDocument` (page 2087)).

If the function `PMSessionBeginPage` returns `noErr`, you must later call the function `PMSessionEndPage`, even if errors occur within the scope of `PMSessionBeginPage` and `PMSessionEndPage`. You should not call `PMSessionEndPage` if `PMSessionBeginPage` returns an error.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Related Sample Code

CarbonSketch

Declared In

`PMApplication.h`

PMSessionPageSetupDialog

Displays the Page Setup dialog and records the user's selections in a page format object.

```
OSStatus PMSessionPageSetupDialog (
   PMPrintSession printSession,
   PMPageFormat pageFormat,
   Boolean *accepted
);
```

Parameters

printSession

The printing session for which you want to display the dialog.

pageFormat

The page format object in which the user's selections are recorded.

accepted

A pointer to your Boolean variable. On return, `true` if the user clicks the OK button, or `false` if the user clicks Cancel. If you are using a sheet dialog, you should ignore the value returned in this parameter.

Return Value

A result code. See Core Printing Result Codes.

Discussion
You must call this function between the creation and release of a printing session. See the function `PMCreateSession`. Before you call the function `PMSessionPageSetupDialog` you should call the function `PMSessionValidatePageFormat` to make sure page format settings are updated and valid. You should call the function `PMSessionPageSetupDialog` outside the scope of your print loop.

The Page Setup dialog shows the current settings contained in the page format object. If the user changes these settings and clicks the OK button, the page format object is updated by the printing system with the user's selections. If the user clicks the Cancel button, the page format object is returned unchanged.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code

Declared In
`PMApplication.h`

PMSessionPageSetupDialogInit

Initializes a custom Page Setup dialog. (Deprecated in Mac OS X v10.4. Use a printing dialog extension instead.)

```
OSStatus PMSessionPageSetupDialogInit (
   PMPrintSession printSession,
   PMPageFormat pageFormat,
   PMDialog *newDialog
);
```

Parameters

printSession
The current printing session.

pageFormat
A page format object.

newDialog
On return, a pointer to an initialized `PMDialog` object, ready for customization by your application. Because the `PMSessionPageSetupDialogMain` (page 2090) function does not include a parameter for passing this `PMDialog` object to your dialog initialization callback function, your application should store this pointer in a global variable or as extended data in the `PMPageFormat` object.

Return Value
A result code. See Core Printing Result Codes.

Discussion
The function `PMSessionPageSetupDialogInit` is valid only between the creation and release of a printing session and after creating a page format object. You should call this function only if you create a custom dialog using the `AppendDITL` method. In Mac OS X, you should create a custom dialog by writing a printing dialog extension. If you use this function to extend a printing dialog in Mac OS X, you cannot use sheets.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
PMApplicationDeprecated.h

PMSessionPageSetupDialogMain

Displays your application's custom Page Setup dialog. (Deprecated in Mac OS X v10.4. Use a printing dialog extension instead.)

```
OSStatus PMSessionPageSetupDialogMain (
   PMPrintSession printSession,
   PMPageFormat pageFormat,
   Boolean *accepted,
   PMPageSetupDialogInitUPP myInitProc
);
```

Parameters

printSession
The current printing session.

pageFormat
A page format object.

accepted
A pointer to your Boolean variable. On return, `true` if the user clicks the OK button, or `false` if the user clicks Cancel.

myInitProc
A universal procedure pointer to your dialog initialization function. Your initialization function is defined by the callback `PMPageSetupDialogInitProcPtr`.

Return Value
A result code. See Core Printing Result Codes.

Discussion
The function `PMSessionPageSetupDialogMain` is valid only between the creation and release of a printing session and after calling the function `PMSessionPageSetupDialogInit`. You should call this function only if you create a custom dialog using the `AppendDITL` method. In Mac OS X, you should create a custom dialog by writing a printing dialog extension. If you use this function to extend a printing dialog in Mac OS X, you cannot use sheets.

Your dialog initialization function is called before your custom Page Setup dialog is displayed. Your initialization function can append items to the Page Setup dialog, and should install an item proc using the `PMSetItemProc` (page 2096) function. You must pass the same page format object to each of the functions `PMSessionPageSetupDialogMain` and `PMSessionPageSetupDialogInit` (page 2089).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
PMApplicationDeprecated.h

PMSessionPrintDialog

Displays the Print dialog and records the user's selections in a print settings object.

```
OSStatus PMSessionPrintDialog (
   PMPrintSession printSession,
   PMPrintSettings printSettings,
   PMPageFormat constPageFormat,
   Boolean *accepted
);
```

Parameters

printSession

The printing session for which you want to display the dialog.

printSettings

The print settings object in which the user's selections are recorded.

constPageFormat

The page format object for the specified printing session.

accepted

A pointer to your Boolean variable. On return, `true` if the user accepts the dialog or `false` if the user cancels the dialog. If you are using a sheet dialog, you should ignore the value of this parameter.

Return Value

A result code. See Core Printing Result Codes.

Discussion

You must call this function between the creation and release of a printing session. See the function `PMCreateSession`. Before you call the function `PMSessionPrintDialog` you should call the function `PMSessionValidatePrintSettings` to make sure print settings are updated and valid. You should call the function `PMSessionPrintDialog` outside the scope of your print loop.

The Print dialog shows the current settings in the print settings object. If the user changes these settings and accepts the dialog, the print settings object is updated by the printing system with the user's selections. If the user cancels the dialog, the print settings object is returned unchanged.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

PMSessionPrintDialogInit

Initializes a custom Print dialog. (Deprecated in Mac OS X v10.4. Use a printing dialog extension instead.)

```
OSStatus PMSessionPrintDialogInit (
   PMPrintSession printSession,
   PMPrintSettings printSettings,
   PMPageFormat constPageFormat,
   PMDialog *newDialog
);
```

Parameters

printSession

The current printing session.

printSettings

A print settings object.

constPageFormat

A page format object.

newDialog

On return, a pointer to an initialized `PMDialog` object, ready for customization by your application. Because the `PMSessionPrintDialogMain` (page 2092) function does not include a parameter for passing this `PMDialog` object to your dialog initialization callback function, your application should store this pointer in a global variable or as extended data in the `PMPrintSettings` object. See the discussion of the `PMPrintDialogInitProcPtr` (page 2102) callback function for more information.

Return Value

A result code. See Core Printing Result Codes.

Discussion

The function `PMSessionPrintDialogInit` is valid only between the creation and release of a printing session and after creating a print settings object. You should call this function only if you create a custom dialog using the `AppendDITL` method. In Mac OS X, you should create a custom dialog by writing a printing dialog extension. If you use this function to extend a printing dialog in Mac OS X, you cannot use sheets.

PMSessionPrintDialogMain

Displays your application's custom Print dialog. (Deprecated in Mac OS X v10.4. Use a printing dialog extension instead.)

```
OSStatus PMSessionPrintDialogMain (
   PMPrintSession printSession,
   PMPrintSettings printSettings,
   PMPageFormat constPageFormat,
   Boolean *accepted,
   PMPrintDialogInitUPP myInitProc
);
```

Parameters

printSession

The current printing session.

printSettings

A print settings object.

constPageFormat

A page format object.

accepted

A pointer to your Boolean variable. On return, `true` if the user accepts the dialog or `false` if the user cancels the dialog.

myInitProc

A universal procedure pointer to your dialog initialization function. Your initialization function is defined by the callback `PMPrintDialogInitProcPtr`

Return Value

A result code. See Core Printing Result Codes.

Discussion

The function `PMSessionPrintDialogMain` is valid only between the creation and release of a printing session and after calling the function `PMSessionPrintDialogInit`. You should call this function only if you create a custom dialog using the `AppendDITL` method. In Mac OS X, you should create a custom dialog by writing a printing dialog extension. If you use this function to extend a printing dialog in Mac OS X, you cannot use sheets.

Your dialog initialization function is called before your custom Print dialog is displayed. Your initialization function can append items to the Print dialog, and should install an item proc using the `PMSetItemProc` (page 2096) function. You must pass the same page format and print settings objects to each of the functions `PMSessionPrintDialogMain` and `PMSessionPrintDialogInit` (page 2091).

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`PMApplicationDeprecated.h`

PMSessionUseSheets

Specifies that a printing dialog should be displayed as a sheet and specifies a function to call when the user dismisses the printing dialog.

```
OSStatus PMSessionUseSheets (
   PMPrintSession printSession,
   WindowRef documentWindow,
   PMSheetDoneUPP sheetDoneProc
);
```

Parameters

printSession

The printing session for which you want to display the dialog.

documentWindow

The window to which the sheet dialog should be attached.

sheetDoneProc

A universal procedure pointer to your sheet-done function. The printing system calls this function when the user dismisses the dialog. Your sheet-done function is defined by the callback type `PMSheetDoneProcPtr` (page 2103).

Return Value

A result code. See Core Printing Result Codes.

Discussion

You must call this function between the creation and release of a printing session. See the function `PMCreateSession`.

When a printing dialog is displayed as a sheet, calls to the functions `PMSessionPageSetupDialog` (page 2088) and `PMSessionPrintDialog` (page 2091) return control immediately to your application, with the value of the `accepted` parameter undefined. The printing dialog sheet continues to be displayed until the user dismisses the dialog, at which time the printing system calls your sheet-done function. The page format and print settings objects associated with the dialog should not be used or changed until the sheet-done function is called.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`PMApplication.h`

PMSetDialogAccepted

Indicates that the user confirmed a custom dialog. (Deprecated in Mac OS X v10.4. Use a printing dialog extension instead.)

```
OSStatus PMSetDialogAccepted (
   PMDialog pmDialog,
   Boolean process
);
```

Parameters

pmDialog

A `PMDialog` object representing your customized Page Setup or Print dialog.

process

Pass `true` if the user confirms the dialog. In the case of the Page Setup dialog, this means the user clicked the OK button; in the case of the Print dialog, this means the user clicked the Print button. Pass `false` if the user clicks the Cancel button.

Return Value
A result code. See Core Printing Result Codes.

Discussion
The function `PMSetDialogAccepted` is valid between the creation and release of a printing session and while displaying your custom Page Setup or Print dialog.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`PMApplicationDeprecated.h`

PMSetDialogDone

Indicates that the user finished with a custom dialog. (Deprecated in Mac OS X v10.4. Use a printing dialog extension instead.)

```
OSStatus PMSetDialogDone (
   PMDialog pmDialog,
   Boolean done
);
```

Parameters

pmDialog

A `PMDialog` object representing your custom Page Setup or Print dialog.

done

Pass `true` when your callback function has finished with this dialog.

Return Value
A result code. See Core Printing Result Codes.

Discussion
The function `PMSetDialogDone` is valid between the creation and release of a printing session and while displaying your custom Page Setup or Print dialog.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`PMApplicationDeprecated.h`

PMSetItemProc

Installs an item proc callback function for items in a custom dialog. (Deprecated in Mac OS X v10.4. Use a printing dialog extension instead.)

```
OSStatus PMSetItemProc (
   PMDialog pmDialog,
   PMItemUPP itemProc
);
```

Parameters

pmDialog

A `PMDialog` object representing your custom Page Setup or Print dialog.

itemProc

A universal procedure pointer to your dialog item event handling function.

Return Value

A result code. See Core Printing Result Codes.

Discussion

The function `PMSetItemProc` is valid between the creation and release of a printing session and after creating your custom Page Setup or Print dialog.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`PMApplicationDeprecated.h`

PMSetModalFilterProc

Installs an event handling callback function for a modal dialog. (Deprecated in Mac OS X v10.4. Use a printing dialog extension instead.)

```
OSStatus PMSetModalFilterProc (
   PMDialog pmDialog,
   ModalFilterUPP filterProc
);
```

Parameters

pmDialog

A `PMDialog` object representing the Page Setup or Print dialog for which you want to install an event handling function.

filterProc

A universal procedure pointer to the event handling function you want called while the Page Setup or Print dialog is displayed. In Mac OS X this function is not called.

Return Value

A result code. See Core Printing Result Codes.

Discussion
The function `PMSetModalFilterProc` is valid between the creation and release of a printing session. You must install your filter procedure before calling `PMSessionPageSetupDialogMain` or `PMSessionPrintDialogMain`.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`PMApplicationDeprecated.h`

PMShowPageSetupDialogAsSheet

Displays a Page Setup dialog as a sheet attached to a window.

```
OSStatus PMShowPageSetupDialogAsSheet (
    PMPrintSession printSession,
    PMPageFormat pageFormat,
    WindowRef documentWindow,
    PMSheetDoneUPP sheetDoneProc
);
```

Parameters

printSession
The printing session for which you want to display the dialog.

pageFormat
The initial page format settings.

documentWindow
The window to which the Page Setup dialog sheet should be attached.

sheetDoneProc
A pointer to a sheet-done callback function that you provide. Your function is called when the user dismisses the dialog. See `PMSheetDoneProcPtr` (page 2103) for information about how to implement this callback.

Return Value
A result code. See Core Printing Result Codes.

Discussion
This function is asynchronous; it displays the dialog in a sheet and returns immediately. When the user dismisses the dialog, the printing system calls the function specified in the *sheetDoneProc* parameter, passing it a Boolean value that indicates whether the user pressed the OK button.

Special Considerations

In Mac OS X v10.5 and later, you should use this function if you want to display the Page Setup dialog as a document-modal sheet. This function replaces the older method of calling `PMSessionUseSheets` (page 2093) and `PMSessionPageSetupDialog` (page 2088).

Availability
Available in Mac OS X v10.5 and later.
Not available to 64-bit applications.

Declared In
PMApplication.h

PMShowPrintDialogWithOptions

Displays a Print dialog with a specified set of controls.

```
OSStatus PMShowPrintDialogWithOptions (
    PMPrintSession printSession,
    PMPrintSettings printSettings,
    PMPageFormat pageFormat,
    PMPrintDialogOptionFlags printDialogOptions,
    Boolean *accepted
);
```

Parameters

printSession
The printing session for which you want to display the dialog.

printSettings
The initial print settings for the Print dialog.

pageFormat
The initial page format settings for the Print dialog.

printDialogOptions
Flags that specify what controls are displayed in the expanded version of the Print dialog. See "Print Dialog Options" (page 2106) for a description of the flags you can use to specify the dialog options.

accepted
A pointer to a Boolean value. On return, `true` if the user accepts the dialog or `false` if the user cancels the dialog.

Return Value
A result code. See Core Printing Result Codes.

Discussion
In Mac OS X v10.5 and later, you can use this function to display the Print dialog with an optional set of controls in the expanded version of the dialog. When the Print dialog is first displayed, the user sees a simplified dialog with a disclosure button. If the button is pressed, the dialog expands and includes the controls specified in the *printDialogOptions* parameter. This function only allows you to specify controls for which flags are defined. The expanded dialog may also contain other controls that are not optional.

When you call this function, you should be prepared for the possibility that the page format settings may change. The expanded Print dialog could allow the user to modify page format settings explicitly. Even if the dialog is displayed with the default set of options, there may be other controls in the Print dialog that cause the page format settings to change.

This function is synchronous; it doesn't return until the user dismisses the dialog.

Availability
Available in Mac OS X v10.5 and later.
Not available to 64-bit applications.

Declared In
PMApplication.h

PMShowPrintDialogWithOptionsAsSheet

Displays a Print dialog with a specified set of controls as a sheet attached to a window.

```
OSStatus PMShowPrintDialogWithOptionsAsSheet (
    PMPrintSession printSession,
    PMPrintSettings printSettings,
    PMPageFormat pageFormat,
    PMPrintDialogOptionFlags printDialogOptions,
    WindowRef documentWindow,
    PMSheetDoneUPP sheetDoneProc
);
```

Parameters

printSession
The printing session for which you want to display the dialog.

printSettings
The initial print settings for the Print dialog.

pageFormat
The initial page format settings for the Print dialog.

printDialogOptions
Flags that specify what controls are displayed in the expanded version of the Print dialog. See "Print Dialog Options" (page 2106) for a description of the flags you can use to specify dialog options.

documentWindow
The window to which the Print dialog sheet should be attached.

sheetDoneProc
A pointer to a sheet-done callback function that you provide. Your function is called when the user dismisses the dialog. See `PMSheetDoneProcPtr` (page 2103) for information about how to implement this callback.

Return Value

A result code. See Core Printing Result Codes.

Discussion

In Mac OS X v10.5 and later, you can use this function to display the Print dialog with an optional set of controls in the expanded version of the dialog. When the Print dialog is first displayed, the user sees a simplified dialog with a disclosure button. If the button is pressed, the dialog expands and includes the controls specified in the *printDialogOptions* parameter. This function only allows you to specify controls for which flags are defined. The expanded dialog may also contain other controls that are not optional.

When you call this function, you should be prepared for the possibility that the page format settings may change. The expanded Print dialog could allow the user to modify page format settings explicitly. Even if the dialog is displayed with the default set of options, there may be other controls in the Print dialog that cause the page format settings to change.

This function is asynchronous; it displays the dialog in a sheet and returns immediately. When the user dismisses the dialog, the printing system calls the function specified in the *sheetDoneProc* parameter, passing it a Boolean value that indicates whether the user accepted or canceled the dialog.

Special Considerations

In Mac OS X v10.5 and later, you should use this function if you want to display the Print dialog as a document-modal sheet. This function replaces the older method of calling `PMSessionUseSheets` (page 2093) and `PMSessionPrintDialog` (page 2091).

Availability
Available in Mac OS X v10.5 and later.
Not available to 64-bit applications.

Declared In
`PMApplication.h`

Callbacks by Task

Sheet Dialog Callback

`PMSheetDoneProcPtr` (page 2103)
Defines a pointer to a sheet-done function. The function is called when the user dismisses a printing dialog presented as a sheet.

Legacy Callbacks

`PMPageSetupDialogInitProcPtr` (page 2101)
Defines a pointer to a dialog initialization function for your custom Page Setup dialog. (Deprecated. Use a printing dialog extension instead.)

`PMPrintDialogInitProcPtr` (page 2102)
Defines a pointer to a dialog initialization function for your custom Print dialog. (Deprecated. Use a printing dialog extension instead.)

`PMItemProcPtr` (page 2100)
Defines a pointer to a dialog item proc function that handles items you add to your custom Page Setup or Print dialog. (Deprecated. Use a printing dialog extension instead.)

Callbacks

PMItemProcPtr

Defines a pointer to a dialog item proc function that handles items you add to your custom Page Setup or Print dialog. (**Deprecated.** Use a printing dialog extension instead.)

```
typedef void (*PMItemProcPtr) (
    DialogRef theDialog,
    SInt16 item
);
```

You would declare your event handling function like this if you were to name it `MyPMItemCallback`:

```
void MyPMItemCallback (
    DialogRef theDialog,
    SInt16 item
);
```

Parameters

theDialog

A reference to your customized Page Setup or Print dialog (`PMDialog`). You can use the function `PMGetDialogPtr` to get a dialog reference.

item

The number of the dialog item.

Discussion

You should provide an item proc callback function if you add items to a custom dialog you create using the `AppendDITL` method. In Mac OS X, you should create a custom dialog by writing a printing dialog extension.

Your function is called by the printing system after you create a custom Page Setup or Print dialog and register your dialog item proc function by calling the function `PMSetItemProc`. In Mac OS X, your function is called for items you add to your custom Page Setup or Print dialog. Your item proc function should call the function `PMSessionSetError` if the user cancels, otherwise the printing system won't know about the user cancellation.

To provide a pointer to your item proc function, you create a universal procedure pointer (UPP) of type `PMItemUPP`, using the function `NewPMItemUPP`. You can do so with code similar to the following:

```
PMItemUPP MyPMItemCallbackUPP;
MyPMItemCallbackUPP = NewPMPItemUPP (&MyPMItemCallback);
```

After you are finished with your item proc function, you can dispose of the UPP with the function `DisposePMItemUPP`. However, if you will use the same event handling function for subsequent displays of a printing dialog, you can reuse the same UPP, rather than dispose of it and later create a new UPP.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`PMApplicationDeprecated.h`

PMPageSetupDialogInitProcPtr

Defines a pointer to a dialog initialization function for your custom Page Setup dialog. (**Deprecated.** Use a printing dialog extension instead.)

```
typedef void (*PMPageSetupDialogInitProcPtr) (
    PMPageFormat pageFormat,
    PMDialog *theDialog
);
```

You would declare your dialog initialization function like this if you were to name it `MyPageSetupDialogInitCallback`:

```
void MyPageSetupDialogInitCallback (
    PMPageFormat pageFormat,
    PMDialog *theDialog
);
```

Parameters

pageFormat

A `PMPageFormat` object.

theDialog

A pointer to the `PMDialog` object representing your custom Page Setup dialog. You obtain this object from the function `PMSessionPageSetupDialogInit`. Your application should store a pointer to the dialog object in a global variable or as extended data in the `PMPageFormat` object, where it is accessible by your initialization function.

Discussion

You should set up a dialog initialization callback only if you need to use a custom dialog you create using the `AppendDITL` method. In Mac OS X, you should create a custom dialog by writing a printing dialog extension. Your initialization function can append items to the Page Setup dialog. If you use this function to extend a printing dialog in Mac OS X, you cannot use sheets.

You pass a pointer to your dialog initialization function as a parameter to the function `PMSessionPageSetupDialogMain`. Your dialog initialization function is called before your custom Page Setup dialog is displayed. Your initialization function can append items to the Page Setup dialog, and should install an item proc using the function `PMSetitemProc`.

To provide a pointer to your dialog initialization function, you create a universal procedure pointer (UPP) of type `PMPageSetupDialogInitUPP`, using the function `NewPMPageSetupDialogInitUPP`. You can do so with code similar to the following:

```
PMPageSetupDialogInitUPP MyPageSetupDialogInitCallbackUPP;
MyPageSetupDialogInitCallbackUPP =      NewPMPageSetupDialogInitUPP
(MyPageSetupDialogInitCallback);
```

After you are finished with your dialog initialization function, you can dispose of the UPP with the function `DisposePMPageSetupDialogInitUPP`. However, if you plan to use the same dialog initialization function for subsequent display of the Page Setup dialog, you can reuse the same UPP, rather than dispose of it and later create a new UPP.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`PMApplicationDeprecated.h`

PMPrintDialogInitProcPtr

Defines a pointer to a dialog initialization function for your custom Print dialog. (**Deprecated.** Use a printing dialog extension instead.)

```
typedef void (*PMPrintDialogInitProcPtr) (
    PMPrintSettings printSettings,
    PMDialog *theDialog
);
```

You would declare your dialog initialization function like this if you were to name it `MyPrintDialogInitCallback`:

```
void MyPrintDialogInitCallback (
```

```
    PMPrintSettings printSettings,
    PMDialog *theDialog
);
```

Parameters

printSettings

A `PMPrintSettings` object.

theDialog

A pointer to the `PMDialog` object representing your custom Print dialog. You obtain this object from the function `PMSessionPrintDialogInit`. Your application should store a pointer to the dialog object in a global variable or as extended data in the `PMPrintSettings` object, where it is accessible by your initialization function.

Discussion

You should set up a dialog initialization callback if you need to use a custom dialog you create using the `AppendDITL` method. In Mac OS X, you should create a custom dialog by writing a printing dialog extension. Your initialization function can append items to the Print dialog. If you use this function to extend a printing dialog in Mac OS X, you cannot use sheets.

You pass a pointer to your dialog initialization function as a parameter to the function `PMSessionPrintDialogMain`. Your dialog initialization function is called before your custom Print dialog is displayed. Your initialization function can append items to the Print dialog, and should install an item proc using the function `PMSetitemProc`.

To provide a pointer to your dialog initialization function, you create a universal procedure pointer (UPP) of type `PMPrintDialogInitUPP`, using the function `NewPMPrintDialogInitUPP`. You can do so with code similar to the following:

```
PMPrintDialogInitUPP MyPrintDialogInitCallbackUPP;
MyPrintDialogInitCallbackUPP = NewPMPrintDialogInitUPP
(&MyPrintDialogInitCallback);
```

After you are finished with your dialog initialization function, you can dispose of the UPP with the function `DisposePMPrintDialogInitUPP`. However, if you will use the same dialog initialization function for subsequent displays of the Print dialog, you can reuse the same UPP, rather than dispose of it and later create a new UPP.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`PMApplicationDeprecated.h`

PMSheetDoneProcPtr

Defines a pointer to a sheet-done function. The function is called when the user dismisses a printing dialog presented as a sheet.

```
typedef void (*PMSheetDoneProcPtr) (
    PMPrintSession printSession,
    WindowRef documentWindow,
    Boolean accepted
);
```

You would declare your sheet-done function like this if you were to name it `MyPrintSheetDoneCallback`:

```
void MyPrintSheetDoneCallback (
    PMPrintSession printSession,
    WindowRef documentWindow,
    Boolean accepted
);
```

Parameters

printSession

The printing session object for the dialog.

documentWindow

The document window to which the sheet is attached.

accepted

A `Boolean` value indicating whether the user accepted (`true`) or canceled (`false`) the dialog.

Discussion

You pass a universal procedure pointer to your sheet-done callback function as a parameter to the functions `PMSessionUseSheets` (page 2093), `PMShowPrintDialogWithOptionsAsSheet` (page 2099), and `PMShowPageSetupDialogAsSheet` (page 2097). Your sheet-done function is called when the user dismisses the dialog. If the user accepted the dialog, your function should take appropriate action depending on whether the Page Setup or Print dialog is being shown.

To provide a pointer to your sheet-done function, you create a universal procedure pointer (UPP) of type `PMSheetDoneUPP`, using the function `NewPMSheetDoneUPP`. You can do so with code similar to the following:

```
PMSheetDoneUPP gMyPrintSheetDoneUPP;
gMyPrintSheetDoneUPP = NewPMSheetDoneUPP (&MyPrintSheetDoneProc);
```

You should declare your universal procedure pointer as a global variable to allow for multiple windows, each with a dialog available at one time.

When your print job is completed, you should use the function `DisposePMSheetDoneUPP` function to dispose of the universal procedure pointer associated with your sheet-done function. However, if you plan to use the same sheet-done function in subsequent print jobs, you can reuse the same UPP, rather than dispose of it and later create a new UPP.

The sheet-done function does not have a parameter for application-supplied data. Instead, you can attach any data your application needs to the window as a property using the Window Manager function `SetWindowProperty` and retrieve the data using the function `GetWindowProperty`.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`PMApplication.h`

Data Types

PMItemUPP

A type that defines a universal procedure pointer to an item proc callback.

```
typedef PMItemProcPtr PMItemUPP;
```

Discussion
This data type is used by functions that are deprecated. For more information, see the description of the `PMItemProcPtr` (page 2100) callback function.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`PMApplicationDeprecated.h`

PMPageSetupDialogInitUPP

A type that defines a universal procedure pointer to a Page Setup dialog initialization callback.

```
typedef PMPageSetupDialogInitProcPtr PMPageSetupDialogInitUPP;
```

Discussion
This data type is used by functions that are deprecated. For more information, see the description of the `PMPageSetupDialogInitProcPtr` (page 2101) callback function.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`PMApplicationDeprecated.h`

PMPrintDialogInitUPP

A type that defines a universal procedure pointer to a Print dialog initialization callback.

```
typedef PMPrintDialogInitProcPtr PMPrintDialogInitUPP;
```

Discussion
This data type is used by functions that are deprecated. For more information, see the description of the `PMPrintDialogInitProcPtr` (page 2102) callback function.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
PMApplicationDeprecated.h

PMSheetDoneUPP

A type that defines a universal procedure pointer to a sheet-done callback function.

```
typedef PMSheetDoneProcPtr PMSheetDoneUPP;
```

Discussion
For more information, see the description of the PMSheetDoneProcPtr (page 2103) callback function.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
PMApplication.h

Constants

Print Dialog Options

Flags that specify items to show in the expanded Print dialog in Mac OS X v10.5 and later.

```
typedef OptionBits PMPrintDialogOptionFlags;
enum {
    kPMHideInlineItems = (0L << 0),
    kPMShowDefaultInlineItems = (1L << 15),
    kPMShowInlineCopies = (1L << 0),
    kPMShowInlinePageRange = (1L << 1),
    kPMShowInlinePageRangeWithSelection = (1L << 6),
    kPMShowInlinePaperSize = (1L << 2),
    kPMShowInlineOrientation = (1L << 3),
    kPMShowInlineScale = (1L << 7),
    kPMShowPageAttributesPDE = (1L << 8),
};
```

Constants

kPMHideInlineItems
Show nothing in the inline portion of the Print dialog.
Available in Mac OS X v10.5 and later.
Not available to 64-bit applications.
Declared in PMApplication.h.

kPMShowDefaultInlineItems
Show the default set of items (copies & page range) in the inline portion of the Print dialog.
Available in Mac OS X v10.5 and later.
Not available to 64-bit applications.
Declared in PMApplication.h.

`kPMShowInlineCopies`
: Show the copies edit-text field, the collated check box, and the two-sided check box (if the printer supports it) in the top portion of the Print dialog.

  Available in Mac OS X v10.5 and later.

  Not available to 64-bit applications.

  Declared in `PMApplication.h`.

`kPMShowInlinePageRange`
: Show the page range radio buttons and the from & to page edit-text fields in the top portion of the Print dialog.

  Available in Mac OS X v10.5 and later.

  Not available to 64-bit applications.

  Declared in `PMApplication.h`.

`kPMShowInlinePageRangeWithSelection`
: Show the page range radio buttons with the addition of a selection button and the From & To Page edit-text fields in the top portion of the Print dialog.

  Available in Mac OS X v10.5 and later.

  Not available to 64-bit applications.

  Declared in `PMApplication.h`.

`kPMShowInlinePaperSize`
: Show the formatting paper size popup menu in the top portion of the Print dialog.

  Available in Mac OS X v10.5 and later.

  Not available to 64-bit applications.

  Declared in `PMApplication.h`.

`kPMShowInlineOrientation`
: Show the page orientation buttons in the top portion of the Print dialog.

  Available in Mac OS X v10.5 and later.

  Not available to 64-bit applications.

  Declared in `PMApplication.h`.

`kPMShowInlineScale`
: Show the scale edit-text field in the top portion of the Print dialog.

  Available in Mac OS X v10.5 and later.

  Not available to 64-bit applications.

  Declared in `PMApplication.h`.

`kPMShowPageAttributesPDE`
: Add a separate pane to the Print dialog that contains the Page Setup dialog information (paper size, orientation, and scale).

  Available in Mac OS X v10.5 and later.

  Not available to 64-bit applications.

  Declared in `PMApplication.h`.

Declared In
`PMApplication.h`

Data Browser Reference

Framework:	Carbon/Carbon.h
Declared in	Controls.h ControlDefinitions.h

Overview

The data browser application programming interface (API) provides a convenient way to present data for browsing and to create easily customized lists whose columns can be sorted, moved, and resized. It supports two presentation styles, each of which is derived from an abstract table-view base class:

- **List view**, which lets you present items in multiple columns with the option to create hierarchical lists whose contents can be disclosed by the user
- **Column view**, which provides in-place browsing using fixed navigation columns

The data browser programming interface has some routines that apply to both views while others are unique to one view. For functions that can be called for either, there may be differences in how the functions operate. Such differences are noted in the documentation for individual functions.

These terms are essential to understanding the reference:

- An **item** in a data browser refers to the data displayed at a particular row and column intersection. In list view, two values identify each item—an item ID and a property ID. In column view, one value—the item ID—uniquely identifies an item.
- An **item ID** is a unique 32-bit ID number that your application uses to refer to data. When you ask the data browser to display one or more items, you provide an item ID for each data item. You can store the actual data in memory, on disk, or across a network. Item IDs must be greater than `0`, which is used internally by the data browser. Item IDs can be values such as pointer values, data file offsets, and 32-bit TCP/IP host addresses.
- A **Property ID** is a non-zero, 32-bit unsigned integer value that uniquely identifies a list view column. Property IDs do not need to be ordered or sequential, but they cannot be values 0 through 1023 because those values are reserved by Apple. A property ID is typically defined as a four-character sequence. For example, a column that displays dates could be assigned the property ID `DATE`.

  Columns in column view don't use application-defined property IDs. Instead, columns in column view have the predefined property `kDataBrowserItemSelfIdentityProperty`.

After you've created, formatted, and configured a data browser, most of the work of keeping the data browser updated and responsive to user interaction happens through callbacks you provide. For example, all of the functions that get and set item data are called from within an item-data callback provided by your application. Your application has a wide latitude in what it can choose to handle through callbacks and the tasks it lets

the system perform. At the very least, your application must provide an item-data callback. Otherwise no data will ever be written to the data browser user interface. Depending on the nature of your application, you may also want to provide callbacks to handle drag-and-drop behavior, to support contextual menus, and to perform custom drawing or some other custom behavior.

The data browser is available with CarbonLib 1.1 and later and in Mac OS X.

For conceptual information and instructions on how to write code that uses a data browser to display data, see *Data Browser Programming Guide*.

Functions by Task

Creating and Configuring a Data Browser

`CreateDataBrowserControl` (page 2125)
Creates a data browser programmatically.

`SetDataBrowserViewStyle` (page 2230)
Sets the view style of the specified data browser.

`GetDataBrowserViewStyle` (page 2174)
Obtains the current view style for the specified data browser.

Manipulating Data Browser Attributes

`GetDataBrowserUserState` (page 2173)
Obtains the current view style settings for a list view.

`SetDataBrowserUserState` (page 2230)
Restores the view-style settings in list view to a previous state set by the user.

`SetDataBrowserActiveItems` (page 2199)
Sets what determines the active state of the items in a data browser.

`GetDataBrowserActiveItems` (page 2139)
Obtains what determines the active state of the items in a data browser.

`SetDataBrowserScrollBarInset` (page 2220)
Sets the inset values to use for the scroll bars of a data browser.

`GetDataBrowserScrollBarInset` (page 2162)
Obtains the inset rectangle used by a data browser to position the scroll bar.

`SetDataBrowserTarget` (page 2229)
Sets the target for a data browser.

`GetDataBrowserTarget` (page 2172)
Obtains the target for the data browser

`SetDataBrowserSortOrder` (page 2223)
Sets the sorting order for a list in list view.

`GetDataBrowserSortOrder` (page 2164)
Gets the sorting order of the list view column that's currently set for sorting.

SetDataBrowserScrollPosition (page 2221)
Scrolls a list to the specified position.

GetDataBrowserScrollPosition (page 2162)
Obtains the scrolling position of a list.

SetDataBrowserHasScrollBars (page 2206)
Sets the display state of horizontal and vertical scroll bars for a list view data browser.

GetDataBrowserHasScrollBars (page 2144)
Obtains the display state of horizontal and vertical scroll bars for a list view data browser.

SetDataBrowserSortProperty (page 2223)
Designates the list view column to use for sorting.

GetDataBrowserSortProperty (page 2165)
Obtains the property ID of the column currently used for sorting in list view.

SetDataBrowserSelectionFlags (page 2222)
Sets allowable selection behavior for a data browser.

GetDataBrowserSelectionFlags (page 2164)
Obtains the current selection behavior for a data browser.

SetDataBrowserPropertyFlags (page 2219)
Sets the appearance and behavior attributes for a column in list view.

GetDataBrowserPropertyFlags (page 2161)
Obtains the appearance and behavior attributes for a column.

SetDataBrowserEditText (page 2205)
Modifies the displayed contents of a text item while it is being edited.

CopyDataBrowserEditText (page 2125)
Copies the text being edited by the user.

GetDataBrowserEditText (page 2143)
Obtains the text being edited by the user.

SetDataBrowserEditItem (page 2204)
Programmatically starts or ends an editing session.

GetDataBrowserEditItem (page 2143)
Obtains the item ID and property ID values of the current editing session.

GetDataBrowserItemPartBounds (page 2156)
Obtains the bounds of a visual part of an item.

Setting Up and Installing Callbacks

InitDataBrowserCallbacks (page 2175)
Initializes a data browser callback structure in preparation for adding your own callbacks to the structure.

SetDataBrowserCallbacks (page 2200)
Sets the callback routines to use with a data browser, replacing any previously installed callbacks.

GetDataBrowserCallbacks (page 2140)
Obtains the callback routines installed for notifying your application of changes to a data browser and for providing the data to be displayed by the data browser.

`InitDataBrowserCustomCallbacks` (page 2176)
Initializes the data browser custom callback structure in preparation for adding your own callbacks for custom drawing or custom behavior to the structure.

`SetDataBrowserCustomCallbacks` (page 2203)
Sets the custom callback routines to use with a data browser, replacing any previously installed custom callbacks.

`GetDataBrowserCustomCallbacks` (page 2142)
Obtains the callbacks installed to implement custom drawing and behavior for the content in a data browser.

Formatting Table View

Table view is a base class from which list and column views are derived. Some functions in this group can be used with both list and column views, while others are useful only in list view.

`RemoveDataBrowserTableViewColumn` (page 2198)
Removes a column from a list view data browser.

`GetDataBrowserTableViewColumnCount` (page 2166)
Obtains the number of columns in a data browser.

`SetDataBrowserTableViewHiliteStyle` (page 2226)
Sets the highlighting style to use for a list view data browser.

`GetDataBrowserTableViewHiliteStyle` (page 2169)
Obtains the highlighting style used for a list view data browser.

`SetDataBrowserTableViewRowHeight` (page 2228)
Sets the default row height for all rows in a data browser.

`GetDataBrowserTableViewRowHeight` (page 2172)
Obtains the default row height used for all rows in a data browser.

`SetDataBrowserTableViewColumnWidth` (page 2225)
Sets the default column width for all columns in a data browser.

`GetDataBrowserTableViewColumnWidth` (page 2167)
Obtains the default column width used for all columns in a data browser.

`SetDataBrowserTableViewItemRowHeight` (page 2227)
Sets the row height for a single row in a list view data browser.

`GetDataBrowserTableViewItemRowHeight` (page 2170)
Obtains the row height for a single row in a list view data browser.

`SetDataBrowserTableViewNamedColumnWidth` (page 2228)
Sets the column width for a single column in a list view data browser.

`GetDataBrowserTableViewNamedColumnWidth` (page 2171)
Obtains the column width for a single column in a data browser.

`SetDataBrowserTableViewGeometry` (page 2225)
Sets whether columns and rows can have variable widths in list view.

`GetDataBrowserTableViewGeometry` (page 2168)
Determines whether columns and rows are set to have variable widths.

`GetDataBrowserTableViewItemID` (page 2169)
Obtains the item ID for the item displayed in the specified row.

`SetDataBrowserTableViewItemRow` (page 2226)
Changes the visual position for an item in a list view data browser.

`GetDataBrowserTableViewItemRow` (page 2170)
Obtains the visual position for the specified item in list view.

`SetDataBrowserTableViewColumnPosition` (page 2224)
Changes the visual position of a column in list view.

`GetDataBrowserTableViewColumnPosition` (page 2166)
Obtains the column position for an item in a data browser.

`GetDataBrowserTableViewColumnProperty` (page 2167)
Obtains the property ID for a column in a data browser.

Formatting List View

`AutoSizeDataBrowserListViewColumns` (page 2122)
Adjusts the size of columns displayed in list view to take best advantage of the available space.

`AddDataBrowserListViewColumn` (page 2121)
Adds a column to a data browser that uses list view.

`GetDataBrowserListViewHeaderDesc` (page 2160)
Obtains a header description for a column in list view.

`SetDataBrowserListViewHeaderDesc` (page 2218)
Provides a description for a column title in list view.

`SetDataBrowserListViewHeaderBtnHeight` (page 2217)
Sets the height of the rectangular area where the column title appears.

`GetDataBrowserListViewHeaderBtnHeight` (page 2159)
Obtains the height of the rectangular area where the column title appears.

`SetDataBrowserListViewUsePlainBackground` (page 2219)
Specifies whether list view uses a plain white background.

`GetDataBrowserListViewUsePlainBackground` (page 2160)
Determines whether list view is set to use a plain white background.

`SetDataBrowserListViewDisclosureColumn` (page 2216)
Specifies whether there is a column that has disclosure triangles and, if so, which column.

`GetDataBrowserListViewDisclosureColumn` (page 2158)
Obtains the property ID of the column whose items can display a disclosure triangle, and tells whether a disclosed item expands the row or adds rows.

Formatting Column View

`SetDataBrowserColumnViewPath` (page 2202)
Sets a path for a column view.

`GetDataBrowserColumnViewPath` (page 2141)
Obtains the current path for a selection in column view.

`GetDataBrowserColumnViewPathLength` (page 2142)
Obtains the length of the current path for a column view.

`SetDataBrowserColumnViewDisplayType` (page 2202)
Sets the display type for a data browser in column view.

`GetDataBrowserColumnViewDisplayType` (page 2140)
Obtains the display type for a column view.

