A pointer to an object defining the destination coordinate space to which the size is to be converted. You may pass an object of type `WindowRef` (page 1987) or `HIViewRef` (page 2497). If no object is necessary, you must pass `NULL`. See "Coordinate Space Constants" (page 2324) for details on which coordinate spaces require objects.

Discussion
When converting a size structure (width and height) from one coordinate space to another, this function takes into account the scale factor of your application's user interface. If the source or destination object is a view, the view should already be embedded in a window. If both the source and destination objects are views, the views are not required to be embedded in the same window.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`HIGeometry.h`

Data Types

HIPoint

Defines the position of a point using floating-point coordinates.

```
typedef CGPoint HIPoint;
```

Discussion
The `HIPoint` type is a data structure that defines the position of a point (x,y) in a floating-point coordinate space. When you obtain a point of type `HIPoint` from an HIToolbox function or a Carbon event, typically the y-axis of the drawing coordinate space is inverted with the origin (0,0) in the upper-left corner of the main display. Note that although it replaces the QuickDraw `Point` data structure, the `HIPoint` data structure does not contain the same fields.

Availability
Available in Mac OS X v10.1 and later.

Declared In
`HIGeometry.h`

HISize

Defines the width and height of an object using floating-point coordinates.

```
typedef CGSize HISize;
```

Availability
Available in Mac OS X v10.2 and later.

Declared In
HIGeometry.h

HIRect

Defines the position and size of a rectangle using floating-point coordinates.

```
typedef CGRect HIRect;
```

Discussion
The HIRect type is a data structure that defines the position and size (width and height) of a rectangle in a floating-point coordinate space. When you obtain a rectangle of type HIRect from an HIToolbox function or a Carbon event, typically the y-axis of the drawing coordinate space is inverted with the origin (0,0) in the upper-left corner of the main display. In this case, the position or origin of the rectangle is its upper-left corner. Note that although it replaces the QuickDraw Rect data structure, the HIRect data structure does not contain the same fields.

Availability
Available in Mac OS X v10.2 and later.

Declared In
HIGeometry.h

Constants

Coordinate Space Constants

Specify coordinate spaces used in HIToolbox.

```
typedef UInt32 HICoordinateSpace;
enum {
    kHICoordSpace72DPIGlobal      = 1,
    kHICoordSpaceScreenPixel      = 2,
    kHICoordSpaceWindow           = 3,
    kHICoordSpaceView             = 4
};
```

Constants
kHICoordSpace72DPIGlobal
Specifies a global coordinate space that has been adjusted by the scale factor of your application's user interface. For example, if a user interface object is 125 x 100 pixels on the screen and the scale factor is 1.25, the size of the object in this coordinate space is 100 x 80. The origin of this coordinate space is the upper-left corner of the main display, and the y-axis is inverted. This is the compatibility coordinate space; Carbon functions that do not take an explicit HICoordinateSpace parameter, such as existing Window Manager, QuickDraw, and Display Manager functions, assume that coordinate parameters are expressed in this space. When the scale factor is 1.0, this coordinate space and kHICoordSpaceScreenPixel are the same.

Available in Mac OS X v10.4 and later.

Declared in HIGeometry.h.

`kHICoordSpaceScreenPixel`

Specifies a coordinate space defined by the screen size in pixels. The origin of this coordinate space is the upper-left corner of the main display, and the y-axis is inverted. When the scale factor of your application's user interface is 1.0, this coordinate space and `kHICoordSpace72DPIGlobal` are the same.

Available in Mac OS X v10.4 and later.

Declared in `HIGeometry.h`.

`kHICoordSpaceWindow`

Specifies the coordinate space of a window of type `WindowRef` (page 1987). The origin of this coordinate space is the upper-left corner of the window's structure region, and the y-axis is inverted. When this constant is passed to a function as a source or destination coordinate space, you must also pass a window as a source or destination object.

Available in Mac OS X v10.4 and later.

Declared in `HIGeometry.h`.

`kHICoordSpaceView`

Specifies the coordinate space of a view of type `HIViewRef` (page 2497). The origin of this coordinate space is the upper-left corner of the view's bounds, and the y-axis is inverted. When this constant is passed to a function as a source or destination coordinate space, you must also pass a view as a source or destination object.

Available in Mac OS X v10.4 and later.

Declared in `HIGeometry.h`.

Declared In
`HIGeometry.h`

HIObject Reference

Framework: Carbon/Carbon.h

Declared in HIObject.h

Overview

HIObject is the base class for various objects in the HIToolbox. In Mac OS X v10.2 and later, most common user interface objects (controls, windows, menus, toolbars, and toolbar items) are derived from HIObject. Code that is external to HIToolbox can also create its own subclasses of these objects using the routines contained in this API. There are also polymorphic functions one can use on any HIObject for getting the class ID, and so on.

HIObjects are actually Core Foundation CF types under the hood. This means that they can be put into CF collections and you can retain/release them.

An HIObject is essentially a very basic building-block object which contains an event target. You can create these objects to use as your own Carbon Event receptors in your application, or you can subclass existing HIToolbox objects to suit your needs.

You register your subclasses with `HIObjectRegisterSubclass` (page 2335), passing your class ID, the parent class, and an event handler. You also pass a list of events the handler is interested in.

To create an object of your subclass, you call `HIObjectCreate` (page 2330), passing the class reference you registered, as well as an initialization event.

Construction is two-phase: first the basic construction of the object is done, then initialization is performed. The HIToolbox sends construction events bottom-up, as you would expect in C++ or the like. Here is the list of what goes on to create an object:

1) The HIToolbox creates the base HIObject

2) It then installs the event handler you specified when you registered your subclass. Your handler must listen for `kEventHIObjectConstruct` and `kEventHIObjectDestruct` events. If it does not, the class cannot be registered (you will get a `paramErr`).

3) Next, the HIToolbox directly calls your handler with an `kEventHIObjectConstruct` event. When called like this, you are not really being called in the context of a handler stack, so you cannot do things like `CallNextEventHandler`. The `userData` parameter is what you specified when you registered the class. Typically, during construction you will allocate memory yourself to store your own instance data; this allocation might be as simple as calling `malloc` or `NewPtr`, or it might involve creating your own C++ object. In the construct event, you are passed the base `HIObjectRef` of the object being created. Typically you would store this `HIObjectRef` in your own instance data for later use. When handling this construct event, you should be sure to use `SetEventParameter` to set the `kEventParamHIObjectInstance` parameter in the construction event with your own instance data. You must use `typeVoidPtr` as the type.

4) The HIToolbox looks for your instance of `typeVoidPtr` after you handle the construct event. It then takes that data and stores it off with the object and also sets the user data of the event handler it installed to be this instance data. This means that following the construct event, all calls to your event handler will have the instance data you returned to us.

5) Once construction has completed successfully, we will send your object the initialize event passed into `HIObjectCreate`. At this point, all events are now sent to your object using standard Carbon event mechanisms (it is only the construct event which is special). When we send the initialization event to your subclass, you should pass the event to your superclass before proceeding. You do this with `CallNextEventHandler`. Once back from that call, you should verify that the result is noErr, indicating that the superclass did in fact initialize properly. If it did not, your should return the error that `CallNextEventHandler` returned from your handler as well. The object will be destroyed by the HIToolbox. Your object should be able to be destroyed in a partially initialized state such as this. This stage is optional, i.e. an object does not need to respond to the initialize event unless it is expecting certain parameters to be passed to it at creation time. This is where those parameters can be fetched.

6) Once initialization is successful, the `HIObjectRef` is returned to the caller of `HIObjectCreate`.

When someone has called `CFRelease` enough such that the reference count of the object drops to zero, the object is destroyed. The HIToolbox will send a `kEventHIObjectDestruct` event to your object. Do not call `CallNextEventHandler`. Just clean up and return from your handler.

For more information about HIObjects and the HIView subclass, see *HIView Programming Guide*.

Functions by Task

Registering and Creating HIObjects

`HIObjectRegisterSubclass` (page 2335)
Registers an HIObject subclass.

`HIObjectCreate` (page 2330)
Creates an object derived from HIObject.

`HIObjectCreateFromBundle` (page 2331)
Obtains the HIObject for the given bundle.

`HIObjectUnregisterClass` (page 2340)
Unregisters a previously registered subclass of HIObject.

HIObject Utility Functions

`HIObjectCopyClassID` (page 2329)
Obtains the class ID of a given HIObject.

`HIObjectIsOfClass` (page 2333)
Determines whether an object is of a certain class.

`HIObjectDynamicCast` (page 2331)
Obtains the instance data for a specific class of an HIObject.

`HIObjectGetEventTarget` (page 2332)
Obtains the event target of an `HIObjectRef`.

Accessibility Functions

`HIObjectSetAccessibilityIgnored` (page 2337)
Marks an HIObject as ignored (or not) for the purposes of the accessibility APIs.

`HIObjectIsAccessibilityIgnored` (page 2332)
Reports whether the given HIObject is marked as ignored for accessibility.

`HIObjectSetAuxiliaryAccessibilityAttribute` (page 2338)
Associates an additional accessibility attribute with an HIObject.

`HIObjectOverrideAccessibilityContainment` (page 2334)
Overrides the AXUIElement references supplied by an HIObject.

Archiving Functions

`HIObjectIsArchivingIgnored` (page 2333)
Obtains a Boolean value indicating whether an HIObject is marked as ignored for archiving.

`HIObjectSetArchivingIgnored` (page 2337)
Changes the state of archiving for an HIObject.

`HIObjectCopyCustomArchiveData` (page 2330)
Copies custom archive data that is associated with an HIObject.

`HIObjectSetCustomArchiveData` (page 2339)
Associates custom archive data with an HIObject.

Miscellaneous Functions

`HIObjectPrintDebugInfo` (page 2335)
Prints the internal information of an HIObject for debugging purposes.

Functions

HIObjectCopyClassID

Obtains the class ID of a given HIObject.

```
CFStringRef HIObjectCopyClassID (
   HIObjectRef inObject
);
```

Parameters

inObject
The object whose class ID you want.

Return Value
A reference to the object's class ID.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`HIObject.h`

HIObjectCopyCustomArchiveData

Copies custom archive data that is associated with an HIObject.

```
OSStatus HIObjectCopyCustomArchiveData (
   HIObjectRef inObject,
   CFDictionaryRef *outCustomData
);
```

Parameters

inObject
The HIObject whose custom archive data you want to retrieve.

outCustomData
On return, a pointer to the custom data, or `NULL` if no custom archive data is associated with the specified object. The caller is responsible for releasing the dictionary when it is no longer needed.

Return Value
An operating system result code.

Discussion
This function would be used by an archive editor to get custom archive data associated with an HIObject so that the data can be edited.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`HIObject.h`

HIObjectCreate

Creates an object derived from HIObject.

```
OSStatus HIObjectCreate (
   CFStringRef inClassID,
   EventRef inConstructData,
   HIObjectRef *outObject
);
```

Parameters

inClassID
The class ID of the class of object you want to instantiate.

inConstructData

If your class (or any class you derive from) accepts creation parameters, you need to pass an event into this parameter. The class must be `kEventClassHIObject`, and the kind should be `kEventHIObjectInitialize`. Any other parameters should be added as necessary. Specific subclasses of HIObject which require initialization parameters will specify those parameters in the appropriate headers.

outObject

The instance of the object you create.

Return Value
A result code. See "HIObject Result Codes" (page 2345).

Availability
Available in Mac OS X v10.2 and later.

Declared In
`HIObject.h`

HIObjectCreateFromBundle

Obtains the HIObject for the given bundle.

```
OSStatus HIObjectCreateFromBundle (
   CFBundleRef inBundle,
   HIObjectRef *outObject
);
```

Parameters

inBundle

The bundle with which you want to communicate.

outObject

The HIObject associated with the bundle.

Return Value
A result code. See "HIObject Result Codes" (page 2345). If the bundle's HIObject creation function cannot be found, `cfragNoSymbolErr` will be returned.

Discussion
A bundle can be designed to communicate with an application through an HIObject. The bundle must be designed to create an HIObject and have a defined suite of Carbon Events that clients can use to communicate with the bundle's HIObject. Given a CFBundleRef, this API will tell the bundle to create the HIObject and return it to the caller.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`HIObject.h`

HIObjectDynamicCast

Obtains the instance data for a specific class of an HIObject.

```
void * HIObjectDynamicCast (
   HIObjectRef inObject,
   CFStringRef inClassID
);
```

Parameters

inObject

The object whose class ID you want to check.

inClassID

The class ID to get the instance data for.

Return Value

A void * result containing the instance data for the object, or `NULL` if the object is not an instance of the class.

Discussion

The instance data returned is the same instance data the class's construction event handler returns in the instance data parameter. This is stored off with the class reference so that it can be fetched later for use by this function. It allows your subclass to easily get at the data it created, if your subclass needs that data outside of an event handler. (Inside an event handler, your subclass can get at its instance data via the userData parameter to the event handler.)

Availability

Available in Mac OS X v10.2 and later.

Declared In

`HIObject.h`

HIObjectGetEventTarget

Obtains the event target of an `HIObjectRef`.

```
EventTargetRef HIObjectGetEventTarget (
   HIObjectRef inObject
);
```

Parameters

inObject

The object whose target you want.

Return Value

An `EventTargetRef`.

Availability

Available in Mac OS X v10.2 and later.

Declared In

`HIObject.h`

HIObjectIsAccessibilityIgnored

Reports whether the given HIObject is marked as ignored for accessibility.

```
Boolean HIObjectIsAccessibilityIgnored (
   HIObjectRef inObject
);
```

Parameters

inObject

The object whose accessibility ignored state you want to query.

Return Value

A Boolean whose value is `true` if the object is marked as ignored or `false` if the object is not marked as ignored.

Discussion

See the discussion of `HIObjectSetAccessibilityIgnored` (page 2337) for details on what it means to be accessibility ignored.

Availability

Available in Mac OS X v10.2 and later.

Not available to 64-bit applications.

Declared In

`HIAccessibility.h`

HIObjectIsArchivingIgnored

Obtains a Boolean value indicating whether an HIObject is marked as ignored for archiving.

```
Boolean HIObjectIsArchivingIgnored (
   HIObjectRef inObject
);
```

Parameters

inObject

The HIObject whose archiving-ignored state is to be queried.

Return Value

A Boolean whose value is `true` if the specified HIObject is ignored for archiving; otherwise, `false`.

Discussion

By default, HIObjects are marked as ignored for archiving, which indicates that the HIObject does not support the archiving protocol.

Availability

Available in Mac OS X v10.4.

Declared In

`HIObject.h`

HIObjectIsOfClass

Determines whether an object is of a certain class.

```
Boolean HIObjectIsOfClass (
   HIObjectRef inObject,
   CFStringRef inObjectClassID
);
```

Parameters

inObject

The object whose class ID you want to check.

inObjectClassID

The class ID in question.

Return Value
A Boolean whose value is `true` if the object is of the specified class; otherwise, `false`.

Discussion
You can use this to see whether an object you have derives from an expected superclass.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`HIObject.h`

HIObjectOverrideAccessibilityContainment

Overrides the AXUIElement references supplied by an HIObject.

```
OSStatus HIObjectOverrideAccessibilityContainment (
   HIObjectRef inHIObject,
   AXUIElementRef inDesiredParent,
   AXUIElementRef inDesiredWindow,
   AXUIElementRef inDesiredTopLevelUIElement
);
```

Parameters

inHIObject

The object whose parent attribute you want to override.

inDesiredParent

The UI element value you want the HIObject to supply for the parent attribute. This function makes a copy of the `AXUIElementRef`, so you must release `inDesiredParent` when this function returns. Pass `NULL` if you want the specified HIObject to supply its normal parent.

inDesiredWindow

The UI element value you want the HIObject to supply for the window attribute. This function makes a copy of the `AXUIElementRef`, so you must release this parameter when this function returns. Pass `NULL` if you want the specified HIObject to supply its normal window, if any.

inDesiredTopLevelUIElement

The UI element you want the HIObject to supply for the top-level element attribute. This function makes a copy of the `AXUIElementRef`, so you must release this parameter when this function returns. Passing `NULL` indicates that you want the HIObject to supply is normal top-level element, if any.

Return Value
An operating system result code.

Discussion
Use this function to change the parent that an HIObject would normally supply in the accessibility hierarchy. For example, a pop-up control would call this function on its menu so that the menu supplies the pop-up control as the menu's parent instead of the application, which would normally be supplied as the menu's parent. You can also use this function to change the window and the top-level element that an HIObject would normally supply.

If the specified HIObject is a standard HIToolbox construct, for example, an HIView or a menu, the specified HIObject is not added as an accessibility child of its normal parent. If it is not a standard construct, the caller is responsible for ensuring that the specified HIObject is not added as an accessibility child of its normal parent.

If the desired `AXUIElementRef` parent represents an HIView, menu, or window, the specified HIObject is automatically added as an accessibility child of the specified parent. In all other cases, it is the caller's responsibility to add the specified HIObject manually as a child of the specified parent. To represent an HIView, menu, or window, an `AXUIElementRef` object must contain the appropriate `HIObjectRef` value and an identifier value of `0`.

Currently, containment overrides are only supported by HIObjects that are of type HIView, Menu, or Window.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`HIAccessibility.h`

HIObjectPrintDebugInfo

Prints the internal information of an HIObject for debugging purposes.

```
void HIObjectPrintDebugInfo (
   HIObjectRef inObject
);
```

Parameters
`inObject`
The object to inspect.

Discussion
This function sends the information to `stdout`.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`HIObject.h`

HIObjectRegisterSubclass

Registers an HIObject subclass.

```
OSStatus HIObjectRegisterSubclass (
   CFStringRef inClassID,
   CFStringRef inBaseClassID,
   OptionBits inOptions,
   EventHandlerUPP inConstructProc,
   ItemCount inNumEvents,
   const EventTypeSpec *inEventList,
   void *inConstructData,
   HIObjectClassRef *outClassRef
);
```

Parameters

inClassID

The class ID of your class. It should be unique. We recommend using Java-style com.company.foo naming conventions to avoid collisions.

inBaseClassID

The class ID of the class you derive from. Passing `NULL` indicates you want to subclass HIObject (the base class) directly.

inOptions

Any special options for your class. Currently you must pass `0` for this parameter.

inConstructProc

A universal procedure pointer to the event handler for this subclass. You pass the address of an event handler into this parameter. This handler is called directly, rather than through the normal event-dispatching mechanism. This means that the EventHandlerCallRef passed in will be `NULL`, and you cannot use it for calls like `CallNextEventHandler`. Other than that, you should return a result as usual. After your object is constructed, this procedure is installed as the event handler for the remaining events specified in the `inEventList` parameter. In Mac OS X v10.4 and later, passing `NULL` creates an "abstract class" that cannot be instantiated but can still be used as a base class for subclasses. If you pass `NULL`, `HIObjectCreate` on the class ID will return `hiObjectClassIsAbstractErr`.

inNumEvents

The number of events you are installing.

inEventList

The events your handler wants to receive. You must handle the `kEventHIObjectConstruct` and `kEventHIObjectDestruct` event. If these events are not specified, an error is returned.

inConstructData

Pass any info you want passed into your event handler here. For a C++ hierarchy based on HIObjects, you might actually pass a static method to construct your object here, and the base class event handler to do construction as your event handler.

outClassRef

The newly created class reference. Pass `NULL` if you don't care.

Return Value

A result code. See "HIObject Result Codes" (page 2345).

Availability

Available in Mac OS X version 10.2 (v10.2) and later.

Declared In

`HIObject.h`

HIObjectSetAccessibilityIgnored

Marks an HIObject as ignored (or not) for the purposes of the accessibility APIs.

```
OSStatus HIObjectSetAccessibilityIgnored (
   HIObjectRef inObject,
   Boolean inIgnored
);
```

Parameters

inObject

The object whose accessibility ignored state you want to change.

inIgnored

A Boolean whose value is `true` to mark the object as ignored or `false` to mark the object as not ignored.

Return Value

An operating system result code.

Discussion

An HIObject that is ignored for accessibility will never be shown to an assistive application that uses the accessibility APIs to examine an interface. Your application's accessibility implementation can (and should) still report an ignored HIObject as usual. Carbon's accessibility engine will automatically prune any ignored HIObjects out of the data that is shown to an assistive application.

By default, an HIObject is *not* accessibility-ignored.

Availability

Available in Mac OS X v10.2 and later.

Not available to 64-bit applications.

Declared In

`HIAccessibility.h`

HIObjectSetArchivingIgnored

Changes the state of archiving for an HIObject.

```
OSStatus HIObjectSetArchivingIgnored (
   HIObjectRef inObject,
   Boolean inIgnored
);
```

Parameters

inObject

The HIObject whose archiving ignored state is to be changed.

inIgnored

A Boolean whose value is `true` to indicate that the specified HIObject does not support the archiving protocol and should be ignored; otherwise, `false`.

Return Value

An operating system result code.

Discussion
Call this function to mark or unmark an HIObject as ignored for archiving. By default, HIObjects are marked as ignored for archiving. HIObject subclasses supporting archiving with the `kEventHIObjectInitialize` and `kEventHIObjectEncode` events must set their archiving ignored state to `false` in order to receive archiving requests from clients. A client may still reset the archive ignored state to `true` on a particular object. An HIObject marked as ignored for archiving will never be requested to encode itself into an archive.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`HIObject.h`

HIObjectSetAuxiliaryAccessibilityAttribute

Associates an additional accessibility attribute with an HIObject.

```
OSStatus HIObjectSetAuxiliaryAccessibilityAttribute (
   HIObjectRef inHIObject,
   UInt64 inIdentifier,
   CFStringRef inAttributeName,
   CFTypeRef inAttributeData
);
```

Parameters

inHIObject
The part of the object-identifier pair that is to be associated with attribute data.

inIdentifier
The part of the object-identifier pair with which the attribute data is to be associated. Pass `0` if you want to associate the attribute data to the HIObject as a whole. For example, pass `0` if you want to associate a description attribute to a push button.

inAttributeName
The name of the attribute that is to be associated with the object-identifier pair. This string is retained before it is added to the auxiliary attribute store.

inAttributeData
The data that is to become the attribute's value. This data is retained before it is added to the auxiliary attribute store. You should release `inAttributeData` after `HIObjectSetAuxiliaryAccessibilityAttribute` returns. Pass `NULL` to indicate that the named auxiliary attribute should no longer be associated with the object-identifier pair. When you pass `NULL`, any named attribute data that was previously associated with the object-identifier pair is released.

Return Value
An operating system result code.

Discussion
Use this function to provide the name and data for an accessibility attribute you want to add to the UIElement representing an HIObject-identifier pair. Normally, Carbon events are used to supply accessibility attributes dynamically, but `HIObjectSetAuxiliaryAccessibilityAttribute` allows you to supply them statically.

This function is particularly useful for supplying values for the `kAXDescriptionAttribute`, `kAXTitleUIElementAttribute`, `kAXServesAsTitleUIElementAttribute`, `kAXLinkedUIElementsAttribute`, and other attributes whose values are specific to the layout and usage

of your application. Note, however, that this function can associate only attributes whose values do not change. If you need to supply attributes whose values are determined dynamically or whose values can be set, you must install the normal accessibility Carbon event handlers for normal accessibility.

When an accessibility attribute Carbon event is handled by the HIObject with a given identifier, the HIToolbox automatically supplies the names and values of any auxiliary attributes associated with the HIObject-identifier pair.

The auxiliary attribute store is consulted during the HIObject's default handling of accessibility attribute Carbon events. This means that any programmatic handling of a given accessibility attribute is able to override or block consultation of the store. In general, if the HIToolbox or a Carbon event handler can provide the attribute value in some other way, the store is not consulted.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`HIAccessibility.h`

HIObjectSetCustomArchiveData

Associates custom archive data with an HIObject.

```
OSStatus HIObjectSetCustomArchiveData (
   HIObjectRef inObject,
   CFDictionaryRef inCustomData
);
```

Parameters

inObject
The HIObject with which custom archive data is to be associated.

inCustomData
A `CFDictionaryRef` containing the custom archive data that is to be associated with the specified HIObject. Associating the custom archive data replaces any data that was previously associated. To archive, the dictionary's keys and values must use CFType callbacks. Pass `NULL` to clear any custom archive data that was previously associated.

Return Value
An operating system result code.

Discussion
This function might be used by an archive editor to associate custom archive data that it has edited with an HIObject.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`HIObject.h`

HIObjectUnregisterClass

Unregisters a previously registered subclass of HIObject.

```
OSStatus HIObjectUnregisterClass (
   HIObjectClassRef inClassRef
);
```

Parameters

inClassRef

The class reference of the object class you want to unregister.

Discussion

You receive an error if there are subclasses of your class or existing instances of it. All instances and subclasses must be disposed of and unregistered first.

Availability

Available in Mac OS X v10.2 and later.

Declared In

HIObject.h

Constants

Standard Custom Archive Data Dictionary Keys for Custom Initialize Events

Define standard custom archive dictionary keys for custom initialize events.

```
const CFStringRef kHIObjectCustomDataParameterNamesKey;
const CFStringRef kHIObjectCustomDataParameterTypesKey;
const CFStringRef kHIObjectCustomDataParameterValuesKey;
```

Constants

`kHIObjectCustomDataParameterNamesKey`

The value of this key is an array of strings. Each `CFStringRef` contains an `OSType` that is a Carbon event parameter name.

`kHIObjectCustomDataParameterTypesKey`

The value of this key is an array of strings. Each `CFStringRef` contains an `OSType` that is a Carbon event parameter type.

`kHIObjectCustomDataParameterValuesKey`

The value of this key is an array of strings. Each `CFStringRef` contains a representation of the value.

Discussion

The value for each of these constants is a `CFArrayRef` containing CFStringRefs. For a given dictionary, the names, types, and values arrays should each have the same number of CFStrings. The name-type-value triple at the given index in each array represents a Carbon event parameter in the initialization event for the HIObject.

The current supported set of Carbon event parameter types consists of `'cfst'`, `'TEXT'`, `'bool'`, `'cfrn'`, `'doub'`, `'osst'`, `'long'`, `'magn'`, `'hipt'`, `'hisz'`, and `'hirc'`.

Availability

Available in Mac OS v10.4 and later.

Standard Custom Archive Data Dictionary Class and SuperClass Keys

Define standard custom archive data dictionary keys for classes and superclasses.

```
const CFStringRef kHIObjectCustomDataClassIDKey;
const CFStringRef kHIObjectCustomDataSuperClassIDKey;
```

Constants

`kHIObjectCustomDataClassIDKey`
The class ID.

`kHIObjectCustomDataSuperClassIDKey`
The super-class ID key.

Discussion

These keys define a class and superclass for clients that do not implement the object's true class. Each keyed value is an HIObject class ID.

Availability

Available in Mac OS v10.4 and later.

Standard Custom Archive Data Dictionary Key for ProcPointer-Based CDEFs

Define a standard custom archive data dictionary key for ProcPointer-based CDEFs.

```
const CFStringRef kHIObjectCustomDataCDEFProcIDKey;
```

Constants

`kHIObjectCustomDataCDEFProcIDKey`
The standard custom archive data dictionary key for ProcPointer-based CDEFs.

Discussion

The key value is a `CFStringRef`-based signed 16-bit integer. Use `CFStringGetIntValue` in `CFString.h` to convert `CFStringRef` to `SInt16` and to convert `SInt16` to `CFStringRef`.

Availability

Available in Mac OS v10.4 and later.

HIObject Base Class Events

Define the base-class functionality of HIObjects.

```
enum{
    kEventClassHIObject = 'hiob',
    kEventHIObjectConstruct = 1,
    kEventHIObjectInitialize = 2,
    kEventHIObjectDestruct = 3,
    kEventHIObjectIsEqual = 4,
    kEventHIObjectPrintDebugInfo = 5,
    kEventHIObjectEncode = 6
};
```

Constants

`kEventClassHIObject`

The event class for HIObject events.

Available in Mac OS X v10.2 and later.

Declared in `HIObject.h`.

`kEventHIObjectConstruct`

Your object is being constructed. When your event handler is called with this event, it is being called directly and not through the normal event dispatching mechanism. This means that the `EventHandlerCallRef` passed to your handler is `NULL` and `CallNextEventHandler` does not work. You are passed the actual `HIObjectRef` of your base class for you to record in your instance data. (Available in Mac OS X v10.2 and later.)

Available in Mac OS X v10.2 and later.

Declared in `HIObject.h`.

`kEventHIObjectInitialize`

Your object is being initialized. Your handler should pass this onto the superclass first before handling this event. This is done by calling `CallNextEventHandler` with the event. When that function returns, you should make sure the result is `noErr`. If not, you should not continue to initialize your object. (Available in Mac OS X v10.2 and later.)

Available in Mac OS X v10.2 and later.

Declared in `HIObject.h`.

`kEventHIObjectDestruct`

Your object is being destroyed. This is your chance to dispose of anything you might have allocated for your object. Do not call through with `CallNextEventHandler`. (Available in Mac OS X v10.2 and later.)

Available in Mac OS X v10.2 and later.

Declared in `HIObject.h`.

`kEventHIObjectIsEqual`

`HIObjectIsEqual` has been called, and you are being asked to determine whether your object is equivalent to the one being passed to your handler. If your object is equivalent, you should place `true` in the `kEventParamResult` parameter in the event; if your object is not equivalent, place `false` in the `kEventParamResult` parameter. (Available in Mac OS X v10.2 and later.)

Available in Mac OS X v10.2 and later.

Declared in `HIObject.h`.

`kEventHIObjectPrintDebugInfo`
`HIObjectPrintDebugInfo` has been called, and you are being asked to print your information to stdout. This event is sent to all handlers and you should not call `CallNextEventHandler`. (Available in Mac OS X v10.2 and later.)

Available in Mac OS X v10.2 and later.

Declared in `HIObject.h`.

`kEventHIObjectEncode`
`HIArchiveEncodeHIObject` has been called on your HIObject, and you are being asked to encode your object into an archive. Before handling this event, your handler should pass this event to the superclass by calling `CallNextEventHandler` with the event. If `CallNextEventHandler` does not return `noErr`, you should not continue to encode your instance data. (Available in Mac OS X v10.4 and later.)

Available in Mac OS X v10.4 and later.

Declared in `HIObject.h`.

Discussion
You only need to be aware of these events if you are implementing a subclass.

Table 31-1 Parameter names and types for HIObject base class events

Event kind	Parameter name	Parameter type
`kEventHIObjectConstruct`	`kEventParamHIObjectInstance`	`typeHIObjectRef`
`kEventHIObjectInitialize`	`kEventParamHIArchive`	`typeCFTypeRef`
`kEventHIObjectDestruct`		
`kEventHIObjectIsEqual`	`kEventParamDirectObject`	`typeHIObjectRef`
	`kEventParamResult`	`typeBoolean`
`kEventHIObjectPrintDebugInfo`		
`kEventHIObjectEncode`	`kEventParamHIArchive`	`typeCFTypeRef`

HIObject Base Class Event Parameters

Define constants for HIObject base class event parameters.

```
enum {
    kEventParamHIObjectInstance = 'hioi',
    kEventParamHIArchive = 'hiac',
    typeHIObjectRef = 'hiob'
};
```

Constants

`kEventParamHIObjectInstance`

On entry, the HIObject reference for your object. This parameter is currently only used for the `kEventHIObjectConstruct` event. Typically, you read this parameter from the event and store it in your instance data so that when your instance needs to call HIObject APIs, your instance can use this `HIObjectRef`. On exit, the value of this parameter is `typeVoidPtr` and is a pointer to the instance data you have written into the event using `SetEventParameter`. After your event handler returns, the HIToolbox reads your instance data pointer from the event, and installs the event handlers that were passed to `HIObjectRegisterClassSubclass` on the new object. The HIToolbox uses the instance data pointer as the refcon for the event handlers it installed so that your event handlers can retrieve your instance data pointer from the reference constant (the third parameter to an `EventHandlerProcPtr`).(Available in Mac OS X v10.2 and later.)

Available in Mac OS X v10.2 and later.

Declared in `HIObject.h`.

`kEventParamHIArchive`

An HIArchive used to store or retrieve the HIObject. This parameter is passed in the following cases:

- In the `kEventHIObjectInitialize` event when the HIObject is requested to initialize itself from a decoded archive. If the HIObject is to be initialized normally (that is, not from an archive), the initialize event does not contain `kEventParamHIArchive` .
- In the `kEventHIObjectEncode` event, which is sent to request that the HIObject encode itself within an archive.

(Available in Mac OS X v10.4 and later.)

Available in Mac OS X v10.4 and later.

Declared in `HIObject.h`.

Result Codes

Result Code	Value	Description
`hiObjectClassExistsErr`	-22080	You are trying to register a class ID that already exists. Available in Mac OS X v10.2 and later.
`hiObjectClassHasInstancesErr`	-22081	You are trying to unregister a class which has instances that still exist. Available in Mac OS X v10.2 and later.
`hiObjectClassHasSubclassesErr`	-22082	You are trying to unregister a class which has subclasses registered. They must be unregistered before this class can be unregistered. Available in Mac OS X v10.2 and later.

Result Code	Value	Description
`hiObjectClassIsAbstractErr`	-22083	You are trying to create an HIObject class that is defined as being abstract. You must subclass it instead. Available in Mac OS X v10.2 and later.

HIShape Reference

Framework: Carbon/Carbon.h

Declared in HIShape.h

Overview

HIShape is an abstract shape object that replaces the old QuickDraw region handle. HIShape objects are the preferred way to describe regions in HIView views that use Quartz.

One advantage of HIShape objects is that they can be mutable or immutable. Using immutable (that is, fixed) shapes improves performance because copying it simply requires incrementing the reference count, avoiding the handle-to-handle copies required with the older region handles.

Currently, HIShape objects cannot handle floating point–based shape descriptions. Therefore, any coordinates you specify when defining shapes must end on integer boundaries. The purpose of the shape often dictates whether rounding fractional values up or down will give you the best results. For example, shapes that describe a maximum alllowable area, such as the structure region of a window, should be rounded up (or outward) to the nearest integer. Shapes describing a minimum allowable area, such as the opaque region, should be rounded down (or inward). By default, any fractional coordinate values are truncated.

Typical shapes are rectangular, but you can build more complex shapes by combining them with other shapes using the union, intersection, or difference functions. The Quartz-savvy HITheme APIs also let you obtain shapes for various standard control elements.

In most cases, applications will obtain or set shapes in response to a Carbon event using `GetEventParameter` or `SetEventParameter` with the `typeHIShapeRef` parameter type.

The following functions also take HIShape references as parameters:

- `HIViewNewTrackingArea` and `HIViewChangeTrackingArea`, which let you set or change an HIShape-based tracking area in a view (comparable to window tracking regions).
- `HIViewSetNeedsDisplayInShape`, which is the HIShape-compatible version of `HIViewSetNeedsDisplayInRegion`.

Except where noted, HIShape functions return only the result codes `noErr` or `paramErr`.

HIShape objects are available in Mac OS X version 10.2 and later. However, many of the functions that take HIShape parameters are available only in Mac OS X version 10.4 and later.

Functions by Task

Creating Immutable Shapes

`HIShapeCreateWithQDRgn` (page 2352)
Creates an immutable shape from a QuickDraw region.

`HIShapeCreateWithRect` (page 2353)
Creates an immutable shape from a Quartz rectangle.

`HIShapeCreateEmpty` (page 2350)
Creates an empty immutable shape.

`HIShapeCreateCopy` (page 2350)
Creates an immutable copy of a mutable or immutable shape.

`HIShapeCreateIntersection` (page 2351)
Creates an immutable shape that is the intersection of two shapes.

`HIShapeCreateDifference` (page 2350)
Creates an immutable shape that is the difference of two shapes.

`HIShapeCreateUnion` (page 2352) Deprecated in Mac OS X v10.4
Creates an immutable shape that is the union of two shapes.

Creating Mutable Shapes

`HIShapeCreateMutable` (page 2351)
Creates an empty mutable shape.

`HIShapeCreateMutableCopy` (page 2352)
Creates a mutable copy of an existing shape.

`HIShapeSetEmpty` (page 2358)
Sets the specified mutable shape to be empty.

`HIShapeDifference` (page 2353)
Sets a shape to be the difference of two other shapes.

`HIShapeUnion` (page 2359)
Sets a shape to be the union of two other shapes.

`HIShapeOffset` (page 2357)
Moves a shape by a specified offset.

`HIShapeIntersect` (page 2355) Deprecated in Mac OS X v10.4
Sets a shape to be the intersection of two other shapes.

Querying Shapes

`HIShapeIsEmpty` (page 2356)
Determines whether a given shape is empty.

`HIShapeIsRectangular` (page 2357)
Determines whether a given shape is rectangular.

`HIShapeContainsPoint` (page 2349)
Determines whether a shape contains the given point.

Manipulating Shapes

`HIShapeGetTypeID` (page 2355)
Obtains the Core Foundation type ID for the HIShape class.

`HIShapeGetBounds` (page 2355)
Obtains the bounding rectangle for the given shape.

`HIShapeIntersectsRect` (page 2356)
Determines whether a given shape intersects a given rectangle.

`HIShapeGetAsQDRgn` (page 2354)
Creates a QuickDraw region with the same shape as the specified `HIShape`.

`HIShapeReplacePathInCGContext` (page 2358)
Make the current path in a graphics context match a shape.

`HIShapeSetQDClip` (page 2359)
Sets the clip region in the current QuickDraw port to be the specified shape.

Functions

HIShapeContainsPoint

Determines whether a shape contains the given point.

```
Boolean HIShapeContainsPoint (
   HIShapeRef inShape,
   const CGPoint *inPoint
);
```

Parameters

inShape
The shape to test.

inPoint
The point to test.

Return Value
`True` if the shape contains the point, `False` otherwise.

Discussion
This function is comparable to the old QuickDraw function `PtInRgn`.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`HIShape.h`

HIShapeCreateCopy

Creates an immutable copy of a mutable or immutable shape.

```
HIShapeRef HIShapeCreateCopy (
   HIShapeRef inShape
);
```

Parameters

inShape
The shape you want to copy.

Return Value
The newly-created copy.

Discussion
Copying an immutable shape simply increments its reference count. Copying a mutable shape actually duplicates it in memory.

Availability
Available in Mac OS X v10.2 and later.

Declared In
HIShape.h

HIShapeCreateDifference

Creates an immutable shape that is the difference of two shapes.

```
HIShapeRef HIShapeCreateDifference (
   HIShapeRef inShape1,
   HIShapeRef inShape2
);
```

Parameters

inShape1
The first shape.

inShape2
The shape to subtract from the first shape.

Return Value
The newly-created difference shape.

Availability
Available in Mac OS X v10.2 and later.

Declared In
HIShape.h

HIShapeCreateEmpty

Creates an empty immutable shape.

```
HIShapeRef HIShapeCreateEmpty (
   void
);
```

Return Value
The newly-created empty shape.

Availability
Available in Mac OS X v10.4 and later.

Declared In
HIShape.h

HIShapeCreateIntersection

Creates an immutable shape that is the intersection of two shapes.

```
HIShapeRef HIShapeCreateIntersection (
   HIShapeRef inShape1,
   HIShapeRef inShape2
);
```

Parameters

inShape1
An existing shape.

inShape2
Another existing shape.

Return Value
The newly-created intersection shape.

Discussion
If the two shapes do not intersect, the shape returned is empty.

Availability
Available in Mac OS X v10.2 and later.

Declared In
HIShape.h

HIShapeCreateMutable

Creates an empty mutable shape.

```
HIMutableShapeRef HIShapeCreateMutable (
   void
);
```

Return Value
An empty, mutable shape.

Availability
Available in Mac OS X v10.2 and later.

Declared In
HIShape.h

HIShapeCreateMutableCopy

Creates a mutable copy of an existing shape.

```
HIMutableShapeRef HIShapeCreateMutableCopy (
   HIShapeRef inOrig
);
```

Parameters

inOrig
The shape to copy.

Return Value
The newly-created copy.

Availability
Available in Mac OS X v10.2 and later.

Declared In
HIShape.h

HIShapeCreateUnion

Creates an immutable shape that is the union of two shapes.

```
HIShapeRef HIShapeCreateUnion (
   HIShapeRef inShape1,
   HIShapeRef inShape2
);
```

Parameters

inShape1
An existing shape.

inShape2
Another existing shape.

Return Value
The newly-created union shape.

Availability
Available in Mac OS X v10.2 and later.

Declared In
HIShape.h

HIShapeCreateWithQDRgn

Creates an immutable shape from a QuickDraw region.

```
HIShapeRef HIShapeCreateWithQDRgn (
   RgnHandle inRgn
);
```

Parameters

inRgn

The region to convert to an immutable shape.

Return Value
The newly created shape.

Discussion
You can use this function to convert handle-based regions to HIShape objects. However, you should be judicious about how often you convert, as this function does require memory allocation.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`HIShape.h`

HIShapeCreateWithRect

Creates an immutable shape from a Quartz rectangle.

```
HIShapeRef HIShapeCreateWithRect (
   const CGRect *inRect
);
```

Parameters

inRect

The Quartz-based rectangle to convert.

Return Value
The newly-created shape.

Discussion
This function is comparable to the old QuickDraw function `RectRgn`.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`HIShape.h`

HIShapeDifference

Sets a shape to be the difference of two other shapes.

```
OSStatus HIShapeDifference (
   HIShapeRef inShape1,
   HIShapeRef inShape2,
   HIMutableShapeRef outResult
);
```

Parameters

inShape1

The first shape.

inShape2

The shape to subtract from the first.

outResult

The shape to hold the difference of the two shapes. This parameter can be one of the source shapes.

Return Value
A result code.

Discussion
This function is comparable to the old QuickDraw function `DiffRgn`.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`HIShape.h`

HIShapeGetAsQDRgn

Creates a QuickDraw region with the same shape as the specified `HIShape`.

```
OSStatus HIShapeGetAsQDRgn (
   HIShapeRef inShape,
   RgnHandle outRgn
);
```

Parameters

inShape

The shape to convert.

outRgn

A valid region handle. You must obtain this handle by calling `NewRgn` before calling this function.

Return Value
A result code.

Discussion
You can use this function to create a handle-based region from an HIShape object. This conversion requires memory allocation, so you should convert only when necessary.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`HIShape.h`

HIShapeGetBounds

Obtains the bounding rectangle for the given shape.

```
CGRect * HIShapeGetBounds (
   HIShapeRef inShape,
   CGRect *outRect
);
```

Parameters

inShape

The shape whose bounds you want to obtain.

inRect

A pointer to the `HIRect` structure you want filled with the shape bounds.

Return Value

A pointer to the rectangle you passed in the `inRect` parameter, now set to the shape's bounding rectangle.

Discussion

The function result is a pointer to the `HIRect` structure you passed in the `inRect` parameter.

Availability

Available in Mac OS X v10.2 and later.

Declared In

`HIShape.h`

HIShapeGetTypeID

Obtains the Core Foundation type ID for the HIShape class.

```
CFTypeID HIShapeGetTypeID (
   void
);
```

Return Value

The type ID for the HIShape class.

Availability

Available in Mac OS X v10.2 and later.

Declared In

`HIShape.h`

HIShapeIntersect

Sets a shape to be the intersection of two other shapes.

```
OSStatus HIShapeIntersect (
   HIShapeRef inShape1,
   HIShapeRef inShape2,
   HIMutableShapeRef outResult
);
```

Parameters

inShape1

The first shape.

inShape2

The second shape.

outResult

The shape to hold the intersection of the two shapes. This parameter can be one of the source shapes.

Return Value
A result code.

Discussion
This function is comparable to the old QuickDraw function `SectRgn`.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`HIShape.h`

HIShapeIntersectsRect

Determines whether a given shape intersects a given rectangle.

```
Boolean HIShapeIntersectsRect (
   HIShapeRef inShape,
   const CGRect *inRect
);
```

Parameters

inShape

The shape to test.

inRect

The rectangle to test against.

Return Value
Returns `True` if the area of the shape intersects the rectangle, `False` otherwise.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`HIShape.h`

HIShapeIsEmpty

Determines whether a given shape is empty.

```
Boolean HIShapeIsEmpty (
   HIShapeRef inShape
);
```

Parameters

inShape

The shape to test.

Return Value

`True` if the shape's area is empty, `False` otherwise.

Discussion

This function is comparable to the old QuickDraw function `EmptyRgn`.

Availability

Available in Mac OS X v10.2 and later.

Declared In

`HIShape.h`

HIShapeIsRectangular

Determines whether a given shape is rectangular.

```
Boolean HIShapeIsRectangular (
   HIShapeRef inShape
);
```

Parameters

inShape

The shape to test.

Return Value

`True` if the shape's area is rectangular, `False` otherwise.

Availability

Available in Mac OS X v10.2 and later.

Declared In

`HIShape.h`

HIShapeOffset

Moves a shape by a specified offset.

```
OSStatus HIShapeOffset (
   HIMutableShapeRef inShape,
   CGFloat inDX,
   CGFloat inDY
);
```

Parameters

inShape

The shape to offset.

inDx
The desired x-coordinate offset.

inDy
The desired y-coordinate offset.

Return Value
A result code.

Discussion
This function is comparable to the old QuickDraw function `OffsetRgn`.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`HIShape.h`

HIShapeReplacePathInCGContext

Make the current path in a graphics context match a shape.

```
OSStatus HIShapeReplacePathInCGContext (
   HIShapeRef inShape,
   CGContextRef inContext
);
```

Parameters

inShape
The shape to apply to the path.

inContext
The context to apply the shape to.

Return Value
A result code.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`HIShape.h`

HIShapeSetEmpty

Sets the specified mutable shape to be empty.

```
OSStatus HIShapeSetEmpty (
   HIMutableShapeRef inShape
);
```

Parameters

inShape
The shape to empty.

Return Value
A result code.

Discussion
This function is comparable to the old QuickDraw function `SetEmptyRgn`.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`HIShape.h`

HIShapeSetQDClip

Sets the clip region in the current QuickDraw port to be the specified shape.

```
OSStatus HIShapeSetQDClip (
   HIShapeRef inShape,
   CGrafPtr inPort
);
```

Parameters

inShape
The shape to apply to the clip region.

inPort
The clip region to apply the shape to.

Return Value
A result code. If `HIShapeSetQDClip` cannot allocate a QuickDraw region, it returns `memFullErr`.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`HIShape.h`

HIShapeUnion

Sets a shape to be the union of two other shapes.

```
OSStatus HIShapeUnion (
   HIShapeRef inShape1,
   HIShapeRef inShape2,
   HIMutableShapeRef outResult
);
```

Parameters

inShape1
An existing shape.

inShape2
Another existing shape.

outResult
The shape to hold the union of the two shapes. This parameter can be one of the source shapes.

Return Value
A result code.

Discussion
This function is comparable to the old QuickDraw function `UnionRgn`.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`HIShape.h`

Data Types

HIShapeRef

Defines a shape object.

```
typedef const struct __HIShape *HIShapeRef;
```

Discussion
The structure pointed to by this reference is opaque.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`HIShape.h`

HIMutableShapeRef

Defines a mutable shape object.

```
typedef struct __HIShape *HIMutableShapeRef;
```

Discussion
The structure pointed to by this reference is opaque.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`HIShape.h`

HIToolbar Reference

Framework: Carbon/Carbon.h
Declared in HIToolbar.h

Overview

HIToolbar is the Carbon equivalent of the Cocoa toolbar (specifically, the `NSToolbar` and `NSToolbarItem` classes). The toolbar object and the items associated with a toolbar are both subclassed from HIObject. Toolbar items can have HIViews associated with them.

For more information, see Using HIToolbar.

Functions by Task

Creating Toolbars

`HIToolbarCreate` (page 2365)
Creates a toolbar.

Manipulating Toolbars

`HIToolbarChangeAttributes` (page 2364)
Changes the attributes of a toolbar.

`HIToolbarCopyIdentifier` (page 2364)
Obtains the identifier for a toolbar.

`HIToolbarCopyItems` (page 2365)
Obtains the array of toolbar items for a toolbar.

`HIToolbarGetAttributes` (page 2367)
Obtains the attributes for the given toolbar.

`HIToolbarGetDelegate` (page 2367)
Returns the current delegate in use by a toolbar.

`HIToolbarSetDelegate` (page 2382)
Sets the delegate object for a toolbar.

`HIToolbarGetDisplayMode` (page 2367)
Obtains the current display mode of a toolbar.

`HIToolbarSetDisplayMode` (page 2383)
Sets the current display mode of a toolbar.

`HIToolbarGetDisplaySize` (page 2368)
Obtains the current display size of a toolbar.

`HIToolbarSetDisplaySize` (page 2383)
Sets the current display size of a toolbar.

Creating and Adding Toolbar Items

`HIToolbarCreateItemWithIdentifier` (page 2366)
Creates a toolbar item.

`HIToolbarAppendItem` (page 2363)
Appends an item to the toolbar.

`HIToolbarInsertItemAtIndex` (page 2369)
Inserts a toolbar item at a given index into a toolbar.

`HIToolbarRemoveItemAtIndex` (page 2382)
Removes an item at a given index from a toolbar.

`HIToolbarItemCreate` (page 2375)
Creates a toolbar item.

`HIToolbarSetItemsWithIdentifiers` (page 2384)
Sets a toolbar's items all at once.

Manipulating Toolbar Items

`HIToolbarGetSelectedItemInWindow` (page 2368)
Obtains the toolbar item that is selected in a window.

`HIToolbarItemGetToolbar` (page 2377)
Obtains the toolbar associated with a toolbar item.

`HIToolbarItemGetAttributes` (page 2375)
Obtains the attributes of a toolbar item.

`HIToolbarItemGetAttributesInWindow` (page 2376)
Obtains the attributes of a toolbar item in the specified window.

`HIToolbarItemChangeAttributes` (page 2370)
Changes the attributes of a toolbar item.

`HIToolbarItemChangeAttributesInWindow` (page 2370)
Changes the attributes of a toolbar item in a specific window.

`HIToolbarItemCopyHelpText` (page 2372)
Obtains the help tag text for a toolbar item.

`HIToolbarItemSetHelpText` (page 2379)
Sets the help tag text for a toolbar item.

`HIToolbarItemCopyIdentifier` (page 2373)
Obtains the identifier for a given toolbar item.

`HIToolbarItemCopyImage` (page 2373)
Obtains the image for a toolbar item.

`HIToolbarItemSetImage` (page 2380)
Sets the image for a toolbar item.

`HIToolbarItemCopyLabel` (page 2374)
Obtains the label for a toolbar item.

`HIToolbarItemSetLabel` (page 2381)
Sets the label of a toolbar item.

`HIToolbarItemCopyMenu` (page 2374)
Obtains the submenu for a toolbar item.

`HIToolbarItemSetMenu` (page 2381)
Sets the submenu for a toolbar item.

`HIToolbarItemGetCommandID` (page 2377)
Gets the command ID of a toolbar item.

`HIToolbarItemSetCommandID` (page 2378)
Sets the command ID of a toolbar item.

`HIToolbarItemIsEnabled` (page 2378)
Determines if a toolbar item is enabled.

`HIToolbarItemSetEnabled` (page 2378)
Enables or disables a toolbar item.

`HIToolbarItemSetIconRef` (page 2380)
Sets the icon for a toolbar item.

`HIToolbarItemConfigDataChanged` (page 2372)
Tells the toolbar that the configuration for a toolbar item has changed.

Functions

HIToolbarAppendItem

Appends an item to the toolbar.

```
OSStatus HIToolbarAppendItem (
   HIToolbarRef inToolbar,
   HIToolbarItemRef inItem
);
```

Parameters

inToolbar
The toolbar to receive the new item.

inItem
The item reference of the toolbar item you are adding.

Return Value

An operating system result code.

Discussion
This function appends an item to the end of a toolbar. Generally, you should always add items via identifier, and not with this routine.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`HIToolbar.h`

HIToolbarChangeAttributes

Changes the attributes of a toolbar.

```
OSStatus HIToolbarChangeAttributes (
   HIToolbarRef inToolbar,
   OptionBits inAttrsToSet,
   OptionBits inAttrsToClear
);
```

Parameters

inToolbar
The toolbar whose attributes you want to change.

inAttrsToSet
The attributes you want to set. For possible values, see "Toolbar Attributes" (page 2384).

inAttrsToClear
The attributes you want to clear. For possible values, see "Toolbar Attributes" (page 2384).

Return Value
An operating system result code.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`HIToolbar.h`

HIToolbarCopyIdentifier

Obtains the identifier for a toolbar.

```
OSStatus HIToolbarCopyIdentifier (
   HIToolbarRef inToolbar,
   CFStringRef *outIdentifier
);
```

Parameters

inToolbar
The toolbar whose identifier you want to obtain.

outIdentifier
The identifier. You must release it when you are finished with it.

Return Value
An operating system result code.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
HIToolbar.h

HIToolbarCopyItems

Obtains the array of toolbar items for a toolbar.

```
OSStatus HIToolbarCopyItems (
   HIToolbarRef inToolbar,
   CFArrayRef *outItems
);
```

Parameters

inToolbar
The toolbar whose items you want to receive.

outItems
The array of toolbar items owned by the toolbar. You must release the array when you are finished with it.

Return Value
An operating system result code.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
HIToolbar.h

HIToolbarCreate

Creates a toolbar.

```
OSStatus HIToolbarCreate (
   CFStringRef inIdentifier,
   OptionBits inAttributes,
   HIToolbarRef *outToolbar
);
```

Parameters

inIdentifier
The identifier of the toolbar. If you specify that the toolbar auto-saves its configuration, this identifier is used to mark the config info in your application's preferences. You must specify an identifier.

inAttributes
Any attributes you want to set. For possible values, see "Toolbar Attributes" (page 2384).

outToolbar
The toolbar reference to your new toolbar.

Return Value
An operating system result code.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
HIToolbar.h

HIToolbarCreateItemWithIdentifier

Creates a toolbar item.

```
OSStatus HIToolbarCreateItemWithIdentifier (
   HIToolbarRef inToolbar,
   CFStringRef inIdentifier,
   CFTypeRef inConfigData,
   HIToolbarItemRef *outItem
);
```

Parameters

inToolbar
The toolbar you are adding to.

inIdentifier
The identifier of the item you want to add.

inConfigData
Any config data required by the item to safely construct. Standard items do not require any extra data, so `NULL` can be passed.

outItem
The newly created toolbar item.

Return Value
An operating system result code.

Discussion
This function creates an item specified by a particular identifier. Using this function allows you to create any item a delegate supports by naming its identifier. It also allows you to create standard items supplied by the Toolbox, such as the separator item.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
HIToolbar.h

HIToolbarGetAttributes

Obtains the attributes for the given toolbar.

```
OSStatus HIToolbarGetAttributes (
   HIToolbarRef inToolbar,
   OptionBits *outAttributes
);
```

Parameters

inToolbar

The toolbar whose attributes you desire.

outAttributes

The toolbar's attributes. For details, see "Toolbar Attributes" (page 2384).

Return Value

An operating system result code.

Availability

Available in Mac OS X v10.2 and later.

Not available to 64-bit applications.

Declared In

HIToolbar.h

HIToolbarGetDelegate

Returns the current delegate in use by a toolbar.

```
HIObjectRef HIToolbarGetDelegate (
   HIToolbarRef inToolbar
);
```

Parameters

inToolbar

The toolbar you want the delegate from.

Return Value

An HIObjectRef.

Discussion

The delegate handles the event processing for the toolbar.

Availability

Available in Mac OS X v10.2 and later.

Not available to 64-bit applications.

Declared In

HIToolbar.h

HIToolbarGetDisplayMode

Obtains the current display mode of a toolbar.

```
OSStatus HIToolbarGetDisplayMode (
   HIToolbarRef inToolbar,
   HIToolbarDisplayMode *outDisplayMode
);
```

Parameters

inToolbar

The toolbar whose display mode you want to receive.

outDisplayMode

The display mode.

Return Value
An operating system result code.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
HIToolbar.h

HIToolbarGetDisplaySize

Obtains the current display size of a toolbar.

```
OSStatus HIToolbarGetDisplaySize (
   HIToolbarRef inToolbar,
   HIToolbarDisplaySize *outSize
);
```

Parameters

inToolbar

The toolbar whose display size you want to get.

outSize

The display size.

Return Value
An operating system result code.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
HIToolbar.h

HIToolbarGetSelectedItemInWindow

Obtains the toolbar item that is selected in a window.

```
OSStatus HIToolbarGetSelectedItemInWindow (
   HIToolbarRef inToolbar,
   WindowRef inWindow,
   HIToolbarItemRef *outItem
);
```

Parameters

inToolbar

The toolbar in question.

inWindow

A window containing the toolbar.

outItem

On return, the toolbar item that is selected in the specified window, or `NULL` if no item is selected.

Return Value
An operating system result code.

Discussion
Each window that shares a toolbar may have a different selected item. The `HIToolbarGetSelectedItemInWindow` function returns the selected item in a particular window.

Availability
Available in Mac OS X v10.4 and later.

Not available to 64-bit applications.

Declared In
`HIToolbar.h`

HIToolbarInsertItemAtIndex

Inserts a toolbar item at a given index into a toolbar.

```
OSStatus HIToolbarInsertItemAtIndex (
   HIToolbarRef inToolbar,
   HIToolbarItemRef inItem,
   CFIndex inIndex
);
```

Parameters

inToolbar

The toolbar to receive the new item.

inItem

The item reference of the toolbar item you are adding.

inIndex

The index at which you want to add the item. This index is zero-based.

Return Value
An operating system result code.

Discussion
Generally, you should always add items via identifier, and not with this routine.

Availability
Available in Mac OS X v10.2 and later.

Not available to 64-bit applications.

Declared In
`HIToolbar.h`

HIToolbarItemChangeAttributes

Changes the attributes of a toolbar item.

```
OSStatus HIToolbarItemChangeAttributes (
   HIToolbarItemRef inItem,
   OptionBits inAttrsToSet,
   OptionBits inAttrsToClear
);
```

Parameters

inItem

The item in question.

inAttrsToSet

The attributes to set on the item. For possible attributes, see "Toolbar Item Attributes" (page 2391). Use `kHIToolbarItemNoAttributes` if you are clearing attributes.

inAttrsToClear

The attributes to clear on the item. This value can be `kHIToolbarItemNoAttributes` if you are setting attributes.

Return Value
An operating system result code.

Discussion
Only those attributes defined by the `kHIToolbarItemMutableAttrs` constant can be passed into this function.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`HIToolbar.h`

HIToolbarItemChangeAttributesInWindow

Changes the attributes of a toolbar item in a specific window.

```
OSStatus HIToolbarItemChangeAttributesInWindow (
   HIToolbarItemRef inItem,
   WindowRef inWindow,
   OptionBits inAttrsToSet,
   OptionBits inAttrsToClear,
   OptionBits inAttrsToNoLongerOverride
);
```

Parameters

inItem

The item in question.

inWindow

The window containing the item in question.

inAttrsToSet

The attributes to set on the item. For possible attributes, see "Toolbar Item Attributes" (page 2391). Use `kHIToolbarItemNoAttributes` if you are clearing attributes and have no attributes to set.

inAttrsToClear

The attributes to clear on the item. This value can be `kHIToolbarItemNoAttributes` if you are setting attributes and have no attributes to clear.

inAttrsToNoLongerOverride

The attributes that are to no longer be overridden. Calling this function causes the attributes to be removed from the override mask for the toolbar item in the specified window. Their effective values revert to their non-window-specific attribute values.

Return Value

An operating system result code.

Discussion

This function allows the attributes of a toolbar item in the specified window to be overridden. The attributes used to draw the view of a toolbar item in a particular window are determined by combining the non-window-specific attributes for the item set by `HIToolbarItemChangeAttributes` (page 2370) with the window-specific attributes set by this function. As a result, your application can have a toolbar that is shared across several windows with a toolbar item that is enabled in one window and disabled in another window.

When `HIToolbarItemChangeAttributesInWindow` is called to set or clear attributes, the toolbar item adds the changed attributes to a bitmask of attributes, thereby recording which attributes are overridden for a particular window. Once an attribute is overridden for a window (regardless of whether the attribute is set or cleared), the attribute remains overridden for that window until `HIToolbarItemChangeAttributesInWindow` is called with that attribute specified in the `inAttrsToNoLongerOverride` parameter.

Only those attributes defined by the `kHIToolbarItemMutableAttrs` constant can be passed into this function. For details, see "Toolbar Item Attributes" (page 2391).

Availability

Available in Mac OS X v10.4 and later.

Not available to 64-bit applications.

Declared In

`HIToolbar.h`

HIToolbarItemConfigDataChanged

Tells the toolbar that the configuration for a toolbar item has changed.

```
OSStatus HIToolbarItemConfigDataChanged (
   HIToolbarItemRef inItem
);
```

Parameters

inItem

The item whose configuration changed.

Return Value
An operating system result code.

Discussion
This function tells the toolbar that the config data for a toolbar item has changed and should be written to the toolbar configuration preferences. This function is used when a custom toolbar item has extra configuration data that has changed (for example, you've changed an alias that a toolbar item points to). This function does nothing if the toolbar is not set to auto-save its configuration.

Availability
Available in Mac OS X v10.3 and later.
Not available to 64-bit applications.

Declared In
`HIToolbar.h`

HIToolbarItemCopyHelpText

Obtains the help tag text for a toolbar item.

```
OSStatus HIToolbarItemCopyHelpText (
   HIToolbarItemRef inItem,
   CFStringRef *outShortText,
   CFStringRef *outLongText
);
```

Parameters

inItem

The item in question.

outShortText

The short help text. This is what is displayed normally by the help tag system when the user hovers over the toolbar item with the mouse. You should release this string when you are finished with it. If you do not want to receive the short help text, pass `NULL` for this parameter.

outLongText

The long help text. This is what is displayed by the help tag system when the user hovers over the toolbar item with the mouse and holds the command key down. You should release this string when you are finished with it. If you do not want to receive the long help text, pass `NULL` for this parameter.

Return Value
An operating system result code.

Availability
Available in Mac OS X v10.2 and later.

Not available to 64-bit applications.

Declared In
HIToolbar.h

HIToolbarItemCopyIdentifier

Obtains the identifier for a given toolbar item.

```
OSStatus HIToolbarItemCopyIdentifier (
   HIToolbarItemRef inItem,
   CFStringRef *outIdentifier
);
```

Parameters

inItem
The item in question.

outIdentifier
The identifier of the item. You should release this string when you are finished with it.

Return Value
An operating system result code.

Discussion
The toolbar uses this identifier when writing the config information to the preferences (if set up for auto-config).

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
HIToolbar.h

HIToolbarItemCopyImage

Obtains the image for a toolbar item.

```
OSStatus HIToolbarItemCopyImage (
   HIToolbarItemRef inItem,
   CGImageRef *outImage
);
```

Parameters

inItem
The item in question.

outImage
The retained image. You should release it when finished with it.

Return Value
An operating system result code.

Discussion
This image is already retained by the time you receive it, so you can release it when you are done with it.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`HIToolbar.h`

HIToolbarItemCopyLabel

Obtains the label for a toolbar item.

```
OSStatus HIToolbarItemCopyLabel (
   HIToolbarItemRef inItem,
   CFStringRef *outLabel
);
```

Parameters

inItem
The item in question.

outLabel
The label of the item. You should release this when you are finished with it.

Return Value
An operating system result code.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`HIToolbar.h`

HIToolbarItemCopyMenu

Obtains the submenu for a toolbar item.

```
OSStatus HIToolbarItemCopyMenu (
   HIToolbarItemRef inItem,
   MenuRef *outMenu
);
```

Parameters

inItem
The item in question.

outMenu
The retained menu. You should release it when you are finished with it.

Return Value
An operating system result code.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`HIToolbar.h`

HIToolbarItemCreate

Creates a toolbar item.

```
OSStatus HIToolbarItemCreate (
   CFStringRef inIdentifier,
   OptionBits inOptions,
   HIToolbarItemRef *outItem
);
```

Parameters

inIdentifier
The identifier of the item in question.

inOptions
Any options for the item.

outItem
The item you created.

Return Value
An operating system result code.

Discussion
This function creates a toolbar item for use in a toolbar. Typically, you call `HIToolbarItemCreate` from inside your delegate when your delegate is asked to create a toolbar item.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`HIToolbar.h`

HIToolbarItemGetAttributes

Obtains the attributes of a toolbar item.

```
OSStatus HIToolbarItemGetAttributes (
   HIToolbarItemRef inItem,
   OptionBits *outAttributes
);
```

Parameters

inItem
The item in question.

outAttributes
The attributes of the item. For details, see "Toolbar Item Attributes" (page 2391).

Return Value
An operating system result code.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
HIToolbar.h

HIToolbarItemGetAttributesInWindow

Obtains the attributes of a toolbar item in the specified window.

```
OSStatus HIToolbarItemGetAttributesInWindow (
   HIToolbarItemRef inItem,
   WindowRef inWindow,
   OptionBits *outOverriddenAttributes,
   OptionBits *outCombinedAttributes
);
```

Parameters

inItem
The item in question.

inWindow
The window containing `inItem`. Passing `NULL` is the same as calling `HIToolbarItemGetAttributes` (page 2375), which obtains the non-window-specific attributes for the item.

outOverriddenAttributes
On return, a bitmask indicating the attributes for the item that are overridden in the specified window. If you don't need this information, pass `NULL`. For details on this bitmask, see "Toolbar Item Attributes" (page 2391).

outCombinedAttributes
On return, a bitmask indicating the effective attributes for the item in the specified window. The bitmask is produced by combining the non-window-specific attributes for the item with the overridden attributes for this window. If you don't need this information, pass `NULL`. For details on this bitmask, see "Toolbar Item Attributes" (page 2391).

Return Value
An operating system result code.

Discussion
In addition to obtaining the attributes of the given item in a given window, `HIToolbarItemGetAttributesInWindow` obtains information about which attributes are overridden for that window.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
HIToolbar.h

HIToolbarItemGetCommandID

Gets the command ID of a toolbar item.

```
OSStatus HIToolbarItemGetCommandID (
   HIToolbarItemRef inItem,
   MenuCommand *outCommandID
);
```

Parameters

inItem

The item whose command ID is to be obtained.

outCommandID

On return, the item's command ID.

Return Value
An operating system result code.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
HIToolbar.h

HIToolbarItemGetToolbar

Obtains the toolbar associated with a toolbar item.

```
HIToolbarRef HIToolbarItemGetToolbar (
   HIToolbarItemRef inItem
);
```

Parameters

inItem

The item in question.

Return Value
The toolbar item reference of the toolbar this item is bound to, or NULL if this toolbar item is not attached to any toolbar.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
HIToolbar.h

HIToolbarItemIsEnabled

Determines if a toolbar item is enabled.

```
Boolean HIToolbarItemIsEnabled (
   HIToolbarItemRef inItem
);
```

Parameters

inItem

The item in question.

Return Value

A Boolean result indicating whether the item is enabled.

Availability

Available in Mac OS X v10.2 and later.

Not available to 64-bit applications.

Declared In

`HIToolbar.h`

HIToolbarItemSetCommandID

Sets the command ID of a toolbar item.

```
OSStatus HIToolbarItemSetCommandID (
   HIToolbarItemRef inItem,
   MenuCommand inCommandID
);
```

Parameters

inItem

The item whose command ID is to be set.

inCommandID

The command ID to set.

Return Value

An operating system result code.

Discussion

When an toolbar item is clicked, the default behavior is to send out the command assigned to the item. This function lets you to set that command ID. The command is sent out via the `ProcessHICommand` API.

Availability

Available in Mac OS X v10.2 and later.

Not available to 64-bit applications.

Declared In

`HIToolbar.h`

HIToolbarItemSetEnabled

Enables or disables a toolbar item.

```
OSStatus HIToolbarItemSetEnabled (
   HIToolbarItemRef inItem,
   Boolean inEnabled
);
```

Parameters

inItem

The item in question.

inEnabled

The new enabled state.