Adding and Removing Data Items

`AddDataBrowserItems` (page 2120)
Adds one or more items to a data browser.

`RemoveDataBrowserItems` (page 2197)
Removes one or more items from a data browser.

`UpdateDataBrowserItems` (page 2232)
Requests a redraw of one or more items in a data browser.

Accessing and Operating on All Items

`GetDataBrowserItems` (page 2157)
Obtains a list of the items that match a specified state; operates on items in the root container or traverses items in the data hierarchy.

`GetDataBrowserItemCount` (page 2145)
Obtains the number of items whose state matches the specified state.

`ForEachDataBrowserItem` (page 2138)
Applies an item-iterator callback routine to each data item that meets the specified criteria.

Accessing and Displaying Individual Items

`IsDataBrowserItemSelected` (page 2186)
Checks to see if a data item is selected.

`GetDataBrowserItemState` (page 2158)
Obtains the state of an item.

`RevealDataBrowserItem` (page 2199)
Scrolls an item into view, optionally bringing a particular part of that item into view.

Selecting and Editing Items

`EnableDataBrowserEditCommand` (page 2137)
Determines whether the data browser is currently able to process a given editing command.

`ExecuteDataBrowserEditCommand` (page 2138)
Executes an editing command.

`GetDataBrowserSelectionAnchor` (page 2163)
Obtains the first and last items in a selection.

`MoveDataBrowserSelectionAnchor` (page 2186)
Moves or extends the current selection.

`SetDataBrowserSelectedItems` (page 2222)
Modifies the current selection by adding items, removing items, or toggling the selection state of items.

Working With Attributes

`DataBrowserGetAttributes` (page 2127)
Gets the attributes of a data browser.

`DataBrowserChangeAttributes` (page 2127)
Sets the attributes for a data browser.

Working With Containers

`OpenDataBrowserContainer` (page 2196)
Opens a data browser container.

`CloseDataBrowserContainer` (page 2124)
Closes a data browser container.

`SortDataBrowserContainer` (page 2231)
Sorts a hierarchical list of items.

Working With Metrics

`DataBrowserGetMetric` (page 2128)
Gets the value of a specified data browser metric.

`DataBrowserSetMetric` (page 2129)
Sets the value of a specified data browser metric.

Getting and Setting Item Data

The functions in this section are called from within an item-data callback routine (`DataBrowserItemDataProcPtr`) provided by your application. The data browser invokes your item-data callback each time your application needs to provide data for the display. Your callback responds by calling the appropriate function from this section.

`SetDataBrowserItemDataIcon` (page 2209)
Specifies the icon to draw.

`GetDataBrowserItemDataIcon` (page 2148)
Obtains the icon drawn for an item.

`SetDataBrowserItemDataText` (page 2214)
Specifies the text to draw.

`GetDataBrowserItemDataText` (page 2154)
Obtains the text entered by the user.

`SetDataBrowserItemDataValue` (page 2215)
Sets the value of an item; useful for such display types as sliders, progress bars, relevance indicators, and pop-up menus.

`GetDataBrowserItemDataValue` (page 2155)
Obtains the value of an item; useful for such display types as sliders, progress bars, relevance indicators, and pop-up menus.

`SetDataBrowserItemDataMinimum` (page 2213)
Specifies the minimum integer value that can be displayed for an item; useful for such display types as sliders, progress bars, relevance indicators, and pop-up menus.

`GetDataBrowserItemDataMinimum` (page 2152)
Obtains the minimum integer value that can be displayed for an item; useful for such display types as sliders, progress bars, relevance indicators, and pop-up menus.

`SetDataBrowserItemDataMaximum` (page 2212)
Specifies the maximum integer value that can be displayed for an item; useful for such display types as sliders, progress bars, relevance indicators, and pop-up menus.

`GetDataBrowserItemDataMaximum` (page 2151)
Obtains the maximum integer value that can be displayed; useful for such display types as sliders, progress bars, relevance indicators, and pop-up menus.

`SetDataBrowserItemDataBooleanValue` (page 2206)
Specifies a Boolean value for an item.

`GetDataBrowserItemDataBooleanValue` (page 2145)
Obtains the Boolean value for an item.

`SetDataBrowserItemDataMenuRef` (page 2213)
Sets the pop-up menu to display.

`GetDataBrowserItemDataMenuRef` (page 2152)
Obtains the pop-up menu displayed.

`SetDataBrowserItemDataRGBColor` (page 2214)
Specifies a color to use when drawing an item.

`GetDataBrowserItemDataRGBColor` (page 2154)
Obtains the color used to draw an item.

`SetDataBrowserItemDataDrawState` (page 2208)
Specifies whether to draw a checkbox in the active or inactive state.

`GetDataBrowserItemDataDrawState` (page 2148)
Determines whether a checkbox is in the active or inactive state.

`SetDataBrowserItemDataButtonValue` (page 2207)
Specifies a checkbox value.

`GetDataBrowserItemDataButtonValue` (page 2146)
Obtains the value for a checkbox.

`SetDataBrowserItemDataIconTransform` (page 2210)
Specifies a transformation to apply to an icon when it is drawn.

`GetDataBrowserItemDataIconTransform` (page 2149)
Obtains the transformation currently used to display an icon.

`SetDataBrowserItemDataDateTime` (page 2208)
Specifies, as a 32-bit value, a date and time value to display.

`GetDataBrowserItemDataDateTime` (page 2147)
Obtains, as a 32-bit value, the date and time value displayed.

`SetDataBrowserItemDataLongDateTime` (page 2211)
Specifies, as a 64-bit value, a date and time value to display.

`GetDataBrowserItemDataLongDateTime` (page 2150)
Obtains, as a 64-bit value, the date and time value displayed.

`SetDataBrowserItemDataItemID` (page 2210)
Communicates a property of an item when that property is another item's ID.

`GetDataBrowserItemDataItemID` (page 2150)
Obtains the item ID for an item whose property is another item's ID.

`GetDataBrowserItemDataProperty` (page 2153)
Obtains the column property ID for the column in which an item resides.

Working With Universal Procedure Pointers

The functions in this section create and dispose of universal procedure pointers (UPPs) to the callbacks you provide to the data browser. For each callback, there is a New, Dispose, and Invoke function. You don't need to use an Invoke function, because the data browser invokes callbacks for you.

The documentation for the UPP functions in this section is boilerplate text—quite repetitive and you can likely skip over it. The more interesting documentation is for the callbacks themselves, which you can find in the section "Data Browser Callbacks" (page 2233).

`NewDataBrowserItemUPP` (page 2194)
Creates a universal procedure pointer to an item-iterator callback function.

`InvokeDataBrowserItemUPP` (page 2183)
Calls an item-iterator callback function.

`DisposeDataBrowserItemUPP` (page 2135)
Disposes of a universal procedure pointer to an item-iterator callback function.

`NewDataBrowserItemDataUPP` (page 2191)
Creates a universal procedure pointer to an item-data callback function.

`InvokeDataBrowserItemDataUPP` (page 2180)
Calls an item-data callback function.

`DisposeDataBrowserItemDataUPP` (page 2133)
Disposes of a universal procedure pointer to an item-data callback function.

`NewDataBrowserItemCompareUPP` (page 2190)
Creates a universal procedure pointer to an item-comparison callback function.

`InvokeDataBrowserItemCompareUPP` (page 2180)
Calls an item-comparison callback function.

`DisposeDataBrowserItemCompareUPP` (page 2132)
Disposes of a universal procedure pointer to an item-comparison callback function.

`NewDataBrowserItemNotificationUPP` (page 2192)
Creates a universal procedure pointer to an item-notification callback function.

`InvokeDataBrowserItemNotificationUPP` (page 2182)
Calls an item-notification callback function.

DisposeDataBrowserItemNotificationUPP (page 2134)
Disposes of a universal procedure pointer to an item-notification callback function.

NewDataBrowserItemNotificationWithItemUPP (page 2193)
Creates a universal procedure pointer to an item-notification-with-data callback function.

InvokeDataBrowserItemNotificationWithItemUPP (page 2182)
Calls an item-notification-with-data callback function.

DisposeDataBrowserItemNotificationWithItemUPP (page 2134)
Disposes of a universal procedure pointer to an item-notification-with-data callback function.

NewDataBrowserAddDragItemUPP (page 2188)
Creates a universal procedure pointer to an add-drag-item callback function.

InvokeDataBrowserAddDragItemUPP (page 2177)
Calls an add-drag-item callback function.

DisposeDataBrowserAddDragItemUPP (page 2130)
Disposes of a universal procedure pointer to an add-drag-item callback function.

NewDataBrowserAcceptDragUPP (page 2187)
Creates a universal procedure pointer to an accept-drag callback function.

InvokeDataBrowserAcceptDragUPP (page 2177)
Calls an accept-drag callback function.

DisposeDataBrowserAcceptDragUPP (page 2129)
Disposes of a universal procedure pointer to an accept-drag callback function.

NewDataBrowserReceiveDragUPP (page 2195)
Creates a universal procedure pointer to a receive-drag callback function.

InvokeDataBrowserReceiveDragUPP (page 2184)
Calls a receive-drag callback function.

DisposeDataBrowserReceiveDragUPP (page 2136)
Disposes of a universal procedure pointer to a receive-drag callback function.

NewDataBrowserPostProcessDragUPP (page 2194)
Creates a universal procedure pointer to a postprocess-drag callback function.

InvokeDataBrowserPostProcessDragUPP (page 2184)
Calls a postprocess-drag callback function.

DisposeDataBrowserPostProcessDragUPP (page 2135)
Disposes of a universal procedure pointer to a postprocess-drag callback function.

NewDataBrowserGetContextualMenuUPP (page 2189)
Creates a universal procedure pointer to a get-contextual-menu callback function.

InvokeDataBrowserGetContextualMenuUPP (page 2178)
Calls a get-contextual-menu callback function.

DisposeDataBrowserGetContextualMenuUPP (page 2131)
Disposes of a universal procedure pointer to a get-contextual-menu callback function.

NewDataBrowserSelectContextualMenuUPP (page 2195)
Creates a universal procedure pointer to a select-contextual-menu callback function.

InvokeDataBrowserSelectContextualMenuUPP (page 2185)
Calls a select-contextual-menu callback function.

DisposeDataBrowserSelectContextualMenuUPP (page 2136)
Disposes of a universal procedure pointer to a select-contextual-menu callback function.

NewDataBrowserItemHelpContentUPP (page 2192)
Creates a universal procedure pointer to an item-help-content callback function.

InvokeDataBrowserItemHelpContentUPP (page 2181)
Calls an item-help-content callback function.

DisposeDataBrowserItemHelpContentUPP (page 2133)
Disposes of a universal procedure pointer to an item-help-content callback function.

NewDataBrowserDrawItemUPP (page 2188)
Creates a universal procedure pointer to a draw-item callback function.

InvokeDataBrowserDrawItemUPP (page 2177)
Calls a draw-item callback function.

DisposeDataBrowserDrawItemUPP (page 2130)
Disposes of a universal procedure pointer to a draw-item callback function.

NewDataBrowserEditItemUPP (page 2188)
Creates a universal procedure pointer to an edit-item callback function.

InvokeDataBrowserEditItemUPP (page 2178)
Calls an edit-item callback function.

DisposeDataBrowserEditItemUPP (page 2131)
Disposes of a universal procedure pointer to an edit-item callback function.

NewDataBrowserHitTestUPP (page 2189)
Creates a universal procedure pointer to a hit-test callback function.

InvokeDataBrowserHitTestUPP (page 2179)
Calls a hit-test callback function.

DisposeDataBrowserHitTestUPP (page 2131)
Disposes of a universal procedure pointer to a hit-test callback function.

NewDataBrowserTrackingUPP (page 2196)
Creates a universal procedure pointer to a tracking callback function.

InvokeDataBrowserTrackingUPP (page 2185)
Calls a tracking callback function.

DisposeDataBrowserTrackingUPP (page 2137)
Disposes of a universal procedure pointer to a tracking callback function.

NewDataBrowserItemDragRgnUPP (page 2191)
Creates a universal procedure pointer to an item-drag-region callback function.

InvokeDataBrowserItemDragRgnUPP (page 2181)
Calls an item-drag-region callback function.

DisposeDataBrowserItemDragRgnUPP (page 2133)
Disposes of a universal procedure pointer to an item-drag-region callback function.

NewDataBrowserItemAcceptDragUPP (page 2190)
Creates a universal procedure pointer to an item-accept-drag callback function.

InvokeDataBrowserItemAcceptDragUPP (page 2179)
Calls an item-accept-drag callback function.

DisposeDataBrowserItemAcceptDragUPP (page 2132)
Disposes of a universal procedure pointer to an item-accept-drag callback function.

NewDataBrowserItemReceiveDragUPP (page 2193)
Creates a universal procedure pointer to an item-receive-drag callback function.

`InvokeDataBrowserItemReceiveDragUPP` (page 2183)
Calls an item-receive-drag callback function.

`DisposeDataBrowserItemReceiveDragUPP` (page 2135)
Disposes of a universal procedure pointer to an item-receive-drag callback function.

Working With AXUIElement References

`AXUIElementCreateWithDataBrowserAndItemInfo` (page 2123)
Creates an `AXUIElementRef` that represents some part of a data browser accessibility hierarchy.

`AXUIElementGetDataBrowserItemInfo` (page 2123)
Obtains a description of the part of a data browser represented by an `AXUIElementRef`.

Functions

AddDataBrowserItems

Adds one or more items to a data browser.

```
OSStatus AddDataBrowserItems (
   ControlRef browser,
   DataBrowserItemID container,
   ItemCount numItems,
   const DataBrowserItemID *items,
   DataBrowserPropertyID preSortProperty
);
```

Parameters

browser
A data browser.

container
An item ID or the constant `kDataBrowserNoItem`. Pass the item ID that uniquely identifies the container to which you want to add items. Adding one or more items to an existing container opens the container. If you a pass `kDataBrowserNoItem`, the items are added to the root container.

numItems
The number of items in the array pointed to by the `items` parameter.

items
A pointer to an array of item ID values for the items you want to add to the data browser. You supply item ID values based on your own identification scheme. If you pass `NULL`, each time you call `AddDataBrowserItems` the data browser generates item ID values starting at `1`. Calling the function in this way clears whatever items are in the container. Because of this clearing behavior, passing `NULL` is not recommended unless your application uses a data browser to display a simple list that is populated only once with data.

preSortProperty
The property ID of the column whose sorting order matches the sorting order of the `items` array. A property ID is a four-character sequence that you assign to represent a column in list view. Pass `kDataBrowserItemNoProperty` if the `items` array is not sorted or if you don't know the sorting order of your data. You'll get the best performance from this function if you provide a sorting order.

Return Value
A result code. If the item ID specified by the `container` parameter is not classified as a container, returns `errDataBrowserItemNotAdded` if you attempt to add subitems to it. See "Data Browser Result Codes" (page 2298).

Discussion
Hierarchical lists are constructed in a top-down fashion. Your application must install all the top-level, or parent, item IDs in the data browser before it associates a list of item ID values as subitems. You can add items to a parent item only after the parent item is classified as a container. A container is an item for which the property `kDataBrowserItemIsContainerProperty` is set to `true`.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

AddDataBrowserListViewColumn

Adds a column to a data browser that uses list view.

```
OSStatus AddDataBrowserListViewColumn (
   ControlRef browser,
   DataBrowserListViewColumnDesc *columnDesc,
   DataBrowserTableViewColumnIndex position
);
```

Parameters

`browser`
A data browser.

`columnDesc`
A pointer to the list view column description data structure that you have filled out with data that specifies the column property and display information for the column heading.

`position`
The position, among the columns already installed in the data browser, to insert this column. To insert this column to the right of all other columns, pass `kDataBrowserListViewAppendColumn`. The value `0` means the leftmost column.

Return Value
A result code; `paramErr` is returned if the `columnDesc` parameter is not properly initialized. See "Data Browser Result Codes" (page 2298).

Discussion
Typically you use the function `AddDataBrowserListViewColumn` in these cases:

- When you create a data browser programmatically. If you use Interface Builder to design and lay out the data browser, you do not need to call the function `AddDataBrowserListViewColumn`. Interface Builder lets you position a column graphically and then specify the column description in the column pane of the Info window.

- When you switch from column view to list view. Regardless of how you first create a data browser, if your application allows the user to switch between views, you need to add list view columns each time the view switches from column to list view.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

AutoSizeDataBrowserListViewColumns

Adjusts the size of columns displayed in list view to take best advantage of the available space.

```
OSStatus AutoSizeDataBrowserListViewColumns (
   ControlRef browser
);
```

Parameters

browser
A data browser.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
When you call the function `AutoSizeDataBrowserListViewColumns`, it first calculates whether there is extra space or not enough space in the data browser. Then, the columns are resized using the following rules:

- If there is extra space, the data browser gives as much of the extra space as possible to the first column (that is, the leftmost column) without exceeding the maximum width for the column. If there is still space available, the data browser gives as much of the remaining space as possible to the second column without exceeding the maximum width for the column. The data browser continues to disburse space in this manner until there is no more extra space. Thus, it is possible for the first column to get all the extra space.
- If space is needed to fit all the columns, the data browser takes as much of the needed space as possible from the rightmost column (that is, the last column) without letting the column width fall below the minimum width for the column. If more space is needed, the data browser takes as much of the needed space as possible from the next-to-the-last column without letting the column width fall below the minimum width for the column. The data browser continues to adjust space in this manner until all the columns fit within the data browser.

The function `AutoSizeDataBrowserListViewColumns` resizes only if the horizontal scroll bar is turned off. Your application can call the function `SetDataBrowserHasScrollBars` (page 2206) to turn off the horizontal scroll bar.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
HIDataBrowser.h

AXUIElementCreateWithDataBrowserAndItemInfo

Creates an AXUIElementRef that represents some part of a data browser accessibility hierarchy.

```
AXUIElementRef AXUIElementCreateWithDataBrowserAndItemInfo (
   ControlRef inDataBrowser,
   const DataBrowserAccessibilityItemInfo *inInfo
);
```

Parameters

inDataBrowser
A data browser.

inInfo
A DataBrowserAccessibilityItemInfo (page 2260) structure describing the part of the data browser for which you want to create an AXUIElementRef.

Return Value
An AXUIElementRef representing the part, or NULL if an AXUIElementRef cannot be created to represent the part you specified.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
HIDataBrowser.h

AXUIElementGetDataBrowserItemInfo

Obtains a description of the part of a data browser represented by an AXUIElementRef.

```
OSStatus AXUIElementGetDataBrowserItemInfo (
   AXUIElementRef inElement,
   ControlRef inDataBrowser,
   UInt32 inDesiredInfoVersion,
   DataBrowserAccessibilityItemInfo *outInfo
);
```

Parameters

inElement
An AXUIElementRef representing part of a data browser.

inDataBrowser
A data browser.

inDesiredInfoVersion
The version of DataBrowserAccessibilityItemInfo (page 2260) structure you want to get. Currently, the only supported version is zero, so you must pass 0 or 1 as the value of this parameter.

outInfo

On input, a pointer to a `DataBrowserAccessibilityItemInfo` (page 2260) structure. On return, the structure is filled in with a description of the part of the data browser that the `AXUIElementRef` specified by `inElement` represents.

Return Value
A result code. See "Data Browser Result Codes" (page 2298). The function returns `noErr` if it was able to generate a description of the `AXUIElementRef`. If the `AXUIElementRef` does not represent the data browser you passed in, the function returns `paramErr`. If the `AXUIElementRef` represents some non-item part of the data browser, the function returns `errDataBrowserItemNotFound`.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

CloseDataBrowserContainer

Closes a data browser container.

```
OSStatus CloseDataBrowserContainer (
   ControlRef browser,
   DataBrowserItemID container
);
```

Parameters

browser

A data browser.

container

The item ID of the container you want to close.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
Normally the user navigates through a data hierarchy by clicking the disclosure triangle next to a container item in list view, or the container item (such as a folder icon) in column view. In either of these cases, the system automatically opens or closes the container. Under some circumstances your application may need to open or close a container programmatically, such as when you are restoring a display to its last known state. In such cases, you can call the function `OpenDataBrowserContainer` (page 2196) to disclose items in a container or the function `CloseDataBrowserContainer` to hide items in a container.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

CopyDataBrowserEditText

Copies the text being edited by the user.

```
OSStatus CopyDataBrowserEditText (
   ControlRef browser,
   CFStringRef *text
);
```

Parameters

browser

A data browser.

text

On input, a `CFStringRef` variable initialized to anything other than `NULL`. See the Special Considerations for details. On return, a CFString object that contains a copy of the text edited by the user. You are responsible for releasing the string when you no longer need it.

Return Value

A result code. See "Data Browser Result Codes" (page 2298).

Discussion

This function is useful only if an edit session is in progress for an item. You can check whether an edit session is open by calling the function `GetDataBrowserEditItem` (page 2143).

Special Considerations

For versions of Mac OS X prior to v10.4, the `text` parameter must be set to any value other than `NULL`. Do not allocate the CFStringRef, otherwise your application will leak memory. Instead provide code similar to the following to initialize the variable:

```
CFStringRef myText = 0XFFFFFFFF;
```

Availability

Available in CarbonLib 1.5 and later.

Available in Mac OS X version 10.0 and later.

Not available to 64-bit applications.

Declared In

`HIDataBrowser.h`

CreateDataBrowserControl

Creates a data browser programmatically.

```
OSStatus CreateDataBrowserControl (
   WindowRef window,
   const Rect *boundsRect,
   DataBrowserViewStyle style,
   ControlRef *outControl
);
```

Parameters

window

The window in which to place the data browser.

boundsRect

A pointer to a rectangle that specifies the location where you want the control to appear in the window.

style

The view style to use. Pass the constant `kDataBrowserListView` to draw the data browser using list view or `kDataBrowserColumnView` draw the data browser using column view. See "View Styles" (page 2298) for more information on these constants.

outControl

On input, a pointer to a control reference. On return, this is set to the newly created data browser. When you no longer need the data browser, call the Control Manager function `DisposeControl` to release it. When you dispose of the control, deallocate any universal procedure pointers you allocated for use with the control.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
This function creates a data browser programmatically. If you create a data browser using Interface Builder, you don't need to call `CreateDataBrowserControl`. Instead, you call the function `GetControlByID` to obtain a control reference that points to your data browser.

After you create a data browser by calling `CreateDataBrowserControl`, you can set such attributes as sorting order, scroll bars, and scroll position. See "Manipulating Data Browser Attributes" (page 2110) for the functions you can use to set data browser attributes.

You need to set up the display characteristics of the data browser by calling the appropriate functions. See "Formatting Table View" (page 2112), "Formatting List View" (page 2113), and "Formatting Column View" (page 2113) for information on the formatting functions you can call.

You need to call the functions `InitDataBrowserCallbacks` (page 2175) and `SetDataBrowserCallbacks` (page 2200) to install the callbacks needed for your data browser. At the very least, you must provide an item-data callback to add or change data items; you must do so regardless of the content your data browser displays—noncustom or custom. Otherwise, your data browser will be empty. See `DataBrowserItemDataProcPtr` (page 2245) for more information. If you present hierarchical data in list view, or use column view for browsing data, you must provide a callback to handle item notifications. See `DataBrowserItemNotificationProcPtr` (page 2250) and `DataBrowserItemNotificationWithItemProcPtr` (page 2251).

You can optionally provide callbacks to:

- Perform sorting. See `DataBrowserItemCompareProcPtr` (page 2243).
- Handle drag-and-drop behavior. See `DataBrowserAddDragItemProcPtr` (page 2234), `DataBrowserAcceptDragProcPtr` (page 2233), `DataBrowserReceiveDragProcPtr` (page 2256), and `DataBrowserPostProcessDragProcPtr` (page 2255).
- Provide contextual menus. See `DataBrowserGetContextualMenuProcPtr` (page 2238) and `DataBrowserSelectContextualMenuProcPtr` (page 2257).
- Display help tags. See `DataBrowserItemHelpContentProcPtr` (page 2248).

If your data browser uses a list whose columns require custom drawing or behavior, you must also provide callbacks to handle the custom tasks. See `InitDataBrowserCustomCallbacks` (page 2176) and `SetDataBrowserCustomCallbacks` (page 2203) for more information on initializing and installing callbacks for custom behavior. The custom tasks you can handle in list view include:

- Drawing custom content. See `DataBrowserDrawItemProcPtr` (page 2235).
- Supporting editing of custom content. See `DataBrowserEditItemProcPtr` (page 2237). Note that editing is built-in for noncustom content.
- Performing hit-testing and tracking. See `DataBrowserHitTestProcPtr` (page 2240) and `DataBrowserTrackingProcPtr` (page 2259).
- Handling drag-and-drop behavior. See `DataBrowserItemDragRgnProcPtr` (page 2246), `DataBrowserItemAcceptDragProcPtr` (page 2242), and `DataBrowserItemReceiveDragProcPtr` (page 2254).

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

DataBrowserChangeAttributes

Sets the attributes for a data browser.

```
OSStatus DataBrowserChangeAttributes (
   ControlRef inDataBrowser,
   OptionBits inAttributesToSet,
   OptionBits inAttributesToClear
);
```

Parameters

inDataBrowser
A data browser.

inAttributesToSet
The attributes to set. For possible values, see "Data Browser Attributes" (page 2273).

inAttributesToClear
The attributes to clear. For possible values, see "Data Browser Attributes" (page 2273).

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

DataBrowserGetAttributes

Gets the attributes of a data browser.

```
OSStatus DataBrowserGetAttributes (
   ControlRef inDataBrowser,
   OptionBits *outAttributes
);
```

Parameters

inDataBrowser

A data browser.

outAttributes

The attributes to get. This parameter cannot be `NULL`. For possible values, see "Data Browser Attributes" (page 2273).

Return Value

A result code. See "Data Browser Result Codes" (page 2298).

Availability

Available in Mac OS X v10.4 and later.

Not available to 64-bit applications.

Declared In

`HIDataBrowser.h`

DataBrowserGetMetric

Gets the value of a specified data browser metric.

```
OSStatus DataBrowserGetMetric (
   ControlRef inDataBrowser,
   DataBrowserMetric inMetric,
   Boolean *outUsingDefaultValue,
   CGFloat *outValue
);
```

Parameters

inDataBrowser

A data browser.

inMetric

The data browser metric value to get. For possible values, see"Data Browser Metric Values" (page 2274).

outUsingDefaultValue

On return, a Boolean whose value indicates whether the metric's value is determined by the data browser's default values. Pass `NULL` if you don't want this information.

outValue

On return, the value of the metric.

Return Value

A result code. See "Data Browser Result Codes" (page 2298). If the `inDataBrowser` is not an instance of a data browser or if the value specified by `inMetric` is not known, `DataBrowserGetMetric` returns `paramErr`.

Availability

Available in Mac OS X v10.4 and later.

Not available to 64-bit applications.

Declared In
HIDataBrowser.h

DataBrowserSetMetric

Sets the value of a specified data browser metric.

```
OSStatus DataBrowserSetMetric (
   ControlRef inDataBrowser,
   DataBrowserMetric inMetric,
   Boolean inUseDefaultValue,
   CGFloat inValue
);
```

Parameters

inDataBrowser
A data browser.

inMetric
The data browser metric whose value is to be set. For possible values, see "Data Browser Metric Values" (page 2274).

inUsingDefaultValue
A Boolean whose value indicates whether you want the data browser to revert to the default value for the metric. If you pass `true`, `inValue` is ignored and a suitable default value is used. If you pass `false`, `inValue` is set as the value of the metric.

inValue
The value to set for the metric (if the value of `inUsingDefaultValue` is `false`).

Return Value
A result code. See "Data Browser Result Codes" (page 2298). If the `inDataBrowser` is not an instance of a data browser or if the value specified by `inMetric` is not known, `DataBrowserSetMetric` returns `paramErr`.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
HIDataBrowser.h

DisposeDataBrowserAcceptDragUPP

Disposes of a universal procedure pointer to an accept-drag callback function.

```
void DisposeDataBrowserAcceptDragUPP (
   DataBrowserAcceptDragUPP userUPP
);
```

Parameters

userUPP
The universal procedure pointer to dispose of.

Discussion
See the `DataBrowserAcceptDragProcPtr` (page 2233) callback function.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.

Declared In
HIDataBrowser.h

DisposeDataBrowserAddDragItemUPP

Disposes of a universal procedure pointer to an add-drag-item callback function.

```
void DisposeDataBrowserAddDragItemUPP (
   DataBrowserAddDragItemUPP userUPP
);
```

Parameters

userUPP
The universal procedure pointer to dispose of.

Discussion
See the DataBrowserAddDragItemProcPtr (page 2234) callback function.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.

Declared In
HIDataBrowser.h

DisposeDataBrowserDrawItemUPP

Disposes of a universal procedure pointer to a draw-item callback function.

```
void DisposeDataBrowserDrawItemUPP (
   DataBrowserDrawItemUPP userUPP
);
```

Parameters

userUPP
The universal procedure pointer to dispose of.

Discussion
See the DataBrowserDrawItemProcPtr (page 2235) callback function.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.1 and later.

Declared In
HIDataBrowser.h

DisposeDataBrowserEditItemUPP

Disposes of a universal procedure pointer to an edit-item callback function.

```
void DisposeDataBrowserEditItemUPP (
   DataBrowserEditItemUPP userUPP
);
```

Parameters

userUPP

The universal procedure pointer to dispose of.

Discussion

See the `DataBrowserEditItemProcPtr` (page 2237) callback function.

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.1 and later.

Declared In

`HIDataBrowser.h`

DisposeDataBrowserGetContextualMenuUPP

Disposes of a universal procedure pointer to a get-contextual-menu callback function.

```
void DisposeDataBrowserGetContextualMenuUPP (
   DataBrowserGetContextualMenuUPP userUPP
);
```

Parameters

userUPP

The universal procedure pointer to dispose of.

Discussion

See the `DataBrowserGetContextualMenuProcPtr` (page 2238) callback function.

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.0 and later.

Declared In

`HIDataBrowser.h`

DisposeDataBrowserHitTestUPP

Disposes of a universal procedure pointer to a hit-test callback function.

```
void DisposeDataBrowserHitTestUPP (
   DataBrowserHitTestUPP userUPP
);
```

Parameters

userUPP

The universal procedure pointer to dispose of.

Discussion
See the `DataBrowserHitTestProcPtr` (page 2240) callback function.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.1 and later.

Declared In
`HIDataBrowser.h`

DisposeDataBrowserItemAcceptDragUPP

Disposes of a universal procedure pointer to an item-accept-drag callback function.

```
void DisposeDataBrowserItemAcceptDragUPP (
   DataBrowserItemAcceptDragUPP userUPP
);
```

Parameters
userUPP
The universal procedure pointer to dispose of.

Discussion
See the `DataBrowserItemAcceptDragProcPtr` (page 2242) callback function.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.1 and later.

Declared In
`HIDataBrowser.h`

DisposeDataBrowserItemCompareUPP

Disposes of a universal procedure pointer to an item-comparison callback function.

```
void DisposeDataBrowserItemCompareUPP (
   DataBrowserItemCompareUPP userUPP
);
```

Parameters
userUPP
The universal procedure pointer to dispose of.

Discussion
See the `DataBrowserItemCompareProcPtr` (page 2243) callback function.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.

Declared In
`HIDataBrowser.h`

DisposeDataBrowserItemDataUPP

Disposes of a universal procedure pointer to an item-data callback function.

```
void DisposeDataBrowserItemDataUPP (
   DataBrowserItemDataUPP userUPP
);
```

Parameters

userUPP

The universal procedure pointer to dispose of.

Discussion

See the `DataBrowserItemDataProcPtr` (page 2245) callback function.

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.0 and later.

Declared In

`HIDataBrowser.h`

DisposeDataBrowserItemDragRgnUPP

Disposes of a universal procedure pointer to an item-drag-region callback function.

```
void DisposeDataBrowserItemDragRgnUPP (
   DataBrowserItemDragRgnUPP userUPP
);
```

Parameters

userUPP

The universal procedure pointer to dispose of.

Discussion

See the `DataBrowserItemDragRgnProcPtr` (page 2246) callback function.

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.1 and later.

Declared In

`HIDataBrowser.h`

DisposeDataBrowserItemHelpContentUPP

Disposes of a universal procedure pointer to an item-help-content callback function.

```
void DisposeDataBrowserItemHelpContentUPP (
   DataBrowserItemHelpContentUPP userUPP
);
```

Parameters

userUPP

The universal procedure pointer to dispose of.

Discussion
See the `DataBrowserItemHelpContentProcPtr` (page 2248) callback function.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.

Declared In
`HIDataBrowser.h`

DisposeDataBrowserItemNotificationUPP

Disposes of a universal procedure pointer to an item-notification callback function.

```
void DisposeDataBrowserItemNotificationUPP (
   DataBrowserItemNotificationUPP userUPP
);
```

Parameters
userUPP
The universal procedure pointer to dispose of.

Discussion
See the `DataBrowserItemNotificationProcPtr` (page 2250) callback function.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.

Declared In
`HIDataBrowser.h`

DisposeDataBrowserItemNotificationWithItemUPP

Disposes of a universal procedure pointer to an item-notification-with-data callback function.

```
void DisposeDataBrowserItemNotificationWithItemUPP (
   DataBrowserItemNotificationWithItemUPP userUPP
);
```

Parameters
userUPP
The universal procedure pointer to dispose of.

Discussion
See the `DataBrowserItemNotificationWithItemProcPtr` (page 2251) callback function.

Availability
Available in CarbonLib 1.5 and later.
Available in Mac OS X version 10.1 and later.

Declared In
`HIDataBrowser.h`

DisposeDataBrowserItemReceiveDragUPP

Disposes of a universal procedure pointer to an item-receive-drag callback function.

```
void DisposeDataBrowserItemReceiveDragUPP (
   DataBrowserItemReceiveDragUPP userUPP
);
```

Parameters

userUPP

The universal procedure pointer to dispose of.

Discussion

See the `DataBrowserItemReceiveDragProcPtr` (page 2254) callback function.

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.1 and later.

Declared In

`HIDataBrowser.h`

DisposeDataBrowserItemUPP

Disposes of a universal procedure pointer to an item-iterator callback function.

```
void DisposeDataBrowserItemUPP (
   DataBrowserItemUPP userUPP
);
```

Parameters

userUPP

The universal procedure pointer to dispose of.

Discussion

See the `DataBrowserItemProcPtr` (page 2253) callback function.

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.0 and later.

Declared In

`HIDataBrowser.h`

DisposeDataBrowserPostProcessDragUPP

Disposes of a universal procedure pointer to a postprocess-drag callback function.

```
void DisposeDataBrowserPostProcessDragUPP (
   DataBrowserPostProcessDragUPP userUPP
);
```

Parameters

userUPP

The universal procedure pointer to dispose of.

Discussion
See the `DataBrowserPostProcessDragProcPtr` (page 2255) callback function.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.

Declared In
`HIDataBrowser.h`

DisposeDataBrowserReceiveDragUPP

Disposes of a universal procedure pointer to a receive-drag callback function.

```
void DisposeDataBrowserReceiveDragUPP (
   DataBrowserReceiveDragUPP userUPP
);
```

Parameters
userUPP
The universal procedure pointer to dispose of.

Discussion
See the `DataBrowserReceiveDragProcPtr` (page 2256) callback function.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.

Declared In
`HIDataBrowser.h`

DisposeDataBrowserSelectContextualMenuUPP

Disposes of a universal procedure pointer to a select-contextual-menu callback function.

```
void DisposeDataBrowserSelectContextualMenuUPP (
   DataBrowserSelectContextualMenuUPP userUPP
);
```

Parameters
userUPP
The universal procedure pointer to dispose of.

Discussion
See the `DataBrowserSelectContextualMenuProcPtr` (page 2257) callback function.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.

Declared In
`HIDataBrowser.h`

DisposeDataBrowserTrackingUPP

Disposes of a universal procedure pointer to a tracking callback function.

```
void DisposeDataBrowserTrackingUPP (
   DataBrowserTrackingUPP userUPP
);
```

Parameters

userUPP

The universal procedure pointer to dispose of.

Discussion

See the `DataBrowserTrackingProcPtr` (page 2259) callback function.

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.1 and later.

Declared In

`HIDataBrowser.h`

EnableDataBrowserEditCommand

Determines whether the data browser is currently able to process a given editing command.

```
Boolean EnableDataBrowserEditCommand (
   ControlRef browser,
   DataBrowserEditCommand command
);
```

Parameters

browser

A data browser.

command

The editing command you want to enable. You can pass any of the constants described in "Editing Commands" (page 2277).

Return Value

A value of `true` if the requested editing command can be performed by the data browser at this time.

Discussion

Editing commands (Cut, Paste, Copy, and so on) can be enabled for an editable text field that is open and selected and for which the data browser is currently able to process the given command. For example, the data browser can process a Paste command only if there is text available on the Clipboard.

Editing commands are also available for a custom display type when the callbacks you install for the custom display indicate editing is available. Your application can call the function `EnableDataBrowserEditCommand` to discover if a specific editing command can be enabled. To execute an editing command, call the function `ExecuteDataBrowserEditCommand` (page 2138).

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.0 and later.

Not available to 64-bit applications.

Declared In
HIDataBrowser.h

ExecuteDataBrowserEditCommand

Executes an editing command.

```
OSStatus ExecuteDataBrowserEditCommand (
   ControlRef browser,
   DataBrowserEditCommand command
);
```

Parameters

browser
A data browser.

command
The editing command you want to execute. You can pass any of the constants described in "Editing Commands" (page 2277).

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
Editing commands can be executed for an editable text field that is open and selected. Your application can check to see if the editing command is enabled by first calling the function `EnableDataBrowserEditCommand` (page 2137).

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
HIDataBrowser.h

ForEachDataBrowserItem

Applies an item-iterator callback routine to each data item that meets the specified criteria.

```
OSStatus ForEachDataBrowserItem (
   ControlRef browser,
   DataBrowserItemID container,
   Boolean recurse,
   DataBrowserItemState state,
   DataBrowserItemUPP callback,
   void *clientData
);
```

Parameters

browser
A data browser.

container
An item ID or the constant `kDataBrowserNoItem`. To iterate through items that are organized as subitems of a container item, pass the item ID for the container. To iterate through all items displayed at the root of the data browser, pass the constant `kDataBrowserNoItem`.

recurse
A value that indicates whether or not to traverse the entire item hierarchy when applying the callback specified by the `callback` parameter. Pass `true` to apply the callback to all items in the hierarchy. Pass `false` if you want to apply the callback only to those items at the top level of the container or data browser.

state
A value that specifies the state of the items to which to apply the callback. Pass `0` if you want to apply the callback to all items, regardless of state. Otherwise, pass one of the constants described in "Item States" (page 2280).

callback
A universal procedure pointer to your item-iterator callback routine. This routine is called for every item ID that matches the specified criteria. See `DataBrowserItemProcPtr` (page 2253) for more information on the callback routine to supply.

clientData
A pointer to a buffer, local variable, or other storage location created and disposed of by your application and needed by your callback routine.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
The function `ForEachDataBrowserItem` is useful for enumerating and performing an operation on a set of item IDs.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

GetDataBrowserActiveItems

Obtains what determines the active state of the items in a data browser.

```
OSStatus GetDataBrowserActiveItems (
   ControlRef browser,
   Boolean *active
);
```

Parameters

browser
A data browser.

active

On input, a pointer to a Boolean variable. On return, the variable is set to `true` if the active state of each item in the list is determined by the item property `kDataBrowserItemIsActiveProperty`. Otherwise, the variable is set to `false` to indicate that all items are inactive.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

GetDataBrowserCallbacks

Obtains the callback routines installed for notifying your application of changes to a data browser and for providing the data to be displayed by the data browser.

```
OSStatus GetDataBrowserCallbacks (
   ControlRef browser,
   DataBrowserCallbacks *callbacks
);
```

Parameters

browser

The data browser whose callback routines you want to obtain.

callbacks

On input, a pointer to a `DataBrowserCallbacks` structure. On return, the structure contains universal procedure pointers to the callback routines installed for the data browser.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
When `GetDataBrowserCallacks` is used in conjunction with the function `SetDataBrowserCallbacks` (page 2200), your application can override or replace one or more callbacks used by a data browser to notify your application of changes.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

GetDataBrowserColumnViewDisplayType

Obtains the display type for a column view.

```
OSStatus GetDataBrowserColumnViewDisplayType (
   ControlRef browser,
   DataBrowserPropertyType *propertyType
);
```

Parameters

browser

A data browser.

propertyType

On input, a pointer to a display type variable. On return, the variable is set to the data type or control that is displayed in the data browser. No display types other than `kDataBrowserIconAndTextType` are currently supported in column view. See "Display Types" (page 2275) for more information.

Return Value

A result code. See "Data Browser Result Codes" (page 2298).

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.0 and later.

Not available to 64-bit applications.

Declared In

`HIDataBrowser.h`

GetDataBrowserColumnViewPath

Obtains the current path for a selection in column view.

```
OSStatus GetDataBrowserColumnViewPath (
   ControlRef browser,
   Handle path
);
```

Parameters

browser

A data browser.

path

On input, a handle. On return, the handle contains an array of item ID values that specify the current path. Array element `0` is the root; array element `N-1` is the target. You must allocate the handle before calling this function, and you are responsible for disposing of it.

Return Value

A result code. See "Data Browser Result Codes" (page 2298).

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.0 and later.

Not available to 64-bit applications.

Declared In

`HIDataBrowser.h`

GetDataBrowserColumnViewPathLength

Obtains the length of the current path for a column view.

```
OSStatus GetDataBrowserColumnViewPathLength (
   ControlRef browser,
   UInt32 *pathLength
);
```

Parameters

browser

A data browser.

pathLength

On input, a pointer to an unsigned 32-bit integer. On return, this value is set to the number of levels in the path for the currently selected item.

Return Value

A result code. See "Data Browser Result Codes" (page 2298).

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.0 and later.

Not available to 64-bit applications.

Declared In

`HIDataBrowser.h`

GetDataBrowserCustomCallbacks

Obtains the callbacks installed to implement custom drawing and behavior for the content in a data browser.

```
OSStatus GetDataBrowserCustomCallbacks (
   ControlRef browser,
   DataBrowserCustomCallbacks *callbacks
);
```

Parameters

browser

A data browser.

callbacks

On input, a pointer to a `DataBrowserCustomCallbacks` structure. On return, the structure contains universal procedure pointers to the custom callback routines installed for the data browser.

Return Value

A result code. See "Data Browser Result Codes" (page 2298).

Discussion

When `GetDataBrowserCustomCallbacks` is used in conjunction with the function `SetDataBrowserCustomCallbacks` (page 2203), your application can temporarily override or replace one or more callbacks used by a data browser to support custom drawing and custom behavior.

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.0 and later.

Not available to 64-bit applications.

Declared In
HIDataBrowser.h

GetDataBrowserEditItem

Obtains the item ID and property ID values of the current editing session.

```
OSStatus GetDataBrowserEditItem (
   ControlRef browser,
   DataBrowserItemID *item,
   DataBrowserPropertyID *property
);
```

Parameters

browser
A data browser.

item
On input, a pointer to an item ID variable. On return, the variable is set to the item ID of the item that is being edited. If there is no editing session in progress, this parameter is set to `kDataBrowserNoItem`.

property
On input, a pointer to a property ID variable. On return, the variable is set to the property ID of the item that is being edited. If there is no editing session in progress, this parameter is set to `0`.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
HIDataBrowser.h

GetDataBrowserEditText

Obtains the text being edited by the user.

Not Recommended

```
OSStatus GetDataBrowserEditText (
   ControlRef browser,
   CFMutableStringRef text
);
```

Parameters

browser
A data browser.

text

On return, the CFMutableString object is set to the text being edited by the user. Your application must allocate this object and pass it to the data browser. The data browser sets its contents to the current contents of the edit session text field. You must release this object when you no longer need it.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
This function does not work. Instead use `CopyDataBrowserEditText` (page 2125).

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

GetDataBrowserHasScrollBars

Obtains the display state of horizontal and vertical scroll bars for a list view data browser.

```
OSStatus GetDataBrowserHasScrollBars (
   ControlRef browser,
   Boolean *horiz,
   Boolean *vert
);
```

Parameters

browser

A list view data browser.

horiz

On input, a pointer to a Boolean variable. On return, the variable is set to `true` if the browser control has a horizontal scroll bar.

vert

On input, a pointer to a Boolean variable. On return, the variable is set to `true` if the browser control has a vertical scroll bar.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
The function `GetDataBrowserHasScrollBars` is useful for determining if the browser control currently has scroll bars. For example, you would call the function `AutoSizeDataBrowserListViewColumns` (page 2122) only after you have determined the data browser does not have a horizontal scroll bar.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
HIDataBrowser.h

GetDataBrowserItemCount

Obtains the number of items whose state matches the specified state.

```
OSStatus GetDataBrowserItemCount (
   ControlRef browser,
   DataBrowserItemID container,
   Boolean recurse,
   DataBrowserItemState state,
   ItemCount *numItems
);
```

Parameters

browser
A data browser.

container
An item ID or the constant `kDataBrowserNoItem`. To obtain the number of items that are organized as subitems of a container item, pass the item ID for the container. To obtain the number of items displayed at the root of the data browser, provide the constant `kDataBrowserNoItem`.

recurse
A value that indicates whether or not to traverse the entire item hierarchy when counting. Pass `true` to obtain a count for all items in the hierarchy. Pass `false` if you want to count only those items at the top level of the container or data browser.

state
A value that specifies the state of the items to obtain. Only items that have this state are counted. Pass `kDataBrowserItemAnyState` if you want to count all items regardless of state. Otherwise, pass one of the constants described in "Item States" (page 2280).

numItems
On input, a pointer to an unsigned 32-bit integer. On return, this value is set to the number of items in the container that have the specified state.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
HIDataBrowser.h

GetDataBrowserItemDataBooleanValue

Obtains the Boolean value for an item.

```
OSStatus GetDataBrowserItemDataBooleanValue (
   DataBrowserItemDataRef itemData,
   Boolean *theData
);
```

Parameters

itemData

The item data reference for the item whose Boolean value you want to obtain. The item data reference is passed to the callback routine from which you are calling the function `GetDataBrowserItemDataBooleanValue`.

theData

On input, a pointer to a Boolean variable. On return, the variable is set to the Boolean value.

Return Value

A result code. See "Data Browser Result Codes" (page 2298).

Discussion

You can obtain Boolean values for the following properties:

- `kDataBrowserItemIsActiveProperty`
- `kDataBrowserItemIsSelectableProperty`
- `kDataBrowserItemIsEditableProperty`
- `kDataBrowserItemIsContainerProperty`
- `kDataBrowserItemIsOpenableProperty`
- `kDataBrowserItemIsClosableProperty`
- `kDataBrowserItemIsSortableProperty`

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.0 and later.

Not available to 64-bit applications.

Declared In

`HIDataBrowser.h`

GetDataBrowserItemDataButtonValue

Obtains the value for a checkbox.

```
OSStatus GetDataBrowserItemDataButtonValue (
   DataBrowserItemDataRef itemData,
   ThemeButtonValue *theData
);
```

Parameters

itemData

The item data reference for the item whose checkbox setting you want to obtain. The item data reference is passed to the callback routine from which you are calling the function `GetDataBrowserItemDataButtonValue`.

theData

On input, a pointer to a theme button value variable. On return, the variable is set to the checkbox setting. The value can be one of the following theme button value constants defined by the Appearance Manager,:

- `kThemeButtonOff` indicates a checkbox that is not selected.
- `kThemeButtonOn` indicates a checkbox that is selected.
- `kThemeButtonMixed` draws a checkbox that in a mixed state, indicating that a setting is on for some items in a selection and off for others.

See *Appearance Manager Reference* for more information.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
Your item-data callback calls this function in response to a set-data request for items that have the display type `kDataBrowserCheckboxType`.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

GetDataBrowserItemDataDateTime

Obtains, as a 32-bit value, the date and time value displayed.

```
OSStatus GetDataBrowserItemDataDateTime (
   DataBrowserItemDataRef itemData,
   SInt32 *theData
);
```

Parameters

itemData

The item data reference for the item whose date and time value you want to obtain. The item data reference is passed to the callback routine from which you are calling the function `GetDataBrowserItemDataDateTime`.

theData

On input, a 32-bit value. On return, the value is set to the number of elapsed seconds since midnight, January 1, 1904. For more information about date and time encodings used in the Mac OS, see *Date, Time, and Measurement Utilities Reference* in Carbon Text & International Documentation.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
This function works only with items that have the property `kDataBrowserDateTimeType`. If the column has the property `kDataBrowserRelativeDateTime`, the date is displayed relative to the current time for the computer. For example, a time 24 hours prior to the current time is displayed as "Yesterday." Other examples of relative date and time values are "Today, 1:45 PM" and "Yesterday, 7:30 AM."

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

GetDataBrowserItemDataDrawState

Determines whether a checkbox is in the active or inactive state.

```
OSStatus GetDataBrowserItemDataDrawState (
   DataBrowserItemDataRef itemData,
   ThemeDrawState *theData
);
```

Parameters

itemData

The item data reference for the checkbox whose drawing state you want to obtain. This value is passed to the callback routine from which you are calling the function `GetDataBrowserItemDataDrawState`.

theData

On input, a pointer to a theme draw state variable. On return, the variable is set to the drawing state for the item, either `kThemeStateInactive` or `kThemeStateActive`. See *Appearance Manager Reference* for more information on these constants.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
Your item-data callback calls this function in response to a get-data request for items that have display type `kDataBrowserCheckboxType`.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

GetDataBrowserItemDataIcon

Obtains the icon drawn for an item.

```
OSStatus GetDataBrowserItemDataIcon (
   DataBrowserItemDataRef itemData,
   IconRef *theData
);
```

Parameters

itemData

The item data reference for the item whose icon you want to obtain. This value is passed to the callback routine from which you are calling the function `GetDataBrowserItemDataIcon`.

theData

On input, a pointer to an `IconRef` variable. On return, the variable is set to the icon that is displayed. You are responsible for disposing of the `IconRef`.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
You call the function `GetDataBrowserItemDataIcon` from within a `DataBrowserItemDataProcPtr` (page 2245) callback routine to obtain the icon drawn in a column that has the `kDataBrowserIconType` display type or the `kDataBrowserIconAndTextType` display type.

Availability
Available in CarbonLib 1.5 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

GetDataBrowserItemDataIconTransform

Obtains the transformation currently used to display an icon.

```
OSStatus GetDataBrowserItemDataIconTransform (
   DataBrowserItemDataRef itemData,
   IconTransformType *theData
);
```

Parameters

itemData

The item data reference for the item whose icon transformation you want to obtain. This value is passed to the callback routine from which you are calling the function `GetDataBrowserItemDataIconTransform`.

theData

On input, an icon transformation type variable. On return, the variable is set to an icon transformation type. This value can be any of the icon transformation constants defined by Icon Services and Utilities. See *Icon Services and Utilities Reference* for more information.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
This function works only with items that have either the property `kDataBrowserIconAndTextType` or `kDataBrowserIconType`.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

GetDataBrowserItemDataItemID

Obtains the item ID for an item whose property is another item's ID.

```
OSStatus GetDataBrowserItemDataItemID (
   DataBrowserItemDataRef itemData,
   DataBrowserItemID *theData
);
```

Parameters

itemData

The item data reference passed to your item-data callback.

theData

On input, a pointer to an item ID variable. On return, the variable is set to the item ID associated with the `itemData` parameter.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
Typically you do not need to call this function. This function is used for item properties `kDataBrowserParentContainerProperty` or `kDataBrowserContainerAliasIDProperty`.

Availability
Available in CarbonLib 1.5 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

GetDataBrowserItemDataLongDateTime

Obtains, as a 64-bit value, the date and time value displayed.

```
OSStatus GetDataBrowserItemDataLongDateTime (
   DataBrowserItemDataRef itemData,
   LongDateTime *theData
);
```

Parameters

itemData

The item data reference for the item whose long date and time value you want to obtain. The item data reference is passed to the callback routine from which you are calling the function `GetDataBrowserItemDataLongDateTime`.

theData

On input, a 64-bit value. On return, the value is set to the number of seconds elapsed since midnight, January 1, 1904. For more information about date and time encodings used in the Mac OS, see *Date, Time, and Measurement Utilities Reference* in Carbon Text & International Documentation.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
This function works only with items that have the property `kDataBrowserDateTimeType`. If the column has the property `kDataBrowserRelativeDateTime`, the date is displayed relative to the current time for the computer. For example, a time 24 hours prior to the current time is displayed as "Yesterday." Other examples of relative date and time values are "Today, 1:45 PM" and "Yesterday, 7:30 AM."

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

GetDataBrowserItemDataMaximum

Obtains the maximum integer value that can be displayed; useful for such display types as sliders, progress bars, relevance indicators, and pop-up menus.

```
OSStatus GetDataBrowserItemDataMaximum (
   DataBrowserItemDataRef itemData,
   SInt32 *theData
);
```

Parameters

itemData

The item data reference for the item whose maximum value you want to obtain. The item data reference is passed to the callback routine from which you are calling the function `GetDataBrowserItemDataMaximum`.

theData

On input, a pointer to a signed 32-bit integer. On return, this value is set to the maximum value that can be displayed for the item.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

GetDataBrowserItemDataMenuRef

Obtains the pop-up menu displayed.

```
OSStatus GetDataBrowserItemDataMenuRef (
   DataBrowserItemDataRef itemData,
   MenuRef *theData
);
```

Parameters

itemData

The item data reference for the item whose pop-up menu you want to obtain. The item data reference is passed to the callback routine from which you are calling the function `GetDataBrowserItemDataMenuRef`.

theData

On input, a pointer to a menu reference. On return, this is set to the currently displayed pop-up menu. The system retains the menu reference that you pass; you must release it when you no longer need it.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
Your item-data callback calls this function in response to a get-data request for items that have the display type `kDataBrowserPopupMenuType`.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

GetDataBrowserItemDataMinimum

Obtains the minimum integer value that can be displayed for an item; useful for such display types as sliders, progress bars, relevance indicators, and pop-up menus.

```
OSStatus GetDataBrowserItemDataMinimum (
   DataBrowserItemDataRef itemData,
   SInt32 *theData
);
```

Parameters

itemData

The item data reference for the item whose minimum value you want to obtain. The item data reference is passed to the callback routine from which you are calling the function `GetDataBrowserItemDataMinimum`.

theData

On input, a pointer to a signed 32-bit integer. On return, this value is set to the minimum value that can be displayed for the item.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

GetDataBrowserItemDataProperty

Obtains the column property ID for the column in which an item resides.

```
OSStatus GetDataBrowserItemDataProperty (
   DataBrowserItemDataRef itemData,
   DataBrowserPropertyID *theData
);
```

Parameters

itemData

The item data reference for the item whose property ID you want to obtain. This value is passed to the callback routine from which you are calling the function `GetDataBrowserItemDataProperty`.

theData

On input, a pointer to a property ID variable. On return, the variable is set to the property ID for the item.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
When your item-data callback is invoked for an item that has the property `kDataBrowserItemIsEditableProperty`, you call the function `GetDataBrowserItemDataProperty` to obtain the column property ID. Then, your callback can use the column property ID to determine whether the item is in a column whose data can be edited.

For example, consider a list view data browser whose columns are titled "Name" and "Date Modified." Let's say Name can be modified by the user, but the Date Modified column cannot. If the user clicks an item in one of the columns, your item-data callback is called to find out whether the clicked column is editable. Your

callback needs to find out which column the "is editable" request is being made for by calling the function `GetDataBrowserItemDataProperty`. In this example, after you obtain the property ID, you would check whether the column is the Date Modified column or the Name column. You'd allow editing only if the item is in the Name column.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

GetDataBrowserItemDataRGBColor

Obtains the color used to draw an item.

```
OSStatus GetDataBrowserItemDataRGBColor (
   DataBrowserItemDataRef itemData,
   RGBColor *theData
);
```

Parameters

itemData
The item data reference for the item whose color you want to obtain. This value is passed to the callback routine from which you are calling the function `GetDataBrowserItemDataRGBColor`.

theData
On input, an RGB color variable. On return, the variable is set to the RGB values that specify the color of the item.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
Your item-data callback calls this function in response to a get-data request for items that have the display type `kDataBrowserIconType` or `kDataBrowserIconAndTextType`.

As of Mac OS X 10.3, this function does nothing.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

GetDataBrowserItemDataText

Obtains the text entered by the user.

```
OSStatus GetDataBrowserItemDataText (
   DataBrowserItemDataRef itemData,
   CFStringRef *theData
);
```

Parameters

itemData

The item data reference for the item whose text you want to obtain. This value is passed to the callback routine from which you are calling the function `GetDataBrowserItemDataText`.

theData

On input, a `CFStringRef` variable. On return, a CFString object that contains the text. Your application must release the CFString object when it is no longer needed.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
You can call the function `GetDataBrowserItemDataText` from inside an item-data callback routine when the callback's `setValue` parameter is `true`. A value of `true` indicates that the displayed text has been modified by the user. In that case, your application calls `GetDataBrowserItemDataText` to retrieve the modified text.

Note that a column is editable only if the `kDataBrowserPropertyIsEditable` flag is set for the column.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

GetDataBrowserItemDataValue

Obtains the value of an item; useful for such display types as sliders, progress bars, relevance indicators, and pop-up menus.

```
OSStatus GetDataBrowserItemDataValue (
   DataBrowserItemDataRef itemData,
   SInt32 *theData
);
```

Parameters

itemData

The item data reference for the item whose integer value you want to obtain. The item data reference is passed to the callback routine from which you are calling the function `GetDataBrowserItemDataValue`.

theData

On input, a pointer to a signed 32-bit integer. On return, it is set to the displayed value.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
Your application calls the function `GetDataBrowserItemDataValue` to obtain a new value for a display type when your item-data callback routine is called with the `setValue` parameter set to `true`.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

GetDataBrowserItemPartBounds

Obtains the bounds of a visual part of an item.

```
OSStatus GetDataBrowserItemPartBounds (
   ControlRef browser,
   DataBrowserItemID item,
   DataBrowserPropertyID property,
   DataBrowserPropertyPart part,
   Rect *bounds
);
```

Parameters

browser
A data browser.

item
The item ID that identifies the row.

property
The property ID that identifies the column.

part
The part for which you want to obtain information. The information requested depends on the type of information displayed in the column. It is up to your application to ensure it requests the appropriate information. See "Property Parts" (page 2291) for a list of the constants you can provide in this parameter.

bounds
On input, a pointer to a rectangle. On return, the rectangle contains the bounds for the specified part.

Return Value
A result code. If the item is not visible (scrolled off the screen), returns the result `ItemNotFound`. See "Data Browser Result Codes" (page 2298).

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

GetDataBrowserItems

Obtains a list of the items that match a specified state; operates on items in the root container or traverses items in the data hierarchy.

```
OSStatus GetDataBrowserItems (
   ControlRef browser,
   DataBrowserItemID container,
   Boolean recurse,
   DataBrowserItemState state,
   Handle items
);
```

Parameters

browser

A data browser.

container

An item ID or the constant `kDataBrowserNoItem`. To obtain a list of items that are organized as subitems of a container, pass the item ID of the container item. To obtain a list of items displayed in the root container, pass the constant `kDataBrowserNoItem`.

recurse

A value that indicates whether or not to traverse the entire item hierarchy when obtaining item IDs. Pass `true` to obtain item IDs for all items in the hierarchy. Pass `false` if you want to count only those item IDs at the top level of the container. If you pass `true`, you obtain a flattened list of item IDs. The list reflects the hierarchy maintained internally by the data browser and might not reflect the order of the items as they appear onscreen to the user.

state

The state of the items to obtain. Only items that have this state are returned in the `items` parameter. Pass `0` if you want to obtain all items regardless of state. Otherwise, pass one of the constants described in "Item States" (page 2280).

items

On return, the contents of the handle contain an array of item ID values for the matching items. You must allocate and dispose of the handle. To determine the number of items in the array, call the function `GetHandleSize` and divide by the size of `DataBrowserItemID`. Note that the handle contents are completely replaced by the returned array.

Return Value

A result code. See "Data Browser Result Codes" (page 2298).

Discussion

The function `GetDataBrowserItems` is a powerful routine for gathering information about the items displayed in a data browser. For example, to obtain a list of all the items the user has selected in a list, call the function with the `state` parameter set to `kDataBrowserItemIsSelected`. If your application is interested only in determining the number of items in a selection (and not the item IDs of those items), call the function `GetDataBrowserItemCount` (page 2145).

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.0 and later.

Not available to 64-bit applications.

Declared In

`HIDataBrowser.h`

GetDataBrowserItemState

Obtains the state of an item.

```
OSStatus GetDataBrowserItemState (
   ControlRef browser,
   DataBrowserItemID item,
   DataBrowserItemState *state
);
```

Parameters

browser

A data browser.

item

The item ID of the item whose state you want to check.

state

On input, a pointer to an item state variable. On return, the variable is set to a value that specifies the state of the item. See "Item States" (page 2280) for a description of the values that can be returned.

Return Value

A result code. See "Data Browser Result Codes" (page 2298).

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.0 and later.

Not available to 64-bit applications.

Declared In

`HIDataBrowser.h`

GetDataBrowserListViewDisclosureColumn

Obtains the property ID of the column whose items can display a disclosure triangle, and tells whether a disclosed item expands the row or adds rows.

```
OSStatus GetDataBrowserListViewDisclosureColumn (
   ControlRef browser,
   DataBrowserTableViewColumnID *column,
   Boolean *expandableRows
);
```

Parameters

browser

A data browser.

column

On input, a pointer to a column ID variable. On return, the variable is set to the property ID of the currently selected column. If there is no disclosure column, the variable is set to `kDataBrowserItemNoProperty`. The `DataBrowserTableViewColumnID` data type is the same as the `DataBrowserPropertyID` data type.

expandableRows

On input, a pointer to a Boolean variable. On return, the variable specifies how a disclosed row behaves. The value `true` means that a container opens as a single row with an expanded height. The value `false` means a container opens to expose individual rows. See the Discussion for more details on expandable rows.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
When the `expandableRows` variable is set to `true`:

- Disclosure triangles are drawn top-justified in the row.
- Custom row height, if any, for that row is respected only while the row is disclosed. At other times, the default row height is used.

When the `expandableRows` variable is set to `false`:

- Disclosure triangles are centered vertically in the row.
- Custom row height, if any, for that row is always respected.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

GetDataBrowserListViewHeaderBtnHeight

Obtains the height of the rectangular area where the column title appears.

```
OSStatus GetDataBrowserListViewHeaderBtnHeight (
   ControlRef browser,
   UInt16 *height
);
```

Parameters

browser

A data browser.

height

On input, a pointer to an unsigned 16-bit integer. On return, this value is set to the height of the rectangular area where the column title appears. You can save this value if you plan to call the function `SetDataBrowserListViewHeaderBtnHeight` (page 2217) to turn off header button display. You can then use the value later to turn on header button display.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Availability
Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
HIDataBrowser.h

GetDataBrowserListViewHeaderDesc

Obtains a header description for a column in list view.

```
OSStatus GetDataBrowserListViewHeaderDesc (
   ControlRef browser,
   DataBrowserTableViewColumnID column,
   DataBrowserListViewHeaderDesc *desc
);
```

Parameters

browser
A data browser.

column
The property ID for the column whose list view header description you want to obtain. The `DataBrowserTableViewColumnID` data type is the same as the `DataBrowserPropertyID` data type.

desc
On input, a pointer to a list view header description data structure. On return, the structure contains the header description for the specified column in list view.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
If your application allows the user to switch between column and list views, you can call this function to obtain the current header description and then save the description before you switch from list to column view. When you switch from column to list view, you can restore the list view header information by calling the function `SetDataBrowserListViewHeaderDesc` (page 2218) passing the header information you saved.

Availability
Available in CarbonLib 1.5 and later.
Available in Mac OS X version 10.2 and later.
Not available to 64-bit applications.

Declared In
HIDataBrowser.h

GetDataBrowserListViewUsePlainBackground

Determines whether list view is set to use a plain white background.

```
OSStatus GetDataBrowserListViewUsePlainBackground (
   ControlRef browser,
   Boolean *usePlainBackground
);
```

Parameters

browser

A data browser.

usePlainBackground

On input, a pointer to a Boolean variable. On return, the variable is `true` if list view is set to use a plain white background. Regardless of the value that is returned, Mac OS X supports only a plain white background. Mac OS 9 supports a plain white background as well as a shaded background.

Return Value

A result code. See "Data Browser Result Codes" (page 2298).

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.0 and later.

Not available to 64-bit applications.

Declared In

`HIDataBrowser.h`

GetDataBrowserPropertyFlags

Obtains the appearance and behavior attributes for a column.

```
OSStatus GetDataBrowserPropertyFlags (
   ControlRef browser,
   DataBrowserPropertyID property,
   DataBrowserPropertyFlags *flags
);
```

Parameters

browser

A data browser.

property

The property ID of the column whose properties you want to obtain.

flags

On input, a data browser property flags variable. On return, the variable is set to the property flags that specify the appearance and behavior attributes for a column. A `DataBrowserPropertyFlags` value is a 32-bit value that is divided into four parts as follows:

- Bits 0–7 specify properties applied to the data browser as a whole—see "Property Flags: Universal" (page 2284)
- Bits 8–15 modify display behavior—see "Property Flags: Modifiers" (page 2285)
- Bits 16–23 are properties specific to list view—see "Property Flags: Offset and Mask for List View Properties" (page 2288) and "Property Flags: List View Column Behavior" (page 2289)
- Bits 24–31 can be defined by your application—see "Property Flags: Offset and Mask for Client-Defined Properties" (page 2290)

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

GetDataBrowserScrollBarInset

Obtains the inset rectangle used by a data browser to position the scroll bar.

```
OSStatus GetDataBrowserScrollBarInset (
   ControlRef browser,
   Rect *insetRect
);
```

Parameters

browser
A data browser.

insetRect
On input, a pointer to a rectangle structure. On return, the rectangle contains the current inset settings for the data browser scroll bars. The `left` and `right` fields contain the horizontal inset values for the horizontal scroll bar, and the `top` and `bottom` fields contain the vertical inset values for the vertical scroll bar.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
Your application can call the functions `GetDataBrowserScrollBarInset` and `SetDataBrowserScrollBarInset` (page 2220) if you want to place placards or controls beside the horizontal scroll bars or above the vertical ones. To do so, first call `GetDataBrowserScrollBarInset` to obtain the current settings. After modifying the current inset settings to provide space for the placard or control, call `SetDataBrowserScrollBarInset` with the new values.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

GetDataBrowserScrollPosition

Obtains the scrolling position of a list.

```
OSStatus GetDataBrowserScrollPosition (
   ControlRef browser,
   UInt32 *top,
   UInt32 *left
);
```

Parameters

browser

A data browser.

top

On input, a pointer to an unsigned 32-bit integer. On return, this value is set to the current vertical scrolling position.

left

On input, a pointer to an unsigned 32-bit integer. On return, this value is set to the current horizontal scrolling position.

Return Value

A result code. See "Data Browser Result Codes" (page 2298).

Discussion

Normally, you use the function `GetDataBrowserScrollPosition` in conjunction with `SetDataBrowserScrollPosition` (page 2221) to save and restore the scrolling position of a list to the user's last scrolling position. These functions should not be used to scroll particular cells into the view. For that, call the function `RevealDataBrowserItem`.

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.0 and later.

Not available to 64-bit applications.

Declared In

`HIDataBrowser.h`

GetDataBrowserSelectionAnchor

Obtains the first and last items in a selection.

```
OSStatus GetDataBrowserSelectionAnchor (
   ControlRef browser,
   DataBrowserItemID *first,
   DataBrowserItemID *last
);
```

Parameters

browser

A data browser.

first

On input, a pointer to an item ID variable. On return, the variable is set to the item ID of the first item in the selection.

last

On input, a pointer to an item ID variable. On return, the variable is set to the item ID of the last item in the selection.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

GetDataBrowserSelectionFlags

Obtains the current selection behavior for a data browser.

```
OSStatus GetDataBrowserSelectionFlags (
   ControlRef browser,
   DataBrowserSelectionFlags *selectionFlags
);
```

Parameters

browser
A data browser.

selectionFlags
On input, a data browser selection flags variable. On return, the variable is set to the current selection flags. See "User Selection Flags" (page 2296) for a list of the flags that can be returned.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
Selection flags specify the selection behavior available to the user, such as whether the user can select discontinuous items.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

GetDataBrowserSortOrder

Gets the sorting order of the list view column that's currently set for sorting.

```
OSStatus GetDataBrowserSortOrder (
   ControlRef browser,
   DataBrowserSortOrder *order
);
```

Parameters

browser

A data browser.

order

On input, a pointer to a sorting order variable. On return, the variable is set to the sorting order of the current sort column in list view. See "Sorting Orders" (page 2294) for a list of the values that can be returned.

Return Value

A result code. See "Data Browser Result Codes" (page 2298).

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.0 and later.

Not available to 64-bit applications.

Declared In

`HIDataBrowser.h`

GetDataBrowserSortProperty

Obtains the property ID of the column currently used for sorting in list view.

```
OSStatus GetDataBrowserSortProperty (
   ControlRef browser,
   DataBrowserPropertyID *property
);
```

Parameters

browser

A data browser.

property

On input, a pointer to a property ID variable. On return, the variable is set to the property ID of the column used for sorting.

Return Value

A result code. See "Data Browser Result Codes" (page 2298).

Discussion

You can call the function `GetDataBrowserSortProperty` to discover the property ID of the column currently used for sorting. To designate another column for the sorting operation, call the function `SetDataBrowserSortProperty` (page 2223).

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.0 and later.

Not available to 64-bit applications.

Declared In
HIDataBrowser.h

GetDataBrowserTableViewColumnCount

Obtains the number of columns in a data browser.

```
OSStatus GetDataBrowserTableViewColumnCount (
   ControlRef browser,
   UInt32 *numColumns
);
```

Parameters

browser
A data browser.

numColumns
On input, a pointer to an unsigned 32-bit integer. On return, this value is set to the number of columns in the data browser.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
HIDataBrowser.h

GetDataBrowserTableViewColumnPosition

Obtains the column position for an item in a data browser.

```
OSStatus GetDataBrowserTableViewColumnPosition (
   ControlRef browser,
   DataBrowserTableViewColumnID column,
   DataBrowserTableViewColumnIndex *position
);
```

Parameters

browser
A data browser.

column
The property ID for the list view column for which you want to obtain the position. The `DataBrowserTableViewColumnID` data type is the same as the `DataBrowserPropertyID` data type.

position
On input, a pointer to a column index variable. On return, the variable is set to the column index for the item; `0` is the leftmost column.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

GetDataBrowserTableViewColumnProperty

Obtains the property ID for a column in a data browser.

```
OSStatus GetDataBrowserTableViewColumnProperty (
   ControlRef browser,
   DataBrowserTableViewColumnIndex column,
   DataBrowserTableViewColumnID *property
);
```

Parameters

browser
A data browser.

column
The column index of the column whose property ID you want to obtain.

property
On input, a pointer to a column ID variable. On return, the variable is set to the property ID for the column. The `DataBrowserTableViewColumnID` data type is the same as the `DataBrowserPropertyID` data type.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

GetDataBrowserTableViewColumnWidth

Obtains the default column width used for all columns in a data browser.

```
OSStatus GetDataBrowserTableViewColumnWidth (
   ControlRef browser,
   UInt16 *width
);
```

Parameters

browser

A data browser.

width

On input, a pointer to an unsigned 16-bit integer. On return, this value is set to the column width, in pixels.

Return Value

A result code. See "Data Browser Result Codes" (page 2298).

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.0 and later.

Not available to 64-bit applications.

Declared In

`HIDataBrowser.h`

GetDataBrowserTableViewGeometry

Determines whether columns and rows are set to have variable widths.

```
OSStatus GetDataBrowserTableViewGeometry (
   ControlRef browser,
   Boolean *variableWidthColumns,
   Boolean *variableHeightRows
);
```

Parameters

browser

A data browser.

variableWidthColumns

On input, a pointer to a Boolean variable. On return, the variable is set to `true` if column widths can be changed or `false` if they cannot be changed.

variableHeightRows

On input, a pointer to a Boolean variable. On return, the variable is set to `true` if row heights can be changed or `false` if they cannot be changed.

Return Value

A result code. See "Data Browser Result Codes" (page 2298).

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.0 and later.

Not available to 64-bit applications.

Declared In

`HIDataBrowser.h`

GetDataBrowserTableViewHiliteStyle

Obtains the highlighting style used for a list view data browser.

```
OSStatus GetDataBrowserTableViewHiliteStyle (
   ControlRef browser,
   DataBrowserTableViewHiliteStyle *hiliteStyle
);
```

Parameters

browser

A list view data browser.

hiliteStyle

On input, a pointer to a highlighting style variable. On return, the variable is set to the highlighting style in use. See "Table View Highlighting Styles" (page 2294) for a description of the values that can be returned.

Return Value

A result code. See "Data Browser Result Codes" (page 2298).

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.0 and later.

Not available to 64-bit applications.

Declared In

`HIDataBrowser.h`

GetDataBrowserTableViewItemID

Obtains the item ID for the item displayed in the specified row.

```
OSStatus GetDataBrowserTableViewItemID (
   ControlRef browser,
   DataBrowserTableViewRowIndex row,
   DataBrowserItemID *item
);
```

Parameters

browser

A data browser.

row

The row index for the item. The row index is the visual order of rows in the table onscreen. Rows are numbered starting at the top of the table, with the value `0`, and proceeding sequentially to the bottom of the table.

item

On input, a pointer to an item ID variable. On return, the variable is set to the item ID of the data displayed in the row.

Return Value

A result code. See "Data Browser Result Codes" (page 2298).

Discussion
This function is useful only in edge case situations for which you need to know what item ID is displayed in a particular row. For example, if you are performing some fairly involved and complex custom hit-testing, you might need to call this function.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

GetDataBrowserTableViewItemRow

Obtains the visual position for the specified item in list view.

```
OSStatus GetDataBrowserTableViewItemRow (
   ControlRef browser,
   DataBrowserItemID item,
   DataBrowserTableViewRowIndex *row
);
```

Parameters

browser
A data browser.

item
The item ID for the item whose row index you want to obtain.

row
On input, a pointer to a row index variable. On return, the variable is set to the row index for the item.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
You can use this function for items in list view. It is the inverse of the function `GetDataBrowserTableViewItemID` (page 2169).

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

GetDataBrowserTableViewItemRowHeight

Obtains the row height for a single row in a list view data browser.

```
OSStatus GetDataBrowserTableViewItemRowHeight (
   ControlRef browser,
   DataBrowserItemID item,
   UInt16 *height
);
```

Parameters

browser

A data browser.

item

The item ID of the item whose row height you want to obtain.

height

On input, a pointer to an unsigned 16-bit integer. On return, this value is set to the row height, in pixels.

Return Value

A result code. See "Data Browser Result Codes" (page 2298).

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.0 and later.

Not available to 64-bit applications.

Declared In

`HIDataBrowser.h`

GetDataBrowserTableViewNamedColumnWidth

Obtains the column width for a single column in a data browser.

```
OSStatus GetDataBrowserTableViewNamedColumnWidth (
   ControlRef browser,
   DataBrowserTableViewColumnID column,
   UInt16 *width
);
```

Parameters

browser

A data browser.

column

The property ID for the list view column whose width you want to obtain. The `DataBrowserTableViewColumnID` data type is the same as the `DataBrowserPropertyID` data type.

width

On input, a pointer to an unsigned 16-bit integer. On return, this value is set to the width of the column, in pixels.

Return Value

A result code. See "Data Browser Result Codes" (page 2298).

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.0 and later.

Not available to 64-bit applications.

Declared In
HIDataBrowser.h

GetDataBrowserTableViewRowHeight

Obtains the default row height used for all rows in a data browser.

```
OSStatus GetDataBrowserTableViewRowHeight (
   ControlRef browser,
   UInt16 *height
);
```

Parameters

browser

A data browser.

height

On input, a pointer to an unsigned 16-bit integer. On return, this value is set to the row height, in pixels.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
HIDataBrowser.h

GetDataBrowserTarget

Obtains the target for the data browser

```
OSStatus GetDataBrowserTarget (
   ControlRef browser,
   DataBrowserItemID *target
);
```

Parameters

browser

A data browser.

target

On input, a pointer to an item ID variable. On return, the variable is set to the item ID for the currently assigned target.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
In column view, the target is the rightmost column. In list view, the target can be thought of as the root container.

Your application can call the function `SetDataBrowserTarget` (page 2229) to set an item ID to use as a target if you do not want to use the default target set by the data browser.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

GetDataBrowserUserState

Obtains the current view style settings for a list view.

```
OSStatus GetDataBrowserUserState (
   ControlRef browser,
   CFDictionaryRef *stateInfo
);
```

Parameters

browser
A data browser.

stateInfo
On input, a pointer to a `CFDictionaryRef`. On return, a CFDictionary object that contains the current view style settings. You must release the object when you no longer need it by calling the function `CFRelease`. Note that although this parameter is typed as a CFData object, you must treat the result as a CFDictionary object because that is what the system fills out and returns to you.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
You typically use this function to obtain the current user settings for the data browser so that you can save the settings to a preferences file. User settings include data such as sorting order, sorting column, and column widths. Later, you can restore the settings by calling the function `SetDataBrowserUserState` (page 2230).

If you want to save the user settings to disk, you need to determine the length of the user-settings data in bytes. The following code shows how to calculate this length. First you need to convert the CFDictionary object you obtain from the function `GetDataBrowserUserState` to a property list. Then you can call the function `CFDataGetLength` to obtain the length, in bytes, of the property list.

```
CFDataRef myUserState = NULL;
OSStatus status;

ControlRef browser = GetDataBrowserFromWindow (window);
status = GetDataBrowserUserState (browser, &myUserState);

if (noErr == status)
{
```

```
  CFDataRef myTempDataRef = NULL;
  CFIndex index;

  if (myUserState != NULL)
  {
    // Convert the user state dictionary to a property list.
    myTempDataRef = CFPropertyListCreateXMLData (NULL,
                        (CFPropertyListRef) myUserState);
    if (myTempDataRef != NULL)
    {
        // Get the length, in bytes
      index = CFDataGetLength (myTempDataRef);
        // Call your function to save the data
        // You need to release the CFDataRef you created
      CFRelease (myTempDataRef);
    }
  }
 CFRelease (myUserState);
}
```

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

GetDataBrowserViewStyle

Obtains the current view style for the specified data browser.

```
OSStatus GetDataBrowserViewStyle (
   ControlRef browser,
   DataBrowserViewStyle *style
);
```

Parameters

browser
A data browser.

style
On input, a pointer to a view style variable. On return, the variable is set to the current view style for the specified data browser; can be either list view (`kDataBrowserListView`) or column view (`kDataBrowserColumnView`). See "View Styles" (page 2298) for more information on these constants.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

InitDataBrowserCallbacks

Initializes a data browser callback structure in preparation for adding your own callbacks to the structure.

```
OSStatus InitDataBrowserCallbacks (
   DataBrowserCallbacks *callbacks
);
```

Parameters

callbacks

A pointer to a `DataBrowserCallbacks` structure. Before calling the function `InitDataBrowserCallbacks`, set the `version` field of this structure to `kDataBrowserLatestCallbacks`. On return, the fields in this structure are set to `NULL`.

Return Value

A result code. See "Data Browser Result Codes" (page 2298).

Discussion

After you call this function, set the appropriate fields in the `DataBrowserCallbacks` structure to your callbacks. The `DataBrowserCallbacks` structure contains fields for the following:

- `DataBrowserItemDataProcPtr` (page 2245)
- `DataBrowserItemCompareProcPtr` (page 2243)
- `DataBrowserItemNotificationProcPtr` (page 2250) or `DataBrowserItemNotificationWithItemProcPtr` (page 2251) (Mac OS X only)
- `DataBrowserAddDragItemProcPtr` (page 2234)
- `DataBrowserAcceptDragProcPtr` (page 2233)
- `DataBrowserReceiveDragProcPtr` (page 2256)
- `DataBrowserPostProcessDragProcPtr` (page 2255)
- `DataBrowserGetContextualMenuProcPtr` (page 2238)
- `DataBrowserSelectContextualMenuProcPtr` (page 2257)
- `DataBrowserItemHelpContentProcPtr` (page 2248)

After you assign your callbacks to the appropriate field, call the function `SetDataBrowserCallbacks` (page 2200).

Note that this is a different set of callbacks from those that are assigned to fields in the `DataBrowserCustomCallbacks` data structure.

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.0 and later.

Not available to 64-bit applications.

Declared In

`HIDataBrowser.h`

InitDataBrowserCustomCallbacks

Initializes the data browser custom callback structure in preparation for adding your own callbacks for custom drawing or custom behavior to the structure.

```
OSStatus InitDataBrowserCustomCallbacks (
   DataBrowserCustomCallbacks *callbacks
);
```

Parameters

callbacks

A pointer to a `DataBrowserCustomCallbacks` structure. Before calling the function `InitDataBrowserCustomCallbacks`, set the `version` field of this structure to `kDataBrowserLatestCustomCallbacks`. On return, the fields in this structure are set to `NULL`.