Return Value
An operating system result code.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`HIToolbar.h`

HIToolbarItemSetHelpText

Sets the help tag text for a toolbar item.

```
OSStatus HIToolbarItemSetHelpText (
   HIToolbarItemRef inItem,
   CFStringRef inShortText,
   CFStringRef inLongText
);
```

Parameters

inItem

The item in question.

inShortText

The short help text. This is what is displayed normally by the help tag system when the user hovers over the toolbar item with the mouse.

inLongText

The long help text. This is what is displayed by the help tag system when the user hovers over the toolbar item with the mouse and holds the command key down. This parameter is optional, you may pass `NULL`.

Return Value
An operating system result code.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`HIToolbar.h`

HIToolbarItemSetIconRef

Sets the icon for a toolbar item.

```
OSStatus HIToolbarItemSetIconRef (
   HIToolbarItemRef inItem,
   IconRef inIcon
);
```

Parameters

inItem

The item in question.

inIcon

The icon reference. The IconRef is retained by the toolbar item. You can release the reference for this icon when `HIToolbarItemSetIconRef` returns.

Return Value

An operating system result code.

Availability

Available in Mac OS X v10.2 and later.

Not available to 64-bit applications.

Declared In

`HIToolbar.h`

HIToolbarItemSetImage

Sets the image for a toolbar item.

```
OSStatus HIToolbarItemSetImage (
   HIToolbarItemRef inItem,
   CGImageRef inImage
);
```

Parameters

inItem

The item in question.

inImage

The image. This image is retained by the toolbar item. You should release the image when you are finished with it.

Return Value

An operating system result code.

Discussion

Currently, the image should be no higher than 32 pixels. This image is used both in the toolbar as well as the configuration sheet, if the toolbar is configurable.

Availability

Available in Mac OS X v10.2 and later.

Not available to 64-bit applications.

Declared In

`HIToolbar.h`

HIToolbarItemSetLabel

Sets the label of a toolbar item.

```
OSStatus HIToolbarItemSetLabel (
   HIToolbarItemRef inItem,
   CFStringRef inLabel
);
```

Parameters

inItem

The item in question.

inLabel

The label. The toolbox will copy the string passed in.

Return Value

An operating system result code.

Discussion

This is what the toolbar view will display underneath the image. It is also used in the configuration palette for configurable toolbars.

Availability

Available in Mac OS X v10.2 and later.

Not available to 64-bit applications.

Declared In

`HIToolbar.h`

HIToolbarItemSetMenu

Sets the submenu for a toolbar item.

```
OSStatus HIToolbarItemSetMenu (
   HIToolbarItemRef inItem,
   MenuRef inMenu
);
```

Parameters

inItem

The item in question.

inMenu

The menu. It is retained by the toolbar item, so you can safely release it after calling this API. On Mac OS X v10.3 and later, you can pass `NULL` for this parameter to remove and release any menu that might be attached.

Return Value

An operating system result code.

Discussion

Normally, items do not have a submenu. You can attach one with this API. The submenu will, by default, show up both in the 'more items' indicator popup attached to the item name. It will also appear if the toolbar is in text only mode and the label is clicked. You should attach a Carbon Event handler to the menu to handle updating the menu items as appropriate before the menu is displayed.

Availability
Available in Mac OS X v10.2 and later
Not available to 64-bit applications.

Declared In
HIToolbar.h

HIToolbarRemoveItemAtIndex

Removes an item at a given index from a toolbar.

```
OSStatus HIToolbarRemoveItemAtIndex (
   HIToolbarRef inToolbar,
   CFIndex inIndex
);
```

Parameters

inToolbar
The toolbar you are removing the item from.

inIndex
The index of the item to remove. This index is zero-based.

Return Value
An operating system result code.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
HIToolbar.h

HIToolbarSetDelegate

Sets the delegate object for a toolbar.

```
OSStatus HIToolbarSetDelegate (
   HIToolbarRef inToolbar,
   HIObjectRef inDelegate
);
```

Parameters

inToolbar
The toolbar whose delegate you want to set.

inDelegate
The HIObjectRef to act as the delegate.

Return Value
An operating system result code.

Discussion
If a toolbar has custom toolbar items, a delegate is required for the toolbar to work properly. The delegate is asked to create the toolbar items. If the delegate does not respond, the toolbar attempts to create the toolbar items, but it can only create standard items.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`HIToolbar.h`

HIToolbarSetDisplayMode

Sets the current display mode of a toolbar.

```
OSStatus HIToolbarSetDisplayMode (
   HIToolbarRef inToolbar,
   HIToolbarDisplayMode inDisplayMode
);
```

Parameters

inToolbar
The toolbar whose display mode you want to set.

inDisplayMode
The display mode. If the toolbar is visible, it will be redrawn as necessary.

Return Value
An operating system result code.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`HIToolbar.h`

HIToolbarSetDisplaySize

Sets the current display size of a toolbar.

```
OSStatus HIToolbarSetDisplaySize (
   HIToolbarRef inToolbar,
   HIToolbarDisplaySize inSize
);
```

Parameters

inToolbar
The toolbar whose display size you want to set.

inSize
The display size. If the toolbar is visible, it will be redrawn as necessary.

Return Value
An operating system result code.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`HIToolbar.h`

HIToolbarSetItemsWithIdentifiers

Sets a toolbar's items all at once.

```
OSStatus HIToolbarSetItemsWithIdentifiers (
   HIToolbarRef inToolbar,
   CFArrayRef inArray
);
```

Parameters

`inToolbar`
The toolbar whose items you want to set.

`inArray`
The array of toolbar items to create.

Return Value
An operating system result code.

Discussion
This function allows you to set a toolbar's items all at once. The entries in the array `inArray` must be either CFStringRefs or CFDictionaryRefs. You do not need to use the same type for all entries; different entries can be of different types. If an array entry is a CFStringRef, the string must contain a toolbar item identifier. If an array entry is a CFDictionaryRef, the dictionary must contain a CFStringRef specifying a toolbar item identifier and may optionally contain a CFTypeRef specifying the toolbar item's configuration data, if the item requires it. The key for the identifier string is `kHIToolbarIdentifierKey` and the key for the configuration data string is `kHIToolbarDataKey`.

Availability
Available in Mac OS X v10.3 and later.
Not available to 64-bit applications.

Declared In
`HIToolbar.h`

Constants

Toolbar Attributes

Specify constants for toolbar attributes.

```
enum {
    kHIToolbarNoAttributes = 0,
    kHIToolbarAutoSavesConfig = (1 << 0),
    kHIToolbarIsConfigurable = (1 << 1),
    kHIToolbarValidAttrs = kHIToolbarAutoSavesConfig | kHIToolbarIsConfigurable
};
```

Constants

`kHIToolbarNoAttributes`

Pass this to indicate no attributes at all.

Available in Mac OS X v10.2 and later.

Declared in `HIToolbar.h`.

`kHIToolbarAutoSavesConfig`

Pass this attribute to allow the toolbar to save its configuration automatically to your application's preferences. You must make sure to synchronize the preferences at some point to ensure it gets written to disk. The toolbar will also read its configuration from the preferences if this attribute is set.

Available in Mac OS X v10.2 and later.

Declared in `HIToolbar.h`.

`kHIToolbarIsConfigurable`

This attribute indicates that the toolbar is configurable, that is, the user can drag items around and bring up the configuration palette, etc.

Available in Mac OS X v10.2 and later.

Declared in `HIToolbar.h`.

`kHIToolbarValidAttrs`

The set of all valid toolbar attributes.

Available in Mac OS X v10.2 and later.

Declared in `HIToolbar.h`.

Toolbar Command ID Constants

Specify constants for toolbar Command IDs.

```
enum {
    kHICommandCustomizeToolbar = 'tcfg',
    kHICommandShowToolbar = 'tbsh',
    kHICommandHideToolbar = 'tbhd',
    kHIToolbarCommandPressAction = 'tbpr'
};
```

Constants

`kHICommandCustomizeToolbar`

When sent to a window with a toolbar, this command causes the configuration sheet to appear. You can set a menu item's command to this command ID and it will be handled and updated automatically for you. (Available in Mac OX X v10.2 and later.)

Available in Mac OS X v10.2 and later.

Declared in `HIToolbar.h`.

`kHICommandShowToolbar`
Sending this command causes a window's toolbar to be shown. You can set a menu item's command to this ID and it will be handled and updated automatically for you. (Available in Mac OX X v10.2 and later.)

Available in Mac OS X v10.2 and later.

Declared in `HIToolbar.h`.

`kHICommandHideToolbar`
Sending this command causes a window's toolbar to be hidden. You can set a menu item's command to this ID and it will be handled and updated automatically for you. (Available in Mac OX X v10.2 and later.)

Available in Mac OS X v10.2 and later.

Declared in `HIToolbar.h`.

`kHIToolbarCommandPressAction`
This command, when specified as a toolbar's command ID, causes a `kEventToolbarItemPerformAction` event to be generated when the toolbar item's menu item in the toolbar overflow menu is selected. If the item has any other command ID, a `kEventCommandProcess` event, containing the item's command ID, is generated instead. (Available in Mac OX X v10.2.3 and later.)

Available in Mac OS X v10.3 and later.

Declared in `HIToolbar.h`.

Toolbar Display Mode Constants

Specify constants for toolbar display modes.

```
enum {
    kHIToolbarDisplayModeDefault = 0,
    kHIToolbarDisplayModeIconAndLabel = 1,
    kHIToolbarDisplayModeIconOnly = 2,
    kHIToolbarDisplayModeLabelOnly = 3
};
```

Constants

`kHIToolbarDisplayModeDefault`
Use the default display mode. Currently, this is defined as being both icon and label, but could change in the future.

Available in Mac OS X v10.2 and later.

Declared in `HIToolbar.h`.

`kHIToolbarDisplayModeIconAndLabel`
Display the image as well as the label of the toolbar items.

Available in Mac OS X v10.2 and later.

Declared in `HIToolbar.h`.

`kHIToolbarDisplayModeIconOnly`
Display only the image.

Available in Mac OS X v10.2 and later.

Declared in `HIToolbar.h`.

`kHIToolbarDisplayModeLabelOnly`
Display only the label.

Available in Mac OS X v10.2 and later.

Declared in `HIToolbar.h`.

Toolbar Display Size Constants

Specify constants for the display size of items in the toolbar.

```
enum {
    kHIToolbarDisplaySizeDefault = 0,
    kHIToolbarDisplaySizeNormal = 1,
    kHIToolbarDisplaySizeSmall = 2
};
```

Constants

`kHIToolbarDisplaySizeDefault`
This indicates to use the default display size. Currently, this is defined as using 32 x 32 icons (“normal” size).

Available in Mac OS X v10.2 and later.

Declared in `HIToolbar.h`.

`kHIToolbarDisplaySizeNormal`
This size uses a larger text and icon size.

Available in Mac OS X v10.2 and later.

Declared in `HIToolbar.h`.

`kHIToolbarDisplaySizeSmall`
This size uses a smaller text and icon size.

Available in Mac OS X v10.2 and later.

Declared in `HIToolbar.h`.

Toolbar Events

Specify toolbar Carbon event constants.

```
enum {
    kEventToolbarGetDefaultIdentifiers = 1,
    kEventToolbarGetAllowedIdentifiers = 2,
    kEventToolbarCreateItemWithIdentifier = 3,
    kEventToolbarCreateItemFromDrag = 4,
    kEventToolbarItemAdded = 5,
    kEventToolbarItemRemoved = 6,
    kEventToolbarDisplayModeChanged = 7,
    kEventToolbarDisplaySizeChanged = 8,
    kEventToolbarLayoutChanged = 9,
    kEventToolbarGetSelectableIdentifiers = 10,
    kEventToolbarBeginMultiChange = 12,
    kEventToolbarEndMultiChange = 13
};
```

Constants

`kEventToolbarGetDefaultIdentifiers`

This event is sent to the delegate to get a list of all of the default item identifiers that should be created for a toolbar. You are passed a mutable array to fill in with the identifiers. (

Available in Mac OS X v10.2.)

Declared in `HIToolbar.h`.

`kEventToolbarGetAllowedIdentifiers`

This event is sent to the delegate to get a list of all the items which could possibly be added to the toolbar. This is sent out when the configuration sheet is about to be displayed.You are passed a mutable array to fill in with the identifiers. (

Available in Mac OS X v10.2.)

Declared in `HIToolbar.h`.

`kEventToolbarCreateItemWithIdentifier`

This event is sent to the delegate to when the toolbar needs to create an item from an identifier. (

Available in Mac OS X v10.2.)

Declared in `HIToolbar.h`.

`kEventToolbarCreateItemFromDrag`

This event is sent to the delegate to when the toolbar needs to create an item from a drag. This allows you to be able to drag items into a toolbar that aren't normal toolbar items. You might use this to allow your toolbar to accept file system items, for example. (

Declared in `HIToolbar.h`.

Available in Mac OS X v10.2.)

`kEventToolbarItemAdded`

This event is sent when an item is added to the toolbar. The toolbar object sends this event to itself, so you need to install a handler on the toolbar to receive this event. (Available in Mac OS X v10.2 and later.)

Available in Mac OS X v10.3 and later.

Declared in `HIToolbar.h`.

`kEventToolbarItemRemoved`

This event is sent when an item is removed from toolbar. It is called after the item has already been removed. The toolbar object sends this event to itself, so you need to install a handler on the toolbar to receive this event. (Available in Mac OS X v10.2 and later.)

Available in Mac OS X v10.3 and later.

Declared in `HIToolbar.h`.

`kEventToolbarDisplayModeChanged`

This event is sent when the display mode is changed for a toolbar. The toolbar object sends this event to itself, so you need to install a handler on the toolbar to receive this event. (Available in Mac OS X v10.2 and later.)

Available in Mac OS X v10.3 and later.

Declared in `HIToolbar.h`.

`kEventToolbarDisplaySizeChanged`

This event is sent when the display size is changed for a toolbar. The toolbar object sends this event to itself, so you need to install a handler on the toolbar to receive this event. (Available in Mac OS X v10.2 and later.)

Available in Mac OS X v10.3 and later.

Declared in `HIToolbar.h`.

`kEventToolbarLayoutChanged`

Sent when the layout of a toolbar changes (either an item has been moved, or the entire contents have been replaced). Basically it is sent for changes that would require a total resync with the current state of things. The toolbar object sends this event to itself, so you must install a handler on the toolbar to receive this event. (Available in Mac OS X v10.2 and later.)

Available in Mac OS X v10.3 and later.

Declared in `HIToolbar.h`.

`kEventToolbarBeginMultiChange`

This event is sent when multiple attributes are going to be changed at the same time. For example, the display mode and size can change at the same time. When this happens, instead of reacting twice (once for a display mode change and once for a display size change), you can listen to see if more than one attribute is about to change and wait to redraw the toolbar until you receive the `kEventToolbarEndMultiChange` event. The toolbar object sends this event to itself, so you need to install a handler on the toolbar to receive this event. (Available in Mac OS X v10.2 and later.)

Available in Mac OS X v10.3 and later.

Declared in `HIToolbar.h`.

`kEventToolbarEndMultiChange`

This event is sent when multiple changes in the toolbar have been made. For details, see the description of `kEventToolbarBeginMultiChange`. The toolbar object sends this event to itself, so you need to install a handler on the toolbar to receive this event. (Available in Mac OS X v10.2 and later.)

Available in Mac OS X v10.3 and later.

Declared in `HIToolbar.h`.

`kEventToolbarGetSelectableIdentifiers`

This event is sent to the delegate after the user clicks a toolbar item in order to get a list of all the items that can acquire a selection highlight when clicked. You are passed a mutable array to fill in with the identifiers. If you pass back a non-empty array and the clicked item's identifier matches one of the identifiers that is in the list, the toolbar automatically draws that item with a selected highlight and removes highlighting from the previously selected item. Note that the selection only changes in the clicked window — it does not change in other windows that share the same toolbar. To share the selection across all windows that use the same toolbar, you need to manually change the `kHIToolbarItemSelected` attribute for the clicked item using `HIToolbarItemChangeAttributes` (page 2370). In this case, you should not handle the `kEventToolbarGetSelectableIdentifiers` event. (Available in Mac OS X v10.4 and later.)

Available in Mac OS X v10.4 and later.

Declared in `HIToolbar.h`.

Discussion
Table 33-1 lists the parameters and types for toolbar events.

Table 33-1 Parameter names and types for toolbar events

Event kind	Parameter name	Parameter type
kEventToolbarGet-DefaultIdentifiers	kEventParamToolbar	typeHIToolbarRef
	kEventParamMutableArray	typeCFMutableArrayRef
kEventToolbarGet-AllowedIdentifiers	kEventParamToolbar	typeHIToolbarRef
	kEventParamMutableArray	typeCFMutableArrayRef
kEventToolbarGetSelectable-Identifiers	kEventParamToolbar	typeHIToolbarRef
	kEventParamMutableArray	typeCFMutableArrayRef
kEventToolbarCreate-ItemWithIdentifier	kEventParamToolbar	typeHIToolbarRef
	kEventParamToolbar-ItemIdentifier	typeCFStringRef
	kEventParamToolbar-ItemConfigData	typeCFTypeRef
	kEventParamToolbarItem	typeHIToolbarItemRef
kEventToolbarCreate-ItemFromDrag	kEventParamDragRef	typeDragRef
	kEventParamToolbarItem	typeHIToolbarItemRef
kEventToolbarItemAdded	kEventParamToolbarItem	typeHIToolbarItemRef
	kEventParamIndex	typeCFIndex
kEventToolbarItemRemoved	kEventParamToolbarItem	typeHIToolbarItemRef
kEventToolbarDisplay-ModeChanged	*None*	
kEventToolbarDisplay-SizeChanged	*None*	
kEventToolbarLayoutChanged	*None*	
kEventToolbarBeginMultiChange	*None*	
kEventToolbarEndMultiChange	*None*	

Toolbar Event Parameters and Types

Specify constants for toolbar event parameters and types.

```
enum {
    kEventParamToolbar = 'tbar',
    kEventParamToolbarItem = 'tbit',
    kEventParamToolbarItemIdentifier = 'tbii',
    kEventParamToolbarItemConfigData = 'tbid',
    typeHIToolbarRef = 'tbar',
    typeHIToolbarItemRef = 'tbit'
};
```

Constants

`kEventParamToolbar`
The toolbar to which an event was sent.
Available in Mac OS X v10.2 and later.
Declared in `HIToolbar.h`.

`kEventParamToolbarItem`
The toolbar item to which an event was sent.
Available in Mac OS X v10.2 and later.
Declared in `HIToolbar.h`.

`kEventParamToolbarItemIdentifier`
The toolbar item's identifier.
Available in Mac OS X v10.2 and later.
Declared in `HIToolbar.h`.

`kEventParamToolbarItemConfigData`
The toolbar item's configuration information.
Available in Mac OS X v10.2 and later.
Declared in `HIToolbar.h`.

`typeHIToolbarRef`
HIToolbarRef
Available in Mac OS X v10.2 and later.
Declared in `HIToolbar.h`.

`typeHIToolbarItemRef`
HIToolbarItemRef
Available in Mac OS X v10.2 and later.
Declared in `HIToolbar.h`.

Toolbar Item Attributes

Specify constants for toolbar item attributes.

```
enum {
    kHIToolbarItemNoAttributes = 0,
    kHIToolbarItemAllowDuplicates = (1 << 0),
    kHIToolbarItemCantBeRemoved = (1 << 1),
    kHIToolbarItemAnchoredLeft = (1 << 2),
    kHIToolbarItemIsSeparator = (1 << 3),
    kHIToolbarItemSendCmdToUserFocus = (1 << 4),
    kHIToolbarItemLabelDisabled = (1 << 5),
    kHIToolbarItemDisabled = (1 << 6),
    kHIToolbarItemSelected = (1 << 7),

    kHIToolbarItemValidAttrs = kHIToolbarItemAllowDuplicates |
kHIToolbarItemIsSeparator | kHIToolbarItemCantBeRemoved |
kHIToolbarItemAnchoredLeft | kHIToolbarItemSendCmdToUserFocus |
kHIToolbarItemLabelDisabled | kHIToolbarItemDisabled | kHIToolbarItemSelected,
    kHIToolbarItemMutableAttrs = kHIToolbarItemCantBeRemoved |
kHIToolbarItemAnchoredLeft | kHIToolbarItemLabelDisabled |  kHIToolbarItemDisabled
 | kHIToolbarItemSelected
};
```

Constants

`kHIToolbarItemNoAttributes`
Pass this to indicate no attributes at all.

Available in Mac OS X v10.2 and later.

Declared in `HIToolbar.h`.

`kHIToolbarItemAllowDuplicates`
This indicates that an item can have more than one instance of itself in the toolbar. If this is not set, only one can be present. By default, the determining factor for what determines if two items are identical is the toolbar identifier.

Available in Mac OS X v10.2 and later.

Declared in `HIToolbar.h`.

`kHIToolbarItemCantBeRemoved`
This item can be rearranged, but it cannot be removed from the toolbar by the user.

Available in Mac OS X v10.2 and later.

Declared in `HIToolbar.h`.

`kHIToolbarItemAnchoredLeft`
This item cannot be moved at all by the user. It is anchored to the left of the toolbar. It is important that there not be any unanchored items to the left of this item, else dragging items around will be a bit wacky. You are responsible for making sure that anchored items are all on the left. This allows you to do toolbars like the one in the System Preferences app, where the first couple of items are stuck in place.

Available in Mac OS X v10.2 and later.

Declared in `HIToolbar.h`.

`kHIToolbarItemIsSeparator`
This indicates the item acts as a separator. This means two things at present. First, it means that it automatically shows up as a divider line in a menu representation of the toolbar, and second it means the view that represents this item can draw in the full top to bottom space that the toolbar item occupies in the toolbar.

Available in Mac OS X v10.2 and later.

Declared in `HIToolbar.h`.

`kHIToolbarItemSendCmdToUserFocus`
: If this attribute bit is set, the command that gets sent out will be directed at the user focus instead of at the window the toolbar is attached to.

  Available in Mac OS X v10.2 and later.

  Declared in `HIToolbar.h`.

`kHIToolbarItemLabelDisabled`
: If this attribute bit is set, clicking on the label of an item does nothing. This attribute is only considered when a custom view is present. When set, this attribute makes the toolbar item view unresponsive to clicks while still allowing clicks to be sent to the custom view. When the toolbar is in text-only mode and this attribute is set, the label is displayed in a disabled (grayed) appearance. You might want to change this attribute when switching between display modes. For example, the view switcher in the Finder does not respond to clicks on the label when in icon and text mode, but it does respond to clicks when in text-only mode. To change this behavior on the fly, listen for `kEventToolbarItemViewConfigForMode` in your custom view and adjust this attribute as you want. (Available in Mac OS X 10.3 and later.)

  Available in Mac OS X v10.3 and later.

  Declared in `HIToolbar.h`.

`kHIToolbarItemDisabled`
: If this attribute bit is set, the item is disabled. Setting this attribute is the same as calling `HIToolbarItemSetEnabled` (page 2378) on the item with the `inEnabled` parameter set to `false`. (Available in Mac OS X v10.4 and later.)

  Available in Mac OS X v10.4 and later.

  Declared in `HIToolbar.h`.

`kHIToolbarItemSelected`
: If this attribute bit is set, the item is drawn with a selected appearance. (Available in Mac OS X v10.4 and later.)

  Available in Mac OS X v10.4 and later.

  Declared in `HIToolbar.h`.

`kHIToolbarItemValidAttrs`
: The set of all valid toolbar item attributes.

  Available in Mac OS X v10.2 and later.

  Declared in `HIToolbar.h`.

`kHIToolbarItemMutableAttrs`
: The set of toolbar item attributes that can be changed by `HIToolbarItemChangeAttributes` (page 2370) and `HIToolbarItemChangeAttributesInWindow` (page 2370). Any other attribute must be specified when it is created.

  Available in Mac OS X v10.2 and later.

  Declared in `HIToolbar.h`.

Toolbar Item Events

Specify constants for toolbar item events.

```
enum {
    kEventToolbarItemImageChanged = 1,
    kEventToolbarItemLabelChanged = 2,
    kEventToolbarItemHelpTextChanged = 3,
    kEventToolbarItemCommandIDChanged = 4,
    kEventToolbarItemGetPersistentData = 5,
    kEventToolbarItemCreateCustomView = 6,
    kEventToolbarItemEnabledStateChanged = 7,
    kEventToolbarItemPerformAction = 8,
    kEventToolbarItemWouldAcceptDrop = 10,
    kEventToolbarItemAcceptDrop = 11,
    kEventToolbarItemSelectedStateChanged = 12
};
```

Constants

`kEventToolbarItemImageChanged`

This event is sent to the item when the image changes. Any interested parties can install handlers on the toolbar item to receive notifications. (Available in Mac OS X v10.2 and later.)

Available in Mac OS X v10.2 and later.

Declared in `HIToolbar.h`.

`kEventToolbarItemLabelChanged`

This event is sent to the item when the label changes. Any interested parties can install handlers on the toolbar item to receive notifications. (Available in Mac OS X v10.2 and later.)

Available in Mac OS X v10.2 and later.

Declared in `HIToolbar.h`.

`kEventToolbarItemHelpTextChanged`

This event is sent to the item when the help text changes. Any interested parties can install handlers on the toolbar item to receive notifications. (Available in Mac OS X v10.2 and later.)

Available in Mac OS X v10.2 and later.

Declared in `HIToolbar.h`.

`kEventToolbarItemCommandIDChanged`

This event is sent to the item when the command ID changes. Any interested parties can install handlers on the toolbar item to receive notifications. (Available in Mac OS X v10.2 and later.)

Available in Mac OS X v10.2 and later.

Declared in `HIToolbar.h`.

`kEventToolbarItemGetPersistentData`

This event is sent to the item when the toolbar is going to write out the configuration information for the item. Any custom items can listen for this event and add any extra information to what is written out into the config so that it can be reanimated later on from the same config data. Typically, you do not need to handle this event. (Available in Mac OS X v10.2 and later.)

Available in Mac OS X v10.2 and later.

Declared in `HIToolbar.h`.

`kEventToolbarItemCreateCustomView`

This event is sent to the toolbar item when it is time to create a view for it to display its contents. Implementors of custom toolbar items can install a handler for this event to create their own custom views for their items. (Available in Mac OS X v10.2 and later.)

Available in Mac OS X v10.2 and later.

Declared in `HIToolbar.h`.

`kEventToolbarItemEnabledStateChanged`
This event is sent to the item when the enabled state changes. Any interested parties can install handlers on the toolbar item to receive notifications. (Available in Mac OS X v10.3 and later.)

Available in Mac OS X v10.2 and later.

Declared in `HIToolbar.h`.

`kEventToolbarItemPerformAction`
This event is sent when a toolbar item is clicked. Subclasses of toolbar items can choose to do special actions by overriding this event. If this event is unhandled, the default action of sending a command event will occur. (Available in Mac OS X v10.2 and later.)

Available in Mac OS X v10.2 and later.

Declared in `HIToolbar.h`.

`kEventToolbarItemWouldAcceptDrop`
This event is sent when a toolbar item is clicked. Subclasses of toolbar items can choose to do special actions by overriding this event. If this event is unhandled, the default action of sending a command event will occur. (Available in Mac OS X v10.3 and later.)

Available in Mac OS X v10.3 and later.

Declared in `HIToolbar.h`.

`kEventToolbarItemAcceptDrop`
This event is sent when a drag enters a toolbar item. If the toolbar item wants to accept drags, it should respond to this event and return `true` in the `kEventParamResult` parameter. The toolbar item will be highlighted appropriately. If you are using a custom view, you do not need to respond to this event because the view system provides full drag and drop capability in order to support custom items that use the standard view. (Available in Mac OS X v10.3 and later.)

Available in Mac OS X v10.3 and later.

Declared in `HIToolbar.h`.

`kEventToolbarItemSelectedStateChanged`
This event is sent to the item itself when the selected state changes. Any interested parties can install handlers on the toolbar item to receive notifications. (Available in Mac OS X v10.4 and later.)

Available in Mac OS X v10.4 and later.

Declared in `HIToolbar.h`.

Discussion
Table 33-2 lists the parameters and types for toolbar item events.

Table 33-2 Parameter names and types for toolbar item events

Event kind	Parameter name	Parameter type
`kEventToolbarItemImageChanged`	*None*	
`kEventToolbarItemLabelChanged`	*None*	
`kEventToolbarItemHelpTextChanged`	*None*	
`kEventToolbarItemCommandIDChanged`	*None*	
`kEventToolbarItemGetPersistentData`	`kEventParamToolbar-ItemConfigData`	`typeCFTypeRef`
`kEventToolbarItemCreateCustomView`	`kEventParamControlRef`	`typeControlRef`

kEventToolbarItemEnabledStateChanged	kEventParamWindowRef (Optional)	typeWindowRef
kEventToolbarItemPerformAction	*None*	
kEventToolbarItemWouldAcceptDrop	kEventParamDragRef	typeDragRef
	kEventParamResult	typeBoolean
kEventToolbarItemAcceptDrop	kEventParamDragRef	typeDragRef
kEventToolbarItemSelectedStateChanged	kEventParamWindowRef (Optional)	typeWindowRef

Toolbar Item View Events

Specify constants for toolbar item view events.

```
enum {
    kEventToolbarItemViewConfigForMode = 3,
    kEventToolbarItemViewConfigForSize = 4,
    kEventToolbarItemViewEnterConfigMode = 5,
    kEventToolbarItemViewExitConfigMode = 6
};
```

Constants

`kEventToolbarItemViewConfigForMode`

This event notifies a toolbar item view that the toolbar's display mode has changed. A custom toolbar item view can respond in any way it sees fit. Usually, responding to this is not necessary; for example, when the toolbar goes from icon to text only the view is automatically hidden, so there is not much to do. This event is for informational purposes only. (Available in Mac OS X v10.3 and later.)

Available in Mac OS X v10.3 and later.

Declared in `HIToolbar.h`.

`kEventToolbarItemViewConfigForSize`

This event notifies a toolbar item view that the toolbar's display size has changed. A custom toolbar item view can respond to this in any way it sees fit. Usually, responding to this is not necessary. Some custom views might need to flush metrics caches when the display size changes. (Available in Mac OS X v10.3 and later.)

Available in Mac OS X v10.3 and later.

Declared in `HIToolbar.h`.

`kEventToolbarItemViewEnterConfigMode`

This event notifies a toolbar item view that configure mode has been entered. A custom toolbar item view can respond to this in any way it sees fit. For example, the space and flexible space mark themselves to draw a rectangle and merely invalidate so they get redrawn so they can be seen during configuration. (Available in Mac OS X v10.3 and later.)

Available in Mac OS X v10.3 and later.

Declared in `HIToolbar.h`.

`kEventToolbarItemViewExitConfigMode`
This event notifies a toolbar item view that configure mode has been exited. A custom toolbar item view can respond to this event in any way it sees fit. (Available in Mac OS X v10.3 and later.)

Available in Mac OS X v10.3 and later.

Declared in `HIToolbar.h`.

Discussion
Table 33-3 lists the parameters and types for toolbar item view events.

Table 33-3 Parameter names and types for toolbar item view events

Event kind	Parameter name	Parameter type
`kEventToolbarItemViewConfigForMode`	`kEventParamToolbar-DisplayMode`	`typeHIToolbar-DisplayMode`
`kEventToolbarItemViewConfigForSize`	`kEventParamToolbar-DisplaySize`	`typeHIToolbar-DisplaySize`
`kEventToolbarItem-ViewEnterConfigMode`	*None*	
`kEventToolbarItem-ViewExitConfigMode`	*None*	

Toolbar View Display Event Parameters and Types

Specify constants for toolbar display event parameters and types.

```
enum {
    kEventParamToolbarDisplayMode = 'tbdm',
    kEventParamToolbarDisplaySize = 'tbds',
    typeHIToolbarDisplayMode = 'tbdm',
    typeHIToolbarDisplaySize = 'tbds'
};
```

Constants
`kEventParamToolbarDisplayMode`
Indicates that the display mode changed.

Available in Mac OS X v10.3 and later.

Declared in `HIToolbar.h`.

`kEventParamToolbarDisplaySize`
Indicates that the display size changed.

Available in Mac OS X v10.3 and later.

Declared in `HIToolbar.h`.

`typeHIToolbarDisplayMode`
HIToolbarDisplayMode.

Available in Mac OS X v10.3 and later.

Declared in `HIToolbar.h`.

`typeHIToolbarDisplaySize`
: HIToolbarDisplaySize.

Available in Mac OS X v10.3 and later.

Declared in `HIToolbar.h`.

HIView Reference

Framework:	Carbon/Carbon.h
Declared in	HIView.h HICocoaView.h HIImageView.h HISegmentedView.h
Companion guide	HIView Programming Guide

Overview

HIView is an object-oriented view system subclassed from HIObject. All controls are implemented as HIView objects ("views"). You can easily subclass HIView classes, making it easy to implement custom controls. Over time, the HIView API will replace the current Control Manager. Using the HIView model, every item within a window is a view: the root control, controls, and even the standard window "widgets" (close, zoom, and minimize buttons, resize control, and so on). Current Control Manager function calls are layered on top of this HIView model.

Additional benefits of the HIView model include the following:

- Quartz is the native drawing system, but you can still use QuickDraw if desired.
- Modern coordinate system not bounded by the 16-bit space of QuickDraw.
- Simplified coordinate system for view bounds and the position of a view within its parent.
- Views can be ordered within a hierarchy layer; that is, it is easy to place controls in front of or behind other controls.

For additional information about using HIViews, see *HIView Programming Guide*.

Functions by Task

Obtaining and Placing Views

`HIViewGetRoot` (page 2463)
Obtains the root view for a window.

`HIViewFindByID` (page 2451)
Obtains a view by its ID.

HIViewGetSuperview (page 2464)
Returns a view's parent view.

HIViewPlaceInSuperviewAt (page 2473)
Places a view at an absolute location within its parent.

HIViewGetNextView (page 2460)
Returns the view behind the specified view.

HIViewGetPreviousView (page 2462)
Returns the view above the specified view.

Working With Subviews

HIViewAddSubview (page 2442)
Adds a subview to the given parent view.

HIViewRemoveFromSuperview (page 2475)
Removes a view from its parent.

HIViewGetFirstSubview (page 2455)
Returns the first subview of a parent view.

HIViewGetLastSubview (page 2458)
Returns the last subview in a parent view.

HIViewCountSubviews (page 2449)
Returns the number of subviews embedded in a view.

HIViewGetIndexedSubview (page 2457)
Obtains the subview of a view by index.

Manipulating Views

HIViewSetVisible (page 2490)
Hides or shows a view.

HIViewIsVisible (page 2471)
Determines whether a view is visible.

HIViewIsLatentlyVisible (page 2470)
Determines whether a view is latently visible.

HIViewSetHilite (page 2481)
Sets highlighting on a view.

HIViewIsActive (page 2467)
Determines whether a view is active.

HIViewSetActivated (page 2477)
Sets a view to be active or inactive.

HIViewIsEnabled (page 2469)
Determines whether a view is enabled.

HIViewSetEnabled (page 2480)
Enables or disables a view.

`HIViewIsCompositingEnabled` (page 2468)
Determines whether compositing is enabled for a view.

`HIViewSetText` (page 2488)
Sets the text of a view to the specified string.

`HIViewCopyText` (page 2448)
Copies the text of a view.

`HIViewGetValue` (page 2465)
Obtains the value of a view.

`HIViewSetValue` (page 2489)
Sets the value of a view.

`HIViewGetMinimum` (page 2459)
Obtains the minimum value of a view.

`HIViewSetMinimum` (page 2484)
Sets a view's minimum value.

`HIViewGetMaximum` (page 2459)
Obtains a view's maximum value.

`HIViewSetMaximum` (page 2484)
Sets a view's maximum value.

`HIViewGetViewSize` (page 2467)
Obtains the view size of a view.

`HIViewSetViewSize` (page 2489)
Sets the view size of a view.

`HIViewIsValid` (page 2471)
Determines whether the specified view is known to the HIToolbox.

`HIViewGetID` (page 2457)
Obtains the HIViewID of a view.

`HIViewSetID` (page 2482)
Sets the `HIViewID` of a view.

`HIViewGetCommandID` (page 2453)
Obtains the command ID of a view.

`HIViewSetCommandID` (page 2479)
Sets the command ID of a view.

`HIViewGetKind` (page 2458)
Obtains the signature and kind of a view.

`HIViewGetAttributes` (page 2452)
Obtains the attributes for a view.

`HIViewChangeAttributes` (page 2444)
Changes the attributes of a view.

`HIViewGetNeedsDisplay` (page 2460)
Determines whether a view needs to be redrawn.

`HIViewSetNeedsDisplay` (page 2485)
Marks a view as needing or not needing to be redrawn.

`HIViewSetNeedsDisplayInRect` (page 2485)
Uses an `HIRect` to mark a portion of a view as needing or not needing to be redrawn.

`HIViewSetNeedsDisplayInShape` (page 2487)
Uses a shape to mark a portion of a view as needing or not needing to be redrawn.

`HIViewSetNeedsDisplayInRegion` (page 2486)
Uses a region to mark a portion of a view as needing or not needing to be redrawn.

`HIViewRender` (page 2475)
Renders the invalid portions of a view.

`HIViewGetSizeConstraints` (page 2463)
Returns the minimum and maximum size for a control.

`HIViewIsDrawingEnabled` (page 2469)
Determines if drawing is currently enabled for a view.

`HIViewSetDrawingEnabled` (page 2479)
Turns control drawing on or off.

`HIViewScrollRect` (page 2477)
Scrolls a view's contents, or a portion thereof.

`HIViewSetZOrder` (page 2490)
Changes the front-to-back ordering of sibling views.

`HIViewReshapeStructure` (page 2476)
Informs the system that the structure region of the given view has changed shape.

`HIViewRegionChanged` (page 2474)
Informs the system that a region of the view has changed.

`HIViewCopyShape` (page 2448)
Copies the shape of a part of a view.

`HIViewGetOptimalBounds` (page 2461)
Obtains the optimal size and text placement of a view.

`HIViewFlashDirtyArea` (page 2452)
Flashes a window's dirty area.

`HIViewGetWindow` (page 2467)
Obtains a reference to the window to which the specified view is bound.

`HIViewGetFeatures` (page 2454)
Obtains the features of the specified view.

`HIViewChangeFeatures` (page 2444)
Changes the features of a view.

`HIViewGetEventTarget` (page 2454)
Returns the `EventTargetRef` for the specified view.

Managing Focus

`HIViewGetFocusPart` (page 2455)
Obtains the part in the specified view that currently has focus.

`HIViewSetNextFocus` (page 2487)
Sets the view that is to receive keyboard focus when keyboard focus advances from the specified view.

`HIViewAdvanceFocus` (page 2442)
Advances the keyboard focus to the next most appropriate view.

HIViewSubtreeContainsFocus (page 2492)
Determines whether a view or any subviews have keyboard focus.

HIViewSetFirstSubViewFocus (page 2480)
Sets the subview that is first to receive keyboard focus.

Processing Events and Hit-Testing for Views

HIViewClick (page 2445)
Passes a mouse-down event to a view.

HIViewSimulateClick (page 2491)
Simulates a mouse click on a given view.

HIViewGetPartHit (page 2462)
Determines the part hit for a given point.

HIViewGetViewForMouseEvent (page 2466)
Returns the appropriate view to handle a mouse event.

HIViewGetSubviewHit (page 2464)
Returns the child of the given view hit by the point passed in.

Manipulating View Coordinates

HIViewGetBounds (page 2453)
Obtains the local bounds of a view.

HIViewSetBoundsOrigin (page 2478)
Sets the origin of the view.

HIViewGetFrame (page 2456)
Obtains the frame bounds of a view.

HIViewSetFrame (page 2481)
Sets the frame of a view.

HIViewMoveBy (page 2472)
Move a view by the specified distance relative to its current location.

HIViewConvertPoint (page 2446)
Converts a point's coordinates from one view to another.

HIViewConvertRect (page 2447)
Converts a rectangle from one view to another.

HIViewConvertRegion (page 2447)
Converts a region from one view to another.

Creating and Manipulating Combo Boxes

HIComboBoxCreate (page 2411)
Creates a combo box control.

HIComboBoxGetAttributes (page 2412)
Gets the attributes of a combo box.

`HIComboBoxChangeAttributes` (page 2410)
Changes the attributes of a combo box.

`HIComboBoxAppendTextItem` (page 2410)
Appends a text item to the combo box disclosure list.

`HIComboBoxCopyTextItemAtIndex` (page 2411)
Copy a text item from a combo box disclosure list

`HIComboBoxGetItemCount` (page 2413)
Gets the number of items in the combo box disclosure list.

`HIComboBoxInsertTextItemAtIndex` (page 2413)
Inserts a CFString in a combo box disclosure list.

`HIComboBoxRemoveItemAtIndex` (page 2414)
Removes an item from a combo box disclosure list.

`HIComboBoxIsListVisible` (page 2414)
Determines whether a combo box disclosure list is visible.

`HIComboBoxSetListVisible` (page 2415)
Hides or shows a combo box disclosure list.

Creating and Manipulating Image Views

`HIImageViewCreate` (page 2417)
Creates an image view.

`HIImageViewCopyImage` (page 2417)
Obtains the image for an image view.

`HIImageViewSetImage` (page 2419)
Sets the image to display in an image view.

`HIImageViewGetAlpha` (page 2418)
Obtains the alpha value for a view.

`HIImageViewSetAlpha` (page 2419)
Sets the alpha value for an image view.

`HIImageViewGetScaleToFit` (page 2418)
Determines whether an image will scale or clip to the view bounds.

`HIImageViewSetScaleToFit` (page 2421)
Specifies whether an image should scale or clip to the view's bounds.

`HIImageViewIsOpaque` (page 2419)
Determines whether an image view is opaque.

`HIImageViewSetOpaque` (page 2420)
Sets the opacity of an image view.

Creating and Manipulating Scroll Views

`HIScrollViewCreate` (page 2423)
Creates a scroll view.

HIScrollViewGetScrollBarAutoHide (page 2424)
Obtains current setting of a scroll view's scroll bar auto-hide setting.

HIScrollViewSetScrollBarAutoHide (page 2425)
Sets a scroll view's auto-hide setting.

HIScrollViewCanNavigate (page 2423)
Determines whether it is possible to navigate in a scroll view.

HIScrollViewNavigate (page 2424)
Changes the portion of a view's target.

Creating and Manipulating Layouts

HIViewGetLayoutInfo (page 2459)
Obtains the layout information of an view.

HIViewSetLayoutInfo (page 2482)
Sets the layout information of an HIView.

HIViewApplyLayout (page 2443)
Applies the current layout to the specified view.

HIViewSuspendLayout (page 2492)
Suspends layout handling for a view and its children.

HIViewResumeLayout (page 2476)
Resumes layout handling for a view and its children.

HIViewIsLayoutActive (page 2470)
Determines whether layout handling is active or suspended.

HIViewIsLayoutLatentlyActive (page 2471)
Determines whether layout handling is latently active or suspended.

Manipulating Tracking Areas

HIViewNewTrackingArea (page 2473)
Creates a new tracking area for a view.

HIViewChangeTrackingArea (page 2445)
Changes the shape of a tracking area.

HIViewGetTrackingAreaID (page 2465)
Obtains the ID of a tracking area.

HIViewDisposeTrackingArea (page 2450)
Disposes of an existing tracking area.

Creating and Manipulating Search Fields

HISearchFieldCreate (page 2427)
Creates a Search field control.

HISearchFieldSetSearchMenu (page 2429)
Sets the search menu associated with a search field view.

`HISearchFieldGetSearchMenu` (page 2428)
Obtains the search menu associated with a search field.

`HISearchFieldChangeAttributes` (page 2425)
Sets the attributes of a search field.

`HISearchFieldGetAttributes` (page 2428)
Obtains the attributes for a search field.

`HISearchFieldSetDescriptiveText` (page 2429)
Sets the description of the search action for a search field.

`HISearchFieldCopyDescriptiveText` (page 2426)
Obtains the description associated with a search field.

Manipulating Menus

`HIMenuViewGetMenu` (page 2422)
Returns the `MenuRef` associated with a view that is a subclass of HIMenuView.

`HIMenuGetContentView` (page 2421)
Obtains an `HIViewRef` that can be used to draw menu content for a menu.

Manipulating Segmented Views

`HISegmentedViewCreate` (page 2432)
Creates a segmented view.

`HISegmentedViewSetSegmentCount` (page 2439)
Sets the number of segments for a segmented view.

`HISegmentedViewGetSegmentCount` (page 2435)
Obtains the number of segments for a segmented view.

`HISegmentedViewSetSegmentBehavior` (page 2437)
Changes the behavior of an individual segment of a segmented view.

`HISegmentedViewGetSegmentBehavior` (page 2433)
Obtains the behavior of an individual segment of a segmented view.

`HISegmentedViewChangeSegmentAttributes` (page 2430)
Changes the attributes of an individual segment of a segmented view.

`HISegmentedViewGetSegmentAttributes` (page 2433)
Returns the attributes of an individual segment of a segmented view.

`HISegmentedViewSetSegmentValue` (page 2441)
Changes the value of an individual segment of a segmented view.

`HISegmentedViewGetSegmentValue` (page 2436)
Returns the value of an individual segment of a segmented view.

`HISegmentedViewSetSegmentEnabled` (page 2439)
Enables or disables an individual segment of a segmented view.

`HISegmentedViewIsSegmentEnabled` (page 2436)
Determines whether an individual segment of a segmented view is enabled.

HISegmentedViewSetSegmentCommand (page 2437)
Sets the command ID for a segment.

HISegmentedViewGetSegmentCommand (page 2434)
Obtains the command ID associated with a segment.

HISegmentedViewSetSegmentLabel (page 2440)
Sets the label string for a segment.

HISegmentedViewCopySegmentLabel (page 2431)
Obtains a copy of the label string associated with a segment.

HISegmentedViewSetSegmentContentWidth (page 2438)
Specifies how the content width of segment is to be calculated.

HISegmentedViewGetSegmentContentWidth (page 2434)
Obtains the content width of a segment.

HISegmentedViewSetSegmentImage (page 2440)
Sets or clears the image associated with a segment.

HISegmentedViewGetSegmentImageContentType (page 2435)
Obtains the type of image content drawn by a segment.

HISegmentedViewCopySegmentImage (page 2430)
Copies the image drawn by a segment.

Working with Core Graphics Images

HICreateTransformedCGImage (page 2415)
Creates a new Core Graphics image with the standard selected or disabled appearance.

HIViewCreateOffscreenImage (page 2449)
Creates a Core Graphics offscreen image of a view.

HIViewDrawCGImage (page 2450)
Draws a Core Graphics image appropriately for a view.

Working with Grow Boxes

HIGrowBoxViewIsTransparent (page 2416)
Determines whether a grow box view is transparent.

HIGrowBoxViewSetTransparent (page 2416)
Makes a grow box view transparent or opaque.

Using Cocoa Views in Carbon Windows

HICocoaViewCreate (page 2408)
Creates a Carbon view that serves as a wrapper for a Cocoa view.

HICocoaViewSetView (page 2409)
Associates a Cocoa view with a HICocoaView wrapper view.

HICocoaViewGetView (page 2409)
Returns the Cocoa view associated with an existing Carbon wrapper view.

Functions

HICocoaViewCreate

Creates a Carbon view that serves as a wrapper for a Cocoa view.

```
OSStatus HICocoaViewCreate (
    NSView *inNSView,
    OptionBits inOptions,
    HIViewRef *outHIView
);
```

Parameters

inNSView

A pointer to the Cocoa view you want to wrap. This function retains the Cocoa view you pass in; on output, you may safely release the view. If you want to create an empty Carbon wrapper view, you may pass `NULL`. An empty wrapper view does not draw or respond to user interaction; you can associate it with a Cocoa view at a later time using the function `HICocoaViewSetView` (page 2409).

inOptions

Options for the new Carbon wrapper view. Currently this parameter must be 0.

outHIView

A pointer to a variable of type `HIViewRef` (page 2497). On output, your variable contains a new Carbon view that serves as a wrapper for the Cocoa view specified in the `inNSView` parameter. You are responsible for releasing the wrapper view when you no longer need it. Note that if you embed the wrapper view in a Carbon window, the view (along with its associated Cocoa view) will be released automatically when the window is destroyed.

Return Value

An operating system result code. This function returns `paramErr` whenever the `inOptions` parameter is not 0 or the `outHIView` parameter is `NULL`.

Discussion

This function creates an HIView-based wrapper for a Cocoa view. You can embed the new wrapper view in a Carbon window and use standard HIView functions to manipulate the view. HICocoaView is supported only in compositing windows.

The following example shows how to use this function to create a wrapped Cocoa view that can be embedded in a Carbon window:

```
NSView *myCocoaView = [[SomeNSView alloc] init];
HIViewRef myHICocoaView;
HICocoaViewCreate (myCocoaView, 0, &myHICocoaView);
[myCocoaView release];
```

Availability

Available in Mac OS X v10.5 and later.

Not available to 64-bit applications.

Declared In

`HICocoaView.h`

HICocoaViewGetView

Returns the Cocoa view associated with an existing Carbon wrapper view.

```
NSView * HICocoaViewGetView (
    HIViewRef inHIView
);
```

Parameters

inHIView

A wrapper view that has an associated Cocoa view.

Return Value

The Cocoa view associated with the specified wrapper view, or `NULL` if the wrapper view is empty or invalid. If you need to save the Cocoa view for later use, you should retain it.

Availability

Available in Mac OS X v10.5 and later.

Not available to 64-bit applications.

Declared In

`HICocoaView.h`

HICocoaViewSetView

Associates a Cocoa view with a HICocoaView wrapper view.

```
OSStatus HICocoaViewSetView (
    HIViewRef inHIView,
    NSView *inNSView
);
```

Parameters

inHIView

An existing HICocoaView wrapper view.

inNSView

A pointer to a Cocoa view. This function retains the Cocoa view you pass in; on output, you may safely release this view. If the HICocoaView wrapper view specified in the `inHIView` parameter already wraps a Cocoa view, this function releases the wrapped view and replaces it with the Cocoa view you pass in.

Return Value

An operating system result code. This function returns `paramErr` if either parameter is `NULL` or invalid.

Discussion

Typically you'll use this function after you instantiate a nib-based Carbon window that contains an empty HICocoaView wrapper view. The empty wrapper view serves as a placeholder until you call this function to associate a Cocoa view with it. HICocoaView is supported only in compositing windows.

The following example shows how to use this function to associate a Cocoa view with an existing wrapper view:

```
NSView *myCocoaView = [[SomeNSView alloc] init];
HICocoaViewSetView (myHICocoaView, myCocoaView);
[myCocoaView release];
```

Availability
Available in Mac OS X v10.5 and later.
Not available to 64-bit applications.

Declared In
`HICocoaView.h`

HIComboBoxAppendTextItem

Appends a text item to the combo box disclosure list.

```
OSStatus HIComboBoxAppendTextItem (
   HIViewRef inComboBox,
   CFStringRef inText,
   CFIndex *outIndex
);
```

Parameters

inComboBox
The combo box having the disclosure list to which the text is to be appended.

inText
The text item to be appended to the combo box disclosure list.

outIndex
On exit, the index of the new item. Can be `NULL` if you don't want this information.

Return Value
An operating system status code.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`HIComboBox.h`

HIComboBoxChangeAttributes

Changes the attributes of a combo box.

```
OSStatus HIComboBoxChangeAttributes (
   HIViewRef inComboBox,
   OptionBits inAttributesToSet,
   OptionBits inAttributesToClear
);
```

Parameters

inComboBox
The combo box whose attributes you want to change.

inAttributesToSet
The attributes to set. For possible values, see "Combo Box Attributes" (page 2500).

inAttributesToClear

The attributes to clear. For possible values, see "Combo Box Attributes" (page 2500).

Return Value
An operating system status code.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`HIComboBox.h`

HIComboBoxCopyTextItemAtIndex

Copy a text item from a combo box disclosure list

```
OSStatus HIComboBoxCopyTextItemAtIndex (
   HIViewRef inComboBox,
   CFIndex inIndex,
   CFStringRef *outString
);
```

Parameters

inComboBox

The combo box that contains the text item you want to copy.

inIndex

The index of the text item. This function returns `paramErr` if the index is out of the bounds of the combo box disclosure list.

outString

A copy of the string at the specified index. You are responsible for releasing the string.

Return Value
An operating system status code.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`HIComboBox.h`

HIComboBoxCreate

Creates a combo box control.

```
OSStatus HIComboBoxCreate (
   const HIRect *boundsRect,
   CFStringRef text,
   const ControlFontStyleRec *style,
   CFArrayRef list,
   OptionBits inAttributes,
   HIViewRef *outComboBox
);
```

Parameters

boundsRect
The bounding box of the control.

text
The default text in the editable portion of the control. Can be `NULL`.

style
The font style of the both editable text and the text in the disclosure list. Can be `NULL`.

list
The default values available in the disclosure list. Can be `NULL`.

inAttributes
The default attributes of the combo box. For possible values, see "Combo Box Attributes" (page 2500).

outComboBox
On exit, a pointer to a reference for the new control.

Discussion
The combo box can be used in compositing mode, as well as traditional Control Manager mode. When created, this view is invisible. To see the view, you must show the view by calling `HIViewSetVisible` (page 2490).

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`HIComboBox.h`

HIComboBoxGetAttributes

Gets the attributes of a combo box.

```
OSStatus HIComboBoxGetAttributes (
   HIViewRef inComboBox,
   OptionBits *outAttributes
);
```

Parameters

inComboBox
The combo box whose attributes you want to obtain.

outAttributes
The attributes of the combo box. For possible values, see "Combo Box Attributes" (page 2500).

Return Value
An operating system status code.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`HIComboBox.h`

HIComboBoxGetItemCount

Gets the number of items in the combo box disclosure list.

```
ItemCount HIComboBoxGetItemCount (
   HIViewRef inComboBox
);
```

Parameters

inComboBox
The combo box.

Return Value
The number of items in the combo box disclosure list.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`HIComboBox.h`

HIComboBoxInsertTextItemAtIndex

Inserts a CFString in a combo box disclosure list.

```
OSStatus HIComboBoxInsertTextItemAtIndex (
   HIViewRef inComboBox,
   CFIndex inIndex,
   CFStringRef inText
);
```

Parameters

inComboBox
The combo box having the disclosure list in which the text is to be inserted.

inIndex
The index at which the text should be inserted. If the index does not fall within the number of items in the combo box list, the text is appended to the end of the list.

inText
The text item to be inserted in the combo box disclosure list.

Return Value
An operating system status code.

Availability
Available in Mac OS X v10.2 and later.

Not available to 64-bit applications.

Declared In
`HIComboBox.h`

HIComboBoxIsListVisible

Determines whether a combo box disclosure list is visible.

```
Boolean HIComboBoxIsListVisible (
   HIViewRef inComboBox
);
```

Parameters

inComboBox
The Combo box whose disclosure list visibility is to be queried.

Return Value
A Boolean whose value is `true` if the combo box disclosure list is visible; otherwise, `false` to indicate that the combo box disclosure list is hidden.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`HIComboBox.h`

HIComboBoxRemoveItemAtIndex

Removes an item from a combo box disclosure list.

```
OSStatus HIComboBoxRemoveItemAtIndex (
   HIViewRef inComboBox,
   CFIndex inIndex
);
```

Parameters

inComboBox
The combo box having the disclosure list that from which you want to remove an item.

inIndex
The index of the item to remove.

Return Value
An operating system status code.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`HIComboBox.h`

HIComboBoxSetListVisible

Hides or shows a combo box disclosure list.

```
OSStatus HIComboBoxSetListVisible (
   HIViewRef inComboBox,
   Boolean inVisible
);
```

Parameters

inComboBox

The combo box.

inVisible

A Boolean whose value is `true` to make the combo box disclosure list visible or `false` to hide the combo box list.

Return Value

An operating system result code.

Availability

Available in Mac OS X v10.4 and later.

Not available to 64-bit applications.

Declared In

`HIComboBox.h`

HICreateTransformedCGImage

Creates a new Core Graphics image with the standard selected or disabled appearance.

```
OSStatus HICreateTransformedCGImage (
   CGImageRef inImage,
   OptionBits inTransform,
   CGImageRef *outImage
);
```

Parameters

inImage

The original image.

inTransform

The transformation to apply to the image. For possible values, see "Transformation Constants" (page 2525).

outImage

A pointer to a value of type `CGImageRef` that, on return, contains the new image. You are responsible for releasing the image.

Return Value

An operating system result code.

Availability

Available in Mac OS X v10.4 and later.

Not available to 64-bit applications.

Declared In
HIView.h

HIGrowBoxViewIsTransparent

Determines whether a grow box view is transparent.

```
Boolean HIGrowBoxViewIsTransparent (
   HIViewRef inGrowBoxView
);
```

Parameters

inGrowBoxView
The grow box view reference to query.

Return Value
A Boolean value that is `true` if the grow box view is transparent; otherwise, `false` which indicates the grow box view is an opaque white square with grow lines.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
HIWindowViews.h

HIGrowBoxViewSetTransparent

Makes a grow box view transparent or opaque.

```
OSStatus HIGrowBoxViewSetTransparent (
   HIViewRef inGrowBoxView,
   Boolean inTransparent
);
```

Parameters

inGrowBoxView
The grow box view reference.

inTransparent
Pass `true` to make the grow box view use its transparent look or `false` to make the grow box view use its opaque appearance.

Return Value
An operating system result code.

Discussion
This function sets a grow box view to be transparent, meaning the grow box lines are drawn over any content under it. When not transparent, the grow box is an opaque white square with the grow lines.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
HIWindowViews.h

HIImageViewCopyImage

Obtains the image for an image view.

```
CGImageRef HIImageViewCopyImage (
   HIViewRef inView
);
```

Parameters

inView
The image view to query.

Return Value
A Core Graphics (Quartz) image reference, or NULL if there is no image set on the view or if the view ref is invalid.

Discussion
The image is retained, so you should release it when you are finished with it.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
HIImageViews.h

HIImageViewCreate

Creates an image view.

```
OSStatus HIImageViewCreate (
   CGImageRef inImage,
   HIViewRef *outView
);
```

Parameters

inImage
An initial image, or NULL. You can use SetControlData to set the image later.

outControl
The new image view.

Return Value
An operating system result code.

Discussion
The view responds to the scrollable interface and can be used in a scrolling view. You can pass an image initially, or set one later.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
HIImageViews.h

HIImageViewGetAlpha

Obtains the alpha value for a view.

```
CGFloat HIImageViewGetAlpha (
   HIViewRef inView
);
```

Parameters

inView
The image view to query.

Return Value
A floating point number representing the alpha from 0.0 through 1.0.

Discussion
An alpha of 1.0 means that the view is fully opaque, and alpha of 0.0 is means the view is fully transparent.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
HIImageViews.h

HIImageViewGetScaleToFit

Determines whether an image will scale or clip to the view bounds.

```
Boolean HIImageViewGetScaleToFit (
   HIViewRef inView
);
```

Parameters

inView
The image view to query.

Return Value
A Boolean whose value is `true` if the image scales or `false` if the image clips.

Discussion
This function determines whether an image view will scale the image it displays to the view bounds or merely clip to the view bounds.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
HIImageViews.h

HIImageViewIsOpaque

Determines whether an image view is opaque.

```
Boolean HIImageViewIsOpaque (
   HIViewRef inView
);
```

Parameters

inView
The image view to query.

Return Value

A Boolean whose value is `true` if the image view is opaque; otherwise, `false`.

Availability

Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In

`HIImageViews.h`

HIImageViewSetAlpha

Sets the alpha value for an image view.

```
OSStatus HIImageViewSetAlpha (
   HIViewRef inView,
   CGFloat inAlpha
);
```

Parameters

inView
The image view to affect.

inAlpha
The new alpha value.

Return Value

An operating system result code.

Discussion

Allows you to set the alpha for an image, making it more or less transparent. An alpha of 1.0 is fully opaque, and an alpha of 0.0 is fully transparent. The default alpha for an image is 1.0.

Availability

Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In

`HIImageViews.h`

HIImageViewSetImage

Sets the image to display in an image view.

```
OSStatus HIImageViewSetImage (
   HIViewRef inView,
   CGImageRef inImage
);
```

Parameters

inView

The image view to affect.

inImage

The image to set.

Return Value
An operating system status code.

Discussion
The image passed in is retained by the view, so you may release the image after calling this function if you no longer need to reference it.

Availability
Available in Mac OS X v10.2 and later.

Not available to 64-bit applications.

Related Sample Code
CarbonCocoa_PictureCursor

Declared In
`HIImageViews.h`

HIImageViewSetOpaque

Sets the opacity of an image view.

```
OSStatus HIImageViewSetOpaque (
   HIViewRef inView,
   Boolean inOpaque
);
```

Parameters

inView

The image view to set.

inOpaque

A Boolean whose value is `true` to make the image view opaque or `false` to disable the opacity setting.

Return Value
An operating system result code.

Discussion
When opacity is enabled, the image view can make certain optimizations for compositing and scrolling. The alpha-related image view APIs are rendered useless when opacity is enabled. An image view, when created, is opaque by default. You must pass `false` to this function in order to change the alpha, etc. or if your image does not fill the full bounds of the view.

Availability
Available in Mac OS X v10.2 and later.

Not available to 64-bit applications.

Related Sample Code
CarbonCocoa_PictureCursor

Declared In
`HIImageViews.h`

HIImageViewSetScaleToFit

Specifies whether an image should scale or clip to the view's bounds.

```
OSStatus HIImageViewSetScaleToFit (
   HIViewRef inView,
   Boolean inScaleToFit
);
```

Parameters

inView
The image view.

inScaleToFit
A Boolean whose value is `true` to indicate that the image should be scaled to fit the view bounds or `false` to indicate that the image should clip to the view's bounds.

Return Value
An operating system status code.

Discussion
Normally, an image view clips to the view's bounds. Use this function to tell the image view to size the image to fit into the view's bounds.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`HIImageViews.h`

HIMenuGetContentView

Obtains an `HIViewRef` that can be used to draw menu content for a menu.

```
OSStatus HIMenuGetContentView (
   MenuRef inMenu,
   ThemeMenuType inMenuType,
   HIViewRef *outView
);
```

Parameters

inMenu
The menu for which an `HIViewRef` is to be obtained.

inMenuType

The type of menu for which the menu content view is to be returned. The same `MenuRef` may have multiple content views, depending on the menu type being displayed.

outView

A pointer to a value of type `HIViewRef` that, on return, represents the view, or `NULL` if the menu does not use an HIView to draw its content. The caller should not release this view.

Return Value
An operating system result code. If the menu uses an MDEF instead of a view to draw its content, this function sets `outView` to `NULL` and returns `noErr`.

Discussion
If the content view has not yet been created, the Menu Manager will create the content view using the view class ID and initialization event associated with the menu. Note that the menu content view is not the same as the window content view; the menu content view is embedded inside the window content view.

Availability
Available in Mac OS X v10.3 and later.
Not available to 64-bit applications.

Declared In
`Menus.h`

HIMenuViewGetMenu

Returns the `MenuRef` associated with a view that is a subclass of HIMenuView.

```
MenuRef HIMenuViewGetMenu (
   HIViewRef inView
);
```

Parameters

inView

The view whose menu is to be returned.

Return Value
The `MenuRef` associated with the specified view, or `NULL` if a view is passed that is not a subclass of HIMenuView.

Discussion
An HIMenuView subclass might use call this function to determine the menu it should draw.

Special Considerations

Prior to Mac OS X v10.5, this function returns `NULL` if passed an instance of the standard menu view. In Mac OS X v10.5 and later, this function correctly returns the owning menu of an instance of the standard menu view.

Availability
Available in Mac OS X v10.3 and later.
Not available to 64-bit applications.

Declared In
`HIMenuView.h`

HIScrollViewCanNavigate

Determines whether it is possible to navigate in a scroll view.

```
Boolean HIScrollViewCanNavigate (
   HIViewRef inView,
   HIScrollViewAction inAction
);
```

Parameters

inView

The view to query.

inAction

The navigation action to test. For possible values, see "Scroll View Action Constants" (page 2515).

Return Value

A Boolean whose value is `true` if the navigation specified by `inAction` is possible; otherwise, `false`.

Discussion

Use this function to determine whether it is possible to perform a particular navigation within a scroll view. For example, if a scroll view is already at the top of the scrollable content, it is not possible to navigate upward, so the home and page up actions would not be possible. You might use this function to help you update the state of menu items.

Availability

Available in Mac OS X v10.3 and later.

Not available to 64-bit applications.

Declared In

`HIScrollView.h`

HIScrollViewCreate

Creates a scroll view.

```
OSStatus HIScrollViewCreate (
   OptionBits inOptions,
   HIViewRef *outView
);
```

Parameters

inOptions

Options for our scroll view. You must specify either a horizontal or a vertical scroll bar. If neither is passed, an error is returned. For possible values, see "Scroll View Constants" (page 2514).

outView

The new scroll view.

Return Value

An operating system result code.

Discussion

This view has three parts. It can have a horizontal scroll bar, a vertical scroll bar, and a view to be scrolled that must be added by calling `HIViewAddSubview` (page 2442). The added scroll view integrates itself automatically and appropriately.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Related Sample Code
HID Calibrator

Declared In
`HIScrollView.h`

HIScrollViewGetScrollBarAutoHide

Obtains current setting of a scroll view's scroll bar auto-hide setting.

```
Boolean HIScrollViewGetScrollBarAutoHide (
   HIViewRef inView
);
```

Parameters

inView
The view to query.

Return Value
A Boolean whose value is `true` if the auto-hide setting is enabled; otherwise, `false`.

Discussion
When the auto-hide setting is enabled, a scroll view's scroll bars are hidden when the entire scrollable view can be fully displayed in the scroll view's bounds. This is similar to the behavior of the Preview application.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`HIScrollView.h`

HIScrollViewNavigate

Changes the portion of a view's target.

```
OSStatus HIScrollViewNavigate (
   HIViewRef inView,
   HIScrollViewAction inAction
);
```

Parameters

inView
The view to scroll.

inAction
The action to take.

Return Value
An operating system result code.

Discussion
Use this function to programmatically change the portion of a scroll view's target. For example, you can call this function to move to the beginning or end of a document. You can also page up, down, left and right. In general, you should not call this function from embedded content, that is, the scrollable view inside the scroll view. Instead, for those cases, you should position yourself appropriately and tell the scroll view you changed via the `kEventScrollableInfoChanged` Carbon event. This function is merely a programmatic way to scroll as one would by hand using the scroll bars.

Availability
Available in Mac OS X v10.3 and later.
Not available to 64-bit applications.

Declared In
`HIScrollView.h`

HIScrollViewSetScrollBarAutoHide

Sets a scroll view's auto-hide setting.

```
OSStatus HIScrollViewSetScrollBarAutoHide (
   HIViewRef inView,
   Boolean inAutoHide
);
```

Parameters

inView
The view to affect.

inAutoHide
A Boolean whose value is `true` to enable auto-hide and `false` to disable auto-hide.

Return Value
An operating system result code.

Discussion
When the auto-hide setting is enabled, a scroll view's scroll bars are hidden when the entire scrollable view can be fully displayed in the scroll view's bounds. This is similar to the behavior of the Preview application.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Related Sample Code
HID Calibrator

Declared In
`HIScrollView.h`

HISearchFieldChangeAttributes

Sets the attributes of a search field.

```
OSStatus HISearchFieldChangeAttributes (
   HIViewRef inSearchField,
   OptionBits inAttributesToSet,
   OptionBits inAttributesToClear
);
```

Parameters

inSearchField

The search field whose attributes are to be changed.

inAttributesToSet

The attributes to set. For possible values, see "Search Field Attribute Constants" (page 2519).

inAttributesToClear

The attributes to clear. For possible values, see "Search Field Attribute Constants" (page 2519).