Return Value

A result code. See "Data Browser Result Codes" (page 2298).

Discussion

Custom callbacks refer to those callback routines that are used to implement custom drawing or custom behavior in your data browser. The data browser API supports a limited set of built-in display types: text, icon and text, checkboxes, and so forth. If you want to display something else, you install custom callbacks to perform drawing and handle user interaction.

After you call the function `InitDataBrowserCustomCallbacks`, set the appropriate fields in the `DataBrowserCustomCallbacks` structure to your callbacks. The `DataBrowserCustomCallbacks` structure contains fields for the following:

- `DataBrowserDrawItemProcPtr` (page 2235)
- `DataBrowserEditItemProcPtr` (page 2237)
- `DataBrowserHitTestProcPtr` (page 2240)
- `DataBrowserTrackingProcPtr` (page 2259)
- `DataBrowserItemDragRgnProcPtr` (page 2246)
- `DataBrowserItemAcceptDragProcPtr` (page 2242)
- `DataBrowserItemReceiveDragProcPtr` (page 2254)

After you assign your custom callbacks to the appropriate field, call the function `SetDataBrowserCustomCallbacks` (page 2203).

Note that this is a different set of callbacks from those that are assigned to fields in the `DataBrowserCallbacks` data structure.

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.0 and later.

Not available to 64-bit applications.

Declared In

`HIDataBrowser.h`

InvokeDataBrowserAcceptDragUPP

Calls an accept-drag callback function.

```
Boolean InvokeDataBrowserAcceptDragUPP (
   ControlRef browser,
   DragReference theDrag,
   DataBrowserItemID item,
   DataBrowserAcceptDragUPP userUPP
);
```

Discussion
In most cases you do not need to use this function, because the system invokes your callback function for you. See the `DataBrowserAcceptDragProcPtr` (page 2233) callback function for more information and for a description of the parameters.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.

Declared In
`HIDataBrowser.h`

InvokeDataBrowserAddDragItemUPP

Calls an add-drag-item callback function.

```
Boolean InvokeDataBrowserAddDragItemUPP (
   ControlRef browser,
   DragReference theDrag,
   DataBrowserItemID item,
   ItemReference *itemRef,
   DataBrowserAddDragItemUPP userUPP
);
```

Discussion
In most cases you do not need to use this function, because the system invokes your callback function for you. See the `DataBrowserAddDragItemProcPtr` (page 2234) callback function for more information and for a description of the parameters.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.

Declared In
`HIDataBrowser.h`

InvokeDataBrowserDrawItemUPP

Calls a draw-item callback function.

```
void InvokeDataBrowserDrawItemUPP (
   ControlRef browser,
   DataBrowserItemID item,
   DataBrowserPropertyID property,
   DataBrowserItemState itemState,
   const Rect *theRect,
   SInt16 gdDepth,
   Boolean colorDevice,
   DataBrowserDrawItemUPP userUPP
);
```

Discussion
In most cases you do not need to use this function, because the system invokes your callback function for you. See the `DataBrowserDrawItemProcPtr` (page 2235) callback function for more information and for a description of the parameters.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.1 and later.

Declared In
`HIDataBrowser.h`

InvokeDataBrowserEditItemUPP

Calls an edit-item callback function.

```
Boolean InvokeDataBrowserEditItemUPP (
   ControlRef browser,
   DataBrowserItemID item,
   DataBrowserPropertyID property,
   CFStringRef theString,
   Rect *maxEditTextRect,
   Boolean *shrinkToFit,
   DataBrowserEditItemUPP userUPP
);
```

Discussion
In most cases you do not need to use this function, because the system invokes your callback function for you. See the `DataBrowserEditItemProcPtr` (page 2237) callback function for more information and for a description of the parameters.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.1 and later.

Declared In
`HIDataBrowser.h`

InvokeDataBrowserGetContextualMenuUPP

Calls a get-contextual-menu callback function.

```
void InvokeDataBrowserGetContextualMenuUPP (
   ControlRef browser,
   MenuRef *menu,
   UInt32 *helpType,
   CFStringRef *helpItemString,
   AEDesc *selection,
   DataBrowserGetContextualMenuUPP userUPP
);
```

Discussion
In most cases you do not need to use this function, because the system invokes your callback function for you. See the `DataBrowserGetContextualMenuProcPtr` (page 2238) callback function for more information and for a description of the parameters.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.

Declared In
`HIDataBrowser.h`

InvokeDataBrowserHitTestUPP

Calls a hit-test callback function.

```
Boolean InvokeDataBrowserHitTestUPP (
   ControlRef browser,
   DataBrowserItemID itemID,
   DataBrowserPropertyID property,
   const Rect *theRect,
   const Rect *mouseRect,
   DataBrowserHitTestUPP userUPP
);
```

Discussion
In most cases you do not need to use this function, because the system invokes your callback function for you. See the `DataBrowserHitTestProcPtr` (page 2240) callback function for more information and for a description of the parameters.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.1 and later.

Declared In
`HIDataBrowser.h`

InvokeDataBrowserItemAcceptDragUPP

Calls an item-accept-drag callback function.

```
DataBrowserDragFlags InvokeDataBrowserItemAcceptDragUPP (
   ControlRef browser,
   DataBrowserItemID itemID,
   DataBrowserPropertyID property,
   const Rect *theRect,
   DragReference theDrag,
   DataBrowserItemAcceptDragUPP userUPP
);
```

Discussion
In most cases you do not need to use this function, because the system invokes your callback function for you. See the `DataBrowserItemAcceptDragProcPtr` (page 2242) callback function for more information and for a description of the parameters.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.1 and later.

Declared In
`HIDataBrowser.h`

InvokeDataBrowserItemCompareUPP

Calls an item-comparison callback function.

```
Boolean InvokeDataBrowserItemCompareUPP (
   ControlRef browser,
   DataBrowserItemID itemOne,
   DataBrowserItemID itemTwo,
   DataBrowserPropertyID sortProperty,
   DataBrowserItemCompareUPP userUPP
);
```

Discussion
In most cases you do not need to use this function, because the system invokes your callback function for you. See the `DataBrowserItemCompareProcPtr` (page 2243) callback function for more information and for a description of the parameters.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.

Declared In
`HIDataBrowser.h`

InvokeDataBrowserItemDataUPP

Calls an item-data callback function.

```
OSStatus InvokeDataBrowserItemDataUPP (
   ControlRef browser,
   DataBrowserItemID item,
   DataBrowserPropertyID property,
   DataBrowserItemDataRef itemData,
   Boolean setValue,
   DataBrowserItemDataUPP userUPP
);
```

Discussion
In most cases you do not need to use this function, because the system invokes your callback function for you. See the `DataBrowserItemDataProcPtr` (page 2245) callback function for more information and for a description of the parameters.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.

Declared In
`HIDataBrowser.h`

InvokeDataBrowserItemDragRgnUPP

Calls an item-drag-region callback function.

```
void InvokeDataBrowserItemDragRgnUPP (
   ControlRef browser,
   DataBrowserItemID itemID,
   DataBrowserPropertyID property,
   const Rect *theRect,
   RgnHandle dragRgn,
   DataBrowserItemDragRgnUPP userUPP
);
```

Discussion
In most cases you do not need to use this function, because the system invokes your callback function for you. See the `DataBrowserItemDragRgnProcPtr` (page 2246) callback function for more information and for a description of the parameters.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.1 and later.

Declared In
`HIDataBrowser.h`

InvokeDataBrowserItemHelpContentUPP

Calls an item-help-content callback function.

```
void InvokeDataBrowserItemHelpContentUPP (
   ControlRef browser,
   DataBrowserItemID item,
   DataBrowserPropertyID property,
   HMContentRequest inRequest,
   HMContentProvidedType *outContentProvided,
   HMHelpContentRec *ioHelpContent,
   DataBrowserItemHelpContentUPP userUPP
);
```

Discussion
In most cases you do not need to use this function, because the system invokes your callback function for you. See the `DataBrowserItemHelpContentProcPtr` (page 2248) callback function for more information and for a description of the parameters.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.

Declared In
`HIDataBrowser.h`

InvokeDataBrowserItemNotificationUPP

Calls an item-notification callback function.

```
void InvokeDataBrowserItemNotificationUPP (
   ControlRef browser,
   DataBrowserItemID item,
   DataBrowserItemNotification message,
   DataBrowserItemNotificationUPP userUPP
);
```

Discussion
In most cases you don't need to use this function, because the system invokes your callback function for you. See the `DataBrowserItemNotificationProcPtr` (page 2250) callback function for more information and for a description of the parameters.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.

Declared In
`HIDataBrowser.h`

InvokeDataBrowserItemNotificationWithItemUPP

Calls an item-notification-with-data callback function.

```
void InvokeDataBrowserItemNotificationWithItemUPP (
   ControlRef browser,
   DataBrowserItemID item,
   DataBrowserItemNotification message,
   DataBrowserItemDataRef itemData,
   DataBrowserItemNotificationWithItemUPP userUPP
);
```

Discussion
In most cases you don't need to use this function, because the system invokes your callback function for you. See the `DataBrowserItemNotificationWithItemProcPtr` (page 2251) callback function for more information and for a description of the parameters.

Availability
Available in CarbonLib 1.5 and later.
Available in Mac OS X version 10.1 and later.

Declared In
`HIDataBrowser.h`

InvokeDataBrowserItemReceiveDragUPP

Calls an item-receive-drag callback function.

```
Boolean InvokeDataBrowserItemReceiveDragUPP (
   ControlRef browser,
   DataBrowserItemID itemID,
   DataBrowserPropertyID property,
   DataBrowserDragFlags dragFlags,
   DragReference theDrag,
   DataBrowserItemReceiveDragUPP userUPP
);
```

Discussion
In most cases you do not need to use this function, because the system invokes your callback function for you. See the `DataBrowserItemReceiveDragProcPtr` (page 2254) callback function for more information and for a description of the parameters.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.1 and later.

Declared In
`HIDataBrowser.h`

InvokeDataBrowserItemUPP

Calls an item-iterator callback function.

```
void InvokeDataBrowserItemUPP (
   DataBrowserItemID item,
   DataBrowserItemState state,
   void *clientData,
   DataBrowserItemUPP userUPP
);
```

Discussion
In most cases you do not need to use this function, because the system invokes your callback function for you. See the `DataBrowserItemProcPtr` (page 2253) callback function for more information and for a description of the parameters.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.

Declared In
`HIDataBrowser.h`

InvokeDataBrowserPostProcessDragUPP

Calls a postprocess-drag callback function.

```
void InvokeDataBrowserPostProcessDragUPP (
   ControlRef browser,
   DragReference theDrag,
   OSStatus trackDragResult,
   DataBrowserPostProcessDragUPP userUPP
);
```

Discussion
In most cases you do not need to use this function, because the system invokes your callback function for you. See the `DataBrowserPostProcessDragProcPtr` (page 2255) callback function for more information and for a description of the parameters.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.

Declared In
`HIDataBrowser.h`

InvokeDataBrowserReceiveDragUPP

Calls a receive-drag callback function.

```
Boolean InvokeDataBrowserReceiveDragUPP (
   ControlRef browser,
   DragReference theDrag,
   DataBrowserItemID item,
   DataBrowserReceiveDragUPP userUPP
);
```

Discussion
In most cases you do not need to use this function, because the system invokes your callback function for you. See the `DataBrowserReceiveDragProcPtr` (page 2256) callback function for more information and for a description of the parameters.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.

Declared In
`HIDataBrowser.h`

InvokeDataBrowserSelectContextualMenuUPP

Calls a select-contextual-menu callback function.

```
void InvokeDataBrowserSelectContextualMenuUPP (
   ControlRef browser,
   MenuRef menu,
   UInt32 selectionType,
   SInt16 menuID,
   MenuItemIndex menuItem,
   DataBrowserSelectContextualMenuUPP userUPP
);
```

Discussion
In most cases you do not need to use this function, because the system invokes your callback function for you. See the `DataBrowserSelectContextualMenuProcPtr` (page 2257) callback function for more information and for a description of the parameters.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.

Declared In
`HIDataBrowser.h`

InvokeDataBrowserTrackingUPP

Calls a tracking callback function.

```
DataBrowserTrackingResult InvokeDataBrowserTrackingUPP (
   ControlRef browser,
   DataBrowserItemID itemID,
   DataBrowserPropertyID property,
   const Rect *theRect,
   Point startPt,
   EventModifiers modifiers,
   DataBrowserTrackingUPP userUPP
);
```

Discussion
In most cases you do not need to use this function, because the system invokes your callback function for you. See the `DataBrowserTrackingProcPtr` (page 2259) callback function for more information and for a description of the parameters.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.1 and later.

Declared In
`HIDataBrowser.h`

IsDataBrowserItemSelected

Checks to see if a data item is selected.

```
Boolean IsDataBrowserItemSelected (
   ControlRef browser,
   DataBrowserItemID item
);
```

Parameters

browser
A data browser.

item
The item ID of the item to check.

Return Value
A value of `true` if the item is a member of the current selection.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

MoveDataBrowserSelectionAnchor

Moves or extends the current selection.

```
OSStatus MoveDataBrowserSelectionAnchor (
   ControlRef browser,
   DataBrowserSelectionAnchorDirection direction,
   Boolean extendSelection
);
```

Parameters

browser

A data browser.

direction

The direction to move or extend the current selection. You can pass any one of the constants described in "Selection Anchor Directions" (page 2293).

extendSelection

On input, a value that specifies whether to extend the current selection (`true`) or move the selection (`false`).

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

NewDataBrowserAcceptDragUPP

Creates a universal procedure pointer to an accept-drag callback function.

```
DataBrowserAcceptDragUPP NewDataBrowserAcceptDragUPP (
   DataBrowserAcceptDragProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your accept-drag callback function.

Return Value
The universal procedure pointer.

Discussion
See the `DataBrowserAcceptDragProcPtr` (page 2233) callback function.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.

Declared In
`HIDataBrowser.h`

NewDataBrowserAddDragItemUPP

Creates a universal procedure pointer to an add-drag-item callback function.

```
DataBrowserAddDragItemUPP NewDataBrowserAddDragItemUPP (
   DataBrowserAddDragItemProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your add-drag-item callback function.

Return Value

The universal procedure pointer.

Discussion

See the `DataBrowserAddDragItemProcPtr` (page 2234) callback function.

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.0 and later.

Declared In

`HIDataBrowser.h`

NewDataBrowserDrawItemUPP

Creates a universal procedure pointer to a draw-item callback function.

```
DataBrowserDrawItemUPP NewDataBrowserDrawItemUPP (
   DataBrowserDrawItemProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your draw-item callback function.

Return Value

The universal procedure pointer.

Discussion

See the `DataBrowserDrawItemProcPtr` (page 2235) callback function.

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.1 and later.

Declared In

`HIDataBrowser.h`

NewDataBrowserEditItemUPP

Creates a universal procedure pointer to an edit-item callback function.

```
DataBrowserEditItemUPP NewDataBrowserEditItemUPP (
   DataBrowserEditItemProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your edit-item callback function.

Return Value

The universal procedure pointer.

Discussion

See the `DataBrowserEditItemProcPtr` (page 2237) callback function.

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.1 and later.

Declared In

`HIDataBrowser.h`

NewDataBrowserGetContextualMenuUPP

Creates a universal procedure pointer to a get-contextual-menu callback function.

```
DataBrowserGetContextualMenuUPP NewDataBrowserGetContextualMenuUPP (
   DataBrowserGetContextualMenuProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your get-contextual-menu callback function.

Return Value

The universal procedure pointer.

Discussion

See the `DataBrowserGetContextualMenuProcPtr` (page 2238) callback function.

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.0 and later.

Declared In

`HIDataBrowser.h`

NewDataBrowserHitTestUPP

Creates a universal procedure pointer to a hit-test callback function.

```
DataBrowserHitTestUPP NewDataBrowserHitTestUPP (
   DataBrowserHitTestProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your hit-test callback function.

Return Value
The universal procedure pointer.

Discussion
See the `DataBrowserHitTestProcPtr` (page 2240) callback function.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.1 and later.

Declared In
`HIDataBrowser.h`

NewDataBrowserItemAcceptDragUPP

Creates a universal procedure pointer to an item-accept-drag callback function.

```
DataBrowserItemAcceptDragUPP NewDataBrowserItemAcceptDragUPP (
   DataBrowserItemAcceptDragProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your item-accept-drag callback function.

Return Value
The universal procedure pointer.

Discussion
See the `DataBrowserItemAcceptDragProcPtr` (page 2242) callback function.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.1 and later.

Declared In
`HIDataBrowser.h`

NewDataBrowserItemCompareUPP

Creates a universal procedure pointer to an item-comparison callback function.

```
DataBrowserItemCompareUPP NewDataBrowserItemCompareUPP (
   DataBrowserItemCompareProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your item-comparison callback function.

Return Value

The universal procedure pointer.

Discussion

See the `DataBrowserItemCompareProcPtr` (page 2243) callback function.

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.0 and later.

Declared In

`HIDataBrowser.h`

NewDataBrowserItemDataUPP

Creates a universal procedure pointer to an item-data callback function.

```
DataBrowserItemDataUPP NewDataBrowserItemDataUPP (
   DataBrowserItemDataProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your item-data callback function.

Return Value

The universal procedure pointer.

Discussion

See the `DataBrowserItemDataProcPtr` (page 2245) callback function.

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.0 and later.

Declared In

`HIDataBrowser.h`

NewDataBrowserItemDragRgnUPP

Creates a universal procedure pointer to an item-drag-region callback function.

```
DataBrowserItemDragRgnUPP NewDataBrowserItemDragRgnUPP (
   DataBrowserItemDragRgnProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your item-drag-region callback function.

Return Value

The universal procedure pointer.

Discussion

See the `DataBrowserItemDragRgnProcPtr` (page 2246) callback function.

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.1 and later.

Declared In

`HIDataBrowser.h`

NewDataBrowserItemHelpContentUPP

Creates a universal procedure pointer to an item-help-content callback function.

```
DataBrowserItemHelpContentUPP NewDataBrowserItemHelpContentUPP (
   DataBrowserItemHelpContentProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your item-help-content callback function.

Return Value

The universal procedure pointer.

Discussion

See the `DataBrowserItemHelpContentProcPtr` (page 2248) callback function.

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.0 and later.

Declared In

`HIDataBrowser.h`

NewDataBrowserItemNotificationUPP

Creates a universal procedure pointer to an item-notification callback function.

```
DataBrowserItemNotificationUPP NewDataBrowserItemNotificationUPP (
   DataBrowserItemNotificationProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your item-notification callback function.

Return Value

The universal procedure pointer.

Discussion

See the `DataBrowserItemNotificationProcPtr` (page 2250) callback function.

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.0 and later.

Declared In

`HIDataBrowser.h`

NewDataBrowserItemNotificationWithItemUPP

Creates a universal procedure pointer to an item-notification-with-data callback function.

```
DataBrowserItemNotificationWithItemUPP NewDataBrowserItemNotificationWithItemUPP
(
   DataBrowserItemNotificationWithItemProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your item-notification-with-data callback function.

Return Value

The universal procedure pointer.

Discussion

See the `DataBrowserItemNotificationWithItemProcPtr` (page 2251) callback function.

Availability

Available in CarbonLib 1.5 and later.

Available in Mac OS X version 10.1 and later.

Declared In

`HIDataBrowser.h`

NewDataBrowserItemReceiveDragUPP

Creates a universal procedure pointer to an item-receive-drag callback function.

```
DataBrowserItemReceiveDragUPP NewDataBrowserItemReceiveDragUPP (
   DataBrowserItemReceiveDragProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your item-receive-drag callback function.

Return Value
The universal procedure pointer.

Discussion
See the `DataBrowserItemReceiveDragProcPtr` (page 2254) callback function.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.1 and later.

Declared In
`HIDataBrowser.h`

NewDataBrowserItemUPP

Creates a universal procedure pointer to an item-iterator callback function.

```
DataBrowserItemUPP NewDataBrowserItemUPP (
   DataBrowserItemProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your item-iterator callback function.

Return Value
The universal procedure pointer.

Discussion
See the `DataBrowserItemProcPtr` (page 2253) callback function.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.

Declared In
`HIDataBrowser.h`

NewDataBrowserPostProcessDragUPP

Creates a universal procedure pointer to a postprocess-drag callback function.

```
DataBrowserPostProcessDragUPP NewDataBrowserPostProcessDragUPP (
   DataBrowserPostProcessDragProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your postprocess-drag callback function.

Return Value

The universal procedure pointer.

Discussion

See the `DataBrowserPostProcessDragProcPtr` (page 2255) callback function.

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.0 and later.

Declared In

`HIDataBrowser.h`

NewDataBrowserReceiveDragUPP

Creates a universal procedure pointer to a receive-drag callback function.

```
DataBrowserReceiveDragUPP NewDataBrowserReceiveDragUPP (
   DataBrowserReceiveDragProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your receive-drag callback function.

Return Value

The universal procedure pointer.

Discussion

See the `DataBrowserReceiveDragProcPtr` (page 2256) callback function.

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.0 and later.

Declared In

`HIDataBrowser.h`

NewDataBrowserSelectContextualMenuUPP

Creates a universal procedure pointer to a select-contextual-menu callback function.

```
DataBrowserSelectContextualMenuUPP NewDataBrowserSelectContextualMenuUPP (
   DataBrowserSelectContextualMenuProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your select-contextual-menu callback function.

Return Value
The universal procedure pointer.

Discussion
See the `DataBrowserSelectContextualMenuProcPtr` (page 2257) callback function.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.

Declared In
`HIDataBrowser.h`

NewDataBrowserTrackingUPP

Creates a universal procedure pointer to a tracking callback function.

```
DataBrowserTrackingUPP NewDataBrowserTrackingUPP (
   DataBrowserTrackingProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your tracking callback function.

Return Value
The universal procedure pointer.

Discussion
See the `DataBrowserTrackingProcPtr` (page 2259) callback function.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.1 and later.

Declared In
`HIDataBrowser.h`

OpenDataBrowserContainer

Opens a data browser container.

```
OSStatus OpenDataBrowserContainer (
   ControlRef browser,
   DataBrowserItemID container
);
```

Parameters

browser

A data browser.

container

The item ID of the container to open.

Return Value

A result code. See "Data Browser Result Codes" (page 2298).

Discussion

Normally the user navigates through a data hierarchy by clicking the disclosure triangle next to a container item in list view, or the container item (such as a folder icon) in column view. In either of these cases, the system automatically opens or closes the container. Under some circumstances your application may need to open or close a container programmatically, such as when you are restoring a display to its last known state. In such cases, you can call the function `OpenDataBrowserContainer` to disclose items in a container or the function `CloseDataBrowserContainer` (page 2124) to hide items in a container.

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.0 and later.

Not available to 64-bit applications.

Declared In

`HIDataBrowser.h`

RemoveDataBrowserItems

Removes one or more items from a data browser.

```
OSStatus RemoveDataBrowserItems (
   ControlRef browser,
   DataBrowserItemID container,
   ItemCount numItems,
   const DataBrowserItemID *items,
   DataBrowserPropertyID preSortProperty
);
```

Parameters

browser

A data browser.

container

An item ID or the constant `kDataBrowserNoItem`. Pass the item ID that uniquely identifies the container from which you want to remove items. Pass `kDataBrowserNoItem` to remove items from the root container.

numItems

The number of items in the array pointed to by the `items` parameter. To remove all items pass `0` and also pass `NULL` in the items parameter.

items

A pointer to an array of item ID values for the items you want to remove from the data browser. You can delete an arbitrary list of items from a container. To remove all items, pass `NULL`, and also pass `0` in the `numItems` parameter.

preSortProperty

The property ID of the column whose sorting order is the same as the sorting order of the `items` array. A property ID is a value that identifies a column independent of its position in a data browser. Pass `kDataBrowserItemNoProperty` if the `items` array is not sorted or if you don't know the sorting order. You'll get the best performance from this function if you provide a sorting order.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

RemoveDataBrowserTableViewColumn

Removes a column from a list view data browser.

```
OSStatus RemoveDataBrowserTableViewColumn (
   ControlRef browser,
   DataBrowserTableViewColumnID column
);
```

Parameters

browser

A data browser.

column

The property ID for the list view column you want to remove. The `DataBrowserTableViewColumnID` data type is the same as the `DataBrowserPropertyID` data type.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
This function works only for list view.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

RevealDataBrowserItem

Scrolls an item into view, optionally bringing a particular part of that item into view.

```
OSStatus RevealDataBrowserItem (
   ControlRef browser,
   DataBrowserItemID item,
   DataBrowserPropertyID propertyID,
   DataBrowserRevealOptions options
);
```

Parameters

browser

A data browser.

item

The item ID of the item to scroll into view.

propertyID

The property ID of the column to scroll into view. A property ID is a four-character sequence that you assign to represent a column in list view. For column view, pass `kDataBrowserNoItem`.

options

A value that specifies how to position the item in the data browser. See "Reveal Options" (page 2292) for a list of the constants you can supply.

Return Value

A result code. See "Data Browser Result Codes" (page 2298).

Discussion

In most cases the system takes care of scrolling for you. However, this function is useful if your application supports type-select and you want to scroll a matching item into view.

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.0 and later.

Not available to 64-bit applications.

Declared In

`HIDataBrowser.h`

SetDataBrowserActiveItems

Sets what determines the active state of the items in a data browser.

```
OSStatus SetDataBrowserActiveItems (
   ControlRef browser,
   Boolean active
);
```

Parameters

browser

A data browser.

active

A value that specifies the new active state for the items displayed in the list. Pass `true` to make the active state of each item determined by what your callback reports for each item's `kDataBrowserItemIsActiveProperty` property, or `false` to make all items inactive. Inactive items appear dimmed.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
Passing `true` for the `active` parameter does not make all the items active. Instead it sets the active state of each individual item according to the value associated with the `kDataBrowserItemIsActiveProperty` property for that item. This means if the active property for an item is set to `false`, and you pass `true` for the `active` parameter, then the item is inactive.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

SetDataBrowserCallbacks

Sets the callback routines to use with a data browser, replacing any previously installed callbacks.

```
OSStatus SetDataBrowserCallbacks (
   ControlRef browser,
   const DataBrowserCallbacks *callbacks
);
```

Parameters

browser

A data browser.

callbacks

A pointer to a `DataBrowserCallbacks` structure that is filled out with universal procedure pointers (UPPs) to the callback routines your application provides. At a minimum, you need to provide a UPP to an item-data callback (`DataBrowserItemDataProcPtr` (page 2245)).

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
Before calling the function `SetDataBrowserCallbacks` you must first call `InitDataBrowserCallbacks` (page 2175) to initialize the data browser callback structure. Calling `SetDataBrowserCallbacks` replaces any callback routines you installed previously by calling this function.

You can supply the following callbacks. If you don't supply callbacks in cases for which it's optional, you get the default behavior provided by the data browser API.

- DataBrowserItemDataProcPtr (page 2245). You must provide this callback because communicates the text, icons, or other data to display in list view. It also communicates the metadata that defines how data is displayed, such as whether or not an item is a container or has a parent. If you set up your data browser to allow the user to edit, this callback informs your application when the user makes a change.
- DataBrowserItemCompareProcPtr (page 2243). You must provide a sorting callback if you want users to be able to sort the items in a column. If you want containers in a hierarchical list to be sorted independently, then you must provide a sorting callback that handles the hierarchical lists appropriately.
- DataBrowserItemNotificationProcPtr (page 2250). You must provide this (or the next) callback if you have hierarchical data in a list, or if you use column view.
- DataBrowserItemNotificationWithItemProcPtr (page 2251) (Mac OS X only)
- DataBrowserAddDragItemProcPtr (page 2234). You can provide this callback to allow dragging out of your data browser.
- DataBrowserAcceptDragProcPtr (page 2233). You can provide this callback to allow dragging into your data browser; use this to accept a drag item.
- DataBrowserReceiveDragProcPtr (page 2256). You can provide this callback to allow dragging into your data browser; use this to receive a drag item.
- DataBrowserPostProcessDragProcPtr (page 2255). If you provide callbacks to allow dragging into your data browser, you can optionally provide a postprocess-drag callback to perform cleanup tasks.
- DataBrowserGetContextualMenuProcPtr (page 2238). You can optionally support a contextual menu. If so, you'll need to provide the next callback too.
- DataBrowserSelectContextualMenuProcPtr (page 2257)
- DataBrowserItemHelpContentProcPtr (page 2248). You can optionally provide help tags.

Note that this function sets a different set of callbacks from those that are set by calling the function SetDataBrowserCustomCallbacks (page 2203).

To replace a callback, you first need to get the current set of callbacks by calling the function GetDataBrowserCallbacks (page 2140). Set the appropriate fields in the DataBrowserCallbacks structure to your callback. Then you call the function SetDataBrowserCallbacks. Your application can set as many callbacks as appropriate.

The following code shows how to assign UPPs to the callbacks structure and then call the function SetDataBrowserCallbacks. The code assumes you have already called the function InitDataBrowserCallbacks (page 2175) to initialize the data browser callback structure.

```
myCallbacks.u.v1.itemNotificationCallback =
        NewDataBrowserItemNotificationUPP (MyItemNotificationCallback);

myCallbacks.u.v1.acceptDragCallback =
        NewDataBrowserAcceptDragUPP (MyAcceptDragCallback);
myCallbacks.u.v1.receiveDragCallback =
        NewDataBrowserReceiveDragUPP (MyReceiveDragCallback);
myCallbacks.u.v1.addDragItemCallback =
        NewDataBrowserAddDragItemUPP (MyAddDragItemCallback);
myCallbacks.u.v1.itemHelpContentCallback =
        NewDataBrowserItemHelpContentUPP (MyItemHelpContentCallback);
myCallbacks.u.v1.getContextualMenuCallback =
        NewDataBrowserGetContextualMenuUPP (MyGetContextualMenuCallback);
myCallbacks.u.v1.selectContextualMenuCallback =
```

```
        NewDataBrowserSelectContextualMenuUPP (
                    MySelectContextualMenuCallback);
SetDataBrowserCallbacks (browser, &myCallbacks);
```

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

SetDataBrowserColumnViewDisplayType

Sets the display type for a data browser in column view.

```
OSStatus SetDataBrowserColumnViewDisplayType (
   ControlRef browser,
   DataBrowserPropertyType propertyType
);
```

Parameters

`browser`
A data browser.

`propertyType`
The data type to be displayed in the data browser. The default is `kDataBrowserIconAndTextType`. Currently this is the only value you can supply for column view.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
This function is effectively not functional because no display types other than `kDataBrowserIconAndTextType` are currently supported. Note that the rightmost column can have the attribute `kDataBrowserColumnViewPreviewProperty` as long as you provide a callback to display the appropriate icon and text information in the preview column.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

SetDataBrowserColumnViewPath

Sets a path for a column view.

```
OSStatus SetDataBrowserColumnViewPath (
   ControlRef browser,
   UInt32 length,
   const DataBrowserItemID *path
);
```

Parameters

browser

A data browser.

length

The number of items in the array passed in the `path` parameter.

path

The address to the first item in the array of item ID values that specifies the path. Array element `0` is the root; array element `N - 1` is the target.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

SetDataBrowserCustomCallbacks

Sets the custom callback routines to use with a data browser, replacing any previously installed custom callbacks.

```
OSStatus SetDataBrowserCustomCallbacks (
   ControlRef browser,
   const DataBrowserCustomCallbacks *callbacks
);
```

Parameters

browser

A data browser.

callbacks

A pointer to a `DataBrowserCustomCallbacks` structure that is filled out with universal procedure pointers (UPPs) to the custom callback routines your application provides.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
Before calling the function `SetDataBrowserCustomCallbacks` you must first call `InitDataBrowserCustomCallbacks` (page 2176) to initialize the data browser custom callback structure. Calling `SetDataBrowserCustomCallbacks` replaces any callback routines you installed previously by calling this function.

You can supply the following custom callback routines.

- DataBrowserDrawItemProcPtr (page 2235). This callback is invoked by the data browser whenever your content needs to be drawn. You must supply this callback for data whose display type is kDataBrowserCustomType.
- DataBrowserEditItemProcPtr (page 2237). Supply this callback when you want to support editing of your content.
- DataBrowserHitTestProcPtr (page 2240). You can provide this callback to determine if the pointer is over content that can be selected or dragged.
- DataBrowserTrackingProcPtr (page 2259). This callback implements custom tracking behavior.
- DataBrowserItemDragRgnProcPtr (page 2246). You can supply this callback when you need to determine which part of an item to use to create a transparent image for a dragged item.
- DataBrowserItemAcceptDragProcPtr (page 2242). This callback determines if an item can accept a drag object.
- DataBrowserItemReceiveDragProcPtr (page 2254). This callback receives a drop over an item.

Note that this is a different set of callbacks from those that are installed by calling the function SetDataBrowserCallbacks (page 2200).

To replace a callback, you first need to set the appropriate fields in the DataBrowserCustomCallbacks structure to your callbacks. Then you call the function SetDataBrowserCustomCallbacks. The following code shows how to set custom callbacks. It assumes you have already called the function InitDataBrowserCustomCallbacks (page 2176) to initialize the data browser custom callback structure. Your application can set as many callbacks as appropriate.

```
myCustomCallbacks.u.v1.drawItemCallback =
        NewDataBrowserDrawItemUPP (MyDataBrowserDrawItemCallback);
myCustomCallbacks.u.v1.editItemCallback =
        NewDataBrowserEditItemUPP (MyDataBrowserEditItemCallback);
SetDataBrowserCustomCallbacks (browser,&myCustomCallbacks);
```

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
HIDataBrowser.h

SetDataBrowserEditItem

Programmatically starts or ends an editing session.

```
OSStatus SetDataBrowserEditItem (
   ControlRef browser,
   DataBrowserItemID item,
   DataBrowserPropertyID property
);
```

Parameters

browser
A data browser.

item
The item ID of the item to make editable.

property
The property ID of the item to make editable.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
You can call the function `SetDataBrowserEditItem` to begin or end an editing session programmatically for a text item. To begin an editing session for a text item, specify its item ID and property ID. To end an editing session, provide the constant `kDataBrowserNoItem` as the item ID number.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

SetDataBrowserEditText

Modifies the displayed contents of a text item while it is being edited.

```
OSStatus SetDataBrowserEditText (
   ControlRef browser,
   CFStringRef text
);
```

Parameters

browser
A data browser.

text
A CFString object that specifies the text to edit. The data browser makes its own copy of this object so it is safe to release your own reference after you call this function.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
You can use this function to programmatically change the text. For example, to paste data in response to a Paste command. This function is useful only if an edit session is in progress for an item. You can check whether can get session is open by calling the function `GetDataBrowserEditItem` (page 2143).

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

SetDataBrowserHasScrollBars

Sets the display state of horizontal and vertical scroll bars for a list view data browser.

```
OSStatus SetDataBrowserHasScrollBars (
   ControlRef browser,
   Boolean horiz,
   Boolean vert
);
```

Parameters

browser

A list view data browser.

horiz

A value that specifies whether to display the browser control with (`true`) or without (`false`) a horizontal scroll bar.

vert

A value that specifies whether to display the browser control with (`true`) or without (`false`) a vertical scroll bar.

Return Value

A result code. See "Data Browser Result Codes" (page 2298).

Discussion

If the list your application displays is small and its coordinates do not extend beyond the bounds of the area used to display the list, then you can call `SetDataBrowserHasScrollBars` to turn off the display of scroll bars.

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.0 and later.

Not available to 64-bit applications.

Declared In

`HIDataBrowser.h`

SetDataBrowserItemDataBooleanValue

Specifies a Boolean value for an item.

```
OSStatus SetDataBrowserItemDataBooleanValue (
   DataBrowserItemDataRef itemData,
   Boolean theData
);
```

Parameters

itemData

The item data reference for the item whose Boolean value you want to set. The item data reference is passed to the callback routine from which you are calling the function `SetDataBrowserItemDataBooleanValue`.

theData

The value to display.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
Your item-data callback calls this function in response to an inquiry for the following properties:

- `kDataBrowserItemIsActiveProperty`
- `kDataBrowserItemIsSelectableProperty`
- `kDataBrowserItemIsEditableProperty`
- `kDataBrowserItemIsContainerProperty`
- `kDataBrowserItemIsOpenableProperty`
- `kDataBrowserItemIsClosableProperty`
- `kDataBrowserItemIsSortableProperty`

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

SetDataBrowserItemDataButtonValue

Specifies a checkbox value.

```
OSStatus SetDataBrowserItemDataButtonValue (
   DataBrowserItemDataRef itemData,
   ThemeButtonValue theData
);
```

Parameters

itemData
The item data reference for the item whose checkbox value you want to set. The item data reference is passed to the callback routine from which you are calling the function `SetDataBrowserItemDataButtonValue`.

theData
The checkbox setting. You can supply any of the following theme button value constants defined by the Appearance Manager:

- `kThemeButtonOff` draws a checkbox that is not selected.
- `kThemeButtonOn` draws a checkbox that is selected.
- `kThemeButtonMixed` draws a checkbox that in a mixed state, indicating that a setting is on for some items in a selection and off for others.

See *Appearance Manager Reference* for more information.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
Your item-data callback calls this function in response to a set-data request for items that have the display type `kDataBrowserCheckboxType`.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

SetDataBrowserItemDataDateTime

Specifies, as a 32-bit value, a date and time value to display.

```
OSStatus SetDataBrowserItemDataDateTime (
   DataBrowserItemDataRef itemData,
   SInt32 theData
);
```

Parameters

itemData
The item data reference for the item whose date and time value you want to set. The item data reference is passed to the callback routine from which you are calling the function `SetDataBrowserItemDataDateTime`.

theData
A 32-bit value that represents the number of elapsed seconds since midnight, January 1, 1904. For more information about date and time encodings used in the Mac OS, see *Date, Time, and Measurement Utilities Reference*.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
This function works only with items that have the property `kDataBrowserDateTimeType`. If the column has the property `kDataBrowserRelativeDateTime`, the date is displayed relative to the current time for the computer. For example, a time 24 hours before the current time is displayed as "Yesterday." Other examples of relative date and time values are "Today, 1:45 PM" and "Yesterday, 7:30 AM."

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

SetDataBrowserItemDataDrawState

Specifies whether to draw a checkbox in the active or inactive state.

```
OSStatus SetDataBrowserItemDataDrawState (
   DataBrowserItemDataRef itemData,
   ThemeDrawState theData
);
```

Parameters

itemData

The item data reference for the item whose drawing state you want to set. This value is passed to the callback routine from which you are calling the function `SetDataBrowserItemDataDrawState`.

theData

The drawing state to use for the checkbox item. You can supply the following theme drawing state constants:

- `kThemeStateInactive` draws the item in the inactive state.
- `kThemeStateActive` draws the item in the active state.

See *Appearance Manager Reference* for more information on these constants.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
Your item-data callback calls this function in response to a set-data request for items that have the display type `kDataBrowserCheckboxType`.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

SetDataBrowserItemDataIcon

Specifies the icon to draw.

```
OSStatus SetDataBrowserItemDataIcon (
   DataBrowserItemDataRef itemData,
   IconRef theData
);
```

Parameters

itemData

The item data reference for the item whose icon you want to set. This value is passed to the callback routine from which you are calling the function `SetDataBrowserItemDataIcon`.

theData

The icon to display. The data browser retains the icon, so you may release the `IconRef` after the function returns.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
You call the function `SetDataBrowserItemDataIcon` from within a `DataBrowserItemDataProcPtr` (page 2245) callback routine to specify an icon to draw. You can specify an icon for any column that has the `kDataBrowserIconType` display type or the `kDataBrowserIconAndTextType` display type.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

SetDataBrowserItemDataIconTransform

Specifies a transformation to apply to an icon when it is drawn.

```
OSStatus SetDataBrowserItemDataIconTransform (
   DataBrowserItemDataRef itemData,
   IconTransformType theData
);
```

Parameters

itemData
The item data reference for the item whose icon transformation you want to set. This value is passed to the callback routine from which you are calling the function `SetDataBrowserItemDataIconTransform`.

theData
An icon transformation type that specifies how to modify the appearance of the icon. You can pass any of the icon transformation constants defined by Icon Services and Utilities. See *Icon Services and Utilities Reference* for more information.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
This function works only with items that either have the property `kDataBrowserIconAndTextType` or `kDataBrowserIconType`.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

SetDataBrowserItemDataItemID

Communicates a property of an item when that property is another item's ID.