Return Value

An operating system result code.

Availability

Available in Mac OS X v10.3 and later.

Not available to 64-bit applications.

Declared In

`HISearchField.h`

HISearchFieldCopyDescriptiveText

Obtains the description associated with a search field.

```
OSStatus HISearchFieldCopyDescriptiveText (
   HIViewRef inSearchField,
   CFStringRef *outDescription
);
```

Parameters

inSearchField

The search field whose descriptive text is to be obtained.

outDescription

A pointer to a value of type `CFStringRef` that, on return, represents the description that is associated with the search field specified by `inSearchField`. This parameter cannot be `NULL`. If no description is associated with the search field, on return, `outDescription` is set to `NULL`. If there is a description, a `CFStringRef` is created for you; you are responsible for releasing the `CFStringRef` when you no longer need it.

Return Value

An operating system result code.

Availability

Available in Mac OS X v10.3 and later.

Not available to 64-bit applications.

Declared In

`HISearchField.h`

HISearchFieldCreate

Creates a Search field control.

```
OSStatus HISearchFieldCreate (
   const HIRect *inBounds,
   OptionBits inAttributes,
   MenuRef inSearchMenu,
   CFStringRef inDescriptiveText,
   HIViewRef *outRef
);
```

Parameters

inBounds

The initial bounds of the view, or `NULL`. If this parameter is `NULL`, the view is created with empty bounds (0, 0, 0, 0).

inAttributes

The initial attributes of the search field. Indicates whether the field should contain the Cancel icon. For possible values, see "Search Field Attribute Constants" (page 2519).

inSearchMenu

The menu to be associated with this search field, or `NULL`. If `inSearchMenu` is non-`NULL`, the menu will be retained by the search field and the Search icon will be enabled in the left side of the text field. If this parameter is `NULL`, the view will not display the Search icon in the left portion of the text field. You are expected to install handlers on this menu to handle the visual appearance of the menu (for example, to draw check marks or enable items when the menu receives the `kEventMenuEnableItems` Carbon event), and to keep track of what action should be performed by associating HICommands with each menu item and installing a handler for the `kEventClassCommand`/`kEventCommandProcess` Carbon event.

inDescriptiveText

The text to be displayed in the text field when the field does not have focus and contains no user-entered text, or `NULL`. This text should indicate the search criteria. For example, you may want to identify to the user that the search will cover the "Subject" or "Contents" of a selected range of items. If `inDescriptiveText` is non-`NULL`, the text will be retained by the search field.

outRef

On return, a reference for the new view.

Return Value

An operating system result code.

Discussion

This view is designed to be used by applications that provide searching functionality. Visually, it is a standard text field optionally adorned with a Search icon on the left and a Cancel image on the right. The new control is initially invisible.

When the user accepts the text by pressing the Return or Enter key, a Carbon event of `kEventClassTextField` / `kEventTextAccepted` is sent to the control to indicate that the search should begin. This control also responds to all of the standard control tags used by the `EditUnicodeText` control.

Availability

Available in Mac OS X v10.3 and later.

Not available to 64-bit applications.

Declared In

`HISearchField.h`

HISearchFieldGetAttributes

Obtains the attributes for a search field.

```
OSStatus HISearchFieldGetAttributes (
   HIViewRef inSearchField,
   OptionBits *outAttributes
);
```

Parameters

inSearchField

The search field whose attributes are to be obtained.

outAttributes

A pointer to a value of type `OptionBits` that, on return, contains the attributes of the Search field specified by `inSearchField`. This parameter cannot be `NULL`. For possible values, see "Search Field Attribute Constants" (page 2519).

Return Value

An operating system result code.

Availability

Available in Mac OS X v10.3 and later.

Not available to 64-bit applications.

Declared In

`HISearchField.h`

HISearchFieldGetSearchMenu

Obtains the search menu associated with a search field.

```
OSStatus HISearchFieldGetSearchMenu (
   HIViewRef inSearchField,
   MenuRef *outSearchMenu
);
```

Parameters

inSearchField

The search field for which you want to obtain the search menu.

outSearchMenu

A pointer to a value of type `MenuRef` that, on return, represents the menu associated with the search field. The menu is *not* retained on output, and this parameter cannot be `NULL`.

Return Value

An operating system result code.

Availability

Available in Mac OS X v10.3 and later.

Not available to 64-bit applications.

Declared In

`HISearchField.h`

HISearchFieldSetDescriptiveText

Sets the description of the search action for a search field.

```
OSStatus HISearchFieldSetDescriptiveText (
   HIViewRef inSearchField,
   CFStringRef inDescription
);
```

Parameters

inSearchField

The search field whose descriptive text is to be set.

inDescription

The new description for the search field. If the search field already has a description, it will be released. If this parameter is non-`NULL`, it will be retained by the search field. If this parameter is `NULL`, upon return, no description is associated with the search field.

Return Value

An operating system result code.

Availability

Available in Mac OS X v10.3 and later.

Not available to 64-bit applications.

Declared In

`HISearchField.h`

HISearchFieldSetSearchMenu

Sets the search menu associated with a search field view.

```
OSStatus HISearchFieldSetSearchMenu (
   HIViewRef inSearchField,
   MenuRef inSearchMenu
);
```

Parameters

inSearchField

The Search field with which to associate the search menu.

inSearchMenu

The menu to associate with the Search field, or `NULL`. If a menu is already associated with the Search field, that menu is released. If `inSearchMenu` is non-`NULL`, it will be retained by the Search field and the Search icon will be enabled in the left side of the text field. You are expected to install handlers on this menu to handle the visual appearance of the menu (for example, to draw check marks or enable items when the menu receives the `kEventMenuEnableItems` Carbon event). You are also expected to keep track of the actions that should be performed by associating HICommands with each menu item and installing a handler for the `kEventClassCommand`/`kEventCommandProcess` Carbon event. If `inSearchMenu` is `NULL`, the Search icon is removed from the left side of the text field and no menu is associated with the Search field.

Return Value

An operating system result code.

Availability

Available in Mac OS X v10.3 and later.

Not available to 64-bit applications.

Declared In
HISearchField.h

HISegmentedViewChangeSegmentAttributes

Changes the attributes of an individual segment of a segmented view.

```
OSStatus HISegmentedViewChangeSegmentAttributes (
   HIViewRef inSegmentedView,
   UInt32 inSegmentIndexOneBased,
   OptionBits inAttributesToSet,
   OptionBits inAttributesToClear
);
```

Parameters

inSegmentedView
The segmented view that owns the segment whose attributes you want to change.

inSegmentIndexOneBased
The one-based index of the segment whose attributes you want to change. This must be a non-zero value that is no higher than the segmented view's current segment count.

inAttributesToSet
The attribute bits you want to set for the segment. For possible values, see "Segment Attribute Constants" (page 2520).

inAttributesToClear
The attribute bits you want to clear for the segment.

Return Value
An operating system result code.

Discussion
By default, a segment has no attributes.

Availability
Available in Mac OS X v10.3 and later.
Not available to 64-bit applications.

Declared In
HISegmentedView.h

HISegmentedViewCopySegmentImage

Copies the image drawn by a segment.

```
OSStatus HISegmentedViewCopySegmentImage (
   HIViewRef inSegmentedView,
   UInt32 inSegmentIndexOneBased,
   HIViewImageContentInfo *ioImage
);
```

Parameters

inSegmentedView

The segmented view that owns the segment whose image you want to copy.

inSegmentIndexOneBased

The one-based index of the segment whose image you want to set. This must be a non-zero value that is no higher than the segmented view's current segment count.

ioImage

A pointer to a `HIViewImageContentInfo` structure whose `contentType` field specifies the type of image you want to copy. If the segment uses the type of image you specified, on return, the appropriate field of the union contains a copy of the image. If the segment index is an illegal value, the result is undefined. You are responsible for releasing the image.

Return Value

An operating system result code.

Discussion

Call `HISegmentedViewGetSegmentImageContentType` (page 2435) to get the image type.

Availability

Available in Mac OS X v10.3 and later.

Not available to 64-bit applications.

Declared In

`HISegmentedView.h`

HISegmentedViewCopySegmentLabel

Obtains a copy of the label string associated with a segment.

```
OSStatus HISegmentedViewCopySegmentLabel (
   HIViewRef inSegmentedView,
   UInt32 inSegmentIndexOneBased,
   CFStringRef *outLabel
);
```

Parameters

inSegmentedView

The segmented view that owns the segment whose label you want to copy.

inSegmentIndexOneBased

The one-based index of the segment whose label is to be copied. This must be a non-zero value that is no higher than the segmented view's current segment count.

outLabel

A pointer to a `CFStringRef` that represents the copy of the label associated with the segment. You are responsible for releasing the the string containing the copy of the label. If no label is associated with the specified segment, `outLabel` is set to `NULL`.

Return Value
An operating system result code.

Availability
Available in Mac OS X v10.3 and later.
Not available to 64-bit applications.

Declared In
`HISegmentedView.h`

HISegmentedViewCreate

Creates a segmented view.

```
OSStatus HISegmentedViewCreate (
   const HIRect *inBounds,
   HIViewRef *outRef
);
```

Parameters

inBounds
The bounds of the view to be created, or `NULL`. If `NULL`, the view is created with `CGRectZero` bounds.

outRef
A valid pointer to an `HIViewRef` that, on return, represents the newly created view.

Return Value
An operating system result code.

Discussion
You can use a segmented view to implement the icon/column/list view switcher as seen in the Finder. After creating a segmented view, set the number of segments by calling `HISegmentedViewSetSegmentCount` (page 2439). Each segment can be configured independently by calling other HISegmentedView APIs. Changing the number of segments and configuring each segment changes the appearance of the segmented view. After configuring the view, you may want to call `HIViewGetOptimalBounds` (page 2461) on the view and resize it so the content fits optimally.

The value of the whole segmented view corresponds to the index of the currently selected segment with the radio behavior. If you set the value of the whole segmented view to *n* by calling `HIViewSetValue` (page 2489), the value of each radio-behavior segment is set to zero except for the segment at index *n*. If segment *n* also has radio behavior, its value will be set to one. When a radio-behavior segment is clicked, the value of the whole segmented view is set to the segment's index.

Segmented views work in both compositing and non-compositing modes.

Availability
Available in Mac OS X v10.3 and later.
Not available to 64-bit applications.

Declared In
`HISegmentedView.h`

HISegmentedViewGetSegmentAttributes

Returns the attributes of an individual segment of a segmented view.

```
OptionBits HISegmentedViewGetSegmentAttributes (
   HIViewRef inSegmentedView,
   UInt32 inSegmentIndexOneBased
);
```

Parameters

inSegmentedView

The segmented view that owns the segment to query.

inSegmentIndexOneBased

The one-based index of the segment whose attributes you want to query. This must be a non-zero value that is no higher than the segmented view's current segment count.

Return Value

The attribute bits that are set for the specified segment. For possible values, see "Segment Attribute Constants" (page 2520). If the segment index is an illegal value, the result is undefined.

Availability

Available in Mac OS X v10.3 and later.

Not available to 64-bit applications.

Declared In

`HISegmentedView.h`

HISegmentedViewGetSegmentBehavior

Obtains the behavior of an individual segment of a segmented view.

```
HISegmentBehavior HISegmentedViewGetSegmentBehavior (
   HIViewRef inSegmentedView,
   UInt32 inSegmentIndexOneBased
);
```

Parameters

inSegmentedView

The segmented view that owns the segment whose behavior is to be obtained.

inSegmentIndexOneBased

The one-based index of the segment whose behavior you want to obtain. This must be a non-zero value that is no higher than the segmented view's current segment count.

Return Value

A value of type `HISegmentBehavior` describing the behavior of the given segment. For possible values, see "Segment Behavior Constants" (page 2521). If the segment index is an illegal value, the result is undefined.

Availability

Available in Mac OS X v10.3 and later.

Not available to 64-bit applications.

Declared In

`HISegmentedView.h`

HISegmentedViewGetSegmentCommand

Obtains the command ID associated with a segment.

```
UInt32 HISegmentedViewGetSegmentCommand (
   HIViewRef inSegmentedView,
   UInt32 inSegmentIndexOneBased
);
```

Parameters

inSegmentedView

The segmented view that owns the segment for which the command ID is to be obtained.

inSegmentIndexOneBased

The one-based index of the segment for which the command ID is to be obtained. This must be a non-zero value that is no higher than the segmented view's current segment count.

Return Value

The command ID associated with the specified segment. If the segment index is an illegal value, the result is undefined.

Availability

Available in Mac OS X v10.3 and later.

Not available to 64-bit applications.

Declared In

`HISegmentedView.h`

HISegmentedViewGetSegmentContentWidth

Obtains the content width of a segment.

```
CGFloat HISegmentedViewGetSegmentContentWidth (
   HIViewRef inSegmentedView,
   UInt32 inSegmentIndexOneBased,
   Boolean *outAutoCalculated
);
```

Parameters

inSegmentedView

The segmented view that owns the segment whose content width is to be obtained.

inSegmentIndexOneBased

The one-based index of the segment. This must be a non-zero value that is no higher than the segmented view's current segment count.

outAutoCalculateWidth

A pointer to a Boolean whose value, on return, is `true` if the segment calculates its own width automatically; otherwise, `false`. Pass `NULL` if you don't want this information.

Return Value

The width of the content for the given segment. If the segment index is an illegal value, the result is undefined.

Discussion

The content width is the horizontal area taken up by a segment's label (if any) and image (if any).

Availability
Available in Mac OS X v10.3 and later.
Not available to 64-bit applications.

Declared In
`HISegmentedView.h`

HISegmentedViewGetSegmentCount

Obtains the number of segments for a segmented view.

```
UInt32 HISegmentedViewGetSegmentCount (
   HIViewRef inSegmentedView
);
```

Parameters

`inSegmentedView`
The segmented view for which the number of segments is to be obtained.

Return Value
A `UInt32` whose value is the number of segments in the segmented view specified by `inSegmentedView`.

Availability
Available in Mac OS X v10.3 and later.
Not available to 64-bit applications.

Declared In
`HISegmentedView.h`

HISegmentedViewGetSegmentImageContentType

Obtains the type of image content drawn by a segment.

```
HIViewImageContentType HISegmentedViewGetSegmentImageContentType (
   HIViewRef inSegmentedView,
   UInt32 inSegmentIndexOneBased
);
```

Parameters

`inSegmentedView`
The segmented view that owns the segment whose image content type you want to obtain.

`inSegmentIndexOneBased`
The one-based index of the segment whose image you want to set. This must be a non-zero value that is no higher than the segmented view's current segment count.

Return Value
The image content type of the image drawn by the specified segment. If the segment index is an illegal value, the result is undefined.

Availability
Available in Mac OS X v10.3 and later.
Not available to 64-bit applications.

Declared In
HISegmentedView.h

HISegmentedViewGetSegmentValue

Returns the value of an individual segment of a segmented view.

```
SInt32 HISegmentedViewGetSegmentValue (
   HIViewRef inSegmentedView,
   UInt32 inSegmentIndexOneBased
);
```

Parameters

inSegmentedView
The segmented view that owns the segment to query.

inSegmentIndexOneBased
The one-based index of the segment whose value you want to obtain. This must be a non-zero value that is no higher than the segmented view's current segment count.

Return Value
An `SInt32` containing the value of the specified segment. Zero means that the segment is unpressed or unselected, and one means the segment is pressed or selected.

Discussion
Getting a segment value is only meaningful for segments with the sticky, toggles, or radio behaviors. The value of segments that have the momentary behavior is undefined.

Availability
Available in Mac OS X v10.3 and later.
Not available to 64-bit applications.

Declared In
HISegmentedView.h

HISegmentedViewIsSegmentEnabled

Determines whether an individual segment of a segmented view is enabled.

```
Boolean HISegmentedViewIsSegmentEnabled (
   HIViewRef inSegmentedView,
   UInt32 inSegmentIndexOneBased
);
```

Parameters

inSegmentedView
The segmented view that owns the segment to query.

inSegmentIndexOneBased
The one-based index of the segment to query. This must be a non-zero value that is no higher than the segmented view's current segment count.

Return Value
A Boolean whose value is `true` if the segment is enabled or `false` if the segment is not enabled.

Availability
Available in Mac OS X v10.3 and later.
Not available to 64-bit applications.

Declared In
`HISegmentedView.h`

HISegmentedViewSetSegmentBehavior

Changes the behavior of an individual segment of a segmented view.

```
OSStatus HISegmentedViewSetSegmentBehavior (
   HIViewRef inSegmentedView,
   UInt32 inSegmentIndexOneBased,
   HISegmentBehavior inBehavior
);
```

Parameters

inSegmentedView
The segmented view that owns the segment whose behavior is to be set.

inSegmentIndexOneBased
The one-based index of the segment whose behavior you want to set. This must be a non-zero value that is no higher than the segmented view's current segment count.

inBehavior
The behavior you want the segment to have. For possible values, see "Segment Behavior Constants" (page 2521).

Return Value
An operating system result code.

Discussion
By default, a segment has the `kHISegmentBehaviorMomentary` behavior.

Availability
Available in Mac OS X v10.3 and later.
Not available to 64-bit applications.

Declared In
`HISegmentedView.h`

HISegmentedViewSetSegmentCommand

Sets the command ID for a segment.

```
OSStatus HISegmentedViewSetSegmentCommand (
   HIViewRef inSegmentedView,
   UInt32 inSegmentIndexOneBased,
   UInt32 inCommand
);
```

Parameters

inSegmentedView
The segmented view that owns the segment for which the command ID is to be set.

inSegmentIndexOneBased

The one-based index of the segment for which the command ID is to be set. This must be a non-zero value that is no higher than the segmented view's current segment count.

inCommand

The command ID you want to associate with the segment. When the command ID is `0` for a segment, the `kEventCommandProcess` event is not sent when the segment is clicked.

Return Value
An operating system result code.

Discussion
When any non-zero command ID is set, the segmented view sends an HICommand whenever the segment is clicked. By default, the command is sent to the segmented view and up the containment hierarchy. If you want the command to start at the user focus instead, set the `kHISegmentCmdToUserFocus` attribute for the segment.

Availability
Available in Mac OS X v10.3 and later.

Not available to 64-bit applications.

Declared In
`HISegmentedView.h`

HISegmentedViewSetSegmentContentWidth

Specifies how the content width of segment is to be calculated.

```
OSStatus HISegmentedViewSetSegmentContentWidth (
   HIViewRef inSegmentedView,
   UInt32 inSegmentIndexOneBased,
   Boolean inAutoCalculateWidth,
   CGFloat inWidth
);
```

Parameters

inSegmentedView

The segmented view that owns the segment whose method of calculating content width you want to specify.

inSegmentIndexOneBased

The one-based index of the segment. This must be a non-zero value that is no higher than the segmented view's current segment count.

inAutoCalculateWidth

A Boolean whose value is `true` if you want the segment to calculate its own width automatically (in which case, the `inWidth` parameter is ignored), or `false` if you want the value of the `inWidth` parameter to be associated with the segment.

inWidth

The width in pixels.

Return Value
An operating system result code.

Discussion
The content width is the horizontal area taken up by a segment's label (if any) and image (if any).

Availability
Available in Mac OS X v10.3 and later.
Not available to 64-bit applications.

Declared In
`HISegmentedView.h`

HISegmentedViewSetSegmentCount

Sets the number of segments for a segmented view.

```
OSStatus HISegmentedViewSetSegmentCount (
   HIViewRef inSegmentedView,
   UInt32 inSegmentCount
);
```

Parameters

inSegmentedView
The segmented menu for which the number of segments is to be set.

inSegmentCount
A positive integer specifying the number of segments the view is to have.

Return Value
An operating system result code.

Discussion
The content for any previous segments beyond the new count is released. All new segments beyond the previous count are initialized with basic settings: Momentary, no attributes, zero value, enabled, no command, no label, no content, and auto-calculated content width. You should configure any new segments to match your needs.

Availability
Available in Mac OS X v10.3 and later.
Not available to 64-bit applications.

Declared In
`HISegmentedView.h`

HISegmentedViewSetSegmentEnabled

Enables or disables an individual segment of a segmented view.

```
OSStatus HISegmentedViewSetSegmentEnabled (
   HIViewRef inSegmentedView,
   UInt32 inSegmentIndexOneBased,
   Boolean inEnabled
);
```

Parameters

inSegmentedView
The segmented view that owns the segment that is to be enabled or disabled.

inSegmentIndexOneBased

The one-based index of the segment to enable or disable. This must be a non-zero value that is no higher than the segmented view's current segment count.

inEnabled

A Boolean whose value is `true` to enable the segment or `false` to disable the segment.

Return Value
An operating system result code.

Availability
Available in Mac OS X v10.3 and later.
Not available to 64-bit applications.

Declared In
`HISegmentedView.h`

HISegmentedViewSetSegmentImage

Sets or clears the image associated with a segment.

```
OSStatus HISegmentedViewSetSegmentImage (
   HIViewRef inSegmentedView,
   UInt32 inSegmentIndexOneBased,
   const HIViewImageContentInfo *inImage
);
```

Parameters

inSegmentedView

The segmented view that owns the segment whose image you want to set.

inSegmentIndexOneBased

The one-based index of the segment whose image you want to set. This must be a non-zero value that is no higher than the segmented view's current segment count.

inImage

A pointer to an `HIViewImageContentInfo` structure with the image information for the specified segment. Segments support three types of image content: `kControlNoContent`, `kControlContentIconRef`, and `kControlContentCGImageRef`.

Return Value
An operating system result code.

Availability
Available in Mac OS X v10.3 and later.
Not available to 64-bit applications.

Declared In
`HISegmentedView.h`

HISegmentedViewSetSegmentLabel

Sets the label string for a segment.

```
OSStatus HISegmentedViewSetSegmentLabel (
   HIViewRef inSegmentedView,
   UInt32 inSegmentIndexOneBased,
   CFStringRef inLabel
);
```

Parameters

inSegmentedView

The segmented view that owns the segment whose label you want to sets.

inSegmentIndexOneBased

The one-based index of the segment whose label is to be set. This must be a non-zero value that is no higher than the segmented view's current segment count.

inLabel

A `CFStringRef` with the text of the label. The segmented view will copy the string you passed in. To eliminate the label from the segment, pass `NULL` or an empty `CFStringRef`.

Return Value
An operating system result code.

Discussion
By default, a segment has no label string.

Availability
Available in Mac OS X v10.3 and later.

Not available to 64-bit applications.

Declared In
`HISegmentedView.h`

HISegmentedViewSetSegmentValue

Changes the value of an individual segment of a segmented view.

```
OSStatus HISegmentedViewSetSegmentValue (
   HIViewRef inSegmentedView,
   UInt32 inSegmentIndexOneBased,
   SInt32 inValue
);
```

Parameters

inSegmentedView

The segmented view that owns the segment to query.

inSegmentIndexOneBased

The one-based index of the segment whose value you want to change. This must be a non-zero value that is no higher than the segmented view's current segment count.

inValue

The value you want to set. Zero means that the segment is unpressed or unselected, and one means the segment is pressed or selected. Setting any other value will result in an undefined behavior.

Return Value
An operating system result code.

Discussion
Setting a segment value is only meaningful for segments with the sticky, toggles, or radio behaviors. Setting the value of segments that have the momentary behavior to something other than zero results in a behavior that is undefined.

Availability
Available in Mac OS X v10.3 and later.
Not available to 64-bit applications.

Declared In
`HISegmentedView.h`

HIViewAddSubview

Adds a subview to the given parent view.

```
OSStatus HIViewAddSubview (
   HIViewRef inParent,
   HIViewRef inNewChild
);
```

Parameters

inParent
The view that will receive the new subview.

inNewChild
The subview being added.

Return Value
An operating system result code. The result code `errNeedsCompositedWindow` is returned if you try to embed into the content view in a non-compositing window; you can only embed into the content view in a compositing window.

Discussion
The new subview is added to the front of the list of subviews (that is, it is made topmost). The subview being added is not retained by the new parent view. Do not release the view after adding it, or it will cease to exist. All views in a window are released automatically when the window is destroyed.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Related Sample Code
HID Calibrator

Declared In
`HIView.h`

HIViewAdvanceFocus

Advances the keyboard focus to the next most appropriate view.

```
OSStatus HIViewAdvanceFocus (
   HIViewRef inRootForFocus,
   EventModifiers inModifiers
);
```

Parameters

inRootForFocus

The subtree to manipulate. The focus does not leave `inRootToFocus`. Typically, you would pass the content of the window or the root. If focused on the toolbar, for example, the focus is limited to the toolbar only. In this case, for example, the Toolbox passes the toolbar view in as the focus root.

inModifiers

The keyboard event modifiers that caused `HIViewAdvanceFocus` (page 2442) to be called. These modifiers are used to determine the focus direction as well as other alternate focusing behaviors.

Return Value
An operating system result code.

Discussion
Unless overridden in some fashion (either by overriding certain Carbon events or by calling the `HIViewSetNextFocus` (page 2487), the Toolbox uses a spatially determinant method of focusing, attempting to focus left to right and top to bottom in a window, taking groups of controls into account.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewApplyLayout

Applies the current layout to the specified view.

```
OSStatus HIViewApplyLayout (
   HIViewRef inView
);
```

Parameters

inView

The view to which the layout is to be applied.

Return Value
An operating system result code.

Discussion
Side bindings have no effect, but positioning and scaling are applied, in that order.

Availability
Available in Mac OS X v10.3 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewChangeAttributes

Changes the attributes of a view.

```
OSStatus HIViewChangeAttributes (
   HIViewRef inView,
   OptionBits inAttrsToSet,
   OptionBits inAttrsToClear
);
```

Parameters

inView

The view whose attributes you want to change.

inAttrsToSet

The attributes you want to change. For possible values, see "HIView Attributes" (page 2508).

inAttrsToClear

The attributes you want to clear. For possible values, see "HIView Attributes" (page 2508).

Return Value

An operating system result code.

Discussion

You can set and clear attributes simultaneously.

Availability

Available in Mac OS X v10.2 and later.

Not available to 64-bit applications.

Declared In

`HIView.h`

HIViewChangeFeatures

Changes the features of a view.

```
OSStatus HIViewChangeFeatures (
   HIViewRef inView,
   HIViewFeatures inFeaturesToSet,
   HIViewFeatures inFeaturesToClear
);
```

Parameters

inView

The view whose features are to be changed.

inFeaturesToSet

The features that are to be set. For details, see "HIView Feature Constants" (page 2509).

inFeaturesToClear

The features that are to be cleared. For details, see "HIView Feature Constants" (page 2509).

Return Value

An operating system result code.

Discussion
The view itself typically controls its features. For example, the view might decide that under some situations it is opaque and in others it is transparent. In general entities outside of the view itself should not call this function. The only exception might be user-interface building tools that want to make sure a view always responds to clicks, for example, so it could override mouse tracking to drag items.

Availability
Available in Mac OS X v10.3 and later.
Not available to 64-bit applications.

Related Sample Code
HID Calibrator

Declared In
`HIView.h`

HIViewChangeTrackingArea

Changes the shape of a tracking area.

```
OSStatus HIViewChangeTrackingArea (
   HIViewTrackingAreaRef inArea,
   HIShapeRef inShape
);
```

Parameters
inArea
The tracking area to change.
inShape
The shape to use. Pass `NULL` to use the entire structure region of the view.

Return Value
An operating system result code.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewClick

Passes a mouse-down event to a view.

```
OSStatus HIViewClick (
   HIViewRef inView,
   EventRef inEvent
);
```

Parameters
inView
The view to handle the event.

inEvent
The mouse event to handle.

Return Value
An operating system result code.

Discussion
After a successful call to `HIViewGetViewForMouseEvent` for a mouse down event, you should call this function to have the view handle the click. In general we recommend using the Standard Window Handler instead of calling this function yourself.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewConvertPoint

Converts a point's coordinates from one view to another.

```
OSStatus HIViewConvertPoint (
   HIPoint *ioPoint,
   HIViewRef inSourceView,
   HIViewRef inDestView
);
```

Parameters
ioPoint
The point to convert.

inSourceView
The view whose coordinate system `ioPoint` is starting out in. You can pass `NULL` to indicate that `ioPoint` is a window-relative point.

inDestView
The view whose coordinate system `ioPoint` should end up in. You can pass `NULL` to indicate that `ioPoint` is a window-relative point.

Return Value
An operating system result code.

Discussion
Both views must have a common ancestor, that is, they must both be in the same window.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewConvertRect

Converts a rectangle from one view to another.

```
OSStatus HIViewConvertRect (
   HIRect *ioRect,
   HIViewRef inSourceView,
   HIViewRef inDestView
);
```

Parameters

ioRect

The rectangle to convert.

inSourceView

The view whose coordinate system `ioRect` is starting out in. You can pass `NULL` to indicate that `ioRect` is a window-relative rectangle.

inDestView

The view whose coordinate system `ioRect` should end up in. You can pass `NULL` to indicate that `ioRect` is a window-relative rectangle.

Return Value

An operating system result code.

Discussion

Both views must have a common ancestor, that is, they must both be in the same window.

Availability

Available in Mac OS X v10.2 and later.

Not available to 64-bit applications.

Declared In

`HIView.h`

HIViewConvertRegion

Converts a region from one view to another.

```
OSStatus HIViewConvertRegion (
   RgnHandle ioRgn,
   HIViewRef inSourceView,
   HIViewRef inDestView
);
```

Parameters

ioRgn

The region to convert.

inSourceView

The view whose coordinate system `ioRgn` is starting out in. You can pass `NULL` to indicate that `ioRgn` is a window-relative region.

inDestView

The view whose coordinate system `ioRgn` should end up in. You can pass `NULL` to indicate that `ioRgn` is a window-relative region.

Return Value
An operating system result code.

Discussion
Both views must have a common ancestor, that is, they must both be in the same window.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewCopyShape

Copies the shape of a part of a view.

```
OSStatus HIViewCopyShape (
   HIViewRef inView,
   HIViewPartCode inPart,
   HIShapeRef *outShape
);
```

Parameters

inView
The view having a part whose shape is to be copied.

inPart
The part of the view whose shape is to be copied. For possible values, see "HIViewPartCode Constants" (page 2513).

outShape
On exit, the newly created shape. You are responsible for releasing the copied shape.

Return Value
An operating system result code.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewCopyText

Copies the text of a view.

```
CFStringRef HIViewCopyText (
   HIViewRef inView
);
```

Parameters

inView
The view whose text is to be copied.

Return Value
A CFString containing a copy of the view's text. The caller is responsible for releasing the CFString.

Discussion
This function attempts to copy the text that is displayed when drawing the view and is generally successful on views that handle the `kControlEditTextCFStringTag` `GetControlData` tag. If this function can't copy that text, it copies the text in the view's title instead.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewCountSubviews

Returns the number of subviews embedded in a view.

```
CFIndex HIViewCountSubviews (
   HIViewRef inView
);
```

Parameters
inView
The view whose subviews are to be counted.

Return Value
The number of subviews for the specified view.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewCreateOffscreenImage

Creates a Core Graphics offscreen image of a view.

```
OSStatus HIViewCreateOffscreenImage (
   HIViewRef inView,
   OptionBits inOptions,
   HIRect *outFrame,
   CGImageRef *outImage
);
```

Parameters
inView
The view you want to create an image of.
inOptions
Options. Currently you must pass zero.

outFrame

The frame of the view within the resultant image. It is in the coordinate system of the image, where 0,0 is the top left corner of the image. This is so you can know exactly where the control is in the image when the control draws outside its bounds for things such as shadows.

outImage

The image of the view, including anything that would be drawn outside the view's frame.

Return Value
An operating system status code.

Discussion
This function creates an `CGImageRef` for the specified view. The view and any of its children are rendered in the resultant image.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewDisposeTrackingArea

Disposes of an existing tracking area.

```
OSStatus HIViewDisposeTrackingArea (
   HIViewTrackingAreaRef inArea
);
```

Parameters

inArea

The tracking area that is to be disposed of.

Return Value
An operating system result code.

Discussion
All tracking areas attached to a view are automatically disposed of when the view is disposed of, so you don't need to dispose of a tracking area explicitly unless you want to remove it from a view before the view is disposed of.

After you call this function, the reference is invalid.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewDrawCGImage

Draws a Core Graphics image appropriately for a view.

```
OSStatus HIViewDrawCGImage (
   CGContextRef inContext,
   const HIRect *inBounds,
   CGImageRef inImage
);
```

Parameters

inContext

The context to draw in.

inBounds

The bounds to draw the image into.

inImage

The image to draw.

Return Value
An operating system status code.

Discussion
This function is similar to `CGContextDrawImage`, but it flips the context so that the image is drawn correctly. The origin of a view is at the top left corner, so you are really drawing upside-down. This call insulates you from that fact.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewFindByID

Obtains a view by its ID.

```
OSStatus HIViewFindByID (
   HIViewRef inStartView,
   HIViewID inID,
   HIViewRef *outView
);
```

Parameters

inStartView

The view to start searching at.

inID

The ID of the view you are looking for.

outControl

Receives the control if found.

Return Value
An operating system result code.

Discussion
Allows you to find a particular view by its ID. The `HIViewID` type used by this function is identical to the `ControlID` type used by the Control Manager.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Related Sample Code
CarbonCocoa_PictureCursor
HID Calibrator
HID Config Save
QTCarbonShell
QTMetaData

Declared In
`HIView.h`

HIViewFlashDirtyArea

Flashes a window's dirty area.

```
OSStatus HIViewFlashDirtyArea (
   WindowRef inWindow
);
```

Parameters
inWindow
The window whose dirty area is to be flashed.

Return Value
An operating system result code.

Discussion
As a debugging aid, this function flashes the area for an entire window that will be redrawn at the next draw time.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`HIToolboxDebugging.h`

HIViewGetAttributes

Obtains the attributes for a view.

```
OSStatus HIViewGetAttributes (
   HIViewRef inView,
   OptionBits *outAttrs
);
```

Parameters
inView
The view to inspect.

outAttrs
The attributes of the view. For possible values, see "HIView Attributes" (page 2508).

Return Value
An operating system result code.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
HIView.h

HIViewGetBounds

Obtains the local bounds of a view.

```
OSStatus HIViewGetBounds (
   HIViewRef inView,
   HIRect *outRect
);
```

Parameters
inView
The view whose local bounds are to be obtained.

outRect
The local bounds of the view.

Return Value
An operating system result code.

Discussion
The local bounds are the coordinate system that is completely view-relative. A view's top left coordinate starts out at 0, 0. Most operations use local coordinates. Note, however, that the frame is used to move a view, not local coordinates.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Related Sample Code
HID Calibrator
HID Config Save

Declared In
HIView.h

HIViewGetCommandID

Obtains the command ID of a view.

```
OSStatus HIViewGetCommandID (
   HIViewRef inView,
   UInt32 *outCommandID
);
```

Parameters

inView

The view whose command ID is to be obtained.

outID

A pointer to a value of type `UInt32` that, on return, contains the view's command ID.

Return Value
An operating system result code.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewGetEventTarget

Returns the `EventTargetRef` for the specified view.

```
EventTargetRef HIViewGetEventTarget (
   HIViewRef inView
);
```

Parameters

inImage

The view for which the `EventTargetRef` should be returned.

Return Value
The `EventTargetRef`.

Discussion
Once you obtain this reference, you can install an event handler and send events to the target.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewGetFeatures

Obtains the features of the specified view.

```
OSStatus HIViewGetFeatures (
   HIViewRef inView,
   HIViewFeatures *outFeatures
);
```

Parameters

inView

The view to query.

outFeatures

A pointer to a value of the `HIViewFeatures` that, on return, contains the view's features. For more information, see "HIView Feature Constants" (page 2509).

Return Value
An operating system result code.

Discussion
This function returns feature bits for the view but does not return older Control Manager features, such as `kControlSupportsDataAccess`.

Availability
Available in Mac OS X v10.3 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewGetFirstSubview

Returns the first subview of a parent view.

```
HIViewRef HIViewGetFirstSubview (
   HIViewRef inView
);
```

Parameters

inView

The view whose subview you are fetching.

Return Value
An HIView reference, or `NULL` if this view has no subviews or is invalid.

Discussion
Returns the first subview of a container. The first subview is the topmost subview in z-order.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewGetFocusPart

Obtains the part in the specified view that currently has focus.

```
OSStatus HIViewGetFocusPart (
   HIViewRef inView,
   HIViewPartCode *outFocusPart
);
```

Parameters

inView

The view to inquire about.

outFocusPart

The part that currently has focus. For more information, see "HIViewPartCode Constants" (page 2513).

Return Value
An operating system result code.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
HIView.h

HIViewGetFrame

Obtains the frame bounds of a view.

```
OSStatus HIViewGetFrame (
   HIViewRef inView,
   HIRect *outRect
);
```

Parameters

inView

The view whose frame you want to obtain.

outRect

The frame of the view.

Return Value
An operating system result code.

Discussion
The frame bounds is the bounds of a view relative to its parent's local coordinate system.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Related Sample Code
HID Calibrator

Declared In
HIView.h

HIViewGetID

Obtains the HIViewID of a view.

```
OSStatus HIViewGetID (
   HIViewRef inView,
   HIViewID *outID
);
```

Parameters

inView

The view whose validity is to be checked.

outID

A pointer to a value of type `HIViewID` that, on return, contains the view's `HIViewID`.

Return Value

An operating system result code.

Availability

Available in Mac OS X v10.4 and later.

Not available to 64-bit applications.

Declared In

`HIView.h`

HIViewGetIndexedSubview

Obtains the subview of a view by index.

```
OSStatus HIViewGetIndexedSubview (
   HIViewRef inView,
   CFIndex inSubviewIndex,
   HIViewRef *outSubview
);
```

Parameters

inView

The view whose indexed subview is being requested.

inSubviewIndex

The index of the requested subview.

outSubview

A pointer to an `HIViewRef` that, on return, represents the indexed subview.

Return Value

The number of subviews for the specified view.

Discussion

Instead of calling `HIViewGetIndexedSubview` repeatedly, it may be more efficient to iterate through the subviews of a view with calls to `HIViewGetFirstSubview` (page 2455) and `HIViewGetNextView` (page 2460).

Availability

Available in Mac OS X v10.4 and later.

Not available to 64-bit applications.

Declared In
HIView.h

HIViewGetKind

Obtains the signature and kind of a view.

```
OSStatus HIViewGetKind (
   HIViewRef inView,
   HIViewKind *outViewKind
);
```

Parameters

inView

The view whose signature and kind is to be obtained.

outViewKind

A pointer to a HIViewKind structure that, on return, contains the view's signature and kind. For details, see HIViewKind (page 2497).

Return Value
An operating system result code.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
HIView.h

HIViewGetLastSubview

Returns the last subview in a parent view.

```
HIViewRef HIViewGetLastSubview (
   HIViewRef inView
);
```

Parameters

inView

The view whose subview you are fetching.

Return Value
An HIView reference, or NULL if this view has no subviews or is invalid.

Discussion
Returns the last subview of a container. The last subview is the bottommost subview in z-order.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
HIView.h

HIViewGetLayoutInfo

Obtains the layout information of an view.

```
OSStatus HIViewGetLayoutInfo (
   HIViewRef inView,
   HILayoutInfo *outLayoutInfo
);
```

Parameters

inOptions

The view whose layout information is to be obtained.

outLayoutInfo

A pointer to an `HILayoutInfo` (page 2493) into which to copy the view's layout information. If the version field of this structure is not valid, the call will fail.

Return Value

An operating system result code.

Availability

Available in Mac OS X v10.3 and later.

Not available to 64-bit applications.

Related Sample Code

HID Calibrator

Declared In

`HIView.h`

HIViewGetMaximum

Obtains a view's maximum value.

```
SInt32 HIViewGetMaximum (
   HIViewRef inView
);
```

Parameters

inView

The view whose maximum value is to be obtained.

Return Value

The maximum value of the specified view.

Availability

Available in Mac OS X v10.4 and later.

Not available to 64-bit applications.

Declared In

`HIView.h`

HIViewGetMinimum

Obtains the minimum value of a view.

```
SInt32 HIViewGetMinimum (
   HIViewRef inView
);
```

Parameters

inView

The view whose minimum value is to be obtained.

Return Value
The minimum value of the specified view.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewGetNeedsDisplay

Determines whether a view needs to be redrawn.

```
Boolean HIViewGetNeedsDisplay (
   HIViewRef inView
);
```

Parameters

inView

The view to inspect.

Return Value
A Boolean whose value is `true` if the view passed in or any of its subviews require redrawing; otherwise, `false`.

Discussion
A view or subview requires redrawing if any part of the view or subview has been invalidated.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewGetNextView

Returns the view behind the specified view.

```
HIViewRef HIViewGetNextView (
   HIViewRef inView
);
```

Parameters

inView

The view to use as reference.

Return Value
An HIView reference, or `NULL` if this view has no view behind it or is invalid.

Discussion
Returns the view after the specified view, in z-order.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewGetOptimalBounds

Obtains the optimal size and text placement of a view.

```
OSStatus HIViewGetOptimalBounds (
   HIViewRef inView,
   HIRect *outBounds,
   CGFloat *outBaseLineOffset
);
```

Parameters

inView

The view whose optimal size and text placement are to be obtained.

outBounds

A pointer to a value of type `HIRect` that, on return, contains the view's optimal bounds. Pass `NULL` if you don't need this information.

outBaseLineOffset

A pointer to a value of type `float` that, on return, contains the view's optimal text placement. Pass `NULL` if you don't need this information.

Return Value
An operating system result code.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewGetPartHit

Determines the part hit for a given point.

```
OSStatus HIViewGetPartHit (
   HIViewRef inView,
   const HIPoint *inPoint,
   HIViewPartCode *outPart
);
```

Parameters

inView

The view to test the part hit.

inPoint

The view-relative point to use.

outPart

The part hit by `inPoint`.

Return Value
An operating system result code.

Discussion
Given a view, and a view-relative point, this function returns the part code hit as determined by the view.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewGetPreviousView

Returns the view above the specified view.

```
HIViewRef HIViewGetPreviousView (
   HIViewRef inView
);
```

Parameters

inView

The view to use as reference.

Return Value
An HIView reference, or `NULL` if this view has no view in front of it or is invalid.

Discussion
Returns the view before the specified view, in z-order.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewGetRoot

Obtains the root view for a window.

```
HIViewRef HIViewGetRoot (
   WindowRef inWindow
);
```

Parameters

inWindow
The window to get the root for.

Return Value
The root view for the window, or `NULL` if an invalid window is passed.

Discussion
Note that the root view is not the same as the Control Manager root control.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Related Sample Code
CarbonCocoa_PictureCursor
HID Calibrator
HID Config Save
QTCarbonShell
QTMetaData

Declared In
`HIView.h`

HIViewGetSizeConstraints

Returns the minimum and maximum size for a control.

```
OSStatus HIViewGetSizeConstraints (
   HIViewRef inView,
   HISize *outMinSize,
   HISize *outMaxSize
);
```

Parameters

inView
The view to inspect.

outMinSize
The minimum size the view can be.

outMaxSize
The maximum size the view can be.

Return Value
An operating system result code.

Discussion
These sizes can, for example, be used to help auto-position subviews. To get meaningful results, the control must respond to the `kEventControlGetSizeContraints` event.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewGetSubviewHit

Returns the child of the given view hit by the point passed in.

```
OSStatus HIViewGetSubviewHit (
   HIViewRef inView,
   const HIPoint *inPoint,
   Boolean inDeep,
   HIViewRef *outView
);
```

Parameters

inView
The view you wish to position.

inPoint
The mouse coordinate to use. This is passed in the local coordinate system of inView.

inDeep
Pass true to find the deepest child hit, false to go only one level deep (just check direct children of inView).

outView
The view hit by inPoint, or NULL if no subview was hit.

Return Value
An operating system result code.

Discussion
This function is more primitive than using `HIViewGetViewForMouseEvent` (page 2466), and should be used only in non-event-handling cases.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewGetSuperview

Returns a view's parent view.

```
HIViewRef HIViewGetSuperview (
   HIViewRef inView
);
```

Parameters

inView

The view whose parent you are interested in getting.

Return Value
An HIView reference, or `NULL` if this view has no parent or is invalid.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewGetTrackingAreaID

Obtains the ID of a tracking area.

```
OSStatus HIViewGetTrackingAreaID (
   HIViewTrackingAreaRef inArea,
   HIViewTrackingAreaID *outID
);
```

Parameters

inArea

The tracking area whose ID is to be obtained.

outID

On return, the ID for the tracking area specified by `inArea`.

Return Value
An operating system result code.

Discussion
The tracking area ID that is obtained is the value that was specified when `HIViewNewTrackingArea` (page 2473) was called to create the tracking area.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewGetValue

Obtains the value of a view.

```
SInt32 HIViewGetValue (
   HIViewRef inView
);
```

Parameters

inView

The view whose value is to be obtained.

Return Value
The view's value.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
HIView.h

HIViewGetViewForMouseEvent

Returns the appropriate view to handle a mouse event.

```
OSStatus HIViewGetViewForMouseEvent (
   HIViewRef inView,
   EventRef inEvent,
   HIViewRef *outView
);
```

Parameters

inView

The view to start from. You should pass the window's root view.

inEvent

The mouse event in question.

outView

The view that the mouse event should be sent to.

Return Value
An operating system result code.

Discussion
This function is a little higher-level than `HIViewGetSubviewHit` (page 2464). This function finds the deepest view that should handle the mouse event. It also sends a Carbon event to each view asking it to return the appropriate subview, which allows parent views to catch clicks on their subviews. This function is the recommended function to use before processing mouse events. Using one of the more primitive functions may result in an undefined behavior.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
HIView.h

HIViewGetViewSize

Obtains the view size of a view.

```
SInt32 HIViewGetViewSize (
   HIViewRef inView
);
```

Parameters

inView
The view whose view size is to be obtained.

Return Value

The view size.

Discussion

The view size is the size of the content to which a view's display is proportioned. The view size is commonly used to set the proportional size of a scroll bar's thumb indicator.

Availability

Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In

`HIView.h`

HIViewGetWindow

Obtains a reference to the window to which the specified view is bound.

```
WindowRef HIViewGetWindow (
   HIViewRef inView
);
```

Parameters

inView
The view to query.

Return Value

An operating system result code, or `NULL` if the view reference specified by `inView` is invalid or if the view is not bound to any window.

Availability

Available in Mac OS X v10.3 and later.
Not available to 64-bit applications.

Declared In

`HIView.h`

HIViewIsActive

Determines whether a view is active.

```
Boolean HIViewIsActive (
   HIViewRef inView,
   Boolean *outIsLatentActive
);
```

Parameters

inView

The view that is to be queried.

outIsLatentActive

A pointer to a Boolean that, on return, is set to `true` if the view is latently active or `false` if the view is not latently active. Pass `NULL` if you don't need this information.

Return Value
A Boolean whose value indicates whether the view is active (`true`) or not (`false`).

Discussion
A view's active state is affected by the active state of its parents. If `HIViewIsActive` finds that any parent view is inactive, it returns `false` to indicate that the view specified by `inView` is considered to be inactive too. In addition, `HIViewIsActive` can optionally check to see if a view is latently active, even if the view's parents are inactive.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewIsCompositingEnabled

Determines whether compositing is enabled for a view.

```
Boolean HIViewIsCompositingEnabled (
   HIViewRef inView
);
```

Parameters

inView

The view that is to be queried.

Return Value
A Boolean whose value indicates whether compositing is enabled (`true`) or not (`false`).

Discussion
Checking a window's `kWindowCompositingAttribute` attribute is not sufficient for determining whether a view is in compositing or non-compositing mode because some of a window's views can be in either mode at the same time. Call this function to determine the current compositing mode of a view.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewIsDrawingEnabled

Determines if drawing is currently enabled for a view.

```
Boolean HIViewIsDrawingEnabled (
   HIViewRef inView
);
```

Parameters

inView

The view to get the drawing state for.

Return Value

A Boolean value indicating that drawing is on (`true`) or off (`false`).

Availability

Available in Mac OS X v10.2 and later.

Not available to 64-bit applications.

Declared In

`HIView.h`

HIViewIsEnabled

Determines whether a view is enabled.

```
Boolean HIViewIsEnabled (
   HIViewRef inView,
   Boolean *outIsLatentEnabled
);
```

Parameters

inView

The view to query.

outIsLatentEnabled

A pointer to a Boolean that, on return, is set to `true` if the view is latently enabled or `false` if the view is not latently enabled. Pass `NULL` if you don't need this information.

Return Value

A Boolean whose value indicates whether the view is enabled (`true`) or not (`false`).

Discussion

A view's enabled state is affected by the enabled state of its parents. If `HIViewIsEnabled` finds that any parent view is disabled, it returns `false` to indicate that the view specified by `inView` is considered to be disabled too. In addition, `HIViewIsEnabled` can optionally check to see if a view is latently enabled, even if its parents are disabled.

Availability

Available in Mac OS X v10.4 and later.

Not available to 64-bit applications.

Declared In

`HIView.h`

HIViewIsLatentlyVisible

Determines whether a view is latently visible.

```
Boolean HIViewIsLatentlyVisible (
   HIViewRef inView
);
```

Parameters

inView

The view whose latent visibility is to be queried.

Return Value

A Boolean value indicating whether the view is latently visible (`true`) or hidden (`false`).

Discussion

A view's visibility is affected by the visibility of its parents. If any parent view is invisible, the view specified by `inView` is considered to be invisible too. `HIViewIsLatentlyVisible` returns whether a view is latently visible, even if its parents are invisible.

Availability

Available in Mac OS X v10.4 and later.

Not available to 64-bit applications.

Declared In

`HIView.h`

HIViewIsLayoutActive

Determines whether layout handling is active or suspended.

```
Boolean HIViewIsLayoutActive (
   HIViewRef inView
);
```

Parameters

inView

The view for which the status of layout handling is to be determined.

Return Value

A Boolean whose value is `true` if the view would respond to any linked relative's changes; otherwise `false`.

Discussion

A view's layout active state is also affected by the layout active state of its parents. If a parent view has an inactive layout, this view is also considered to have an inactive layout. To determine the latent active state of a view, see `HIViewIsLayoutLatentlyActive` (page 2471).

Note that this function does not determine whether the view's layout is valid.

Availability

Available in Mac OS X v10.3 and later.

Not available to 64-bit applications.

Declared In

`HIView.h`

HIViewIsLayoutLatentlyActive

Determines whether layout handling is latently active or suspended.

```
Boolean HIViewIsLayoutLatentlyActive (
   HIViewRef inView
);
```

Parameters

inView
The view for which the status of layout handling is to be determined.

Return Value

A Boolean whose value is `true` if the view would latently respond to any linked relative's changes; otherwise `false`.

Discussion

This function determines whether a view's layout is latently active, even if one of its parent's layouts is not active.

Availability

Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In

`HIView.h`

HIViewIsValid

Determines whether the specified view is known to the HIToolbox.

```
Boolean HIViewIsValid (
   HIViewRef inView
);
```

Parameters

inView
The view to check.

Return Value

A Boolean whose value is `true` if the view is known to the HIToolbox; otherwise, `false`.

Discussion

This function does *not* check the data in the view for validity.

Availability

Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In

`HIView.h`

HIViewIsVisible

Determines whether a view is visible.

```
Boolean HIViewIsVisible (
   HIViewRef inView
);
```

Parameters

inView

The view whose visibility you want to determine.

Return Value
A Boolean value indicating whether the view is visible (`true`) or hidden (`false`).

Discussion
`HIViewIsVisible` returns the effective visibility of a view, which is determined both by the view's own visibility and the visibility of its parent views. If a parent view is invisible, this view is considered to be invisible too.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewMoveBy

Move a view by the specified distance relative to its current location.

```
OSStatus HIViewMoveBy (
   HIViewRef inView,
   CGFloat inDX,
   CGFloat inDY
);
```

Parameters

inView

The view you want to move.

inDX

The horizontal distance to move the view. Negative values move the view to the left, positive values to the right.

inDY

The vertical distance to move the view. Negative values move the view up, positive values down.

Return Value
An operating system result code.

Discussion
This function affects the view's frame but does not affect the view's bounds.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewNewTrackingArea

Creates a new tracking area for a view.

```
OSStatus HIViewNewTrackingArea (
   HIViewRef inView,
   HIShapeRef inShape,
   HIViewTrackingAreaID inID,
   HIViewTrackingAreaRef *outRef
);
```

Parameters

inView

The view for which a new tracking area is to be created.

inShape

The shape to use. Pass `NULL` to use the entire structure region of the view. On return, you may safely release the shape.

inID

An identifier for the new tracking area. You can specify any value you want, or zero if you don't want to associate an identifier with the new tracking area.

outRef

On return, a reference to the new tracking area. In Mac OS X v10.5 and later, you may pass `NULL` if you don't need this information. The new tracking area is automatically destroyed when the view is released; you do not need to dispose of the tracking area yourself unless you remove it from the view before the view is released.

Return Value

An operating system result code.

Availability

Available in Mac OS X v10.4 and later.

Not available to 64-bit applications.

Related Sample Code

CarbonCocoa_PictureCursor

Declared In

`HIView.h`

HIViewPlaceInSuperviewAt

Places a view at an absolute location within its parent.

```
OSStatus HIViewPlaceInSuperviewAt (
   HIViewRef inView,
   CGFloat inX,
   CGFloat inY
);
```

Parameters

inView

The view you want to position.

inX

The absolute horizontal coordinate at which to position the view.

inY

The absolute vertical coordinate at which to position the view.

Return Value
An operating system result code.

Discussion
This function affects the view's frame but does not affect the view's bounds.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewRegionChanged

Informs the system that a region of the view has changed.

```
OSStatus HIViewRegionChanged (
   HIViewRef inView,
   HIViewPartCode inRegionCode
);
```

Parameters

inView

The view whose region changed.

inView

The region that changed. At present, the region can only be the structure, opaque, and clickable regions. For possible constants, see "HIView Meta-Parts Constants" (page 2511).

Return Value
An operating system result code.

Discussion
The view system may respond to the information provided by this function in some way. For example, if a view's clickable region changes, call this function to tell the Toolbox to resynchronize the region it uses for asynchronous window dragging (if enabled). Likewise, if a view's opaque region changes, call this function to adjust the window's opaque shape.

You don't need to call this function when a view is moved or resized because the HIToolbox automatically handles those kinds of changes.

Availability
Available in Mac OS X v10.3 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewRemoveFromSuperview

Removes a view from its parent.

```
OSStatus HIViewRemoveFromSuperview (
   HIViewRef inView
);
```

Parameters

inView

The view to remove.

Return Value
An operating system result code.

Discussion
The subview that is removed from the parent is not released and still exists.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Related Sample Code
QTCarbonShell

Declared In
`HIView.h`

HIViewRender

Renders the invalid portions of a view.

```
OSStatus HIViewRender (
   HIViewRef inView
);
```

Parameters

inView

The view that is to be rendered.

Return Value
An operating system result code.

Discussion
Normally, areas are redrawn at event loop time, but there might be times when an immediate redraw is needed. You should call this function sparingly because it does a fully composited redraw for the area of the view. That is, all other views that intersect the area of the specified view are also redrawn. Calling this function for several views at a particular level of a hierarchy would be costly, so you should only pass the root view of a window to this function.

The behavior of this function when passed a non-root view changed in Mac OS X v10.4. In Mac OS X v10.3, when called on a non-root view, this function validated all of the views in the window that intersect the specified view, including portions that did not intersect the specified view. Consequently, all of the views were not actually redrawn. In Mac OS X v10.4, when called on a non-root view, this function only validates those portions of each view that intersect the specified view.

Availability
Available in Mac OS X v10.3 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewReshapeStructure

Informs the system that the structure region of the given view has changed shape.

```
OSStatus HIViewReshapeStructure (
   HIViewRef inView
);
```

Parameters

inView
The view to reshape and invalidate.

Return Value
An operating system result code.

Discussion
This function is used by custom views. If a view decides that its structure will change shape, it should call this function. This tells the toolbox to recalculate and invalidate as appropriate. You might, for example, call this function when gaining or losing a focus ring.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewResumeLayout

Resumes layout handling for a view and its children.

```
OSStatus HIViewResumeLayout (
   HIViewRef inView
);
```

Parameters

inView
The view for which layout handling is to be resumed.

Return Value
An operating system result code.

Availability
Available in Mac OS X v10.3 and later.
Not available to 64-bit applications.

Declared In
HIView.h

HIViewScrollRect

Scrolls a view's contents, or a portion thereof.

```
OSStatus HIViewScrollRect (
   HIViewRef inView,
   const HIRect *inRect,
   CGFloat inDX,
   CGFloat inDY
);
```

Parameters

inView
The view to scroll.

inRect
The rect to scroll. Pass NULL to mean the entire view. The rect passed cannot be bigger than the view's bounds. It must be in the local coordinate system of the view.

inDX
The horizontal distance to scroll. Positive values shift to the right, negative values shift to the left.

inDY
The vertical distance to scroll. Positive values shift downward, negative values shift upward.

Return Value
An operating system result code.

Discussion
This function blits the contents of the view as appropriate to scroll and then invalidates those portions that need to be redrawn. Be warned that this is a raw bit scroll. Anything that overlaps the target view will be scrolled as well.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
HIView.h

HIViewSetActivated

Sets a view to be active or inactive.

```
OSStatus HIViewSetActivated (
   HIViewRef inView,
   Boolean inSetActivated
);
```

Parameters

inView
The view that is to be set.

inSetActivated
A Boolean whose value is `true` to set the view to be active or `false` to set the view to be inactive.

Return Value
An operating system result code.

Discussion
This function affects the effective activation of a view, which affects the effective activation of the view's children. If the view is being set to inactive, all children become inactive as well, but their latent activation does not change. If the children are latently inactive and the view is made active, the children remain latently inactive.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewSetBoundsOrigin

Sets the origin of the view.

```
OSStatus HIViewSetBoundsOrigin (
   HIViewRef inView,
   CGFloat inX,
   CGFloat inY
);
```

Parameters
inView
The view whose origin you wish to adjust.
inX
The X coordinate.
inY
The Y coordinate.

Return Value
An operating system result code.

Discussion
This effectively also moves all subcontrols of a view as well. This call will not invalidate the view, in case you might want to move the contents with `HIViewScrollRect` instead of redrawing the complete content.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Related Sample Code
HID Calibrator

Declared In
`HIView.h`

HIViewSetCommandID

Sets the command ID of a view.

```
OSStatus HIViewSetCommandID (
   HIViewRef inView,
   UInt32 inCommandID
);
```

Parameters

inView

The view whose command ID is to be set.

inID

The command ID to set.

Return Value

An operating system result code.

Availability

Available in Mac OS X v10.4 and later.

Not available to 64-bit applications.

Declared In

`HIView.h`

HIViewSetDrawingEnabled

Turns control drawing on or off.

```
OSStatus HIViewSetDrawingEnabled (
   HIViewRef inView,
   Boolean inEnabled
);
```

Parameters

inView

The view to enable or disable drawing for.

inEnabled

A Boolean value indicating whether drawing should be on (`true`) or off (`false`).

Return Value

An operating system result code.

Discussion

You can use this function to ensure that no drawing events are sent to the specified control. Functions such as `Draw1Control` and `HIViewSetNeedsDisplay` cannot draw when control drawing is off.

Availability

Available in Mac OS X v10.2 and later.

Not available to 64-bit applications.

Declared In

`HIView.h`

HIViewSetEnabled

Enables or disables a view.

```
OSStatus HIViewSetEnabled (
   HIViewRef inView,
   Boolean inSetEnabled
);
```

Parameters

inView

The view that is to be set.

inSetEnabled

A Boolean whose value is `true` to enable the view or `false` to disable the view.

Return Value

An operating system result code.

Discussion

Any subviews of the view specified by `inView` become enabled or disabled in accordance with the value of `inSetEnabled`.

Availability

Available in Mac OS X v10.4 and later.

Not available to 64-bit applications.

Declared In

`HIView.h`

HIViewSetFirstSubViewFocus

Sets the subview that is first to receive keyboard focus.

```
OSStatus HIViewSetFirstSubViewFocus (
   HIViewRef inParent,
   HIViewRef inSubView
);
```

Parameters

inParent

The parent view.

inSubView

The first subview that is to receive keyboard focus. Pass `NULL` to tell the view system to use the default rules.

Return Value

An operating system result code.

Discussion

This function sets the first subview to shift focus to whenever the keyboard focus is advanced and the container view is entered.

Availability

Available in Mac OS X v10.2 and later.

Not available to 64-bit applications.

Declared In
HIView.h

HIViewSetFrame

Sets the frame of a view.

```
OSStatus HIViewSetFrame (
   HIViewRef inView,
   const HIRect *inRect
);
```

Parameters

inView
The view whose frame is to be set.

inRect
The new frame to set.

Return Value
An operating system result code.

Discussion
This function effectively moves the view within its parent. It also marks the view (and anything that was exposed behind it) to be redrawn.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Related Sample Code
HID Calibrator

Declared In
HIView.h

HIViewSetHilite

Sets highlighting on a view.

```
OSStatus HIViewSetHilite (
   HIViewRef inView,
   HIViewPartCode inHilitePart
);
```

Parameters

inView
The view for which highlighting is to be set.

inHilitePart
The part of the view whose highlighting is to be set. For possible values, see "HIViewPartCode Constants" (page 2513).

Return Value
An operating system result code.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewSetID

Sets the `HIViewID` of a view.

```
OSStatus HIViewSetID (
   HIViewRef inView,
   HIViewID inID
);
```

Parameters

inView
The view whose `HIViewID` is to be set.

inID
The `HIViewID` to set.

Return Value
An operating system result code.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewSetLayoutInfo

Sets the layout information of an HIView.

```
OSStatus HIViewSetLayoutInfo (
   HIViewRef inView,
   const HILayoutInfo *inLayoutInfo
);
```

Parameters

inView
The view whose layout information is to be set.

inLayoutInfo
A pointer to an `HILayoutInfo` (page 2493) structure containing the layout values that are to be set.

Return Value
An operating system result code.

Discussion
Layouts are used to automatically change the size and positioning of a view when another view changes size or position. Layout changes only take effect in two cases:

- When `HIViewApplyLayout` (page 2443) is called after the view's layout has been set by calling `HIViewSetLayoutInfo`. The `HIViewApplyLayout` function is most useful when first applying a scaling or positioning layout to a view in order to set up the view's initial position and size relative to the view referenced in the layout.
- When the related view changes its size or position.

A layout allows a view's size or position to be modified in three ways: side binding, axial scaling, and axial positioning. In the following examples, View A initially has a left side of 100 and a right side of 150, and is placed inside a parent view that has a width of 275.

- Bindings — Setting up a binding relationship between two views specifies that one edge of a view is to change by an amount equal to the change in an edge of another view. If View A has a right-side binding to its parent's maximum (or right) side, when the parent's right side changes, View A's right side changes by the same amount. If the parent view resizes to be 325 units wide (50 units wider than before), View A is resized so that its left side changes to 150 units and its right side changes to 200, which is 50 units more to the right than before. You can think of bindings as a way to maintain distance. An edge bound to another view's edge always maintains its offset from that related edge. In other view systems, this concept is often referred to as "springs and rods." Note that a binding does *not* cause one side of the view to exactly align with the side of another view; a binding merely causes one side of the view to change by the same amount as another view changes. To align one edge of a view to another view's edge, use positioning. Bindings depend on changes in size or position of the related view. As a result, calling `HIViewApplyLayout` does not activate side bindings, as no changes have occurred. Bindings are implemented using the `HIBinding` (page 2493) structure and one `HISideBinding` (page 2494) structure per view edge.
- Scaling — Setting up a scaling relationship between two views specifies that the axial size (that is, the width or height) of a view is to be a specified ratio of the size of another view when that other view moves or resizes. If View A has an x-axis scaling for its parent view with a ratio of 0.8, when the parent view's width changes, View A's width changes to be the parent's width multiplied by 0.8. If the parent view resizes to be 325 units wide, View A resizes so that its left side stays at 100 and its right side changes to 360 (100 + 325 * 0.8). Note that when a scaling layout is first set up on a view with `HIViewSetLayoutInfo`, no scaling is applied to the view because scaling only occurs when the related view resizes. If scaling is required at initial setup, call `HIViewSetLayoutInfo` and then `HIViewApplyLayout` (page 2443). Scaling is implemented using the `HIScaling` (page 2494) structure and one `HIAxisScale` (page 2494) structure per view axis.
- Positioning — Setting up a positioning relationship between two views specifies that the axial position (i.e., vertical or horizontal) of a view is to change so that the view aligns with the minimum, maximum, or center of another view when that other view resizes. If View A has an x-axis position with its parent view with center positioning specified, when the parent view changes size, View A moves so that it is centered horizontally relative to its parent. If the parent view resizes to be 300 units wide, View A repositions so that its left side is at 125 and its right side is at 175, centered in the parent view. Positioning is implemented using the `HIPositioning` (page 2495) structure and one `HIAxisPosition` (page 2495) per view axis.

The HIView layout engine applies transformations to a view sequentially. First, bindings are applied. Then scaling is applied, which could override some of the previously applied bindings. Then positioning is applied, which could also override some of the previously applied bindings. The bindings are applied recursively to a container's subviews, which requires care on your part to avoid infinite recursion, especially when applying inter-relational bindings. For example, if View A's x axis is scaled relative to View B and View B's x-axis is scaled to View A, your application could hang when the layouts are applied because View A would affect View B, which would affect View A, and so on.

For more information on using the layout engine, see *HIView Programming Guide*.

Availability
Available in Mac OS X v10.3 and later.
Not available to 64-bit applications.

Related Sample Code
HID Calibrator

Declared In
`HIView.h`

HIViewSetMaximum

Sets a view's maximum value.

```
OSStatus HIViewSetMaximum (
   HIViewRef inView,
   SInt32 inMaximum
);
```

Parameters

inView
The view whose maximum value is to be set.

inView
The maximum value to set.

Return Value
An operating system result code.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewSetMinimum

Sets a view's minimum value.

```
OSStatus HIViewSetMinimum (
   HIViewRef inView,
   SInt32 inMinimum
);
```

Parameters

inView
The view whose minimum value is to be set.

inMinimum
The value to set as the view's minimum value.

Return Value
An operating system result code.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewSetNeedsDisplay

Marks a view as needing or not needing to be redrawn.

```
OSStatus HIViewSetNeedsDisplay (
   HIViewRef inView,
   Boolean inNeedsDisplay
);
```

Parameters

inView
The view to mark as dirty (needing to be redrawn) or clean (not needing to be redrawn).

inNeedsDisplay
A Boolean whose value is `true` to mark the view as dirty or `false` to mark it as clean.

Return Value
An operating system result code.

Discussion
If the view is not visible or is obscured completely by other views, no action is taken.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Related Sample Code
HID Calibrator

HID Explorer

Declared In
`HIView.h`

HIViewSetNeedsDisplayInRect

Uses an `HIRect` to mark a portion of a view as needing or not needing to be redrawn.

```
OSStatus HIViewSetNeedsDisplayInRect (
   HIViewRef inView,
   const HIRect *inRect,
   Boolean inNeedsDisplay
);
```

Parameters

inView

The view having a region that is to be marked as dirty (needs to be redrawn) or clean (valid and not needing to be redrawn).

inRect

The area, in view-relative coordinates, that is to be marked.

inNeedsDisplay

A Boolean whose value is `true` to mark the area described by `inRect` as dirty or `false` to mark it as clean.