```
OSStatus SetDataBrowserItemDataItemID (
   DataBrowserItemDataRef itemData,
   DataBrowserItemID theData
);
```

Parameters

itemData

The item data reference passed to your item-data callback.

theData

The item ID to set.

Return Value

A result code. See "Data Browser Result Codes" (page 2298).

Discussion

To display hierarchical data correctly the data browser needs to know whether an item is a container and whether the item is in a container (has a parent). So it sends a get-data request for the properties `kDataBrowserParentContainerProperty` and `kDataBrowserContainerAliasIDProperty` to your item-data callback.

The property `kDataBrowserContainerAliasIDProperty` is sent to your item-data callback to provide your application with a chance to follow an alias that the item might represent. If the incoming item is an alias to another item, you can call `SetDataBrowserItemDataItemID` to inform the data browser which other item the incoming item points to.

The property `kDataBrowserParentContainerProperty` is sent to your item-data callback to check whether an item has a parent. If it does, you call `SetDataBrowserItemDataItemID`, supplying the item ID of the parent in the parameter `theData`. If the item has no parent, set `theData` to `0`.

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.0 and later.

Not available to 64-bit applications.

Declared In

`HIDataBrowser.h`

SetDataBrowserItemDataLongDateTime

Specifies, as a 64-bit value, a date and time value to display.

```
OSStatus SetDataBrowserItemDataLongDateTime (
   DataBrowserItemDataRef itemData,
   const LongDateTime *theData
);
```

Parameters

itemData

The item data reference for the item whose long date and time value you want to set. The item data reference is passed to the callback routine from which you are calling the function `SetDataBrowserItemDataLongDateTime`.

theData

A pointer to a 64-bit value that represents the time as the number of elapsed seconds since midnight, January 1, 1904. For more information about date and time encodings used in the Mac OS, see *Date, Time, and Measurement Utilities Reference* in Carbon Text & International Documentation.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
This function works only with items that have the property `kDataBrowserDateTimeType`. If the column has the property `kDataBrowserRelativeDateTime`, the date is displayed relative to the current time for the computer. For example, a time 24 hours before the current time is displayed as "Yesterday." Other examples of relative date and time values are "Today, 1:45 PM" and "Yesterday, 7:30 AM."

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

SetDataBrowserItemDataMaximum

Specifies the maximum integer value that can be displayed for an item; useful for such display types as sliders, progress bars, relevance indicators, and pop-up menus.

```
OSStatus SetDataBrowserItemDataMaximum (
   DataBrowserItemDataRef itemData,
   SInt32 theData
);
```

Parameters

itemData

The item data reference for the item whose maximum value you want to set. The item data reference is passed to the callback routine from which you are calling the function `SetDataBrowserItemDataMaximum`.

theData

The maximum setting for content displayed for the item.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

SetDataBrowserItemDataMenuRef

Sets the pop-up menu to display.

```
OSStatus SetDataBrowserItemDataMenuRef (
   DataBrowserItemDataRef itemData,
   MenuRef theData
);
```

Parameters

itemData

The item data reference for the item whose pop-up menu value you want to set. The item data reference is passed to the callback routine from which you are calling the function `SetDataBrowserItemDataMenuRef`.

theData

The pop-up menu set to the value you want to display. The system retains the menu reference that you pass; you must release it when you no longer need it. Pass `NULL` if you no longer want a menu.

Return Value

A result code. See "Data Browser Result Codes" (page 2298).

Discussion

Your item-data callback calls this function in response to a set-data request for an item whose display type is `kDataBrowserPopupMenuType`.

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.0 and later.

Not available to 64-bit applications.

Declared In

`HIDataBrowser.h`

SetDataBrowserItemDataMinimum

Specifies the minimum integer value that can be displayed for an item; useful for such display types as sliders, progress bars, relevance indicators, and pop-up menus.

```
OSStatus SetDataBrowserItemDataMinimum (
   DataBrowserItemDataRef itemData,
   SInt32 theData
);
```

Parameters

itemData

The item data reference for the item whose minimum value you want to set. The item data reference is passed to the callback routine from which you are calling the function `SetDataBrowserItemDataMinimum`.

theData

The minimum setting for the displayed content.

Return Value

A result code. See "Data Browser Result Codes" (page 2298).

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

SetDataBrowserItemDataRGBColor

Specifies a color to use when drawing an item.

```
OSStatus SetDataBrowserItemDataRGBColor (
   DataBrowserItemDataRef itemData,
   const RGBColor *theData
);
```

Parameters

itemData

The item data reference for the item whose color you want to set. This value is passed to the callback routine from which you are calling the function `SetDataBrowserItemDataRGBColor`.

theData

A pointer to the RGB values that specify the color to use.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
Typically this function is used to set the color for an item that is an icon type. Your item-data callback calls this function in response to a set-data request for items that have display type `kDataBrowserIconType` or `kDataBrowserIconAndTextType`.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

SetDataBrowserItemDataText

Specifies the text to draw.

```
OSStatus SetDataBrowserItemDataText (
   DataBrowserItemDataRef itemData,
   CFStringRef theData
);
```

Parameters

itemData

The item data reference for the item whose text you want to set. This value is passed to the callback routine from which you are calling the function `SetDataBrowserItemDataText`.

theData

The CFString object that contains the text you want to draw. You are responsible for releasing the CFString object.

Return Value

A result code. See "Data Browser Result Codes" (page 2298).

Discussion

You call the function `SetDataBrowserItemDataText` from inside a data callback routine when the item being drawn is inside a column that has the `kDataBrowserTextType` display type or the `kDataBrowserIconAndTextType` display type.

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.0 and later.

Not available to 64-bit applications.

Declared In

`HIDataBrowser.h`

SetDataBrowserItemDataValue

Sets the value of an item; useful for such display types as sliders, progress bars, relevance indicators, and pop-up menus.

```
OSStatus SetDataBrowserItemDataValue (
   DataBrowserItemDataRef itemData,
   SInt32 theData
);
```

Parameters

itemData

The item data reference for the item whose integer value you want to set. The item data reference is passed to the callback routine from which you are calling the function `SetDataBrowserItemDataValue`.

theData

The value to display. The value must be between the minimum and maximum values specified by calling the functions `SetDataBrowserItemDataMinimum` (page 2213) and `SetDataBrowserItemDataMaximum` (page 2212). Values displayed by a progress bar can vary between the minimum and maximum values, inclusive.

Return Value

A result code. See "Data Browser Result Codes" (page 2298).

Discussion
Your application calls the function `SetDataBrowserItemDataValue` to set a new value for a display type when your item-data callback routine is called with the `setValue` parameter set to `false`.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

SetDataBrowserListViewDisclosureColumn

Specifies whether there is a column that has disclosure triangles and, if so, which column.

```
OSStatus SetDataBrowserListViewDisclosureColumn (
   ControlRef browser,
   DataBrowserTableViewColumnID column,
   Boolean expandableRows
);
```

Parameters

browser
A data browser.

column
The property ID for the column for which you want to set as disclosure column. Only one column in list view can be designated as a disclosure column. Pass `kDataBrowserNoItemProperty` if you do not want a disclosure column. The `DataBrowserTableViewColumnID` data type is the same as the `DataBrowserPropertyID` data type.

expandableRows
A value that specifies how a disclosed row behaves. Pass `true` to have a container open as a single row with an expanded height. Pass `false` to have a container opens to expose other rows. See the Discussion for more details on expandable rows.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
A disclosure triangle next to an item denotes the item is a container. You can use the `expandableRows` parameter to specify whether an opened container displays its items in individual rows, as shown in the top of Figure 27-1 or increases its row height to accommodate the contained information, as shown in the bottom of the figure.

Figure 27-1 A container can open to more rows or expand to show more information

▶ Paper types	

▼ Paper types	
Plain	Letter
Photo Glossy	8 X 10 Borderless

▶ Layout

▼ Layout	
Pages per sheet	2
Layout direction	Left to right
Order	Back to front

When the `expandableRows` parameter is set to `true`:

- Disclosure triangles are drawn top-justified in the row.
- Custom row height, if any, for that row is respected only while the row is disclosed. At other times, the default row height is used.

When the `expandableRows` parameter is set to `false`:

- Disclosure triangles are centered vertically in the row.
- Custom row height, if any, for that row is always respected.

When a disclosure triangle is clicked by the user, your application receives the same notifications regardless of whether `expandableRows` is set to `true` or `false`. When your application receives a notification that an expandable row is toggled to open, call the function `SetDataBrowserTableViewItemRowHeight` (page 2227) to set the row to the appropriate height.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

SetDataBrowserListViewHeaderBtnHeight

Sets the height of the rectangular area where the column title appears.

```
OSStatus SetDataBrowserListViewHeaderBtnHeight (
   ControlRef browser,
   UInt16 height
);
```

Parameters

browser

A data browser.

height

The height, in pixels, to use for the rectangular area where the column title appears. Pass `0` to turn off header button display. To turn on header button display, pass the value previously obtained from the function `GetDataBrowserListViewHeaderBtnHeight` (page 2159). The default height is currently 17 pixels.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

SetDataBrowserListViewHeaderDesc

Provides a description for a column title in list view.

```
OSStatus SetDataBrowserListViewHeaderDesc (
   ControlRef browser,
   DataBrowserTableViewColumnID column,
   DataBrowserListViewHeaderDesc *desc
);
```

Parameters

browser

A data browser.

column

The property ID for the column in list view whose title description you want to set. The `DataBrowserTableViewColumnID` data type is the same as the `DataBrowserPropertyID` data type.

desc

The list view header description structure that you have filled out with data that describes the appearance of a column title in list view.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
This functions allows you to change the behavior or appearance of a column title. Typically you call this function if your application:

- Supports switching between list and column views, and you need to restore previously saved list view title information.
- Creates a list view data browser programmatically and the columns have titles.

Availability
Available in CarbonLib 1.5 and later.
Available in Mac OS X version 10.2 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

SetDataBrowserListViewUsePlainBackground

Specifies whether list view uses a plain white background.

```
OSStatus SetDataBrowserListViewUsePlainBackground (
   ControlRef browser,
   Boolean usePlainBackground
);
```

Parameters

`browser`
A data browser.

`usePlainBackground`
A value that specifies whether to use a plain background (`true`) or not to use a plain background (`false`). A plain background is an all-white background. In Mac OS X, passing `false` currently does nothing, as Mac OS X supports only a plain white background. However, pass `true` if you want a plain white background just in case the API changes in the future. In Mac OS 9, passing `false` causes the data browser to use a shaded background.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
A list view that does not use a plain background can use colors or patterns to distinguish one column from another. For example, you could specify a color to designate a column as the sorted column.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

SetDataBrowserPropertyFlags

Sets the appearance and behavior attributes for a column in list view.

```
OSStatus SetDataBrowserPropertyFlags (
   ControlRef browser,
   DataBrowserPropertyID property,
   DataBrowserPropertyFlags flags
);
```

Parameters

browser

A data browser.

property

The property ID of the column whose appearance and behavior you want to set.

flags

The property flags to apply. A `DataBrowserPropertyFlags` value is a 32-bit value that is divided into four parts as follows:

- Bits 0–7 specify properties applied to the data browser as a whole—see "Property Flags: Universal" (page 2284)
- Bits 8–15 modify display behavior—see "Property Flags: Modifiers" (page 2285)
- Bits 16–23 are properties specific to list view—see "Property Flags: Offset and Mask for List View Properties" (page 2288) and "Property Flags: List View Column Behavior" (page 2289)
- Bits 24–31 can be defined by your application—see "Property Flags: Offset and Mask for Client-Defined Properties" (page 2290)

Return Value

A result code. See "Data Browser Result Codes" (page 2298).

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.0 and later.

Not available to 64-bit applications.

Declared In

`HIDataBrowser.h`

SetDataBrowserScrollBarInset

Sets the inset values to use for the scroll bars of a data browser.

```
OSStatus SetDataBrowserScrollBarInset (
   ControlRef browser,
   Rect *insetRect
);
```

Parameters

browser

A data browser.

insetRect

A pointer to a rectangle that specifies the inset values you want the data browser to use. The left and right fields contain the horizontal inset values for the horizontal scroll bar, and the top and bottom fields contain the vertical inset values for the vertical scroll bar.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
Your application can call the functions `GetDataBrowserScrollBarInset` (page 2162) and `SetDataBrowserScrollBarInset` if you want to place placards or controls beside the horizontal scroll bars or above the vertical ones. To do so, first call `GetDataBrowserScrollBarInset` to obtain the current settings. After modifying the current inset settings to provide space for the placard or control, call `SetDataBrowserScrollBarInset` with the new values.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

SetDataBrowserScrollPosition

Scrolls a list to the specified position.

```
OSStatus SetDataBrowserScrollPosition (
   ControlRef browser,
   UInt32 top,
   UInt32 left
);
```

Parameters

browser
A data browser.

top
The vertical scrolling position to use.

left
The horizontal scrolling position to use.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
The scrolling position `(0,0)` represents the home position, and is located at the top left of the data browser. Horizontal and vertical units are relative to the home position.

You can call this function to scroll a list to any arbitrary scrolling position. Normally, you use the function `GetDataBrowserScrollPosition` (page 2162) in conjunction with `SetDataBrowserScrollPosition` to save and restore the scrolling position of a list to the user's last scrolling position. These functions should not be used to scroll particular cells into the view. For that, call the function `RevealDataBrowserItem`.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
HIDataBrowser.h

SetDataBrowserSelectedItems

Modifies the current selection by adding items, removing items, or toggling the selection state of items.

```
OSStatus SetDataBrowserSelectedItems (
   ControlRef browser,
   ItemCount numItems,
   const DataBrowserItemID *items,
   DataBrowserSetOption operation
);
```

Parameters

browser
A data browser.

numItems
The number of item ID values stored in the array pointed to by the `items` parameter.

items
A pointer to an array of the item IDs to modify the selection with.

operation
The operation you want to perform on the current selection. You can add, assign, toggle, or remove the items specified by the `items` parameter. See "Selection State Options" (page 2293) for a list of the constants you can supply and a complete description of what each constant does.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
HIDataBrowser.h

SetDataBrowserSelectionFlags

Sets allowable selection behavior for a data browser.

```
OSStatus SetDataBrowserSelectionFlags (
   ControlRef browser,
   DataBrowserSelectionFlags selectionFlags
);
```

Parameters

browser
A data browser.

selectionFlags

Flags that specify the selection behavior you want to allow in the data browser. The flags control such things as whether discontinuous selections are allowed by the user. See "User Selection Flags" (page 2296) for detailed descriptions of these flags.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
HIDataBrowser.h

SetDataBrowserSortOrder

Sets the sorting order for a list in list view.

```
OSStatus SetDataBrowserSortOrder (
   ControlRef browser,
   DataBrowserSortOrder order
);
```

Parameters

browser

A data browser.

order

The sorting order. See "Sorting Orders" (page 2294) for a list of the constants you can supply.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
List view tracks the sorting order by column. In Mac OS X, setting the sorting order only affects the sorting order of the column currently set for sorting.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
HIDataBrowser.h

SetDataBrowserSortProperty

Designates the list view column to use for sorting.

```
OSStatus SetDataBrowserSortProperty (
   ControlRef browser,
   DataBrowserPropertyID property
);
```

Parameters

browser

A data browser.

property

The property ID of the column to use for sorting.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
If the list is not currently sorted, or if the list is currently sorted with a different column, then the list is sorted and redrawn. You can all the function `GetDataBrowserSortProperty` to obtain the property ID of the column currently used for sorting.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

SetDataBrowserTableViewColumnPosition

Changes the visual position of a column in list view.

```
OSStatus SetDataBrowserTableViewColumnPosition (
   ControlRef browser,
   DataBrowserTableViewColumnID column,
   DataBrowserTableViewColumnIndex position
);
```

Parameters

browser

A data browser.

column

The property ID for the list view column you want to move. The `DataBrowserTableViewColumnID` data type is the same as the `DataBrowserPropertyID` data type.

position

The position you want to move the column to.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
If you set your list to have the property `kDataBrowserListViewMovableColumn`, the user can rearrange columns by dragging. The function `SetDataBrowserTableViewColumnPosition` provides a way for your application to rearrange columns programmatically.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
HIDataBrowser.h

SetDataBrowserTableViewColumnWidth

Sets the default column width for all columns in a data browser.

```
OSStatus SetDataBrowserTableViewColumnWidth (
   ControlRef browser,
   UInt16 width
);
```

Parameters

browser
A data browser.

width
The column width, in pixels.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
You can override the default width for an individual list view column by calling the function SetDataBrowserTableViewNamedColumnWidth (page 2228).

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
HIDataBrowser.h

SetDataBrowserTableViewGeometry

Sets whether columns and rows can have variable widths in list view.

```
OSStatus SetDataBrowserTableViewGeometry (
   ControlRef browser,
   Boolean variableWidthColumns,
   Boolean variableHeightRows
);
```

Parameters

browser
A data browser.

variableWidthColumns
A Boolean value that specifies whether column widths can be variable (`true`) or not (`false`).

variableHeightRows
A Boolean value that specifies whether row heights can be variable (`true`) or not (`false`).

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
After you call the function `SetDataBrowserTableViewGeometry` to set up variable row heights or columns widths in list view, you can modify individual row heights or columns widths in list view by calling the appropriate function—either `SetDataBrowserTableViewItemRowHeight` (page 2227) or `SetDataBrowserTableViewNamedColumnWidth` (page 2228).

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

SetDataBrowserTableViewHiliteStyle

Sets the highlighting style to use for a list view data browser.

```
OSStatus SetDataBrowserTableViewHiliteStyle (
   ControlRef browser,
   DataBrowserTableViewHiliteStyle hiliteStyle
);
```

Parameters

browser
A list view data browser.

hiliteStyle
The highlighting style you want to use. See "Table View Highlighting Styles" (page 2294) for a description of the constants you can supply.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

SetDataBrowserTableViewItemRow

Changes the visual position for an item in a list view data browser.

```
OSStatus SetDataBrowserTableViewItemRow (
   ControlRef browser,
   DataBrowserItemID item,
   DataBrowserTableViewRowIndex row
);
```

Parameters

browser

A data browser.

item

The item ID for the item whose row you want to set.

row

The row index for the row you want to move the item to.

Return Value

A result code. See "Data Browser Result Codes" (page 2298).

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.0 and later.

Not available to 64-bit applications.

Declared In

`HIDataBrowser.h`

SetDataBrowserTableViewItemRowHeight

Sets the row height for a single row in a list view data browser.

```
OSStatus SetDataBrowserTableViewItemRowHeight (
   ControlRef browser,
   DataBrowserItemID item,
   UInt16 height
);
```

Parameters

browser

A data browser.

item

The item ID for the item whose row height you want to set.

height

The row height, in pixels.

Return Value

A result code. See "Data Browser Result Codes" (page 2298).

Discussion

Before calling this function, you must call the function `SetDataBrowserTableViewGeometry` (page 2225) to set up variable row heights.

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.0 and later.

Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

SetDataBrowserTableViewNamedColumnWidth

Sets the column width for a single column in a list view data browser.

```
OSStatus SetDataBrowserTableViewNamedColumnWidth (
   ControlRef browser,
   DataBrowserTableViewColumnID column,
   UInt16 width
);
```

Parameters

browser
A data browser.

column
The property ID for the list view column whose width you want to set. The `DataBrowserTableViewColumnID` data type is the same as the `DataBrowserPropertyID` data type.

width
The width of the column, in pixels.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
Before calling this function, you must call the function `SetDataBrowserTableViewGeometry` (page 2225) to set up variable column widths.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

SetDataBrowserTableViewRowHeight

Sets the default row height for all rows in a data browser.

```
OSStatus SetDataBrowserTableViewRowHeight (
   ControlRef browser,
   UInt16 height
);
```

Parameters

browser
A data browser.

height
The row height, in pixels.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
This function sets the default row height for all rows. You override the default row height for an individual row by calling the function `SetDataBrowserTableViewItemRowHeight` (page 2227).

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

SetDataBrowserTarget

Sets the target for a data browser.

```
OSStatus SetDataBrowserTarget (
   ControlRef browser,
   DataBrowserItemID target
);
```

Parameters

browser
A data browser.

target
The item ID to assign as the target for the browser control.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
Your application can set an item ID to use as a target if you do not want to use the default target set by the data browser. By default, the target is a container whose ID is `kDataBrowserNoItem`. For the list view, the target can be thought of as the root container. For the column view, the target is the rightmost column. When an item is dragged over a data browser but not dropped over any particular item, the target becomes the destination.

`SetDataBrowserTarget` changes the container that the data browser displays, thereby populating the data browser with items. If you use the function in column view, you must make sure your item-data callback responds to the property `kDataBrowserItemParentContainerProperty` by providing the item ID of the target's parent. This allows the function `SetDataBrowserColumnViewPath` (page 2202) to process the data properly. The target is the leaf node item whose contents you want to display. However, unlike `GetDataBrowserColumnViewPathLength` (page 2142), the function `SetDataBrowserTarget` doesn't offer a way for you to communicate the item IDs of the rest of the column containers, so `SetDataBrowserTarget` asks for them explicitly by requesting the item's parent, then the parent of the item's parent, and so on.

You can pass a noncontainer item to this function in either list or column views. If you do, you must also respond to the property `kDataBrowserItemParentContainerProperty`. The data browser requests the parent of the target so it knows which container to display the contents of in the list view.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

SetDataBrowserUserState

Restores the view-style settings in list view to a previous state set by the user.

```
OSStatus SetDataBrowserUserState (
   ControlRef browser,
   CFDictionaryRef stateInfo
);
```

Parameters

browser
A data browser.

stateInfo
A CFDictionary object that specifies the view-style settings that you want to restore. Note that although this parameter is typed as a CFData object, you must supply a CFDictionary object because that is the form of the data the system expects.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
Typically you use this function to restore the user state you previously obtained by calling the function `GetDataBrowserUserState` (page 2173).

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

SetDataBrowserViewStyle

Sets the view style of the specified data browser.

```
OSStatus SetDataBrowserViewStyle (
   ControlRef browser,
   DataBrowserViewStyle style
);
```

Parameters

browser

A data browser.

style

The view style to use. Pass the constant `kDataBrowserListView` to draw the data browser using list view or `kDataBrowserColumnView` to use column view. See "View Styles" (page 2298) for more information on these constants.

Return Value

A result code. See "Data Browser Result Codes" (page 2298).

Discussion

Although you specify a view style when you call the function `CreateDataBrowserControl` (page 2125), you can call `SetDataBrowserViewStyle` to change the style. Use `SetDataBrowserViewStyle` when you provide users the option of changing between list and column views.

After calling `SetDataBrowserViewStyle`, you need to perform the necessary tasks to configure the data browser for the view style you switched to. If you switch to list view, you need to set up list view header and column descriptions and call the function `AddDataBrowserListViewColumn` (page 2121). You might also need to call other functions such as `SetDataBrowserListViewDisclosureColumn` (page 2216) (for hierarchical lists).

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.0 and later.

Not available to 64-bit applications.

Declared In

`HIDataBrowser.h`

SortDataBrowserContainer

Sorts a hierarchical list of items.

```
OSStatus SortDataBrowserContainer (
   ControlRef browser,
   DataBrowserItemID container,
   Boolean sortChildren
);
```

Parameters

browser

A data browser.

container

An item ID or the constant `kDataBrowserNoItem`. To sort all of the items that are organized as subitems of a container item, pass the item ID for the container item. To sort all of the items displayed at the top level of the data browser, pass the constant `kDataBrowserNoItem`.

sortChildren

A value that indicates whether to sort all items in the container hierarchy. Pass `true` to sort all items in the container hierarchy and `false` to sort just the immediate children of the container.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

UpdateDataBrowserItems

Requests a redraw of one or more items in a data browser.

```
OSStatus UpdateDataBrowserItems (
   ControlRef browser,
   DataBrowserItemID container,
   ItemCount numItems,
   const DataBrowserItemID *items,
   DataBrowserPropertyID preSortProperty,
   DataBrowserPropertyID propertyID
);
```

Parameters

browser

A data browser.

container

An item ID or the constant `kDataBrowserNoItem`. Pass the item ID that uniquely identifies the container. If you are updating one or more items that are in the root container, pass `kDataBrowserNoItem`.

numItems

The number of items in the array pointed to by the `items` parameter.

items

A pointer to an array of item ID values for the items you want to update. If you pass `NULL` or if the value `kDataBrowserNoItem` is an element in this array, then all rows are updated.

preSortProperty

The property ID of the column whose sorting order is the same as the sorting order of the `items` array. A property ID is a four-character sequence that you assign to represent a column in list view. Pass `kDataBrowserItemNoProperty` if the `items` array is not sorted of if you don't know the sorting order.

propertyID

The property ID of the column that must be updated. To update all columns associated with the items in the `items` array, pass `kDataBrowserNoItem`.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
After your application makes changes to any of the data items in a data browser you must update the display by calling the function `UpdateDataBrowserItems`. Calling this function also updates any internal caches allocated by the data browser.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X version 10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDataBrowser.h`

Callbacks

DataBrowserAcceptDragProcPtr

Defines a pointer to an accept-drag callback function that determines whether your application can accept a drag object in the specified location.

```
typedef Boolean (*DataBrowserAcceptDragProcPtr) (
    ControlRef browser,
    DragRef theDrag,
    DataBrowserItemID item
);
```

You would declare an accept-drag callback function named `MyDataBrowserAcceptDragCallback` like this:

```
Boolean MyDataBrowserAcceptDragCallback (
    ControlRef browser,
    DragRef theDrag,
    DataBrowserItemID item
);
```

Parameters

browser
A data browser.

theDrag
The drag reference provided by the data browser to your callback.

item
The item ID of the item the drag object is held over. If the drag object is over the data browser but not over any specific item, the `item` parameter contains the item ID that represents one of the following:

- In list view, the target. (See `SetDataBrowserTarget` (page 2229).)
- In column view, the item ID of the column the drag object is over

Return Value
Your callback returns `true` if it is capable of accepting the drag object in the location designated by the item parameter. Otherwise, your callback returns `false`.

Discussion
The accept-drag callback is called by the data browser when your application needs to determine if it can accept a drag object in a particular location.

To provide a pointer to your accept-drag callback, you create a universal procedure pointer (UPP) of type `DataBrowserAcceptDragUPP`, using the function `NewDataBrowserAcceptDragUPP` (page 2187). You can do so with code similar to the following:

```
DataBrowserAcceptDragUPP MyDataBrowserAcceptDragUPP;
MyDataBrowserAcceptDragUPP = NewDataBrowserAcceptDragUPP
                        (&MyDataBrowserAcceptDragCallback);
```

You can then assign `MyDataBrowserAcceptDragUPP` to the `acceptDragCallback` field of the structure `DataBrowserCallbacks` (page 2264). You install your data browser callbacks using the function `SetDataBrowserCallbacks` (page 2200).

When you no longer need the UPP, remove it using the `DisposeDataBrowserAcceptDragUPP` (page 2129) function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`HIDataBrowser.h`

DataBrowserAddDragItemProcPtr

Defines a pointer to an add-drag-item callback function that adds an item to a drag reference.

```
typedef Boolean (*DataBrowserAddDragItemProcPtr) (
    ControlRef browser,
    DragRef theDrag,
    DataBrowserItemID item,
    ItemReference *itemRef
);
```

You would declare an add-drag-item callback function named `MyDataBrowserAddDragItemCallback` like this:

```
Boolean MyDataBrowserAddDragItemCallback (
    ControlRef browser,
    DragRef theDrag,
    DataBrowserItemID item,
    ItemRef *itemRef
);
```

Parameters
browser
A data browser.

theDrag
The drag reference provided by the data browser to your callback.

item
The item ID of the item to add to the drag object.

itemRef
A pointer to a drag item reference variable. Your callback must set this to the `DragItemRef` value that it passes to the Drag Manager function `AddDragItemFlavor`.

Return Value
Your callback returns `true` to indicate the item should be or is part of the drag object. Your callback returns `false` if the item isn't part of the drag object.

Discussion
The add-drag-item callback is called by the data browser when a drag operation needs to be started. The data browser iterates through the selected items, invoking your callback for each item. Your callback is called after the drag reference is created by the data browser but before the function `TrackDrag` is called by the system.

Your callback adds an item to the drag reference calling the function `AddDragItemFlavor`. When you call `AddDragItemFlavor`, you must provide a unique drag item reference (`DragItemRef`) for each data browser item that you add to the drag. You must also provide the data type of the added item (drag flavor type) and set the appropriate drag flavor flags.

The data browser handles imaging and adds transparency for you. As a result, you do not need to create or add your own transparency information to the drag reference.

To provide a pointer to your add-drag-item callback, you create a universal procedure pointer (UPP) of type `DataBrowserAddDragItemUPP`, using the function `NewDataBrowserAddDragItemUPP` (page 2188). You can do so with code similar to the following:

```
DataBrowserAddDragItemUPP MyDataBrowserAddDragItemUPP;
MyDataBrowserAddDragItemUPP = NewDataBrowserAddDragItemUPP
                        (&MyDataBrowserAddDragItemCallback);
```

You can then assign `MyDataBrowserAddDragItemUPP` to the `addDragItemCallback` field of the structure `DataBrowserCallbacks` (page 2264). You install your data browser callbacks using the function `SetDataBrowserCallbacks` (page 2200).

When you no longer need the UPP, remove it using the `DisposeDataBrowserAddDragItemUPP` (page 2130) function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`HIDataBrowser.h`

DataBrowserDrawItemProcPtr

Defines a pointer to a draw-item callback function that draws a custom item.

```
typedef void (*DataBrowserDrawItemProcPtr) (
    ControlRef browser,
    DataBrowserItemID item,
    DataBrowserPropertyID property,
    DataBrowserItemState itemState,
    const Rect *theRect,
    SInt16 gdDepth,
    Boolean colorDevice
);
```

You would declare a draw-item callback function named `MyDataBrowserDrawItemCallback` like this:

```
void MyDataBrowserDrawItemCallback (
    ControlRef browser,
    DataBrowserItemID item,
    DataBrowserPropertyID property,
    DataBrowserItemState itemState,
    const Rect *theRect,
    SInt16 gdDepth,
    Boolean colorDevice
);
```

Parameters

browser
: A data browser.

item
: The item ID for the item to draw.

property
: The property ID for the item. In list view, this is the four-character sequence that you previously assigned to the column. In column view, this is the property `kDataBrowserItemSelfIdentityProperty`.

itemState
: The state to use when drawing the item. See "Item States" (page 2280) for a description of the constants that can be provided to your callback.

theRect
: A pointer to the bounding rectangle (in local coordinates, relative to the port) that specifies where to draw the item. This rectangle is the content rectangle, not the enclosing rectangle.

gdDepth
: The bit depth of the current QuickDraw graphics port. The data browser sets the current QuickDraw port to the port that you draw into. This may not always be the port of the data browser's own window.

colorDevice
: A value that specifies whether the current QuickDraw port is a color device (`true`) or is not (`false`).

Discussion

The draw-item callback is called by the data browser when an item whose display type is `kDataBrowserCustomType` needs to be drawn. Your application draws the item so it reflects the state specified by the `itemState` parameter.

To provide a pointer to your draw-item callback, you create a universal procedure pointer (UPP) of type `DataBrowserDrawItemUPP`, using the function `NewDataBrowserDrawItemUPP` (page 2188). You can do so with code similar to the following:

```
DataBrowserDrawItemUPP MyDataBrowserDrawItemUPP;
```

```
MyDataBrowserDrawItemUPP = NewDataBrowserDrawItemUPP
                        (&MyDataBrowserDrawItemCallback);
```

You can then assign `MyDataBrowserDrawItemUPP` to the `drawItemCallback` field of the structure `DataBrowserCustomCallbacks` (page 2265). You install your data browser custom callbacks using the function `SetDataBrowserCustomCallbacks` (page 2203).

When you no longer need the UPP, remove it using the `DisposeDataBrowserDrawItemUPP` (page 2130) function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`HIDataBrowser.h`

DataBrowserEditItemProcPtr

Defines a pointer to an edit-item callback function that determines if the data browser should start an edit session for a custom item.

Not Recommended

```
typedef Boolean (*DataBrowserEditItemProcPtr) (
    ControlRef browser,
    DataBrowserItemID item,
    DataBrowserPropertyID property,
    CFStringRef theString,
    Rect *maxEditTextRect,
    Boolean *shrinkToFit
);
```

You would declare an edit-item callback function named `MyDataBrowserEditItemCallback` like this:

```
Boolean MyDataBrowserEditItemCallback (
    ControlRef browser,
    DataBrowserItemID item,
    DataBrowserPropertyID property,
    CFStringRef theString,
    Rect *maxEditTextRect,
    Boolean *shrinkToFit
);
```

Parameters

browser
A data browser.

item
The item ID number for the item.

property
The property ID for the item. In list view, this is the four-character sequence that you previously assigned to the column. In column view, this is the property `kDataBrowserItemSelfIdentityProperty`.

theString

The string to be edited. See Special Considerations for more information.

maxEditTextRect

On input, a pointer to a rectangle structure. On return, set the rectangle to the largest size the edit field can grow to. If the text grows beyond the size of the edit field, the text scrolls as the user types. This parameter is used only if the parameter `shrinkToFit` is `true`. Otherwise, the current size of the text editing field is used.

shrinkToFit

On input, a pointer to a Boolean variable. On return, set this variable to `true` if you want the data browser to expand or shrink the text editing field to match the width of the text in the edit field. Note that this parameter is currently ignored; `shrinkToFit` is always `true` by default.

Return Value

A value that indicates whether or not you want to start an edit operation for the given property of the item. If your application performs the editing operation, your callback returns `true`. Otherwise, your callback returns `false`.

Discussion

The edit-item callback is called by the data browser for an item whose property is `kDataBrowserCustomType`. Your callback must determine whether an editing session should be started and, if so, set the string to be edited, set the size of the edit rectangle, and specify whether the text editing field can adjust to match the width of the text in the edit field.

To provide a pointer to your edit-item callback, you create a universal procedure pointer (UPP) of type `DataBrowserEditItemUPP`, using the function `NewDataBrowserEditItemUPP` (page 2188). You can do so with code similar to the following:

```
DataBrowserEditItemUPP MyDataBrowserEditItemUPP;
MyDataBrowserEditItemUPP = NewDataBrowserEditItemUPP
                        (&MyDataBrowserEditItemCallback);
```

You can then assign `MyDataBrowserEditItemUPP` to the `editItemCallback` field of the structure `DataBrowserCustomCallbacks` (page 2265). You install your data browser custom callbacks using the function `SetDataBrowserCustomCallbacks` (page 2203).

When you no longer need the UPP, remove it using the `DisposeDataBrowserEditItemUPP` (page 2131) function.

Special Considerations

This callback does not work properly. The `theString` parameter is an immutable sting, which means it is not possible for the callback to set the string to the text that is to be edited.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`HIDataBrowser.h`

DataBrowserGetContextualMenuProcPtr

Defines a pointer to a get-contextual-menu callback function that obtains a menu and information about the menu.

```
typedef void (*DataBrowserGetContextualMenuProcPtr) (
    ControlRef browser,
    MenuRef *menu,
    UInt32 *helpType,
    CFStringRef *helpItemString,
    AEDesc *selection
);
```

You would declare a get-contextual-menu callback function named `MyDataBrowserGetContextualMenuCallback` like this:

```
void MyDataBrowserGetContextualMenuCallback (
    ControlRef browser,
    MenuRef *menu,
    UInt32 *helpType,
    CFStringRef *helpItemString,
    AEDesc *selection
);
```

Parameters

browser

A data browser.

menu

On input, a pointer to a menu. Your callback must set the pointer to the menu that you want to have displayed for the given item. Your application is responsible for disposing of the menu; you typically perform this task in the callback `DataBrowserSelectContextualMenuProcPtr` (page 2257).

helpType

On input, a pointer to an unsigned 32-bit integer. On return, this value specifies the type of help available for this item. This value is then passed by the data browser to the Menu Manager function `ContextualMenuSelect`. You can provide one of the following values:

- `kCMHelpItemNoHelp` if your application does not support help. The Menu Manager inserts an appropriate string into the menu and then disables the associated help item.
- `kCMHelpItemAppleGuide` if your application supports Apple Guide help. The Menu Manager inserts the name of the main Apple Guide file into the menu and enables the associated help item. You can pass this in Mac OS 9. Apple Guide is not supported in Mac OS X. In Mac OS X, this value is ignored; a generic, but inactive, help item is displayed.
- `kCMHelpItemOtherHelp` if your application supports some other form of help. In this case, your application must pass a valid string in the `helpItemString` parameter. The Menu Manager inserts the string in the menu and enables the associated help item.

See *Menu Manager Reference* for more information about these constants.

helpItemString

On input, a `CFStringRef` variable. On return, a CFString object that contains the name of the item to display in the contextual menu. This is the first item that appears in the contextual menu. If you pass `NULL`, the default string (“Help”) is displayed. Data Browser does not retain the string; it releases it.

selection

On input, a pointer to an empty `AEDesc` data structure. On return, the structure contains the data supplied by your callback. The data browser passes this structure to the function `ContextualMenuSelect`.

Discussion
The get-contextual-menu callback is called by the data browser when the user Control-clicks in the data browser. You application provides a menu and information about help that is (or is not) available for the data browser. You can determine what to provide for the content of the menu and what information to put in the `AEDesc` structure by calling the function `GetDataBrowserItems` with the `state` parameter set to `kDataBrowserItemIsSelected`. This tells you what items are selected, which you can then use to choose the appropriate information to supply.

To provide a pointer to your get-contextual-menu callback, you create a universal procedure pointer (UPP) of type `DataBrowserGetContextualMenuUPP`, using the function `NewDataBrowserGetContextualMenuUPP` (page 2189). You can do so with code similar to the following:

```
DataBrowserGetContextualMenuUPP MyDataBrowserGetContextualMenuUPP;
MyDataBrowserGetContextualMenuUPP = NewDataBrowserGetContextualMenuUPP
                        (&MyDataBrowserGetContextualMenuCallback);
```

You can then assign `MyDataBrowserGetContextualMenuUPP` to the `getContextualMenuCallback` field of the structure `DataBrowserCallbacks` (page 2264). You install your data browser callbacks using the function `SetDataBrowserCallbacks` (page 2200).

When you no longer need the UPP, remove it using the `DisposeDataBrowserGetContextualMenuUPP` (page 2131) function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`HIDataBrowser.h`

DataBrowserHitTestProcPtr

Defines a pointer to a hit-test callback function that determines if the pointer is over content that can be selected or dragged.

```
typedef Boolean (*DataBrowserHitTestProcPtr) (
    ControlRef browser,
    DataBrowserItemID itemID,
    DataBrowserPropertyID property,
    const Rect *theRect,
    const Rect *mouseRect
);
```

You would declare a hit-test callback function named `MyDataBrowserHitTestCallback` like this:

```
Boolean MyDataBrowserHitTestCallback (
    ControlRef browser,
    DataBrowserItemID itemID,
    DataBrowserPropertyID property,
    const Rect *theRect,
    const Rect *mouseRect
);
```

Parameters

browser

A data browser.

itemID

The item ID number for the item over which the pointer is located.

property

The property ID for the column in which the pointer is located. In list view, this is the four-character sequence that you previously assigned to the column. In column view, this is the property `kDataBrowserItemSelfIdentityProperty`.

theRect

A pointer to the bounding rectangle, in local coordinates, of the item.

mouseRect

A pointer to a rectangle structure that contains the local coordinates of the selection. If the top-left and bottom-right coordinates of this rectangle are identical, then a single point is being tested. If they differ, then the data browser is testing to see whether your custom item is inside of the bounding rectangle of a selection.

Return Value

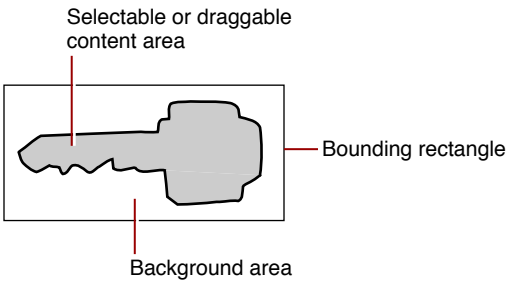
Your application returns a `true` value for either of the following conditions:

- The pointer is located over the part of the item that can be selected or dragged.
- The rectangle provided in the parameter `mouseRect` intersects with the content area of the item that can be selected or dragged.

Discussion

The hit-test callback is called by the data browser when the user hovers the pointer over, clicks the mouse within, or drags within an item whose display type is `kDataBrowserCustomType`. Your callback can use the functions `SetRect` or `SectRgn` to determine if the selectable content of the custom item is part of the selection. Figure 27-2 illustrates a situation for which the selectable or draggable content area differs from the background area in which the item is displayed.

Figure 27-2 Differentiation between the selectable content and background



To provide a pointer to your hit-test callback, you create a universal procedure pointer (UPP) of type `DataBrowserHitTestItemUPP`, using the function `NewDataBrowserHitTestUPP` (page 2189). You can do so with code similar to the following:

```
DataBrowserHitTestUPP MyDataBrowserHitTestUPP;
MyDataBrowserHitTestUPP = NewDataBrowserHitTestUPP
                        (&MyDataBrowserHitTestCallback);
```

You can then assign `MyDataBrowserHitTestUPP` to the `hitTestCallback` field of the structure `DataBrowserCustomCallbacks` (page 2265). You install your data browser custom callbacks using the function `SetDataBrowserCustomCallbacks` (page 2203).

When you no longer need the UPP, remove it using the `DisposeDataBrowserHitTestUPP` (page 2131) function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`HIDataBrowser.h`

DataBrowserItemAcceptDragProcPtr

Defines a pointer to an item-accept-drag callback function that determines if a custom item can accept a drag object.