Return Value
An operating system result code.

Discussion
If the view is not visible or is obscured completely by other views, no action is taken. The area specified by `inRect` is intersected with the view's visible region.

Availability
Available in Mac OS X v10.4 and later.

Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewSetNeedsDisplayInRegion

Uses a region to mark a portion of a view as needing or not needing to be redrawn.

```
OSStatus HIViewSetNeedsDisplayInRegion (
   HIViewRef inView,
   RgnHandle inRgn,
   Boolean inNeedsDisplay
);
```

Parameters

inView

The view having a region that is to be marked as dirty (needs to be redrawn) or clean (valid and not needing to be redrawn).

inRgn

The region, in view-relative coordinates, to mark as dirty or clean.

inNeedsDisplay

A Boolean whose value is `true` to mark the region described by `inRgn` as dirty or `false` to mark it as clean.

Return Value
An operating system result code.

Discussion
If the view is not visible or is obscured completely by other views, no action is taken. The specified region is effectively intersected with the view's visible region.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewSetNeedsDisplayInShape

Uses a shape to mark a portion of a view as needing or not needing to be redrawn.

```
OSStatus HIViewSetNeedsDisplayInShape (
   HIViewRef inView,
   HIShapeRef inArea,
   Boolean inNeedsDisplay
);
```

Parameters

`inView`
The view having a shape that is to be marked as dirty (needs to be redrawn) or clean (valid and not needing to be redrawn).

`inArea`
The area, in view-relative coordinates, that is to be marked.

`inNeedsDisplay`
A Boolean whose value is `true` to mark the area described by `inArea` as dirty or `false` to mark it as clean.

Return Value
An operating system result code.

Discussion
If the view is not visible or is obscured completely by other views, no action is taken. The area specified by `inArea` is intersected with the view's visible region.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewSetNextFocus

Sets the view that is to receive keyboard focus when keyboard focus advances from the specified view.

```
OSStatus HIViewSetNextFocus (
   HIViewRef inView,
   HIViewRef inNextFocus
);
```

Parameters

inView

The view.

inNextFocus

The view that is to receive keyboard focus when focus is advanced from the view specified by `inView`. The view must have the same parent as the view specified by `inView`. Pass `NULL` to tell the view system to use the default rules.

Return Value
An operating system result code.

Discussion
This function sets the view to which keyboard focus is to be shifted the next time keyboard focus is advanced from the view specified by `inView`.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewSetText

Sets the text of a view to the specified string.

```
OSStatus HIViewSetText (
   HIViewRef inView,
   CFStringRef inText
);
```

Parameters

inView

The view whose text is to be set.

inText

The text that is to be set.

Return Value
An operating system result code.

Discussion
This function attempts to set the text that is displayed when drawing the view and is generally successful on views that handle the `kControlEditTextCFStringTag` `SetControlData` tag. If this function can't set that text, it sets the text in the view's title instead.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Related Sample Code
HID Explorer

Declared In
`HIView.h`

HIViewSetValue

Sets the value of a view.

```
OSStatus HIViewSetValue (
   HIViewRef inView,
   SInt32 inValue
);
```

Parameters

inView
The view whose value is to be set.

inValue
The value to set.

Return Value
An operating system result code.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewSetViewSize

Sets the view size of a view.

```
OSStatus HIViewSetViewSize (
   HIViewRef inView,
   SInt32 inViewSize
);
```

Parameters

inView
The view whose view size is to be set.

inViewSize
The view size that is to be set.

Return Value
An operating system result code.

Discussion
The view size is the size of the content to which a view's display is proportioned. The view size is commonly used to set the proportional size of a scroll bar's thumb indicator.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewSetVisible

Hides or shows a view.

```
OSStatus HIViewSetVisible (
   HIViewRef inView,
   Boolean inVisible
);
```

Parameters

inView
The view to hide or show.

inVisible
A Boolean value that indicates whether you want to hide the view (`false`) or show the view (`true`).

Return Value
An operating system result code.

Discussion
Marks the area the view will occupy or previously occupied as needing to be redrawn later.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Related Sample Code
CarbonCocoa_PictureCursor
HID Calibrator

Declared In
`HIView.h`

HIViewSetZOrder

Changes the front-to-back ordering of sibling views.

```
OSStatus HIViewSetZOrder (
   HIViewRef inView,
   HIViewZOrderOp inOp,
   HIViewRef inOther
);
```

Parameters

inView
The view whose Z-order you want to change.

inOp

Causes `inView` to be ordered above or below `inOther`. For possible values, see "HIView Z-Ordering Constants" (page 2511).

inOther

Another optional view to use as a reference. Pass `NULL` to indicate an absolute position.

Return Value
An operating system result code.

Discussion
For example, passing `kHIViewZOrderAbove` as the value on `inOp` and `NULL` as the value of `inOther` moves a view to the front of all of its siblings. Passing `kHIViewZOrderBelow` as the value of `inOp` and `NULL` as the value of `inOther` moves a view to the back of all its siblings.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewSimulateClick

Simulates a mouse click on a given view.

```
OSStatus HIViewSimulateClick (
   HIViewRef inView,
   HIViewPartCode inPartToClick,
   UInt32 inModifiers,
   HIViewPartCode *outPartClicked
);
```

Parameters

inView

The view to test the part hit.

inPartToClick

The part the view should consider to be clicked.

inModifiers

The modifiers the view can consider for its click action.

outPartClicked

The part that was hit; can be `kHIViewNoPart` if no action occurred. For possible values, see "HIViewPartCode Constants" (page 2513). Pass `NULL` if you don't need the part code returned.

Return Value
An operating system result code.

Discussion
This function is used to simulate a mouse click on a given view. It sends a `kEventControlSimulateHit` event to the specified view and also sends `kEventControlHit` and (if the Hit event is not handled) `kEventCommandProcess` events.

Note that not all windows respond to the events that this API sends. A fully Carbon-event-based window most likely responds exactly as if the user had really clicked in the view. A window that uses Classic event record-based APIs (`WaitNextEvent` or `ModalDialog`) typically does not respond at all. To simulate a click in such a window, you may need to post a mouse-down/mouse-up pair or use a Dialog Manager event filter proc to simulate a hit in a dialog item.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewSubtreeContainsFocus

Determines whether a view or any subviews have keyboard focus.

```
Boolean HIViewSubtreeContainsFocus (
   HIViewRef inSubtreeStart
);
```

Parameters

inSubtreeStart
The view to query.

Return Value
A Boolean whose value is `true` if the view or any of its children have keyboard focus; otherwise, `false`.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

HIViewSuspendLayout

Suspends layout handling for a view and its children.

```
OSStatus HIViewSuspendLayout (
   HIViewRef inView
);
```

Parameters

inView
The view for which layout handling is to be suspended.

Return Value
An operating system result code.

Availability
Available in Mac OS X v10.3 and later.
Not available to 64-bit applications.

Declared In
`HIView.h`

Data Types

HILayoutInfo

Structure that stores the layout of an HIView.

```
struct HILayoutInfo {
    UInt32 version;
    HIBinding binding;
    HIScaling scale;
    HIPositioning position;
};
```

Fields

`version`
The version of this structure. The current version is `kHILayoutInfoVersionZero`.

`binding`
An `HIBinding` structure describing the bindings to apply to the sides of an HIView.

`scale`
An `HIScaling` structure describing the axial scaling to apply to an HIView.

`position`
An `HIPositioning` structure describing the positioning to apply to an HIView.

Discussion
This structure is provided as a parameter to `HIViewGetLayoutInfo` (page 2459) and `HIViewSetLayoutInfo` (page 2482).

HIBinding

Represents a set of top, left, bottom, and right bindings for an view.

```
struct HIBinding {
    HISideBinding top;
    HISideBinding left;
    HISideBinding bottom;
    HISideBinding right;
};
```

Fields

`top`
The top side bindings.

`left`
The left side bindings.

`bottom`
The bottom side bindings.

`right`
The right side bindings.

Discussion
These constants are used in conjunction with the HIView layout engine.

HISideBinding

Structure for storing the binding for the side of a view.

```
struct HISideBinding {
    HIViewRef toView;
    HIBindingKind kind;
    float offset;
};
```

Fields
`toView`
An `HIViewRef` to the view to which this side is bound. This field can be `NULL`, which indicates that the side is bound to its parent view.

`kind`
The bind kind. For possible values, see "HILayout Binding Kind Constants" (page 2505).

`offset`
Reserved; must be set to zero.

Discussion
The layout engine can automatically reposition and resize views for which relationships have been set up. (Call `HIViewSetLayoutInfo` (page 2482) to establish these relationships.) A side binding is entirely related to the change of the parent's position or size but only as the size affects the maximum edge position. A side binding doesn't mean "move to where my relative's side is" but rather "move as my relative's side has moved."

HIScaling

A set of scaling descriptions for the axes of a view.

```
struct HIScaling {
    HIAxisScale x;
    HIAxisScale y;
};
```

Fields
`x`
The horizontal scaling for a view.

`x`
The vertical scaling for a view.

HIAxisScale

Represents a scale description for an axis of a view.

```
struct HIAxisScale {
    HIViewRef toView;
    HIScaleKind kind;
    float ratio;
};
```

Fields

`toView`

An `HIViewRef` to the view to which this axis is scaled. This field can be `NULL`, which indicates that the axis is scaled relative to its parent's view.

`kind`

The type of scaling. Currently, this field must be `kHILayoutScaleAbsolute`.

`ratio`

A value that indicates how much to scale the view. Zero indicates no scaling. A value of one indicates that the view is to always have the same axial size.

HIPositioning

A positioning description for an HIView.

```
struct HIPositioning {
    HIAxisPosition x;
    HIAxisPosition y;
};
```

Fields

`x`

The X axis.

`y`

The Y axis.

HIAxisPosition

An axial position description for an HIView.

```
struct HIAxisPosition {
    HIViewRef toView;
    HIPositionKind kind;
    float offset;
};
```

Fields

`toView`

An `HIViewRef` to the view relative to which a view positioned. This field can be `NULL`, which indicates that the axis is positioned relative to its parent's view.

`kind`

The type of positioning. For possible values, see "HIPositionKind Constants" (page 2506).

`offset`

After the position kind has been applied, the origin component that corresponds to the positioning axis is offset by this value. For example, left aligned + 10.

HIViewContentInfo

Describes the content of a view.

```
struct HIViewContentInfo {
    HIViewContentType contentType;
    union {
        IconSuiteRef iconSuite;
        IconRef iconRef;
        CGImageRef imageRef;
    } u;
};
typedef struct HIViewContentInfo HIViewContentInfo;
typedef HIViewContentInfo * HIViewContentInfoPtr;
```

Fields

`contentType`
The type of content in the union. For possible values, see "HIViewContentType Constants" (page 2512).

Availability

Available in Mac OS X v10.4 and later.

Declared In

`HIView.h`

HIViewID

Defines the HIView ID.

```
typedef ControlID HIViewID;
```

Availability

Available in Mac OS X v10.2 and later.

Declared In

`HIView.h`

HIViewFrameMetrics

Describes the offsets from the structure to the content area of a view.

```
struct HIViewFrameMetrics {
    float top;
    float left;
    float bottom;
    float right;
};
```

Fields

`top`
Height of the top of the structure area.

`left`
Width of the left of the structure area.

`bottom`
Height of the bottom of the structure area.

`right`
Width of the right of the structure area.

Discussion
The top metric is the difference between the vertical coordinate of the top edge of the view's structure region and the vertical coordinate of the top edge of the view's content region. This structure is returned by a view in response to a `kEventControlGetFrameMetrics` event.

HIViewKind

Represents the signature and kind of the view.

```
struct HIViewKind {
    OSType signature;
    OSType kind;
}
```

Fields
`signature`
The signature of the view. Apple reserves all signatures made up of only lowercase characters.

`kind`
The kind of the view. Apple reserves all kinds made up of only lowercase characters.

HIViewRef

Define an HIView reference.

```
typedef ControlRef HIViewRef;
```

Availability
Available in Mac OS X v10.2 and later.

Declared In
`HIObject.h`

HIViewTrackingAreaRef

Define an HIView tracking area reference.

```
typedef struct OpaqueHIViewTrackingAreaRef HIViewTrackingAreaRef;
```

Availability
Available in Mac OS X v10.4 and later.

Declared In
`HIView.h`

HIViewTrackingAreaID

Define an HIView tracking area ID.

```
typedef UInt64 HIViewTrackingAreaID;
```

Availability
Available in Mac OS X v10.4 and later.

Declared In
`HIView.h`

Constants

Class ID Constants

Specify class identifiers for view-related subclasses of HIObject.

```
#define kHIViewClassID              CFSTR("com.apple.hiview")
#define kHIGrowBoxViewClassID       CFSTR("com.apple.higrowboxview")
#define kHIImageViewClassID         CFSTR("com.apple.HIImageView")
#define kHIMenuViewClassID          CFSTR("com.apple.HIMenuView")
#define kHIStandardMenuViewClassID  CFSTR("com.apple.HIStandardMenuView")
#define kHISegmentedViewClassID     CFSTR("com.apple.HISegmentedView")
#define kHIScrollViewClassID        CFSTR("com.apple.HIScrollView")
#define kHIComboBoxClassID          CFSTR("com.apple.HIComboBox")
#define kHISearchFieldClassID       CFSTR("com.apple.HISearchField")
#define kHICocoaViewClassID         CFSTR("com.apple.HICocoaView")
```

Constants

`kHIViewClassID`
Class identifier for the HIView class.
Available in Mac OS X v10.2 and later.
Declared in `HIView.h`.

`kHIGrowBoxViewClassID`
Class identifier for the HIGrowBoxView class.
Available in Mac OS X v10.2 and later.
Declared in `HIWindowViews.h`.

`kHIImageViewClassID`
Class identifier for the HIImageView class.
Available in Mac OS X v10.3 and later.
Declared in `HIImageViews.h`.

`kHIMenuViewClassID`
Class identifier for the HIMenuView class.
Available in Mac OS X v10.3 and later.
Declared in `HIMenuView.h`.

`kHIStandardMenuViewClassID`
Class identifier for the HIStandardMenuView class.
Available in Mac OS X v10.3 and later.
Declared in `HIMenuView.h`.

`kHISegmentedViewClassID`
Class identifier for the HISegmentedView class.
Available in Mac OS X v10.3 and later.
Declared in `HISegmentedView.h`.

`kHIScrollViewClassID`
Class identifier for the HIScrollView class.
Available in Mac OS X v10.3 and later.
Declared in `HIScrollView.h`.

`kHIComboBoxClassID`
Class identifier for the HIComboBox class.
Available in Mac OS X v10.3 and later.
Declared in `HIComboBox.h`.

`kHISearchFieldClassID`
Class identifier for the HISearchField class.
Available in Mac OS X v10.3 and later.
Declared in `HISearchField.h`.

`kHICocoaViewClassID`
Class identifier for the HICocoaView class.
Available in Mac OS X v10.5 and later.
Declared in `HICocoaView.h`.

Clock Event Constant

Specify the constant for changes in date or time in the clock control (`kEventClassClockView`).

```
enum {
    kEventClockDateOrTimeChanged = 1
};
```

Constants

`kEventClockDateOrTimeChanged`
An event sent by the clock control when the user changes the date or time. Clients can register for this notification in order to update state based on the date or time in the clock. This event is sent to the view only; it is not propagated. The event is sent to all handlers installed on the control.
Available in Mac OS X v10.4 and later.
Declared in `HIClockView.h`.

Discussion

Table 34-1 shows the event parameters associated with this event.

Table 34-1 Parameter names and types for date or time change events

Event kind	Parameter name	Parameter type

kEventClockDateOrTimeChanged	kEventParamDirectObject	typeControlRef

Combo Box Attributes

Specify constants for combo box attributes.

```
enum {
    kHIComboBoxNoAttributes = 0L,
    kHIComboBoxAutoCompletionAttribute = (1L << 0),
    kHIComboBoxAutoDisclosureAttribute = (1L << 1),
    kHIComboBoxAutoSortAttribute = (1L << 2),
    kHIComboBoxAutoSizeListAttribute = (1L << 3),
    kHIComboBoxStandardAttributes = (kHIComboBoxAutoCompletionAttribute |
kHIComboBoxAutoDisclosureAttribute | kHIComboBoxAutoSizeListAttribute)
};
```

Constants

`kHIComboBoxNoAttributes`
Indicates the lack of any attributes.

Available in Mac OS X v10.2 and later.

Declared in `HIComboBox.h`.

`kHIComboBoxAutoCompletionAttribute`
The control will attempt to auto complete the text the user is typing with an item in the combo box list that is the closest appropriate match.

Available in Mac OS X v10.2 and later.

Declared in `HIComboBox.h`.

`kHIComboBoxAutoDisclosureAttribute`
The control will disclose the combo box list after the user enters text.

Available in Mac OS X v10.2 and later.

Declared in `HIComboBox.h`.

`kHIComboBoxAutoSortAttribute`
The items in the combo box list will be automatically sorted in alphabetical order.

Available in Mac OS X v10.2 and later.

Declared in `HIComboBox.h`.

`kHIComboBoxAutoSizeListAttribute`
The combo box list will be automatically sized to fit the Human Interface Guidelines.

Available in Mac OS X v10.2 and later.

Declared in `HIComboBox.h`.

`kHIComboBoxStandardAttributes`
The minimum set of commonly used combo box attributes.

Available in Mac OS X v10.2 and later.

Declared in `HIComboBox.h`.

Combo Box Data Tags

Specify constants for combo box data tags.

```
enum {
    kHIComboBoxListTag = 'cbls',
    kHIComboBoxListPixelWidthTag = 'cblw',
    kHIComboBoxListPixelHeightTag = 'cblh',
    kHIComboBoxNumVisibleItemsTag = 'cbni'
};
```

Constants

`kHIComboBoxListTag`

Extract the contents of the combo box list as a `CFArray`. The `CFArray` is retained; if you get the array, you own it and must release it. If you set it by calling `SetControlData`, the toolbox makes a copy of it, and you are free to release your reference. The reference count is bumped on get/retains on set.

Available in Mac OS X v10.2 and later.

Declared in `HIComboBox.h`.

`kHIComboBoxListPixelWidthTag`

A `UInt32` containing the width of the combo box list. The width can be customized. This tag disables the auto size attribute.

Available in Mac OS X v10.2 and later.

Declared in `HIComboBox.h`.

`kHIComboBoxListPixelHeightTag`

A `UInt32` containing the height of the combo box list. The height can be customized. This tag disables the auto size attribute.

Available in Mac OS X v10.2 and later.

Declared in `HIComboBox.h`.

`kHIComboBoxNumVisibleItemsTag`

A `UInt32` containing the number of visible items in the combo box list. The number can be customized. This tag disables the auto size attribute.

Available in Mac OS X v10.2 and later.

Declared in `HIComboBox.h`.

Discussion

The combo box view also supports these tags previously defined for the `EditUnicodeText` control. These tags are available through `GetControlData` and `SetControlData` with a `ControlPartCode` of `kHIComboBoxEditTextPart`:

- `kControlFontStyleTag`
- `kControlEditTextFixedTextTag`
- `kControlEditTextTextTag`
- `kControlEditTextKeyFilterTag`
- `kControlEditTextValidationProcTag`
- `kControlEditUnicodeTextPostUpdateProcTag`
- `kControlEditTextSelectionTag`
- `kControlEditTextKeyScriptBehaviorTag`

- kControlEditTextCharCount
- kControlEditTextCFStringTag

Combo Box List Item Event Constants

Specify a constant for combo box list item events (kEventClassHIComboBox).

```
enum {
    kEventComboBoxListItemSelected = 1,
    kEventParamComboBoxListSelectedItemIndex = 'cbli'
};
```

Constants

kEventComboBoxListItemSelected

This event is sent as a notification when an item in the combo box disclosure list has been selected. This event is sent to all handlers installed on the control. This does not imply that the selection has been accepted; for that you will need to register for the kEventClassTextField/kEventTextAccepted event.

Available in Mac OS X v10.4 and later.

Declared in HIComboBox.h.

kEventParamComboBoxListSelectedItemIndex

Indicates the index of a selected combo box list item.

Available in Mac OS X v10.4 and later.

Declared in HIComboBox.h.

Discussion

Table 34-2 shows the event parameters associated with these events.

Table 34-2 Parameter names and types for combo box events

Event kind	Parameter name	Parameter type
kEventComboBoxList-ItemSelected	kEventParamDirectObject	typeControlRef
	kEventParamComboBoxListItemSelected-ItemIndex	typeCFIndex

Combo Box Part Constants

Specify constants for combo box part codes.

```
enum {
    kHIComboBoxEditTextPart = 5,
    kHIComboBoxDisclosurePart = 28
};
```

Constants

`kHIComboBoxEditTextPart`
Edit text part.
Available in Mac OS X v10.2 and later.
Declared in `HIComboBox.h`.

`kHIComboBoxDisclosurePart`
Disclosure part.
Available in Mac OS X v10.2 and later.
Declared in `HIComboBox.h`.

Discussion

Combo box part code constants are used when calling `HIViewSetHilite` (page 2481), `HIViewCopyShape` (page 2448) and are returned by `HIViewRegionChanged` (page 2474), `HIViewGetFocusPart` (page 2455). They are also used by the hit testing functions, `HIViewSimulateClick` (page 2491) and `HIViewGetPartHit` (page 2462).

Control Kind Constants

Specify constants for control kinds.

```
enum {
    kControlKindHIScrollView = 'scrl',
    kControlKindHIImageView = 'imag',
    kControlKindHIComboBox = 'cbbx',
    kControlKindHISearchField = 'srfd',
    kControlKindHIMenuView = 'menu',
    kControlKindHIStandardMenuView = 'smnu',
    kHISegmentedViewKind = 'sgmt',
    kControlKindHIGrowBoxView = 'grow',
    kControlKindHICocoaView = 'hins'
};
```

Constants

`kControlKindHIScrollView`
Control kind for a scroll view.
Available in Mac OS X v10.4 and later.
Declared in `HIScrollView.h`.

`kControlKindHIImageView`
Control kind for an image view.
Available in Mac OS X v10.4 and later.
Declared in `HIImageViews.h`.

`kControlKindHIComboBox`
Control kind for a combo box.
Available in Mac OS X v10.2 and later.
Declared in `HIComboBox.h`.

`kControlKindHISearchField`
Control kind for a search field.
Available in Mac OS X v10.3 and later.
Declared in `HISearchField.h`.

`kControlKindHIMenuView`
Control kind for a menu view.
Available in Mac OS X v10.4 and later.
Declared in `HIMenuView.h`.

`kControlKindHIStandardMenuView`
Control kind for a standard menu view.
Available in Mac OS X v10.4 and later.
Declared in `HIMenuView.h`.

`kHISegmentedViewKind`
Control kind for a segmented view.
Available in Mac OS X v10.3 and later.
Declared in `HISegmentedView.h`.

`kControlKindHIGrowBoxView`
Control kind for a grow box view.
Available in Mac OS X v10.4 and later.
Declared in `HIWindowViews.h`.

`kControlKindHICocoaView`
Control kind for a view that wraps a Cocoa view.
Available in Mac OS X v10.5 and later.
Declared in `HICocoaView.h`.

Discussion
These constants are returned by `HIViewGetKind` (page 2458) and `GetControlKind` (page 598).

Event Class Constants

Specify event class constants.

```
enum {
    kEventClassClockView = 'cloc',
    kEventClassScrollable = 'scrl',
    kEventClassHIComboBox = 'hicb',
    kEventClassSearchField = 'srfd',
    kEventClassTextField = 'txfd'
};
```

Constants
`kEventClassClockView`
Event class for events related to a clock view.
Available in Mac OS X v10.4 and later.
Declared in `HIClockView.h`.

`kEventClassScrollable`
Event class for events related to a scrollable view.
Available in Mac OS X v10.2 and later.
Declared in `HIScrollView.h`.

`kEventClassHIComboBox`
Event class for events related to a combo box view.
Available in Mac OS X v10.4 and later.
Declared in `HIComboBox.h`.

`kEventClassSearchField`
Event calls for events related to a search field view.
Available in Mac OS X v10.3 and later.
Declared in `HISearchField.h`.

`kEventClassTextField`
Event class for events related to text field views.
Available in Mac OS X v10.3 and later.
Declared in `HITextViews.h`.

HILayout Binding Kind Constants

Specify binding constants used by the HIView layout engine.

```
enum {
    kHILayoutBindNone = 0,
    kHILayoutBindMin = 1,
    kHILayoutBindMax= 2,
    kHILayoutBindLeft = kHILayoutBindMin,
    kHILayoutBindRight = kHILayoutBindMax,
    kHILayoutBindTop = kHILayoutBindMin,
    kHILayoutBindBottom = kHILayoutBindMax
};
typedef UInt16 HIBindingKind;
```

Constants

`kHILayoutBindNone`
No binding is to occur.
Available in Mac OS X v10.3 and later.
Declared in `HIView.h`.

`kHILayoutBindMin`
Bind to the minimum of the axis.
Available in Mac OS X v10.3 and later.
Declared in `HIView.h`.

`kHILayoutBindMax`
Bind to the maximum of the axis.
Available in Mac OS X v10.3 and later.
Declared in `HIView.h`.

`kHILayoutBindLeft`
Synonym for `kHILayoutBindMin`.

Available in Mac OS X v10.3 and later.

Declared in `HIView.h`.

`kHILayoutBindRight`
Synonym for `kHILayoutBindMax`.

Available in Mac OS X v10.3 and later.

Declared in `HIView.h`.

`kHILayoutBindTop`
Synonym for `kHILayoutBindMin`.

Available in Mac OS X v10.3 and later.

Declared in `HIView.h`.

`kHILayoutBindBottom`
Synonym for `kHILayoutBindMax`.

Available in Mac OS X v10.3 and later.

Declared in `HIView.h`.

Discussion
Mac OS X v10.3 provides a layout engine for HIViews that allows applications to specify the layout relationships between multiple views. When necessary, the layout engine automatically repositions and resizes views that have layout information. For more information on how to use the layout engine, see `HIViewSetLayoutInfo` (page 2482).

Horizontal and vertical bindings are very similar in application, but along different axes, so the binding kinds have been abstracted to minimum and maximum. Synonyms are provided for convenience, and you are encouraged to use them.

HILayoutInfoVersion Constant

Specify version `0` of the `HILayoutInfo` structure

```
enum {
    kHILayoutInfoVersionZero = 0
};
```

Constants
`kHILayoutInfoVersionZero`
The version of the `HILayoutInfo` structure is `0`.

Available in Mac OS X v10.3 and later.

Declared in `HIView.h`.

HIPositionKind Constants

Specify position constants used by the HIView layout engine.

```
enum {
    kHILayoutPositionNone = 0,
    kHILayoutPositionCenter = 1,
    kHILayoutPositionMin = 2,
    kHILayoutPositionMax = 3,
    kHILayoutPositionLeft = kHILayoutPositionMin,
    kHILayoutPositionRight = kHILayoutPositionMax,
    kHILayoutPositionTop = kHILayoutPositionMin,
    kHILayoutPositionBottom = kHILayoutPositionMax
};
typedef UInt16 HIPositionKind;
```

Constants

`kHILayoutPositionNone`
No positioning is to occur.
Available in Mac OS X v10.3 and later.
Declared in `HIView.h`.

`kHILayoutPositionCenter`
Bind to the center.
Available in Mac OS X v10.3 and later.
Declared in `HIView.h`.

`kHILayoutPositionMin`
Bind to the minimum of the axis.
Available in Mac OS X v10.3 and later.
Declared in `HIView.h`.

`kHILayoutPositionMax`
Bind to the maximum of the axis.
Available in Mac OS X v10.3 and later.
Declared in `HIView.h`.

`kHILayoutPositionLeft`
Synonym for `kHILayoutPositionMin`.
Available in Mac OS X v10.3 and later.
Declared in `HIView.h`.

`kHILayoutPositionRight`
Synonym for `kHILayoutPositionMax`.
Available in Mac OS X v10.3 and later.
Declared in `HIView.h`.

`kHILayoutPositionTop`
Synonym for `kHILayoutPositiondMin`.
Available in Mac OS X v10.3 and later.
Declared in `HIView.h`.

`kHILayoutPositionBottom`
Synonym for `kHILayoutPositionMax`.
Available in Mac OS X v10.3 and later.
Declared in `HIView.h`.

HIScaleKind Constant

Specify a constant that indicates the scale is determined from the axis size.

```
enum {
    kHILayoutScaleAbsolute = 0
};
typedef UInt16 HIScaleKind;
```

Constants

`kHILayoutScaleAbsolute`

Indicates that the scale is determined from the axis size.

Available in Mac OS X v10.3 and later.

Declared in `HIView.h`.

Discussion

This constant is used in conjunction with the HIView layout engine.

HIView Attributes

Specify constants that change the behavior of controls.

```
enum {
    kHIViewAttributeSendCommandToUserFocus = 1 << 0,
    kHIViewAttributeIsFieldEditor = 1 << 1,
    kHIViewSendCommandToUserFocus = kHIViewAttributeSendCommandToUserFocus
};
```

Constants

`kHIViewAttributeSendCommandToUserFocus`

When set, the control sends the command it generates to the user focus; the command propagates as it would naturally from there. (The default is to send the command to itself and then to its parent and so forth.) You may want to use this setting for views that are not typically in a focused window. For example, a push button in a toolbar window might use this setting to cause its command to be sent to the focused window rather than to the toolbar window.

Available in Mac OS X v10.4 and later.

Declared in `HIView.h`.

`kHIViewAttributeIsFieldEditor`

Indicates that text editing controls should behave appropriately for editing fields in a dialog; specifically, the control should ignore the Return, Enter, Escape, and Tab keys, and allow them to be processed by other participants in the event flow.

Available in Mac OS X v10.4 and later.

Declared in `HIView.h`.

`kHIViewSendCommandToUserFocus`

Legacy constant. Use `kHIViewAttributeSendCommandToUserFocus` instead.

Available in Mac OS X v10.2 and later.

Declared in `HIView.h`.

Discussion

These constants are used by `HIViewGetAttributes` (page 2452) to get a view's attributes and by `HIViewChangeAttributes` (page 2444) to set or change a view's attributes.

HIView Feature Constants

Specify constants for view features.

```
enum {
    kHIViewFeatureSupportsGhosting = 1 << 0,
    kHIViewFeatureAllowsSubviews = 1 << 1,
    kHIViewFeatureGetsFocusOnClick = 1 << 8,
    kHIViewFeatureSupportsLiveFeedback = 1 << 10,
    kHIViewFeatureSupportsRadioBehavior = 1 << 11,
    kHIViewFeatureAutoToggles = 1 << 14,
    kHIViewFeatureIdlesWithTimer = 1 << 23,
    kHIViewFeatureInvertsUpDownValueMeaning = 1 << 24,
    kHIViewFeatureIsOpaque = 1 << 25,
    kHIViewFeatureDoesNotDraw = 1 << 27,
    kHIViewFeatureDoesNotUseSpecialParts = 1 << 28,
    kHIViewFeatureIgnoresClicks = 1 << 29
};
typedef UInt64 HIViewFeatures;
```

Constants

`kHIViewFeatureSupportsGhosting`
This view supports using the ghosting protocol when live tracking is not enabled. Use this constant instead of the legacy constant, `kHIViewSupportsGhosting`.

Available in Mac OS X v10.4 and later.

Declared in `HIView.h`.

`kHIViewFeatureAllowsSubviews`
This view allows subviews to be embedded within it. Use this constant instead of the legacy constant, `kHIViewAllowsSubviews`.

Available in Mac OS X v10.4 and later.

Declared in `HIView.h`.

`kHIViewFeatureGetsFocusOnClick`
If this view is clicked, the keyboard focus should be set to this view automatically; used primarily for edit text controls. Use this constant instead of the legacy constant, `kHIViewGetsFocusOnClick`.

Available in Mac OS X v10.4 and later.

Declared in `HIView.h`.

`kHIViewFeatureSupportsLiveFeedback`
This view supports the live feedback protocol, which is necessary for implementing live scroll bar tracking. Clients of a view should never disable this bit. Use this constant instead of the legacy constant, `kHIViewSupportsLiveFeedback`.

Available in Mac OS X v10.4 and later.

Declared in `HIView.h`.

`kHIViewFeatureSupportsRadioBehavior`
This view can be placed in a radio group. Radio buttons and bevel buttons report this behavior. Use this constant instead of the legacy constant, `kHIViewSupportsRadioBehavior`.

Available in Mac OS X v10.4 and later.

Declared in `HIView.h`.

`kHIViewFeatureAutoToggles`
: This view supports the auto-toggle protocol and should at the very least auto-toggle between off and on. The view can support a Carbon event for more advanced auto-toggling of its value. The tab view supports this, for example, so that when a tab is clicked its value changes automatically. Use this constant instead of the legacy constant, `kHIViewAutoToggles`.

  Available in Mac OS X v10.4 and later.

  Declared in `HIView.h`.

`kHIViewFeatureIdlesWithTimer`
: An informational bit. Turning this bit off would not necessarily disable any timer a view might be using, but a timer could obey this bit if desired. Use this constant instead of the legacy constant, `kHIViewIdlesWithTimer`.

  Available in Mac OS X v10.4 and later.

  Declared in `HIView.h`.

`kHIViewFeatureInvertsUpDownValueMeaning`
: This bit tells the Control Manager that when the Up button part of the control is clicked, the value of the control should increase. A Scroll bar, conversely, decreases in value when its Up button is clicked. Use this constant instead of the legacy constant, `kHIViewInvertsUpDownValueMeaning`.

  Available in Mac OS X v10.4 and later.

  Declared in `HIView.h`.

`kHIViewFeatureIsOpaque`
: When set, the view's structure region is used to determine the view's opaque region, and calling the view can usually be avoided. Use this constant instead of the legacy constant, `kHIViewIsOpaque`.

  Available in Mac OS X v10.4 and later.

  Declared in `HIView.h`.

`kHIViewFeatureDoesNotDraw`
: This bit is an optimization that tells the Control Manager that a view is transparent and does not do any drawing, so the Control Manager doesn't have to invalidate the view and instead should invalidate views behind this view. For example, on a metal window, the content view is actually fully transparent, so invalidating it is unnecessary. Use this constant instead of the legacy constant, `kHIViewDoesNotDraw`.

  Available in Mac OS X v10.4 and later.

  Declared in `HIView.h`.

`kHIViewFeatureDoesNotUseSpecialParts`
: Indicates to the Control Manager that this view doesn't use the special part codes for indicator, inactive, and disabled. Use this constant instead of the legacy constant, `kHIViewDoesNotUseSpecialParts`.

  Available in Mac OS X v10.4 and later.

  Declared in `HIView.h`.

`kHIViewFeatureIgnoresClicks`
: When set, this bit tells the Control Manager that it does not need to ask the control for it's clickable region. A view such as the visual separator would set this bit, and metal windows set this bit when doing asynchronous window dragging. This bit is typically set in conjunction with the `kHIViewFeatureDoesNotDrawBit`. Use this constant instead of the legacy constant, `kHIViewIgnoresClicks`.

  Available in Mac OS X v10.4 and later.

  Declared in `HIView.h`.

Discussion
View feature flags are generally determined by the view itself and are not typically changed by clients of the view. Call `HIViewGetFeatures` (page 2454) to obtain a view's features, and `HIViewChangeFeatures` (page 2444) to set and clear a view's features.

HIView Meta-Parts Constants

Specify meta-parts constants used when calling `HIViewCopyShape`.

```
enum {
    kHIViewStructureMetaPart = -1,
    kHIViewContentMetaPart = -2,
    kHIViewOpaqueMetaPart = -3,
    kHIViewClickableMetaPart = -4
};
```

Constants

`kHIViewStructureMetaPart`
The structure region is the total area over which the view draws.
Available in Mac OS X v10.4 and later.
Declared in `HIView.h`.

`kHIViewContentMetaPart`
The content region is only defined by views that can embed other views. It is the area that embedded content can live.
Available in Mac OS X v10.4 and later.
Declared in `HIView.h`.

`kHIViewOpaqueMetaPart`
The portion of the view that is opaque. No views behind this portion of the view will be asked to draw because their drawing would be completely overwritten by this view's drawing.
Available in Mac OS X v10.4 and later.
Declared in `HIView.h`.

`kHIViewClickableMetaPart`
Used for asynchronous window dragging only. The default is the structure region.
Available in Mac OS X v10.4 and later.
Declared in `HIView.h`.

Discussion
Meta-parts are used when calling `HIViewCopyShape` (page 2448). Meta-parts define a region of a view and they might be defined by a view. Along with these parts, you can also pass in normal part codes to get the regions of those parts. Not all views fully support this feature.

HIView Z-Ordering Constants

Specify constants that set a view's z-order.

```
enum {
    kHIViewZOrderAbove = 1,
    kHIViewZOrderBelow = 2,
};
typedef UInt32 HIViewZOrderOp;
```

Constants

`kHIViewZOrderAbove`
Order the view above another view.
Available in Mac OS X v10.2 and later.
Declared in `HIView.h`.

`kHIViewZOrderBelow`
Order the view below another view.
Available in Mac OS X v10.2 and later.
Declared in `HIView.h`.

Discussion
These constants are used when calling `HIViewSetZOrder` (page 2490).

HIViewContentType Constants

Specify constants that describe a view's content.

```
enum {
    kHIViewContentTextOnly = 0,
    kHIViewContentNone = 0,
    kHIViewContentIconSuiteRef = 129,
    kHIViewContentIconRef = 132,
    kHIViewContentCGImageRef = 134
};
```

Constants

`kHIViewContentTextOnly`
The view has no content other than text.
Available in Mac OS X v10.4 and later.
Declared in `HIView.h`.

`kHIViewContentNone`
The view has no content.
Available in Mac OS X v10.4 and later.
Declared in `HIView.h`.

`kHIViewContentIconSuiteRef`
The view's content is an `IconSuiteRef`.
Available in Mac OS X v10.4 and later.
Declared in `HIView.h`.

`kHIViewContentIconRef`
The view's content is an `IconRef`.
Available in Mac OS X v10.4 and later.
Declared in `HIView.h`.

`kHIViewContentCGImageRef`
The view's content is an `CGImageRef`.

Available in Mac OS X v10.4 and later.

Declared in `HIView.h`.

Discussion
These constants are used in the `HIViewContentInfo` structure. For information on that structure, see HIViewContentInfo (page 2496).

HIViewPartCode Constants

Specify view parts constants.

```
enum {
    kHIViewNoPart = 0,
    kHIViewIndicatorPart = 129,
    kHIViewDisabledPart = 254,
    kHIViewInactivePart = 255,
    kHIViewEntireView = kHIViewNoPart
};
typedef ControlPartCode HIViewPartCode;
```

Constants
`kHIViewNoPart`
The entire view; used when not referring to a specific part.

Available in Mac OS X v10.4 and later.

Declared in `HIView.h`.

`kHIViewIndicatorPart`
Indicator part.

Available in Mac OS X v10.4 and later.

Declared in `HIView.h`.

`kHIViewDisabledPart`
Disabled part.

Available in Mac OS X v10.4 and later.

Declared in `HIView.h`.

`kHIViewInactivePart`
Inactive part.

Available in Mac OS X v10.4 and later.

Declared in `HIView.h`.

`kHIViewEntireView`
The entire view; used when not referring to a specific part.

Available in Mac OS X v10.4 and later.

Declared in `HIView.h`.

Discussion
These constants are used when calling `HIViewSetHilite` (page 2481), `HIViewRegionChanged` (page 2474), `HIViewCopyShape` (page 2448), `HIViewSimulateClick` (page 2491), `HIViewGetPartHit` (page 2462), and `HIViewGetFocusPart` (page 2455). These constants are also used with various `kEventClassControl` Carbon events.

Mouse Tracking Area Event Constants

Specify constants for mouse tracking area events (`kEventClassControl`).

```
enum {
    kEventControlTrackingAreaEntered = 23,
    kEventControlTrackingAreaExited = 24,
    kEventParamHIViewTrackingArea = 'ctra',
    typeHIViewTrackingAreaRef = 'ctra'
};
```

Constants

`kEventControlTrackingAreaEntered`

If you installed a mouse tracking area in your view, you will receive this event when the mouse enters that area. The tracking area reference is sent with the event.

Available in Mac OS X v10.4 and later.

Declared in `HIView.h`.

`kEventControlTrackingAreaExited`

If you installed a mouse tracking area in your view, you will receive this event when the mouse leaves that area. The tracking area reference is sent with the event.

Available in Mac OS X v10.4 and later.

Declared in `HIView.h`.

`kEventParamHIViewTrackingArea`

An `HIViewTrackingAreaRef` for the tracking area that was entered.

Available in Mac OS X v10.4 and later.

Declared in `HIView.h`.

Discussion

Table 34-3 shows the event parameters associated with these events.

Table 34-3 Parameter names and types for mouse tracking area events

Event kind	Parameter name	Parameter type
`kEventControl-TrackingAreaEntered`	`kEventParamHIViewTrackingArea`	`typeHIViewTrackingAreaRef`
	`kEventParamKeyModifiers`	`typeUInt32`
	`kEventParamMouseLocation`	`typeHIPoint`
`kEventControl-TrackingAreaExited`	`kEventParamHIViewTrackingArea`	`typeHIViewTrackingAreaRef`
	`kEventParamKeyModifiers`	`typeUInt32`
	`kEventParamMouseLocation`	`typeHIPoint`

Scroll View Constants

Specify constants for scroll view options.

```
enum {
    kHIScrollViewOptionsVertScroll = (1 << 0),
    kHIScrollViewOptionsHorizScroll = (1 << 1),
    kHIScrollViewOptionsAllowGrow = (1 << 2),
    kHIScrollViewValidOptions = (kHIScrollViewOptionsVertScroll |
kHIScrollViewOptionsHorizScroll | kHIScrollViewOptionsAllowGrow)
};
```

Constants

`kHIScrollViewOptionsVertScroll`
Indicates that a vertical scroll bar is desired.

Available in Mac OS X v10.2 and later.

Declared in `HIScrollView.h`.

`kHIScrollViewOptionsHorizScroll`
Indicates that a horizontal scroll bar is desired.

Available in Mac OS X v10.2 and later.

Declared in `HIScrollView.h`.

`kHIScrollViewOptionsAllowGrow`
Indicates that space for a grow box should be taken into account when laying out scroll bars. In Mac OS X v10.3 and earlier, if both horizontal and vertical scroll bars are requested, this attribute is assumed. In Mac OS X v10.4 and later, this attribute is *not* assumed; this allows the scroll view to support independent auto-hiding of the two scroll bars in Mac OS X v10.4 and later. If you want to preserve space for the grow box on all systems, specify this option bit.

Available in Mac OS X v10.2 and later.

Declared in `HIScrollView.h`.

`kHIScrollViewValidOptions`
All valid scroll view options.

Available in Mac OS X v10.2 and later.

Declared in `HIScrollView.h`.

Discussion

These constants are used in conjunction with `HIScrollViewCreate` (page 2423).

Scroll View Action Constants

Specify constants for scroll view navigation actions.

```
enum {
    kHIScrollViewScrollToTop = (1 << 0),
    kHIScrollViewScrollToBottom = (1 << 1),
    kHIScrollViewScrollToLeft = (1 << 2),
    kHIScrollViewScrollToRight = (1 << 3),
    kHIScrollViewPageUp = (1 << 4),
    kHIScrollViewPageDown = (1 << 5),
    kHIScrollViewPageLeft = (1 << 6),
    kHIScrollViewPageRight = (1 << 7)
};
typedef UInt32 HIScrollViewAction;
```

Constants

`kHIScrollViewScrollToTop`
The scroll view should move to the top of the content.
Available in Mac OS X v10.3 and later.
Declared in `HIScrollView.h`.

`kHIScrollViewScrollToBottom`
The scroll view should move to the bottom of the content.
Available in Mac OS X v10.3 and later.
Declared in `HIScrollView.h`.

`kHIScrollViewScrollToLeft`
The scroll view should move to the left of the content.
Available in Mac OS X v10.3 and later.
Declared in `HIScrollView.h`.

`kHIScrollViewScrollToRight`
The scroll view should move to the right of the content.
Available in Mac OS X v10.3 and later.
Declared in `HIScrollView.h`.

`kHIScrollViewPageUp`
The scroll view should page up.
Available in Mac OS X v10.3 and later.
Declared in `HIScrollView.h`.

`kHIScrollViewPageDown`
The scroll view should page down.
Available in Mac OS X v10.3 and later.
Declared in `HIScrollView.h`.

`kHIScrollViewPageLeft`
The scroll view should page left.
Available in Mac OS X v10.3 and later.
Declared in `HIScrollView.h`.

`kHIScrollViewPageRight`
The scroll view should page right.
Available in Mac OS X v10.3 and later.
Declared in `HIScrollView.h`.

Discussion
These constants are used in conjunction with `HIScrollViewNavigate` (page 2424) and `HIScrollViewCanNavigate` (page 2423).

Scrollable Event Constants

Specify constants for scrollable events (`kEventClassScrollable`).

```
enum {
    kEventScrollableGetInfo = 1,
    kEventScrollableInfoChanged = 2,
    kEventScrollableScrollTo = 10
};
```

Constants

`kEventScrollableGetInfo`
This event is sent by an HIScrollView to its scrollable view to determine the current size and origin of the scrollable view. A scrollable view must implement this event in order to scroll properly inside an HIScrollView.

Available in Mac OS X v10.2 and later.

Declared in `HIScrollView.h`.

`kEventScrollableInfoChanged`
This event is not sent by an HIScrollView itself. Instead, it may be sent to an instance of HIScrollView to notify the scroll view that the size or origin of its scrollable view has changed. The HIScrollView responds to this event by sending a `kEventScrollableGetInfo` event to its scrollable view. It then updates the scroll bars appropriately to reflect the changes. It does *not* move the origin of the scrollable view at all. This event is just a notification to allow the scroll view to sync up with its scrollable view.

Available in Mac OS X v10.2 and later.

Declared in `HIScrollView.h`.

`kEventScrollableScrollTo`
This event is sent by an HIScrollView to its scrollable view to request that the scrollable view update its current origin and redraw. Typically, a scrollable view scrolls its content by setting its bounds origin using `HIViewSetBoundsOrigin` (page 2478) or by offsetting its drawing by the scroll origin. If the view embeds other views, it must use `HIViewSetBoundsOrigin` to allow the embedded views to scroll along with their containing view. A view that uses `HIViewSetBoundsOrigin` should call that API in response to this event. A view that offsets its drawing by the scroll origin should update its current origin in its own instance data in response to this event. A scrollable view should also use `HIViewScrollRect` (page 2477) to scroll its content or `HIViewSetNeedsDisplay` (page 2485) to cause itself to redraw using the new origin point. A scrollable view must implement this event in order to scroll properly inside an HIScrollView.

Available in Mac OS X v10.2 and later.

Declared in `HIScrollView.h`.

Discussion
Table 34-4 shows the event parameters associated with these events.

Table 34-4 Parameter names and types for scrollable events

Event kind	Parameter name	Parameter type
`kEventScrollableGetInfo`	`kEventParamImageSize`	`typeHISize`

	kEventParamViewSize	typeHISize
	kEventParamLineSize	typeHISize
	kEventParamOrigin	typeHIPoint
kEventScrollableInfoChanged	kEventParamOrigin	typeHIPoint
kEventScrollableScrollTo	kEventParamOrigin	typeHIPoint

Scrollable Event Parameter Constants

Specify scrollable event parameter constants.

```
enum {
    kEventParamImageSize = 'imsz',
    kEventParamViewSize = 'vwsz',
    kEventParamLineSize = 'lnsz',
    kEventParamOrigin = 'orgn'
};
```

Constants

`kEventParamImageSize`

A value of type `typeHISize` representing the image size. The image size is the total size of the scrollable view, including any parts of the view that are not currently visible. For example, a scrollable view that displays a hundred page document would return an image size equal to one hundred times the height of the page.

Available in Mac OS X v10.2 and later.

Declared in `HIScrollView.h`.

`kEventParamViewSize`

A value of type `typeHISize` representing the view size. The view size is the current size of the scrollable view. Typically, this is the same as the view's bounds and can be acquired by calling `HIViewGetBounds` (page 2453).

Available in Mac OS X v10.2 and later.

Declared in `HIScrollView.h`.

`kEventParamLineSize`

A value of type `typeHISize` representing the line size. The line size is the distance that the HIScrollView should scroll its subview when the user clicks a scroll bar arrow. For example, this might be 10 pixels vertically and 20 pixels horizontally.

Available in Mac OS X v10.2 and later.

Declared in `HIScrollView.h`.

`kEventParamOrigin`
: A value of type `typeHIPoint` representing the origin. The origin is the current view-relative origin within the total scrollable image that is displayed at the top left corner of the view. These coordinates should always be greater than or equal to zero and less than or equal to the view's image size minus its view size. Typically, a view that implements the `kEventScrollableScrollTo` event by calling `HIViewSetBoundsOrigin` (page 2478) returns the current bounds origin for this parameter, and a view implements the `ScrollTo` event by storing the origin in its instance data returns its stored origin for this parameter. For example, a scrollable view that currently is displaying page ten of a hundred page document would return a horizontal origin of zero and a vertical origin equal to ten times the height of the page.

Available in Mac OS X v10.2 and later.

Declared in `HIScrollView.h`.

Search Field Attribute Constants

Specify constants for search field attributes.

```
enum {
    kHISearchFieldNoAttributes = 0,
    kHISearchFieldAttributesCancel = (1 << 0),
    kHISearchFieldAttributesSearchIcon = (1 << 1)
};
```

Constants

`kHISearchFieldNoAttributes`
: Indicates that this view does not have any attributes.

Available in Mac OS X v10.3 and later.

Declared in `HISearchField.h`.

`kHISearchFieldAttributesCancel`
: Indicates that this view contains a Cancel button.

Available in Mac OS X v10.3 and later.

Declared in `HISearchField.h`.

`kHISearchFieldAttributesSearchIcon`
: Indicates that this view contains the Search icon in the text field. If a menu is associated with the search field, this attribute is implicitly set and the Search icon will display with a menu disclosure badge.

Available in Mac OS X v10.4 and later.

Declared in `HISearchField.h`.

Discussion

These constants are used when calling `HISearchFieldCreate` (page 2427), `HISearchFieldGetAttributes` (page 2428), and `HISearchFieldChangeAttributes` (page 2425).

Search Field Data Tags

Specify constants for search field data tags.

Discussion
Search field views support these tags previously defined for the `EditUnicodeText` control. These tags are available through `GetControlData` and `SetControlData` with a `ControlPartCode` of `kControlEditTextPart`:

- `kControlFontStyleTag`
- `kControlEditTextFixedTextTag`
- `kControlEditTextTextTag`
- `kControlEditTextKeyFilterTag`
- `kControlEditTextValidationProcTag`
- `kControlEditUnicodeTextPostUpdateProcTag`
- `kControlEditTextSelectionTag`
- `kControlEditTextKeyScriptBehaviorTag`
- `kControlEditTextCharCount`
- `kControlEditTextCFStringTag`

Availability
Available in Mac OS X v10.3 and later.

Search Field Part Code Constants

Specify constants for search field part codes.

```
enum {
    kControlSearchFieldCancelPart = 30,
    kControlSearchFieldMenuPart = 31
};
```

Constants

`kControlSearchFieldCancelPart`
Cancel part.
Available in Mac OS X v10.3 and later.
Declared in `HISearchField.h`.

`kControlSearchFieldMenuPart`
Menu part.
Available in Mac OS X v10.3 and later.
Declared in `HISearchField.h`.

Segment Attribute Constants

Specify segment attribute constants.

```
enum {
    kHISegmentNoAttributes = 0,
    kHISegmentSendCmdToUserFocus = (1 << 0)
};
```

Constants

`kHISegmentNoAttributes`

Indicates no attributes.

Available in Mac OS X v10.3 and later.

Declared in `HISegmentedView.h`.

`kHISegmentSendCmdToUserFocus`

If this attribute bit is set, the command that is sent when the segment is clicked will be directed at the user focus instead of up the segmented view's containment hierarchy.

Available in Mac OS X v10.3 and later.

Declared in `HISegmentedView.h`.

Discussion

These constants are used when calling `HISegmentedViewCreate` (page 2432) and `HISegmentedViewChangeSegmentAttributes` (page 2430).

Segment Behavior Constants

Specify segment behavior constants.

```
enum {
    kHISegmentBehaviorMomentary = 1,
    kHISegmentBehaviorRadio = 2,
    kHISegmentBehaviorToggles = 3,
    kHISegmentBehaviorSticky = 4
};
```

Constants

`kHISegmentBehaviorMomentary`

Pops back up after being pressed, just like a push button.

Available in Mac OS X v10.3 and later.

Declared in `HISegmentedView.h`.

`kHISegmentBehaviorRadio`

Stays pressed until another segment with the radio behavior is pressed. This makes the segment behave like a radio button. After this segment is clicked, the segmented view's value is changed to this segment's one-based index.

Available in Mac OS X v10.3 and later.

Declared in `HISegmentedView.h`.

`kHISegmentBehaviorToggles`

Behaves like a check box. When clicked, it toggles back and forth between checked and unchecked states. Currently, this constant should not be used; if you use it, you get the same effect as if you used `kHISegmentBehaviorMomentary`.

Available in Mac OS X v10.3 and later.

Declared in `HISegmentedView.h`.

`kHISegmentBehaviorSticky`

After being pressed, this type of segment stays pressed until it is unpressed programmatically. Currently, this constant should not be used; if you use it, you get the same effect as if you used `kHISegmentBehaviorMomentary`.

Available in Mac OS X v10.3 and later.

Declared in `HISegmentedView.h`.

Discussion
These constants are used in conjunction with `HISegmentedViewSetSegmentBehavior` (page 2437) and `HISegmentedViewGetSegmentBehavior` (page 2433).

Standard View Constants

Specify IDs of views that are commonly used.

```
const HIViewID kHIViewWindowContentID;
const HIViewID kHIViewWindowGrowBoxID;
const HIViewID kHIViewMenuContentID;
```

Constants
`kHIViewWindowContentID`

The standard view ID for the content view of a window.

Available in Mac OS X v10.2 and later.

Declared in `HIWindowViews.h`.

`kHIViewWindowGrowBoxID`

The standard view ID for the grow box view of a window. Not all windows have grow boxes, so you might not find this view if you look for it.

Available in Mac OS X v10.2 and later.

Declared in `HIWindowViews.h`.

`kHIViewMenuContentID`

The standard view ID for the content view of a menu. The Menu Manager assigns this view ID to all menu content views.

Available in Mac OS X v10.3 and later.

Declared in `HIMenuView.h`.

Text Field Event Constants

Specify constants for text field events (`kEventClassTextField`).

```
enum {
    kEventTextAccepted = 1,
    kEventTextShouldChangeInRange = 2,
    kEventTextDidChange = 3
};
```

Constants

`kEventTextAccepted`

This event is sent as a notification when the text contained in a control's editable text field has been accepted by the user. Text is accepted when the user presses Return or Enter on the keyboard for the `EditUnicodeText`, `HIComboBox`, and `HISearchField` controls, or when the text has changed in the field and the field loses focus for the `EditUnicodeText`, `HIComboBox`, `HISearchField` and `HITextView` controls. This event is sent to the control containing the text field only, it is not propagated. It is sent to all handlers installed on the control containing the text field.

Available in Mac OS X v10.3 and later.

Declared in `HITextViews.h`.

`kEventTextShouldChangeInRange`

This event is sent whenever the text is about to be modified in text field, either by user input or in other scenarios such as a paste from the clipboard, spell-checking word correction, or Mac OS X Service operation. You can change the text that is inserted by providing a replacement string as a parameter to this event. This event is only sent for Unicode text controls; it is not sent for the Classic non-Unicode `EditText` control. This event is not sent prior to programmatic modification of the text field contents using `SetControlData`. This event is not sent while an active inline editing session is in progress. Once the inline text has been confirmed, this event is sent prior to the confirmed text being inserted into the text field. If you need control over keystrokes during an inline editing session, you can use the `kEventTextInputFilterText` event. This event is sent to the control containing the text field only; it does not propagate.

Available in Mac OS X v10.4 and later.

Declared in `HITextViews.h`.

`kEventTextDidChange`

This event is sent to indicate that the contents of an editable text field have changed. This event is sent by all of the Unicode-based editable text views: `HIComboBox`, `HISearchField`, `HITextView` and `EditUnicodeText`. This event is not sent for the Classic non-Unicode `EditText` control. Note that this event is sent after inline editing operations, such as pressing a dead key, or using a input method that creates an inline editing hole. Most clients of this event should ignore the event during inline editing, and only respond to changes to the text after inline editing completes. A client can check for the presence of the `kEventParamUnconfirmedRange` parameter to determine whether inline editing is currently active; if this parameter is present, the client may wish to ignore the event. This event is not sent after programmatic modification of the text field contents using `SetControlData`. This event is sent only to the control containing the text field; it does not propagate. It is sent to all handlers registered for it.

Available in Mac OS X v10.4 and later.

Declared in `HITextViews.h`.

Discussion

Table 34-5 shows the event parameters associated with these events.

Table 34-5 Parameter names and types for text field events

Event kind	Parameter name	Parameter type
`kEventTextAccepted`	`kEventParamDirectObject`	`typeControlRef`

kEventTextShouldChangeInRange	kEventParamTextSelection	typeCFRange
	kEventParamCandidateText	typeCFStringRef
	kEventParamReplacementText (Optional)	typeCFStringRef
kEventTextDidChange	kEventParamUnconfirmedRange	typeCFRange
	kEventParamUnconfirmedText	typeCFStringRef

Text Field Event Parameter Constants

Specify constants for text field event parameters.

```
enum {
    kEventParamTextSelection = 'txsl',
    kEventParamCandidateText = 'tstx',
    kEventParamReplacementText = 'trtx',
    kEventParamUnconfirmedRange = 'tunr',
    kEventParamUnconfirmedText = 'txun'
};
```

Constants

`kEventParamTextSelection`

The range of the selection that is about to be changed. The units of the selection are in the same units that are returned in a `EditTextSelectionRec`, when called with `GetControlData` using `kControlEditTextSelectionTag`.

Available in Mac OS X v10.4 and later.

Declared in `HITextViews.h`.

`kEventParamCandidateText`

The text that is to replace the selection. Note that this string was originally created with `CFStringCreateWithCharactersNoCopy`, and the original text has a limited life span. If for some reason you need to retain the text past the end of your event handler, you should extract the characters from the string with `CFStringGetCharacters`, and then store those characters or create a new `CFString` from them.

Available in Mac OS X v10.4 and later.

Declared in `HITextViews.h`.

`kEventParamReplacementText`

Optional replacement text.

Available in Mac OS X v10.4 and later.

Declared in `HITextViews.h`.

`kEventParamUnconfirmedRange`

If the text field currently has an open inline hole, this parameter contains the range of text inside the hole. This parameter is optional and is only present during inline editing.

Available in Mac OS X v10.4 and later.

Declared in `HITextViews.h`.

`kEventParamUnconfirmedText`
If the text field currently has an open inline hole, this parameter contains the non-confirmed text currently being edited inside the hole. This parameter is optional and is only present during inline editing. Note that this string was originally created with `CFStringCreateWithCharactersNoCopy`, and the original text has a limited life span. If for some reason you need to retain the text past the end of your event handler, you should extract the characters from the string with `CFStringGetCharacters`, and then store those characters or create a new `CFString` from them.

Available in Mac OS X v10.4 and later.

Declared in `HITextViews.h`.

Transformation Constants

Specify transformation constants.

```
enum {
    kHITransformNone = 0x00,
    kHITransformDisabled = 0x01,
    kHITransformSelected = 0x4000
};
```

Constants

`kHITransformNone`
No visual transformation should be applied.

Available in Mac OS X v10.4 and later.

Declared in `HIView.h`.

`kHITransformDisabled`
The image should be transformed to use a disabled appearance. This transformation should not be combined with any other transformations.

Available in Mac OS X v10.4 and later.

Declared in `HIView.h`.

`kHITransformSelected`
The image should be transformed to use a selected appearance. This transformation should not be combined with any other transformations.

Available in Mac OS X v10.4 and later.

Declared in `HIView.h`.

Discussion
These constants are used when calling `HICreateTransformedCGImage` (page 2415).

kHIViewKindSignatureApple

Specify the signature of all HIToolbox views.

```
enum {
    kHIViewKindSignatureApple = 'appl'
};
```

Constants

`kHIViewKindSignatureApple`

Signature of all toolbox views.

Available in Mac OS X v10.4 and later.

Declared in `HIView.h`.

Result Codes

This table lists the result codes defined in HIView.

Result Code	Value	Description
`errNeedsCompositedWindow`	-30598	This result code is returned by an HIView or a Control Manager function when an action that requires a compositing window is attempted on a non-compositing window. It may also be returned when the value of a parameter is not valid for the requested action, even though the window is a compositing window. Available in Mac OS X v10.3 and later.

HTML Rendering Library Reference (Not Recommended)

Framework: Carbon/Carbon.h

Declared in HTMLRendering.h

Overview

Important: The HTML Rendering Library is deprecated as of Mac OS X v10.4. A much more complete solution for displaying HTML and web content in your application is provided by the Web Kit. See *WebKit Objective-C Programming Guide* for guidelines on using the Web Kit.

Whereas the HTML Rendering Library takes a specified HTML file and draws text and images in a window, the Web Kit inserts a browser window into your document. The user can specify any URL and follow links in the Web Kit view window. Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. With the Web Kit, your application can include anything from an HTML viewing window to a full-featured web browser.

Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

The HTML Rendering Library gives your application the ability to draw text and images in a window, as specified by HTML data. Note that this API does not include other features of HTML browsers, such as history tracking or plug-in support. The kinds of tasks you can perform with the HTML Rendering Library include

- formatting and updating the rendering area with such elements as borders, scroll bars, and size boxes in scroll bars
- setting such graphics and display options as screen depth and graphics ports
- working with events
- drawing pages from HTML data
- obtaining information about pages
- converting URL and file system specification data

Functions by Task

Identifying The HTML Rendering Library

`HRHTMLRenderingLibAvailable` (page 2559)
Reports whether the HTML Rendering Library is available. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`HRGetHTMLRenderingLibVersion` (page 2545) Deprecated in Mac OS X v10.4
Identifies which version of the HTML Rendering Library is available. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

Handling Newly Visited Links

`DisposeHRNewURLUPP` (page 2534) Deprecated in Mac OS X v10.4
Disposes of a previously obtained UPP. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`HRRegisterNewURLUPP` (page 2563) Deprecated in Mac OS X v10.4
Registers an application-defined function that handles newly visited links. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`HRUnregisterNewURLUPP` (page 2574) Deprecated in Mac OS X v10.4
Unregisters a previously registered application-defined function. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`NewHRNewURLUPP` (page 2586) Deprecated in Mac OS X v10.4
Obtains a UPP for an application-defined function that handles newly visited links. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

Handling Previously Visited Links

`DisposeHRWasURLVisitedUPP` (page 2536) Deprecated in Mac OS X v10.4
Disposes of a previously obtained UPP. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`HRRegisterWasURLVisitedUPP` (page 2565) Deprecated in Mac OS X v10.4
Registers an application-defined function that handles previously visited links. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`HRUnregisterWasURLVisitedUPP` (page 2577) Deprecated in Mac OS X v10.4
Unregisters a previously registered application-defined function. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`NewHRWasURLVisitedUPP` (page 2588) Deprecated in Mac OS X v10.4
Obtains a UPP for an application-defined function that handles previously visited links. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

Obtaining and Disposing of HRReference Values

`HRDisposeReference` (page 2538) Deprecated in Mac OS X v10.4
Disposes of a previously obtained `HRReference`. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`HRNewReference` (page 2561) Deprecated in Mac OS X v10.4
Obtains a new `HRReference`. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`HRNewReferenceInWindow` (page 2561) Deprecated in Mac OS X v10.4
Obtains a new `HRReference`. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

Formatting the Rendering Area

`HRSetDrawBorder` (page 2568) Deprecated in Mac OS X v10.4
Specifies whether to draw a border around the rendering area. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`HRSetGrowboxCutout` (page 2571) Deprecated in Mac OS X v10.4
Specifies whether to allow for a size box when drawing scrollbars. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`HRSetScrollbarState` (page 2572) Deprecated in Mac OS X v10.4
Specifies how scrollbars are drawn. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

Intercepting and Redirecting URL's

`DisposeHRURLToFSSpecUPP` (page 2535) Deprecated in Mac OS X v10.4
Disposes of a previously obtained UPP. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`HRRegisterURLToFSSpecUPP` (page 2564) Deprecated in Mac OS X v10.4
Registers an application-defined function that handles previously visited links. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`HRUnregisterURLToFSSpecUPP` (page 2576) Deprecated in Mac OS X v10.4
Unregisters a previously registered application-defined function. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`NewHRURLToFSSpecUPP` (page 2587) Deprecated in Mac OS X v10.4
Obtains a UPP for an application-defined function that intercepts URL's. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

Setting and Updating the Rendering Area

`HRDraw` (page 2539) Deprecated in Mac OS X v10.4
Updates a specified region for a given `HRReference`. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`HRDrawInPort` (page 2540) Deprecated in Mac OS X v10.4
Updates a specified region for a given `HRReference`. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`HRGetRenderedImageSize` (page 2547) Deprecated in Mac OS X v10.4
Reports the size of the rendered image. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`HRGetRenderedImageSize32` (page 2548) Deprecated in Mac OS X v10.4
Reports the size of the rendered image. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`HRScrollToImageLocation32` (page 2567) Deprecated in Mac OS X v10.4
Scrolls to a specified view of the HTML rendering area. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`HRScrollToLocation` (page 2568) Deprecated in Mac OS X v10.4
Scrolls to a specified view of the HTML rendering area. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`HRSetRenderingRect` (page 2571) Deprecated in Mac OS X v10.4
Specifies the boundaries of the HTML rendering area. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

Setting Graphics and Display Options

`HRForceQuickdraw` (page 2540) Deprecated in Mac OS X v10.4
Forces all images to be drawn with QuickDraw. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`HRFreeMemory` (page 2541) Deprecated in Mac OS X v10.4
Attempts to release cache memory for use by your application. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`HRScreenConfigurationChanged` (page 2566) Deprecated in Mac OS X v10.4
Informs the HTML Rendering Library that the screen depth has changed. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`HRSetGrafPtr` (page 2570) Deprecated in Mac OS X v10.4
Sets a new `GrafPort` for a given `HRReference`. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

Working With Events

`HRActivate` (page 2537) Deprecated in Mac OS X v10.4
Activates the window associated with a given `HRReference`. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`HRDeactivate` (page 2537) Deprecated in Mac OS X v10.4
Deactivates the window associated with a given `HRReference`. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`HRIsHREvent` (page 2560) Deprecated in Mac OS X v10.4
Gives the HTML Rendering Library an opportunity to handle events. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

Navigating HTML Pages

`HRGoToAnchor` (page 2552) Deprecated in Mac OS X v10.4
Specifies an HTML anchor to scroll into view. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`HRGoToAnchorCFString` (page 2553) Deprecated in Mac OS X v10.4
Specifies an HTML anchor to scroll into view. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`HRGoToCFURL` (page 2553) Deprecated in Mac OS X v10.4
Renders a local file specified as a URL. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`HRGoToData` (page 2554) Deprecated in Mac OS X v10.4
Specifies HTML data for rendering. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`HRGoToFile` (page 2555) Deprecated in Mac OS X v10.4
Specifies an HTML file for rendering. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`HRGoToFSRef` (page 2556) Deprecated in Mac OS X v10.4
Renders a set of HTML data from a specified buffer. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`HRGoToPtr` (page 2557) Deprecated in Mac OS X v10.4
Renders a set of HTML data from a specified buffer. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`HRGoToURL` (page 2558) Deprecated in Mac OS X v10.4
Renders a local file specified as a URL. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

Obtaining Information About Pages

`HRGetBaseURL` (page 2542) Deprecated in Mac OS X v10.4
Obtains the base URL of a given HTML page. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`HRGetBaseURLAsCFString` (page 2543) Deprecated in Mac OS X v10.4
Obtains the base URL of a given HTML page. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`HRGetHTMLFile` (page 2543) Deprecated in Mac OS X v10.4
Obtains a file system specification record for a given HTML page. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`HRGetHTMLFileAsFSRef` (page 2544) Deprecated in Mac OS X v10.4
Obtains an `FSRef` for a given HTML page. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`HRGetHTMLURL` (page 2546) Deprecated in Mac OS X v10.4
Obtains the URL for a given HTML page. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

HRGetHTMLURLAsCFURL (page 2546) Deprecated in Mac OS X v10.4
Obtains the URL for a given HTML page. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

HRGetRootURL (page 2549) Deprecated in Mac OS X v10.4
Obtains the root URL for all relative links on a given HTML page. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

HRGetRootURLAsCFString (page 2549) Deprecated in Mac OS X v10.4
Obtains the root URL for all relative links on a given HTML page. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

HRGetTitle (page 2550) Deprecated in Mac OS X v10.4
Obtains the title of a given HTML page. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

HRGetTitleAsCFString (page 2551) Deprecated in Mac OS X v10.4
Obtains the title of a given HTML page. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

Converting URL and FSSpec Data

HRUtilCreateFullCFURL (page 2577) Deprecated in Mac OS X v10.4
Obtains a full URL from a given set of relative URLs. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

HRUtilCreateFullURL (page 2578) Deprecated in Mac OS X v10.4
Obtains a full URL from a given set of relative URLs. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

HRUtilGetFSRefFromURL (page 2579) Deprecated in Mac OS X v10.4
Obtains a FSRef from a given set of relative URL's. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

HRUtilGetFSSpecFromURL (page 2580) Deprecated in Mac OS X v10.4
Obtains a FSSpec from a given set of relative URL's. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

HRUtilGetURLFromFSRef (page 2581) Deprecated in Mac OS X v10.4
Obtains a full URL from a given FSRef. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

HRUtilGetURLFromFSSpec (page 2581) Deprecated in Mac OS X v10.4
Obtains a full URL from a given FSSpec. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

Working With Universal Procedure Pointers

DisposeHRNewCFURLUPP (page 2534) Deprecated in Mac OS X v10.4
(Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

DisposeHRURLToFSRefUPP (page 2535) Deprecated in Mac OS X v10.4
(Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

DisposeHRWasCFURLVisitedUPP (page 2536) Deprecated in Mac OS X v10.4
(Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`HRRegisterNewCFURLUPP` (page 2562) Deprecated in Mac OS X v10.4
(Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`HRRegisterURLToFSRefUPP` (page 2564) Deprecated in Mac OS X v10.4
(Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`HRRegisterWasCFURLVisitedUPP` (page 2565) Deprecated in Mac OS X v10.4
(Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`HRUnregisterNewCFURLUPP` (page 2574) Deprecated in Mac OS X v10.4
(Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`HRUnregisterURLToFSRefUPP` (page 2575) Deprecated in Mac OS X v10.4
(Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`HRUnregisterWasCFURLVisitedUPP` (page 2576) Deprecated in Mac OS X v10.4
(Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`InvokeHRNewCFURLUPP` (page 2582) Deprecated in Mac OS X v10.4
(Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`InvokeHRNewURLUPP` (page 2583) Deprecated in Mac OS X v10.4
(Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`InvokeHRURLToFSRefUPP` (page 2583) Deprecated in Mac OS X v10.4
(Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`InvokeHRURLToFSSpecUPP` (page 2584) Deprecated in Mac OS X v10.4
(Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`InvokeHRWasCFURLVisitedUPP` (page 2584) Deprecated in Mac OS X v10.4
(Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`InvokeHRWasURLVisitedUPP` (page 2585) Deprecated in Mac OS X v10.4
(Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`NewHRNewCFURLUPP` (page 2585) Deprecated in Mac OS X v10.4
(Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`NewHRURLToFSRefUPP` (page 2586) Deprecated in Mac OS X v10.4
(Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`NewHRWasCFURLVisitedUPP` (page 2587) Deprecated in Mac OS X v10.4
(Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

Miscellaneous

`HRSetEmbeddingControl` (page 2569) Deprecated in Mac OS X v10.4
Sets the `ControlRef` for embedding controls. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

`HRSetWindowRef` (page 2573) Deprecated in Mac OS X v10.4
Sets the controlling window. (Deprecated. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

Functions

DisposeHRNewCFURLUPP

(Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
void DisposeHRNewCFURLUPP (
   HRNewCFURLUPP userUPP
);
```

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability

Available in CarbonLib 1.3 and later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`HTMLRendering.h`

DisposeHRNewURLUPP

Disposes of a previously obtained UPP. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
void DisposeHRNewURLUPP (
   HRNewURLUPP userUPP
);
```

Parameters

userUPP

A Universal Procedure Pointer (UPP) that you previously obtained by calling the function `NewHRNewURLUPP` (page 2586).