```
typedef DataBrowserDragFlags (*DataBrowserItemAcceptDragProcPtr)  (
    ControlRef browser,
    DataBrowserItemID itemID,
    DataBrowserPropertyID property,
    const Rect *theRect,
    DragRef theDrag
);
```

You would declare an item-accept-drag callback function named `MyDataBrowserItemAcceptDragCallback` like this:

```
DataBrowserDragFlags MyDataBrowserItemAcceptDragCallback (
    ControlRef browser,
    DataBrowserItemID itemID,
    DataBrowserPropertyID property,
    const Rect *theRect,
    DragRef theDrag
);
```

Parameters

browser
A data browser.

itemID
The item ID number for the item the drag object is held over. If the drag object is over the data browser but not over any specific item, the `item` parameter contains the item ID that represents one of the following:

- The target in list view. (See `SetDataBrowserTarget` (page 2229).)
- The column the drag object is over in column view

property
The property ID of the column the dragged object is over. In list view, this is the four-character sequence that you previously assigned to the column. In column view, this is the property `kDataBrowserItemSelfIdentityProperty`.

theRect
A pointer to the bounding rectangle of the item, in local coordinates relative to the current port.

theDrag
The drag reference provided by the data browser to your callback.

Return Value
If your callback determines the drag object can be accepted, return a nonzero value that has the bit `kDataBrowserItemIsDragTarget` set. Otherwise return `kDataBrowserItemNoState`. The return value is then passed to your item-receive-drag callback in the `dragFlags` parameter.

Discussion
The item-accept-drag callback is called by the data browser for an item whose display type is `kDataBrowserCustomType` when a drag object is moved over the item. Your application determines whether or not the associated item can accept the drag object. If the item cannot accept the drag object, return `0`. Otherwise, if the item is an acceptable drop location for the drag object, return a nonzero value.

If the drag object was acceptable and the drop occurs over that same item ID and property ID pair, the `DataBrowserDragFlags` values you returned from your item-accept-drag callback are passed in the `dragFlags` parameter to your item-receive-drag callback. This allows you to generate state information during drag tracking that can be communicated to you at drop time.

Do not call the function `SetOrigin` in this or any of the other drag processing callbacks.

To provide a pointer to your item-accept-drag callback, you create a universal procedure pointer (UPP) of type `DataBrowserItemAcceptDragUPP`, using the function `NewDataBrowserItemAcceptDragUPP` (page 2190). You can do so with code similar to the following:

```
DataBrowserItemAcceptDragUPP MyDataBrowserItemAcceptDragUPP;
MyDataBrowserItemAcceptDragUPP = NewDataBrowserItemAcceptDragUPP
                        (&MyDataBrowserItemAcceptDragCallback);
```

You can then assign `MyDataBrowserItemAcceptDragUPP` to the `itemAcceptDragCallback` field of the structure `DataBrowserCustomCallbacks` (page 2265). You install your data browser custom callbacks using the function `SetDataBrowserCustomCallbacks` (page 2203).

When you no longer need the UPP, remove it using the `DisposeDataBrowserItemAcceptDragUPP` (page 2132) function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`HIDataBrowser.h`

DataBrowserItemCompareProcPtr

Defines a pointer to an item-comparison callback function that orders the values displayed in a column.

```
typedef Boolean (*DataBrowserItemCompareProcPtr) (
    ControlRef browser,
    DataBrowserItemID itemOne,
    DataBrowserItemID itemTwo,
    DataBrowserPropertyID sortProperty
);
```

You would declare an item-comparison callback function named `MyDataBrowserItemCompareCallback` like this:

```
Boolean MyDataBrowserItemCompareCallback (
    ControlRef browser,
    DataBrowserItemID itemOne,
    DataBrowserItemID itemTwo,
    DataBrowserPropertyID sortProperty
);
```

Parameters

browser
A data browser.

itemOne
The item ID of the first item to use in the comparison.

itemTwo
The item ID of the second item to use in the comparison.

sortProperty
The property ID for the column to sort. In list view, this is the four-character sequence that you previously assigned to the column. In column view, this is the property `kDataBrowserItemSelfIdentityProperty`.

Return Value
Your callback returns `true` if the value of the data referenced by `itemOne` is less than the value of the data referenced by `itemTwo`. It returns `false` if the value of the data referenced by `itemOne` is greater than or equal to the value of the data referenced by `itemTwo`.

Discussion
The item-comparison callback is called by the data browser when it needs to order the values displayed in a column. Your callback determines the display type of the data, then carries out the appropriate comparison for that data.

If you want your callback to use secondary and tertiary sorting, your application must keep track of previous sorting operations. Then you must make sure that each time a user clicks a column, the column is sorted, but the associated sorting orders for secondary and tertiary items in the column are preserved.

To provide a pointer to your item-comparison callback, you create a universal procedure pointer (UPP) of type `DataBrowserItemCompareUPP`, using the function `NewDataBrowserItemCompareUPP` (page 2190). You can do so with code similar to the following:

```
DataBrowserItemCompareUPP MyDataBrowserItemCompareUPP;
MyDataBrowserItemCompareUPP = NewDataBrowserItemCompareUPP
                            (&MyDataBrowserItemCompareCallback);
```

You can then assign `MyDataBrowserItemCompareUPP` to the `itemCompareCallback` field of the structure `DataBrowserCallbacks` (page 2264). You install your data browser callbacks using the function `SetDataBrowserCallbacks` (page 2200).

When you no longer need the UPP, remove it using the `DisposeDataBrowserItemCompareUPP` (page 2132) function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`HIDataBrowser.h`

DataBrowserItemDataProcPtr

Defines a pointer to an item-data callback function that gets and sets properties for individual items in a data browser.

```
typedef OSStatus (*DataBrowserItemDataProcPtr) (
    ControlRef browser,
    DataBrowserItemID item,
    DataBrowserPropertyID property,
    DataBrowserItemDataRef itemData,
    Boolean setValue
);
```

You would declare an item-data callback function named `MyDataBrowserItemDataCallback` like this:

```
OSStatus MyDataBrowserItemDataCallback (
    ControlRef browser,
    DataBrowserItemID item,
    DataBrowserPropertyID property,
    DataBrowserItemDataRef itemData,
    Boolean setValue
);
```

Parameters

browser
The data browser.

item
The item ID of the item whose data is set or obtained.

property
A property ID. This value can be any of the following:

- A four-character sequence that you assign to represent a column in list view.
- Any of the API-defined properties, such as `kDataBrowserItemSelfIdentityProperty` for a column in column view or `kDataBrowserItemIsContainerProperty` for an item in list or column view that has children. See "Properties" (page 2282) for a complete list and more information on the API-defined properties.

itemData
The data buffer that either contains the data to set or receives the data to obtain.

setValue

A value that indicates whether data is to be obtained or set. This value is `false` if your application needs to set the value of the item by calling one of the set functions described in the section "Getting and Setting Item Data" (page 2115). This value is `true` if the value of the item has changed. In this case, you should call the appropriate get function, passing the item data reference provided to you in the `itemData` parameter.

Return Value
A result code. See "Data Browser Result Codes" (page 2298).

Discussion
The item-data callback communicates data between the data browser and your application. When the data browser needs to display a value for an item, it invokes your callback to request the data. If the user changes the value, the data browser invokes your callback with a new copy of the data that you can use to replace your application's internal copy. Your application must supply an item-data callback; otherwise, your data browser will not contain any data.

Your callback determines the kind of data is associated with an item and whether data needs to be obtained or set. Then, your callback takes the appropriate action by calling one of the functions listed in "Getting and Setting Item Data" (page 2115).

To provide a pointer to your item-data callback, you create a universal procedure pointer (UPP) of type `DataBrowserItemDataUPP`, using the function `NewDataBrowserItemDataUPP` (page 2191). You can do so with code similar to the following:

```
DataBrowserItemDataUPP MyDataBrowserItemDataUPP;
MyDataBrowserItemDataUPP = NewDataBrowserItemDataUPP
                           (&MyDataBrowserItemDataCallback);
```

You can then assign `MyDataBrowserItemDataUPP` to the `itemDataCallback` field of the structure `DataBrowserCallbacks` (page 2264). You install your data browser callbacks using the function `SetDataBrowserCallbacks` (page 2200).

When you no longer need the UPP, remove it using the `DisposeDataBrowserItemDataUPP` (page 2133) function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`HIDataBrowser.h`

DataBrowserItemDragRgnProcPtr

Defines a pointer to an item-drag-region callback function that determines which part of the item rectangle to use when creating a transparent image for a dragged custom item.

```
typedef void (*DataBrowserItemDragRgnProcPtr) (
    ControlRef browser,
    DataBrowserItemID itemID,
    DataBrowserPropertyID property,
    const Rect *theRect,
    RgnHandle dragRgn
);
```

You would declare an item-drag-region callback function named `MyDataBrowserItemDragRgnCallback` like this:

```
void MyDataBrowserItemDragRgnCallback (
    ControlRef browser,
    DataBrowserItemID itemID,
    DataBrowserPropertyID property,
    const Rect *theRect,
    RgnHandle dragRgn
);
```

Parameters

browser
: A data browser.

itemID
: The item ID number for the row for which the drag image is generated.

property
: The property ID for the column for which the drag image is generated. In list view, this is the four-character sequence that you previously assigned to the column. In column view, this is the property `kDataBrowserItemSelfIdentityProperty`.

theRect
: A pointer to the bounding rectangle of the item, in local coordinates.

dragRgn
: On return, the drag region set to the portion of the rectangle to use for the transparent drag image. Typically this is the boundary of the content area inside your custom item. This region is used as a mask when passed to your custom draw-item callback.

Discussion

The item-drag-region callback is called by the data browser for an item whose display type is `kDataBrowserCustomType` when a drag is about to begin. Your application determines which part of the item rectangle to use when creating the transparent image that appears during a drag operation. The data browser uses this area as a clipping region when it invokes your draw-item callback.

Do not call the function `SetOrigin` in this or any of the other drag processing callbacks.

To provide a pointer to your item-drag-region callback, you create a universal procedure pointer (UPP) of type `DataBrowserItemDragRgnUPP`, using the function `NewDataBrowserItemDragRgnUPP` (page 2191). You can do so with code similar to the following:

```
DataBrowserItemDragRgnUPP MyDataBrowserItemDragRgnUPP;
MyDataBrowserItemDragRgnUPP = NewDataBrowserItemDragRgnUPP
                        (&MyDataBrowserItemDragRgnCallback);
```

You can then assign `MyDataBrowserItemDragRgnUPP` to the `itemDragRgnCallback` field of the structure `DataBrowserCustomCallbacks` (page 2265). You install your data browser custom callbacks using the function `SetDataBrowserCustomCallbacks` (page 2203).

When you no longer need the UPP, remove it using the `DisposeDataBrowserItemDragRgnUPP` (page 2133) function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`HIDataBrowser.h`

DataBrowserItemHelpContentProcPtr

Defines a pointer to an item-help-content callback function that provides help tag content for an item.

```
typedef void (*DataBrowserItemHelpContentProcPtr) (
    ControlRef browser,
    DataBrowserItemID item,
    DataBrowserPropertyID property,
    HMContentRequest inRequest,
    HMContentProvidedType *outContentProvided,
    HMHelpContentPtr ioHelpContent
);
```

You would declare an item-help-content callback function named `MyDataBrowserItemHelpContentCallback` like this:

```
void DataBrowserItemHelpContentCallback (
    ControlRef browser,
    DataBrowserItemID item,
    DataBrowserPropertyID property,
    HMContentRequest inRequest,
    HMContentProvidedType *outContentProvided,
    HMHelpContentPtr ioHelpContent
);
```

Parameters

browser
A data browser.

item
The item ID of the item to provide help for.

property
The property ID of the column to provide help for. In list view, this is the four-character sequence that you previously assigned to the column. In column view, this is the property `kDataBrowserItemSelfIdentityProperty`.

inRequest

On input, a value that indicates the nature of the help tag content request. Your callback is passed one of the following constants:

- `kHMSupplyContent` indicates your callback needs to supply help content.
- `kHMDisposeContent` indicates your callback must dispose of help content.

outContentProvided

On input, a help-content-type variable. On return, the variable is set to one of the following constants that indicate whether your item-help callback was able to fulfill the request specified in the `inRequest` parameter:

- `kHMContentProvided` indicates help content is provided in the `ioHelpContent` parameter.
- `kHMContentNotProvided` indicates help content is not provided. When your callback returns this constant, the Carbon Help Manager consults other help content providers in the hierarchy until the request for help tag content is fulfilled, the top of the hierarchy is reached, or a help tag callback notifies the Carbon Help Manager to stop propagating the request.
- `kHMContentNotProvidedDontPropagate` indicates help content is not provided. When your callback returns this constant, the Carbon Help Manager assumes that there is no help content for the data browser item and does not propagate the request.

See *Carbon Help Manager Reference* for more information on these constants.

ioHelpContent

A help tag structure that describes the help tag for the item. On input, the data browser passes a value in the version field. If the value of the `inRequest` parameter is `kHMSupplyContent`, your callback must fill in the remaining fields of the structure or specify that it is unable to fulfill the help tag content request.

Discussion

The item-help-content callback is called by the data browser when the user hovers the pointer over an item in a data browser for which you've registered a help tag callback. Your application fills in the help tag structure pointed to by the `ioHelpContent` parameter.

When the help tag for the item is no longer needed, the data browser invokes your callback with a `kHMDisposeContent` request. When you receive this request, free any memory allocated for the help tag content and perform any other cleanup tasks that are necessary.

To provide a pointer to your item-help-content callback, you create a universal procedure pointer (UPP) of type `DataBrowserItemHelpContentUPP`, using the function `NewDataBrowserItemHelpContentUPP` (page 2192). You can do so with code similar to the following:

```
DataBrowserItemHelpContentUPP MyDataBrowserItemHelpContentUPP;
MyDataBrowserItemHelpContentUPP = NewDataBrowserItemHelpContentUPP
                        (&MyDataBrowserItemHelpContentCallback);
```

You can then assign `MyDataBrowserItemHelpContentUPP` to the `itemHelpContentCallback` field of the structure `DataBrowserCallbacks` (page 2264). You install your data browser callbacks using the function `SetDataBrowserCallbacks` (page 2200).

When you no longer need the UPP, remove it using the `DisposeDataBrowserItemHelpContentUPP` (page 2133) function.

Availability

Available in Mac OS X v10.0 and later.

Declared In
HIDataBrowser.h

DataBrowserItemNotificationProcPtr

Defines a pointer to an item-notification callback function that notifies your application of changes in the data browser.

```
typedef void (*DataBrowserItemNotificationProcPtr) (
    ControlRef browser,
    DataBrowserItemID item,
    DataBrowserItemNotification message
);
```

You would declare an item-notification callback function named `MyDataBrowserItemNotificationCallback` like this:

```
void MyDataBrowserItemNotificationCallback (
    ControlRef browser,
    DataBrowserItemID item,
    DataBrowserItemNotification message
);
```

Parameters

browser
A data browser.

item
The item ID of the item that generated the notification.

message
A notification. See "Item Notifications" (page 2278) for a description of the values that can be provided to your callback.

Discussion

The item-notification callback is called by the data browser to notify your application of actions taken by the user (such as editing started, container opened, container closed) or any other condition that your application might choose to respond to. Your item-notification callback can evaluate the notification and take appropriate action.

To provide a pointer to your item-notification callback, you create a universal procedure pointer (UPP) of type `DataBrowserItemNotificationUPP`, using the function `NewDataBrowserItemNotificationUPP` (page 2192). You can do so with code similar to the following:

```
DataBrowserItemNotificationUPP MyDataBrowserItemNotificationUPP;
MyDataBrowserItemNotificationUPP = NewDataBrowserItemNotificationUPP
                            (&MyDataBrowserItemNotificationCallback);
```

You can then assign `MyDataBrowserItemNotificationUPP` to the `itemNotificationCallback` field of the structure `DataBrowserCallbacks` (page 2264). You install your data browser callbacks using the function `SetDataBrowserCallbacks` (page 2200).

When you no longer need the UPP, remove it using the `DisposeDataBrowserItemNotificationUPP` (page 2134) function.

Special Considerations

In CarbonLib the item-notification callback is invoked with the three parameters shown in `DataBrowserItemNotificationProcPtr` (page 2250). The four-parameter version—`DataBrowserItemNotificationWithItemProcPtr` (page 2251)—does not provide valid data in the fourth parameter. Any attempt to use the invalid data in a CarbonLib application may result in a crash.

In Mac OS X, the item-notification callback is invoked with the four parameters shown in `DataBrowserItemNotificationWithItemProcPtr` (page 2251). In Mac OS X you have the option of using the `DataBrowserItemNotificationProcPtr` (page 2250) or the `DataBrowserItemNotificationWithItemProcPtr` (page 2251). Which one you choose depends on whether your application needs to use the data passed to your callback in the fourth parameter (the `itemData` parameter).

Availability

Available in Mac OS X v10.1 and later.

Declared In

`HIDataBrowser.h`

DataBrowserItemNotificationWithItemProcPtr

Defines a pointer to an item-notification-with-data callback function that notifies your application of changes in the data browser and supplies any data associated with the changes.

```
typedef void (*DataBrowserItemNotificationWithItemProcPtr) (
    ControlRef browser,
    DataBrowserItemID item,
    DataBrowserItemNotification message,
    DataBrowserItemDataRef itemData
);
```

You would declare an item-notification-with-data callback function named `MyDataBrowserItemNotificationWithItemCallback` like this:

```
void MyDataBrowserItemNotificationWithItemCallback (
    ControlRef browser,
    DataBrowserItemID item,
    DataBrowserItemNotification message,
    DataBrowserItemDataRef itemData
);
```

Parameters

browser

A data browser.

item

The item ID of the item that generated the notification.

message

A notification. See "Item Notifications" (page 2278) for a description of the values that can be provided to your callback.

itemData

The data associated with the changes in the data browser that caused this callback to be invoked. You pass this data to functions that get and set item data (such as `SetDataBrowserItemDataIcon` (page 2209), `SetDataBrowserItemDataText` (page 2214), `GetDataBrowserItemDataIcon` (page 2148), and `GetDataBrowserItemDataText` (page 2154)). See "Getting and Setting Item Data" (page 2115) for a list of all the function that can use item data.

Discussion

The item-notification-with-data callback is called by the data browser to notify your application of actions taken by the user (such as editing started, container opened, container closed) or any other condition that your application might choose to respond to. Your item-notification-with-data callback can evaluate the notification and take appropriate action. Unlike the callback `DataBrowserItemNotificationProcPtr` (page 2250), the callback `DataBrowserItemNotificationWithItemProcPtr` (page 2251) provides a fourth parameter that contains any data associated with the item from which the notification is generated. This data is available only to Mac OS X applications. See Special Considerations for more details.

To provide a pointer to your item-notification-with-data callback, you create a universal procedure pointer (UPP) of type `DataBrowserItemNotificationWithItemUPP`, using the function `NewDataBrowserItemNotificationWithItemUPP` (page 2193). You can do so with code similar to the following:

```
DataBrowserItemNotificationWithItemUPP
                    MyDataBrowserItemNotificationWithItemUPP;
MyDataBrowserItemNotificationWithItemUPP =
                NewDataBrowserItemNotificationWithItemUPP
                (&MyDataBrowserItemNotificationWithItemCallback);
```

You can then assign `MyDataBrowserItemNotificationWithItemUPP` to the `itemNotificationCallback` field of the structure `DataBrowserCallbacks` (page 2264). You install your data browser callbacks using the function `SetDataBrowserCallbacks` (page 2200).

When you no longer need the UPP, remove it using the `DisposeDataBrowserItemNotificationWithItemUPP` (page 2134) function.

Special Considerations

In CarbonLib the item-notification callback is invoked with the three parameters shown in `DataBrowserItemNotificationProcPtr` (page 2250). The four-parameter version (`DataBrowserItemNotificationWithItemProcPtr` (page 2251)) does not provide valid data in the fourth parameter. Any attempt to use the invalid data in a CarbonLib application may result in a crash.

In Mac OS X, the item-notification callback is invoked with the four parameters shown in `DataBrowserItemNotificationWithItemProcPtr` (page 2251). In Mac OS X you have the option of using the `DataBrowserItemNotificationProcPtr` (page 2250) or the `DataBrowserItemNotificationWithItemProcPtr` (page 2251). Which one you choose depends on whether your application needs to use the data passed to your callback in the fourth parameter (`itemData`).

Availability

Available in Mac OS X v10.1 and later.

Declared In

`HIDataBrowser.h`

DataBrowserItemProcPtr

Defines a pointer to an item-iterator callback function that is applied by the function `ForEachDataBrowserItem` to each item in a data browser.

```
typedef void (*DataBrowserItemProcPtr) (
    DataBrowserItemID item,
    DataBrowserItemState state,
    void *clientData
);
```

You would declare an item-iterator callback function named `MyDataBrowserItemCallback` like this:

```
void MyDataBrowserItemCallback (
    DataBrowserItemID item,
    DataBrowserItemState state,
    void *clientData
);
```

Parameters

item

The item ID of the item to operate on.

state

The state of the item. See "Item States" (page 2280) for a description of possible states. If the function `ForEachDataBrowserItem` (page 2138) is set up to operate on items of a specified state, then the state passed to your callback includes the state specified as a parameter to `ForEachDataBrowserItem`.

clientData

A pointer to a buffer, local variable, or other storage location created and disposed of by your application, and supplied to the data browser with a previous call to `ForEachDataBrowserItem`.

Discussion

An item-iterator callback is supplied as a parameter to the function `ForEachDataBrowserItem`. The function applies your callback to each data item that meets the criteria specified by the function `ForEachDataBrowserItem`.

To provide a pointer to your item-iterator callback, you create a universal procedure pointer (UPP) of type `DataBrowserItemUPP`, using the function `NewDataBrowserItemUPP` (page 2194). You can do so with code similar to the following:

```
DataBrowserItemUPP MyDataBrowserItemUPP;
MyDataBrowserItemUPP = NewDataBrowserItemUPP
                            (&MyDataBrowserItemCallback);
```

You can then pass `MyDataBrowserItemUPP` in the `callback` parameter of the function `ForEachDataBrowserItem`. When you no longer need the UPP, remove it using the `DisposeDataBrowserItemUPP` (page 2135) function.

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X version 10.0 and later.

Declared In

`HIDataBrowser.h`

DataBrowserItemReceiveDragProcPtr

Defines a pointer to an item-receive-drag callback function that receives a drop over a custom item.

```
typedef Boolean (*DataBrowserItemReceiveDragProcPtr) (
    ControlRef browser,
    DataBrowserItemID itemID,
    DataBrowserPropertyID property,
    DataBrowserDragFlags dragFlags,
    DragRef theDrag
);
```

You would declare an item-receive-drag callback function named `MyDataBrowserItemReceiveDragCallback` like this:

```
Boolean MyDataBrowserItemReceiveDragCallback (
    ControlRef browser,
    DataBrowserItemID itemID,
    DataBrowserPropertyID property,
    DataBrowserDragFlags dragFlags,
    DragRef theDrag
);
```

Parameters

browser
: A data browser.

itemID
: The item ID number for the item over which the drop occurred.

property
: The property ID for the column in which the drop occurred. In list view, this is the four-character sequence that you previously assigned to the column. In column view, this is the property `kDataBrowserItemSelfIdentityProperty`.

dragFlags
: A drag flag. This value is `kDataBrowserItemIsDragTarget` if your item-accept-drag callback determined the drag object can be accepted.

theDrag
: The drag reference provided by the data browser to your callback.

Return Value

A value that indicates whether the drop is received. Your callback returns `true` if it successfully receives the drag object. If it returns `false`, zoom-back animation occurs.

Discussion

After your item-accept-drag callback has determined that a location can accept a drag object and after a drop operation occurs, the data browser calls your item-receive-drag callback. Your application takes whatever actions necessary to add the dropped data to the data browser.

Do not call the function `SetOrigin` in this or any of the drag processing callbacks.

To provide a pointer to your item-receive-drag callback, you create a universal procedure pointer (UPP) of type `DataBrowserItemReceiveDragUPP`, using the function `NewDataBrowserItemReceiveDragUPP` (page 2193). You can do so with code similar to the following:

```
DataBrowserItemReceiveDragUPP MyDataBrowserItemReceiveDragUPP;
```

```
MyDataBrowserItemReceiveDragUPP = NewDataBrowserItemReceiveDragUPP
                        (&MyDataBrowserItemReceiveDragCallback);
```

You can then assign `MyDataBrowserItemReceiveDragUPP` to the `itemReceiveDragCallback` field of the structure `DataBrowserCustomCallbacks` (page 2265). You install your data browser custom callbacks using the function `SetDataBrowserCustomCallbacks` (page 2203).

When you no longer need the UPP, remove it using the `DisposeDataBrowserItemReceiveDragUPP` (page 2135) function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`HIDataBrowser.h`

DataBrowserPostProcessDragProcPtr

Defines a pointer to a postprocess-drag callback function that performs necessary cleanup tasks, such as deallocating resources that were allocated by your other drag processing callbacks.

```
typedef void (*DataBrowserPostProcessDragProcPtr) (
    ControlRef browser,
    DragRef theDrag,
    OSStatus trackDragResult
);
```

You would declare a postprocess-drag callback function named `MyDataBrowserPostProcessDragCallback` like this:

```
void MyDataBrowserPostProcessDragCallback (
    ControlRef browser,
    DragRef theDrag,
    OSStatus trackDragResult
);
```

Parameters

browser
A data browser.

theDrag
The drag reference provided by the data browser to your callback.

trackDragResult
The result returned by the function `TrackDrag` and passed to your callback by the data browser.

Discussion
This callback is called after starting a drag from within the data browser. It is not called if the drag originated from somewhere else.

The postprocess-drag callback is called by the data browser after a drag process is complete and any drag processing callback routines you installed (add drag, accept drag, or receive drag callbacks) were called during the drag operation. Your postprocess-drag callback deallocates any resources that were allocated by

your other drag-processing callbacks. Your postprocess-drag callback is called immediately before the drag reference is deallocated by the data browser so your application should not assume the drag reference exists after your callback completes.

To provide a pointer to your postprocess-drag callback, you create a universal procedure pointer (UPP) of type `DataBrowserPostProcessDragUPP`, using the function `NewDataBrowserPostProcessDragUPP` (page 2194). You can do so with code similar to the following:

```
DataBrowserPostProcessDragUPP MyDataBrowserPostProcessDragUPP;
MyDataBrowserPostProcessDragUPP = NewDataBrowserPostProcessDragUPP
                        (&MyDataBrowserPostProcessDragCallback);
```

You can then assign `MyDataBrowserPostProcessDragUPP` to the `postProcessDragCallback` field of the structure `DataBrowserCallbacks` (page 2264). You install your data browser callbacks using the function `SetDataBrowserCallbacks` (page 2200).

When you no longer need the UPP, remove it using the `DisposeDataBrowserPostProcessDragUPP` (page 2135) function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`HIDataBrowser.h`

DataBrowserReceiveDragProcPtr

Defines a pointer to a receive-drag callback function that extract items from a drag object and handles the drag item appropriately.

```
typedef Boolean (*DataBrowserReceiveDragProcPtr) (
    ControlRef browser,
    DragRef theDrag,
    DataBrowserItemID item
);
```

You would declare a receive-drag callback function named `MyDataBrowserReceiveDragCallback` like this:

```
Boolean MyDataBrowserReceiveDragCallback (
    ControlRef browser,
    DragRef theDrag,
    DataBrowserItemID item
);
```

Parameters

browser
A data browser.

theDrag
The drag reference provided by the data browser to your callback.

item

The item ID of the item over which the drop operation occurred. If the drag object is over the data browser, but not over any specific item, the `item` parameter contains the item ID that represents one of the following:

- In list view, the target. (See `SetDataBrowserTarget` (page 2229).)
- In column view, the item ID that represents the column the drag object is over

Return Value
Your callback returns `true` if it successfully processes the information in the drag object. Otherwise, your callback returns `false` to have zoom-back animation occur for the drag object, thereby indicating to the user that the drag operation was not successful.

Discussion
The receive-drag callback is called by the data browser when your application needs to receive a drag object. Your application extracts the items it needs from the drag object and processes them appropriately.

To provide a pointer to your receive-drag callback, you create a universal procedure pointer (UPP) of type `DataBrowserReceiveDragUPP`, using the function `NewDataBrowserReceiveDragUPP` (page 2195). You can do so with code similar to the following:

```
DataBrowserReceiveDragUPP MyDataBrowserReceiveDragUPP;
MyDataBrowserReceiveDragUPP = NewDataBrowserReceiveDragUPP
                        (&MyDataBrowserReceiveDragCallback);
```

You can then assign `MyDataBrowserReceiveDragUPP` to the `receiveDragCallback` field of the structure `DataBrowserCallbacks` (page 2264). You install your data browser callbacks using the function `SetDataBrowserCallbacks` (page 2200).

When you no longer need the UPP, remove it using the `DisposeDataBrowserReceiveDragUPP` (page 2136) function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`HIDataBrowser.h`

DataBrowserSelectContextualMenuProcPtr

Defines a pointer to a select-contextual-menu callback function that processes a contextual menu selection.

```
typedef void (*DataBrowserSelectContextualMenuProcPtr) (
    ControlRef browser,
    MenuRef menu,
    UInt32 selectionType,
    SInt16 menuID,
    MenuItemIndex menuItem
);
```

You would declare a select-contextual-menu callback function named `MyDataBrowserSelectContextualMenuCallback` like this:

```
void MyDataBrowserSelectContextualMenuCallback (
    ControlRef browser,
```

```
    MenuRef menu,
    UInt32 selectionType,
    SInt16 menuID,
    MenuItemIndex menuItem
);
```

Parameters

browser

A data browser.

menu

On input, the menu reference your application provided to the data browser in the callback `DataBrowserGetContextualMenuProcPtr` (page 2238).

selectionType

On input, the selection type provided to the data browser from the Menu Manager function `ContextualMenuSelect`.

menuID

On input, the menu ID of the menu selected. This value is `0` if no selection was made.

menuItem

The menu item index of the item selected.

Discussion

The select-contextual-menu callback is called by the data browser when the user finishes interacting with a contextual menu. Your callback needs to:

- Check whether the user chose an item from the menu. If so, process the selection appropriately. Note that your callback is invoked even if the user does not choose an item from the menu.
- Optionally dispose of the menu you allocated in your get-contextual-menu callback, and that is passed to your select-contextual-menu callback in the `menu` parameter.

To provide a pointer to your select-contextual-menu callback, you create a universal procedure pointer (UPP) of type `DataBrowserSelectContextualMenuUPP`, using the function `NewDataBrowserSelectContextualMenuUPP` (page 2195). You can do so with code similar to the following:

```
DataBrowserSelectContextualMenuUPP MyDataBrowserSelectContextualMenuUPP;
MyDataBrowserSelectContextualMenuUPP =
                 NewDataBrowserSelectContextualMenuUPP
                (&MyDataBrowserSelectContextualMenuCallback);
```

You can then assign `MyDataBrowserSelectContextualMenuUPP` to the `selectContextualMenuCallback` field of the structure `DataBrowserCallbacks` (page 2264). You install your data browser callbacks using the function `SetDataBrowserCallbacks` (page 2200).

When you no longer need the UPP, remove it using the `DisposeDataBrowserSelectContextualMenuUPP` (page 2136) function.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`HIDataBrowser.h`

DataBrowserTrackingProcPtr

Defines a pointer to a tracking callback function that implements tracking behavior for such tasks as highlighting a button or providing animation when the user clicks a custom item.

```
typedef DataBrowserTrackingResult (*DataBrowserTrackingProcPtr)  (
    ControlRef browser,
    DataBrowserItemID itemID,
    DataBrowserPropertyID property,
    const Rect *theRect,
    Point startPt,
    EventModifiers modifiers
);
```

You would declare a tracking callback function named `MyDataBrowserTrackingCallback` like this:

```
DataBrowserTrackingResult MyDataBrowserTrackingCallback (
    ControlRef browser,
    DataBrowserItemID itemID,
    DataBrowserPropertyID property,
    const Rect *theRect,
    Point startPt,
    EventModifiers modifiers
);
```

Parameters

browser
: A data browser.

itemID
: The item ID number for the item the user clicked.

property
: The property ID for the column in which the pointer is located. In list view, this is the four-character sequence that you previously assigned to the column. In column view, this is the property `kDataBrowserItemSelfIdentityProperty`.

theRect
: A pointer to the bounding rectangle of the item, in local coordinates relative to the current port.

startPt
: The location of the pointer at the start of the click.

modifiers
: The state of the modifier keys. See *Carbon Event Manager Reference* in Carbon Events & Other Input Documentation for a list of the constants that can be passed to your callback.

Return Value

A tracking result that indicates whether further processing is required by the data browser. Your callback returns `kDataBrowserStopTracking`, `kDataBrowserContentHit`, or `kDataBrowserNothingHit`. See the Discussion for more details.

Discussion

The tracking callback is called by the data browser for an item whose display type is `kDataBrowserCustomType` when a mouse click is inside the content area of the item. Your tracking callback is called only for mouse-down events and only after your `DataBrowserHitTestProcPtr` (page 2240) callback returns `true`. Your tracking callback performs one of following tasks:

- Provides its own custom tracking behavior and animation and returns the result `kDataBrowserStopTracking`. This result informs the data browser that your application handled the click and no further processing is required. The data browser does not attempt to display a contextual menu, start a drag operation, process a double-click, or draw a selection rectangle. You are responsible for all facets of click handling if you return `kDataBrowserStopTracking`.
- Returns the value `kDataBrowserNothingHit` to indicate a negative hit and no further processing needs to take place. This result indicates that a nonselectable portion—whitespace—was hit. The data browser won't select the item, but it could, for example, start a selection rectangle.
- Returns the value `kDataBrowserContentHit` to request that the data browser continues to process the click. This result indicates that a selectable portion of the item is hit. The data browser selects the item and takes other appropriate actions.

To provide a pointer to your tracking callback, you create a universal procedure pointer (UPP) of type `DataBrowserTrackingUPP`, using the function `NewDataBrowserTrackingUPP` (page 2196). You can do so with code similar to the following:

```
DataBrowserTrackingUPP MyDataBrowserTrackingUPP;
MyDataBrowserTrackingUPP = NewDataBrowserTrackingUPP
                        (&MyDataBrowserTrackingCallback);
```

You can then assign `MyDataBrowserTrackingUPP` to the `trackingCallback` field of the structure `DataBrowserCustomCallbacks` (page 2265). You install your data browser custom callbacks using the function `SetDataBrowserCustomCallbacks` (page 2203).

When you no longer need the UPP, remove it using the `DisposeDataBrowserTrackingUPP` (page 2137) function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`HIDataBrowser.h`

Data Types

DataBrowserAccessibilityItemInfo

Contains a structure that describes data browser accessibility item information.

```
struct DataBrowserAccessibilityItemInfo {
    UInt32 version;
    union {
        DataBrowserAccessibilityItemInfoV0 v0;
        DataBrowserAccessibilityItemInfoV1 v1;
    } u;
typedef struct DataBrowserAccessibilityItemInfoV0 v0;
typedef struct DataBrowserAccessibilityItemInfoV1 v1;
```

Fields

`version`

Identifies how to interpret the following union. Set this field to `0` if you fill out the union's data in the form of a `DataBrowserAccessibilityItemInfoV0` structure. Set this field to `1` if you fill out the union's data in the form of a `DataBrowserAccessibilityItemInfoV1` structure.

`u.v0`

A `DataBrowserAccessibilityItemInfoV0` (page 2261) structure.

`u.v1`

A `DataBrowserAccessibilityItemInfoV1` (page 2262) structure.

DataBrowserAccessibilityItemInfoV0

Contains a description of data browser accessibility item information.

```
struct DataBrowserAccessibilityItemInfoV0 {
    DataBrowserItemID container;
    DataBrowserItemID item;
    DataBrowserPropertyID columnProperty;
    DataBrowserPropertyPart propertyPart;
    }
typedef struct DataBrowserAccessibilityItemInfoV0  DataBrowserAccessibilityInfoV0;
```

Fields

`container`

The `DataBrowserItemID` of the container the `AXUIElementRef` represents or lives within. Even `kDataBrowserNoItem` might be meaningful, since it is the root container ID if you haven't overridden it via `SetDataBrowserTarget` (page 2229). In list view, the container helps narrow down the `AXUIElementRef` to either a disclosed child of another row, or the list as a whole. In column view, the container helps narrow down the `AXUIElementRef` to a column. See also the description of the `columnProperty` field.

`item`

The `DataBrowserItemID` of the item the `AXUIElementRef` represents or lives within. If `item` is `kDataBrowserNoItem`, the `AXUIElementRef` represents just the container. In list view, `item` helps narrow down the `AXUIElementRef` to a row or the root container as a whole. In column view, `item` helps narrow down the `AXUIElementRef` to a cell or a column as a whole. See also the description of the `columnProperty` field.

`columnProperty`
: The `DataBrowserPropertyID` of the column the `AXUIElementRef` represents or lives within. If `columnProperty` is `kDataBrowserItemNoProperty` and `item` is not `kDataBrowserNoItem`, the `AXUIElementRef` represents a whole row. In list view, this field helps narrow down the `AXUIElementRef` to a cell or a row as a whole. In column view, `columnProperty` must always be set to `kDataBrowserItemNoProperty` unless the `AXUIElementRef` represents the preview column. When the `AXUIElementRef` represents the preview column, `columnProperty` must always be set to `kDataBrowserColumnViewPreviewProperty` and the other fields of this structure must be set to `0` or the equivalent constant.

`propertyPart`
: The `DataBrowserPropertyPart` of the sub-cell part the `AXUIElementRef` represents. Examples include the disclosure triangle in a cell, the text in a cell, and the check box in a cell. If `propertyPart` is `kDataBrowserPropertyEnclosingPart` and `columnProperty` is not `kDataBrowserItemNoProperty`, the `AXUIElementRef` represents the cell as a whole. In both list view and column view, this field helps narrow down the `AXUIElementRef` to either a sub-cell part or a cell as a whole. For column view, see also the description of the `columnProperty` field.

DataBrowserAccessibilityItemInfoV1

Contains a description of data browser accessibility item information that includes a row and a column index.

```
struct DataBrowserAccessibilityItemInfoV1 {
    DataBrowserItemID container;
    DataBrowserItemID item;
    DataBrowserPropertyID columnProperty;
    DataBrowserPropertyPart propertyPart;
    DataBrowserTableViewRowIndex rowIndex;
    DataBrowserTableViewColumnIndex columnIndex;
    }
typedef struct DataBrowserAccessibilityItemInfoV1  DataBrowserAccessibilityInfoV1;
```

Fields

`container`
: The `DataBrowserItemID` of the container the `AXUIElementRef` represents or lives within. Even `kDataBrowserNoItem` might be meaningful, since it is the root container ID if you haven't overridden it via `SetDataBrowserTarget` (page 2229). In list view, the container helps narrow down the `AXUIElementRef` to either a disclosed child of another row, or the list as a whole. In column view, the container helps narrow down the `AXUIElementRef` to a column. See also the description of the `columnProperty` field.

`item`
: The `DataBrowserItemID` of the item the `AXUIElementRef` represents or lives within. If `item` is `kDataBrowserNoItem`, the `AXUIElementRef` represents just the container. In list view, `item` helps narrow down the `AXUIElementRef` to a row or the root container as a whole. In column view, `item` helps narrow down the `AXUIElementRef` to a cell or a column as a whole. See also the description of the `columnProperty` field.

`columnProperty`
: The `DataBrowserPropertyID` of the column the `AXUIElementRef` represents or lives within. If `columnProperty` is `kDataBrowserItemNoProperty` and `item` is not `kDataBrowserNoItem`, the `AXUIElementRef` represents a whole row. In list view, this field helps narrow down the `AXUIElementRef` to a cell or a row as a whole. In column view, `columnProperty` must always be set to `kDataBrowserItemNoProperty` unless the `AXUIElementRef` represents the preview column. When the `AXUIElementRef` represents the preview column, `columnProperty` must always be set to `kDataBrowserColumnViewPreviewProperty` and the other fields of this structure must be set to `0` or the equivalent constant.

`propertyPart`
: The `DataBrowserPropertyPart` of the sub-cell part the `AXUIElementRef` represents. Examples include the disclosure triangle in a cell, the text in a cell, and the check box in a cell. If `propertyPart` is `kDataBrowserPropertyEnclosingPart` and `columnProperty` is not `kDataBrowserItemNoProperty`, the `AXUIElementRef` represents the cell as a whole. In both list view and column view, this field helps narrow down the `AXUIElementRef` to either a sub-cell part or a cell as a whole. For column view, see also the description of the `columnProperty` field.

`rowIndex`
: The zero-based `DataBrowserTableViewRowIndex` of the row specified by the other parts of this structure. If the other parts of this structure do not specify a row or a part thereof, this field must be set to 0. Because this field is zero based, you must test the other parts of this structure to see whether this field is meaningful. In list view, when the other parts of this structure specify an item or part thereof, this field must be set to the row index at which the specified item can be found. In column view, when the other parts of this structure specify a cell or part thereof, this field must be set to the row index at which the specified cell can be found.

`propertyPart`
: The zero-based `DataBrowserTableViewColumnIndex` of the column specified by the other parts of this structure. If the other parts of this structure do not specify a column or a part thereof, this field must be set to zero. Because this field is zero based, you must test the other parts this structure to see whether this field is meaningful. In list view, when the other parts of this structure specify a cell or part thereof, this field must be set to the column index at which the specified cell can be found. In column view, when the other parts of this structure specify a column or part thereof, this field must be set to the column index at which the specified cell can be found.

DataBrowserPropertyDesc

Contains property and display information for a list view column.

```
struct DataBrowserPropertyDesc {
    DataBrowserPropertyID propertyID;
    DataBrowserPropertyType propertyType;
    DataBrowserPropertyFlags propertyFlags;
};
typedef struct DataBrowserPropertyDesc DataBrowserPropertyDesc;
```

Fields

`propertyID`
: A four-character sequence that uniquely identifies the column. If you use Interface Builder to design the data browser, this is the unique value you enter in the Property ID field in the column paned of the Info window for a list view column. (For example, `mTxt` or `BLUE`). The four-character sequence must have at least one uppercase letter in it because sequences that are all lowercase are reserved for Apple.

`propertyType`
: The data type or control type to be displayed in the column. See "Display Types" (page 2275) for a list of the possible values for this field.

`propertyFlags`
: A value that contains property flags that control the display or interaction provided by the column. This is a 32-bit value that is divided into four parts as follows:

- Bits 0–7 specify properties applied to the data browser as a whole—see "Property Flags: Universal" (page 2284)
- Bits 8–15 modify display behavior—see "Property Flags: Modifiers" (page 2285)
- Bits 16–23 are properties specific to list view—see "Property Flags: Offset and Mask for List View Properties" (page 2288) and "Property Flags: List View Column Behavior" (page 2289)
- Bits 24–31 can be defined by your application—see "Property Flags: Offset and Mask for Client-Defined Properties" (page 2290)

Availability
Available in Mac OS X v10.0 and later.

Declared In
`HIDataBrowser.h`

DataBrowserCallbacks

Contains universal procedure pointers (UPPs) to callback functions used to obtain information from your application or notify your application of changes to the data browser.

```
struct DataBrowserCallbacks {
    UInt32 version
    union {
        struct {
            DataBrowserItemDataUPP itemDataCallback;
            DataBrowserItemCompareUPP itemCompareCallback;
            DataBrowserItemNotificationUPP itemNotificationCallback;
            DataBrowserAddDragItemUPP addDragItemCallback;
            DataBrowserAcceptDragUPP acceptDragCallback;
            DataBrowserReceiveDragUPP receiveDragCallback;
            DataBrowserPostProcessDragUPP postProcessDragCallback;
            DataBrowserItemHelpContentUPP itemHelpContentCallback;
            DataBrowserGetContextualMenuUPP getContextualMenuCallback;
            DataBrowserSelectContextualMenuUPP selectContextualMenuCallback;
        } v1;
    } u;
};
typedef struct DataBrowserCallbacks DataBrowserCallbacks;
```

Fields

`version`
: The version of the custom callbacks structure. Set this field to the constant `kDataBrowserLatestCallbacks`.

`u.v1.itemDataCallback`
: A universal procedure pointer to an item-data callback.

`u.v1.itemCompareCallback`
A universal procedure pointer to an item-compare callback.

`u.v1.itemNotificationCallback`
A universal procedure pointer to an item-notification callback or item-notification-with-data callback.

`u.v1.addDragItemCallback`
A universal procedure pointer to an add-drag-item callback.

`u.v1.acceptDragCallback`
A universal procedure pointer to an accept-drag callback.

`u.v1.receiveDragCallback`
A universal procedure pointer to a receive-drag callback.

`u.v1.postProcessDragCallback`
A universal procedure pointer to a postprocess-drag callback.

`u.v1.itemHelpContentCallback`
A universal procedure pointer to an item-help-content callback.

`u.v1.getContextualMenuCallback`
A universal procedure pointer to a get-contextual-menu callback.

`u.v1.selectContextualMenuCallback`
A universal procedure pointer to a select-contextual-menu callback.

Discussion
Your application does not need to fill out the entire data structure. It must provide a UPP to an item-data callback. You provide UPPs only for the other tasks your application wants to handle. For more information on installing callbacks, see the functions `InitDataBrowserCallbacks` (page 2175) and `SetDataBrowserCallbacks` (page 2200).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`HIDataBrowser.h`

DataBrowserCustomCallbacks

Contains universal procedure pointers (UPPs) to callback functions that implement custom drawing and user interaction for columns that have the display type `kDataBrowserCustomType`.

```
struct DataBrowserCustomCallbacks {
    UInt32 version
    union {
        struct {
            DataBrowserDrawItemUPP drawItemCallback;
            DataBrowserEditItemUPP editTextCallback;
            DataBrowserHitTestUPP hitTestCallback;
            DataBrowserTrackingUPP trackingCallback;
            DataBrowserItemDragRgnUPP dragRegionCallback;
            DataBrowserItemAcceptDragUPP acceptDragCallback;
            DataBrowserItemReceiveDragUPP receiveDragCallback;
        } v1;
    } u;
};
typedef struct DataBrowserCustomCallbacks DataBrowserCustomCallbacks;
```

Fields

`version`
The version of the custom callbacks structure. Use `kDataBrowserLatestCustomCallbacks`.

`u.v1.drawItemCallback`
A universal procedure pointer to a draw-item callback.

`u.v1.editTextCallback`
A universal procedure pointer to an edit-text callback.

`u.v1.hitTestCallback`
A universal procedure pointer to a hit-test callback

`u.v1.trackingCallback`
A universal procedure pointer to a tracking callback.

`u.v1.dragRegionCallback`
A universal procedure pointer to an item-drag-region callback.

`u.v1.acceptDragCallback`
A universal procedure pointer to an item-accept-drag callback.

`u.v1.receiveDragCallback`
A universal procedure pointer to an item-receive-drag callback.

Discussion

Your application can use the `DataBrowserCustomCallbacks` structure to provide callbacks that control the presentation of user interface elements displayed inside a data browser. Your application does not need to fill out the entire data structure. You need to provide UPPs only for tasks your application wants to handle. For more information on installing callbacks, see the functions `InitDataBrowserCustomCallbacks` (page 2176) and `SetDataBrowserCustomCallbacks` (page 2203).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`HIDataBrowser.h`

DataBrowserDragFlags

Defines a data type for values used in drag callbacks.

```
typedef unsigned long DataBrowserDragFlags;
```

Discussion
This data type is used as a return value for the item-accept-drag callback (`DataBrowserItemAcceptDragProcPtr` (page 2242)) and as a parameter to the item-receive-drag callback (`DataBrowserItemReceiveDragProcPtr` (page 2254)). The values associated with this data type are `kDataBrowserItemIsDragTarget` and `kDataBrowserItemNoState`. See "Item States" (page 2280) for more information on these constants.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`HIDataBrowser.h`

DataBrowserItemDataRef

Defines a data type for a pointer that specifies an item.

```
typedef void *DataBrowserItemDataRef;
```

Discussion
Functions listed in "Getting and Setting Item Data" (page 2115) are called from within a data browser item-data callback routine (`DataBrowserItemDataProcPtr` (page 2245)). Each of these functions use a `DataBrowserItemDataRef` data type to specify the item to get or set data for.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`HIDataBrowser.h`

DataBrowserItemID

Defines a data type for a value that identifies an item independent of its position in a data browser.

```
typedef UInt32 DataBrowserItemID;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`HIDataBrowser.h`

DataBrowserPropertyFlags

Defines a data type for a value that specifies the behavior and look of a data browser.

```
typedef unsigned long DataBrowserPropertyFlags;
```

Discussion
These constants in the following sections are `DataBrowserPropertyFlags` data types:

- "Property Flags: Universal" (page 2284). Bits 0–7 modify the appearance or behavior of display properties.
- "Property Flags: Modifiers" (page 2285). Bits 8–15 specify how the data associated with a display type is displayed.
- "Property Flags: Offset and Mask for List View Properties" (page 2288). Specify an offset and mask for bits 16–23.
- "Property Flags: List View Column Behavior" (page 2289). Bits 16–23 specify behaviors for columns in list view.
- "Property Flags: Offset and Mask for Client-Defined Properties" (page 2290). Specify an offset and mask for bits 24–31.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`HIDataBrowser.h`

DataBrowserPropertyID

Defines a data type for a value that identifies a column independent of its position in a data browser.

```
typedef UInt32 DataBrowserPropertyID;
```

Discussion
Typically, this is a four-character sequence that you assign to represent a column in list view. For example, a column that displays song titles could be assigned a property ID of `SONG` and you'd assign it to a constant in your application using code similar to the following:

```
kSongColumn = SONG;
```

Then, each time call a function that requires a parameter of type `DataBrowserPropertyID`, supply the appropriate application-defined constant.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`HIDataBrowser.h`

DataBrowserTableViewRowIndex

Defines a data type for a value that specifies a row position in a table view.

```
typedef UInt32 DataBrowserTableViewRowIndex;
```

Discussion
Row indices are zero based.

Availability
Available in Mac OS X v10.0 and later.

Declared In
HIDataBrowser.h

DataBrowserTableViewColumnIndex

Defines a data type for a value that specifies column position in a table view.

```
typedef UInt32 DataBrowserTableViewColumnIndex;
```

Discussion
This data type is typically used for table-view formatting. Column indices are zero based.

Availability
Available in Mac OS X v10.0 and later.

Declared In
HIDataBrowser.h

DataBrowserTableViewColumnID

Defines a data type for a value that identifies a column independent of its position in a data browser.

```
typedef DataBrowserPropertyID DataBrowserTableViewColumnID;
```

Discussion
For details on using this data type, see DataBrowserPropertyID (page 2268).

Availability
Available in Mac OS X v10.0 and later.

Declared In
HIDataBrowser.h

DataBrowserTableViewColumnDesc

Defines a data type for a table view column description.

```
typedef DataBrowserPropertyDesc DataBrowserTableViewColumnDesc;
```

Discussion
See the DataBrowserPropertyDesc (page 2263) data structure for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
HIDataBrowser.h

DataBrowserListViewHeaderDesc

Describes the appearance of a column title in list view.

```
struct DataBrowserListViewHeaderDesc {
    UInt32 version;
    UInt16 minimumWidth;
    UInt16 maximumWidth;
    SInt16 titleOffset;
    CFStringRef titleString;
    DataBrowserSortOrder initialOrder;
    ControlFontStyleRec btnFontStyle;
    ControlButtonContentInfo btnContentInfo;
};
typedef struct DataBrowserListViewHeaderDesc DataBrowserListViewHeaderDesc;
```

Fields

`version`
The format of the structure. Set this field to the value `kDataBrowserListViewLatestHeaderDesc`.

`minimumWidth`
For resizable columns, the smallest width to which the column can be resized. If the column is not resizable, set this to the same value as the `maximumWidth` field.

`maximumWidth`
For resizable columns, the largest width to which the column can be resized. If the column is not resizable, set this to the same value as the `minimumWidth` field.

`titleOffset`
An offset, in pixels, from the left side of the column that specifies where the title text will be drawn. The title alignment (set in the `just` field of the `btnFontStyle` parameter) and the `titleOffset` values dictate the alignment and offset (inset by default) of the content of the column when displaying one of he predefined display types. Typically the title offset is set to `0`.

`titleString`
The text to use for the column title. Set the string to `NULL` if you do not want to display a title.

`initialOrder`
The initial sorting order to use for the column when the column is the current sort column. After the data browser is visible, the user can change the sorting order. You can assign one of the following values:

- `kDataBrowserOrderIncreasing` means this column sorts in ascending order.
- `kDataBrowserOrderDecreasing` means this column sorts in descending order.

`btnFontStyle`
A structure that describes the contents of the column heading and how to draw them. This allows you to customize the font that the column title is drawn with, which is independent of the font used to draw the data in the column.

`btnContentInfo`
A structure that defines the icon, if any, to use for the column heading.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`HIDataBrowser.h`

DataBrowserListViewColumnDesc

Contains property information for a list view column and specifies display information for the column title.

```
struct DataBrowserListViewColumnDesc {
    DataBrowserTableViewColumnDesc propertyDesc;
    DataBrowserListViewHeaderDesc headerBtnDesc;
};
typedef struct DataBrowserListViewColumnDesc DataBrowserListViewColumnDesc;
```

Fields

`propertyDesc`

A structure that contains property and display information for a column. See `DataBrowserTableViewColumnDesc` (page 2269) for more information.

`headerBtnDesc`

A structure that contains display information for the column title. See `DataBrowserListViewHeaderDesc` (page 2269) for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`HIDataBrowser.h`

kHIDataBrowserClassID

Defines the HIObject class ID for the HIDataBrowser class.

```
#define kHIDataBrowserClassID CFSTR("com.apple.HIDataBrowser");
```

Availability
Available in Mac OS X v10.4 and later.

Constants

Callback Data Structure Version

Specifies the version of the latest standard callback data structure.

```
enum {
    kDataBrowserLatestCallbacks = 0
};
```

Constants

`kDataBrowserLatestCallbacks`

A convenience constant used in the `DataBrowserCallbacks` (page 2264) data structure to specify the version of the structure.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

Control Data Tags

Define data-browser-specific tags for use with the Control Manager functions `GetControlData` and `SetControlData`.

```
enum {
  kControlDataBrowserIncludesFrameAndFocusTag = 'brdr',
  kControlDataBrowserKeyFilterTag = kControlEditTextKeyFilterTag,
  kControlDataBrowserEditTextKeyFilterTag =
                kControlDataBrowserKeyFilterTag,
  kControlDataBrowserEditTextValidationProcTag =
                kControlEditTextValidationProcTag
};
```

Constants

`kControlDataBrowserIncludesFrameAndFocusTag`
Include the frame and user focus. The associated data is of type `Boolean`.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kControlDataBrowserKeyFilterTag`
Use a filter. The associated data is a universal procedure pointer to a `ControlKeyFilterProcPtr` callback. This callback is invoked when the user edits an item.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kControlDataBrowserEditTextKeyFilterTag`
Use a text filter. This is a duplicate of `kControlDataBrowserKeyFilterTag`.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kControlDataBrowserEditTextValidationProcTag`
Use a callback to validate the text. The associated data is a universal procedure pointer to a `ControlEditTextValidataionProcPtr` callback. This callback is invoked when the user finishes editing an item.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

Discussion

You can use these options with the Control Manger functions `GetControlData` and `SetControlData`.

Custom Callback Data Structure Version

Specifies the version of the latest custom callback data structure.

```
enum {
    kDataBrowserLatestCustomCallbacks = 0
};
```

Constants

`kDataBrowserLatestCustomCallbacks`
A convenience constant used in the `DataBrowserCustomCallbacks` (page 2265) data structure to specify the version of the structure.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

Data Browser Attributes

Specifies data browser attribute constants.

```
enum {
kDataBrowserAttributeNone = 0,
kDataBrowserAttributeColumnViewResizeWindow = (1 << 0),
kDataBrowserAttributeListViewAlternatingRowColors = (1 <<
1)
kDataBrowserAttributeListViewDrawColumnDividers = (1 << 2)
};
```

Constants

`kDataBrowserAttributeNone`
The data browser has no attributes.

Available in Mac OS X v10.4 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserAttributeColumnViewResizeWindow`
In column view, this data browser is allowed to resize the owning window whenever necessary. This includes, but is not necessarily limited to, situations where column resize operations need more visible space in the window. If you turn this attribute on, your window must tolerate being resized behind your application's back. If your window needs to react to bounds changes, use a `kEventWindowBoundsChanged` event handler. If you need to constrain your window's minimum and maximum bounds, use the `kEventWindowGetMinimumSize` and `kEventWindowGetMaximumSize` handlers, the `SetWindowResizeLimits` function, or something similar.

Available in Mac OS X v10.4 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserAttributeListViewAlternatingRowColors`
In list view, this data browser should draw alternating row background colors. However, note that this attribute does not work with variable row heights as of Mac OS X v10.4.

Available in Mac OS X v10.4 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserAttributeListViewDrawColumnDividers`
In list view, this data browser should draw a vertical line between the columns.

Available in Mac OS X v10.4 and later.

Declared in `HIDataBrowser.h`.

Discussion
Use these constants in conjunction with `DataBrowserGetAttributes` (page 2127) and `DataBrowserChangeAttributes` (page 2127).

Availability
Available in Mac OS X v10.4 and later.

Data Browser Control Kind Tag

Specifies the control type is a data browser.

```
enum {
kControlKindDataBrowser       = 'datb'
};
```

Constants
`kControlKindDataBrowser`
The data browser control type.
Available in Mac OS X v10.0 and later.
Declared in `HIDataBrowser.h`.

Discussion
When you call the function `GetControlKind` with a control reference that represents a data browser, you obtain the data browser tag `kControlKindDataBrowser` as the control type.

Data Browser Metric Values

Specifies constants used by `DataBrowserSetMetric`.

```
enum {
kDataBrowserMetricCellContentInset = 1,
kDataBrowserMetricIconAndTextGap = 2,
kDataBrowserMetricDisclosureColumnEdgeInset = 3,
kDataBrowserMetricDisclosureTriangleAndContentGap = 4,
kDataBrowserMetricDisclosureColumnPerDepthGap = 5,
kDataBrowserMetricLast = kDataBrowserMetricDisclosureColumnPerDepthGap
};
typedef UInt32 DataBrowserMetric;
```

Constants
`kDataBrowserMetricCellContentInset`
The content (icon, text, etc.) within a cell is drawn a certain amount in from the left and right edges of the cell. This metric governs the amount of inset.
Available in Mac OS X v10.4 and later.
Declared in `HIDataBrowser.h`.

`kDataBrowserMetricIconAndTextGap`
This metric controls the space between the icon and text within a column of type `kDataBrowserIconAndTextType`.
Available in Mac OS X v10.4 and later.
Declared in `HIDataBrowser.h`.

`kDataBrowserMetricDisclosureColumnEdgeInset`
In list view only, this metric is used instead of (not in addition to) `DataBrowserMetricCellContentInset` for the side of the cell in the disclosure column that displays the disclosure triangle.

Available in Mac OS X v10.4 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserMetricDisclosureTriangleAndContentGap`
In list view only, this metric controls the amount of space between the disclosure triangle and the cell's content.

Available in Mac OS X v10.4 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserMetricDisclosureColumnPerDepthGap`
In list view only, this metric controls the amount of space in the disclosure column for each level of indentation in progressively deeper hierarchies of disclosed items.

Available in Mac OS X v10.4 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserMetricLast`
Same as `kDataBrowserMetricDisclosureColumnPerDepthGap`.

Available in Mac OS X v10.4 and later.

Declared in `HIDataBrowser.h`.

Display Types

Specify a data type or control to display in a column.

```
typedef OSType DataBrowserPropertyType;
enum {
    kDataBrowserCustomType = 0x3F3F3F3F,
    kDataBrowserIconType = 'icnr',
    kDataBrowserTextType = 'text',
    kDataBrowserDateTimeType = 'date',
    kDataBrowserSliderType = 'sldr',
    kDataBrowserCheckboxType = 'chbx',
    kDataBrowserProgressBarType = 'prog',
    kDataBrowserRelevanceRankType = 'rank',
    kDataBrowserPopupMenuType = 'menu',
    kDataBrowserIconAndTextType = 'ticn'
};
```

Constants

`kDataBrowserCustomType`
Displays custom data defined by your application. You must install callbacks to handle items of this type. Use custom types with caution. In some cases custom types do not display properly or exhibit the appropriate behavior.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserIconType`
Displays icons. The associated data for the icon can be of type `IconRef`, `IconTransformType`, and `RGBColor`.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserTextType`
Displays text. The associated data is a CFString object.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserDateTimeType`
Displays date and time information. The associated data can be of type `DateTime` or `LongDateTime`.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserSliderType`
Displays slider controls. The associated data are values that define the minimum and maximum values and the current value for the slider. Avoid using slider controls in a data browser because, in some cases, they do not display properly onscreen.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserCheckboxType`
Displays checkbox controls. The associated data is the current value of the checkbox and a `ThemeButtonValue` value. Avoid using checkbox controls in a data browser because, in some cases, they do not display properly onscreen.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserProgressBarType`
Displays progress bar controls. The associated data are values that define the minimum and maximum values and the current setting for the progress bar.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserRelevanceRankType`
Displays relevance indicators. The associated data are values that define the minimum and maximum values and the current setting for the relevance indicator. Avoid using relevance indicators in a data browser because, in some cases, they do not display properly onscreen.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserPopupMenuType`
Displays pop-up menus. The associated data is a `MenuRef` data type, a menu item ID, and the value of the pop-up menu, which indicates the item of the menu to draw in the pop-up menu. Avoid using pop-up menu controls in a data browser because, in some cases, they do not display properly onscreen.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserIconAndTextType`
Displays icon and text data. The associated data can be of any data type used for icons or text, such as an `IconRef` data type and a CFString object.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

Discussion
You can use these constants to define what is displayed in a column. Each constant defines a presentation style and implies a specific set of primitive types or data structures.

Editing Commands

Specifies editing actions to apply to a data browser item.

```
typedef UInt32 DataBrowserEditCommand;
enum {
    kDataBrowserEditMsgUndo = kHICommandUndo,
    kDataBrowserEditMsgRedo = kHICommandRedo,
    kDataBrowserEditMsgCut = kHICommandCut,
    kDataBrowserEditMsgCopy = kHICommandCopy,
    kDataBrowserEditMsgPaste = kHICommandPaste,
    kDataBrowserEditMsgClear = kHICommandClear,
    kDataBrowserEditMsgSelectAll = kHICommandSelectAll
};
```

Constants
`kDataBrowserEditMsgUndo`
Undo the last editing operation.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserEditMsgRedo`
Redo the last editing operation that was undone.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserEditMsgCut`
Cut the contents of the selection to the Clipboard.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserEditMsgCopy`
Copy the contents of the selection o the Clipboard.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserEditMsgPaste`
Replace the contents of the selection with the contents of the Clipboard.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserEditMsgClear`
Remove the contents of the selection.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserEditMsgSelectAll`
Select all of the text inside of the current edit session.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

Discussion
These options are for use with the functions `EnableDataBrowserEditCommand` (page 2137) and `ExecuteDataBrowserEditCommand` (page 2138).

Item Notifications

Specify notifications provided by the data browser to your application.

```
typedef UInt32 DataBrowserItemNotification;
enum {
    kDataBrowserItemAdded = 1,
    kDataBrowserItemRemoved = 2,
    kDataBrowserEditStarted = 3,
    kDataBrowserEditStopped = 4,
    kDataBrowserItemSelected = 5,
    kDataBrowserItemDeselected = 6,
    kDataBrowserItemDoubleClicked = 7,
    kDataBrowserContainerOpened = 8,
    kDataBrowserContainerClosing = 9,
    kDataBrowserContainerClosed = 10,
    kDataBrowserContainerSorting = 11,
    kDataBrowserContainerSorted = 12,
    kDataBrowserUserStateChanged = 13,
    kDataBrowserSelectionSetChanged = 14,
    kDataBrowserTargetChanged = 15,
    kDataBrowserUserToggledContainer = 16
};
```

Constants
`kDataBrowserItemAdded`
The specified item has been added to a container in the data browser.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserItemRemoved`
The specified item has been removed from a container in the data browser.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserEditStarted`
An text editing session has started for the specified item.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserEditStopped`
An text editing session has stopped for the specified item.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserItemSelected`
An item has been added to the selection set.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserItemDeselected`
An item has been removed from the selection set.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserItemDoubleClicked`
The user double-clicked an item.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserContainerOpened`
A container has been opened.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserContainerClosing`
A container is about to close. This notification is sent at the start of the close operation. The container still contains its child items and it is still valid to pass them to data browser functions. The data browser handles closing automatically, so typically applications do not look for this notification. You'd use this only if you are interested in fetching information on the items before the close actually happens.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserContainerClosed`
A container has been closed. This notification is sent after the close operation, so it is no longer valid to pass child items to data browser functions.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserContainerSorting`
A container is about to be sorted.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserContainerSorted`
A container has been sorted.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserUserStateChanged`
The user has reformatted the view for the target. For example, the user changed a sorting order or a column width.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserSelectionSetChanged`
The selection set has been modified.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserTargetChanged`
The target has changed to the specified item.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserUserToggledContainer`
The user has toggled opened or closed a container by clicking a disclosure triangle.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

Discussion
These notifications are used with the callbacks `DataBrowserItemNotificationProcPtr` (page 2250) and `DataBrowserItemNotificationWithItemProcPtr` (page 2251). Notifications sent for containers are the same regardless of whether the container opens to an expandable row or to individual rows for each item in the container.

Item States

Indicate the current state of an item in the data browser.

```
typedef UInt32 DataBrowserItemState;
enum {
    kDataBrowserItemNoState = 0,
    kDataBrowserItemAnyState = (unsigned long) (-1),
    kDataBrowserItemIsSelected = 1 << 0,
    kDataBrowserContainerIsOpen = 1 << 1,
    kDataBrowserItemIsDragTarget = 1 << 2
};
```

Constants
`kDataBrowserItemNoState`
The state is undefined.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserItemAnyState`
Any state is acceptable.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserItemIsSelected`
The item is selected.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserContainerIsOpen`
The item container is open. This state applies to:

- A parent item in a hierarchical list in list view
- An item in column view if the item's contents are displayed in the next column

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserItemIsDragTarget`
The item is a drag target.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

List View Header Description Version

Defines the version of the list view header description data structure.

```
enum {
    kDataBrowserListViewLatestHeaderDesc = 0
};
```

Constants

`kDataBrowserListViewLatestHeaderDesc`
A convenience constant that specifies the version of the list view header description data structure.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

List View Append Column

Defines the last column as the column to use for an append operation.

```
enum {
    kDataBrowserListViewAppendColumn = kDataBrowserTableViewLastColumn
};
```

Constants

`kDataBrowserListViewAppendColumn`
The column to use for an append operation.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

No Item Constant

Specifies that there is no item to provide or obtain.

```
enum {
    kDataBrowserNoItem = 0L
};
```

Constants

`kDataBrowserNoItem`
A convenience constant used when there is no item to provide or obtain. This value is of type `DataBrowserItemID`.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

Properties

Specify attributes for items, containers, and columns.

```
enum {
    kDataBrowserItemNoProperty = 0L,
    kDataBrowserItemIsActiveProperty = 1L,
    kDataBrowserItemIsSelectableProperty = 2L,
    kDataBrowserItemIsEditableProperty = 3L,
    kDataBrowserItemIsContainerProperty = 4L,
    kDataBrowserContainerIsOpenableProperty = 5L,
    kDataBrowserContainerIsClosableProperty = 6L,
    kDataBrowserContainerIsSortableProperty = 7L,
    kDataBrowserItemSelfIdentityProperty = 8L,
    kDataBrowserContainerAliasIDProperty = 9L,
    kDataBrowserColumnViewPreviewProperty = 10L,
    kDataBrowserItemParentContainerProperty = 11L
};
```

Constants

`kDataBrowserItemNoProperty`
No property; no associated data.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserItemIsActiveProperty`
The active state of the item. The associated data is of type `Boolean`. The default value `true` indicates the item is active.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserItemIsSelectableProperty`
The selection capability of the item. The associated data is of type `Boolean`. The default value `true` indicates the item can be selected.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserItemIsEditableProperty`
The editing capability of the item. The associated data is of type `Boolean`. The default value `false` indicates the item cannot be edited.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserItemIsContainerProperty`
The container attribute for an item. The associated data is of type `Boolean`. The default value `false` indicates the item cannot contain other items.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserContainerIsOpenableProperty`
The opening capability of a container item. The associated data is of type `Boolean`. The default value `true` indicates the container can be opened.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserContainerIsClosableProperty`
The closing capability of a container item. The associated data is of type `Boolean`. The default value `true` indicates the container can be closed.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserContainerIsSortableProperty`
The sorting capability of container item. The associated data is of type `Boolean`. The default value `true` indicates the items in the container can be sorted.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserItemSelfIdentityProperty`
This property is used only in column view for the item-data and item-compare callbacks. You should not use this property for anything else. It is passed to your item-data callback when the data browser needs to know the data to draw to represent the item. It is your responsibility to provide the data to display for that item in whatever format would be appropriate for the column view display type, which is `kDataBrowserIconAndTextType`.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserContainerAliasIDProperty`
An alias or symbolic link from an item to a container item. The associated data is of type `DataBrowserItemID`. This property is sent to your item-data callback to provide your application with a chance to follow an alias that the item might represent. If the incoming item is an alias to another item, you can call the function `SetDataBrowserItemDataItemID` to inform the data browser which other item the incoming item points to.

This property is sent only from column view. Your support for it is optional. Your response allows the data browser to be a bit more memory efficient with its internal storage. If a given item is an alias to an item whose contents are already displayed in one column of the column view, the contents can be shared between those two columns.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserColumnViewPreviewProperty`

The column displays a preview. There is no associated data. Available only in column view. This property is sent to your draw-item callback to indicate the need for you to draw a preview of the given item. It can be sent to other callbacks to provide an opportunity for your application to draw or track in the preview column.

You can also pass this in the `propertyID` parameter of the function `RevealDataBrowserItem` (along with the appropriate item ID of the item whose preview is displayed) to make sure the preview column is visible to the user.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserItemParentContainerProperty`

Designates the parent of the specified item. The associated data is of type `DataBrowserItemID`. This is sent to your item-data callback when the data browser needs to know the parent container item for a given item.

In column view, this allows the function `SetDataBrowserTarget` (page 2229) to process the data properly. The target is the leaf node item whose contents you want to display, which is the rightmost column in column view. However, unlike `SetDataBrowserColumnViewPath`, the function `SetDataBrowserTarget` doesn't offer a way for you to communicate the item IDs of the rest of the column containers, so `SetDataBrowserTarget` asks for them explicitly by requesting the item's parent, then the parent of the item's parent, and so on. (Your item-data callback might be called with the parent container property at times other than an explicit call to `SetDataBrowserTarget`, so your item-data callback should support this property.)

In list view, this property allows you to pass a non-container to `SetDataBrowserTarget`. In this case, the data browser requests the parent of the target so it knows which container to display the contents of in the list view. (Again, your item-data callback might be called with the parent container property at times other than an explicit call to `SetDataBrowserTarget`, so your item-data callback should be sure to support this property.)

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

Discussion
You can use these constants along with the appropriate value to manage the attributes of items in a data browser. Typically your item-data callback responds to inquires about these properties by calling the appropriate accessor function from within the callback. See `DataBrowserItemDataProcPtr` (page 2245) for more information on the item-data callback. "Getting and Setting Item Data" (page 2115) describes the accessor functions.

Property Flags: Universal

Modify the appearance or behavior of display properties.

```
enum {
    kDataBrowserUniversalPropertyFlagsMask = 0xFF,
    kDataBrowserPropertyIsMutable = 1 << 0,
    kDataBrowserDefaultPropertyFlags = 0 << 0,
    kDataBrowserUniversalPropertyFlags =  kDataBrowserUniversalPropertyFlagsMask,
    kDataBrowserPropertyIsEditable = kDataBrowserPropertyIsMutable
};
```

Constants

`kDataBrowserUniversalPropertyFlagsMask`
Test for universal property flags. This constant is used by the data browser; your application doesn't need to use it.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserPropertyIsMutable`
The property is mutable. You can assign this flag to the `propertyFlags` field of the `DataBrowserPropertyDesc` structure. You must set this flag is you want to allow editing of the text part of the property.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserDefaultPropertyFlags`
The default properties. You can assign this flag to the `propertyFlags` field of the `DataBrowserPropertyDesc` structure if all you need is the default behavior. The default is for all flags to be off.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserUniversalPropertyFlags`
Universal property flags. This constant is used by the data browser; your application doesn't need to use it.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserPropertyIsEditable`
The data can be edited. You must set this flag if you want to allow editing of the text part of the property. This flag can be set if the values displayed in the column can be changed. If your application specifies this flag, then it must also provide a callback that allows the data browser to retrieve and store data values displayed in this column. You can assign this flag to the `propertyFlags` field of the `DataBrowserPropertyDesc` structure.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

Discussion

These constants reside in bits 0–7 of the `DataBrowserPropertyFlags` data type.

Property Flags: Modifiers

Specify how to display the data associated with a display type.

```
enum {
    kDataBrowserPropertyFlagsOffset = 8,
    kDataBrowserPropertyFlagsMask =
                0xFF << kDataBrowserPropertyFlagsOffset,
    kDataBrowserCheckboxTriState  =
                1 << kDataBrowserPropertyFlagsOffset,
    kDataBrowserDateTimeRelative  =
                1 << (kDataBrowserPropertyFlagsOffset),
    kDataBrowserDateTimeDateOnly  =
                1 << (kDataBrowserPropertyFlagsOffset + 1),
    kDataBrowserDateTimeTimeOnly  =
                1 << (kDataBrowserPropertyFlagsOffset + 2),
    kDataBrowserDateTimeSecondsToo =
                1 << (kDataBrowserPropertyFlagsOffset + 3),
    kDataBrowserSliderPlainThumb  =
            kThemeThumbPlain << kDataBrowserPropertyFlagsOffset,
    kDataBrowserSliderUpwardThumb =
            kThemeThumbUpward << kDataBrowserPropertyFlagsOffset,
    kDataBrowserSliderDownwardThumb =
            kThemeThumbDownward << kDataBrowserPropertyFlagsOffset,
    kDataBrowserDoNotTruncateText =
                3 << kDataBrowserPropertyFlagsOffset,
    kDataBrowserTruncateTextAtEnd =
                2 << kDataBrowserPropertyFlagsOffset,
    kDataBrowserTruncateTextMiddle =
                0 << kDataBrowserPropertyFlagsOffset,
    kDataBrowserTruncateTextAtStart =
                1 << kDataBrowserPropertyFlagsOffset,
    kDataBrowserPopupMenuButtonless =
                1 << kDataBrowserPropertyFlagsOffset,
    kDataBrowserPropertyModificationFlags =
                 kDataBrowserPropertyFlagsMask,
    kDataBrowserRelativeDateTime  = kDataBrowserDateTimeRelative
};
```

Constants

`kDataBrowserPropertyFlagsOffset`

The offset value for this set of property flags.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserPropertyFlagsMask`

Use to set or test for property modifier flags.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserCheckboxTriState`

Modifies the `kDataBrowserCheckboxType` display type to display a checkbox that can have on, off, and mixed-mode states instead of just on and off states.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserDateTimeRelative`

Modifies the `kDataBrowserDateTimeType` display type to display relative date and time.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserDateTimeDateOnly`
Modifies the `kDataBrowserDateTimeType` display type to display only the date.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserDateTimeTimeOnly`
Modifies the `kDataBrowserDateTimeType` display type to display only the time.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserDateTimeSecondsToo`
Modifies the `kDataBrowserDateTimeType` display type to display the time with seconds.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserSliderPlainThumb`
Modifies the `kDataBrowserSliderType` display type to display a round thumb.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserSliderUpwardThumb`
Modifies the `kDataBrowserSliderType` display type to display a directional thumb that points up.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserSliderDownwardThumb`
Modifies the `kDataBrowserSliderType` display type to display a directional thumb that points down.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserDoNotTruncateText`
Modifies the `kDataBrowserTextType` and the `kDataBrowserIconAndTextType` display types so they do not truncate text.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserTruncateTextAtEnd`
Modifies the `kDataBrowserTextType` and the `kDataBrowserIconAndTextType` display types so they truncate text, if needed, at the end of the text string.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserTruncateTextMiddle`
Modifies the `kDataBrowserTextType` and the `kDataBrowserIconAndTextType` display types so they truncate text, if needed, in the middle of the text string.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserTruncateTextAtStart`
Modifies the `kDataBrowserTextType` and the `kDataBrowserIconAndTextType` display type so they truncate text, if needed, at the beginning of the text string.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserPopupMenuButtonless`
This flag is only for use with columns of type `kDataBrowserPopupMenuType` and indicates that the popup is to be drawn in a sleek buttonless fashion. The text is drawn next to a popup glyph, and the whole cell is clickable.

Available on Mac OS X v10.4 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserPropertyModificationFlags`
Old name. Instead use `kDataBrowserPropertyFlagsMask`.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserRelativeDateTime`
Old name. Instead use `kDataBrowserDateTimeRelative`.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

Discussion
These constants reside in bits 8–15 of the `DataBrowserPropertyFlags` data type.

Property Flags: Offset and Mask for List View Properties

Specify an offset and mask for bits 16–23 of the `DataBrowserPropertyFlag` data type.

```
enum {
    kDataBrowserViewSpecificFlagsOffset = 16,
    kDataBrowserViewSpecificFlagsMask =
            0xFF << kDataBrowserViewSpecificFlagsOffset,
    kDataBrowserViewSpecificPropertyFlags =
            kDataBrowserViewSpecificFlagsMask
};
```

Constants
`kDataBrowserViewSpecificFlagsOffset`
The offset value for this set of property flags.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserViewSpecificFlagsMask`
Use to set or test for view-specific property flags.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserViewSpecificPropertyFlags`
Old name. Instead use `kDataBrowserViewSpecificFlagsMask`.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

Discussion
See also "Property Flags: List View Column Behavior" (page 2289).

Property Flags: List View Column Behavior

Specify behaviors for columns in list view.

```
typedef DataBrowserPropertyFlags DataBrowserListViewPropertyFlags;
enum {
    kDataBrowserListViewSelectionColumn =
                kDataBrowserTableViewSelectionColumn,
    kDataBrowserListViewMovableColumn =
                1 << (kDataBrowserViewSpecificFlagsOffset  + 1),
    kDataBrowserListViewSortableColumn =
                1 << (kDataBrowserViewSpecificFlagsOffset  + 2),
    kDataBrowserListViewTypeSelectColumn =
                1 << (kDataBrowserViewSpecificFlagsOffset  + 3),
    kDataBrowserListViewNoGapForIconInHeaderButton =
                1 << (kDataBrowserViewSpecificFlagsOffset  + 4),
    kDataBrowserListViewDefaultColumnFlags =
              kDataBrowserListViewMovableColumn +
              kDataBrowserListViewSortableColumn
};
```

Constants
`kDataBrowserListViewSelectionColumn`
If you are using a minimally highlighted list, this indicates to draw the contents of this column as highlighted when the item is selected. (Minimal highlighting is the highlighting used by the Finder for list view prior to Mac OS X version 10.3.)

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserListViewMovableColumn`
The column is movable.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserListViewSortableColumn`
The column can be sorted.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserListViewTypeSelectColumn`
: The column is capable of being selected and having text entered. If one or more of your list view columns are marked as type-selectable, the data browser handles type-selection for you automatically. You can use this flag with columns whose display type is `kDataBrowserTextType`, `kDataBrowserIconAndTextType`, or `kDataBrowserDateTimeType`. If you set this flag for a column of another type, the type-select behavior is undefined. Turning on this flag causes the data browser to obtain keyboard input using a Carbon event handler instead of relying on calls to the function `HandleControlKey`.