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In
HTMLRendering.h

DisposeHRURLToFSRefUPP

(Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
void DisposeHRURLToFSRefUPP (
   HRURLToFSRefUPP userUPP
);
```

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability
Available in CarbonLib 1.3 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
HTMLRendering.h

DisposeHRURLToFSSpecUPP

Disposes of a previously obtained UPP. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
void DisposeHRURLToFSSpecUPP (
   HRURLToFSSpecUPP userUPP
);
```

Parameters

userUPP

A Universal Procedure Pointer (UPP) that you previously obtained by calling the function NewHRURLToFSSpecUPP (page 2587).

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability
Available in CarbonLib 1.1 and later.

Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
HTMLRendering.h

DisposeHRWasCFURLVisitedUPP

(Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
void DisposeHRWasCFURLVisitedUPP (
   HRWasCFURLVisitedUPP userUPP
);
```

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability
Available in CarbonLib 1.3 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
HTMLRendering.h

DisposeHRWasURLVisitedUPP

Disposes of a previously obtained UPP. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
void DisposeHRWasURLVisitedUPP (
   HRWasURLVisitedUPP userUPP
);
```

Parameters

userUPP

A Universal Procedure Pointer (UPP) that you previously obtained by calling the function NewHRWasURLVisitedUPP (page 2588).

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`HTMLRendering.h`

HRActivate

Activates the window associated with a given `HRReference`. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
OSStatus HRActivate (
   HRReference hrRef
);
```

Parameters

hrRef

An `HRReference` value previously obtained by your application.

Return Value
A result code. See "HTML Rendering Library Result Codes" (page 2597).

Discussion
Call this function whenever the window associated with a given `HRReference` becomes active. This allows the HTML Rendering Library to activate scrollbars and handle events as appropriate.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability
Available in CarbonLib 1.1 and later when running Mac OS 9 or later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`HTMLRendering.h`

HRDeactivate

Deactivates the window associated with a given `HRReference`. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
OSStatus HRDeactivate (
   HRReference hrRef
);
```

Parameters

hrRef

An `HRReference` value previously obtained by your application.

Return Value
A result code. See "HTML Rendering Library Result Codes" (page 2597).

Discussion
Call this function whenever the window associated with a given `HRReference` becomes inactive.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability
Available in CarbonLib 1.1 and later when running Mac OS 9 or later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`HTMLRendering.h`

HRDisposeReference

Disposes of a previously obtained `HRReference`. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
OSStatus HRDisposeReference (
   HRReference hrRef
);
```

Parameters

hrRef

An `HRReference` value previously obtained by your application.

Return Value
A result code. See "HTML Rendering Library Result Codes" (page 2597).

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability
Available in CarbonLib 1.1 and later when running Mac OS 9 or later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`HTMLRendering.h`

HRDraw

Updates a specified region for a given `HRReference`. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
OSStatus HRDraw (
   HRReference hrRef,
   RgnHandle updateRgnH
);
```

Parameters

hrRef

An `HRReference` value previously obtained by your application.

updateRgnH

A handle of type `RgnHandle`. This handle specifies the region that you want the HTML Rendering Library to update. Specify the region in the `GrafPort's` local coordinates. If you pass `NULL`, the HTML Rendering Library updates the entire rectangle you previously specified with the function `HRSetRenderingRect` (page 2571).

Return Value
A result code. See "HTML Rendering Library Result Codes" (page 2597).

Discussion
Be sure to specify the dimensions of the rendering area by calling the function `HRSetRenderingRect` (page 2571) at least once before you call the `HRDraw` function.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability
Available in CarbonLib 1.1 and later when running Mac OS 9 or later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`HTMLRendering.h`

HRDrawInPort

Updates a specified region for a given `HRReference`. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
OSStatus HRDrawInPort (
   HRReference hrRef,
   RgnHandle updateRgnH,
   CGrafPtr grafPtr
);
```

Parameters

hrRef

A reference to the renderer object.

updateRgnH

The region to be updated.

grafPtr

A graf pointer to render HTML into.

Return Value

A result code. See "HTML Rendering Library Result Codes" (page 2597).

Discussion

All the drawing will now happen in the specified port. This is the API you want to use to draw in an offscreen port, for example when printing. You could also use this API to draw in an on screen port.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability

Available in CarbonLib 1.3 and later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`HTMLRendering.h`

HRForceQuickdraw

Forces all images to be drawn with QuickDraw. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
OSStatus HRForceQuickdraw (
   HRReference hrRef,
   Boolean forceQuickdraw
);
```

Parameters

hrRef

An `HRReference` value previously obtained by your application.

forceQuickdraw

Pass a value of `true` in this parameter to force all images to be drawn with QuickDraw.

Return Value
A result code. See "HTML Rendering Library Result Codes" (page 2597).

Discussion
This function may be useful when working with print drivers that require QuickDraw for image capturing.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability
Available in CarbonLib 1.1 and later when running Mac OS 9 or later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`HTMLRendering.h`

HRFreeMemory

Attempts to release cache memory for use by your application. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
SInt32 HRFreeMemory (
   Size inBytesNeeded
);
```

Parameters

inBytesNeeded

A value indicating how many bytes of cache memory your application desires to obtain.

Return Value
A value indicating how many bytes of cache memory the HTML Rendering Library makes available to your application.

Discussion
Call the `HRFreeMemory` function to flush images and movies from the HTML Rendering Library cache. Be sure to check the function result to determine whether sufficient memory was made available to your application.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability

Available in CarbonLib 1.1 and later when running Mac OS 9 or later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`HTMLRendering.h`

HRGetBaseURL

Obtains the base URL of a given HTML page. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
OSStatus HRGetBaseURL (
   HRReference hrRef,
   Handle baseURLH
);
```

Parameters

hrRef

A `HRReference` value previously obtained by your application.

baseURLH

A handle. Make sure you allocate a valid handle with the `NewHandle` function. On return, this handle (which may be resized) references a C string containing the root URL of the given file. If the current page does not contain a `BASE` tag, the handle is empty.

Return Value

A result code. See "HTML Rendering Library Result Codes" (page 2597).

Discussion

The URL returned by this function begins with `'file:///'`.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability

Available in CarbonLib 1.1 and later when running Mac OS 9 or later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In
`HTMLRendering.h`

HRGetBaseURLAsCFString

Obtains the base URL of a given HTML page. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
OSStatus HRGetBaseURLAsCFString (
   HRReference hrRef,
   CFStringRef *baseString
);
```

Parameters

hrRef

A `HRReference` value previously obtained by your application.

baseString

On return, this handle references a `CFString` containing the root URL of the given file.

Return Value
A result code. See "HTML Rendering Library Result Codes" (page 2597).

Discussion
Use these API from a Carbon application instead of using `HRGetRootURL` (page 2549), `HRGetBaseURL` (page 2542), `HRGetHTMLURL` (page 2546), `HRGetTitle` (page 2550)and `HRGetHTMLFile` (page 2543). These APIs are same in behavior with their old counter parts. The only difference is that they take `CFString`, `CFURLRef`, and `FSRef` as parameters.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability
Available in CarbonLib 1.3 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`HTMLRendering.h`

HRGetHTMLFile

Obtains a file system specification record for a given HTML page. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
OSStatus HRGetHTMLFile (
   HRReference hrRef,
   FSSpec *fsspec
);
```

Parameters

hrRef

An `HRReference` value previously obtained by your application.

fsspec

A pointer to a file system specification record (`FSSpec`). On return, the `FSSpec` contains file specification data for the page specified in the `hrRef` parameter.

Return Value
A result code. See "HTML Rendering Library Result Codes" (page 2597).

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability
Available in CarbonLib 1.1 and later when running Mac OS 9 or later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`HTMLRendering.h`

HRGetHTMLFileAsFSRef

Obtains an `FSRef` for a given HTML page. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
OSStatus HRGetHTMLFileAsFSRef (
   HRReference hrRef,
   FSRef *fref
);
```

Parameters

hrRef

An `HRReference` value previously obtained by your application.

fref

A pointer to an (`FSRef`). On return, the `FSRef` contains file specification data for the page specified in the `hrRef` parameter.

Return Value
A result code. See "HTML Rendering Library Result Codes" (page 2597).

Discussion

Use these API from a Carbon application instead of using `HRGetRootURL` (page 2549), `HRGetBaseURL` (page 2542), `HRGetHTMLURL` (page 2546), `HRGetTitle` (page 2550)and `HRGetHTMLFile` (page 2543). These APIs are same in behavior with their old counter parts. The only difference is that they take `CFString`, `CFURLRef`, and `FSRef` as parameters.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability

Available in CarbonLib 1.3 and later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`HTMLRendering.h`

HRGetHTMLRenderingLibVersion

Identifies which version of the HTML Rendering Library is available. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
OSStatus HRGetHTMLRenderingLibVersion (
   NumVersion *returnVers
);
```

Parameters

returnVers

A pointer to a `NumVersion` structure. On return, this structure contains a value identifying the installed version of the HTML Rendering Library.

Return Value

A result code. See "HTML Rendering Library Result Codes" (page 2597).

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability

Available in CarbonLib 1.1 and later when running Mac OS 9 or later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In
`HTMLRendering.h`

HRGetHTMLURL

Obtains the URL for a given HTML page. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
OSStatus HRGetHTMLURL (
   HRReference hrRef,
   Handle HTMLURLH
);
```

Parameters

hrRef

An `HRReference` value previously obtained by your application.

HTMLURLH

A handle. Make sure you allocate a valid handle with the `NewHandle` function. On return, this handle (which may be resized) references a C string containing the URL of the given file.

Return Value
A result code. See "HTML Rendering Library Result Codes" (page 2597).

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability
Available in CarbonLib 1.1 and later when running Mac OS 9 or later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`HTMLRendering.h`

HRGetHTMLURLAsCFURL

Obtains the URL for a given HTML page. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
OSStatus HRGetHTMLURLAsCFURL (
   HRReference hrRef,
   CFURLRef *theURL
);
```

Parameters

hrRef

An `HRReference` value previously obtained by your application.

theURL

On return, this references a `CFURL` containing the URL of the given file.

Return Value
A result code. See "HTML Rendering Library Result Codes" (page 2597).

Discussion
Use these API from a Carbon application instead of using `HRGetRootURL` (page 2549), `HRGetBaseURL` (page 2542), `HRGetHTMLURL` (page 2546), `HRGetTitle` (page 2550)and `HRGetHTMLFile` (page 2543). These APIs are same in behavior with their old counter parts. The only difference is that they take `CFString`, `CFURLRef`, and `FSRef` as parameters.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability
Available in CarbonLib 1.3 and later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In
`HTMLRendering.h`

HRGetRenderedImageSize

Reports the size of the rendered image. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
OSStatus HRGetRenderedImageSize (
   HRReference hrRef,
   Point *renderingSize
);
```

Parameters

hrRef

An `HRReference` value previously obtained by your application.

renderingSize

A pointer to a value of type `Point`. On return, the HTML Rendering Library uses this value to report the size of the entire HTML page; that is, the smallest rectangle that fully encloses the entire rendered page (as drawn without scrollbars).

Return Value
A result code. See "HTML Rendering Library Result Codes" (page 2597).

Discussion
The HTML Rendering Library attempts to limit the width of the rendered page to the width of the rectangle you specify by calling the function `HRSetRenderingRect` (page 2571). The length of the page is calculated based on the resulting width.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability

Available in CarbonLib 1.1 and later when running Mac OS 9 or later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`HTMLRendering.h`

HRGetRenderedImageSize32

Reports the size of the rendered image. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
OSStatus HRGetRenderedImageSize32 (
   HRReference hrRef,
   UInt32 *height,
   UInt32 *width
);
```

Parameters

hrRef

A reference to the renderer object.

height

On return, the height of the image.

width

On return, the width of the image.

Return Value

A result code. See "HTML Rendering Library Result Codes" (page 2597).

Discussion

Use this API when the rendered image could have coordinates larger than what SInt16 can hold.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability

Available in CarbonLib 1.3 and later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In
`HTMLRendering.h`

HRGetRootURL

Obtains the root URL for all relative links on a given HTML page. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
OSStatus HRGetRootURL (
   HRReference hrRef,
   Handle rootURLH
);
```

Parameters

hrRef

An `HRReference` value previously obtained by your application.

rootURLH

A handle. Make sure you allocate a valid handle with the `NewHandle` function. On return, this handle (which may be resized) references a C string containing the root URL of the given file.

Return Value
A result code. See "HTML Rendering Library Result Codes" (page 2597).

Discussion
The root URL is normally the URL of the page specified in the `hrRef` parameter, unless the page contains a `<BASE>` tag specifying a different root URL.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability
Available in CarbonLib 1.1 and later when running Mac OS 9 or later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`HTMLRendering.h`

HRGetRootURLAsCFString

Obtains the root URL for all relative links on a given HTML page. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
OSStatus HRGetRootURLAsCFString (
   HRReference hrRef,
   CFStringRef *rootString
);
```

Parameters

hrRef

An `HRReference` value previously obtained by your application.

rootString

On return, this references a `CFString` containing the root URL of the given file.

Return Value

A result code. See "HTML Rendering Library Result Codes" (page 2597).

Discussion

Use these API from a Carbon application instead of using `HRGetRootURL` (page 2549), `HRGetBaseURL` (page 2542), `HRGetHTMLURL` (page 2546), `HRGetTitle` (page 2550)and `HRGetHTMLFile` (page 2543). These APIs are same in behavior with their old counter parts. The only difference is that they take `CFString`, `CFURLRef`, and `FSRef` as parameters.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability

Available in CarbonLib 1.3 and later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`HTMLRendering.h`

HRGetTitle

Obtains the title of a given HTML page. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
OSStatus HRGetTitle (
   HRReference hrRef,
   StringPtr title
);
```

Parameters

hrRef

An `HRReference` value previously obtained by your application.

title

A `StringPtr`. On return, the HTML Rendering Library stores the contents of the `TITLE` tag of the given page in the referenced string.

Return Value
A result code. See "HTML Rendering Library Result Codes" (page 2597).

Discussion
This function converts any HTML entities into Mac OS characters before storing them in the string specified in the `title` parameter.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability
Available in CarbonLib 1.1 and later when running Mac OS 9 or later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`HTMLRendering.h`

HRGetTitleAsCFString

Obtains the title of a given HTML page. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
OSStatus HRGetTitleAsCFString (
   HRReference hrRef,
   CFStringRef *title
);
```

Parameters

hrRef
An `HRReference` value previously obtained by your application.

title
A `CFStringRef`. On return, the HTML Rendering Library stores the contents of the `TITLE` tag of the given page in the referenced string.

Return Value
A result code. See "HTML Rendering Library Result Codes" (page 2597).

Discussion
Use these API from a Carbon application instead of using `HRGetRootURL` (page 2549), `HRGetBaseURL` (page 2542), `HRGetHTMLURL` (page 2546), `HRGetTitle` (page 2550)and `HRGetHTMLFile` (page 2543). These APIs are same in behavior with their old counter parts. The only difference is that they take `CFString`, `CFURLRef`, and `FSRef` as parameters.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very

quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability
Available in CarbonLib 1.3 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`HTMLRendering.h`

HRGoToAnchor

Specifies an HTML anchor to scroll into view. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
OSStatus HRGoToAnchor (
   HRReference hrRef,
   const char *anchorName
);
```

Parameters

hrRef
An `HRReference` value previously obtained by your application.

anchorName
A pointer to a C string containing the name of an anchor on the current HTML page.

Return Value
A result code. See "HTML Rendering Library Result Codes" (page 2597).

Discussion
Note that anchors are case sensitive.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability
Available in CarbonLib 1.1 and later when running Mac OS 9 or later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`HTMLRendering.h`

HRGoToAnchorCFString

Specifies an HTML anchor to scroll into view. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
OSStatus HRGoToAnchorCFString (
   HRReference hrRef,
   CFStringRef anchorName
);
```

Parameters

hrRef

A reference to the renderer object.

anchorName

The name of the anchor to display.

Return Value

A result code. See "HTML Rendering Library Result Codes" (page 2597).

Discussion

Use these functions instead of using the functions `HRGoToFile` (page 2555), `HRGoToURL` (page 2558), `HRGoToAnchor` (page 2552)and `HRGoToPtr` (page 2557). These functions are the same in behavior with their old counter parts. The only difference is that they take `FSRef`, `CFURLRef`, `CFString`, and `CFData` as parameters.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability

Available in CarbonLib 1.3 and later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`HTMLRendering.h`

HRGoToCFURL

Renders a local file specified as a URL. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
OSStatus HRGoToCFURL (
   HRReference hrRef,
   CFURLRef url,
   Boolean addToHistory,
   Boolean forceRefresh
);
```

Parameters

hrRef

A reference to the renderer object.

url

A reference to the URL to render.

addToHistory

Pass `true` if this file URL should be added to the history.

forceRefresh

Pass `true` if the rendering area should be refreshed.

Return Value

A result code. See "HTML Rendering Library Result Codes" (page 2597).

Discussion

Use these functions instead of using the functions `HRGoToFile` (page 2555), `HRGoToURL` (page 2558), `HRGoToAnchor` (page 2552)and `HRGoToPtr` (page 2557). These functions are the same in behavior with their old counter parts. The only difference is that they take `FSRef`, `CFURLRef`, `CFString`, and `CFData` as parameters.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability

Available in CarbonLib 1.3 and later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`HTMLRendering.h`

HRGoToData

Specifies HTML data for rendering. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
OSStatus HRGoToData (
   HRReference hrRef,
   CFDataRef data,
   Boolean addToHistory,
   Boolean forceRefresh
);
```

Parameters

hrRef

A reference to the renderer object.

data

A reference to data in the memory to render.

addToHistory

Pass `true` if this file URL should be added to the history.

forceRefresh

Pass `true` if the rendering area should be refreshed.

Return Value

A result code. See "HTML Rendering Library Result Codes" (page 2597).

Discussion

Use these functions instead of using the functions `HRGoToFile` (page 2555), `HRGoToURL` (page 2558), `HRGoToAnchor` (page 2552)and `HRGoToPtr` (page 2557). These functions are the same in behavior with their old counter parts. The only difference is that they take `FSRef`, `CFURLRef`, `CFString`, and `CFData` as parameters.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability

Available in CarbonLib 1.3 and later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`HTMLRendering.h`

HRGoToFile

Specifies an HTML file for rendering. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
OSStatus HRGoToFile (
   HRReference hrRef,
   const FSSpec *fsspec,
   Boolean addToHistory,
   Boolean forceRefresh
);
```

Parameters

hrRef

An `HRReference` value previously obtained by your application.

fsspec

A pointer to a file system specification record (`FSSpec`) for the HTML file that you wish to have rendered by the HTML Rendering Library.

addToHistory

Pass `true` in this parameter if you wish to have this file added to the list of visited links.

forceRefresh

Pass `true` in this parameter if you wish to force a screen update.

Return Value

A result code. See "HTML Rendering Library Result Codes" (page 2597).

Discussion

Note that the HTML Rendering Library calls your `HRNewURLProcPtr` (page 2589) application-defined function (if you use one) with this FSSpec. If you need to pass a URL instead of an FSSpec, use the function `HRGoToURL` (page 2558).

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability

Available in CarbonLib 1.1 and later when running Mac OS 9 or later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`HTMLRendering.h`

HRGoToFSRef

Renders a set of HTML data from a specified buffer. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
OSStatus HRGoToFSRef (
   HRReference hrRef,
   const FSRef *fref,
   Boolean addToHistory,
   Boolean forceRefresh
);
```

Parameters

hrRef

A reference to the renderer object.

fref

A reference to the HTML file that is to be opened and rendered.

addToHistory

Pass `true` if this file URL should be added to the history.

forceRefresh

Pass `true` if the rendering area should be refreshed.

Return Value

A result code. See "HTML Rendering Library Result Codes" (page 2597).

Discussion

Use these functions instead of using the functions `HRGoToFile` (page 2555), `HRGoToURL` (page 2558), `HRGoToAnchor` (page 2552)and `HRGoToPtr` (page 2557). These functions are the same in behavior with their old counter parts. The only difference is that they take `FSRef`, `CFURLRef`, `CFString`, and `CFData` as parameters.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability

Available in CarbonLib 1.3 and later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`HTMLRendering.h`

HRGoToPtr

Renders a set of HTML data from a specified buffer. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
OSStatus HRGoToPtr (
   HRReference hrRef,
   char *buffer,
   UInt32 bufferSize,
   Boolean addToHistory,
   Boolean forceRefresh
);
```

Parameters

hrRef

An `HRReference` value previously obtained by your application.

buffer

A pointer to a buffer containing HTML data.

bufferSize

A value specifying the number of bytes in the buffer.

addToHistory

Pass `true` in this parameter if you wish to have this data added to the list of visited links.

forceRefresh

Pass `true` in this parameter if you wish to force a screen update.

Return Value

A result code. See "HTML Rendering Library Result Codes" (page 2597).

Discussion

The HTML Rendering Library displays the HTML source data pointed to by the handle. It does not copy the handle, so you should not dispose of it until you are sure you no longer need it. Note that any relative links you specify in the HTML data are relative to your application, as the HTML data has no associated URL.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability

Available in CarbonLib 1.1 and later when running Mac OS 9 or later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`HTMLRendering.h`

HRGoToURL

Renders a local file specified as a URL. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
OSStatus HRGoToURL (
   HRReference hrRef,
   const char *url,
   Boolean addToHistory,
   Boolean forceRefresh
);
```

Parameters

hrRef

An `HRReference` value previously obtained by your application.

url

A pointer to a C string containing a Universal Resource Locator (URL).

addToHistory

Pass `true` in this parameter if you wish to have this file added to the list of visited links.

forceRefresh

Pass `true` in this parameter if you wish to force a screen update.

Return Value
A result code. See "HTML Rendering Library Result Codes" (page 2597).

Discussion
Use this function for rendering local files. The URL should begin with '`file:///`'. Note that the HTML Rendering Library calls your `HRNewURLProcPtr` (page 2589) application-defined function (if you use one) with this URL. If you need to pass an `FSSpec` instead of a URL, use the function `HRGoToURL` (page 2558).

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability
Available in CarbonLib 1.1 and later when running Mac OS 9 or later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`HTMLRendering.h`

HRHTMLRenderingLibAvailable

Reports whether the HTML Rendering Library is available. (**Deprecated.** Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
pascal Boolean HRHTMLRenderingLibAvailable
```

Return Value
Returns `true` if the HTML Rendering Library is available; returns `false` otherwise.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`HTMLRendering.h`

HRIsHREvent

Gives the HTML Rendering Library an opportunity to handle events. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
Boolean HRIsHREvent (
   const EventRecord *eventRecord
);
```

Parameters

eventRecord

A pointer to an `EventRecord`.

Return Value

Returns `true` if the HTML Rendering Library handles the specified event; returns `false` otherwise.

Discussion

Call the `HRIsHREvent` function with every event received by your application. This ensures that the HTML Rendering Library has an opportunity to handle user clicks and cursor changes.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability

Available in CarbonLib 1.1 and later when running Mac OS 9 or later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`HTMLRendering.h`

HRNewReference

Obtains a new `HRReference`. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
OSStatus HRNewReference (
   HRReference *hrRef,
   OSType rendererType,
   GrafPtr grafPtr
);
```

Parameters

hrRef

A pointer to a `HRReference` value. On return, your application uses this value to call other functions in the HTML Rendering Library.

rendererType

A value of type `OSType` identifying the type of HTML renderer available. Currently, the constant `kHRRendererHTML32Type` is the only value you may pass in this parameter.

grafPtr

A pointer to a valid `GrafPort`.

Return Value

A result code. See "HTML Rendering Library Result Codes" (page 2597).

Discussion

When your application has no further need for a particular `HRReference`, dispose of it by calling the function `HRDisposeReference` (page 2538).

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability

Available in CarbonLib 1.1 and later when running Mac OS 9 or later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`HTMLRendering.h`

HRNewReferenceInWindow

Obtains a new `HRReference`. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
OSStatus HRNewReferenceInWindow (
   HRReference *hrRef,
   OSType rendererType,
   WindowRef inWindowRef
);
```

Parameters

hrRef

A pointer to the new reference created and returned by the renderer.

rendererType

The type of the renderer—for example `kHRRendererHTML32Type`. Only this type is supported for now.

inWindowRef

A reference to the window for which rendering area will be specified.

Return Value

A result code. See "HTML Rendering Library Result Codes" (page 2597).

Discussion

All the controls created by the HTML renderer will be embedded in the root control of the window specified by the window reference.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability

Available in CarbonLib 1.3 and later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`HTMLRendering.h`

HRRegisterNewCFURLUPP

(Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
void HRRegisterNewCFURLUPP (
   HRNewCFURLUPP inURLUPP,
   HRReference hrRef,
   void *inRefCon
);
```

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very

quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability
Available in CarbonLib 1.3 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`HTMLRendering.h`

HRRegisterNewURLUPP

Registers an application-defined function that handles newly visited links. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
void HRRegisterNewURLUPP (
   HRNewURLUPP inNewURLUPP,
   HRReference hrRef,
   void *inRefCon
);
```

Parameters

inNewURLUPP
A Universal Procedure Pointer (UPP). You obtain this UPP by calling the function `NewHRNewURLUPP` (page 2586).

hrRef
An `HRReference` value previously obtained by your application.

inRefCon
An arbitrary value set by your application. This value is passed by your application when you call the `HRRegisterNewURLUPP` function and passed back when the HTML Rendering Library calls your function `HRNewURLProcPtr` (page 2589). You may find this value useful for referring to an object instance or a structure, for example.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability
Available in CarbonLib 1.1 and later when running Mac OS 9 or later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`HTMLRendering.h`

HRRegisterURLToFSRefUPP

(Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
void HRRegisterURLToFSRefUPP (
   HRURLToFSRefUPP inURLToFSRefUPP,
   HRReference hrRef,
   void *inRefCon
);
```

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability

Available in CarbonLib 1.3 and later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`HTMLRendering.h`

HRRegisterURLToFSSpecUPP

Registers an application-defined function that handles previously visited links. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
void HRRegisterURLToFSSpecUPP (
   HRURLToFSSpecUPP inURLToFSSpecUPP,
   HRReference hrRef,
   void *inRefCon
);
```

Parameters

inURLToFSSpecUPP

A Universal Procedure Pointer (UPP). You obtain this UPP by calling the function `NewHRURLToFSSpecUPP` (page 2587).

hrRef

An `HRReference` value previously obtained by your application.

inRefCon

An arbitrary value set by your application. This value is passed by your application when you call the `HRRegisterURLToFSSpecUPP` function and passed back when the HTML Rendering Library calls your function `HRURLToFSSpecProcPtr` (page 2591). You may find this value useful for referring to an object instance or a structure, for example.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very

quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability
Available in CarbonLib 1.1 and later when running Mac OS 9 or later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`HTMLRendering.h`

HRRegisterWasCFURLVisitedUPP

(Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
void HRRegisterWasCFURLVisitedUPP (
   HRWasCFURLVisitedUPP inWasCFURLVisitedUPP,
   HRReference hrRef,
   void *inRefCon
);
```

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability
Available in CarbonLib 1.3 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`HTMLRendering.h`

HRRegisterWasURLVisitedUPP

Registers an application-defined function that handles previously visited links. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
void HRRegisterWasURLVisitedUPP (
   HRWasURLVisitedUPP inWasURLVisitedUPP,
   HRReference hrRef,
   void *inRefCon
);
```

Parameters

inWasURLVisitedUPP

A Universal Procedure Pointer (UPP). You obtain this UPP by calling the function `NewHRWasURLVisitedUPP` (page 2588).

hrRef

An `HRReference` value previously obtained by your application.

inRefCon

An arbitrary value set by your application. This value is passed by your application when you call the function and passed back when the HTML Rendering Library calls your `MyHRWasURLVisitedProc` function. You may find this value useful for referring to an object instance or a structure, for example.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability

Available in CarbonLib 1.1 and later when running Mac OS 9 or later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`HTMLRendering.h`

HRScreenConfigurationChanged

Informs the HTML Rendering Library that the screen depth has changed. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
void HRScreenConfigurationChanged (
   void
);
```

Discussion

Call the `HRScreenConfigurationChanged` function every time the screen depth changes or the user's monitor configuration changes. This allows the HTML Rendering Library to redraw correctly.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability
Available in CarbonLib 1.1 and later when running Mac OS 9 or later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`HTMLRendering.h`

HRScrollToImageLocation32

Scrolls to a specified view of the HTML rendering area. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
OSStatus HRScrollToImageLocation32 (
   HRReference hrRef,
   SInt32 h,
   SInt32 v
);
```

Parameters

hrRef
A reference to the renderer object.

h
The horizontal location.

v
The vertical location.

Return Value
A result code. See "HTML Rendering Library Result Codes" (page 2597).

Discussion
Use this API when specifying a location to scroll to. Location is specified in image space.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability
Available in CarbonLib 1.3 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`HTMLRendering.h`

HRScrollToLocation

Scrolls to a specified view of the HTML rendering area. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
OSStatus HRScrollToLocation (
   HRReference hrRef,
   Point *location
);
```

Parameters

hrRef

An `HRReference` value previously obtained by your application.

location

A pointer to a value of type `Point`. Your application uses this value to specify the upper left corner of the visible portion of the rendering area.

Return Value

A result code. See "HTML Rendering Library Result Codes" (page 2597).

Discussion

The HTML Rendering Library limits scrolling to the available rendering area.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability

Available in CarbonLib 1.1 and later when running Mac OS 9 or later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`HTMLRendering.h`

HRSetDrawBorder

Specifies whether to draw a border around the rendering area. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
OSStatus HRSetDrawBorder (
   HRReference hrRef,
   Boolean drawBorder
);
```

Parameters

hrRef

An `HRReference` value previously obtained by your application.

drawBorder

If you pass `true`, the HTML Rendering Library draws a border around the rendering area. If you pass `false`, the HTML Rendering Library draws the rendering area without a border. The default setting is `false`.

Return Value
A result code. See "HTML Rendering Library Result Codes" (page 2597).

Discussion
You may use this optional function to specify whether a border is drawn around the rendering area. This might be useful when you specify a rendering area in a window containing other elements, for example. The default setting is to render without a border.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability
Available in CarbonLib 1.1 and later when running Mac OS 9 or later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`HTMLRendering.h`

HRSetEmbeddingControl

Sets the `ControlRef` for embedding controls. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
OSStatus HRSetEmbeddingControl (
   HRReference hrRef,
   ControlRef controlRef
);
```

Parameters

hrRef

A reference to the renderer object.

controlRef

All the future controls created by renderer are embedded in this `controlRef`.

Return Value
A result code. See "HTML Rendering Library Result Codes" (page 2597).

Discussion
Use this API to tell the HTML Renderer to embed all the controls it has created so far and the new controls it creates after this call in the given control. This is particularly useful if you wish to have HTML displayed within your dialog. For example, Software Update needs this.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability

Available in CarbonLib 1.3 and later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`HTMLRendering.h`

HRSetGrafPtr

Sets a new `GrafPort` for a given `HRReference`. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
OSStatus HRSetGrafPtr (
   HRReference hrRef,
   GrafPtr grafPtr
);
```

Parameters

hrRef

An `HRReference` value previously obtained by your application.

grafPtr

A pointer to a valid `GrafPort`. This value replaces any `GrafPort` previously specified for the given `HRReference`.

Return Value

A result code. See "HTML Rendering Library Result Codes" (page 2597).

Discussion

Call this function whenever the `GrafPort` changes for a given `HRReference`, as occurs during printing, for example. Be sure to call the `HRSetGrafPtr` function again to reset the original `GrafPort` when necessary.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability

Available in CarbonLib 1.1 and later when running Mac OS 9 or later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In
`HTMLRendering.h`

HRSetGrowboxCutout

Specifies whether to allow for a size box when drawing scrollbars. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
OSStatus HRSetGrowboxCutout (
   HRReference hrRef,
   Boolean allowCutout
);
```

Parameters

hrRef

An `HRReference` value previously obtained by your application.

allowCutout

If you pass `true` in this parameter, the HTML Rendering Library draws scroll bars that provide space for a size box. If you pass `false` in this parameter, the HTML Rendering Library draws scroll bars that extend all the way to the bottom right corner of the rendering area. The default setting is `false`.

Return Value
A result code. See "HTML Rendering Library Result Codes" (page 2597).

Discussion
You may find it useful to specify a cutout for a size box if the HTML rendering area you specify extends to the lower right corner of a window. The default setting is to draw scrollbars without leaving room for a size box.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability
Available in CarbonLib 1.1 and later when running Mac OS 9 or later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`HTMLRendering.h`

HRSetRenderingRect

Specifies the boundaries of the HTML rendering area. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
OSStatus HRSetRenderingRect (
   HRReference hrRef,
   const Rect *renderingRect
);
```

Parameters

hrRef

An `HRReference` value previously obtained by your application.

renderingRect

A pointer to a value of type `Rect`. This value specifies the boundaries of the HTML rendering area. Specify the boundaries in the `GrafPort's` port coordinates.

Return Value

A result code. See "HTML Rendering Library Result Codes" (page 2597).

Discussion

The HTML Rendering Library draws all elements, including scroll bars, inside the area you specify with the function `HRSetRenderingRect` (page 2571).

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability

Available in CarbonLib 1.1 and later when running Mac OS 9 or later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`HTMLRendering.h`

HRSetScrollbarState

Specifies how scrollbars are drawn. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
OSStatus HRSetScrollbarState (
   HRReference hrRef,
   HRScrollbarState hScrollbarState,
   HRScrollbarState vScrollbarState
);
```

Parameters

hrRef

An `HRReference` value previously obtained by your application.

hScrollbarState

A value of type `HRScrollbarState`. See Scrollbar State (page 2596) for a list of the constants you may pass in this parameter.

vScrollbarState
A value of type `HRScrollbarState`. See Scrollbar State (page 2596) for a list of the constants you may pass in this parameter.

Return Value
A result code. See "HTML Rendering Library Result Codes" (page 2597).

Discussion
You can specify one of three values for scrollbars:

- `eHRScrollbarOn` tells the HTML Rendering Library to draw scrollbars at all times. If the data does not fill the current view, the scroll bars are inactive.
- `eHRScrollbarOff` tells the HTML Rendering Library never to draw scrollbars. You may find this option useful if the HTML rendering area you specify does not extend to the edge of a window.
- `eHRScrollbarAuto` tells the HTML Rendering Library to draw scrollbars as needed. This is the default setting.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability
Available in CarbonLib 1.1 and later when running Mac OS 9 or later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`HTMLRendering.h`

HRSetWindowRef

Sets the controlling window. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
OSStatus HRSetWindowRef (
   HRReference hrRef,
   WindowRef windowRef
);
```

Parameters

hrRef
A reference to the renderer object.

windowRef
A new reference to the window to be attached to the `hrRef`.

Return Value
A result code. See "HTML Rendering Library Result Codes" (page 2597).

Discussion
All the controls created by the HTML renderer will be moved in the root control of the window specified by the window reference. All the drawing will now happen in the specified window.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability
Available in CarbonLib 1.3 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`HTMLRendering.h`

HRUnregisterNewCFURLUPP

(Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
void HRUnregisterNewCFURLUPP (
   HRReference hrRef
);
```

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability
Available in CarbonLib 1.3 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`HTMLRendering.h`

HRUnregisterNewURLUPP

Unregisters a previously registered application-defined function. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
void HRUnregisterNewURLUPP (
   HRReference hrRef
);
```

Parameters

hrRef

An `HRReference` value. You pass the same `HRReference` value that you passed to register the application-defined function.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability

Available in CarbonLib 1.1 and later when running Mac OS 9 or later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`HTMLRendering.h`

HRUnregisterURLToFSRefUPP

(Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
void HRUnregisterURLToFSRefUPP (
   HRReference hrRef
);
```

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability

Available in CarbonLib 1.3 and later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`HTMLRendering.h`

HRUnregisterURLToFSSpecUPP

Unregisters a previously registered application-defined function. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
void HRUnregisterURLToFSSpecUPP (
   HRReference hrRef
);
```

Parameters

hrRef

An `HRReference` value. You pass the same `HRReference` value that you passed to register the application-defined function.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability

Available in CarbonLib 1.1 and later when running Mac OS 9 or later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`HTMLRendering.h`

HRUnregisterWasCFURLVisitedUPP

(Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
void HRUnregisterWasCFURLVisitedUPP (
   HRReference hrRef
);
```

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability

Available in CarbonLib 1.3 and later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`HTMLRendering.h`

HRUnregisterWasURLVisitedUPP

Unregisters a previously registered application-defined function. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
void HRUnregisterWasURLVisitedUPP (
   HRReference hrRef
);
```

Parameters

hrRef

An `HRReference` value. You pass the same `HRReference` value that you passed to register the application-defined function.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability

Available in CarbonLib 1.1 and later when running Mac OS 9 or later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`HTMLRendering.h`

HRUtilCreateFullCFURL

Obtains a full URL from a given set of relative URLs. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
OSStatus HRUtilCreateFullCFURL (
   CFStringRef rootString,
   CFStringRef linkString,
   CFURLRef *url
);
```

Parameters

rootString

A `CFStringRef` that refers to a `CFString` containing the root URL that the HTML Rendering Library will use to create the full URL. The root URL typically identifies an HTML source page.

linkString

A `CFStringRef` that refers to a `CFString` containing the link URL that the HTML Rendering Library will use to create the full URL. The link URL typically identifies a link being clicked on.

url

A `CFURLRef`. On return, this handle references a full URL created from the specified root URL and the specified link URL.

Return Value

A result code. See "HTML Rendering Library Result Codes" (page 2597).

Discussion

Use these API from a Carbon application instead of using `HRUtilCreateFullURL` (page 2578), `HRUtilGetFSSpecFromURL` (page 2580), and `HRUtilGetURLFromFSSpec` (page 2581). These APIs are same in behavior with their old counter parts. The only difference is that they take `CFURLRef`, and `FSRef` as parameters.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability

Available in CarbonLib 1.3 and later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`HTMLRendering.h`

HRUtilCreateFullURL

Obtains a full URL from a given set of relative URLs. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
OSStatus HRUtilCreateFullURL (
   const char *rootURL,
   const char *linkURL,
   Handle fullURLH
);
```

Parameters

rootURL

A pointer to a C string containing the root URL that the HTML Rendering Library will use to create the full URL. The root URL typically identifies an HTML source page.

linkURL

A pointer to a C string containing the link URL that the HTML Rendering Library will use to create the full URL. The link URL typically identifies a link being clicked on.

fullURLH

A handle. On return, this handle references a full URL created from the specified root URL and the specified link URL. You must allocate this handle with the function `NewHandle` before calling `HRUtilCreateFullURL`. The HTML Rendering Library resizes the handle and terminates the C string with a `NULL` character.

Return Value

A result code. See "HTML Rendering Library Result Codes" (page 2597).

Discussion

This function allows you to obtain a full URL to use when a relative URL is inappropriate. This might be useful when you need to pass a URL to another application, for example.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability

Available in CarbonLib 1.1 and later when running Mac OS 9 or later.

Available in Mac OS X 10.0 and later.

Deprecated in Mac OS X v10.4.

Declared In

`HTMLRendering.h`

HRUtilGetFSRefFromURL

Obtains a `FSRef` from a given set of relative URL's. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
OSStatus HRUtilGetFSRefFromURL (
   CFStringRef rootString,
   CFStringRef linkString,
   FSRef *destRef
);
```

Parameters

rootString

A reference to a `CFString` containing the root URL that the HTML Rendering Library will use to create the full URL. The root URL typically identifies an HTML source page.

linkString

A reference to a `CFString` containing the link URL that the HTML Rendering Library will use to create the full URL. The link URL typically identifies a link being clicked on.

destRef

A pointer to a `FSRef`. On return, this points to the `FSRef` of the full URL calculated from the specified root url and the specified link URL.

Return Value

A result code. See "HTML Rendering Library Result Codes" (page 2597).

Discussion

Use these API from a Carbon application instead of using `HRUtilCreateFullURL` (page 2578), `HRUtilGetFSSpecFromURL` (page 2580), and `HRUtilGetURLFromFSSpec` (page 2581). These APIs are same in behavior with their old counter parts. The only difference is that they take `CFURLRef`, and `FSRef` as parameters.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very

quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability
Available in CarbonLib 1.3 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`HTMLRendering.h`

HRUtilGetFSSpecFromURL

Obtains a `FSSpec` from a given set of relative URL's. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
OSStatus HRUtilGetFSSpecFromURL (
   const char *rootURL,
   const char *linkURL,
   FSSpec *destSpec
);
```

Parameters

rootURL
A pointer to a C string containing the root URL that the HTML Rendering Library will use to create the full URL. The root URL typically identifies an HTML source page.

linkURL
A pointer to a C string containing the link URL that the HTML Rendering Library will use to create the full URL. The link URL typically identifies a link being clicked on.

destSpec
A pointer to a file system specification record (`FSSpec`). On return, this points to the `FSSPec` of the full URL calculated from the specified root url and the specified link URL.

Return Value
A result code. See "HTML Rendering Library Result Codes" (page 2597).

Discussion
This function allows you to obtain an `FSSpec` to use when a relative URL is inappropriate. This might be useful for Apple events, for example

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability

Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
HTMLRendering.h

HRUtilGetURLFromFSRef

Obtains a full URL from a given FSRef. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
OSStatus HRUtilGetURLFromFSRef (
   const FSRef *fileRef,
   CFURLRef *url
);
```

Parameters

fileRef

A pointer to an existing FSRef.

url

A pointer to a CFURLRef. On return, the CFURL contains the URL of the given FSSpec.

Return Value
A result code. See "HTML Rendering Library Result Codes" (page 2597).

Discussion
Use these API from a Carbon application instead of using HRUtilCreateFullURL (page 2578), HRUtilGetFSSpecFromURL (page 2580), and HRUtilGetURLFromFSSpec (page 2581). These APIs are same in behavior with their old counter parts. The only difference is that they take CFURLRef, and FSRef as parameters.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Availability
Available in CarbonLib 1.3 and later.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
HTMLRendering.h

HRUtilGetURLFromFSSpec

Obtains a full URL from a given FSSpec. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
OSStatus HRUtilGetURLFromFSSpec (
   const FSSpec *fsspec,
   Handle urlHandle
);
```

Parameters

fsspec

A pointer to an existing file system specification record (`FSSpec`).

urlHandle

A handle to a C string. On return, this C string contains the URL of the given `FSSpec`. You must allocate this handle with the function `NewHandle` before calling `HRUtilGetURLFromFSSpec`. The HTML Rendering Library resizes the handle and terminates the C string with a `NULL` character.

Return Value

A result code. See "HTML Rendering Library Result Codes" (page 2597).

Discussion

This function allows you to obtain a URL from a given `FSSpec`. This might be useful when you have previously obtained an `FSSpec` and need to pass it to an application that requires URL data, for example.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

HTMLRendering.h

NewHRNewURLUPP

Obtains a UPP for an application-defined function that handles newly visited links. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
HRNewURLUPP NewHRNewURLUPP (
   HRNewURLProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your application-defined function that handles newly visited links. For more information, see `HRNewURLProcPtr` (page 2589).

Return Value

A Universal Procedure Pointer. You pass this pointer to the function `HRRegisterNewURLUPP` (page 2563). See the description of the `HRNewURLUPP` data type.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

HTMLRendering.h

NewHRURLToFSSpecUPP

Obtains a UPP for an application-defined function that intercepts URL's. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
HRURLToFSSpecUPP NewHRURLToFSSpecUPP (
   HRURLToFSSpecProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your application-defined function that intercepts URL's. For more information, see the function HRURLToFSSpecProcPtr (page 2591).

Return Value
A Universal Procedure Pointer. You pass this pointer to the function HRRegisterURLToFSSpecUPP (page 2564). See the description of the HRURLToFSSpecUPP data type.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Although the Web Kit is an Objective-C interface, you can call it from a Carbon application. See Accessing the Web Kit From Carbon Applications for details.

Declared In
`HTMLRendering.h`

NewHRWasURLVisitedUPP

Obtains a UPP for an application-defined function that handles previously visited links. (Deprecated in Mac OS X v10.4. Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
HRWasURLVisitedUPP NewHRWasURLVisitedUPP (
   HRWasURLVisitedProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your application-defined function that handles visited links. For more information, see the function `HRWasURLVisitedProcPtr` (page 2593).

Return Value
A Universal Procedure Pointer. You pass this pointer to the function `HRRegisterWasURLVisitedUPP` (page 2565). See the description of the `HRWasURLVisitedUPP` data type.

Special Considerations

Because the Web Kit takes a completely different approach to displaying HTML and web content from that used by the HTML Rendering Library, you cannot make a one-to-one substitution of Web Kit methods for HTML Rendering Library functions. However, the basic features of the Web Kit can be implemented very quickly, and Web Kit offers much greater capability than the HTML Rendering Library. Declared In
`HTMLRendering.h`

Callbacks

HRNewCFURLProcPtr

(**Deprecated.** Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
typedef OSStatus (*HRNewCFURLProcPtr)
(
    CFURLRef url,
    CFStringRef targetString,
    Boolean addToHistory,
    void * refCon
);
```

If you name your function `MyHRNewCFURLProc`, you would declare it like this:

```
OSStatus MyHRNewCFURLProc (
    CFURLRef url,
    CFStringRef targetString,
    Boolean addToHistory,
    void * refCon
);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`HTMLRendering.h`

HRNewURLProcPtr

An application-defined function that tracks newly visited links. (**Deprecated.** Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
typedef OSStatus (*HRNewURLProcPtr) (
    const char * url,
    const char * targetFrame,
    Boolean addToHistory,
    void * refCon
);
```

If you name your function `MyHRNewURLProc`, you would declare it like this:

```
OSStatus MyHRNewURLProc (
    const char * url,
    const char * targetFrame,
    Boolean addToHistory,
    void * refCon
);
```

Parameters

`url`
A pointer to a C string containing the URL of the link.

`targetFrame`
A pointer to a C string containing the name of the target frame.

`addToHistory`
The HTML Rendering Library passes `true` in this parameter to indicate that you should add this link to a link-tracking history. It is up to your application to do any link-tracking.

refCon

An arbitrary value set by your application. This value is passed by your application when you call the function `HRRegisterNewURLUPP` (page 2563) and passed back when the HTML Rendering Library calls your `MyNewURLProc` function. You may find this value useful for referring to an object instance or a structure, for example.

Return Value
A result code. See "HTML Rendering Library Result Codes" (page 2597).

Discussion
You may find this function useful for maintaining a history list, for example. The sequence of steps required to implement an application-defined function to track visited links is as follows:

1. Obtain a UPP for your application-defined function by calling the function `NewHRNewURLUPP` (page 2586).
2. Register your application-defined function by passing the UPP to the function `HRRegisterNewURLUPP` (page 2563).
3. When the HTML Rendering Library calls your application-defined function, take note of the URL being visited.

When you are done using your application-defined function:

1. Unregister your application-defined function by calling the function `HRUnregisterNewURLUPP` (page 2574).
2. Dispose of the UPP by calling the function `DisposeHRNewURLUPP` (page 2534).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`HTMLRendering.h`

HRURLToFSRefProcPtr

(**Deprecated.** Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
typedef OSStatus (*HRURLToFSRefProcPtr)
(
    CFStringRef rootString,
    CFStringRef linkString,
    FSRef * fref,
    URLSourceType urlSourceType,
    void * refCon
);
```

If you name your function `MyHRURLToFSRefProc`, you would declare it like this:

```
OSStatus MyHRURLToFSRefProc (
    CFStringRef rootString,
    CFStringRef linkString,
    FSRef * fref,
    URLSourceType urlSourceType,
```

```
    void * refCon
);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`HTMLRendering.h`

HRURLToFSSpecProcPtr

Converts URL data to a file system specification. (**Deprecated.** Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
typedef OSStatus (*HRURLToFSSpecProcPtr)
(
    const char * rootURL,
    const char * linkURL,
    FSSpec * fsspec,
    URLSourceType urlSourceType,
    void * refCon
);
```

If you name your function `MyHRURLToFSSpecProc`, you would declare it like this:

```
OSStatus MyHRURLToFSSpecProc (
    const char * rootURL,
    const char * linkURL,
    FSSpec * fsspec,
    URLSourceType urlSourceType,
    void * refCon
);
```

Parameters

rootURL
A pointer to a C string containing the root URL of the file to be loaded.

linkURL
A pointer to a C string containing the link URL of the file to be loaded.

fsspec
A pointer to a file system specification record (`FSSpec`) that you use to specify the file to which the HTML Rendering Library redirects the user.

urlSourceType

The HTML Rendering Library passes one of the following constants to indicate the type of file being searched for:

- `kHRLookingForHTMLSource` indicates that the file is an HTML source document.
- `kHRLookingForImage` indicates that the file is an image.
- `kHRLookingForEmbedded` indicates that the file is an embedded object, such as a QuickTime movie.
- `kHRLookingForImageMap` indicates that the file is an HTML image map.
- `kHRLookingForFrame` indicates that the file is an HTML frameset.

refCon

An arbitrary value set by your application. This value is passed by your application when you call the function and passed back when the HTML Rendering Library calls your `MyHRURLToFSSpecProc` function. You may find this value useful for referring to an object instance or a structure, for example.

Return Value
A result code. See "HTML Rendering Library Result Codes" (page 2597).

Discussion
This function may be useful if you want to redirect certain URL's to application-specific files, for example. The sequence of steps required to implement an application-defined function to intercept URL's is as follows:

1. Obtain a UPP for your application-defined function by calling the function `NewHRURLToFSSpecUPP` (page 2587).
2. Register your application-defined function by passing the UPP to the function `HRRegisterURLToFSSpecUPP` (page 2564).
3. Respond when the HTML Rendering Library calls your application-defined function.

When you are done with your application-defined function:

1. Unregister your application-defined function by calling the function `HRUnregisterURLToFSSpecUPP` (page 2576).
2. Dispose of the UPP by calling the function `DisposeHRURLToFSSpecUPP` (page 2535).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`HTMLRendering.h`

HRWasCFURLVisitedProcPtr

(**Deprecated.** Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
typedef Boolean (*HRWasCFURLVisitedProcPtr)
(
    CFURLRef url,
    void * refCon
);
```

If you name your function `MyHRWasCFURLVisitedProc`, you would declare it like this:

```
Boolean MyHRWasCFURLVisitedProc (
    CFURLRef url,
    void * refCon
);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`HTMLRendering.h`

HRWasURLVisitedProcPtr

Keeps track of whether a given URL has been previously visited. (**Deprecated.** Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
typedef Boolean (*HRWasURLVisitedProcPtr)
(
    const char * url,
    void * refCon
);
```

If you name your function `MyHRWasURLVisitedProc`, you would declare it like this:

```
Boolean MyHRWasURLVisitedProc (
    const char * url,
    void * refCon
);
```

Parameters

`url`

A pointer to a C string containing the URL of the link.

`refCon`

An arbitrary value set by your application. This value is passed by your application when you call the function and passed back when the HTML Rendering Library calls your `MyHRWasURLVisitedProc` function. You may find this value useful for referring to an object instance or a structure, for example.

Return Value
If the given URL was previously visited, your application-defined function should return `true`. If the given URL was not previously visited, your application-defined function should return `false`.

Discussion
The sequence of steps required to implement an application-defined function to handle previously visited links is as follows:

1. Obtain a UPP for your application-defined function by calling the function `NewHRWasURLVisitedUPP` (page 2588).
2. Register your application-defined function by passing the UPP to the function `HRRegisterWasURLVisitedUPP` (page 2565).
3. Respond when the HTML Rendering Library calls your application-defined function.

When you are done using your application-defined function:

1. Unregister your application-defined function by calling the function `HRUnregisterWasURLVisitedUPP` (page 2577).
2. Dispose of the UPP by calling the function `DisposeHRWasURLVisitedUPP` (page 2536).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`HTMLRendering.h`

(**Deprecated.** Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
typedef HRWasCFURLVisitedProcPtr HRWasCFURLVisitedUPP;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`HTMLRendering.h`

HRWasURLVisitedUPP

(**Deprecated.** Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
typedef HRWasURLVisitedProcPtr HRWasURLVisitedUPP;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`HTMLRendering.h`

Constants

Scrollbar State

(**Deprecated.** Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
typedef SInt16 HRScrollbarState;
enum {
    eHRScrollbarOn = 0,
    eHRScrollbarOff = 1,
    eHRScrollbarAuto = 2
};
```

Constants

`eHRScrollbarOn`
Tells the HTML Rendering Library to draw scrollbars at all times. If the data does not fill the current view, the scroll bars are inactive.

Available in Mac OS X v10.0 and later.

Declared in `HTMLRendering.h`.

`eHRScrollbarOff`
Tells the HTML Rendering Library never to draw scrollbars. You may find this option useful if the HTML rendering area you specify does not extend to the edge of a window.

Available in Mac OS X v10.0 and later.

Declared in `HTMLRendering.h`.

`eHRScrollbarAuto`
Tells the HTML Rendering Library to draw scrollbars as needed. This is the default setting.

Available in Mac OS X v10.0 and later.

Declared in `HTMLRendering.h`.

Renderer HTML Type

(**Deprecated.** Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
enum {
    kHRRendererHTML32Type = 'ht32'
};
```

URL Source Type

(**Deprecated.** Use Web Kit instead; see *WebKit Objective-C Programming Guide*.Use Web Kit instead; see *WebKit Objective-C Programming Guide*.)