Declared in `HIDataBrowser.h`.

Available in Mac OS X 10.3 and later.

`kDataBrowserListViewNoGapForIconInHeaderButton`
: Normally the text in a header button for a column of type `kDataBrowserIconAndTextType` is aligned as though it has an icon next to it even if no icon is specified for the header button. This flag indicates that space should not be reserved for an icon if no icon is provided for the header button. This flag allows a client to justify the left edge of the text in a header button to the left edge of the icon in the cells beneath it.

Declared in `HIDataBrowser.h`.

Available in Mac OS X v10.4 and later.

`kDataBrowserListViewDefaultColumnFlags`
: The default properties. You can assign this flag to the `propertyFlags` field of the `DataBrowserPropertyDesc` structure if all you need is the default behavior for list view.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

Discussion
These constants reside in bits 16–23 of the `DataBrowserPropertyFlags` data type and are specific to a list view.

Property Flags: Offset and Mask for Client-Defined Properties

Specify an offset and mask for the high 8 bits of the `DataBrowserPropertyFlag` data type.

```
enum {
    kDataBrowserClientPropertyFlagsOffset = 24,
    kDataBrowserClientPropertyFlagsMask = (unsigned long)
            (0xFF << kDataBrowserClientPropertyFlagsOffset)
};
```

Constants
`kDataBrowserClientPropertyFlagsOffset`
: The offset value for this set of property flags.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserClientPropertyFlagsMask`
: The mask value for this set of property flags.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

Discussion
Bits 24–31 of the `DataBrowserPropertyFlags` data type are reserved for use by your application. You can set and query them for your own purposes.

Property Parts

Specify the visual components of a data type or control displayed in a column.

```
typedef OSType DataBrowserPropertyPart;
enum {
    kDataBrowserPropertyEnclosingPart = 0,
    kDataBrowserPropertyContentPart = '----',
    kDataBrowserPropertyDisclosurePart = 'disc',
    kDataBrowserPropertyTextPart = kDataBrowserTextType,
    kDataBrowserPropertyIconPart = kDataBrowserIconType,
    kDataBrowserPropertySliderPart = kDataBrowserSliderType,
    kDataBrowserPropertyCheckboxPart = kDataBrowserCheckboxType,
    kDataBrowserPropertyProgressBarPart = kDataBrowserProgressBarType,
    kDataBrowserPropertyRelevanceRankPart =
                kDataBrowserRelevanceRankType
};
```

Constants

`kDataBrowserPropertyEnclosingPart`
The outer boundary of an item.
Available in Mac OS X v10.0 and later.
Declared in `HIDataBrowser.h`.

`kDataBrowserPropertyContentPart`
The content of an item.
Available in Mac OS X v10.0 and later.
Declared in `HIDataBrowser.h`.

`kDataBrowserPropertyDisclosurePart`
The location of a disclosure rectangle.
Available in Mac OS X v10.0 and later.
Declared in `HIDataBrowser.h`.

`kDataBrowserPropertyTextPart`
The location where text is drawn.
Available in Mac OS X v10.0 and later.
Declared in `HIDataBrowser.h`.

`kDataBrowserPropertyIconPart`
The location where an icon is displayed.
Available in Mac OS X v10.0 and later.
Declared in `HIDataBrowser.h`.

`kDataBrowserPropertySliderPart`
The location of a slider.
Available in Mac OS X v10.0 and later.
Declared in `HIDataBrowser.h`.

`kDataBrowserPropertyCheckboxPart`
The location of a checkbox.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserPropertyProgressBarPart`
The location of a progress bar.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserPropertyRelevanceRankPart`
The location of a relevance indicator.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

Discussion
You can pass these constants as a parameter to the function `GetDataBrowserItemPartBounds` (page 2156) to obtain a rectangle that contains the bounds for the specified part.

Reveal Options

Specify how to position an item in a data browser.

```
typedef UInt8 DataBrowserRevealOptions;
enum {
    kDataBrowserRevealOnly = 0,
    kDataBrowserRevealAndCenterInView = 1 << 0,
    kDataBrowserRevealWithoutSelecting = 1 << 1
};
```

Constants
`kDataBrowserRevealOnly`
Move the content of the data browser as little as possible to make the item visible, and show the item in a selected state.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserRevealAndCenterInView`
Reveal the item so that, if possible, the item is centered in the data browser.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserRevealWithoutSelecting`
Reveal the item but do not select it.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

Discussion
You can pass reveal options as a parameter to the function `RevealDataBrowserItem` (page 2199). You can pass more than one at a time for combined functionality.

Selection Anchor Directions

Specify an anchor direction to apply when the user drags a data selection.

```
typedef UInt32 DataBrowserSelectionAnchorDirection;
enum {
    kDataBrowserSelectionAnchorUp = 0,
    kDataBrowserSelectionAnchorDown = 1,
    kDataBrowserSelectionAnchorLeft = 2,
    kDataBrowserSelectionAnchorRight = 3
};
```

Constants

`kDataBrowserSelectionAnchorUp`
Apply the anchor direction at the top of the selection set.
Available in Mac OS X v10.0 and later.
Declared in `HIDataBrowser.h`.

`kDataBrowserSelectionAnchorDown`
Apply the anchor direction at the bottom of the selection set.
Available in Mac OS X v10.0 and later.
Declared in `HIDataBrowser.h`.

`kDataBrowserSelectionAnchorLeft`
Apply the anchor direction at the left of the selection set.
Available in Mac OS X v10.0 and later.
Declared in `HIDataBrowser.h`.

`kDataBrowserSelectionAnchorRight`
Apply the anchor direction at the right of the selection set.
Available in Mac OS X v10.0 and later.
Declared in `HIDataBrowser.h`.

Discussion

These options are for use with the function `MoveDataBrowserSelectionAnchor` (page 2186).

Selection State Options

Specify how the selection state should be affected by a given list of items.

```
typedef UInt32 DataBrowserSetOption;
enum {
    kDataBrowserItemsAdd = 0,
    kDataBrowserItemsAssign = 1,
    kDataBrowserItemsToggle = 2,
    kDataBrowserItemsRemove = 3
};
```

Constants

`kDataBrowserItemsAdd`
Add specified items to the existing set or selection.
Available in Mac OS X v10.0 and later.
Declared in `HIDataBrowser.h`.

`kDataBrowserItemsAssign`
Assign the destination set to the specified item and redraw the list appropriately.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserItemsToggle`
Toggle the membership state of the specified items. Any of the items in the current selection are removed from the selection, and those items that are not in the selection are added to the selection.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserItemsRemove`
Remove specified items from the existing set and redraw the items so they are not highlighted.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

Discussion
These options are for use with the function `SetDataBrowserSelectedItems` (page 2222).

Sorting Orders

Specify the order in which to sort data.

```
typedef UInt16 DataBrowserSortOrder;
enum {
    kDataBrowserOrderUndefined = 0,
    kDataBrowserOrderIncreasing = 1,
    kDataBrowserOrderDecreasing = 2
};
```

Constants
`kDataBrowserOrderUndefined`
This constant has no meaning in the context of your application; don't use it.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserOrderIncreasing`
Sort in increasing order.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserOrderDecreasing`
Sort in decreasing order.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

Table View Highlighting Styles

Specify a highlighting style to use in list view.

```
typedef UInt32 DataBrowserTableViewHiliteStyle;
enum {
    kDataBrowserTableViewMinimalHilite = 0,
    kDataBrowserTableViewFillHilite = 1
};
```

Constants

`kDataBrowserTableViewMinimalHilite`

Use minimal highlighting. This is the highlighting used by the Finder for list view prior to Mac OS X v. 10.3. For this style, the highlight color for active items is `kThemeBrushPrimaryHighlightColor` and for inactive items the color is `kThemeBrushSecondaryHighlightColor`.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserTableViewFillHilite`

Use full-row highlighting. This is the highlighting used by the Finder for list view in Mac OS X v. 10.3. For this style, the highlight color in Mac OS X v. 10.3 for active items is `kThemeBrushAlternatePrimaryHighlightColor` and for inactive items the color is `kThemeBrushSecondaryHighlightColor`. Prior to Mac OS X v. 10.3 the highlight color for active and inactive items is `kThemeBrushPrimaryHighlightColor`.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

Table View Last Column Value

Specifies the last column position.

```
enum {
    kDataBrowserTableViewLastColumn = -1
};
```

Constants

`kDataBrowserTableViewLastColumn`

The last column position.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

Table View Property Flag

Specifies a table view property.

```
typedef UInt32 DataBrowserTableViewPropertyFlags;
enum {
   kDataBrowserTableViewSelectionColumn = 1 <<  kDataBrowserViewSpecificFlagsOffset
};
```

Constants

`kDataBrowserTableViewSelectionColumn`

The column can be selected.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

Tracking Results

Specify the outcome of tracking a drag operation.

```
typedef SInt16 DataBrowserTrackingResult;
enum {
    kDataBrowserContentHit = 1,
    kDataBrowserNothingHit = 0,
    kDataBrowserStopTracking = -1
};
```

Constants

`kDataBrowserContentHit`
Indicates that a selectable portion of the item was hit. The data browser will select the item and do other relevant actions as appropriate.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserNothingHit`
Indicates that a nonselectable portion—whitespace—was hit. The data browser won't select the item, but it could, for example, start a selection rectangle.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

`kDataBrowserStopTracking`
Indicates the callback handled the click completely. The data browser will not attempt to display a contextual menu, start a drag, process a double-click, or draw a selection rectangle. The callback is responsible for all facets of click handling if it returns this value.

Available in Mac OS X v10.0 and later.

Declared in `HIDataBrowser.h`.

Discussion

These constants are returned from the custom tracking callback, `DataBrowserTrackingProcPtr` (page 2259).

User Selection Flags

Specify allowable selection behavior.

```
typedef UInt32 DataBrowserSelectionFlags;
enum {
    kDataBrowserDragSelect = 1 << 0,
    kDataBrowserSelectOnlyOne = 1 << 1,
    kDataBrowserResetSelection = 1 << 2,
    kDataBrowserCmdTogglesSelection = 1 << 3,
    kDataBrowserNoDisjointSelection = 1 << 4,
    kDataBrowserAlwaysExtendSelection = 1 << 5,
    kDataBrowserNeverEmptySelectionSet = 1 << 6
};
```

Constants

`kDataBrowserDragSelect`
: Allows items to be selected by dragging. If the user to clicks the mouse to select a nondraggable item and drags the mouse, any item the pointer moves over is selected. This is on by default.

  Available in Mac OS X v10.0 and later.

  Declared in `HIDataBrowser.h`.

`kDataBrowserSelectOnlyOne`
: Only one item can be selected at a time. If you use this flag in conjunction with the flag `kDataBrowserDragSelect`, then as the user drags, previous items are deselected as each new item is dragged over.

  Available in Mac OS X v10.0 and later.

  Declared in `HIDataBrowser.h`.

`kDataBrowserResetSelection`
: Clears all selected items before processing the next selection. This is off by default.

  Available in Mac OS X v10.0 and later.

  Declared in `HIDataBrowser.h`.

`kDataBrowserCmdTogglesSelection`
: Enables use of a command to toggle items in and out of a selection. This is on by default.

  Available in Mac OS X v10.0 and later.

  Declared in `HIDataBrowser.h`.

`kDataBrowserNoDisjointSelection`
: Prevents a discontinuous selection.

  Available in Mac OS X v10.0 and later.

  Declared in `HIDataBrowser.h`.

`kDataBrowserAlwaysExtendSelection`
: Multiple items can be selected without holding down a modifier key.

  Available in Mac OS X v10.0 and later.

  Declared in `HIDataBrowser.h`.

`kDataBrowserNeverEmptySelectionSet`
: There must always be at least one selected item; the user cannot deselect the last selected item.

  Available in Mac OS X v10.0 and later.

  Declared in `HIDataBrowser.h`.

Discussion

You can use one or more of these flags together.

View Styles

Specify a style to use when displaying data in a data browser.

```
typedef OSType DataBrowserViewStyle;
enum {
    kDataBrowserNoView = '????',
    kDataBrowserListView = 'lstv',
    kDataBrowserColumnView = 'clmv'
};
```

Constants

`kDataBrowserNoView`
There is no view.
Available in Mac OS X v10.0 and later.
Declared in `HIDataBrowser.h`.

`kDataBrowserListView`
Display data in a list. Lists can be hierarchical.
Available in Mac OS X v10.0 and later.
Declared in `HIDataBrowser.h`.

`kDataBrowserColumnView`
Display data in columns that can be browsed.
Available in Mac OS X v10.0 and later.
Declared in `HIDataBrowser.h`.

Result Codes

The most common result codes returned by the data browser are listed here.

Result Code	Value	Description
`errDataBrowserNotConfigured`	-4970	The data browser is not properly configured. Available in Mac OS X v10.0 and later.
`errDataBrowserItemNotFound`	-4971	The item is not in the data browser. Available in Mac OS X v10.0 and later.
`errDataBrowserPropertyNotFound`	-4972	The property is not in the data browser. Available in Mac OS X v10.0 and later.
`errDataBrowserInvalidPropertyPart`	-4973	The property part is not valid. Available in Mac OS X v10.0 and later.
`errDataBrowserInvalidPropertyData`	-4974	The property data is not valid. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
`errDataBrowserItemNotAdded`	-4975	The item was not added to the data browser. Available in Mac OS X v10.0 and later.
`errDataBrowserPropertyNotSupported`	-4979	The property is not supported in the data browser. Available in Mac OS X v10.0 and later.

Fonts Panel Reference

Framework: CommonPanels.framework
Declared in FontPanel.h

Overview

The Fonts Panel programming interface is a collection of functions and data types that support the use of a Fonts panel in a Carbon application. The Fonts panel is the preferred user interface for fonts in Mac OS X.

Functions

FPIsFontPanelVisible

Checks whether the Fonts panel is visible.

```
Boolean FPIsFontPanelVisible (
   void
);
```

Return Value
Returns `true` if the Fonts panel is visible; `false` otherwise. See the Mac Types documentation for a description of the `Boolean` data type.

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X version 10.2.

Declared In
`FontPanel.h`

FPShowHideFontPanel

Shows or hides the Fonts panel.

```
OSStatus FPShowHideFontPanel (
   void
);
```

Return Value
A result code. See "Fonts Panel Results Codes" (page 2308).

Discussion
The function `FPShowHideFontPanel` shows the Fonts panel if the panel is not visible and hides the Fonts panel if the panel is visible.

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X version 10.2.

Declared In
`FontPanel.h`

SetFontInfoForSelection

Sets the selections that appear in the Fonts panel.

```
OSStatus SetFontInfoForSelection (
   OSType iStyleType,
   UInt32 iNumStyles,
   void *iStyles,
   EventTargetRef iFPEventTarget
);
```

Parameters

`iStyleType`
The type of style data you are passing to the Fonts panel. Pass `kFontSelectionQDType` if you supply a `FontSelectionQDStyle` data structure in the `iStyles` parameter. Pass `kFontSelectionATSUIType` if you supply `ATSUStyle` data in the `iStyles` parameter.

`iNumStyles`
The number of styles passed in the `iStyles` parameter.

`iStyles`
A pointer to an array of data structures that correspond to the style type specified by the `iStyleType` parameter.

`iFPEventTarget`
The event target you want to receive the Carbon event `kEventFontSelection` that is associated with the Fonts panel. You typically specify the event target for the window that is sending the style selection to the Fonts panel.

Return Value
A result code. See "Fonts Panel Results Codes" (page 2308).

Discussion
You can programmatically set a selection in the Fonts panel by calling the function `SetFontInfoForSelection`. You can call this function even when the Fonts panel is not open or visible. When the Fonts panel becomes visible later, the style information specified in the most recent call to `SetFontInfoForSelection` is selected in the panel.

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X version 10.2.

Declared In
`FontPanel.h`

Data Types

FontSelectionQDStyle

Contains QuickDraw style font information.

```
struct FontSelectionQDStyle {
    UInt32 version;
    FMFontFamilyInstance instance;
    FMFontSize size;
    Boolean hasColor;
    UInt8 reserved;
    RGBColor color;
};
typedef struct FontSelectionQDStyle FontSelectionQDStyle;
typedef FontSelectionQDStyle * FontSelectionQDStylePtr;
```

Fields

`version`
: Specifies the version number of the data structure.

`instance`
: Specifies a font family instance.

`size`
: Specifies the font size in points.

`hasColor`
: Specifies whether the font has a color other than black.

`reserved`
: Reserved for future use.

`color`
: Specifies the font color.

Discussion

You should use this data structure to specify QuickDraw-style font information when you call the function `SetFontInfoForSelection` (page 2302). When you use this data structure, you must pass the constant `kFontSelectionQDType` in the `iStyleType` parameter of the function.

Availability

Available in Mac OS X v10.2 and later.

Declared In

`FontPanel.h`

FontSelectionQDStylePtr

A pointer to a data structure that contains QuickDraw style font information.

```
typedef FontSelectionQDStyle * FontSelectionQDStylePtr;
```

Discussion

See `FontSelectionQDStyle` (page 2303) for more information.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`FontPanel.h`

Constants

Font Event Class

Specifies a Carbon event related to font selection or handling.

```
enum {
    kEventClassFont = 'font'
};
```

Constants

`kEventClassFont`
Specifies a Carbon event related to font selection or handling.
Available in Mac OS X v10.2 and later.
Declared in `FontPanel.h`.

Declared In
`FontPanel.h`

Fonts Panel Events

Specify a Fonts panel Carbon event.

```
enum {
    kEventFontPanelClosed = 1,
    kEventFontSelection = 2
};
```

Constants

`kEventFontPanelClosed`
Specifies a close event in the Fonts panel. Your application should update the user interface as necessary. For example, you may need to change a Hide Fonts Panel menu command to Show Fonts Panel.
Available in Mac OS X v10.2 and later.
Declared in `FontPanel.h`.

`kEventFontSelection`
Specifies a selection event in the Fonts panel. Your application can obtain the selections from the event parameters associated with this event. Your application must check for all those parameters it handles and apply the selections to the text.
Available in Mac OS X v10.2 and later.
Declared in `FontPanel.h`.

Discussion
When the user closes the Fonts panel, the action generates the Carbon event `kEventWindowClosed`. You can then update any menu items or other controls whose state may need to change. The event `kEventWindowClosed` has no parameters. However, when the user selects an item in the Fonts panel, the system sends the Carbon event `kEventFontSelection` to the event target you specified when your application called the Fonts Panel function `SetFontInfoForSelection` (page 2302). The event `kEventFontSelection` has parameters that reflect the current Fonts panel selection.

Declared In
`FontPanel.h`

Font Information Types

Specify the type of font information.

```
enum {
    kFontSelectionATSUIType = 'astl',
    kFontSelectionQDType = 'qstl'
};
```

Constants
`kFontSelectionATSUIType`
Specifies ATSUI data (`ATSUStyle`).
Available in Mac OS X v10.2 and later.
Declared in `FontPanel.h`.

`kFontSelectionQDType`
Specifies QuickDraw data (`FontSelectionQDStyle`).
Available in Mac OS X v10.2 and later.
Declared in `FontPanel.h`.

Discussion
These constants specify the type of font information passed to the function `SetFontInfoForSelection` (page 2302).

Declared In
`FontPanel.h`

Font Information Versions

Specify the supported versions of the `FontSelectionQDStyle` data structure.

```
enum {
    kFontSelectionQDStyleVersionZero = 0
};
```

Constants
`kFontSelectionQDStyleVersionZero`
Specifies version 0 of a QuickDraw font selection.
Available in Mac OS X v10.2 and later.
Declared in `FontPanel.h`.

Discussion
You should always set the `version` field in the `FontSelectionQDStyle` data structure to this constant

Declared In
`FontPanel.h`

Fonts Panel Command

Specifies the four-character code for the show/hide Fonts panel command.

```
enum {
    kHICommandShowHideFontPanel = 'shfp'
};
```

Constants
`kHICommandShowHideFontPanel`
Specifies the four-character code for the show/hide Fonts panel command.
Available in Mac OS X v10.2 and later.
Declared in `FontPanel.h`.

Discussion
If the user closes the Fonts panel directly, your application receives a `kEventFontPanelClosed` Carbon event. You can then call the Carbon Event Manager function `GetEventParameter` to extract the HI command from the event.

Declared In
`FontPanel.h`

Font Parameters and Data Types

Specify font event parameters and their associated data types.

```
enum {
    typeATSUFontID = typeUInt32,
    typeATSUSize = typeFixed,
    typeFMFontFamily = typeSInt16,
    typeFMFontStyle = typeSInt16,
    typeFMFontSize = typeSInt16,
    typeFontColor = typeRGBColor,
    kEventParamATSUFontID = 'auid',
    kEventParamATSUFontSize = 'ausz',
    kEventParamFMFontFamily = 'fmfm',
    kEventParamFMFontStyle = 'fmst',
    kEventParamFMFontSize = 'fmsz',
    kEventParamFontColor = 'fclr'
};
```

Constants
`typeATSUFontID`
Specifies that an `ATSUFontID` is of type `UInt32`.
Available in Mac OS X v10.2 and later.
Declared in `FontPanel.h`.

`typeATSUSize`
Specifies that an `ATSUSize` is of type `Fixed`.

Available in Mac OS X v10.2 and later.

Declared in `FontPanel.h`.

`typeFMFontFamily`
Specifies that an `FMFontFamily` is of type `SInt16`.

Available in Mac OS X v10.2 and later.

Declared in `FontPanel.h`.

`typeFMFontStyle`
Specifies that an `FMFontStyle` is of type `SInt16`.

Available in Mac OS X v10.2 and later.

Declared in `FontPanel.h`.

`typeFMFontSize`
Specifies that an `FMFontSize` is of type `SInt16`.

Available in Mac OS X v10.2 and later.

Declared in `FontPanel.h`.

`typeFontColor`
Specifies that a font color is of type `RGBColor`.

Available in Mac OS X v10.2 and later.

Declared in `FontPanel.h`.

`kEventParamATSUFontID`
Specifies the four-character code associated with an `ATSUFontID` selection in the Fonts panel.

Available in Mac OS X v10.2 and later.

Declared in `FontPanel.h`.

`kEventParamATSUFontSize`
Specifies the four-character code associated with an `ATSUFontSize` selection in the Fonts panel.

Available in Mac OS X v10.2 and later.

Declared in `FontPanel.h`.

`kEventParamFMFontFamily`
Specifies the four-character code associated with an `FMFontFamily` selection in the Fonts panel.

Available in Mac OS X v10.2 and later.

Declared in `FontPanel.h`.

`kEventParamFMFontStyle`
Specifies the four-character code associated with an `FMFontStyle` selection in the Fonts panel.

Available in Mac OS X v10.2 and later.

Declared in `FontPanel.h`.

`kEventParamFMFontSize`
Specifies the four-character code associated with an `FMFontSize` selection in the Fonts panel.

Available in Mac OS X v10.2 and later.

Declared in `FontPanel.h`.

`kEventParamFontColor`

Specifies the four-character code associated with a font color selection in the Fonts panel.

Available in Mac OS X v10.2 and later.

Declared in `FontPanel.h`.

Discussion

Table 28-1 (page 2308) lists the parameters and data types associated with the Carbon event `kEventFontSelection`.

Table 28-1 Parameters and parameter data types for a font selection event.

Parameter	Data type
`kEventParamATSUFontID`	`typeATSUFontID`
`kEventParamATSUFontSize`	`typeATSUFontSize`
`kEventParamFMFontFamily`	`typeFMFontFamily`
`kEventParamFMFontStyle`	`typeFMFontStyle`
`kEventParamFMFontSize`	`typeFMFontSize`
`kEventParamFontColor`	`typeFontColor`

Declared In

`FontPanel.h`

Result Codes

The most common result codes returned by the Fonts Panel programming interface are listed below.

Result Code	Value	Description
`fontPanelShowErr`	-8880	The Fonts panel could not be opened. Available in Mac OS X v10.2 and later.
`fontPanelSelectionStyleErr`	-8881	Your application specified an invalid style type in the `iStyleType` parameter of the `SetFontInfoForSelection` (page 2302) function. Available in Mac OS X v10.2 and later.
`fontPanelFontSelectionQDStyleVersionErr`	-8882	Your application specified an invalid version in the `version` field of the `FontSelectionQDStyle` data structure. Available in Mac OS X v10.2 and later.

HIArchive Reference

Framework: Carbon/Carbon.h

Declared in HIArchive.h

Overview

HIArchive provides a convenient and standardized mechanism for flattening data objects so they can be stored in memory or on disk. Applications can use these archives whenever they need to package complex data. For example, you can use archives to:

- Store document data
- Transfer data using pasteboards, drag-and-drop, streams, or Apple events
- Store localization strings and user interface elements in the same package

HIArchive encodes archives in the binary property list format. You can convert archives to a text XML format using the `plutil` property list tool accessible from Terminal. HIArchive is comparable to (and uses the same underlying mechanism as) the Cocoa NSKeyedArchiver/Unarchiver classes.

For details about using HIArchive, see *HIArchive Programming Guide*.

HIArchive is available in Mac OS X version 10.4 and later.

Functions by Task

Storing Objects in an Archive

`HIArchiveCreateForEncoding` (page 2312)
Creates an HIArchive object to store objects.

`HIArchiveEncodeBoolean` (page 2314)
Stores a Boolean value in an archive.

`HIArchiveEncodeNumber` (page 2315)
Stores a number in an archive.

`HIArchiveEncodeCFType` (page 2314)
Stores a CFType object in an archive.

`HIArchiveCopyEncodedData` (page 2311)
Compresses an archive for storage.

Retrieving Objects from an Archive

`HIArchiveCreateForDecoding` (page 2311)
Creates an HIArchive object to retrieve objects.

`HIArchiveDecodeBoolean` (page 2312)
Retrieves a Boolean value from an archive.

`HIArchiveDecodeNumber` (page 2313)
Retrieves a number from an archive.

`HIArchiveCopyDecodedCFType` (page 2310)
Retrieves a CFType object from an archive.

Miscellaneous Function

`HIArchiveGetTypeID` (page 2316)
Obtains the CFType ID for HIArchive objects.

Functions

HIArchiveCopyDecodedCFType

Retrieves a CFType object from an archive.

```
OSStatus HIArchiveCopyDecodedCFType (
   HIArchiveRef inDecoder,
   CFStringRef inKey,
   CFTypeRef *outCFType
);
```

Parameters

inDecoder
The archive holding the CFType object to retrieve.

inKey
A Core Foundation string key identifying the CFType object to retrieve.

outCFType
On return, `outCFType` points to the retrieved CFType object.

Return Value
A result code.

Discussion
You also use this function for retrieving HIObjects and objects subclassed from HIObject.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`HIArchive.h`

HIArchiveCopyEncodedData

Compresses an archive for storage.

```
OSStatus HIArchiveCopyEncodedData (
   HIArchiveRef inEncoder,
   CFDataRef *outData
);
```

Parameters

inEncoder

The archive to compress.

outData

On return, `outData` points to the compressed archive.

Return Value

A result code.

Discussion

When you have finished adding data to an archive, calling `HIArchiveCopyEncodedData` compresses the data and returns it to you as a CFData object. You can use the returned data reference to store or transfer the data as you choose, for example writing it to a file or copying it to a pasteboard.

After compression, you can release the original HIArchive reference by calling `CFRelease`.

Availability

Available in Mac OS X v10.4 and later.

Not available to 64-bit applications.

Declared In

`HIArchive.h`

HIArchiveCreateForDecoding

Creates an HIArchive object to retrieve objects.

```
OSStatus HIArchiveCreateForDecoding (
   CFDataRef inData,
   OptionBits inOptions,
   HIArchiveRef *outDecoder
);
```

Parameters

inData

A CFData reference pointing to archived data. This archive was originally written to a data stream using `HIArchiveCopyEncodedData` (page 2311). This data reference does not have to be the one originally returned by `HIArchiveCopyEncodedData` (page 2311), but it must contain a copy of the same data.

inOptions

Any decoding options. Currently the only option is `kHIArchiveDecodeSuperclassForUnregisteredObjects`.

outDecoder

On return, `outDecoder` points to the newly created HIArchive object.

Return Value
A result code.

Discussion
You use this function when you want to retrieve data from an existing HIArchive.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`HIArchive.h`

HIArchiveCreateForEncoding

Creates an HIArchive object to store objects.

```
OSStatus HIArchiveCreateForEncoding (
   HIArchiveRef *outEncoder
);
```

Parameters

outEncoder
On return, `outEncoder` points to the newly created HIArchive object.

Return Value
A result code.

Discussion
Before you can archive any objects, you must create an HIArchive object in which to store them.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`HIArchive.h`

HIArchiveDecodeBoolean

Retrieves a Boolean value from an archive.

```
OSStatus HIArchiveDecodeBoolean (
   HIArchiveRef inDecoder,
   CFStringRef inKey,
   Boolean *outBoolean
);
```

Parameters

inDecoder
The archive holding the Boolean value.

inKey
A Core Foundation string key identifying the Boolean to retrieve.

outBoolean
On return, outBoolean points to the retrieved Boolean value.

Return Value
A result code.

Discussion
This function is a convenience wrapper that calls HIArchiveCopyDecodedCFType (page 2310) to obtain a CFBoolean value.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
HIArchive.h

HIArchiveDecodeNumber

Retrieves a number from an archive.

```
OSStatus HIArchiveDecodeNumber (
   HIArchiveRef inDecoder,
   CFStringRef inKey,
   CFNumberType inNumberType,
   void *outNumberValue
);
```

Parameters
inDecoder
The archive holding the number to retrieve.

inKey
A Core Foundation string key identifying the number to retrieve.

inNumberType
A CFNumber type identifying the type of number value to be retrieved. For example, kCFNumberSInt32Type. See CFNumber Reference in Core Foundation Reference Documentation for additional possible values.

outNumberValue
Before calling, outNumberValue must point to a number variable of the type and size you specified in inNumberType. On return, outNumberValue points to the retrieved number.

Return Value
A result code.

Discussion
This function is a convenience wrapper that calls HIArchiveCopyDecodedCFType (page 2310) to obtain a CFNumber value.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
HIArchive.h

HIArchiveEncodeBoolean

Stores a Boolean value in an archive.

```
OSStatus HIArchiveEncodeBoolean (
   HIArchiveRef inEncoder,
   CFStringRef inKey,
   Boolean inBoolean
);
```

Parameters

inEncoder
The archive to store the Boolean value.

inKey
A Core Foundation string key identifying the Boolean value.

inBoolean
The Boolean value.

Return Value
A result code.

Discussion
This function is a convenience wrapper that calls `HIArchiveEncodeCFType` (page 2314) with a CFBoolean value.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`HIArchive.h`

HIArchiveEncodeCFType

Stores a CFType object in an archive.

```
OSStatus HIArchiveEncodeCFType (
   HIArchiveRef inEncoder,
   CFStringRef inKey,
   CFTypeRef inCFType
);
```

Parameters

inEncoder
The archive to store the CFType object.

inKey
A Core Foundation string key identifying the CFType object.

inCFType
The CFType object to store in the archive.

Return Value
A result code.

Discussion
You can only encode base CFType objects that correspond to archivable NSFoundation objects. For example, type `CFStringRef` is supported, but type `HIShapeRef` is not.

You also use this function for storing HIObjects and objects subclassed from HIObject. Currently only the following HIObject subclass types support archiving:

- `HIObjectRef`
- `HIViewRef`
- `WindowRef`
- `ControlRef`
- `MenuRef`

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`HIArchive.h`

HIArchiveEncodeNumber

Stores a number in an archive.

```
OSStatus HIArchiveEncodeNumber (
   HIArchiveRef inEncoder,
   CFStringRef inKey,
   CFNumberType inNumberType,
   const void *inNumberValue
);
```

Parameters

inEncoder
The archive to store the number.

inKey
A Core Foundation string key identifying the number.

inNumberType
A CFNumber type identifying the type of number value to be stored, for example, `kCFNumberSInt32Type`. See CFNumber Reference in Core Foundation Reference Documentation for additional possible values.

inNumberValue
A pointer to the number value.

Return Value
A result code.

Discussion
This function is a convenience wrapper that calls `HIArchiveEncodeCFType` (page 2314) with a CFNumber value.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`HIArchive.h`

HIArchiveGetTypeID

Obtains the CFType ID for HIArchive objects.

```
CFTypeID HIArchiveGetTypeID (
   void
);
```

Return Value
The Core Foundation type ID for the HIArchive object type.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`HIArchive.h`

Data Types

HIArchiveRef

Defines an uncompressed archive object.

```
typedef struct OpaqueHIArchiveRef* HIArchiveRef;
```

Discussion
The structure pointed to by this reference is opaque. `HIArchiveRef` is a CFType, and therefore responds to `CFRetain` and `CFRelease` calls.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`HIArchive.h`

Constants

Archive Decoding Option Constant

Defines options available when calling `HIArchiveCreateForDecoding` (page 2311).

```
enum {

  kHIArchiveDecodeSuperclassForUnregisteredObjects = (1 <<  0)
};
```

Constants

`kHIArchiveDecodeSuperclassForUnregisteredObjects`

If the class of the HIObject you are attempting to decode is not a registered subclass, this option allows `HIArchiveCopyDecodedCFType` (page 2310) to instantiate the object as its superclass, if it exists. For example, if your application has not yet registered `com.myCorp.mycustomView` before attempting to unarchive an instance of that HIView, HIArchive instantiates the data as class `com.apple.hiview`. Only data written to the superclass is decoded; any data unique to the unregistered subclass is ignored. Specifying this option also signals the HIObject to load its custom archive data so you can access it by calling `HIObjectCopyCustomArchiveData`.

This option can be useful when creating an archive editor that doesn't implement all the objects contained in a client archive.

Available in Mac OS X v10.4 and later.

Declared in `HIArchive.h`.

Result Codes

Result Code	Value	Description
`noErr`	0	No error. Available in Mac OS X v10.0 and later.
`hiArchiveTypeMismatchErr`	-6780	The encoding or decoding archive was passed into a noncorresponding function. (For example, an archive created for encoding was passed into a decoding function.) Available in Mac OS X v10.4 and later.
`hiArchiveKeyNotAvailableErr`	-6781	The requested key does not exist in the specified archive. Available in Mac OS X v10.4 and later.
`hiArchiveEncodingCompleteErr`	-6782	`HIArchiveCopyEncodedData` (page 2311) was called on this archive, so no more data can be added. Available in Mac OS X v10.4 and later.
`hiArchiveHIObjectIgnoresArchivingErr`	-6783	The HIObject you wanted to encode does not support the HIArchive protocol. Available in Mac OS X v10.4 and later.

HIGeometry Reference

Framework: Carbon/Carbon.h

Declared in HIGeometry.h

Overview

HIGeometry is a Quartz-compatible API for describing and manipulating basic geometric objects such as points, rectangles, and sizes. HIGeometry expresses all coordinates using floating-point numbers. This API provides functions to convert an object's coordinates into a different coordinate space. These functions support resolution independence mode drawing by taking into account the scale factor of your application's user interface.

Functions by Task

Getting the Scale Factor

`HIGetScaleFactor` (page 2320)
Returns the scale factor of an application's user interface.

Converting Coordinates

These functions allow conversion between global pixel coordinates, global virtual (72-dpi) coordinates, window coordinates, and view coordinates.

`HIPointConvert` (page 2320)
Converts a point from one coordinate space to another.

`HIRectConvert` (page 2321)
Converts a rectangle from one coordinate space to another.

`HISizeConvert` (page 2322)
Converts a size structure from one coordinate space to another.

Functions

HIGetScaleFactor

Returns the scale factor of an application's user interface.

```
float HIGetScaleFactor (
   void
);
```

Return Value
A positive number that represents the scale factor of your application.

Discussion
The scale factor of your application's user interface is the ratio between device space units and user space units. For example, if the scale factor is 2.0 and you draw a horizontal line with a length of 10 units, the graphics system will display a line with a length of 20 pixels.

The scale factor is initialized when your application launches. In Mac OS X v10.4, the scale factor is always 1.0 (unless you use the Quartz Debug application to change it). In future versions of Mac OS X, the scale factor may vary based on user preference or the resolution of the main display.

Application frameworks such as Cocoa and Carbon use the scale factor to adjust the size of your application's user interface so that it has the appropriately scaled appearance when viewed on the main display.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

`HIWindowGetScaleMode` (page 1889)

Declared In
`HIGeometry.h`

HIPointConvert

Converts a point from one coordinate space to another.

```
void HIPointConvert (
   HIPoint *ioPoint,
   HICoordinateSpace inSourceSpace,
   void *inSourceObject,
   HICoordinateSpace inDestinationSpace,
   void *inDestinationObject
);
```

Parameters
ioPoint
A pointer to the point to convert. On output, the point contains the destination coordinates.

inSourceSpace

A constant specifying the source coordinate space from which the point is to be converted. Some coordinate spaces require the caller to pass extra information in the `inSourceObject` parameter.

inSourceObject

A pointer to an object defining the source coordinate space from which the point is to be converted. You may pass an object of type `WindowRef` (page 1987) or `HIViewRef` (page 2497). If no object is necessary, you must pass `NULL`. See "Coordinate Space Constants" (page 2324) for details on which coordinate spaces require objects.

inDestinationSpace

A constant specifying the destination coordinate space to which the point is to be converted. Some coordinate spaces require the caller to pass extra information in the `inDestinationObject` parameter.

inDestinationObject

A pointer to an object defining the destination coordinate space to which the point is to be converted. You may pass an object of type `WindowRef` (page 1987) or `HIViewRef` (page 2497). If no object is necessary, you must pass `NULL`. See "Coordinate Space Constants" (page 2324) for details on which coordinate spaces require objects.

Discussion

When converting a point from one coordinate space to another, this function takes into account the scale factor of your application's user interface. If the source or destination object is a view, the view should already be embedded in a window. If both the source and destination objects are views, the views are not required to be embedded in the same window.

Availability

Available in Mac OS X v10.4 and later.

Declared In

`HIGeometry.h`

HIRectConvert

Converts a rectangle from one coordinate space to another.

```
void HIRectConvert (
   HIRect *ioRect,
   HICoordinateSpace inSourceSpace,
   void *inSourceObject,
   HICoordinateSpace inDestinationSpace,
   void *inDestinationObject
);
```

Parameters

ioRect

A pointer to the rectangle to convert. On output, the rectangle contains the destination origin and size.

inSourceSpace

A constant specifying the source coordinate space from which the rectangle is to be converted. Some coordinate spaces require the caller to pass extra information in the `inSourceObject` parameter.

inSourceObject

A pointer to an object defining the source coordinate space from which the rectangle is to be converted. You may pass an object of type `WindowRef` (page 1987) or `HIViewRef` (page 2497). If no object is necessary, you must pass `NULL`. See "Coordinate Space Constants" (page 2324) for details on which coordinate spaces require objects.

inDestinationSpace

A constant specifying the destination coordinate space to which the rectangle is to be converted. Some coordinate spaces require the caller to pass extra information in the `inDestinationObject` parameter.

inDestinationObject

A pointer to an object defining the destination coordinate space to which the rectangle is to be converted. You may pass an object of type `WindowRef` (page 1987) or `HIViewRef` (page 2497). If no object is necessary, you must pass `NULL`. See "Coordinate Space Constants" (page 2324) for details on which coordinate spaces require objects.

Discussion

When converting a rectangle from one coordinate space to another, this function takes into account the scale factor of your application's user interface. If the source or destination object is a view, the view should already be embedded in a window. If both the source and destination objects are views, the views are not required to be embedded in the same window.

Availability

Available in Mac OS X v10.4 and later.

Declared In

`HIGeometry.h`

HISizeConvert

Converts a size structure from one coordinate space to another.

```
void HISizeConvert (
   HISize *ioSize,
   HICoordinateSpace inSourceSpace,
   void *inSourceObject,
   HICoordinateSpace inDestinationSpace,
   void *inDestinationObject
);
```

Parameters

ioSize

A pointer to the size structure to convert. On output, the structure contains the destination size.

inSourceSpace

A constant specifying the source coordinate space from which the size is to be converted. Some coordinate spaces require the caller to pass extra information in the `inSourceObject` parameter.

inSourceObject

A pointer to an object defining the source coordinate space from which the size is to be converted. You may pass an object of type `WindowRef` (page 1987) or `HIViewRef` (page 2497). If no object is necessary, you must pass `NULL`. See "Coordinate Space Constants" (page 2324) for details on which coordinate spaces require objects.

inDestinationSpace

A constant specifying the destination coordinate space to which the size is to be converted. Some coordinate spaces require the caller to pass extra information in the `inDestinationObject` parameter.

inDestinationObject