```
typedef UInt16 URLSourceType;
enum {
    kHRLookingForHTMLSource = 1,
    kHRLookingForImage = 2,
    kHRLookingForEmbedded = 3,
    kHRLookingForImageMap = 4,
    kHRLookingForFrame = 5
};
```

Constants

`kHRLookingForHTMLSource`
Indicates that the file is an HTML source document.
Available in Mac OS X v10.0 and later.
Declared in `HTMLRendering.h`.

`kHRLookingForImage`
Indicates that the file is an image.
Available in Mac OS X v10.0 and later.
Declared in `HTMLRendering.h`.

`kHRLookingForEmbedded`
Indicates that the file is an embedded object, such as a QuickTime movie.
Available in Mac OS X v10.0 and later.
Declared in `HTMLRendering.h`.

`kHRLookingForImageMap`
Indicates that the file is an HTML image map.
Available in Mac OS X v10.0 and later.
Declared in `HTMLRendering.h`.

`kHRLookingForFrame`
Indicates that the file is an HTML frameset.
Available in Mac OS X v10.0 and later.
Declared in `HTMLRendering.h`.

Result Codes

The most common result codes returned by HTML Rendering Library are listed in the table below. HTML Rendering Library may also return codes `noErr` (0), and `paramErr` (-50).

Result Code	Value	Description
`hrHTMLRenderingLibNotInstalledErr`	-5360	The HTML Rendering Library is not available. Available in Mac OS X v10.0 and later.
`hrMiscellaneousExceptionErr`	-5361	An unexpected exception occurred. Available in Mac OS X v10.0 and later.
`hrUnableToResizeHandleErr`	-5362	Unable to resize a handle to the required size. Available in Mac OS X v10.0 and later.

Multilingual Text Engine Reference

Framework: Carbon/Carbon.h

Declared in MacTextEditor.h

Overview

Multilingual Text Engine (MLTE) is an API that allows your application to provide Carbon-compliant Unicode text editing. This document is relevant for anyone who is writing an application that needs to display static Unicode text or provide Unicode-compliant text editing fields. You can also use MLTE if your application provides text editing support within a full-size window. For more information about basic text processing and using MLTE, see the document "Handling Unicode Text Editing with MLTE."

Carbon fully supports the Multilingual Text Engine, and Apple recommends that you adopt Multilingual Text Engine as a replacement for TextEdit.

Functions by Task

Displaying Static Text

`TXNDrawUnicodeTextBox` (page 2639)
Draws a Unicode string in the specified rectangle.

`TXNDrawCFStringTextBox` (page 2637)
Draws text from a Core Foundation string (`CFString`) in the specified rectangle.

Initializing and Terminating MLTE

`TXNInitTextension` (page 2662)
Initializes MLTE.

`TXNVersionInformation` (page 2698)
Gets the version number of MLTE and the set of features in this version.

Working With MLTE Objects

`TXNCreateObject` (page 2630)
Creates a new MLTE text object which is an opaque structure that handles text formatting at the document level.

`TXNGetAccessibilityHIObject` (page 2645)
Obtains an `HIObjectRef` representing the MLTE object for accessibility purposes.

`TXNDeleteObject` (page 2632)
Deletes a previously allocated text object.

`TXNDataSize` (page 2632)
Reports the amount of memory used to hold the text in a given text object.

`TXNAttachObjectToWindowRef` (page 2620)
Attaches a text object to a window.

`TXNGetWindowRef` (page 2660)
Returns a reference to the window to which the specified text object is attached.

Responding to Events

`TXNGetEventTarget` (page 2651)
Obtains the current event target for a TXNObject.

`TXNSetEventTarget` (page 2686)
Sets a Carbon Event target for MLTE Carbon Event handlers.

`TXNGetCommandEventSupport` (page 2647)
Obtains the command event support that is currently set for an MLTE object.

`TXNSetCommandEventSupport` (page 2681)
Enables and disables support for menu commands in MLTE.

`TXNAdjustCursor` (page 2619)
Obtains the current cursor position and draws the cursor in a form appropriate to the content over which it is placed.

`TXNClick` (page 2626)
Processes a mouse-down event in a window's content area.

`TXNEchoMode` (page 2640)
Determines whether a specified character is drawn instead of the glyph associated with the input character.

`TXNFocus` (page 2644)
Changes the focus of a text object.

`TXNForceUpdate` (page 2644)
Forces an update of the view rectangle and the scroll bars.

`TXNGetSleepTicks` (page 2658)
Reports the appropriate amount of time to allot to background processes, depending on the state of the window.

`TXNIdle` (page 2662)
Does idle time processing, such as flashing the cursor.

`TXNKeyDown` (page 2666)
Processes a key-down event.

`TXNUpdate` (page 2698)
Redraws everything in a frame in response to an update event.

`TXNScroll` (page 2679)
Scrolls the text within a view rectangle of the specified text object.

`TXNRegisterScrollInfoProc` (page 2675)
Installs or uninstalls a scrolling callback function on a text object.

Working With HITextView

`HITextViewCreate` (page 2610)
Creates an HITextView that is initially invisible.

`HITextViewGetTXNObject` (page 2611)
Obtains the text object associated with an HITextView.

`HITextViewCopyBackgroundColor` (page 2610)
Obtains the background color of the view.

`HITextViewSetBackgroundColor` (page 2612)
Sets the background color of the view.

Editing Data

`TXNDrawObject` (page 2638)
Draws a text object in the last window set by your application.

`TXNClear` (page 2624)
Deletes the current selection.

`TXNCopy` (page 2628)
Copies the current selection to the private MLTE scrap.

`TXNCut` (page 2631)
Deletes the current selection and copies it to the private MLTE scrap.

`TXNIsScrapPastable` (page 2665)
Tests whether the Clipboard contains data that is supported by MLTE.

`TXNPaste` (page 2671)
Pastes the contents of the private MLTE scrap into the text object.

`TXNGetData` (page 2649)
Copies a range of data.

`TXNGetDataEncoded` (page 2650)
Copies the text in a specified range, and if necessary, translates the text to match your application's preferred encoding.

`TXNSetData` (page 2683)
Replaces a range of data (text, graphics, and so forth).

`TXNCanRedoAction` (page 2622)
Indicates whether an action can be redone.

`TXNRedo` (page 2675)
Redoes the last command.

`TXNCanUndoAction` (page 2624)
Indicates whether an action can be undone.

`TXNUndo` (page 2697)
Undoes the last command.

Managing Fonts and Font Menus

`TXNCountRunsInRange` (page 2629)
Obtains a count of the style runs in a range of data.

`TXNGetIndexedRunInfoFromRange` (page 2654)
Gets information about a run in a range of data.

`TXNSetTypeAttributes` (page 2694)
Sets text attributes (such as size and style) for the current selection or the text defined by a range you specify.

`TXNGetContinuousTypeAttributes` (page 2648)
Checks to see if the attributes of the current selection are continuous.

`TXNDisposeFontMenuObject` (page 2633) Deprecated in Mac OS X v10.5
Disposes of a Font menu object.

`TXNDoFontMenuSelection` (page 2633) Deprecated in Mac OS X v10.5
Changes the font of the current selection.

`TXNGetFontMenuHandle` (page 2653) Deprecated in Mac OS X v10.5
Gets the Font menu handle that belongs to a Font menu object.

`TXNNewFontMenuObject` (page 2666) Deprecated in Mac OS X v10.5
Creates a new Font menu object.

`TXNPrepareFontMenu` (page 2672) Deprecated in Mac OS X v10.5
Prepares a Font menu for display.

`TXNGetFontDefaults` (page 2652) Deprecated in Mac OS X v10.4
Makes a copy of the font descriptions for a given text object.

`TXNSetFontDefaults` (page 2688) Deprecated in Mac OS X v10.4
Specifies the font descriptions for each script used in a text object.

Managing Layout and Formatting

`TXNRecalcTextLayout` (page 2675)
Recalculates the text layout based on new view and destination rectangles.

`TXNSetTXNObjectControls` (page 2693)
Sets formatting and privileges attributes (such as justification, line direction, tab values, and read-only status) that apply to the entire text object.

`TXNGetTXNObjectControls` (page 2659)
Gets the current formatting and privileges attributes (such as justification, line direction, tab values, and read-only status) for a text object.

`TXNGetLineCount` (page 2656)
Gets the total number of lines in a text object.

`TXNGetLineMetrics` (page 2656)
Gets information about line width and height for a specified line of data in a text object.

`TXNHIPointToOffset` (page 2661)
Gets the offset value that corresponds to a point in local coordinates.

`TXNOffsetToHIPoint` (page 2670)
Obtains the local coordinates of the point that corresponds to a specified offset of a text object.

Managing Selections

`TXNGetSelection` (page 2658)
Gets the absolute offsets of the current selection.

`TXNIsSelectionEmpty` (page 2665)
Determines whether the current selection is empty.

`TXNSelectAll` (page 2680)
Selects all data in the frame of a text object.

`TXNSetSelection` (page 2692)
Specifies the selection range or the position of the insertion point.

`TXNShowSelection` (page 2696)
Scrolls the current selection into view.

Controlling the Frame and Window

`TXNGetViewRect` (page 2660)
Gets the rectangle that describes the current view of the document.

`TXNGrowWindow` (page 2661)
Adjusts the size of a window in response to mouse-down events in the size region of the window.

`TXNResizeFrame` (page 2676)
Resizes the view and destination rectangles.

`TXNSetBackground` (page 2681)
Sets the background on which the text object's data is drawn.

`TXNSetFrameBounds` (page 2688)
Changes the boundaries of a text object's frame.

`TXNZoomWindow` (page 2700)
Increases the size of the data displayed in a window in response to a click in the zoom box.

`TXNSetHIRectBounds` (page 2689)
Sets the view rectangle and/or the destination rectangle.

`TXNGetHIRect` (page 2653)
Obtains the values for the current view, destination, or text rectangle.

`TXNSetScrollbarState` (page 2691)
Sets the state of the scroll bars so they are drawn correctly in response to activate events.

Searching

`TXNFind` (page 2641)
Finds a piece of text or a graphics, sound, or movie object.

Managing Files

`TXNFlattenObjectToCFDataRef` (page 2643)
Flattens a text object so it can be saved to disk or embedded with other data.

`TXNRevert` (page 2677)
Reverts to the last saved version of a document.

`TXNReadFromCFURL` (page 2673)
Reads data from a `CFURLRef` into a TXNObject.

`TXNCopyTypeIdentifiersForRange` (page 2628)
Obtains an array of universal type identifiers for a TXNObject.

`TXNWriteRangeToCFURL` (page 2699)
Writes a range of a text object to a file or to a special file bundle.

Printing

`TXNPageSetup` (page 2671)
Displays the Page Setup dialog for the current default printer and manages changes, such as reformatting the text, in response to page layout changes.

`TXNPrint` (page 2673)
Prints the document so it is formatted to fit the page size selected for the printer.

Supporting Drag and Drop

`TXNDragReceiver` (page 2634)
Handles dragged data in a text object for which a custom drag handler is already in place.

`TXNDragTracker` (page 2635)
Handles tracking a drag event in a text object for which a custom drag handler is already in place.

Keeping Track of User Actions

`TXNGetChangeCount` (page 2647)
Retrieves the number of times a document has been changed.

`TXNGetCountForActionType` (page 2649)
Gets the number of times a given type of action has occurred.

`TXNClearCountForActionType` (page 2626)
Sets the counter for the specified action type to zero.

`TXNBeginActionGroup` (page 2621)
Starts an action group.

`TXNEndActionGroup` (page 2641)
Ends an action group.

`TXNSetActionNameMapper` (page 2680)
Sets a callback that MLTE uses to obtain the localized string representing an action or an action group.

Managing Spell Checking As You Type

`TXNGetSpellCheckAsYouType` (page 2659)
Determines whether the "Spell Check as You Type" feature is enabled.

`TXNSetSpellCheckAsYouType` (page 2693)
Enables and disables the "Spell Check as You Type" feature.

Working with the Contextual Menu

`TXNSetContextualMenuSetup` (page 2682)
Provides a callback function that is called before MLTE displays its contextual menu.

Working With UPP Pointers for MLTE Callback Functions

`NewTXNActionNameMapperUPP` (page 2616)
Creates a new universal procedure pointer (UPP) to an action name mapper callback function.

`InvokeTXNActionNameMapperUPP` (page 2613)
Calls your action name mapper callback function.

`DisposeTXNActionNameMapperUPP` (page 2608)
Disposes of the universal procedure pointer (UPP) to your action name mapper callback function.

`NewTXNContextualMenuSetupUPP` (page 2616)
Creates a new universal procedure pointer (UPP) to a contextual menu setup callback function.

`InvokeTXNContextualMenuSetupUPP` (page 2614)
Calls your contextual menu setup callback function.

`DisposeTXNContextualMenuSetupUPP` (page 2608)
Disposes of the universal procedure pointer (UPP) to your contextual menu setup callback function.

`NewTXNFindUPP` (page 2617)
Creates a new universal procedure pointer (UPP) to a find callback function that uses your criteria for matching.

`InvokeTXNFindUPP` (page 2614)
Calls your find callback function.

`DisposeTXNFindUPP` (page 2609)
Disposes of the universal procedure pointer (UPP) to your find callback function.

`NewTXNScrollInfoUPP` (page 2617)
Creates a new universal procedure pointer (UPP) to a scrolling callback function.

`InvokeTXNScrollInfoUPP` (page 2615)
Calls your scrolling callback function.

`DisposeTXNScrollInfoUPP` (page 2609)
Disposes of the universal procedure pointer (UPP) to your scrolling callback function.

Not Recommended

This section lists functions that are not recommended and you should no longer use. The Carbon Porting Notes for each function provide information on what you should do in place of using the function.

`TXNActivate` (page 2618) Deprecated in Mac OS X v10.3
Sets the state of the scroll bars so they are drawn correctly in response to activate events. (Deprecated. Use `TXNSetScrollbarState` (page 2691) instead.)

`TXNAttachObjectToWindow` (page 2620) Deprecated in Mac OS X v10.3
Attaches a text object to a window. (Deprecated. Use `TXNAttachObjectToWindowRef` (page 2620) instead.)

`TXNConvertFromPublicScrap` (page 2627) Deprecated in Mac OS X v10.3
Converts the Clipboard content to the private MLTE scrap. (Deprecated. This function isn't needed in Mac OS X.)

`TXNConvertToPublicScrap` (page 2627) Deprecated in Mac OS X v10.3
Converts the private MLTE scrap content to the Clipboard. (Deprecated. This function isn't needed in Mac OS X.)

`TXNDraw` (page 2636) Deprecated in Mac OS X v10.3
Redraws the text area, including any scroll bars associated with the text frame. (Deprecated. Use the `TXNDrawObject` (page 2638).)

`TXNGetRectBounds` (page 2657) Deprecated in Mac OS X v10.3
Obtains the values for the current view, destination, and text rectangles. (Deprecated. Use `TXNGetHIRect` (page 2653) instead.)

`TXNIsObjectAttachedToSpecificWindow` (page 2663) Deprecated in Mac OS X v10.3
Determines whether a text object is attached to a specified window. (Deprecated. Use `TXNGetWindowRef` (page 2660) instead.)

`TXNIsObjectAttachedToWindow` (page 2664) Deprecated in Mac OS X v10.3
Checks to see if a text object is attached to a window. (Deprecated. Use `TXNGetWindowRef` (page 2660) instead.)

`TXNNewObject` (page 2667) Deprecated in Mac OS X v10.3
Creates a new MLTE text object which is an opaque structure that handles text formatting at the document level. (Deprecated. Use `TXNCreateObject` (page 2630) instead.)

`TXNOffsetToPoint` (page 2670) Deprecated in Mac OS X v10.3
Gets the local coordinates of the point that corresponds to a specified offset of a text object. (Deprecated. Use `TXNOffsetToHIPoint` (page 2670) instead.)

`TXNPointToOffset` (page 2672) Deprecated in Mac OS X v10.3
Gets the offset value that corresponds to a point in local coordinates. (Deprecated. Use `TXNHIPointToOffset` (page 2661) instead.)

`TXNSetDataFromFile` (page 2685) Deprecated in Mac OS X v10.3
Replaces a range of data with the contents of a file. (Deprecated. Use `TXNSetDataFromCFURLRef` (page 2684) instead.)

`TXNSetRectBounds` (page 2690) Deprecated in Mac OS X v10.3
Set the view rectangle and/or the destination rectangle. (Deprecated. Use `TXNSetHIRectBounds` (page 2689) instead.)

`TXNTerminateTextension` (page 2696) Deprecated in Mac OS X v10.3
Closes the MLTE library. (Deprecated. This function is no longer needed.)

`TXNSetViewRect` (page 2695) Deprecated in Mac OS X v10.2
Sets the rectangle that describes the current view into the document; changes the amount of text that is viewable. (Deprecated. Use `TXNSetFrameBounds` (page 2688) or `TXNSetRectBounds` (page 2690) instead.)

`DisposeTXNActionKeyMapperUPP` (page 2608) Deprecated in Mac OS X v10.4
Disposes of the universal procedure pointer (UPP) to your action key mapping callback function. (Deprecated. Use `TXNActionNameMapperProcPtr` instead.)

`InvokeTXNActionKeyMapperUPP` (page 2613) Deprecated in Mac OS X v10.4
Calls your action key mapping callback function. (Deprecated. Use `TXNActionNameMapperProcPtr` instead.)

`NewTXNActionKeyMapperUPP` (page 2616) Deprecated in Mac OS X v10.4
Creates a new universal procedure pointer (UPP) to a callback function that uses your criteria for mapping actions. (Deprecated. Use `TXNActionNameMapperProcPtr` instead.)

`TXNCanRedo` (page 2622) Deprecated in Mac OS X v10.4
Returns whether the most recently undone action is redoable and indicates the type of action that can be redone. (Deprecated. Use `TXNCanRedoAction` (page 2622) instead.)

`TXNCanUndo` (page 2623) Deprecated in Mac OS X v10.4
Returns whether the most recent action is undoable and provides a value that indicates the type of action than can be undone. (Deprecated. Use `TXNCanUndoAction` (page 2624) instead.)

`TXNClearActionChangeCount` (page 2625) Deprecated in Mac OS X v10.4
Resets the specified action counters to zero. (Deprecated. Use `TXNClearCountForActionType` (page 2626) instead.)

`TXNGetActionChangeCount` (page 2646) Deprecated in Mac OS X v10.4
Retrieves the number of times the specified action or actions have occurred since the count was initialized or cleared. (Deprecated. Use `TXNGetCountForActionType` (page 2649) instead.)

`TXNSave` (page 2677) Deprecated in Mac OS X v10.4
Saves the contents of the document as the file type you specify. (Deprecated. Use `TXNWriteRangeToCFURL` (page 2699) instead.)

`TXNSetDataFromCFURLRef` (page 2684) Deprecated in Mac OS X v10.4
Replaces a range of data with the contents of a file. (Deprecated. Use `TXNReadFromCFURL` (page 2673) instead.)

Unsupported Functions

This section lists functions that are not supported and cannot be called in Mac OS X.

`TXNTSMCheck` (page 2697)
Checks to see if the Text Services Manager (TSM) is active.

Functions

DisposeTXNActionKeyMapperUPP

Disposes of the universal procedure pointer (UPP) to your action key mapping callback function. (Deprecated in Mac OS X v10.4. Use `TXNActionNameMapperProcPtr` instead.)

Not recommended.

```
void DisposeTXNActionKeyMapperUPP (
   TXNActionKeyMapperUPP userUPP
);
```

Discussion
See the callback `TXNActionKeyMapperProcPtr` (page 2700) for more information.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`MacTextEditor.h`

DisposeTXNActionNameMapperUPP

Disposes of the universal procedure pointer (UPP) to your action name mapper callback function.

```
void DisposeTXNActionNameMapperUPP (
   TXNActionNameMapperUPP userUPP
);
```

Parameters

userUPP
The `TXNActionNameMapperUPP` that is to be disposed of.

Discussion
See the callback `TXNActionNameMapperProcPtr` (page 2702) for more information.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`MacTextEditor.h`

DisposeTXNContextualMenuSetupUPP

Disposes of the universal procedure pointer (UPP) to your contextual menu setup callback function.

```
void DisposeTXNContextualMenuSetupUPP (
   TXNContextualMenuSetupUPP userUPP
);
```

Parameters

userUPP

The `TXNContextualMenuSetupUPP` that is to be disposed of.

Discussion
See the callback `TXNContextualMenuSetupProcPtr` (page 2702) for more information.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`MacTextEditor.h`

DisposeTXNFindUPP

Disposes of the universal procedure pointer (UPP) to your find callback function.

```
void DisposeTXNFindUPP (
   TXNFindUPP userUPP
);
```

Discussion
See the callback `TXNFindProcPtr` (page 2703) for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MacTextEditor.h`

DisposeTXNScrollInfoUPP

Disposes of the universal procedure pointer (UPP) to your scrolling callback function.

```
void DisposeTXNScrollInfoUPP (
   TXNScrollInfoUPP userUPP
);
```

Discussion
See the callback `TXNScrollInfoProcPtr` (page 2705) for more information.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`MacTextEditor.h`

HITextViewCopyBackgroundColor

Obtains the background color of the view.

```
OSStatus HITextViewCopyBackgroundColor (
   HIViewRef inTextView,
   CGColorRef *outColor
);
```

Parameters

inTextView

The HITextView associated with the text object whose background color you want to copy.

outColor

A `CGColorRef` representing the color or pattern that is used for drawing the background of the text view. If the returned `CGColorRef` is not `NULL`, it is retained on return. You are responsible for releasing this `CGColorRef` when you are no longer referencing it. If the returned value is `NULL`, the background is not drawn.

Return Value

A result code. See "MLTE Result Codes" (page 2773).

Availability

Available in Mac OS X v10.4 and later.

Not available to 64-bit applications.

Declared In

`HITextViews.h`

HITextViewCreate

Creates an HITextView that is initially invisible.

```
OSStatus HITextViewCreate (
   const HIRect *inBoundsRect,
   OptionBits inOptions,
   TXNFrameOptions inTXNFrameOptions,
   HIViewRef *outTextView
);
```

Parameters

inBoundsRect

The bounding box of the view. Pass `NULL`, if you want to initialize the bounds of the view to `0`.

inOptions

Reserved for future use; you must pass `0`.

inTXNFrameOptions

The frame options you want to set for the text view.

outTextView

On output, points to the newly-created text view.

Return Value

A result code. See "MLTE Result Codes" (page 2773).

Discussion
An HITextView is an MLTE text view that can be embedded in the HIView hierarchy. The view can be embedded in an HIScrollView if you want scroll bars and can also be used in a composited window. For more information on HIView, see the document *Introducing HIView*, available from the Apple Developer Documentation website.

When you call the function `HITextViewCreate` to create a text view, an MLTE text object (`TXNObject`) is allocated and attached to the text view. You can extract the text object by calling the function `HITextViewGetTXNObject`. You can supply the extracted text object as a parameter to many of the MLTE functions that take a text object as a parameter. However, not all MLTE functions that take a text object can operate on an MLTE object that comes from an HITextView. In general, you cannot use MLTE functions that may alter the geometry of the object or explicitly invoke drawing. If you do, the function returns the result code `kTXNDisabledFunctionalityErr`.

The following MLTE functions return an error if you pass a text object that comes from an HITextView:

- `TXNAttachObjectToWindowRef`
- `TXNGetWindowRef`
- `TXNDrawObject`
- `TXNSetScrollbarState`
- `TXNGrowWindow`
- `TXNZoomWindow`
- `TXNResizeFrame`
- `TXNSetFrameBounds`
- `TXNSetViewRect`
- `TXNDraw`
- `TXNFocus`
- `TXNUpdate`
- `TXNForceUpdate`
- `TXNPageSetup`
- `TXNPrint`
- `TXNIdle`

Availability
Available in Mac OS X v10.3 and later.
Not available to 64-bit applications.

Declared In
`HITextViews.h`

HITextViewGetTXNObject

Obtains the text object associated with an HITextView.

```
TXNObject HITextViewGetTXNObject (
   HIViewRef inTextView
);
```

Parameters

inTextView

The HITextView associated with the text object you want to retrieve.

Return Value
Returns the text object associated with the given view.

Discussion
You can supply the extracted text object as a parameter to many of the MLTE functions that take a text object as a parameter. However, not all MLTE functions that take a text object can operate on an MLTE object that comes from an HITextView. In general, you cannot use MLTE functions that may alter the geometry of the object or explicitly invoke drawing. If you do, the function returns the result code `kTXNDisabledFunctionalityErr`. See `HITextViewCreate` (page 2610) for a list of the functions that return an error if you pass a text object that comes from an HITextView.

Availability
Available in Mac OS X v10.3 and later.
Not available to 64-bit applications.

Related Sample Code
QTMetaData

Declared In
`HITextViews.h`

HITextViewSetBackgroundColor

Sets the background color of the view.

```
OSStatus HITextViewSetBackgroundColor (
   HIViewRef inTextView,
   CGColorRef inColor
);
```

Parameters

inTextView

The HITextView whose background color is to be set.

inColor

A `CGColorRef` representing the color or pattern that is to fill the background of the text view. The `CGColorRef` is retained by this function. If the text view already contains a background color, it is released prior to the new color being retained. If `inColor` is `NULL`, the background of the text view will not draw.

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Discussion
This function allows you to provide alpha.

Availability
Available in Mac OS X v10.4 and later.

Not available to 64-bit applications.

Declared In
HITextViews.h

InvokeTXNActionKeyMapperUPP

Calls your action key mapping callback function. (Deprecated in Mac OS X v10.4. Use `TXNActionNameMapperProcPtr` instead.)

Not recommended.

```
CFStringRef InvokeTXNActionKeyMapperUPP (
   TXNActionKey actionKey,
   UInt32 commandID,
   TXNActionKeyMapperUPP userUPP
);
```

Return Value
See the Base Services documentation for a description of the `CFStringRef` data type.

Discussion
See the callback `TXNActionKeyMapperProcPtr` (page 2700) for more information.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
MacTextEditor.h

InvokeTXNActionNameMapperUPP

Calls your action name mapper callback function.

```
CFStringRef InvokeTXNActionNameMapperUPP (
   CFStringRef actionName,
   UInt32 commandID,
   void *inUserData,
   TXNActionNameMapperUPP userUPP
);
```

Parameters

actionName
The action name.

commandID
The command ID of the menu item that is to be mapped.

iUserData
A pointer to user-defined data that will be passed to your action name mapper callback.

userUPP
The callback function that is to be called. For more information, see `NewTXNActionNameMapperUPP` (page 2616).

Return Value
A `CFStringRef`.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`MacTextEditor.h`

InvokeTXNContextualMenuSetupUPP

Calls your contextual menu setup callback function.

```
void InvokeTXNContextualMenuSetupUPP (
   MenuRef iContextualMenu,
   TXNObject object,
   void *inUserData,
   TXNContextualMenuSetupUPP userUPP
);
```

Parameters

iContextualMenu
The contextual menu.

object
The TXNObject for which the contextual menu is to be displayed.

iUserData
A pointer to user-defined data that will be passed to your contextual menu setup callback.

userUPP
The callback function that is to be called. For more information, see `NewTXNContextualMenuSetupUPP` (page 2616).

Availability
Available in Mac OS X v10.4 and later.

Declared In
`MacTextEditor.h`

InvokeTXNFindUPP

Calls your find callback function.

```
OSStatus InvokeTXNFindUPP (
   const TXNMatchTextRecord *matchData,
   TXNDataType iDataType,
   TXNMatchOptions iMatchOptions,
   const void *iSearchTextPtr,
   TextEncoding encoding,
   TXNOffset absStartOffset,
   ByteCount searchTextLength,
   TXNOffset *oStartMatch,
   TXNOffset *oEndMatch,
   Boolean *ofound,
   URefCon refCon,
   TXNFindUPP userUPP
);
```

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Discussion
You can call an invoke function rather than calling your routine directly if you want to support code portability across compiler targets. See the callback `TXNFindProcPtr` (page 2703) for parameter descriptions and other information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MacTextEditor.h`

InvokeTXNScrollInfoUPP

Calls your scrolling callback function.

```
void InvokeTXNScrollInfoUPP (
   SInt32 iValue,
   SInt32 iMaximumValue,
   TXNScrollBarOrientation iScrollBarOrientation,
   SRefCon iRefCon,
   TXNScrollInfoUPP userUPP
);
```

Discussion
You can call an invoke function rather than calling your routine directly if you want to support code portability across compiler targets. See the callback `TXNScrollInfoProcPtr` (page 2705) for parameter descriptions and other information.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`MacTextEditor.h`

NewTXNActionKeyMapperUPP

Creates a new universal procedure pointer (UPP) to a callback function that uses your criteria for mapping actions. (Deprecated in Mac OS X v10.4. Use `TXNActionNameMapperProcPtr` instead.)

Not recommended.

```
TXNActionKeyMapperUPP NewTXNActionKeyMapperUPP (
   TXNActionKeyMapperProcPtr userRoutine
);
```

Return Value
A universal procedure pointer.

Discussion
See the callback `TXNActionKeyMapperProcPtr` (page 2700) for more information.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`MacTextEditor.h`

NewTXNActionNameMapperUPP

Creates a new universal procedure pointer (UPP) to an action name mapper callback function.

```
TXNActionNameMapperUPP NewTXNActionNameMapperUPP (
   TXNActionNameMapperProcPtr userRoutine
);
```

Parameters

userRoutine
The action name mapper callback function for which a UPP is to be created.

Return Value
A universal procedure pointer.

Discussion
See the callback `TXNActionNameMapperProcPtr` (page 2702) for more information.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`MacTextEditor.h`

NewTXNContextualMenuSetupUPP

Creates a new universal procedure pointer (UPP) to a contextual menu setup callback function.

```
TXNContextualMenuSetupUPP NewTXNContextualMenuSetupUPP (
   TXNContextualMenuSetupProcPtr userRoutine
);
```

Parameters

userRoutine

The contextual menu setup callback function for which a UPP is to be created.

Return Value
A universal procedure pointer.

Discussion
For more information, see the callback `TXNContextualMenuSetupProcPtr` (page 2702).

Availability
Available in Mac OS X v10.4 and later.

Declared In
`MacTextEditor.h`

NewTXNFindUPP

Creates a new universal procedure pointer (UPP) to a find callback function that uses your criteria for matching.

```
TXNFindUPP NewTXNFindUPP (
   TXNFindProcPtr userRoutine
);
```

Return Value
A universal procedure pointer.

Discussion
See the callback `TXNFindProcPtr` (page 2703) for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MacTextEditor.h`

NewTXNScrollInfoUPP

Creates a new universal procedure pointer (UPP) to a scrolling callback function.

```
TXNScrollInfoUPP NewTXNScrollInfoUPP (
   TXNScrollInfoProcPtr userRoutine
);
```

Return Value
A universal procedure pointer.

Discussion
See the callback `TXNScrollInfoProcPtr` (page 2705) for more information.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`MacTextEditor.h`

TXNActivate

Sets the state of the scroll bars so they are drawn correctly in response to activate events. (Deprecated in Mac OS X v10.3. Use `TXNSetScrollbarState` (page 2691) instead.)

Not recommended.

```
OSStatus TXNActivate (
   TXNObject iTXNObject,
   TXNFrameID iTXNFrameID,
   TXNScrollBarState iActiveState
);
```

Parameters

iTXNObject
The text object that identifies the document to be activated.

iTXNFrameID
The frame ID of the document that is to be activated. You obtain a frame ID from `TXNNewObject` (page 2667) when you create a text object.

iActiveState
A value that indicates the state of the scroll bars. See Scroll Bar States (page 2760) for a description of possible values. If you pass the `kScrollBarsAlwaysActive` constant, the scroll bars are always active, whether or not the frame's text area currently has keyboard focus. Passing `kScrollBarsAlwaysActive` can be useful for a window such as a dialog box that may contain multiple text areas, each of which may have a scrollable frame. If you pass `kScrollBarsSyncWithFocus`, MLTE synchronizes the activity state of the scroll bars with the focus state of the frame. Therefore, only when the frame has keyboard focus does it have active scroll bars. A value of `kScrollBarsSyncWithFocus` is the default and is typically recommended if you have only one frame per window.

Return Value
A result code. See "MLTE Result Codes" (page 2773). `TXNActivate` returns a parameter error if you pass an invalid text object or frame ID.

Discussion
You typically call `TXNActivate` in response to an activate event. If the text object was previously inactive, `TXNActivate` removes any visual indication of its prior inactive state (such as a dimmed or framed selection area or inactive scroll bars). Before you call the `TXNActivate` function, you should make sure that the window belongs to your application.

The `TXNActivate` function does not change the keyboard focus. This means your application can have a text area that is not focused, but in which the scroll bars are active. This lets application users scroll the inactive text without changing the focus from another text area.

If you want to display a text area that has both keyboard focus and active scroll bars, you must call the `TXNFocus` (page 2644) function immediately before you call the `TXNActivate` function. Note that MLTE does not retain information about keyboard focus. So if, for example, you set the keyboard focus on a text area and the window containing the text area becomes deactivated, you must call the `TXNFocus` (page 2644) function when the window becomes activated again.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.3.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNAdjustCursor

Obtains the current cursor position and draws the cursor in a form appropriate to the content over which it is placed.

```
void TXNAdjustCursor (
   TXNObject iTXNObject,
   RgnHandle ioCursorRgn
);
```

Parameters

iTXNObject
The text object that identifies the text area for which MLTE should adjust the cursor.

ioCursorRgn
A handle to a region created by your application. Pass `NULL` if you do not want `TXNAdjustCursor` to provide information about the cursor position to your application. If you do want to obtain the cursor's current position, pass a valid region handle in this parameter. If you pass a valid region handle and the cursor is over the text area or its scroll bars, on return `TXNAdjustCursor` sets the region to a 2-pixel by 2-pixel square, centered on the cursor's hot spot. If the cursor is not over the text area or its scroll bars, or if you have passed `NULL`, `TXNAdjustCursor` does not adjust the input value.

Discussion
If the cursor is over a text area, `TXNAdjustCursor` sets the cursor to an I-beam. If the cursor is over graphics, a sound file, a movie, a scroll bar, or outside of a window, `TXNAdjustCursor` sets the cursor to an arrow. Before you call the `TXNAdjustCursor` function, you should make sure that the window belongs to your application.

You can pass the region handle returned by the `TXNAdjustCursor` function in the `ioCursorRgn` parameter to the `WaitNextEvent` function; this ensures that you receive mouse-moved events if the cursor moves outside that region. If you then receive a mouse-moved event, you can call `TXNAdjustCursor` again to ensure that the cursor type is appropriate to its new position. Alternately, to ensure that the cursor is adjusted correctly, you can simply call `TXNAdjustCursor` with every event that your application receives.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNAttachObjectToWindow

Attaches a text object to a window. (Deprecated in Mac OS X v10.3. Use `TXNAttachObjectToWindowRef` (page 2620) instead.)

Not recommended.

```
OSStatus TXNAttachObjectToWindow (
   TXNObject iTXNObject,
   GWorldPtr iWindow,
   Boolean iIsActualWindow
);
```

Parameters

`iTXNObject`

The text object with which you want to associate the window.

`iWindow`

A pointer to the graphics port to which the object should be attached. The graphics port may be a window (`WindowRef`) or a generic graphics port (`CGrafPtr`, `GWorldPtr`). If it is a window, note that you must typecast the window reference to a `GWorldPtr` data type.

`iIsActualWindow`

A `Boolean` value. Pass `true` if the `iWindow` parameter you passed refers to a Window Manager window (`WindowRef`), not a generic graphics port. Pass `false` if the `iWindow` parameter you passed does not refer to a window. If you pass `false`, MLTE never calls window-specific functions such as `InvalRect` or `BeginUpdate` for this text object, and it is your program's responsibility to handle any window-related functionality.

Return Value

A result code. See "MLTE Result Codes" (page 2773). `TXNAttachObjectToWindow` returns `paramErr` if the text object that you pass is invalid.

Discussion

You may create a text object without an associated window pointer by passing `NULL` in the `iWindow` parameter of the `TXNNewObject` (page 2667) function. However, if you do so, you must call the `TXNAttachObjectToWindow` function to associate a window with that object before you call any other MLTE function.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.3.

Not available to 64-bit applications.

Declared In

`MacTextEditor.h`

TXNAttachObjectToWindowRef

Attaches a text object to a window.

```
OSStatus TXNAttachObjectToWindowRef (
   TXNObject iTXNObject,
   WindowRef iWindowRef
);
```

Parameters

iTXNObject

The text object with which you want to associate the window. You can call the function `TXNCreateObject` to allocate a text object.

iWindowRef

A `WindowRef` that specifies the window to which you want to attach the text object.

Return Value
A result code. See "MLTE Result Codes" (page 2773). Returns `paramErr` if the text object that you pass is invalid.

Availability
Available in Mac OS X v10.3 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNBeginActionGroup

Starts an action group.

```
OSStatus TXNBeginActionGroup (
   TXNObject iTXNObject,
   CFStringRef iActionGroupName
);
```

Parameters

iTXNObject

The text object for which an action group is to be started.

iActionGroupName

A client-supplied string that is to be used to describe the action group.

Return Value
A result code. See "MLTE Result Codes" (page 2773). The error `kTXNOperationNotAllowedErr` is returned if an undo action group has already been started but has not yet terminated.

Discussion
Every supported edit action after `TXNBeginActionGroup` is called is added to the group until`TXNCanUndoAction` (page 2624) is called. When MLTE receives an undo or redo command, it treats all actions added to the group as a single operation to undo or redo. Nesting of groups is not allowed. Calling `TXNBeginActionGroup` twice without calling `TXNCanUndoAction` in between results in an error. If an action group is active, `TXNCanUndoAction` (page 2624) and `TXNCanRedoAction` (page 2622) return `false`.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNCanRedo

Returns whether the most recently undone action is redoable and indicates the type of action that can be redone. (Deprecated in Mac OS X v10.4. Use `TXNCanRedoAction` (page 2622) instead.)

Not recommended.

```
Boolean TXNCanRedo (
   TXNObject iTXNObject,
   TXNActionKey *oTXNActionKey
);
```

Parameters

iTXNObject

The text object for the document you want to examine.

oTXNActionKey

A pointer to a value of type `TXNActionKey`. On return, this value specifies the action that can be redone. See Action Constants (page 2719) for a description of possible values. You can use this information to customize the Redo menu item for the specific action to be redone. For example, if the value obtained by `TXNCanRedo` is `kTXNTypingAction`, you can map that value to a string that reads "Redo Typing" on a system localized for U.S. English. MLTE does not perform the mapping your program is responsible for mapping the key to the appropriate localized string you want displayed to the user. Pass `NULL` if you do not want to obtain this information.

Return Value

A `Boolean` value. If `true`, the last command is redoable; otherwise the last command cannot be redone.

Discussion

You can call the `TXNCanRedo` function to determine whether the Redo item in the Edit menu should be enabled.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`MacTextEditor.h`

TXNCanRedoAction

Indicates whether an action can be redone.

```
Boolean TXNCanRedoAction (
   TXNObject iTXNObject,
   CFStringRef *oActionName
);
```

Parameters

iTXNObject

The text object having an action that is to be queried.

oActionName

On input, a pointer a `CFStringRef` that, on return, contains the name of the action that can be redone, if there is one. The returned string is either a string defined by MLTE or the string that you passed to `TXNBeginActionGroup` (page 2621) to create a new action group. You are responsible for retaining and releasing the string. Pass `NULL` if you don't want to receive the name of the action.

Return Value
A Boolean whose value is `true` if the last action can be redone; you should enable the Redo item in the Edit menu, if there is one. If this function returns `false`, the last action cannot be redone and you should not enable the Redo item in the Edit menu.

Discussion
This function tells the client whether the current item on the undo stack is redoable and is usually used to determine whether the Redo item in the Edit menu should be enabled. This function optionally obtains the action name that should be used in the Redo item. When the current undo item is an action group, the string used to name the group is returned. For information on action groups, see `TXNBeginActionGroup` (page 2621) and `TXNEndActionGroup` (page 2641).

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNCanUndo

Returns whether the most recent action is undoable and provides a value that indicates the type of action than can be undone. (Deprecated in Mac OS X v10.4. Use `TXNCanUndoAction` (page 2624) instead.)

Not recommended.

```
Boolean TXNCanUndo (
   TXNObject iTXNObject,
   TXNActionKey *oTXNActionKey
);
```

Parameters

iTXNObject

The text object for the document you want to examine.

oTXNActionKey

A pointer to a value of type `TXNActionKey`. On return, this value identifies the action that can be undone. See Action Constants (page 2719) for a description of possible values. You can use this information to customize the Undo menu item for the specific action to be undone. For example, if the value obtained by `TXNCanUndo` is `kTXNTypingAction`, you can map that value to a string that reads "Undo Typing" on a system localized for U.S. English. MLTE does not perform such a mapping your program is responsible for mapping the key to the appropriate localized string you want displayed to the user. Pass `NULL` if you do not wish to obtain this information.

Return Value
A `Boolean` value. If `true`, the last command is undoable; otherwise the last command cannot be undone.

Discussion
You can call `TXNCanUndo` to determine whether the Undo item in the Edit menu should be enabled.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNCanUndoAction

Indicates whether an action can be undone.

```
Boolean TXNCanUndoAction (
   TXNObject iTXNObject,
   CFStringRef *oActionName
);
```

Parameters

iTXNObject

The text object having an action that is to be queried.

oActionName

On input, a pointer a `CFStringRef` that, on return contains the name of the action that can be undone, if there is one. The returned string is either a string defined by MLTE or the string that you passed to `TXNBeginActionGroup` (page 2621) to create a new action group. You are responsible for retaining and releasing the string. Pass `NULL` if you don't want to receive the name of the action.

Return Value
A Boolean whose value is `true` if the last action can be undone; you should enable the Undo item in the Edit menu, if there is one. If this function returns `false`, the last action cannot be undone and you should not enable the Undo item in the Edit menu.

Discussion
This function is usually used to determine whether the Undo item in the Edit menu should be enabled and to obtain the action name that should be used in that item. When the last action is an action group, the string used to name the group is returned.

If you have asked MLTE to handle updating for the Redo and Undo commands in the Edit menu, you should call `TXNSetActionNameMapper` (page 2680) after calling `TXNCanUndoAction` so that MLTE can call back to get the correct strings for those items.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNClear

Deletes the current selection.

```
OSStatus TXNClear (
   TXNObject iTXNObject
);
```

Parameters

iTXNObject

The text object for the current text area.

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Discussion
To remove a selected object from a text area, a user can either press the Delete key or choose Clear from the Edit menu. Before you call the `TXNClear` function, you can use the `TXNIsSelectionEmpty` (page 2665) function to determine whether any text is selected. Unlike the function `TXNCut` (page 2631), the `TXNClear` function does not add the deleted selection to the private MLTE scrap.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNClearActionChangeCount

Resets the specified action counters to zero. (Deprecated in Mac OS X v10.4. Use `TXNClearCountForActionType` (page 2626) instead.)

Not recommended.

```
OSStatus TXNClearActionChangeCount (
   TXNObject iTXNObject,
   TXNCountOptions iOptions
);
```

Parameters

iTXNObject

The text object whose action counter you want to reset.

iOptions

The `TXNCountOptions` to use when resetting the count. See Action Count Masks (page 2721) for information on the options you can supply.

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Discussion
You can use this function to clear the action counters as needed for your application.

Availability
Available in Mac OS X v10.1 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
MacTextEditor.h

TXNClearCountForActionType

Sets the counter for the specified action type to zero.

```
OSStatus TXNClearCountForActionType (
   TXNObject iTXNObject,
   CFStringRef iActionTypeName
);
```

Parameters

iTXNObject

The text object having one or more counters that are to be set to zero.

iActionTypeName

The action type for which the counter is to be set to zero. This parameter can be a string that was passed to `TXNBeginActionGroup` (page 2621) or one of the constants described in Action Constants (page 2719).

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
MacTextEditor.h

TXNClick

Processes a mouse-down event in a window's content area.

```
void TXNClick (
   TXNObject iTXNObject,
   const EventRecord *iEvent
);
```

Parameters

iTXNObject

The text object in which the mouse-down event occurred.

iEvent

A pointer to the event record that contains the mouse-down event to process.

Discussion
When you pass the event to the `TXNClick` function, it responds to the user's action by scrolling, selecting text, playing a sound or movie, handling a drag–and-drop operation, or responding to a double- or triple-click, as appropriate. Before you call `TXNClick`, you should make sure that the front window belongs to your application.

Availability
Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNConvertFromPublicScrap

Converts the Clipboard content to the private MLTE scrap. (Deprecated in Mac OS X v10.3. This function isn't needed in Mac OS X.)

Not recommended.

```
OSStatus TXNConvertFromPublicScrap (
   void
);
```

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Discussion
You should call the `TXNConvertFromPublicScrap` function after another application has modified the contents of the Clipboard. Calling the `TXNConvertFromPublicScrap` function ensures that the contents of the system Clipboard are available to your application. Typically, when you receive a resume event, you call the Scrap Manager function `GetCurrentScrap` to determine whether the Clipboard content has been modified. If so, you should then call `TXNConvertFromPublicScrap`.

Special Considerations

The function `TXNConvertFromPublicScrap` is no longer needed in Mac OS X version 10.2 and later. Calling the function `TXNPaste` automatically handles conversion from public scrap.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.3.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNConvertToPublicScrap

Converts the private MLTE scrap content to the Clipboard. (Deprecated in Mac OS X v10.3. This function isn't needed in Mac OS X.)

Not recommended.

```
OSStatus TXNConvertToPublicScrap (
   void
);
```

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.3.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNCopy

Copies the current selection to the private MLTE scrap.

```
OSStatus TXNCopy (
   TXNObject iTXNObject
);
```

Parameters

iTXNObject
The text object for the current text area.

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Discussion
You can use the `TXNCopy` function to respond to a user-requested copy action. Before you call `TXNCopy`, you can use the `TXNIsSelectionEmpty` (page 2665) function to determine whether any text is selected.

The `TXNCopy` function copies the current selection to the MLTE scrap. In a Carbon application, the Scrap Manager automatically converts your application's private scrap to the Clipboard so it is available to other applications. In a Classic application, you must call the function `TXNConvertToPublicScrap` (page 2627) after you call `TXNCopy`.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNCopyTypeIdentifiersForRange

Obtains an array of universal type identifiers for a TXNObject.

```
OSStatus TXNCopyTypeIdentifiersForRange (
   TXNObject iTXNObject,
   TXNOffset iStartOffset,
   TXNOffset iEndOffset,
   CFArrayRef *oTypeIdentifiersForRange
);
```

Parameters

iTXNObject
The text object.

iStartOffset
The starting offset in `iTXNObject`.

iEndOffset
The ending offset in `iTXNObject`.

oTypeIdentifiersForRange
A pointer to a `CFArrayRef`. On return, the array contains the list of universal type identifiers that MLTE supports. Each entry in the array is a `CFStringRef`.

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Discussion
Some file formats support limited embedding of data when writing to disk, and use attachments, such as Rich Text Format (RTF), instead.

Use this function to get a list of universal type identifiers that can be used when calling `TXNWriteRangeToCFURL` (page 2699) to write the object out to disk with no data loss. Note that support for new document formats could be added in the future.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNCountRunsInRange

Obtains a count of the style runs in a range of data.

```
OSStatus TXNCountRunsInRange (
   TXNObject iTXNObject,
   TXNOffset iStartOffset,
   TXNOffset iEndOffset,
   ItemCount *oRunCount
);
```

Parameters
iTXNObject
The text object for the current text area.

iStartOffset
The beginning offset of the range of data in the document that you want to examine. Note that this offset is a generic counter of elements (such as characters, pictures, and movies), not an offset into memory.

iEndOffset
The ending offset of the range of data in the document that you want to examine. Note that this offset is a generic counter of elements, not an offset into memory.

oRunCount
On return, a pointer to the number of style runs in the specified range.

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Discussion
Given a range of data in a document that is specified by a starting and ending offset, you can use the `TXNCountRunsInRange` function to obtain a count of the changes in text styles, graphics, movies, or sounds in that range. Once you have a run count, you can supply this information to the function `TXNGetIndexedRunInfoFromRange` (page 2654) in order to obtain information about the runs themselves.

Offsets in MLTE are always character offsets.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNCreateObject

Creates a new MLTE text object which is an opaque structure that handles text formatting at the document level.

```
OSStatus TXNCreateObject (
   const HIRect *iFrameRect,
   TXNFrameOptions iFrameOptions,
   TXNObject *oTXNObject
);
```

Parameters

iFrameRect
A pointer to a rectangle used to specify the destination and view rectangles for the text object. Pass `NULL` if you want to use the window port rectangle as the view and destination rectangles when the object is attached later to a window. See the function `TXNAttachObjectToWindowRef`.

iFrameOptions
A value that specifies the options you want the frame to support. See Frame Option Masks (page 2749) for a description of possible values.

oTXNObject
On input, a pointer to a structure of type `TXNObject`. On output, points to the opaque text object data structure allocated by the function. You need to pass this object to most MLTE functions.

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Discussion
For each document, a new text object is allocated by the `TXNCreateObject` function and returned in the `oTXNObject` parameter. The object is allocated only if no errors occur. If there is an error during the allocation process, MLTE frees the text object.

If you are writing a text editing application, you may want to call the `TXNCreateObject` function when the application launches (a new document will be displayed) and whenever the user selects New from the File menu. In addition, many MLTE functions require you to pass a text object.

If you want to create a read-only document, you need to pass the option `kTXNReadOnlyMask` in the `iFrameOptions` parameter. Note that this option puts the text object into a state that does not allow user input. However, your application can put data into the text object by calling the function `TXNSetData`. If

you want the text object set into a more restrictive read-only state that does not allow user input or your application to put data into the text object programmatically, you need to call the function `TXNSetTXNObjectControls`, passing the tag `kTXNIOPrivilegesTag`. If you choose to set the text object into this restrictive state, you will get an error if you try to call the function `TXNSetData` on the text object. (In this case, you can change the text object to a less restrictive state by calling `TXNSetTXNObjectControls`, passing the tag `kTXNNoUserIOTag`.)

Because of how MLTE uses Carbon events internally, the window in which the document is displayed must have the standard event handlers installed. You can install standard event handlers in one of the following ways:

- When you create the window, add the attribute `kWindowStandardHandlerAttribute` to the window. See *Window Manager Reference* for more information.
- Call the Carbon Event Manager function `InstallStandardEventHandler` on the window's event target. See *Handling Carbon Events* for more information.

Availability
Available in Mac OS X v10.3 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNCut

Deletes the current selection and copies it to the private MLTE scrap.

```
OSStatus TXNCut (
   TXNObject iTXNObject
);
```

Parameters

iTXNObject
The text object for the current text area.

Return Value
A result code. See "MLTE Result Codes" (page 2773).`TXNCut` also returns Scrap Manager errors.

Discussion
You can use the `TXNCut` function to respond to a user-requested cut action. Before you call `TXNCut`, you can use the `TXNIsSelectionEmpty` (page 2665) function to determine whether any text is selected. The `TXNCut` function deletes the current selection and then copies it to the private MLTE scrap. In a Carbon application, the Scrap Manager automatically converts your application's private scrap to the Clipboard so it is available to other applications. In a Classic application, you must call the function `TXNConvertToPublicScrap` (page 2627) after you call `TXNCut` to move the selection to the Clipboard.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNDataSize

Reports the amount of memory used to hold the text in a given text object.

```
ByteCount TXNDataSize (
   TXNObject iTXNObject
);
```

Parameters

iTXNObject

The text object that you want to examine.

Return Value

The number of bytes required to hold the characters.

Discussion

You can use this function to determine how large a handle should be if, for example, you copy text. Note that because every individual sound, picture, or movie in a text object is represented by a single character in the text buffer, the `TXNDataSize` function returns a value that does not necessarily represent the true size of any non-text data.

If you are using Unicode and you want to know the number of characters, divide the returned `ByteCount` value by `sizeof(UniChar)` or 2, since MLTE uses the 16-bit Unicode Transformation Format (UTF-16).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`MacTextEditor.h`

TXNDeleteObject

Deletes a previously allocated text object.

```
void TXNDeleteObject (
   TXNObject iTXNObject
);
```

Parameters

iTXNObject

The text object you want to delete.

Discussion

You should call the `TXNDeleteObject` function when you close the window associated with a text object. The function `TXNDeleteObject` releases the specified text object and all associated data structures from memory. If the object has multiple frames, all frames are deleted.

Version Notes

Multiple frames are not yet implemented in MLTE.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In
MacTextEditor.h

TXNDisposeFontMenuObject

Disposes of a Font menu object. (Deprecated in Mac OS X v10.5.)

```
OSStatus TXNDisposeFontMenuObject (
   TXNFontMenuObject iTXNFontMenuObject
);
```

Parameters

iTXNFontMenuObject
The Font menu object which you want to dispose of.

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Discussion
The `TXNDisposeFontMenuObject` function releases the specified Font menu object from memory. Note that `TXNDisposeFontMenuObject` does not dispose of the main Font menu handle that is associated with the Font menu object. You are responsible for disposing of the Font menu handle after calling `TXNDisposeFontMenuObject`. However, `TXNDisposeFontMenuObject` does dispose of any submenus that MLTE creates to support Apple Type Services for Unicode Imaging (ATSUI) fonts.

A good time to call the `TXNDisposeFontMenuObject` function is when your application quits (that is usually when your application no longer needs the Font menu). You can dispose of the Font menu object as part of a "terminate" function you create to do cleanup and termination tasks.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
MacTextEditor.h

TXNDoFontMenuSelection

Changes the font of the current selection. (Deprecated in Mac OS X v10.5.)

```
OSStatus TXNDoFontMenuSelection (
   TXNObject iTXNObject,
   TXNFontMenuObject iTXNFontMenuObject,
   SInt16 iMenuID,
   SInt16 iMenuItem
);
```

Parameters

iTXNObject
The text object that contains the current selection.

iTXNFontMenuObject
The Font menu object that identifies the current Font menu.

menuID

The menu ID of the selected menu. You should supply the high 16 bits of the long word obtained from the Menu Manager function `MenuSelect`. You must pass the menu ID because the Font menu may have hierarchical submenus.

menuItem

A value that identifies the selected menu item. You should supply the low 16 bits of the long word obtained from the Menu Manager function `MenuSelect`.

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Discussion
When you receive a mouse-down event in a menu used in your application, you typically call the Menu Manager function `MenuSelect` to determine which menu and menu item the user has chosen. After calling the `MenuSelect` function, you should check whether the mouse-down event occurred in a menu specific to your application, other than the standard menus such as File, Edit, and Font. If the mouse-down event did not occur in a menu specific to your application, you should pass the IDs of the menu and menu item to the `TXNDoFontMenuSelection` function. If the value you supply in the `iMenuID` parameter identifies the Font menu or one of its submenus, `TXNDoFontMenuSelection` changes the font of the currently selected text to the font that the user selects.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNDragReceiver

Handles dragged data in a text object for which a custom drag handler is already in place.

```
OSErr TXNDragReceiver (
   TXNObject iTXNObject,
   TXNFrameID iTXNFrameID,
   WindowRef iWindow,
   DragReference iDragReference,
   Boolean iDifferentObjectSameWindow
);
```

Parameters

iTXNObject

The text object that is receiving the dragged data.

iTXNFrameID

The frame ID of the text object that is receiving the dragged data. You obtain a `TXNFrameID` when you create a text object with the `TXNNewObject` (page 2667) function.

iWindow

A pointer to the window containing the text object that is receiving the dragged data. You obtain this pointer from the appropriate Drag Manager function.

iDragReference

The drag reference you want MLTE to handle. You obtain a drag reference by calling the appropriate Drag Manager function.

iDifferentObjectSameWindow

A `Boolean` value. Pass `true` if the drag operation is in the same window that it started in, but in a different text object within that window. If there is only one text object in a window, you should always pass `false`. You should also pass `false` if the drag operation has moved into a different window than the one in which it originated. You can determine whether the drag operation has left the originating window by calling the Drag Manager function `GetDragAttributes`.

Return Value
A result code. See "MLTE Result Codes" (page 2773). A Drag Manager result code.

Discussion
You would not typically use the `TXNDragReceiver` function, because MLTE provides basic drag management for you.

However, you might call `TXNDragReceiver` if your application needs to examine the dragged data prior to MLTE handling it, or if you have multiple text objects in a window, or if you have your own drag management infrastructure that you want to use.

You must inform MLTE that you wish to handle some aspect of the drag process by passing the `TXNFrameOptions` value `kTXNDoNotInstallDragProcsMask` in the `iFrameOptions` parameter of `TXNNewObject` (page 2667). If you do so, you are responsible for calling the drag handlers for the drag operation. Then, you should call `TXNDragReceiver` when your drag receiver is called and you want MLTE to take over control of the drag reception process.

When you call `TXNDragReceiver`, MLTE takes over the drag operation and handles everything from that point onward. This includes determining whether the text object is a valid drop target and if the dragged data is an MLTE-supported type, as well as managing the addition of the dragged data to the text object.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNDragTracker

Handles tracking a drag event in a text object for which a custom drag handler is already in place.

```
OSErr TXNDragTracker (
   TXNObject iTXNObject,
   TXNFrameID iTXNFrameID,
   DragTrackingMessage iMessage,
   WindowRef iWindow,
   DragReference iDragReference,
   Boolean iDifferentObjectSameWindow
);
```

Parameters

iTXNObject

The text object in which you need to track a drag event.

iTXNFrameID
The frame ID of the text object in which you need to track a drag event. You obtain a `TXNFrameID` when you create a text object with the `TXNNewObject` (page 2667) function.

iMessage
A drag message obtained from the appropriate Drag Manager function.

iWindow
A pointer to the window containing the text object in which you need to track a drag event. You obtain this pointer from the appropriate Drag Manager function.

iDragReference
The drag reference that you want MLTE to handle. You obtain a drag reference by calling the appropriate Drag Manager function.

iDifferentObjectSameWindow
A value of type `Boolean`. If your application displays more than one text object per window, pass `true` when the drag operation moves out of one object's view rectangle and into another text object's view rectangle.

Return Value
A result code. See "MLTE Result Codes" (page 2773). A Drag Manager result code.

Discussion
You would not typically use the `TXNDragTracker` function, because MLTE provides basic drag management for you.

However, you might call `TXNDragTracker` if your application needs to examine the dragged data prior to MLTE handling it, or if you have multiple text objects in a window, or if you have your own drag management infrastructure that you want to use.

You must inform MLTE that you wish to handle some aspect of the drag process by passing the `TXNFrameOptions` value `kTXNDoNotInstallDragProcsMask` in the `iFrameOptions` parameter of `TXNNewObject` (page 2667). If you do so, you are responsible for calling the drag handlers for the drag operation. Then, you should call `TXNDragTracker` when your drag tracker is called and you want MLTE to take over control of the drag tracking process.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNDraw

Redraws the text area, including any scroll bars associated with the text frame. (Deprecated in Mac OS X v10.3. Use the `TXNDrawObject` (page 2638).)

Not recommended.

```
void TXNDraw (
   TXNObject iTXNObject,
   GWorldPtr iDrawPort
);
```

Parameters

iTXNObject

The text object whose text is to be redrawn.

iDrawPort

A value of type `GWorldPtr`. Pass a valid pointer or `NULL`. If you pass `NULL`, the `TXNDraw` function redraws the text area into the port that is currently associated with the text object. If you pass a valid pointer instead of `NULL`, `TXNDraw` redraws the text area into the specified port, and does not update the selection. You should pass `NULL` if you want to draw on the screen but pass a valid pointer if you want to take a snapshot of the screen to save or print.

Discussion

You can call the `TXNDraw` function in response to an update event for a window that contains multiple text objects or other graphic elements. If necessary, your application is also responsible for calling the Window Manager functions `BeginUpdate` and `EndUpdate` in response to the update event.

If there is nothing in your window except a single MLTE text object, you should call the `TXNUpdate` (page 2698) function to redraw the area instead of calling `TXNDraw`. The `TXNUpdate` f unction draws everything in the frame, and you do not have to call the Window Manager functions `BeginUpdate` and `EndUpdate` yourself.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.3.

Not available to 64-bit applications.

Declared In

`MacTextEditor.h`

TXNDrawCFStringTextBox

Draws text from a Core Foundation string (`CFString`) in the specified rectangle.

```
OSStatus TXNDrawCFStringTextBox (
   CFStringRef iText,
   Rect *ioBox,
   ATSUStyle iStyle,
   const TXNTextBoxOptionsData *iOptions
);
```

Parameters

iText

A reference to the Core Foundation string you want drawn in the text box. A Core Foundation string is an array of Unicode characters along with a count of the number of characters in the string. A CFString object is stored as efficiently as possible, so the memory required to store the string is often less than that required to store a simple array of Unicode characters.

ioBox

On input, a pointer to the rectangle that specifies the text box in which the text is to be displayed. On return, MLTE updates the rectangle to reflect the minimum bounding rectangle that encloses the text. If you pass the constant `kTXNDontUpdateBoxRectMask` in the `ioOptions` parameter then the rectangle is not updated. If the rectangle already has text displayed in it, you should call the QuickDraw function `EraseRect` before you call the `TXNDrawUnicodeTextBox` function. The drawing is clipped to the rectangle unless you specify a rotation as one of the text options you set with the `ioOptions` parameter.

iStyle

An ATSUI style to use to display the text. This parameter is optional. If you pass `NULL`, MLTE creates an ATSUI style based on the information (text size, type face, color, and so forth) associated with the current graphics port. See the Apple Type Services for Unicode Imaging documentation for a description of the `ATSUStyle` data type.

iOptions

A pointer to a `TXNTextBoxOptionsData` structure associated with this text object. This is optional. If you pass `NULL`, MLTE uses the settings for the current graphics port. You can use the `TXNTextBoxOptionsData` structure to specify a number of options, such as text orientation (vertical or horizontal), justification, alignment, and font substitution for text that cannot be rendered using the specified font. See Text Box Options Masks (page 2770) for a description of the options you can specify.

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Discussion
You can use the `TXNDrawCFStringTextBox` function to display mono-style Unicode text. You do not need to initialize MLTE to use this function because it uses Apple Type Services for Unicode Imaging (ATSUI) directly.

If you display text justified, it is justified in the direction of the display. Horizontal text is justified horizontally, but not vertically. Vertical text is justified vertically, but not horizontally.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNDrawObject

Draws a text object in the last window set by your application.

```
OSStatus TXNDrawObject (
   TXNObject iTXNObject,
   const HIRect *iClipRect,
   TXNDrawItems iDrawItems
);
```

Parameters

iTXNObject

The text object you want to draw. You can call the function `TXNCreateObject` to allocate a text object.

iClipRect

A pointer to an `HIRect` data structure. If the rectangle is `NULL` MLTE uses the view rectangle when drawing. Otherwise, MLTE uses the rectangle that is the intersection of the `iClipRect` rectangle and the view rectangle.

iDrawItems

A Draw Items Masks (page 2737) value that specifies which elements are drawn. Pass `kTXNDrawItemScrollbarsMask` if you want the scroll bars drawn; `kTXNDrawItemTextMask` to render the text; `kTXNDrawItemTextAndSelectionMask` to render the text and the current selection, and `kTXNDrawItemAllMask` to draw the scroll bars, text, and the current selection.

Discussion

This function has no effect for text objects that have the visibility tag set to `false`.

Availability

Available in Mac OS X v10.3 and later.

Not available to 64-bit applications.

Declared In

`MacTextEditor.h`

TXNDrawUnicodeTextBox

Draws a Unicode string in the specified rectangle.

```
OSStatus TXNDrawUnicodeTextBox (
   const UniChar iText[],
   UniCharCount iLen,
   Rect *ioBox,
   ATSUStyle iStyle,
   const TXNTextBoxOptionsData *iOptions
);
```

Parameters

iText

The Unicode string you want drawn in the text box. The string should be in 16-bit Unicode Transformation Format (UTF-16).

iLen

The number of Unicode characters contained in the Unicode string.

ioBox

On input, a pointer to the rectangle, in local coordinates, that specifies the text box in which the text is to be displayed. On return, MLTE updates the rectangle to reflect the minimum bounding rectangle that encloses the text. If you pass the constant `kTXNDontUpdateBoxRectMask` in the `ioOptions` parameter, the rectangle is not updated. If the rectangle already has text displayed in it, you should call the QuickDraw function `EraseRect` before you call the `TXNDrawUnicodeTextBox` function. The drawing is clipped to the rectangle unless you specify a rotation as one of the text options you set with the `ioOptions` parameter.

iStyle

An ATSUI style to use to display the text. This parameter is optional. If you pass `NULL`, MLTE creates an ATSUI style based on the information (text size, type face, color, and so forth) associated with the current graphics port. See the Apple Type Services for Unicode Imaging documentation for a description of the `ATSUStyle` data type.

ioOptions

A pointer to a `TXNTextBoxOptionsData` structure associated with this text object. This is optional. If you pass `NULL`, MLTE uses the settings for the current graphics port. You can use the `TXNTextBoxOptionsData` structure to specify a number of options, such as text orientation (vertical or horizontal), justification, alignment, and font substitution for text that cannot be rendered using the specified font. See Text Box Options Masks (page 2770) for a description of the options you can specify.

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Discussion
You can use the `TXNDrawUnicodeTextBox` function to display mono-style Unicode text. You do not need to initialize MLTE to use this function because it uses Apple Type Services for Unicode Imaging (ATSUI) directly.

If you display text justified, it is justified in the direction of the display. Horizontal text is justified horizontally, but not vertically. Vertical text is justified vertically, but not horizontally.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNEchoMode

Determines whether a specified character is drawn instead of the glyph associated with the input character.

```
OSStatus TXNEchoMode (
   TXNObject iTXNObject,
   UniChar iEchoCharacter,
   TextEncoding iEncoding,
   Boolean iOn
);
```

Parameters

iTXNObject

The text object for the current text area.

iEchoCharacter

A value that specifies the substitute character.

iEncoding

The text encoding from which the substitute character is drawn. See the Text Encoding Conversion Manager reference documentation for a discussion of the text encoding data type and of possible text encoding values.

iOn

A `Boolean` value. Pass `true` to turn on character substitution. Pass `false` to turn it off. When you enable character substitution for a text object, all characters in the text area have the character specified by the `iEchoCharacter` parameter substituted for the actual glyph when MLTE draws the text.

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Discussion
You can use the `TXNEchoMode` function when you want to hide what the user types, such as a password in a login dialog box.

The substitution character is a `UniChar` data type to facilitate passing any 2-byte character. The encoding parameter actually determines the encoding MLTE uses to locate a font and display a character. Thus if you want to display the diamond character from the Shift-JIS encoding for Mac OS, you would pass the value `0x86A6` for the character, but pass an encoding value that represents Mac OS Japanese encoding.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNEndActionGroup

Ends an action group.

```
OSStatus TXNEndActionGroup (
   TXNObject iTXNObject
);
```

Parameters

iTXNObject
The text object for which an action group is to be ended.

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Discussion
The call is ignored if there is no active action group.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNFind

Finds a piece of text or a graphics, sound, or movie object.

```
OSStatus TXNFind (
   TXNObject iTXNObject,
   const TXNMatchTextRecord *iMatchTextDataPtr,
   TXNDataType iDataType,
   TXNMatchOptions iMatchOptions,
   TXNOffset iStartSearchOffset,
   TXNOffset iEndSearchOffset,
   TXNFindUPP iFindProc,
   SRefCon iRefCon,
   TXNOffset *oStartMatchOffset,
   TXNOffset *oEndMatchOffset
);
```

Parameters

iTXNObject

The text object to be searched.

iMatchTextDataPtr

A pointer to a data structure that contains the text to match, the length of that text, and the text's encoding. Pass `NULL` if you are looking for a graphics, sound, or movie object.

iDataType

The type of data for which you want to search. See Supported Data Types (page 2765) for a description of possible values. If the data type is `kTXNPictureFile`, `kTXNMovieFile`, or `kTXNSoundFile`, the default behavior is to match on any nontext object. If you want to find a specific data type, you can provide a custom find callback or ignore types that do not match what you want to find.

iMatchOptions

The matching rules to use in the find operation. See Search Criteria Masks (page 2762) for a description of possible values.

iStartSearchOffset

The offset at which the search should begin. You can use `kTXNStartOffset` if you want to search from the start of the object's data.

iEndSearchOffset

The offset at which the search should end. You can use `kTXNEndOffset` if you want to search to the end of the object's data.

iFindProc

The custom callback you want used in place of the default matching behavior. You can pass `NULL` if you want to use the default matching behavior.

iRefCon

An signed 32-bit integer. You can use this for whatever your application needs. It is passed to the custom callback specified by `iFindProc`.

oStartMatchOffset

On return, a pointer to the absolute offset that identifies the start of the match. It is set to a value of `kTXNUseCurrentSelection` if there is no match.

oEndMatchOffset

On return, a pointer to the absolute offset that identifies the end of the match. It is set to a value of `kTXNUseCurrentSelection` if there is no match.

Return Value

A result code. See "MLTE Result Codes" (page 2773).

Discussion
By default, text is matched on the basis of a binary comparison. If you set the `iMatchOptions` variable to ignore case, the characters to be searched are duplicated and case neutralized. If the want to search a large amount of text, a case insensitive search can fail due to insufficient memory.

If you set the `iMatchOptions` variable to find an entire word, then once a match is found, the matched text is tested to see if it is a word. If the `kTXNUseEncodingWordRulesBit` is set, then the Script Manager `FindWord` function is called to make this determination. If the text being searched is Unicode text, then the ATSUI word-determining functions are used to test for a word.

If the application is looking for a nontext type, then each nontext type in the document is returned. The `iFindProc` parameter lets you provide a more elaborate search engine (such as a regular expression processor) should you need one.

Offsets in MLTE are always character offsets.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNFlattenObjectToCFDataRef

Flattens a text object so it can be saved to disk or embedded with other data.

```
OSStatus TXNFlattenObjectToCFDataRef (
   TXNObject iTXNObject,
   TXNDataType iTXNDataType,
   CFDataRef *oDataRef
);
```

Parameters

`iTXNObject`
The text object that identifies the document you want to flatten. You can either call the function `TXNCreateObject` to allocate a text object or you can call the function `HITextViewGetTXNObject` (page 2611) to obtain the text object associated with an HITextView.

`iTXNDataType`
A value that specifies the format in which the data is written out.

`oDataRef`
On input, points to a structure of type `CFDataRef`. On output, points to a flattened version of the text object in the format specified by the `iTXNDataType` parameter. You are responsible to retain the returned `CFDataRef`.

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Discussion
This function supports the following data types:

- `kTXNTextData`, for text data.
- `kTXNUnicodeTextData`, for plain UTF-16.

- `kTXNTextAndMultimediaData`, for data in MLTE format.
- `kTXNRichTextFormatData`, for data in RTF format.

Availability
Available in Mac OS X v10.3 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNFocus

Changes the focus of a text object.

```
void TXNFocus (
   TXNObject iTXNObject,
   Boolean iBecomingFocused
);
```

Parameters

iTXNObject
The text object whose focus you want to change.

iBecomingFocused
If you pass `true`, the text object receives focus. This means the current selection or insertion point is active, text input appears at the insertion point, and the keyboard and font are synchronized. (Note that the font and keyboard are synchronized only if keyboard synchronization is enabled. See Keyboard Synchronization Settings (page 2756).) If the scroll bars are not already active, they are activated. If you pass `false`, the text object's current selection or insertion point is inactive.

Discussion
You should use the `TXNActivate` (page 2618) function to make scroll bars active while text input is not focused. This behavior is often desirable for windows with multiple text areas that are scrollable.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNForceUpdate

Forces an update of the view rectangle and the scroll bars.

```
void TXNForceUpdate (
   TXNObject iTXNObject
);
```

Parameters

iTXNObject
The text object you want to update.

Discussion
This function operates similarly to the Window Manager functions `InvalRect` and `InvalRgn`. For example, when the user increases the size of a window that contains text from a text object, the `TXNForceUpdate` function adds the new region (including two rectangles formerly occupied by the scroll bars in the smaller content area) to the update region.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNGetAccessibilityHIObject

Obtains an `HIObjectRef` representing the MLTE object for accessibility purposes.

```
OSStatus TXNGetAccessibilityHIObject (
   TXNObject iTXNObject,
   HIObjectRef *oHIObjectRef
);
```

Parameters

`iTXNObject`
The text object.

`oHIObjectRef`
On input, a pointer an `HIObjectRef` that, on return, represents the text object specified by `iTXNObject` as an accessible object.

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Discussion
For each MLTE object that a view creates, the view needs to call this function to get an `HIObjectRef` that can be used to represent the MLTE object as an accessible object.

After the view gets this `HIObjectRef`, it must add the `HIObjectRef` as a child of itself. The accessibility engine then routes events to MLTE accessible objects automatically.

The view must install Carbon Event handlers for `kEventAccessibleGetAllAttributeNames` and `kEventAccessibleGetNamedAttribute`, using the `HIObjectRef` as the target, to provide information for at least the following required attributes:

- kAXRoleAttribute
- kAXRoleDescriptionAttribute
- kAXWindowAttribute
- kAXPositionAttribute
- kAXSizeAttribute

MLTE also installs handlers for `kEventAccessibleGetAllAttributeNames` and `kEventAccessibleGetNamedAttribute`. Note that these handlers are not called unless the client-installed handlers return `eventNotHandledErr`. These handlers return information for the following attributes:

- kAXEnabledAttribute
- kAXFocusedAttribute
- kAXValueAttribute
- kAXSelectedTextAttribute
- kAXSelectedTextRangeAttribute
- kAXNumberOfCharactersAttribute
- kAXLineForIndexParameterizedAttribute
- kAXRangeForLineParameterizedAttribute
- kAXStringForRangeParameterizedAttribute
- kAXRangeForPositionParameterizedAttribute
- kAXRangeForIndexParameterizedAttribute
- kAXBoundsForRangeParameterizedAttribute
- kAXStyleRangeForIndexParameterizedAttribute

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNGetActionChangeCount

Retrieves the number of times the specified action or actions have occurred since the count was initialized or cleared. (Deprecated in Mac OS X v10.4. Use `TXNGetCountForActionType` (page 2649) instead.)

Not recommended.

```
OSStatus TXNGetActionChangeCount (
   TXNObject iTXNObject,
   TXNCountOptions iOptions,
   ItemCount *oCount
);
```

Parameters

iTXNObject
The text object whose action count you want to retrieve.

iOptions
The `TXNCountOptions` to use when retrieving the count. See Action Count Masks (page 2721) for information on the options you can supply.

oCount
On return, a pointer to the action count.

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Availability
Available in Mac OS X v10.1 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNGetChangeCount

Retrieves the number of times a document has been changed.

```
ItemCount TXNGetChangeCount (
   TXNObject iTXNObject
);
```

Parameters

iTXNObject
The text object whose changes you want to count.

Return Value
The total number of changes since the document was last saved. If the document is new, the number of changes since it was created.

Discussion
The change count increments for every executed command such as Cut or Copy. An uninterrupted sequence of key-down events increments the count by 1. The count is cleared each time the text object is saved. You can use this function to determine if your application should make the Save item in the File menu active.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNGetCommandEventSupport

Obtains the command event support that is currently set for an MLTE object.

```
OSStatus TXNGetCommandEventSupport (
   TXNObject iTXNObject,
   TXNCommandEventSupportOptions *oOptions
);
```

Parameters

iTXNObject
The text object.

oOptions

A pointer to a value of type `TXNCommandEventSupportOptions` that, on return, contains the option settings for the text object specified by `iTXNObject`. For possible values, see Command Event Support Options (page 2729).

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Availability
Available in Mac OS X v10.4 and later.

Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNGetContinuousTypeAttributes

Checks to see if the attributes of the current selection are continuous.

```
OSStatus TXNGetContinuousTypeAttributes (
   TXNObject iTXNObject,
   TXNContinuousFlags *oContinuousFlags,
   ItemCount iCount,
   TXNTypeAttributes ioTypeAttributes[]
);
```

Parameters

iTXNObject

The text object that contains the current selection.

oContinuousFlags

On return, a pointer to a value that specifies whether text attributes are continuous. See Continuous Style Information Masks (page 2731) for a description of possible values. If a particular bit is set and if your application has passed a `tag` value in a `TXNTypeAttributes` structure in the array that corresponds to the bit, then your application should display a check mark next to the appropriate menu item.

ioCount

The number of `TXNTypeAttributes` structures in the `ioTypeAttributes` array.

ioTypeAttributes

An array of `TXNTypeAttributes` structures. The `tag` values in this array indicate the text attributes in which the application is interested. It cannot be `NULL`. If you are using ATSUI and you want to know the ATSUI font ID, you should set the `tag` field to `kATSUFontTag`, which is a constant in `ATSUnicode.h`. If you are using ATSUI and you set the `tag` field to a QuickDraw font ID, then the QuickDraw font to which the ATSUI font maps is returned. Note that this is not always the same font since many ATSUI fonts are not supported by QuickDraw.

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Discussion
You can use this function to determine whether your application should display check marks in the Font, Style, Size, and Color menus. If these are the only attributes in which you are interested, you can use this function on systems that use QuickDraw or Apple Type Services for Unicode Imaging (ATSUI).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNGetCountForActionType

Gets the number of times a given type of action has occurred.

```
OSStatus TXNGetCountForActionType (
   TXNObject iTXNObject,
   CFStringRef iActionTypeName,
   ItemCount *oCount
);
```

Parameters

iTXNObject
The text object to query.

iActionTypeName
The action type that is to be included when retrieving the count. This parameter can be the string that was passed to `TXNBeginActionGroup` (page 2621) or one of the constants described in Action Constants (page 2719).

oCount
On return, the number of times the action specified by `iActionTypeName` has occurred.

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Discussion
Call `TXNClearCountForActionType` (page 2626) to reset the counters.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNGetData

Copies a range of data.

```
OSStatus TXNGetData (
   TXNObject iTXNObject,
   TXNOffset iStartOffset,
   TXNOffset iEndOffset,
   Handle *oDataHandle
);
```

Parameters

iTXNObject

The text object that contains the data you want to copy.

iStartOffset

The absolute offset from which data copying should begin. Make sure the `iStartOffset` and `iEndOffset` parameters do not specify a range that includes text and nontext data (that is, crosses a data type boundary). You can use the `TXNGetSelection` (page 2658) function to get the absolute offsets of the current selection.

iEndOffset

The absolute offset at which data copying should end. You can use the `TXNGetSelection` function to get the absolute offsets of the current selection.

oDataHandle

A pointer to a handle. On return, the handle points to the requested data. `TXNGetData` allocates the handle as necessary. Your application must dispose of the handle.

Return Value

A result code. See "MLTE Result Codes" (page 2773). The `iStartOffset` and `iEndOffset` parameters can specify a range that crosses a style run boundary but not a range that crosses a data type boundary. If the range includes text and nontext data, the `TXNGetData` function returns the error code `kTXNIllegalToCrossDataBoundariesErr`.

Discussion

You first need to use the `TXNCountRunsInRange` (page 2629) function to find the number of data runs in a given range. Then you can examine each run's type and text attributes with the `TXNGetIndexedRunInfoFromRange` (page 2654) function. Finally, use the `TXNGetData` function to examine data for each run of interest to you. The function does not check to see that the copied data aligns on a word boundary; data is simply copied as specified by the offset values.

Offsets in MLTE are always character offsets.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`MacTextEditor.h`

TXNGetDataEncoded

Copies the text in a specified range, and if necessary, translates the text to match your application's preferred encoding.

```
OSStatus TXNGetDataEncoded (
   TXNObject iTXNObject,
   TXNOffset iStartOffset,
   TXNOffset iEndOffset,
   Handle *oDataHandle,
   TXNDataType iEncoding
);
```

Parameters

iTXNObject

The text object that contains the data you want to copy.

iStartOffset

The absolute offset from which data copying should begin. You can use the `TXNGetSelection` (page 2658) function to get the absolute offsets of the current selection.

iEndOffset

The absolute offset at which data copying should end. You can use the `TXNGetSelection` (page 2658) function to get the absolute offsets of the current selection.

oDataHandle

A pointer to a handle. On return, a handle to the requested data. `TXNGetDataEncoded` allocates the handle as necessary. Your application must dispose of the handle. If there is no text in the range specified, the returned handle is `NULL`, and the function returns `noErr`.

encoding

The type of data to be encoded. See Supported Data Types (page 2765) for a full description of possible values. You should specify either the `kTXNTextData` or `kTXNUnicodeTextData` constant. If the `iEncoding` parameter specifies an encoding different from that used to store the text data internally, the Conversion Manager translates the data to the specified type (text or Unicode). If the `iEncoding` parameter is not recognized, the data is returned in the current encoding. On systems that do not use ATSUI version 1.1 or later, the current encoding is the Mac OS encoding. Otherwise, the current encoding is Unicode.

Return Value

A result code. See "MLTE Result Codes" (page 2773).

Discussion

Offsets in MLTE are always character offsets.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`MacTextEditor.h`

TXNGetEventTarget

Obtains the current event target for a TXNObject.

```
OSStatus TXNGetEventTarget (
   TXNObject iTXNObject,
   HIObjectRef *oEventTarget
);
```

Parameters

iTXNObject

The text object.

oEventTarget

A pointer to an `HIObjectRef` that, on return, points to the current event target for the TXNObject specified by `iTXNObject`.

Return Value

A result code. See "MLTE Result Codes" (page 2773).

Discussion

This function obtains the current event target for the TXNObject specified by `iTXNObject`. Use this function to obtain the target and then install your own handlers.

Availability

Available in Mac OS X v10.4 and later.

Not available to 64-bit applications.

Declared In

`MacTextEditor.h`

TXNGetFontDefaults

Makes a copy of the font descriptions for a given text object. (Deprecated in Mac OS X v10.4.)

```
OSStatus TXNGetFontDefaults (
   TXNObject iTXNObject,
   ItemCount *ioCount,
   TXNMacOSPreferredFontDescription oFontDefaults[]
);
```

Parameters

iTXNObject

The text object for the document whose default font settings you want to copy.

ioCount

A pointer to a value of type `ItemCount`. You need to call the `TXNGetFontDefaults` function twice (see Discussion). The first time you call the function, pass `NULL`. On return, the `ioCount` parameter specifies the number of font descriptions associated with the text object. The second time you call `TXNGetFontDefaults`, on return the `ioCount` parameter points to the number of font descriptions in the `iFontDefaults` array.

iFontDefaults

An array of `TXNMacOSPreferredFontDescription` structures to be filled. You need to call the `TXNGetFontDefaults` function twice (see Discussion). The first time you call the function pass `NULL`. The second time you call `TXNGetFontDefaults`, you can initialize the `iFontDefaults` array to have the number of elements specified by the `ioCount` parameter. Then on return, the `iFontDefaults` parameter contains the font descriptions for the text object.

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Discussion
You need to call this function twice: once to get the number of font default descriptions (returned in the `ioCount` parameter), and the second time to get the font default data.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNGetFontMenuHandle

Gets the Font menu handle that belongs to a Font menu object. (Deprecated in Mac OS X v10.5.)

```
OSStatus TXNGetFontMenuHandle (
   TXNFontMenuObject iTXNFontMenuObject,
   MenuRef *oFontMenuHandle
);
```

Parameters

iTXNFontMenuObject
A Font menu object.

fontMenuHandle
A pointer to a menu handle. On return, a pointer to the Font menu created when the Font menu object was created. MLTE makes a copy of the menu handle. Your application should not dispose of the menu handle until it disposes of the Font menu object by calling the `TXNDisposeFontMenuObject` (page 2633).

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNGetHIRect

Obtains the values for the current view, destination, or text rectangle.

```
OSStatus TXNGetHIRect (
   TXNObject iTXNObject,
   TXNRectKey iTXNRectKey,
   HIRect *oRectangle
);
```

Parameters

iTXNObject

The text object for the current text area. You can either call the function `TXNCreateObject` to allocate a text object or you can call the function `HITextViewGetTXNObject` (page 2611) to obtain the text object associated with an HITextView.

iTXNRectKey

A value that specifies the rectangle you want the function to obtain. See `Rectangle Keys` (page 2759) for a list of the constants you can supply.

oRectangle

On output, points to the `HIRect` data structure that contains the coordinates for the requested rectangle.

Return Value

A result code. See "MLTE Result Codes" (page 2773).

Availability

Available in Mac OS X v10.3 and later.

Not available to 64-bit applications.

Declared In

`MacTextEditor.h`

TXNGetIndexedRunInfoFromRange

Gets information about a run in a range of data.

```
OSStatus TXNGetIndexedRunInfoFromRange (
   TXNObject iTXNObject,
   ItemCount iIndex,
   TXNOffset iStartOffset,
   TXNOffset iEndOffset,
   TXNOffset *oRunStartOffset,
   TXNOffset *oRunEndOffset,
   TXNDataType *oRunDataType,
   ItemCount iTypeAttributeCount,
   TXNTypeAttributes *ioTypeAttributes
);
```

Parameters

iTXNObject

The text object for the current text area.

iIndex

The value that corresponds to the run for which you want to get information. You call the `TXNCountRunsInRange` (page 2629) function to get the number of runs in a range. The `iIndex` parameter is zero-based, so its possible values are from 0 to the number of runs in a range minus 1. Note that the index is relative to the first run in the range specified by the `iStartOffset` and `iEndOffset` parameters, not for the entire document.

iStartOffset

The offset at which you want to start to obtain run information. This value must be the same value that you passed previously to the function `TXNCountRunsInRange`.

iEndOffset

The offset at which you want run information to end. This value must be the same value that you passed previously to the function `TXNCountRunsInRange`.

oRunStartOffset

On return, a pointer to a value that identifies the start of run relative to the beginning of the text, not the beginning of the range you specified in the `iStartOffset` parameter.

oRunEndOffset

On return, a pointer to a value that identifies the end of the run relative to the beginning of the text, not the beginning of the range you specified in the `iStartOffset` parameter.

oRunDataType

On return, a pointer to a value that identifies the type of data in the run. See Supported Data Types (page 2765) for a description of possible values.

iTypeAttributeCount

The number of font attributes.

ioTypeAttributes

A pointer to a structure of type `TXNTypeAttributes`. On input, you specify the attribute (such as size) in the `tag` field and the attribute size in the `size` field. You can pass `NULL` for the `data` field only if the size of the returned value <= 4. Otherwise a pointer to an appropriately sized block of data must be placed in one of the other members of the `ioTypeAttributes` union, such as, `dataPtr`, `atsuFeatures`, `atsuVariations`. On return, the `data` field contains the attribute data. The `data` field is a union that serves either as a 32-bit integer or a 32-bit pointer, depending on the `size` field.

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Discussion
You should first call the `TXNCountRunsInRange` function to get the count. The `TXNTypeAttributes` structure must specify the text attribute in which the application is interested. In other words, the `tag` and `size` fields must be set.

Offsets in MLTE are always character offsets.

If a tag specified in the `ioTypeAttributes` parameter is not recognized by MLTE—that is, the tag isn't a `TXTNTag` value, a `TXNTypeRunAttributes` value, or a valid style run attribute tag (`ATSUAttributeTag`)—then the constant `kTXNAttributeTagInvalidForRunErr` is returned in the `ioTypeAttributes->data.dataValue` field for that particular tag. The function continues to process the remaining tags, but returns the result code `kTXNSomeOrAllTagsInvalidForRunErr`. Both of these values (`kTXNAttributeTagInvalidForRunErr` and `kTXNSomeOrAllTagsInvalidForRunErr`) are used either when a tag is not recognized or a tag is recognized but some error occurred in trying to obtain the attribute.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNGetLineCount

Gets the total number of lines in a text object.

```
OSStatus TXNGetLineCount (
   TXNObject iTXNObject,
   ItemCount *oLineTotal
);
```

Parameters

iTXNObject

The text object that identifies the document whose line count you want to get.

oLineTotal

On return, a pointer to the number of lines in the text object.

Return Value

A result code. See "MLTE Result Codes" (page 2773).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`MacTextEditor.h`

TXNGetLineMetrics

Gets information about line width and height for a specified line of data in a text object.

```
OSStatus TXNGetLineMetrics (
   TXNObject iTXNObject,
   unsigned long iLineNumber,
   Fixed *oLineWidth,
   Fixed *oLineHeight
);
```

Parameters

iTXNObject

The text object that identifies the document whose line metrics you want to get.

iLineNumber

A value that specifies the line whose metrics you want to retrieve. You should use the `TXNGetLineCount` (page 2656) function to determine how many lines are in the text object so that you specify a valid line number. Line numbers start at 0.

oLineWidth

On return, a pointer to the width of the line, in pixels.

oLineHeight

On return, a pointer to the height of the line, in pixels.

Return Value

A result code. See "MLTE Result Codes" (page 2773).

Discussion

You can use height and width information to adjust the size of the text object's frame.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNGetRectBounds

Obtains the values for the current view, destination, and text rectangles. (Deprecated in Mac OS X v10.3. Use `TXNGetHIRect` (page 2653) instead.)

Not recommended.

```
OSStatus TXNGetRectBounds (
   TXNObject iTXNObject,
   Rect *oViewRect,
   TXNLongRect *oDestinationRect,
   TXNLongRect *oTextRect
);
```

Parameters

iTXNObject
The text object for the current text area.

oViewRect
On output, a pointer to the `Rect` data structure that contains the coordinates for the view rectangle. If you do not want to obtain this structure, pass `NULL`. The view rectangle specifies the area of the text you see. Scroll bars are drawn inside the view rectangle.

oDestinationRect
On output, a pointer to the `TXNLongRect` data structure that contains the coordinates for the destination rectangle. If you do not want to obtain this structure, pass `NULL`. The destination rectangle controls how text is laid out.

oTextRect
On output, a pointer to the `TXNLongRect` data structure that contains the coordinates for the text rectangle. If you do not want to obtain this structure, pass `NULL`. The text rectangle is the smallest rectangle needed to contain the current text. MLTE calculates the text rectangle by measuring each line of text. So this can be slow performance. The width of the text rectangle is the width of the longest line in the text.

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Discussion
You need only to pass pointers for the rectangles for which you want to obtain coordinates.

Availability
Available in Mac OS X v10.1 and later.
Deprecated in Mac OS X v10.3.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNGetSelection

Gets the absolute offsets of the current selection.

```
void TXNGetSelection (
   TXNObject iTXNObject,
   TXNOffset *oStartOffset,
   TXNOffset *oEndOffset
);
```

Parameters

iTXNObject

The text object for the current text area.

oStartOffset

On return, a pointer to the absolute starting offset of the current selection.

oEndOffset

On return, a pointer to the absolute ending offset of current selection.

Discussion

Offsets in MLTE are always character offsets. Each embedded graphics or sound object is counted as one character.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Related Sample Code

QTMetaData

Declared In

`MacTextEditor.h`

TXNGetSleepTicks

Reports the appropriate amount of time to allot to background processes, depending on the state of the window.

```
UInt32 TXNGetSleepTicks (
   TXNObject iTXNObject
);
```

Parameters

iTXNObject

The text object that identifies the current document.

Return Value

The appropriate wait time, in ticks. You pass this value to the `WaitNextEvent` function.

Discussion

In a cooperative processing environment, your application must determine how much time to give to background processes. A tick is 1/60 of a second.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In
MacTextEditor.h

TXNGetSpellCheckAsYouType

Determines whether the "Spell Check as You Type" feature is enabled.

```
Boolean TXNGetSpellCheckAsYouType (
   TXNObject iTXNObject
);
```

Parameters

iTXNObject
The text object to query.

Return Value
A Boolean whose value is `true` if the "Spell Check as You Type" feature is enabled; otherwise, `false`.

Discussion
Call `TXNSetSpellCheckAsYouType` (page 2693) to enable or disable the "Spell Check as You Type" feature.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
MacTextEditor.h

TXNGetTXNObjectControls

Gets the current formatting and privileges attributes (such as justification, line direction, tab values, and read-only status) for a text object.

```
OSStatus TXNGetTXNObjectControls (
   TXNObject iTXNObject,
   ItemCount iControlCount,
   const TXNControlTag iControlTags[],
   TXNControlData oControlData[]
);
```

Parameters

iTXNObject
The text object that identifies the document to be activated.

iControlCount
The number of items in the `iControlTags` array.

iControlTags
An array of values that specify the kind of formatting information you want returned in the `oControlData` array. See Formatting and Privileges Settings (page 2742) for a description of possible values.

oControlData

An array of TXNControlData (page 2711) unions. On return, the array contains the information that was requested through the iControlTags array. Your application must allocate the oControlData array.

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
MacTextEditor.h

TXNGetViewRect

Gets the rectangle that describes the current view of the document.

```
void TXNGetViewRect (
   TXNObject iTXNObject,
   Rect *oViewRect
);
```

Parameters

iTXNObject

The text object for the current text area.

oViewRect

On return, a pointer to a rectangle that describes the view of the document. The area described by the oViewRect parameter does not include the area that encloses the scroll bars. The coordinates of this rectangle are local to the window.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
MacTextEditor.h

TXNGetWindowRef

Returns a reference to the window to which the specified text object is attached.

```
WindowRef TXNGetWindowRef (
   TXNObject iTXNObject
);
```

Parameters

iTXNObject

The text object for which you want to obtain a window reference. You can call the function TXNCreateObject to allocate a text object.

Return Value
The window to which the text object is attached. Returns NULL if no window is attached.

Availability
Available in Mac OS X v10.3 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNGrowWindow

Adjusts the size of a window in response to mouse-down events in the size region of the window.

```
void TXNGrowWindow (
   TXNObject iTXNObject,
   const EventRecord *iEvent
);
```

Parameters

iTXNObject
The text object for the current text area.

iEvent
A pointer to the event record that contains the mouse-down event you want to apply to the window.

Discussion
The text object must be contained in a window and not a subframe of the window; otherwise the function does not adjust the size of the window. Before you call `TXNGrowWindow`, you should make sure that the front window belongs to your application.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNHIPointToOffset

Gets the offset value that corresponds to a point in local coordinates.

```
OSStatus TXNHIPointToOffset (
   TXNObject iTXNObject,
   const HIPoint *iHIPoint,
   TXNOffset *oOffset
);
```

Parameters

iTXNObject
The text object for which you want to obtain an offset value. You can either call the function `TXNCreateObject` to allocate a text object or you can call the function `HITextViewGetTXNObject` (page 2611) to obtain the text object associated with an HITextView.

iHIPoint
The local coordinates of the point for which you want to obtain the offset value.

oOffset
On output, a pointer to the offset that corresponds to the value of the `iHIPoint` parameter.

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Discussion
Offsets in MLTE are always character offsets.

Availability
Available in Mac OS X v10.3 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNIdle

Does idle time processing, such as flashing the cursor.

```
void TXNIdle (
   TXNObject iTXNObject
);
```

Parameters
iTXNObject
The text object that identifies the current document.

Discussion
Before you call the `TXNIdle` function, you should make sure that the front window belongs to your application.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNInitTextension

Initializes MLTE.

```
OSStatus TXNInitTextension (
   const TXNMacOSPreferredFontDescription iDefaultFonts[],
   ItemCount iCountDefaultFonts,
   TXNInitOptions iUsageFlags
);
```

Parameters

iDefaultFonts

An array of `TXNMacOSPreferredFontDescription` structures. You use this to specify a table of font information that includes the font family ID, point size, style, and script code. The table can be `NULL` or can have an entry for any script for which you would like to designate a default font. To designate that MLTE should use the default settings for a specified script, you need to supply a valid script code value in the `TextEncoding` field of the font description structure and a value of `kTXNUseScriptDefaultValue` in all other fields of the structure. In Mac OS X, the default settings are read from the Theme settings. In Mac OS 9, the default settings are read from the Script Manager.

iCountDefaultFonts

The number of scripts for which you are designating a default font in the `iDefaultFonts` array.

iUsageFlags

A value that specifies whether embedded objects should be supported. You can also specify whether MLTE should use QuickDraw as the imaging system and whether temporary memory should be used. See Initialization Option Masks (page 2754) for a description of possible values.

Return Value

A result code. See "MLTE Result Codes" (page 2773).

Discussion

For systems prior to Mac OS X v10.3, you should call this function along with any other initialization calls you make when your application starts up. If you call this function a second time, it has no effect; the defaults you set up the first time you called the `TXNInitTextension` function are in effect until you call the `TXNTerminateTextension` (page 2696) function.

For Mac OS X v10.3 and later, you do not have to call this function. However, you may want to call this function to set default fonts that are different from the system default font or to enable multimedia support.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`MacTextEditor.h`

TXNIsObjectAttachedToSpecificWindow

Determines whether a text object is attached to a specified window. (Deprecated in Mac OS X v10.3. Use `TXNGetWindowRef` (page 2660) instead.)

Not recommended.

```
OSStatus TXNIsObjectAttachedToSpecificWindow (
   TXNObject iTXNObject,
   WindowRef iWindow,
   Boolean *oAttached
);
```

Parameters

iTXNObject

The text object that identifies the document you want to check.

iWindow

A reference to the window against which to check attachment.

oAttached

On output, `true` if the text object is attached to the specified window; `false` otherwise.

Return Value

A result code. See "MLTE Result Codes" (page 2773).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.3.

Not available to 64-bit applications.

Declared In

`MacTextEditor.h`

TXNIsObjectAttachedToWindow

Checks to see if a text object is attached to a window. (Deprecated in Mac OS X v10.3. Use `TXNGetWindowRef` (page 2660) instead.)

Not recommended.

```
Boolean TXNIsObjectAttachedToWindow (
   TXNObject iTXNObject
);
```

Parameters

iTXNObject

The text object that identifies the document you want to check.

Return Value

A `Boolean` value; returns `true` if the object is attached.

Discussion

You can call this before you call the `TXNAttachObjectToWindow` (page 2620) function to make sure the text object is not already attached to a window. If you pass `NULL` in the `iWindow` parameter of `TXNNewObject` (page 2667) you create a text object without an associated window pointer.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.3.

Not available to 64-bit applications.

Declared In
MacTextEditor.h

TXNIsScrapPastable

Tests whether the Clipboard contains data that is supported by MLTE.

```
Boolean TXNIsScrapPastable (
   void
);
```

Return Value
Returns `true` if the data type on the Clipboard is supported.

Discussion
You can call the `TXNIsScrapPastable` function to determine if the Paste item in the Edit menu should be active.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
MacTextEditor.h

TXNIsSelectionEmpty

Determines whether the current selection is empty.

```
Boolean TXNIsSelectionEmpty (
   TXNObject iTXNObject
);
```

Parameters
iTXNObject
The text object for the current text area.

Return Value
A `Boolean` value. It is `true` if the current selection is empty.

Discussion
You can use the `TXNIsSelectionEmpty` function to determine whether your application should enable the Cut, Copy, and Clear items in the Edit menu.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
MacTextEditor.h

TXNKeyDown

Processes a key-down event.

```
void TXNKeyDown (
   TXNObject iTXNObject,
   const EventRecord *iEvent
);
```

Parameters

iTXNObject

The text object that identifies the active document.

iEvent

A pointer to the event record that contains the key-down event you want handled. You cannot pass `NULL`.

Discussion

Before you call the `TXNKeyDown` function, you should make sure that the front window belongs to your application. Text input occurs in the text object's window. This is always the case unless the application has requested text input through a bottom-line window (a small window that appears at the bottom of the screen) or has turned off the Text Services Manager (TSM).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`MacTextEditor.h`

TXNNewFontMenuObject

Creates a new Font menu object. (Deprecated in Mac OS X v10.5.)

```
OSStatus TXNNewFontMenuObject (
   MenuRef iFontMenuHandle,
   SInt16 iMenuID,
   SInt16 iStartHierMenuID,
   TXNFontMenuObject *oTXNFontMenuObject
);
```

Parameters

iFontMenuHandle

A value of type `MenuRef` obtained by calling the Menu Manager functions `CreateNewMenu`, `NewMenu`, `CreateMenuFromNib`, or `GetMenu`. Before calling `TXNNewFontMenuObject`, initialize the `menuData` field of the handle to specify the menu title, in Pascal string format. You must make sure the string is localized appropriately.

iMenuID

The menu ID of the Font menu.

iStartHierMenuID

The first MenuID to use if any hierarchical menus need to be created. This function calls `SetMenuItemHierarchicalID` to create hierarchical menus, so the value of this parameter must follow the rules for that function. On systems less than Mac OS 8.5, the submenuID must be less than 255. For systems after Mac OS 8.5, the range can be as large as large 32767. However, it is important to remember that `TXNNewFontMenuObject` only uses `iStartHierMenuID` as a starting ID when adding hierarchical menus. Therefore provide plenty of room to increment this value. For example, on a system less than Mac OS 8.5, start at 175. On systems after than Mac OS 8.5, do not use a value more than 32000.

oTXNFontMenuObject

A pointer to a structure of type `TXNFontMenuObject` (page 2712). On return, a new Font menu object.

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Discussion
A good time to call the `TXNNewFontMenuObject` function is when you are preparing to display your menu bar. This function fills the Font menu with font names. Later, you can pass the Font menu object along with a text object to the `TXNDoFontMenuSelection` function which handles all aspects of user interaction with the Font menu.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNNewObject

Creates a new MLTE text object which is an opaque structure that handles text formatting at the document level. (Deprecated in Mac OS X v10.3. Use `TXNCreateObject` (page 2630) instead.)

Not recommended.

```
OSStatus TXNNewObject (
   const FSSpec *iFileSpec,
   WindowRef iWindow,
   const Rect *iFrame,
   TXNFrameOptions iFrameOptions,
   TXNFrameType iFrameType,
   TXNFileType iFileType,
   TXNPermanentTextEncodingType iPermanentEncoding,
   TXNObject *oTXNObject,
   TXNFrameID *oTXNFrameID,
   TXNObjectRefcon iRefCon
);
```

Parameters

iFileSpec

A pointer to a variable of type `FSSpec`. If you pass `NULL` you start with an empty document. Otherwise, the contents of the file to which `iFileSpec` points are read into the object. The referenced file must consist entirely of data that MLTE can read (`'TEXT'`, `'RTF '`, `'utxt'`, or `'txtn'`). If the referenced file contains your application's private data and data that MLTE can read, you should call the `TXNNewObject` function with the `iFileSpec` parameter set to `NULL`. Once `TXNNewObject` creates the text object, your application can read the private data into the text object by calling the `TXNSetDataFromFile` (page 2685) function.

iWindow

A reference to the window in which the document will be displayed. This parameter can be `NULL`. If it is `NULL`, you must attach a window or graphics port to the text object by using the `TXNAttachObjectToWindow` (page 2620) function.

iFrame

A pointer to a variable of type `Rect`. If you pass `NULL`, the window's `portRect` rectangle is used as the frame. If you do not want to fill the entire window, you use the `iFrame` parameter to specify the area to fill.

iFrameOptions

A value that specifies the options you want the frame to support. See Frame Option Masks (page 2749) for a description of possible values.

If you want to create a read-only document, you need to pass the option `kTXNReadOnlyMask`. Note that this option puts the text object into a state that does not allow user input. However, your application can put data into the text object by calling the function `TXNSetData`. If you want the text object set into a more restrictive read-only state that does not allow user input or your application to put data into the text object programmatically, you need to call the function `TXNSetTXNObjectControls`, passing the tag `kTXNIOPrivilegesTag`. If you choose to set the text object into this restrictive state, you will get an error if you try to call the function `TXNSetData` on the text object. (In this case, you can change the text object to a less restrictive state by calling `TXNSetTXNObjectControls`, passing the tag `kTXNNoUserIOTag`.)

iFrameType

A value that specifies the frame type of the text object. See Supported Frame Types (page 2767) for a description of possible values.

iFileType

A value that specifies the file type of the text object. See Supported File Types (page 2766) for a description of possible values. You should specify the primary file type. If you use the `kTXNTextensionFile` constant, files are saved in a custom format. If you want saved files to be plain text files, you should specify the `kTXNTextFile` constant, then use the `iframeOptions` parameter to specify whether the plain text files should be saved with `kTXNSingleStylePerTextDocumentResType` or `kTXNMultipleStylesPerTextDocumentResType` resources.

iPermanentEncoding

A value that specifies the encoding in which the document is saved. See Text Encoding Preferences (page 2772) for a description of possible values.

oTXNObject

A pointer to a structure of type `TXNObject`. On return, this points to the opaque text object data structure allocated by the function. You need to pass this object to most MLTE functions.

oTXNFrameID

On return, a pointer to the unique ID for the text object's frame. However, in MLTE version 1.1 and earlier, the frame ID is always set to 0.

iRefCon

A value of type `TXNObjectRefcon`. You can define how to use this for your application. You can set this to any value and retrieve it later.

Return Value

A result code. See "MLTE Result Codes" (page 2773).

Discussion

For each document, a new text object is allocated by the `TXNNewObject` function and returned in the `oTXNObject` parameter. The object is allocated only if no errors occur, including errors that may occur when reading a file. If there is an error during the allocation process, MLTE frees the text object.

If you are writing a text editing application, you may want to call the `TXNNewObject` function when the application launches (a new document will be displayed) and whenever the user selects New from the File menu.

Many MLTE functions require you to pass a text object; some functions also require the frame ID supplied back to your application in the `oTXNFrameID` parameter of `TXNNewObject`.

Because of how MLTE uses Carbon events internally, the window in which the document is displayed must have the standard event handlers installed. You can do this in one of the following ways:

- When you create the window, add the attribute `kWindowStandardHandlerAttribute` to the window. See *Inside Mac OS X: Window Manager Reference* for more information.
- Call the Carbon Event Manager function `InstallStandardEventHandler` on the window's event target. See *Inside Mac OS X: Handling Carbon Events* for more information.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.3.

Not available to 64-bit applications.

Declared In

`MacTextEditor.h`

TXNOffsetToHIPoint

Obtains the local coordinates of the point that corresponds to a specified offset of a text object.

```
OSStatus TXNOffsetToHIPoint (
   TXNObject iTXNObject,
   TXNOffset iOffset,
   HIPoint *oHIPoint
);
```

Parameters

iTXNObject

The text object for which you want to obtain the local coordinates of a point. You can either call the function `TXNCreateObject` to allocate a text object or you can call the function `HITextViewGetTXNObject` (page 2611) to obtain the text object associated with an HITextView.

iOffset

The offset value of the point for which you want to obtain the local coordinates.

oPoint

On output, a pointer to the local coordinates of the point that corresponds to the value of the `iOffset` parameter.

Return Value

A result code. See "MLTE Result Codes" (page 2773).

Discussion

Offsets in MLTE are always character offsets.

Availability

Available in Mac OS X v10.3 and later.

Not available to 64-bit applications.

Declared In

`MacTextEditor.h`

TXNOffsetToPoint

Gets the local coordinates of the point that corresponds to a specified offset of a text object. (Deprecated in Mac OS X v10.3. Use `TXNOffsetToHIPoint` (page 2670) instead.)

Not recommended.

```
OSStatus TXNOffsetToPoint (
   TXNObject iTXNObject,
   TXNOffset iOffset,
   Point *oPoint
);
```

Parameters

iTXNObject

The text object for which you want to obtain the local coordinates of a point.

iOffset

An offset value.

oPoint
On return, a pointer to the local coordinates of the point that corresponds to the value of the `iOffset` parameter.

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Discussion
Offsets in MLTE are always character offsets.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.3.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNPageSetup

Displays the Page Setup dialog for the current default printer and manages changes, such as reformatting the text, in response to page layout changes.

```
OSStatus TXNPageSetup (
   TXNObject iTXNObject
);
```

Parameters
iTXNObject
The text object for the active document.

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNPaste

Pastes the contents of the private MLTE scrap into the text object.

```
OSStatus TXNPaste (
   TXNObject iTXNObject
);
```

Parameters
iTXNObject
The text object that identifies the current document.

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Discussion
Before you call `TXNPaste`, you can call the `TXNIsScrapPastable` (page 2665) function to determine if the current scrap contains data supported by MLTE.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNPointToOffset

Gets the offset value that corresponds to a point in local coordinates. (Deprecated in Mac OS X v10.3. Use `TXNHIPointToOffset` (page 2661) instead.)

Not recommended.

```
OSStatus TXNPointToOffset (
   TXNObject iTXNObject,
   Point iPoint,
   TXNOffset *oOffset
);
```

Parameters

iTXNObject
The text object for which you want to obtain an offset value.

iPoint
The local coordinates of a point.

oOffset
On return, a pointer to the offset that corresponds to the value of the `iPoint` parameter.

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Discussion
Offsets in MLTE are always character offsets.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.3.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNPrepareFontMenu

Prepares a Font menu for display. (Deprecated in Mac OS X v10.5.)

```
OSStatus TXNPrepareFontMenu (
   TXNObject iTXNObject,
   TXNFontMenuObject iTXNFontMenuObject
);
```

Parameters

iTXNObject

The text object that identifies the document with the Font menu you want to prepare. Pass `NULL` to display an inactive menu (dimmed).

iTXNFontMenuObject

A Font menu object.

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Discussion
You should call the `TXNPrepareFontMenu` function just before your application opens the Font menu for your user. If the text object's current selection is a single font, MLTE places a check mark next to the menu item for that font.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNPrint

Prints the document so it is formatted to fit the page size selected for the printer.

```
OSStatus TXNPrint (
   TXNObject iTXNObject
);
```

Parameters

iTXNObject

The text object that identifies the document you want to print.

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNReadFromCFURL

Reads data from a `CFURLRef` into a TXNObject.

```
OSStatus TXNReadFromCFURL (
   TXNObject iTXNObject,
   TXNOffset iStartOffset,
   TXNOffset iEndOffset,
   CFDictionaryRef iDataOptions,
   CFURLRef iFileURL,
   CFDictionaryRef *oDocumentAttributes
);
```

Parameters

iTXNObject

The text object into which data read from `iFileURL` is to be added.

iStartOffset

The offset in `iTXNObject` at which to start placing data read from `iFileURL`.

iEndOffset

The offset in `iTXNObject` at which to stop placing data read from `iFileURL`.

iDataOptions

Options for reading the data. See Data Option Key Value Constants (page 2733) for a list of the supported options. If this parameter is `NULL`, the data is read in using MLTE's native format.

iFileURL

A `CFURLRef` to the data that is to be added to the text object specified by `inTXNObject`.

oDocumentAttributes

A value of type CFDictionary that, on return, contains the document attributes present in the data stream, if the file format supports them; otherwise this parameter is `NULL`. The native MLTE file format and RTF support embedded document attributes. See Document Attribute Keys (page 2735) for a list of supported attributes. If this parameter is `NULL`, no document attributes are written out.

Return Value

A result code. See "MLTE Result Codes" (page 2773).

Discussion

This function reads data from a file or a special file bundle (directory) into a text object. Offset parameters are used to specify whether the new data is inserted, appended or replaces an existing data range in the text object. Clients can specify the document format and encoding of the data using the `iDataOptions` parameter. This functions also returns the document attributes present in the data stream. Document attributes are supported only for the rich text file formats supported by MLTE, which are RTF and MLTE native file format.

If the caller passes a pointer to a `CFDictionaryRef`, this function returns a reference to a dictionary of attributes, if there is one, that the caller is responsible for releasing. In all other cases, this function sets the reference to `NULL`. Here is some sample code:

```
CFDictionaryRef oDocumentAttributes = NULL;
status = TXNReadFromCFURL (....,&oDocumentAttributes);
if (oDocumentAttributes != NULL) ::CFRelease(oDocumentAttributes);
```

Availability

Available in Mac OS X v10.4 and later.

Not available to 64-bit applications.

Declared In

`MacTextEditor.h`

TXNRecalcTextLayout

Recalculates the text layout based on new view and destination rectangles.

```
void TXNRecalcTextLayout (
   TXNObject iTXNObject
);
```

Parameters

iTXNObject

The text object whose layout you want to recalculate.

Discussion

You can call the function `TXNRecalcTextLayout` if you call the function `TXNSetRectBounds` (page 2690) with the `iUpdate` parameter set to `false`. `TXNRecalcTextLayout` recalculates the text layout as well as where the scroll bars, if any, should be placed. When you call `TXNRecalcTextLayout`, MLTE generates an update event to redraw the text object.

Availability

Available in Mac OS X v10.1 and later.

Not available to 64-bit applications.

Declared In

`MacTextEditor.h`

TXNRedo

Redoes the last command.

```
void TXNRedo (
   TXNObject iTXNObject
);
```

Parameters

iTXNObject

The text object for the document you want to examine.

Discussion

If the user undoes an action and then undoes it again, the second undo is the same as a redo.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`MacTextEditor.h`

TXNRegisterScrollInfoProc

Installs or uninstalls a scrolling callback function on a text object.

```
void TXNRegisterScrollInfoProc (
   TXNObject iTXNObject,
   TXNScrollInfoUPP iTXNScrollInfoUPP,
   SRefCon iRefCon
);
```

Parameters

iTXNObject

The text object on which you want to install a callback to scroll text.

iTXNScrollInfoUPP

A universal procedure pointer to the callback function you want MLTE to call whenever a scroll bar for the text object must be updated.

iRefCon

A 32-bit value that is passed to your callback.

Discussion

You can call the function `TXNRegisterScrollInfoProc` to install a text-scrolling callback on a text object. This is useful if your application draws and handles its own scrolling widgets. Once you register your callback (`TXNScrollInfoUPP`), MLTE invokes your callback each time it is necessary to update the values and maximum values of your scrolling widget. For example when the user presses the Return key to add a new line, MLTE calculates a new maximum value for the text object. Your callback is then called with the newly-calculated maximum value. To turn off your callback call the function `TXNRegisterScrollInfoProc` with a value of `NULL` for the `iTXNScrollInfoUPP` parameter.

Availability

Available in Mac OS X v10.2 and later.

Not available to 64-bit applications.

Declared In

`MacTextEditor.h`

TXNResizeFrame

Resizes the view and destination rectangles.

```
void TXNResizeFrame (
   TXNObject iTXNObject,
   UInt32 iWidth,
   UInt32 iHeight,
   TXNFrameID iTXNFrameID
);
```

Parameters

iTXNObject

The text object for the current text area.

iWidth

The new width of the view and destination rectangles in pixels.

iHeight

The new height of the view and destination rectangles in pixels.

iTXNFrameID

The frame ID of the frame associated with the view and destination rectangles you want to resize. You obtain the frame ID when you call the `TXNNewObject` (page 2667) function.

Discussion
You need to call the function `TXNSetFrameBounds` (page 2688) if you want to reset the frame bounds.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNRevert

Reverts to the last saved version of a document.

```
OSStatus TXNRevert (
   TXNObject iTXNObject
);
```

Parameters
iTXNObject
The text object for the active document.

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Discussion
You can use the `TXNRevert` function with files that contain only text as well as files that were created using MLTE. If the file was not previously saved, the document reverts to an empty document. To revert to data that is embedded in a private file type, use the `TXNSetSelection` (page 2692) function to select all of the current data and then use the `TXNSetDataFromFile` (page 2685) function to read in the old data.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNSave

Saves the contents of the document as the file type you specify. (Deprecated in Mac OS X v10.4. Use `TXNWriteRangeToCFURL` (page 2699) instead.)

Not recommended.

```
OSStatus TXNSave (
   TXNObject iTXNObject,
   TXNFileType iType,
   OSType iResType,
   TXNPermanentTextEncodingType iPermanentEncoding,
   const FSSpec *iFileSpecification,
   SInt16 iDataReference,
   SInt16 iResourceReference
);
```

Parameters

iTXNObject

The text object for the active document.

iType

The file type to which the text object should be saved. The type must be `kTXNTextensionFile`, `kTXNTextFile`, or `kTXNUnicodeTextData`. See Supported File Types (page 2766) for more information on file type constants.

iResType

The type of resource that should be used to save the style information if the file is being saved as plain text. This parameter is ignored for file types that are not plain text.

iPermanentEncoding

The encoding in which to save the document. If the internal encoding used by MLTE does not match the requested encoding type, the text is translated by the Conversion Manager.

iFileSpecification

A pointer to a variable that specifies the location of the file. This parameter is retained and used in calls to the `TXNRevert` (page 2677) function. It is not retained once the text object is deleted or disposed of.

iDataReference

The data fork reference number of the open file.

iResourceReference

The resource fork reference number of the open file. This parameter is ignored if the file type is not `kTXNTextFile`. You can save text without style information by passing `-1` for this parameter.

Return Value

A result code. See "MLTE Result Codes" (page 2773).

Discussion

You must first open the file to which you want to save the document. If you are saving the file as plain text and the application has specified a resource type in which to save style attributes, then you must also open the file's resource fork.

MLTE does not move the marker before writing the file. You must make sure the file marker of the opened file is at the position where you want data to be written. Typically, this is position 0, but you can specify any valid file position. This behavior lets you write private data, followed by data that is written by MLTE, which can subsequently be followed by more private data or even another MLTE file.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNScroll

Scrolls the text within a view rectangle of the specified text object.

```
OSStatus TXNScroll (
   TXNObject iTXNObject,
   TXNScrollUnit iVerticalScrollUnit,
   TXNScrollUnit iHorizontalScrollUnit,
   long *ioVerticalDelta,
   long *ioHorizontalDelta
);
```

Parameters

iTXNObject

The text object whose text you want to scroll.

iVerticalScrollUnit

Specifies the units to use for the `ioVerticalDelta` parameter. Pass `kTXNScrollUnitsInPixels` to specify pixels, pass `kTXNScrollUnitsInLines` to specify a count of lines, and pass `kTXNScrollUnitsInViewRects` to specify the height of the current view rectangle (`viewRect`). Note that scrolling in line units is the slowest because each line must be measured by MLTE before the text scrolls. See Scroll Units (page 2761) for more information.

iHorizontalScrollUnit

Specifies the units to use for the `ioHorizontalDelta` parameter. Pass `kTXNScrollUnitsInPixels` to specify pixels, pass `kTXNScrollUnitsInLines` to specify a count of lines, and pass `kTXNScrollUnitsInViewRects` to specify the height of the current view rectangle (`viewRect`). Note that scrolling in line units is the slowest because each line must be measured by MLTE before the text scrolls. See Scroll Units (page 2761) for more information.

ioVerticalDelta

On input, the number of units by which to scroll in the vertical direction. You specify the units in the `iVerticalScollUnit` parameter. On output, the number of units actually scrolled in the vertical direction. A positive value indicates to move the text in a downward direction.

ioHorizontalDelta

On input, the number of units by which to scroll in the horizontal direction. You specify the units in the `iHorizontalScrollUnit` parameter. On output, the number of units actually scrolled in the horizontal direction. A positive value indicates to move the text to the right.

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Discussion
The function `TXNScroll` moves the text within the view rectangle of the specified text object by the designated number of units. You can use this function to scroll the text in a text object in response to user input in a control other than the standard scroll bars that MLTE supplies.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
MacTextEditor.h

TXNSelectAll

Selects all data in the frame of a text object.

```
void TXNSelectAll (
   TXNObject iTXNObject
);
```

Parameters

iTXNObject
The text object for the current text area.

Discussion
You can check whether your application should enable the Select All menu item by calling the `TXNDataSize` (page 2632) function to check if the text object contains any data.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
MacTextEditor.h

TXNSetActionNameMapper

Sets a callback that MLTE uses to obtain the localized string representing an action or an action group.

```
OSStatus TXNSetActionNameMapper (
   TXNObject iTXNObject,
   TXNActionNameMapperUPP iStringForKeyProc,
   const void *iUserData
);
```

Parameters

iTXNObject
The text object for which the callback is to be set.

iStringForKeyProc
The callback.

iUserData
A pointer to user-defined data that will help you map the action key to a string.

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Discussion
If you have asked MLTE to handle updating for the Redo and Undo commands in the Edit menu, you should call this function so that MLTE can call your callback, which provides the correct string for each of those commands.

When MLTE's handler for `kEventClassCommand`/`kEventCommandUpdateStatus` is called for the Redo or Undo command, MLTE checks to see if a `TXNActionNameMapperProc` has been installed. If a `TXNActionNameMapperProc` is installed, it is called to get the correct string for updating the menu item. The client can used the action name and the command ID to determine the appropriate string.

For information on a `TXNActionNameMapperProc`, see TXNActionNameMapperProcPtr (page 2702).

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNSetBackground

Sets the background on which the text object's data is drawn.

```
OSStatus TXNSetBackground (
   TXNObject iTXNObject,
   const TXNBackground *iBackgroundInfo
);
```

Parameters

iTXNObject
The text object that identifies the document to be activated.

iBackgroundInfo
A pointer to a structure that describes the background.

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Version Notes
MLTE supports only color as the background.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNSetCommandEventSupport

Enables and disables support for menu commands in MLTE.

```
OSStatus TXNSetCommandEventSupport (
   TXNObject iTXNObject,
   TXNCommandEventSupportOptions iOptions
);
```

Parameters

iTXNObject

The TXNObject.

iOptions

The menu commands for which support is to be enabled or disabled. For possible values, see Command Event Support Options (page 2729).

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Discussion
When `TXNAttachObjectToWindow` (page 2620) or `TXNSetEventTarget` (page 2686) is called to associate an MLTE object with an HIObject that can serve as an event target, most handlers are installed and activated immediately.

However, when the handlers for the kEventClassCommand class are installed, they are not activated. Call this function to activate the handlers for this class, which provide support for the menu commands. This approach means that an application can install handlers on top of these and be sure that enabling or disabling the MLTE handlers does not change the order of the handler chain.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNSetContextualMenuSetup

Provides a callback function that is called before MLTE displays its contextual menu.

```
OSStatus TXNSetContextualMenuSetup (
   TXNObject iTXNObject,
   TXNContextualMenuSetupUPP iMenuSetupProc,
   const void *iUserData
);
```

Parameters

iTXNObject

The text object.

iMenuSetupProc

The callback. For more information, see `NewTXNContextualMenuSetupUPP` (page 2616).

iUserData

A pointer to user-defined data that will be passed to the callback specified by the `iMenuSetupProc` parameter.

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Discussion
The callback function specified by `iMenuSetupProc` is called just before MLTE displays its contextual menu. The menu that is passed to the callback contains MLTE-specific items only. The client items and handlers should be installed each time the callback is called.

When the callback is called, MLTE has selected the word the user clicked with the Option key pressed. For convenience, the TXNObject associated with the callback is passed to the callback as well as the data specified by `iUserData`.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNSetData

Replaces a range of data (text, graphics, and so forth).

```
OSStatus TXNSetData (
   TXNObject iTXNObject,
   TXNDataType iDataType,
   const void *iDataPtr,
   ByteCount iDataSize,
   TXNOffset iStartOffset,
   TXNOffset iEndOffset
);
```

Parameters

iTXNObject
The text object that identifies the document in which you want to replace data.

iDataType
The type of the replacement data. See Supported Data Types (page 2765) for a description of possible values.

iDataPtr
A pointer to the data that will replace the data that is in the range specified by the `iStartOffset` and `iEndOffset` parameters.

iDataSize
The size of the data (in bytes) to which `iDataPtr` points.

iStartOffset
The beginning of the range of data to replace. You can use the `TXNGetSelection` (page 2658) function to get the absolute offsets of the current selection.

iEndOffset
The end of the range to replace. You can use the `TXNGetSelection` (page 2658) function to get the absolute offsets of the current selection. If you want to insert text, the ending and starting offsets should be the same value.

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Discussion
If you have a text object that has word wrap disabled, and you want to avoid horizontal scrolling, you can try the following. After you call the function `TXNSetData`, call `TXNSetSelection` (page 2692) with the value of the ending offset set to what it was before you called `TXNSetData`. Then, call the function `TXNShowSelection` (page 2696) to scroll the text back into view.

Offsets in MLTE are always character offsets.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
QTMetaData

Declared In
`MacTextEditor.h`

TXNSetDataFromCFURLRef

Replaces a range of data with the contents of a file. (Deprecated in Mac OS X v10.4. Use `TXNReadFromCFURL` (page 2673) instead.)

Not recommended.

```
OSStatus TXNSetDataFromCFURLRef (
   TXNObject iTXNObject,
   CFURLRef iURL,
   TXNOffset iStartOffset,
   TXNOffset iEndOffset
);
```

Parameters

iTXNObject

The text object that identifies the document in which you want to replace data. You can either call the function `TXNCreateObject` to allocate a text object or you can call the function `HITextViewGetTXNObject` (page 2611) to obtain the text object associated with an HITextView.

iURL

A reference to the Core Foundation URL that specifies the file which contains the data you want to add to the object.

iStartOffset

The starting position at which to insert the file into the document. If you want to replace the current selection, set the `iStartOffset` parameter to `kTXNUseCurrentSelection`. If you want to replace the entire document, set the `iStartOffset` parameter to `0`. Offsets in MLTE are always character offsets.

iEndOffset

The ending position of the range being replaced by the file. You can use the `TXNGetSelection` function to get the absolute offsets of the current selection. Offsets in MLTE are always character offsets.

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Discussion
Your application must open the file and set the `iStartOffset` parameter to the appropriate value before you call the `TXNSetDataFromCFURLRef` function. If you want to embed MLTE data within private data or other MLTE data, you must set the file position to the appropriate position.

In the (now deprecated) function `TXNNewObject` your could pass a file reference and MLTE supported functionality to revert back to the original file reference. When you call the function `TXNSetDataFromCFURLRef`, MLTE saves the `CFURLRef`. If you change the contents of the text object and then call the function `TXNRevert`, the document reverts to the contents specified by the saved `CFURLRef`.

Availability
Available in Mac OS X v10.3 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNSetDataFromFile

Replaces a range of data with the contents of a file. (Deprecated in Mac OS X v10.3. Use `TXNSetDataFromCFURLRef` (page 2684) instead.)

Not recommended.

```
OSStatus TXNSetDataFromFile (
   TXNObject iTXNObject,
   SInt16 iFileRefNum,
   OSType iFileType,
   ByteCount iFileLength,
   TXNOffset iStartOffset,
   TXNOffset iEndOffset
);
```

Parameters

iTXNObject
The text object that identifies the document in which you want to replace data.

iFileRefNum
The file reference obtained when you opened the file.

iFileType
The file type of the file from which you are getting data. MLTE supports `'RTF '` as well as the file types specified by the constants described in Supported File Types (page 2766).

iFileLength
A value that specifies how much data should be read. This parameter is ignored if the file type is the custom file format (represented by the constant `kTXNTextensionFile`) that MLTE supports. This parameter is useful when your application uses MLTE to read data that is embedded in your application's private file. If you want MLTE to deal with the entire file, set the `iFileLength` parameter to a value of `kTXNEndOffset`.

iStartOffset
The starting position at which to insert the file into the document. You can use the `TXNGetSelection` function to get the absolute offsets of the current selection. If you want to replace the entire document, then set the `iStartOffset` parameter to 0.

iEndOffset
The ending position of the range being replaced by the file. You can use the `TXNGetSelection` function to get the absolute offsets of the current selection.

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Discussion
Your application must open the data fork of the file and set the `iStartOffset` parameter to the appropriate value before you call the `TXNSetDataFromFile` function. If you want to embed MLTE data within private data or other MLTE data, you must set the file position to the appropriate position.

Offsets in MLTE are always character offsets.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.3.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNSetEventTarget

Sets a Carbon Event target for MLTE Carbon Event handlers.

```
OSStatus TXNSetEventTarget (
   TXNObject iTXNObject,
   HIObjectRef iEventTarget
);
```

Parameters
iTXNObject
The TXNObject.

iEventTarget
The `HIObjectRef` that is to be set as the event target for all of the Carbon Event handlers of the TXNObject specified by `iTXNObject`.

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Discussion
The default target for a TXNObject that is not contained in an HITextView is the window of the TXNObject. Call this function when you want to override or set the Carbon Event target for a TXNObject.

Note that if the TXNObject already has a default target when this function is called, the handlers are removed from the old target before the new handlers are installed.

When this function returns, these handlers for Carbon Events are installed and active for the `kEventClassTextInput` class:

- `kEventTextInputUpdateActiveInputArea`
- `kEventTextInputUnicodeForKeyEvent`
- `kEventTextInputUnicodeText`

- kEventTextInputOffsetToPos
- kEventTextInputPosToOffset
- kEventTextInputGetSelectedText

When this function returns, these handlers for Carbon Events are installed and active for the kEventClassTSMDocumentAccess class:

- kEventTSMDocumentAccessGetLength
- kEventTSMDocumentAccessGetSelectedRange
- kEventTSMDocumentAccessGetCharactersPtr
- kEventTSMDocumentAccessGetCharactersPtrForLargestBuffer
- kEventTSMDocumentAccessGetCharacters
- kEventTSMDocumentAccessGetFont
- kEventTSMDocumentAccessGetGlyphInfo

When this function returns, these handlers for Carbon Events are installed and active for the kEventClassFont class:

- kEventFontPanelClosed
- kEventFontSelection

When this function returns, these handlers for Carbon Events are installed and inactive by default for the kEventClassCommand class:

- kEventProcessCommand
- kEventCommandUpdateStatus

The kEventClassCommand handlers support the following commands:

- kHICommandUndo
- kHICommandRedo
- kHICommandSelectAll
- kHICommandCut
- kHICommandCopy
- kHICommandPaste
- kHICommandClear
- kHICommandShowSpellingPanel
- kHICommandCheckSpelling
- kHICommandChangeSpelling
- kHICommandCheckSpellingAsYouType
- kHICommandIgnoreSpelling

- `kHICommandLearnWord`

Activate command support by calling `TXNSetCommandEventSupport` (page 2681) with the appropriate options.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNSetFontDefaults

Specifies the font descriptions for each script used in a text object. (Deprecated in Mac OS X v10.4.)

```
OSStatus TXNSetFontDefaults (
   TXNObject iTXNObject,
   ItemCount iCount,
   const TXNMacOSPreferredFontDescription iFontDefaults[]
);
```

Parameters

iTXNObject
The text object for the document whose fonts you want to specify.

iCount
The number of font descriptions in the `iFontDefaults` array.

iFontDefaults
An array of `TXNMacOSPreferredFontDescription` structures that contain the font description you want to use for each script.

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNSetFrameBounds

Changes the boundaries of a text object's frame.

```
void TXNSetFrameBounds (
   TXNObject iTXNObject,
   SInt32 iTop,
   SInt32 iLeft,
   SInt32 iBottom,
   SInt32 iRight,
   TXNFrameID iTXNFrameID
);
```

Parameters

iTXNObject
The text object for the current text area.

iTop
The top boundary of the rectangle.

iLeft
The left boundary of the rectangle.

iBottom
The bottom boundary of the rectangle.

iRight
The right boundary of the rectangle.

iTXNFrameID
The frame ID of the frame you want to move. You obtain a frame ID when you call the `TXNNewObject` (page 2667) function.

Discussion
If you want to change the view and destination rectangles, you should call the `TXNResizeFrame` (page 2676) function.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNSetHIRectBounds

Sets the view rectangle and/or the destination rectangle.

```
void TXNSetHIRectBounds (
   TXNObject iTXNObject,
   const HIRect *iViewRect,
   const HIRect *iDestinationRect,
   Boolean iUpdate
);
```

Parameters

iTXNObject
The text object for the current text area. You can call the function `TXNCreateObject` to allocate a text object.

iViewRect

A pointer to rectangle that contains the new coordinates for the view rectangle. If you do not want to change the view rectangle pass `NULL`. You cannot set the view rectangle for text objects into an HITextView, you can only set the destination rectangle.

iDestinationRect

A pointer to a rectangle that contains the new coordinates for the destination rectangle. If you do not want to change the destination rectangle pass `NULL`.

iUpdate

A value that specifies whether you want the text and scroll bars recalculated and redrawn. Pass `true` to recalculate and redraw; otherwise pass `false`. You must pass `false` for text objects into an HITextView.

Discussion

The view rectangle controls the text you see. The destination rectangle controls how text is laid out. You can specify coordinates for one or both rectangles. Scroll bars are drawn inside the view rectangle.

Availability

Available in Mac OS X v10.3 and later.

Not available to 64-bit applications.

Declared In

`MacTextEditor.h`

TXNSetRectBounds

Set the view rectangle and/or the destination rectangle. (Deprecated in Mac OS X v10.3. Use `TXNSetHIRectBounds` (page 2689) instead.)

Not recommended.

```
void TXNSetRectBounds (
   TXNObject iTXNObject,
   const Rect *iViewRect,
   const TXNLongRect *iDestinationRect,
   Boolean iUpdate
);
```

Parameters

iTXNObject

The text object for the current text area.

iViewRect

A pointer to a `Rect` data structure that contains the new coordinates for the view rectangle. If you do not want to change the view rectangle pass `NULL`.

iDestinationRect

A pointer to a `TXNLongRect` data structure that contains the new coordinates for the destination rectangle. If you do not want to change the destination rectangle pass `NULL`.

iUpdate

Pass `true` if you want the text and location of the scroll bars recalculated and redrawn; otherwise pass `false`.

Discussion
You can specify coordinates for one or both rectangles. The view rectangle controls the text you see. The destination rectangle controls how text is laid out. Scroll bars are drawn inside the view rectangle.

If you set the `iViewRect` parameter to a location not currently represented by the scroll bar and you pass `NULL` for the *`iDestinationRect`* parameter, it becomes impossible to scroll to the left bounds of the destination rectangle. If you want to position the view rectangle inside the destination rectangle, you should supply a custom scrolling callback. See `TXNScrollInfoProcPtr` (page 2705).

Availability
Available in Mac OS X v10.1 and later.
Deprecated in Mac OS X v10.3.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNSetScrollbarState

Sets the state of the scroll bars so they are drawn correctly in response to activate events.

```
OSStatus TXNSetScrollbarState (
   TXNObject iTXNObject,
   TXNScrollBarState iActiveState
);
```

Parameters

`iTXNObject`
The text object that identifies the document you want activated. You can call the function `TXNCreateObject` to allocate a text object.

`iActiveState`
A value that indicates the state of the scroll bars. See Scroll Bar States (page 2760) for a description of possible values. If you pass the `kScrollBarsAlwaysActive` constant, the scroll bars are always active, whether or not the frame text area currently has keyboard focus. Passing `kScrollBarsAlwaysActive` can be useful for a window such as a dialog that may contain multiple text areas, each of which may have a scrollable frame. If you pass `kScrollBarsSyncWithFocus`, MLTE synchronizes the activity state of the scroll bars with the focus state of the frame. Therefore, only when the frame has keyboard focus does it have active scroll bars. A value of `kScrollBarsSyncWithFocus` is the default and is typically recommended if you have only one frame per window.

Return Value
A result code. See "MLTE Result Codes" (page 2773). This function returns an error if the text object is in an HITextView.

Discussion
This function is a macro that calls the function `TXNActivate` with the `TXNFrameID` parameter set to `0`. You typically call `TXNSetScrollbarState` in response to an activate event. If the text object was previously inactive, `TXNSetScrollbarState` removes any visual indication of its prior inactive state (such as a dimmed or framed selection area or inactive scroll bars). Before you call the `TXNSetScrollbarState` function, you should make sure that the window belongs to your application.

The `TXNSetScrollbarState` function does not change the keyboard focus. This means your application can have a text area that is not focused, but in which the scroll bars are active. This lets application users scroll the inactive text without changing the focus from another text area.

If you want to display a text area that has both keyboard focus and active scroll bars, you must call the `TXNFocus` (page 2644) function immediately before you call the `TXNSetScrollbarState` function. Note that MLTE does not retain information about keyboard focus. So if, for example, you set the keyboard focus on a text area and the window containing the text area becomes deactivated, you must call the `TXNFocus` (page 2644) function when the window becomes activated again.

Availability
Available in Mac OS X v10.3 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNSetSelection

Specifies the selection range or the position of the insertion point.

```
OSStatus TXNSetSelection (
   TXNObject iTXNObject,
   TXNOffset iStartOffset,
   TXNOffset iEndOffset
);
```

Parameters

iTXNObject
The text object that identifies the document for which you want to set the selection range or insertion point position.

iStartOffset
The new starting offset. Offset values are character offsets.

iEndOffset
The new ending offset. Offset values are character offsets.

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Discussion
You can use the `TXNSetSelection` function to highlight an initial default value in a document, such as a data-entry form, or to position the insertion point at the start of the field where you want the user to enter a value. To position the insertion point, specify the same value for the `iStartOffset` and `iEndOffset` parameters.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNSetSpellCheckAsYouType

Enables and disables the "Spell Check as You Type" feature.

```
OSStatus TXNSetSpellCheckAsYouType (
   TXNObject iTXNObject,
   Boolean iActivate
);
```

Parameters

iTXNObject

The text object for which the "Spell Check as You Type" feature is to be enabled or disabled.

iActivate

A Boolean whose value is `true` to enable the "Spell Check as You Type" feature or `false` to disable it.

Return Value

A result code. See "MLTE Result Codes" (page 2773). If `TXNSetCommandEventSupport` (page 2681) has not been called to enable the event handler for spell checking, an error is returned.

Availability

Available in Mac OS X v10.4 and later.

Not available to 64-bit applications.

Declared In

`MacTextEditor.h`

TXNSetTXNObjectControls

Sets formatting and privileges attributes (such as justification, line direction, tab values, and read-only status) that apply to the entire text object.

```
OSStatus TXNSetTXNObjectControls (
   TXNObject iTXNObject,
   Boolean iClearAll,
   ItemCount iControlCount,
   const TXNControlTag iControlTags[],
   const TXNControlData iControlData[]
);
```

Parameters

iTXNObject

The text object that identifies the document for which you want to set formatting and privileges attributes.

iClearAll

A `Boolean` value. If you set this to `true`, all formatting and privileges attributes are reset to their default value. That is, `true` clears existing tags and resets each to its default value.

iControlCount

The number of items in the `iControlTags` array.

iControlTags

An array of values that specifies kind of data that is passed in the `iControlData` parameter. See Formatting and Privileges Settings (page 2742) for a description of possible values. On systems that use Apple Type Services for Unicode Imaging (ATSUI), you can also pass any of the following ATSUI attribute tag constants:

- `kATSULineDirectionTag`
- `kATSULineJustificationFactorTag`
- `kATSULineFlushFactorTag`
- `kATSULineBaselineValuesTag`
- `kATSULineLayoutOptionsTag`
- `kATSUCGContextTag`

See the ATSUI documentation for a description of these ATSUI constants.

iControlData

An array of `TXNControlData` (page 2711) unions that contain the information your application wants to set. The value you supply to the `iControlTags` parameter specifies how the union of type `TXNControlData` is treated. You must make sure that the value you assign to the `iControlData` parameter is the appropriate type implied by the value you passed in the `iControlTags` parameter.

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Discussion
On systems that use Apple Type Services for Unicode Imaging (ATSUI), the ATSUI line control attribute tags can be passed to this function in the `iControlTag` parameter. This is the case for all the ATSUI tags except `kATSULineRotationTag`. ATSUI tags are applied to the entire text object.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNSetTypeAttributes

Sets text attributes (such as size and style) for the current selection or the text defined by a range you specify.

```
OSStatus TXNSetTypeAttributes (
   TXNObject iTXNObject,
   ItemCount iAttrCount,
   const TXNTypeAttributes iAttributes[],
   TXNOffset iStartOffset,
   TXNOffset iEndOffset
);
```

Parameters

iTXNObject

The text object that contains the current selection.

iAttrCount

The number of font attributes in the `iAttributes` array.

iAttributes

An array of `TXNTypeAttributes` structures in which you specify the attributes you want to set. Values passed in the `iAttributes` array that are less than or equal to `sizeof(UInt32)` are passed by value. Values greater than `sizeof(UInt32)` are passed as a pointer. That is, the third field of the `TXNTypeAttributes` structure is a union that serves as either a 32-bit integer or a 32-bit pointer.

iStartOffset

The starting offset at which you want the application to begin setting attributes. If you want to use the current selection, set `iStartOffset` to `kTXNUseCurrentSelection`.

iEndOffset

The offset at which you want the application to stop setting attributes. If you want to use the current selection, set `iEndOffset` to `kTXNUseCurrentSelection`.

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Discussion
You can use this function to clear ATSUI font features and ATSUI font variations. To clear either the features or the variations, you must `OR` the `kTXNClearTheseFontFeatures` constant with the current ATSUI font feature or font variation setting. See Clearance Settings (page 2729) for more information.

Offsets in MLTE are always character offsets.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNSetViewRect

Sets the rectangle that describes the current view into the document; changes the amount of text that is viewable. (Deprecated in Mac OS X v10.2. Use `TXNSetFrameBounds` (page 2688) or `TXNSetRectBounds` (page 2690) instead.)

Not recommended.

```
void TXNSetViewRect (
   TXNObject iTXNObject,
   const Rect *iViewRect
);
```

Parameters

iTXNObject

The text object for the current text area.

iViewRect

On input, points to a rectangle that describes the new view of the document.

Discussion
The `TXNSetViewRect` function does not change where a line of text wraps. Line wrapping is controlled by the `TXNSetFrameBounds` (page 2688) function.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.2.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNShowSelection

Scrolls the current selection into view.

```
void TXNShowSelection (
   TXNObject iTXNObject,
   Boolean iShowEnd
);
```

Parameters

iTXNObject
The text object for the current text area.

iShowEnd
A `Boolean` value. If you set this to `true`, the end of the selection is scrolled into view. Otherwise, the beginning of the selection is scrolled into view.

Discussion
You can use this to scroll text into view after you have called the `TXNFind` (page 2641) function and the matching text is not in the current view of the text object.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNTerminateTextension

Closes the MLTE library. (Deprecated in Mac OS X v10.3. This function is no longer needed.)

Not recommended.

```
void TXNTerminateTextension (
   void
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.3.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNTSMCheck

Checks to see if the Text Services Manager (TSM) is active.

Not Supported

```
Boolean TXNTSMCheck (
    TXNObject iTXNObject,
    EventRecord *iEvent
);
```

Parameters

iTXNObject

The text object that identifies the current document. Pass `NULL` when there is no active text object and you want to check for TSM activity.

iEvent

A pointer to an event record structure. This can be `NULL`.

Return Value

A `Boolean` value. It is `true` if TSM is active and `false` if TSM is not active.

Discussion

The purpose of this function is to ensure input methods have enough time to respond. Call this when the `WaitNextEvent` function returns `false` or there is no active text object. For a Unicode application, if the event is a key-down event, `TXNTSMCheck` will also process the event and set the event to `NULL`.

Declared In

`MacTextEditor.h`

TXNUndo

Undoes the last command.

```
void TXNUndo (
   TXNObject iTXNObject
);
```

Parameters

iTXNObject

The text object for the document you want to examine.

Discussion

The undo stack is 32 levels deep. That is, undoable actions are tracked until the total count is 32. If a user undoes two actions, the Redo command must be used twice to get back to the original state. If more than 32 actions are performed, the oldest actions are forgotten as each new action takes place.

If the user performs a new action after choosing Redo from the Edit menu, the redone action is no longer available to be undone. For example, a user performs the following actions: types some text, cuts some text, pastes some text, types some text; undoes the last typing action, and undoes the paste operation; redoes the paste; types some new text. After the new text has been typed, the undo stack contains the first text that was typed, the cut action, and the new text that was just typed.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In
MacTextEditor.h

TXNUpdate

Redraws everything in a frame in response to an update event.

```
void TXNUpdate (
   TXNObject iTXNObject
);
```

Parameters

iTXNObject

The text object that identifies the document to be updated.

Discussion
This function calls the Window Manager `BeginUpdate` and `EndUpdate` functions for the window that you pass to the `TXNNewObject` function. You shouldn't use it for windows that contain something else besides the text object. If the window contains something in addition to the text object, you should use the `TXNDraw` (page 2636) function instead of the `TXNUpdate` function.

Before you call `TXNUpdate`, you should make sure that the window belongs to your application. The `TXNUpdate` function redraws any content that needs updating regardless of the layer in which your window is located.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
MacTextEditor.h

TXNVersionInformation

Gets the version number of MLTE and the set of features in this version.

```
TXNVersionValue TXNVersionInformation (
   TXNFeatureBits *oFeatureFlags
);
```

Parameters

oFeatureFlags

On return, a pointer to a value that indicates the set of features in use in this version. See Frame Option Bits (page 2746) and ATSUI Feature Masks (page 2726) for a description of possible values.

Return Value
A value that specifies the version of MLTE. See the description of the `TXNVersionValue` data type.

Discussion
If the bit `kTXNWillDefaultToATSUIBit` is set, then by default MLTE uses ATSUI to image and measure text and uses Unicode to store characters. If the bit `kTXNWillDefaultToCarbonEventBit` is set, then, by default, MLTE uses Carbon events and Apple events are not supported.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNWriteRangeToCFURL

Writes a range of a text object to a file or to a special file bundle.

```
OSStatus TXNWriteRangeToCFURL (
   TXNObject iTXNObject,
   TXNOffset iStartOffset,
   TXNOffset iEndOffset,
   CFDictionaryRef iDataOptions,
   CFDictionaryRef iDocumentAttributes,
   CFURLRef iFileURL
);
```

Parameters

iTXNObject
The text object having a range that is to be written.

iStartOffset
The offset in `iTXNObject` at which to start writing data to `iFileURL`.

iEndOffset
The offset in `iTXNObject` at which to stop writing data to `iFileURL`.

iDataOptions
A CFDictionaryRef that specifies options for writing out the data. See Data Option Key Value Constants (page 2733) for a list of the supported options. If this parameter is `NULL`, the data is written out using MLTE's native format.

iDocumentAttributes
The document attributes that are to be embedded in the data stream. This parameter is only supported when writing out the data using one of the following formats: RTF and MLTE native format. Only the key / values defined in Document Attribute Keys (page 2735) are written out. The content of the dictionary is ignored for any other format. If the dictionary is `NULL`, no attributes are added to the data stream.

iFileURL
`CFURLRef` for an existing file or directory, whichever is appropriate for the file type. On return, `iFileURL` contains a copy of the data in the given range for the `iTXNObject` with the format and encoding specified by `iDataOptions`.

Return Value
A result code. See "MLTE Result Codes" (page 2773).

Discussion
This function writes a range of a text object to a file or a special file bundle (directory). It supports several document formats and encodings, which can be specified in the data options dictionary. Clients can specify additional document attributes when data is written out using a file format, such as RTF and native MLTE file format) that supports such attributes.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNZoomWindow

Increases the size of the data displayed in a window in response to a click in the zoom box.

```
void TXNZoomWindow (
   TXNObject iTXNObject,
   SInt16 iPart
);
```

Parameters

iTXNObject
The text object for the current text area.

iPart
The location, in global coordinates, of the cursor at the time the user pressed the mouse button. You obtain this value from the Window Manager function `FindWindow`.

Discussion
Before you call the `TXNZoomWindow` function, you should make sure that the window belongs to your application. You should use the `TXNZoomWindow` function only when a text object has a viewable area that occupies the entire window; for example, if you passed `NULL` for the `iFrame` parameter when you called the `TXNNewObject` (page 2667) function to create the text object. You cannot use `TXNZoomWindow` if the text object is contained in a subframe of a window.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

Callbacks

TXNActionKeyMapperProcPtr

Defines a pointer to an action key mapping function that customizes the Redo and Undo menu items with the specific action that can be redone or undone. (**Deprecated.** Use `TXNActionNameMapperProcPtr` (page 2702) instead.)

```
typedef CFStringRef(* TXNActionKeyMapperProcPtr)
(
    TXNActionKey actionKey,
    UInt32 commandID
);
```

You would declare your function like this if you were to name it `MyTXNActionKeyMapperFunction`:

```
CFStringRef MyTXNActionKeyMapperCallback
(
    TXNActionKey actionKey,
    UInt32 commandID
);
```

Parameters

actionKey

A value of type `TXNActionKey` that indicates an editing action taken by the user.

commandID

The command ID of menu command chosen by the user.

Return Value

The localized string you want to map to the `TXNActionKey`.

Discussion

Your callback is invoked each time you ask MLTE to handle command updates for the Edit menu. MLTE calls your callback whenever it receives a Carbon event of class `kEventClassCommand` and event kind `kEventComandUpdateStatus` for the command ID `kHICommandUndo`. In other words, whenever the undo-command item in the menu needs to be updated. Your callback should examine the `actionKey` parameter and return an appropriately localized `CFStringRef` that describes the undo action. MLTE calls the function `SetMenuItemWithCFString` to update the menu item's text. You are responsible for releasing the `CFString`; MLTE does not call the function `CFRelease` on the string.

You provide a pointer to your action key mapping callback function when you build a dictionary to support Carbon events in MLTE. The pointer should be the value associated with the dictionary key `kTXNActionKeyMapperKey`. You then assign the dictionary to a `TXNCarbonEventInfo` (page 2709) data structure. You treat the data structure as an object control. That is, you associate the `TXNCarbonEventInfo` data structure with a text object by calling the function `TXNSetTXNObjectControls` (page 2693), supplying `kTXNUseCarbonEvents` in the `iControlsTags` parameter and the `TXNCarbonEventInfo` data structure in the `iControlData` parameter.

To provide a pointer to your action key mapping callback function, you use the `NewTXNActionKeyMapperUPP` function to create a universal procedure pointer (UPP) of type `TXNActionKeyMapperUPP`. You can do so with code similar to the following:

```
TXNActionKeyMapperUPP MyTXNActionKeyMapperUPP;
MyTXNActionKeyMapperUPP = NewTXNActionKeyMapperUPP
                        (&MyActionKeyMapperFunction);
```

When you are finished with your action key mapper callback function, you should use the `DisposeTXNActionKeyMapperUPP` function to dispose of the UPP associated with it. However, if you plan to use the same action key mapper callback later in your application, you can reuse the same UPP, rather than dispose of it and later create a new UPP.

Availability

Available in Mac OS X v10.0 and later.

Declared In
MacTextEditor.h

TXNActionNameMapperProcPtr

Defines a pointer to an action name mapping function that customizes the Redo and Undo menu items with the specific action that can be redone or undone.

```
typedef CFStringRef TXNActionNameMapperProcPtr (
      CFStringRef actionName,
      UInt32 commandID,
      void * inUserData
);
```

If you name your function `MyTXNActionNameMapperProc`, you would declare it like this:

```
CFStringRef MyTXNActionNameMapperProc (
      CFStringRef actionName,
      UInt32 commandID,
      void * inUserData
);
```

Parameters

actionName
The name of the action.

commandID
The command ID of the menu command.

inUserData
User-defined data that was provided in the inUserData parameter when `InvokeTXNActionNameMapperUPP` (page 2613) was called.

Availability
Available in Mac OS X v10.4 and later.

Declared In
MacTextEditor.h

TXNContextualMenuSetupProcPtr

Defines a pointer to a contextual menu setup function.

```
typedef void TXNContextualMenuSetupProcPtr (
      MenuRef iContextualMenu,
      TXNObject object,
      void * inUserData
);
```

If you name your function `MyTXNContextualMenuSetupProc`, you would declare it like this:

```
void MyTXNContextualMenuSetupProc (
      MenuRef iContextualMenu,
      TXNObject object,
      void * inUserData
```

```
);
```

Parameters

iContextualMenu

The MLTE contextual menu.

TXNObject

The TXNObject for which `MyTXNContextualMenuSetupProc` was called.

inUserData

User-defined data that was passed to `TXNSetContextualMenuSetup` (page 2682).

Availability
Available in Mac OS X v10.4 and later.

Declared In
`MacTextEditor.h`

TXNFindProcPtr

Defines a pointer to a find function that customizes a search tailored to your application's needs.

```
typedef OSStatus (*TXNFindProcPtr) (
    const TXNMatchTextRecord * matchData,
    TXNDataType iDataType,
    TXNMatchOptions iMatchOptions,
    const void * iSearchTextPtr,
    TextEncoding encoding,
    TXNOffset absStartOffset,
    ByteCount searchTextLength,
    TXNOffset * oStartMatch,
    TXNOffset * oEndMatch,
    Boolean * ofound,
    UInt32 refCon
);
```

If you name your function `MyTXNFindProc`, you would declare it like this:

```
OSStatus TXNFindProcPtr (
    const TXNMatchTextRecord * matchData,
    TXNDataType iDataType,
    TXNMatchOptions iMatchOptions,
    const void * iSearchTextPtr,
    TextEncoding encoding,
    TXNOffset absStartOffset,
    ByteCount searchTextLength,
    TXNOffset * oStartMatch,
    TXNOffset * oEndMatch,
    Boolean * ofound,
    UInt32 refCon
);
```

Parameters

matchData

A pointer to a `TXNMatchTextRecord` structure containing the text to match, the length of that text, and the text's encoding. Pass `NULL` if you are looking for a graphics, sound, or movie object.

iDataType

The type of data for which you want to search. See Supported Data Types (page 2765) for a description of possible values.

iMatchOptions

A value that specifies the matching rules to use in the find operation. See Search Criteria Masks (page 2762) for a description of possible values.

iSearchTextPtr

A pointer to the text to search.

encoding

The encoding of the text to search.

absStartOffset

The offset at which the search should begin. The constant `kTXNStartOffset` specifies the start of the object's data.

searchTextLength

The length, in bytes, of the text to search.

oStartMatch

On return, a pointer to the absolute offset that identifies the start of the match. Your function should set this to `kTXNUseCurrentSelection` if there is no match.

oEndMatch

On return, a pointer to the absolute offset that identifies the end of the match. Your function should set this to `kTXNUseCurrentSelection` if there is no match.

ofound

On return, a pointer to a `Boolean` value; `true` if a match is found.

refCon

An unsigned 32-bit integer your application can use as needed.

Return Value

A result code. See "MLTE Result Codes" (page 2773).

Discussion

You pass a pointer to your find callback function as a parameter to the `TXNFind` (page 2641) function. To provide a pointer to your find callback function, you use the `NewTXNFindUPP` (page 2617) function to create a universal procedure pointer (UPP) of type `TXNFindUPP`. You can do so with code similar to the following:

```
 TXNFindUPP MyTXNFindUPP;
MyTXNFindUPP = NewTXNFindUPP (&MyFindCallback)
```

When you are finished with your find callback function, you should use the `DisposeTXNFindUPP` (page 2609) function to dispose of the UPP associated with it. However, if you plan to use the same find callback function in subsequent calls to the `TXNFind` function, you can reuse the same UPP, rather than dispose of it and later create a new UPP.

Availability

Available in Mac OS X v10.0 and later.

Declared In
MacTextEditor.h

TXNScrollInfoProcPtr

Defines a pointer to a customized scrolling function.

```
typedef void TXNScrollInfoProcPtr (
      SInt32 iValue,
      SInt32 iMaximumValue,
      TXNScrollBarOrientation iScrollBarOrientation,
      SInt32 iRefCon
);
```

If you name your function `MyTXNScrollInfoProc`, you would declare it like this:

```
void MyTXNScrollInfoProc (
      SInt32 iValue,
      SInt32 iMaximumValue,
      TXNScrollBarOrientation iScrollBarOrientation,
      SInt32 iRefCon
);
```

Parameters

iValue
The scroll bar value.

iMaximumValue
The scroll bar maximum value.

iScrollBarOrientation
The orientation of the scroll bar. See Scroll Bar Orientation (page 2760) for more information.

iRefCon
An unsigned 32-bit integer your application can use as needed. This is set and used by your application as needed.

Discussion
You can create a callback to handle and draw your own scroll bar. MLTE calls your callback each time the scroll bar value and the maximum value of the scroll bar needs to be updated. You install a text-scrolling callback on an MLTE text object by calling the function `TXNRegisterScrollInfoProc` (page 2675). When you no longer want the text-scrolling callback invoked on the text object, you can call the function `TXNRegisterScrollInfoProc` with the `iTXNScrollInfoUPP` set to `NULL`.

Availability
Available in Mac OS X v10.2 and later.

Declared In
MacTextEditor.h

Data Types

TXNActionNameMapperUPP

Defines a universal procedure pointer to an action name mapper callback function.

```
typedef TXNScrollActionNameProcPtr TXNActionNameMapperUPP;
```

Discussion
See `TXNActionNameMapperProcPtr` (page 2702) for more information.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`MacTextEditor.h`

TXNActionKeyMapperUPP

Defines a universal procedure pointer to an action key mapping callback function.

```
typedef TXNActionKeyMapperProcPtr TXNActionKeyMapperUPP;
```

Discussion
See `TXNActionKeyMapperProcPtr` (page 2700) for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MacTextEditor.h`

TXNATSUIFeatures

Contains information about ATSUI font features.

```
struct TXNATSUIFeatures {
    ItemCount featureCount;
    ATSUFontFeatureType * featureTypes;
    ATSUFontFeatureSelector * featureSelectors;
};
typedef struct TXNATSUIFeatures TXNATSUIFeatures;
```

Fields

`featureCount`
The number of features described in this structure.

`featureTypes`
A pointer to a variable of type `ATSUFontFeatureType`. The `ATSUFontFeatureType` type represents the attributes of a particular font feature, such as the presence of ligatures in a font.

`featureSelectors`
: A pointer to a variable of type `ATSUFontFeatureSelector`. The `ATSUFontFeatureSelector` type represents the state of a feature (on or off).

Discussion
Used in the `TXNAttributeData` (page 2707) union.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MacTextEditor.h`

TXNATSUIVariations

Contains information about ATSUI variations.

```
struct TXNATSUIVariations {
    ItemCount variationCount;
    ATSUFontVariationAxis * variationAxis;
    ATSUFontVariationValue * variationValues;
};
typedef struct TXNATSUIVariations TXNATSUIVariations;
```

Fields
`variationCount`
: The number of variables described in this structure.

`variationAxis`
: A pointer to a variable of type `ATSUFontVariationAxis`. The `ATSUFontVariationAxis` type represents a stylistic attribute and the range of values used to express this attribute for a font.

`variationValues`
: A pointer to a variable of type `ATSUFontVariationValue`. The `ATSUFontVariationValue` type represents the range of values that a font can use for a particular font variation.

Discussion
Used in the `TXNAttributeData` (page 2707) union.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MacTextEditor.h`

TXNAttributeData

Contains information about text attributes in a text object.

```
union TXNAttributeData {
    void * dataPtr;
    UInt32 dataValue;
    TXNATSUIFeatures *atsuFeatures;
    TXNATSUIVariations *atsuVariations;
    CFURLRef urlReference;
};
typedef union TXNAttributeData TXNAttributeData;
```

Fields

`dataPtr`
A pointer to attribute data. For example, a pointer to a font name.

`dataValue`
A value that specifies a text attribute. For example, a value that specifies a font style.

`atsuFeatures`
A pointer to a `TXNATSUIFeatures` (page 2706) structure. For example, a structure that contains information about the ligatures in a font.

`atsuVariations`
A pointer to a `TXNATSUIVariations` (page 2707) structure. For example, a structure that contains information about the range of values used to express a particular stylistic attribute.

`urlReference`
A URL that specifies the location of attribute data.

Discussion
Used in the `TXNTypeAttributes` (page 2718) structure. The data contained in the union is determined by the value in the `size` field of the `TXNTypeAttributes` structure.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MacTextEditor.h`

TXNBackground

Specifies the background for text and other data in a text object.

```
struct TXNBackground {
    TXNBackgroundType bgType;
    TXNBackgroundData bg;
};
typedef struct TXNBackground TXNBackground;
```

Fields

`bgType`
Defines the type of data. See `TXNBackgroundType` data type.

`bg`
Specifies the data MLTE should use as a background.

Discussion
Used in the `TXNSetBackground` (page 2681) function.

Version Notes
MLTE 1.1 and earlier supports only color.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MacTextEditor.h`

TXNBackgroundData

Represents background data used in the `TXNBackground` structure.

```
union TXNBackgroundData {
    RGBColor color;
};
typedef union TXNBackgroundData TXNBackgroundData;
```

Fields

`color`
A value that specifies the background color on which data is displayed. Color is the only background data that is currently supported.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MacTextEditor.h`

TXNCarbonEventInfo

Contains information needed for MLTE to support Carbon events.

```
struct TXNCarbonEventInfo {
    Boolean useCarbonEvents;
    UInt8 filler;
    UInt16 flags;
    CFDictionaryRef fDictionary;
};
typedef struct TXNCarbonEventInfo TXNCarbonEventInfo;
```

Fields

`useCarbonEvents`
Pass `true` to specify a Carbon event, otherwise Apple events will be used by the system to handle MLTE events.

`filler`
Padding you don't need to pass anything.

`flags`
There are currently two flags defined: `kTXNNoAppleEventHandlersMask` and `kTXNRestartAppleEventHandlersMask`. When you request Carbon event support for text input events, it's best to specify the `kTXNNoAppleEventHandlersMask` mask.

`fDictionary`

A reference to a Core Foundation dictionary. (A dictionary is a collection of key-value pairs.) For MLTE to support Carbon events, you need to build a dictionary whose keys are strings that represent the events you want handled (such as "TextInput" or "WindowResize") and whose values are event target references associated with the events. See "Dictionary Keys" for a list of the predefined keys you can use to build the dictionary.

Discussion

You set up MLTE to support Carbon events by passing the `TXNCarbonEventInfo` structure when you call the function `TXNSetTXNObjectControls` (page 2693). Note that MLTE does not handle subclass Carbon events dispatched by the standard handler unless you install the standard handler on the window by calling the Carbon Event Manager function `InstallStandardEventHandler` or by writing code that performs the tasks done by `InstallStandardEventHandler`.

MLTE supports four classes of Carbon events:

- `kEventClassTextInput`
- `kEventClassWindow`
- `kEventClassCommand`
- `kEventClassMenu`

The event kinds supported within each class are listed in Table 36-1. You don't need to specify event kinds to MLTE; the table is provided so you can see the kind of events that MLTE supports. When you set up support for Carbon events, MLTE handles all the calls to the Carbon Event Manager that actually install and set up the handlers that take care of the Carbon events for a text object. See *Inside Mac OS X: Handling Carbon Events* and the *Carbon Event Manager Reference* for more information on Carbon events and for the most recent list of event classes and kinds supported by MLTE.

Table 36-1 Event classes and kinds supported by MLTE

Event Class	Event Kind	Means
`kEventClassTextInput`	`kEventUnicodeForKeyEvent`	Text characters produced by a keyboard
	`kEventOffsetToPos`	Map character index to screen position
	`kEventPosToOffset`	Map screen position to character index
	`kEventGetSelectedText`	Determine currently selected text
	`kEventUpdateActiveInputArea`	Manage contents of an inline input session
`kEventClassWindow`	`kEventWindowActivated`	Window activated (brought to front)
	`kEventWindowDeactivated`	Window deactivated (sent behind)
	`kEventWindowDrawContent`	Draw window's contents on screen
	`kEventWindowClickContentRgn`	Mouse click in content region
`kEventClassCommand`	`kEventCommandProcess`	Menu item chosen or a control with a command has been pressed

	kEventCommandUpdateStatus	Determine enabled or disabled status of command
kEventClassMenu	kEventMenuEnableItems	Font selected from a Font menu

Availability
Available in Mac OS X v10.0 and later.

Declared In
MacTextEditor.h

TXNContextualMenuSetupUPP

Defines a universal procedure pointer to a contextual menu setup callback function.

```
typedef TXNContextualMenuSetupProcPtr TXNContextualMenuSetupUPP;
```

Discussion
See TXNContextualMenuSetupProcPtr (page 2702) for more information.

Availability
Available in Mac OS X v10.4 and later.

Declared In
MacTextEditor.h

TXNControlData

Contains information about formatting and other settings that control how a text object is displayed or behaves.

```
union TXNControlData {
    UInt32 uValue;
    SInt32 sValue;
    TXNTab tabValue;
    TXNMargins *marginsPtr;
};
typedef union TXNControlData TXNControlData;
```

Fields

uValue
: A control setting. You should use this field for control settings, except tab and margins, whose value is unsigned.

sValue
: A control setting. You should use this only for control settings, except tab and margins, whose value is signed. There currently are no control settings whose value is signed.

tabValue
: A structure that contains tab distance and tab type settings.

marginsPtr
: A pointer to a TXNMargins (page 2714) structure that specifies the top, left, and right margin settings.

Discussion
The `TXNControlData` data type is a parameter in the `TXNSetTXNObjectControls` (page 2693) and `TXNGetTXNObjectControls` (page 2659) functions. The data contained in the union is determined by the `iControlData` parameter of those functions.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MacTextEditor.h`

TXNErrors

Defines result codes. (**Deprecated.** Use `OSStatus` instead.)

```
typedef OSStatus TXNErrors;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MacTextEditor.h`

TXNFindUPP

Defines a universal procedure pointer to a find callback function.

```
typedef TXNFindProcPtr TXNFindUPP;
```

Discussion
See `TXNFindProcPtr` (page 2703) for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MacTextEditor.h`

TXNFontMenuObject

Contains private variables necessary to represent an MLTE Font menu.

```
typedef struct OpaqueTXNFontMenuObject * TXNFontMenuObject;
```

Discussion
Used in the functions `TXNNewFontMenuObject` (page 2666), `TXNPrepareFontMenu` (page 2672), `TXNGetFontMenuHandle` (page 2653), `TXNDoFontMenuSelection` (page 2633), and `TXNDisposeFontMenuObject` (page 2633).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
MacTextEditor.h

TXNFrameID

Represents the text frame to which actions should be applied.

```
typedef UInt32 TXNFrameID;
```

Discussion
Used in the functions TXNNewObject (page 2667), TXNActivate (page 2618), TXNResizeFrame (page 2676), TXNSetFrameBounds (page 2688), TXNDragReceiver (page 2634), and TXNDragTracker (page 2635).

Availability
Available in Mac OS X v10.0 and later.

Declared In
MacTextEditor.h

TXNLongRect

Contains coordinates for a view or text rectangle. (**Deprecated.** No longer needed.)

```
struct TXNLongRect {
    SInt32 top;
    SInt32 left;
    SInt32 bottom;
    SInt32 right;
};
typedef struct TXNLongRect TXNLongRect;
```

Fields

`top`
The top coordinate of the rectangle.

`left`
The left-side coordinate of the rectangle.

`bottom`
The bottom coordinate of the rectangle.

`right`
The right-side coordinate of the rectangle.

Special Considerations

The TXNLongRect data structure is passed as a parameter to the functions TXNSetRectBounds (page 2690) and TXNGetRectBounds (page 2657), which are deprecated. You should instead use the functions TXNSetHIRectBounds (page 2689) and TXNGetHIRect (page 2653), which take an HIRect data structure as a parameter instead of a TXNLongRect data structure

Availability
Available in Mac OS X v10.1 and later.

Declared In
MacTextEditor.h

TXNMacOSPreferredFontDescription

Contains information about the preferred font, font size, and style for a given text encoding.

```
struct TXNMacOSPreferredFontDescription {
    UInt32 fontID;
    Fixed pointSize;
    TextEncoding encoding;
    Style fontStyle;
};
typedef struct TXNMacOSPreferredFontDescription  TXNMacOSPreferredFontDescription;
```

Fields

`fontID`
The ID of the preferred font.

`pointSize`
The point size of the preferred font.

`encoding`
The text encoding of the preferred font.

`fontStyle`
The font style of the preferred font.

Discussion

Used in the functions `TXNInitTextension` (page 2662), `TXNSetFontDefaults` (page 2688), and `TXNGetFontDefaults` (page 2652).

Availability

Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In

`MacTextEditor.h`

TXNMargins

Contains the margin values of a text object.

```
struct TXNMargins {
    SInt16 topMargin;
    SInt16 leftMargin;
    SInt16 bottomMargin;
    SInt16 rightMargin;
};
typedef struct TXNMargins TXNMargins;
```

Fields

`topMargin`
The location of the top margin. Available in MLTE version 1.2 and later.

`leftMargin`
The location of the left margin. Available in MLTE version 1.2 and later.

`bottomMargin`
The location of the bottom margin. This is a placeholder; it is currently not possible to set the bottom margin.

`rightMargin`
The location of the right margin. Available in MLTE version 1.2 and later.

Discussion
This structure is used as a field in the `TXNControlData` (page 2711) union.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MacTextEditor.h`

TXNMatchTextRecord

Contains information about the text to be matched in a find operation.

```
struct TXNMatchTextRecord {
    const void * iTextPtr;
    SInt32 iTextToMatchLength;
    TextEncoding iTextEncoding;
};
typedef struct TXNMatchTextRecord TXNMatchTextRecord;
```

Fields
`iTextPtr`
A pointer to the text to be matched.

`iTextToMatchLength`
The length of text to which the `iTextPtr` parameter points.

`iTextEncoding`
The encoding used by the text to be matched.

Discussion
Used in the `TXNFind` (page 2641) function and the callback `TXNFindProcPtr` (page 2703).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MacTextEditor.h`

TXNObject

Contains private variables and functions necessary to represent text and handle text formatting at a document level.

```
typedef struct OpaqueTXNObject * TXNObject;
```

Discussion
You obtain a structure of type `TXNObject` from the `TXNNewObject` (page 2667) function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
MacTextEditor.h

TXNObjectRefCon

Contains data specific to your application. (**Deprecated.** Used only in the `TXNNewObject` (page 2667) function, which is deprecated.)

```
typedef void * TXNObjectRefCon;
```

Declared In
MacTextEditor.h

TXNScrollInfoUPP

Defines a universal procedure pointer to a scroll callback function.

```
typedef TXNScrollInfoProcPtr TXNScrollInfoUPP;
```

Discussion
See `TXNScrollInfoProcPtr` (page 2705) for more information.

Availability
Available in Mac OS X v10.2 and later.

Declared In
MacTextEditor.h

TXNTab

Contains tab information for a text object.

```
struct TXNTab {
    SInt16 value;
    TXNTabType tabType;
    UInt8 filler;
};
typedef struct TXNTab TXNTab;
```

Fields

`value`
The distance between tabs.

`tabType`
The type of tab settings, such as right or left. See Tab Types (page 2767) for a description of possible values.

`filler`
An unsigned 8-bit integer that exists only to make the structure exactly 4 bytes in size.

Discussion
Passed in the `iControlData` parameter of the `TXNSetTXNObjectControls` (page 2693) function when the value of the `iControlTags` parameter is `kTXNTabSettingsTag`, or returned in the `oControlData` parameter of the `TXNGetTXNObjectControls` (page 2659) function when the value of the `iControlTags` parameter is `kTXNTabSettingsTag`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MacTextEditor.h`

TXNTextBoxOptionsData

Contains information about how text appears in a Unicode text box.

```
struct TXNTextBoxOptionsData {
    TXNTextBoxOptions optionTags;
    Fract flushness;
    Fract justification;
    Fixed rotation;
    void * options;
};
typedef struct TXNTextBoxOptionsData TXNTextBoxOptionsData;
```

Fields

`optionTags`
Specifies the field in this structure at which MLTE should look. See Text Box Options Masks (page 2770) for a description of possible values. You must supply the data associated with this tag in the appropriate field. For example, if you set the value of the `optionTags` field to `kTXNSetJustificationMask`, you must specify the type of justification in the `justification` field.

`flushness`
Indicates whether text should be displayed flush left, flush right, or centered in the text box. You should use one of the line justification constants defined in ATSUnicode.h. The possible values are `kATSUStartAlignment`, `kATSUEndAlignment`, and `kATSUCenterAlignment`.

`justification`
The type of justification to use in the text box. You should use one of the line justification constants defined in ATSUnicode.h. The possible values are `kATSUNoJustification` and `kATSUFullJustification`.

`rotation`
The angle of rotation for text in the text box.

`options`
Reserved for future use. This should be set to `NULL`.

Discussion
Used in the `TXNDrawUnicodeTextBox` (page 2639) and `TXNDrawCFStringTextBox` (page 2637) functions.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacTextEditor.h`

TXNTypeAttributes

Contains information about attributes for a text object.

```
struct TXNTypeAttributes {
    TXTNTag tag;
    ByteCount size;
    TXNAttributeData data;
};
typedef struct TXNTypeAttributes TXNTypeAttributes;
```

Fields

`tag`
: A value that specifies the type of information contained in the `data` field. See Font Run Attributes (page 2739) for a description of possible values.

`size`
: The size of the attribute. See Font Run Attribute Sizes (page 2740) for a description of possible values.

`data`
: A union that serves either as a 32-bit integer or a 32-bit pointer, depending on the `size` field.

Discussion
Used in the functions `TXNSetTypeAttributes` (page 2694), `TXNGetContinuousTypeAttributes` (page 2648), and `TXNGetIndexedRunInfoFromRange` (page 2654).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MacTextEditor.h`

TXNVersionValue

Specifies the version of MLTE in use.

```
typedef UInt32 TXNVersionValue;
```

Discussion
Returned by the `TXNVersionInformation` (page 2698) function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MacTextEditor.h`

TXTNTag

Specifies the type of information you want passed in the `data` field of the `TXNTypeAttributes` structure. (**Deprecated.** Use `TXNTypeRunAttributes` (page 2739).)

```
typedef FourCharCode TXTNTag;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
MacTextEditor.h

Constants

Action Constants

Specify constants for actions used when calling TXNCanUndoAction (page 2624) and TXNCanRedoAction (page 2622).

```
const CFStringRef kTXNActionTyping;
const CFStringRef kTXNActionCut;
const CFStringRef kTXNActionPaste;
const CFStringRef kTXNActionClear;
const CFStringRef kTXNActionChangeFont;
const CFStringRef kTXNActionChangeColor;
const CFStringRef kTXNActionChangeSize;
const CFStringRef kTXNActionChangeStyle;
const CFStringRef kTXNActionAlignLeft;
const CFStringRef kTXNActionAlignCenter;
const CFStringRef kTXNActionAlignRight;
const CFStringRef kTXNActionDrop;
const CFStringRef kTXNActionMove;
const CFStringRef kTXNActionChangeFontFeature;
const CFStringRef kTXNActionChangeFontVariation;
const CFStringRef kTXNActionChangeGlyphVariation;
const CFStringRef kTXNActionChangeTextPosition;
const CFStringRef kTXNActionUndoLast;
```

Constants

kTXNActionTyping
A typing action.

kTXNActionCut
A cut action.

kTXNActionPaste
A paste action.

kTXNActionClear
A clear action.

kTXNActionChangeFont
A font change action.

kTXNActionChangeColor
A color change action.

kTXNActionChangeSize
A size change action.

kTXNActionChangeStyle
A change in style action.

kTXNActionAlignLeft
An align left action.

`kTXNActionAlignCenter`
An align center action.

`kTXNActionAlignRight`
An align right action.

`kTXNActionDrop`
A drop action.

`kTXNActionMove`
A move action.

`kTXNActionChangeFontFeature`
A change font feature action.

`kTXNActionChangeFontVariation`
A change in font variation action.

`kTXNActionChangeGlyphVariation`
A change glyph variation action.

`kTXNActionChangeTextPosition`
A change text position action; includes changing the space before and after characters and shifting the text's baseline.

`kTXNActionUndoLast`
Used in undo and redo functions if none of the other constants apply.

Discussion
Use these constants when calling the `TXNCanUndoAction` (page 2624) and `TXNCanRedoAction` (page 2622) functions.

Declared In
`MacTextEditor.h`

Action Count Constants

Represent action types use by `TXNGetCountForActionType` (page 2649) and `TXNClearCountForActionType` (page 2626).

```
const CFStringRef kTXNActionCountOfTextChanges;
const CFStringRef kTXNActionCountOfStyleChanges;
const CFStringRef kTXNActionCountOfAllChanges;
```

Constants
`kTXNActionCountOfTextChanges`
Count of text changes. All text changes other than style changes and custom defined actions are included in this action count. Includes key presses, inline sessions, cut, copy, and paste, and drop. Undo and redo events of these kinds are also included in this action count.

`kTXNActionCountOfStyleChanges`
Count of text style changes. Style changes include changing font, font face, font size, font feature, font variation, font color, glyph variation, and text position. Undo or redo events of these kinds are also included in this action count.

`kTXNActionCountOfAllChanges`
Total count of actions including all text and style changes, as well as custom defined actions.

Declared In
`MacTextEditor.h`

Action Count Bits

Specify actions to be included in an action count when calling `TXNGetActionChangeCount` (page 2646) and `TXNClearActionChangeCount` (page 2625). (**Deprecated.** See Action Count Constants (page 2720).)

```
enum {
    kTXNTextInputCountBit = 0,
    kTXNRunCountBit = 1
};
```

Constants

`kTXNTextInputCountBit`

When this bit is set, general text input events that affect the content of the document are included in the action count. General text input events include key presses, inline sessions, pasting, cutting, dropping, and other editing events. Undo or redo events of text input events are also included in the action count.

Available in Mac OS X v10.1 and later.

Declared in `MacTextEditor.h`.

`kTXNRunCountBit`

When this bit is set, general style changes to the text are included in the action count. Style changes include changes to the text face, font, font size and so forth. Undo and redo events of style changes are also included in the action count.

Available in Mac OS X v10.1 and later.

Declared in `MacTextEditor.h`.

Declared In

`MacTextEditor.h`

Action Count Masks

Set or test action count bits for use with `TXNGetActionChangeCount` (page 2646) and `TXNClearActionChangeCount` (page 2625). (**Deprecated.** See Action Count Constants (page 2720).)

```
typedef OptionBits TXNCountOptions;
enum {
    kTXNTextInputCountMask = 1L << kTXNTextInputCountBit,
    kTXNRunCountMask = 1L << kTXNRunCountBit,
    kTXNAllCountMask = kTXNTextInputCountMask | kTXNRunCountMask
};
```

Constants

`kTXNTextInputCountMask`

Use to set or test for the `kTXNTextInputCountBit`.

Available in Mac OS X v10.1 and later.

Declared in `MacTextEditor.h`.

`kTXNRunCountMask`

Used to set or test for the `kTXNRunCountBit`.

Available in Mac OS X v10.1 and later.

Declared in `MacTextEditor.h`.

`kTXNAllCountMask`
Use to set or text for both `kTXNTextInputCountBit` and `kTXNRunCountBit`.

Available in Mac OS X v10.1 and later.

Declared in `MacTextEditor.h`.

Declared In
`MacTextEditor.h`

Action Types

Specify constants for editing actions taken by the user in versions of Mac OS X prior to Mac OS X v10.4. (**Deprecated.** These constants were used in the `TXNCanUndo` (page 2623) and `TXNCanRedo` (page 2622) functions, which are deprecated in Mac OS X v10.4. Use the `TXNCanUndoAction` (page 2624) and `TXNCanRedoAction` (page 2622) functions instead.)

```
typedef UInt32 TXNActionKey;
enum {
    kTXNTypingAction = 0,
    kTXNCutAction = 1,
    kTXNPasteAction = 2,
    kTXNClearAction = 3,
    kTXNChangeFontAction = 4,
    kTXNChangeFontColorAction = 5,
    kTXNChangeFontSizeAction = 6,
    kTXNChangeStyleAction = 7,
    kTXNAlignLeftAction = 8,
    kTXNAlignCenterAction = 9,
    kTXNAlignRightAction = 10,
    kTXNDropAction = 11,
    kTXNMoveAction = 12,
    kTXNFontFeatureAction = 13,
    kTXNFontVariationAction = 14,
    kTXNUndoLastAction = 1024
};
```

Constants
`kTXNTypingAction`
A typing action.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNCutAction`
A cut action.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNPasteAction`
A paste action.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNClearAction`
A clear action.
Available in Mac OS X v10.0 and later.
Declared in `MacTextEditor.h`.

`kTXNChangeFontAction`
A font change action.
Available in Mac OS X v10.0 and later.
Declared in `MacTextEditor.h`.

`kTXNChangeFontColorAction`
A change in font color action.
Available in Mac OS X v10.0 and later.
Declared in `MacTextEditor.h`.

`kTXNChangeFontSizeAction`
A change in font size action.
Available in Mac OS X v10.0 and later.
Declared in `MacTextEditor.h`.

`kTXNChangeStyleAction`
A change in font style action.
Available in Mac OS X v10.0 and later.
Declared in `MacTextEditor.h`.

`kTXNAlignLeftAction`
An align left action.
Available in Mac OS X v10.0 and later.
Declared in `MacTextEditor.h`.

`kTXNAlignCenterAction`
An align center action.
Available in Mac OS X v10.0 and later.
Declared in `MacTextEditor.h`.

`kTXNAlignRightAction`
An align right action.
Available in Mac OS X v10.0 and later.
Declared in `MacTextEditor.h`.

`kTXNDropAction`
A drop action.
Available in Mac OS X v10.0 and later.
Declared in `MacTextEditor.h`.

`kTXNMoveAction`
A move selection action.
Available in Mac OS X v10.0 and later.
Declared in `MacTextEditor.h`.

`kTXNFontFeatureAction`
A change in font feature action.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNFontVariationAction`
A change in font variation action.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNUndoLastAction`
Use this if none of the other constants apply.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

Declared In
`MacTextEditor.h`

Apple Event Handler Bits

Specify whether Apple events should be used.

```
enum {
    kTXNNoAppleEventHandlersBit = 0,
    kTXNRestartAppleEventHandlersBit = 1
};
```

Constants
`kTXNNoAppleEventHandlersBit`

When this bit is set, Apple event handlers are not used. (**Deprecated.** There is no replacement.)

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNRestartAppleEventHandlersBit`

When this bit is set, Apple event handlers are started up. (**Deprecated.** There is no replacement.)

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

Special Considerations

MLTE does not support Apple events in Mac OS X version 10.1 and later.

Declared In
`MacTextEditor.h`

Apple Event Handler Masks

Set or test Apple event handler bits.

```
enum {
    kTXNNoAppleEventHandlersMask = 1 << kTXNNoAppleEventHandlersBit,
    kTXNRestartAppleEventHandlersMask = 1 << kTXNRestartAppleEventHandlersBit
};
```

Constants

`kTXNNoAppleEventHandlersMask`

Use to set or test for the `kTXNNoAppleEventHandlersBit`. Use this if you want Apple event handlers removed. (**Deprecated.** There is no replacement.)

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNRestartAppleEventHandlersMask`

Used to set or test for the `kTXNRestartAppleEventHandlersBit`. Use this if you want to subsequently restart Apple event handlers after removing your own text handlers. (**Deprecated.** There is no replacement.)

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

Discussion

These constants are currently the only settings for the flags field of `TXNCarbonEventInfo`.

Special Considerations

MLTE does not support Apple events in Mac OS X version 10.1 and later

Declared In

`MacTextEditor.h`

ATSUI Feature Bits

Specify the default imaging system.

```
enum {
    kTXNWillDefaultToATSUIBit = 0,
    kTXNWillDefaultToCarbonEventBit = 1
};
```

Constants

`kTXNWillDefaultToATSUIBit`

When this bit is set, indicates ATSUI is the default imaging system.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNWillDefaultToCarbonEventBit`

When this bit is set, indicates MLTE uses Carbon events by default.

Available in Mac OS X v10.1 and later.

Declared in `MacTextEditor.h`.

Declared In

`MacTextEditor.h`

ATSUI Feature Masks

Specifies new features and represents the default imaging system.

```
typedef OptionBits TXNFeatureBits;
enum {
    kTXNWillDefaultToATSUIMask = 1L << kTXNWillDefaultToATSUIBit,
    kTXNWillDefaultToCarbonEventMask = 1L << kTXNWillDefaultToCarbonEventBit
};
```

Constants

`kTXNWillDefaultToATSUIMask`

Test for ATSUI as the default imaging system.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNWillDefaultToCarbonEventMask`

Test for Carbon events as the default event handling mechanism.

Available in Mac OS X v10.1 and later.

Declared in `MacTextEditor.h`.

Discussion

You can use this to test for bit 0 in the `oFeatureFlags` parameter returned by the `TXNVersionInformation` (page 2698) function.

Declared In

`MacTextEditor.h`

Automatic Indentation Settings

Specify the automatic indentation setting for a text object.

```
enum {
    kTXNAutoIndentOff = false,
    kTXNAutoIndentOn = true
};
```

Constants

`kTXNAutoIndentOff`

Automatic indenting is not enabled.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNAutoIndentOn`

Automatic indenting is enabled. You can enable this feature only if automatic word wrapping is not enabled.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

Discussion

Passed in the `iControlData` parameter of the `TXNSetTXNObjectControls` (page 2693) function when the value of the `iControlTags` parameter is `kTXNAutoIndentStateTag`, or returned in the `oControlData` parameter of the `TXNGetTXNObjectControls` (page 2659) function when the value of the `iControlTags` parameter is `kTXNAutoIndentStateTag`.

Declared In
MacTextEditor.h

Automatic Scrolling Behavior

Specify automatic scrolling behavior for a text object.

```
enum {
    kTXNAutoScrollInsertionIntoView = 0,
    kTXNAutoScrollNever = 1,
    kTXNAutoScrollWhenInsertionVisible = 2
};
typedef UInt32 TXNAutoScrollBehavior;
```

Constants

`kTXNAutoScrollInsertionIntoView`
The default auto scrolling behavior. When text is inserted, the document is scrolled to show the new insertion. This was the only type of autoscrolling prior to Mac OS X v10.4.

Available in Mac OS X v10.4 and later.

Declared in `MacTextEditor.h`.

`kTXNAutoScrollNever`
Never autoscroll, even when dragging the mouse or inserting text. The only way to scroll the document is for the user to use the scrollbar or to scroll programatically.

Available in Mac OS X v10.4 and later.

Declared in `MacTextEditor.h`.

`kTXNAutoScrollWhenInsertionVisible`
Autoscrolling only happens when the insertion offset is currently in the user's view. If the user is looking at the first page of a ten page document and text is inserted at the end of the document, no autoscrolling occurs. However, if the user was looking at page ten and text is inserted there, the document would scroll. This type of autoscrolling is best for implementing terminal or log windows.

Available in Mac OS X v10.4 and later.

Declared in `MacTextEditor.h`.

Declared In
MacTextEditor.h

Carbon Event Dictionary Keys

Specify Carbon events to be handled by MLTE.

```
#define kTXNTextHandlerKey CFSTR("TextInput")
#define kTXNWindowEventHandlerKey CFSTR("WindowEvent")
#define kTXNWindowResizeEventHandlerKey CFSTR("WindowResize")
#define kTXNCommandTargetKey CFSTR("CommandTarget")
#define kTXNCommandUpdateKey CFSTR("CommandUpdate")
#define kTXNFontMenuObjectKey CFSTR("FontMenuObject")
#define kTXNActionNameMapperKey CFSTR("ActionNameMapper")
#define kTXNWheelMouseEventHandlerKey CFSTR("WheelMouseEvent")
#define kTXNTSMDocumentAccessHandlerKey CFSTR("TSMDocumentAccess")
#define kTXNFontPanelEventHandlerKey CFSTR("FontPanel")
#define kTXNFontMenuRefKey CFSTR("FontMenuRef")
#define kTXNActionKeyMapperKey CFSTR("ActionKeyMapper")
```

Constants

`kTXNTextHandlerKey`
Indicates the Carbon event class `kEventClassTextInput` and the event kinds `kEventTextInputUpdateActiveInputArea`, `kEventTextInputUnicodeForKeyEvent`, `kEventTextInputOffsetToPos`, `kEventTextInputPosToOffset`, and `kEventTextInputGetSelectedText`.

`kTXNWindowEventHandlerKey`
Indicates the Carbon event class `kEventClassWindow` and the event kinds `kEventWindowActivated`, `kEventWindowDeactivated`, `kEventWindowDrawContent`, and `kEventWindowClickContentRegion`.

`kTXNWindowResizeEventHandlerKey`
Indicates the Carbon event class `kEventClassWindow` and a window resizing event.

`kTXNCommandTargetKey`
Indicates the Carbon event class `kEventClassCommand` and the event kind `kEventCommandProcess`.

`kTXNCommandUpdateKey`
Indicates the Carbon event class `kEventClassCommand` and the event kind `kEventCommandUpdate`.

`kTXNFontMenuObjectKey`
Indicates the Carbon event class `kEventClassMenu` and the event kind `kEventMenuEnableItems`.

`kTXNActionNameMapperKey`
Indicates an action key mapper callback function. Available in Mac OS X v10.4; use instead of `kTXNActionKeyMapperKey`.

`kTXNWheelMouseEventHandlerKey`
Indicates the handler for wheel mouse events.

`kTXNTSMDocumentAccessHandlerKey`
Indicates the handler for TSM document access events.

`kTXNFontPanelEventHandlerKey`
Indicates the handler for Font Panel events.

`kTXNFontMenuRefKey`
Indicates the Carbon event class `kEventClassMenu`.

`kTXNActionKeyMapperKey`
Indicates an action key mapper callback function. (**Deprecated.** Use `kTXNActionNameMapperKey` instead.)

Declared In
`MacTextEditor.h`

Clearance Settings

Clear formatting and privileges settings.

```
enum {
    kTXNClearThisControl = 0xFFFFFFFF,
    kTXNClearTheseFontFeatures = 0x80000000
};
```

Constants

`kTXNClearThisControl`

Clears control settings. If you want to clear a setting associated with a control tag, you can call the `TXNSetTXNObjectControls` (page 2693) function with the value of the `iControlData` parameter set to `kTXNClearThisControl`. MLTE resets the value of the control specified in the `iControlTag` parameter of the `TXNSetTXNObjectControls` (page 2693) function to the default value for that control.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNClearTheseFontFeatures`

Clears font feature settings. You can use this constant when you call the `TXNSetTypeAttributes` (page 2694) function to clear all of the ATSUI font features or ATSUI font variations.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

Declared In

`MacTextEditor.h`

Command Event Support Options

Specify options for enabling support for command events in a TXNObject.

```
enum {
    kTXNSupportEditCommandProcessing = 1 << 0,
    kTXNSupportEditCommandUpdating = 1 << 1,
    kTXNSupportSpellCheckCommandProcessing = 1 << 2,
    kTXNSupportSpellCheckCommandUpdating = 1 << 3,
    kTXNSupportFontCommandProcessing = 1 << 4,
    kTXNSupportFontCommandUpdating = 1 << 5
};
typedef UInt32 TXNCommandEventSupportOptions;
```

Constants

`kTXNSupportEditCommandProcessing`

Setting this bit when calling `TXNSetTXNObjectControls` (page 2693) enables support for processing the menu item associated with `kHICommandUndo`, `kHICommandRedo`, `kHICommandCut`, `kHICommandCopy`, `kHICommandPaste`, `kHICommandClear`, and `kHICommandSelectAll`. If this bit is not set when `TXNSetTXNObjectControls` (page 2693) is called, support is disabled.

Available in Mac OS X v10.4 and later.

Declared in `MacTextEditor.h`.

`kTXNSupportEditCommandUpdating`

Setting this bit when calling `TXNSetTXNObjectControls` (page 2693) enables support for updating the menu item associated with `kHICommandUndo`, `kHICommandRedo`, `kHICommandCut`, `kHICommandCopy`, `kHICommandPaste`, `kHICommandClear`, and `kHICommandSelectAll`. For Undo, the item is enabled if there are any undoable actions in MLTE's command stack, and, if you have installed an action key mapper proc, it is called to get the appropriate string for the Undo item. For Redo, the item is enabled if there are any redoable actions; if you have installed an action key mapper callback, it is called to get the appropriate string for the Redo item. For Cut and Clear, the item is enabled if there is current selection that is not empty; otherwise, these items are disabled. For Paste, the item is enabled if the clipboard is not empty; it is disabled if the clipboard is empty or contains data that MLTE cannot parse. For Select All, the item is always updated. If this bit is not set when `TXNSetTXNObjectControls` (page 2693) is called, support is disabled.

Available in Mac OS X v10.4 and later.

Declared in `MacTextEditor.h`.

`kTXNSupportSpellCheckCommandProcessing`

Setting this bit when calling `TXNSetTXNObjectControls` (page 2693) enables support for spell checking. The spell checking commands supported are: Show Spelling Panel (`'shsp'`), Check Spelling (`'cksp'`), Change Spelling (`'chsp'`), enable check spelling as you type (`'aspc'`), ignore spelling (`'igsp'`), and learn spelling (`'lrwd'`). If this bit is not set when `TXNSetTXNObjectControls` (page 2693) is called, support is disabled.

Available in Mac OS X v10.4 and later.

Declared in `MacTextEditor.h`.

`kTXNSupportSpellCheckCommandUpdating`

Enables support for updating the menu item associated with a given spell checking command. Once `kTXNSupportSpellCheckCommandUpdating` is enabled, the Show Spelling and Check Spelling items are always enabled. The Change Spelling item is included in a spelling menu only if the current selection is a misspelled word; it is disabled if the current selection is empty or not a misspelled word. The Check Spelling as You Type item is always enabled. It is checked if this feature has been enabled. By default when you turn on spell checking, this item is enabled. If this feature has been disabled, the item is not checked. Ignore Spelling usually does not have a corresponding menu item. If a menu does have this item, Ignore Spelling is disabled if the current selection is empty or is not a misspelled word. It is enabled if the current selection is a misspelled word. Learn Spelling typically does not have a corresponding menu item. If a menu does have this item, Learn Spelling is disabled if the current selection is empty or is not a misspelled word. It is enabled if the current selection is a misspelled word. If this bit is not set when `TXNSetTXNObjectControls` (page 2693) is called, support is disabled.

Available in Mac OS X v10.4 and later.

Declared in `MacTextEditor.h`.

`kTXNSupportFontCommandProcessing`

Setting this bit enables Carbon Font Panel support. Once enabled, MLTE handles the following Carbon Events defined in `FontPanel.h`: `kHICommandShowHideFontPanel` and `kEventFontPanelClosed` to show and hide the Carbon font panel, `kEventFontSelection` event to update the document after the selection of a new font, size, style, color, or any feature settings from the Typography Panel. If this bit is not set when `TXNSetTXNObjectControls` (page 2693) is called, support is disabled.

Available in Mac OS X v10.4 and later.

Declared in `MacTextEditor.h`.

`kTXNSupportFontCommandUpdating`
Setting this bit enables support for updating the selection in Carbon Font Panel when the current selection in an MLTE document is changed. When this bit is set, `kTXNSupportFontCommandProcessing` must also be set. If this bit is not set when `TXNSetTXNObjectControls` (page 2693) is called, support is disabled.

Available in Mac OS X v10.4 and later.

Declared in `MacTextEditor.h`.

Declared In
`MacTextEditor.h`

Continuous Style Information Bits

Specify whether font information is continuous.

```
enum {
    kTXNFontContinuousBit = 0,
    kTXNSizeContinuousBit = 1,
    kTXNStyleContinuousBit = 2,
    kTXNColorContinuousBit = 3
};
```

Constants
`kTXNFontContinuousBit`
When this bit is set, the font is continuous in a text run.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNSizeContinuousBit`
When this bit is set, the font size is continuous in a text run.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNStyleContinuousBit`
When this bit is set, the font style is continuous in a text run.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNColorContinuousBit`
When this bit is set, the font color is continuous in a text run.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

Declared In
`MacTextEditor.h`

Continuous Style Information Masks

Represents continuous style information needed by your application.

```
typedef OptionBits TXNContinuousFlags;
enum {
    kTXNFontContinuousMask = 1L << kTXNFontContinuousBit,
    kTXNSizeContinuousMask = 1L << kTXNSizeContinuousBit,
    kTXNStyleContinuousMask = 1L << kTXNStyleContinuousBit,
    kTXNColorContinuousMask = 1L << kTXNColorContinuousBit
};
```

Constants

`kTXNFontContinuousMask`
Use to test for continuous font information in a text run.
Available in Mac OS X v10.0 and later.
Declared in `MacTextEditor.h`.

`kTXNSizeContinuousMask`
Use to test for continuous size information in a text run.
Available in Mac OS X v10.0 and later.
Declared in `MacTextEditor.h`.

`kTXNStyleContinuousMask`
Use to test for continuous style information in a text run.
Available in Mac OS X v10.0 and later.
Declared in `MacTextEditor.h`.

`kTXNColorContinuousMask`
Use to test for continuous color information in a text run.
Available in Mac OS X v10.0 and later.
Declared in `MacTextEditor.h`.

Discussion
Used in the `TXNGetContinuousTypeAttributes` (page 2648) function.

Declared In
`MacTextEditor.h`

Data Offsets

Specifies offsets to use when manipulating data in a text object. Offsets in MLTE are always character offsets.

```
typedef UInt32 TXNOffset;
enum {
    kTXNUseCurrentSelection = 0xFFFFFFFF,
    kTXNStartOffset = 0,
    kTXNEndOffset = 0x7FFFFFFF
};
```

Constants

`kTXNUseCurrentSelection`
Use the current selection.
Available in Mac OS X v10.0 and later.
Declared in `MacTextEditor.h`.

`kTXNStartOffset`
The first offset of the text in a text object.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNEndOffset`
The last offset of the text in a text object.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

Discussion
These constants can be passed and returned in functions that have the parameter of type `TXNOffset`.

Declared In
`MacTextEditor.h`

Data Option Key Value Constants

Specifies constants used as key values in Data Option dictionaries.

```
const CFStringRef kTXNPlainTextDocumentType
const CFStringRef kTXNMLTEDocumentType
const CFStringRef kTXNRTFDocumentType
const CFStringRef kTXNQuickTimeDocumentType
```

Constants
`kTXNPlainTextDocumentType`
Plain text document.

`kTXNMLTEDocumentType`
Native MLTE document type.

`kTXNRTFDocumentType`
Rich text format (RTF) document type.

`kTXNQuickTimeDocumentType`
Multimedia file that can be opened by QuickTime importers. This document type is only supported for reading data, not for writing data.

Discussion
These constants are passed in Data Option dictionary keys to `TXNReadFromCFURL` (page 2673) and `TXNWriteRangeToCFURL` (page 2699) to specify options that are to be used when reading data into a TXNObject and when writing data from a TXNObject to a file or special file bundle (directory).

Declared In
`MacTextEditor.h`

Data Option Key Constants

Specifies keys for use in dictionaries passed as parameters to `TXNReadFromCFURL` (page 2673) and `TXNWriteRangeToCFURL` (page 2699).

```
const CFStringRef kTXNDataOptionDocumentTypeKey
const CFStringRef kTXNDataOptionCharacterEncodingKey
```

Constants

`kTXNDataOptionDocumentTypeKey`
: `CFString` specifying the document format. The following constants are supported: `kTXNPlainTextDocumentType`, `kTXNMLTEDocumentType`, `kTXNRTFDocumentType`, and `kTXNQuickTimeDocumentType`. For information on these constants, see Data Option Key Value Constants (page 2733).

`kTXNDataOptionCharacterEncodingKey`
: CFNumber of type `kCFNumberSInt32Type` containing the character encoding as specified in `CFString.h` and `CFStringEncodingExt.h`.

Discussion

Data options are used to specify options for reading in and writing out data.

Declared In

`MacTextEditor.h`

Default Font Name

Specifies the default font name.

```
enum {
    kTXNDefaultFontName = 0
};
```

Constants

`kTXNDefaultFontName`
: The default font name.

Discussion

MLTE used these constants in an earlier version in which only a single font was allowed. You can now specify an array of font descriptions by using the `TXNMacOSPreferredFontDescription` (page 2714) structure. See the function `TXNInitTextension` (page 2662) for a description of how to specify defaults for a font.

Declared In

`MacTextEditor.h`

Default Font Size

Specifies the default font size.

```
enum {
    kTXNDefaultFontSize = 0x000C0000
};
```

Constants

`kTXNDefaultFontSize`
: Sets default font size.

  Available in Mac OS X v10.1 and later.

  Not available to 64-bit applications.

  Declared in `MacTextEditor.h`.

Declared In
MacTextEditor.h

Default Font Style

Specifies the default font style.

```
enum {
    kTXNDefaultFontStyle = normal
};
```

Constants
kTXNDefaultFontStyle
Sets default font style.

Available in Mac OS X v10.1 and later.

Not available to 64-bit applications.

Declared in MacTextEditor.h.

Declared In
MacTextEditor.h

Document Attribute Keys

Specify dictionary keys for document attribute dictionaries used by TXNWriteRangeToCFURL (page 2699) and TXNReadFromCFURL (page 2673).

```
const CFStringRef kTXNDocumentAttributeTitleKey;
const CFStringRef kTXNDocumentAttributeCompanyNameKey;
const CFStringRef kTXNDocumentAttributeSubjectKey;
const CFStringRef kTXNDocumentAttributeAuthorKey;
const CFStringRef kTXNDocumentAttributeKeywordsKey;
const CFStringRef kTXNDocumentAttributeCommentKey;
const CFStringRef kTXNDocumentAttributeEditorKey;
const CFStringRef kTXNDocumentAttributeCreationTimeKey;
const CFStringRef kTXNDocumentAttributeModificationTimeKey;
const CFStringRef kTXNDocumentAttributeCopyrightKey;
```

Constants
kTXNDocumentAttributeTitleKey
CFString containing the document's title.

kTXNDocumentAttributeCompanyNameKey
CFString containing the company name.

kTXNDocumentAttributeSubjectKey
CFString containing the document's subject.

kTXNDocumentAttributeAuthorKey
CFString containing the name of the document's author.

kTXNDocumentAttributeKeywordsKey
CFArray of values of type CFString containing keywords.

kTXNDocumentAttributeCommentKey
CFString containing comments.

`kTXNDocumentAttributeEditorKey`
`CFString` containing the name of the person who last edited the document.

`kTXNDocumentAttributeCreationTimeKey`
`CFAbsoluteTime` containing document comments; note that this is not the file system creation date of the file, but of the document, as it is stored in the document.

`kTXNDocumentAttributeModificationTimeKey`
`CFAbsoluteTime` containing the last modification date of the document contents.

`kTXNDocumentAttributeCopyrightKey`
`CFString` containing the copyright of the document.

Discussion
Use these constants when working with document attribute dictionaries that are passed to `TXNWriteRangeToCFURL` (page 2699) and `TXNReadFromCFURL` (page 2673).

When writing data out, document attributes are embedded into the data stream for document formats that support them (i.e. MLTE native format and RTF). When reading data in, document attributes are extracted from the data stream if the document format supports them.

Declared In
`MacTextEditor.h`

Drag and Drop Constants

Specify whether or not drag and drop is enabled.

```
enum {
    kTXNEnableDragAndDrop = false,
    kTXNDisableDragAndDrop = true
};
```

Constants
`kTXNEnableDragAndDrop`
Enables drag and drop when passed as a parameter to the function `TXNSetTXNObjectControls` (page 2693). Indicates drag and drop is disabled when returned from the function `TXNGetTXNObjectControls` (page 2659).

Available in Mac OS X v10.1 and later.

Declared in `MacTextEditor.h`.

`kTXNDisableDragAndDrop`
Disables drag and drop when passed as a parameter to the function `TXNSetTXNObjectControls` (page 2693). Indicates drag and drop is enabled when returned from the function `TXNGetTXNObjectControls` (page 2659).

Available in Mac OS X v10.1 and later.

Declared in `MacTextEditor.h`.

Declared In
`MacTextEditor.h`

Draw Items Bits

Specify which elements of the text object to render.

```
enum {
    kTXNDrawItemScrollbarsBit= 0,
    kTXNDrawItemTextBit= 1,
    kTXNDrawItemTextAndSelectionBit = 2
};
```

Constants

`kTXNDrawItemScrollbarsBit`
Specifies to draw the scroll bars.
Available in Mac OS X v10.3 and later.
Declared in `MacTextEditor.h`.

`kTXNDrawItemTextBit`
Specifies to render the text.
Available in Mac OS X v10.3 and later.
Declared in `MacTextEditor.h`.

`kTXNDrawItemTextAndSelectionBit`
Specifies to render the text and the current selection.
Available in Mac OS X v10.3 and later.
Declared in `MacTextEditor.h`.

Discussion

See `Draw Items Masks` (page 2737).

Declared In

`MacTextEditor.h`

Draw Items Masks

Test for draw-items bits.

```
enum {
    kTXNDrawItemScrollbarsMask = 1UL << kTXNDrawItemScrollbarsBit,
    kTXNDrawItemTextMask = 1UL << kTXNDrawItemTextBit,
    kTXNDrawItemTextAndSelectionMask = 1UL <<
kTXNDrawItemTextAndSelectionBit,
    kTXNDrawItemAllMask =  0xFFFFFFFF
};
typedef OptionBits TXNDrawItems;
```

Constants

`kTXNDrawItemScrollbarsMask`
Use to set or test for the `kTXNDrawItemScrollbarsBit`.
Available in Mac OS X v10.3 and later.
Declared in `MacTextEditor.h`.

`kTXNDrawItemTextMask`
Used to set or test for the `kTXNDrawItemTextBit`.
Available in Mac OS X v10.3 and later.
Declared in `MacTextEditor.h`.

`kTXNDrawItemTextAndSelectionMask`
Use to set or text for the `kTXNDrawItemTextAndSelectionBit`.

Available in Mac OS X v10.3 and later.

Declared in `MacTextEditor.h`.

`kTXNDrawItemAllMask`
Used to set all draw-items bits or test to see whether all draw-items bits are set. Setting all bits specifies to draw the scroll bars, text, and the current selection.

Available in Mac OS X v10.3 and later.

Declared in `MacTextEditor.h`.

Discussion
These constants can be passed as parameters to the function `TXNDrawObject` (page 2638).

Declared In
`MacTextEditor.h`

Font Defaults

Specify a variety of font settings.

```
enum {
    kTXNDontCareTypeSize = 0xFFFFFFFF,
    kTXNDontCareTypeStyle = 0xFF,
    kTXNIncrementTypeSize = 0x00000001,
    kTXNDecrementTypeSize = 0x80000000,
    kTXNUseScriptDefaultValue = -1,
    kTXNNoFontVariations = 0x7FFF
};
```

Constants
`kTXNDontCareTypeSize`
Use the application default font size.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNDontCareTypeStyle`
Use “normal” should as the font style.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNIncrementTypeSize`
Increase the font size should by one point.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNDecrementTypeSize`
Decrease the font size by one point.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

Discussion
These constants can be used as parameters in a variety of functions that control font attributes, such as the `TXNSetFontDefaults` (page 2688) and `TXNSetTypeAttributes` (page 2694) functions.

Declared In
`MacTextEditor.h`

Font Run Attributes

Specifies a font attribute (font family, size, style, and so forth) for a text run in a text object.

```
typedef FourCharCode TXNTypeRunAttributes;
enum {
    kTXNQDFontNameAttribute = 'fntn',
    kTXNQDFontFamilyIDAttribute = 'font',
    kTXNQDFontSizeAttribute = 'size',
    kTXNQDFontStyleAttribute = 'face',
    kTXNQDFontColorAttribute = 'klor',
    kTXNTextEncodingAttribute = 'encd',
    kTXNATSUIFontFeaturesAttribute = 'atfe',
    kTXNATSUIFontVariationsAttribute = 'atva',
    kTXNURLAttribute = 'urla'
    kTXNATSUIStyle  = 'astl'
};
```

Constants

`kTXNQDFontNameAttribute`
Specifies that the `data` field of the `TXNTypeAttributes` (page 2718) structure contains a font name.
Available in Mac OS X v10.0 and later.
Declared in `MacTextEditor.h`.

`kTXNQDFontFamilyIDAttribute`
Specifies that the `data` field of the `TXNTypeAttributes` (page 2718) structure contains a font family ID.
Available in Mac OS X v10.0 and later.
Declared in `MacTextEditor.h`.

`kTXNQDFontSizeAttribute`
Specifies that the `data` field of the `TXNTypeAttributes` (page 2718) structure contains a font size. Obsolete; incorrect font sizes are always returned as a fixed value. (**Deprecated.** Use `kTXNFontSizeAttribute` instead.)
Available in Mac OS X v10.0 and later.
Declared in `MacTextEditor.h`.

`kTXNQDFontStyleAttribute`
Specifies that the `data` field of the `TXNTypeAttributes` (page 2718) structure contains a font style.
Available in Mac OS X v10.0 and later.
Declared in `MacTextEditor.h`.

`kTXNQDFontColorAttribute`
Specifies that the `data` field of the `TXNTypeAttributes` (page 2718) structure contains a font color.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNTextEncodingAttribute`
Specifies that the `data` field of the `TXNTypeAttributes` (page 2718) structure contains a text encoding.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNATSUIFontFeaturesAttribute`
Specifies that the `data` field of the `TXNTypeAttributes` (page 2718) structure contains ATSUI font features.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNURLAttribute`
Specifies that the `data` field of the `TXNTypeAttributes` (page 2718) structure contains a URL.

Available in Mac OS X v10.2 and later.

Declared in `MacTextEditor.h`.

`kTXNATSUIStyle`
Specifies that the `data` field of the `TXNTypeAttributes` (page 2718) structure contains an ATSUI style.

Available in Mac OS X v10.3 and later.

Declared in `MacTextEditor.h`.

Discussion
You pass these constants in the `tag` field of the `TXNTypeAttributes` (page 2718) structure. You can supplement these with the style attributes defined for ATSUI.

Declared In
`MacTextEditor.h`

Font Run Attribute Sizes

Describes the size of a font attribute.

```
typedef ByteCount TXNTypeRunAttributeSizes;
enum {
    kTXNQDFontNameAttributeSize = sizeof(Str255),
    kTXNQDFontFamilyIDAttributeSize = sizeof(SInt16),
    kTXNQDFontSizeAttributeSize = sizeof(SInt16),
    kTXNQDFontStyleAttributeSize = sizeof(Style),
    kTXNQDFontColorAttributeSize = sizeof(RGBColor),
    kTXNTextEncodingAttributeSize = sizeof(TextEncoding),
    kTXNFontSizeAttributeSize = sizeof(Fixed),
    kTXNATSUIStyleSize = sizeof(ATSUStyle)
};
```

Constants

`kTXNQDFontNameAttributeSize`
The size of a QuickDraw font name.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNQDFontFamilyIDAttributeSize`
The size of a font family ID attribute.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNQDFontSizeAttributeSize`
Obsolete don't use. (**Deprecated.** Instead, use `kTXNFontSizeAttributeSize`.)

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNQDFontStyleAttributeSize`
The size of font style attribute.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNQDFontColorAttributeSize`
The size of a font color attribute.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNTextEncodingAttributeSize`
The size of text encoding attribute.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNFontSizeAttributeSize`
The size of the font size attribute. Use this instead of the `kTXNQDFontSizeAttributeSize` constant. Font sizes are always returned as a `Fixed` value.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNATSUIStyleSize`
The size of the ATSUI style attribute.

Available in Mac OS X v10.3 and later.

Declared in `MacTextEditor.h`.

Discussion
You pass these constants in the `size` field of the `TXNTypeAttributes` (page 2718) structure.

Declared In
`MacTextEditor.h`

Formatting and Privileges Settings

Specifies the formatting and privileges information to get from or set for a text object.

```
typedef FourCharCode TXNControlTag;
enum {
    kTXNLineDirectionTag = 'lndr',
    kTXNJustificationTag = 'just',
    kTXNIOPrivilegesTag = 'iopv',
    kTXNSelectionStateTag = 'slst',
    kTXNInlineStateTag = 'inst',
    kTXNWordWrapStateTag = 'wwrs',
    kTXNKeyboardSyncStateTag = 'kbsy',
    kTXNAutoIndentStateTag = 'auin',
    kTXNTabSettingsTag = 'tabs',
    kTXNRefConTag = 'rfcn',
    kTXNMarginsTag = 'marg',
    kTXNFlattenMoviesTag = 'flat',
    kTXNDoFontSubstitution = 'fSub',
    kTXNNoUserIOTag = 'nuio',
    kTXNUseCarbonEvents = 'cbcb',
    kTXNDrawCaretWhenInactiveTag = 'dcrt',
    kTXNDrawSelectionWhenInactiveTag = 'dsln',
    kTXNDisableDragAndDropTag = 'drag',
    kTXNSingleLevelUndoTag = 'undo',
    kTXNVisibilityTag = 'visb'
    kTXNDisableLayoutAndDrawTag = kTXNVisibilityTag,
    kTXNAutoScrollBehaviorTag = ‘sbev’
};
```

Constants

`kTXNLineDirectionTag`
Specifies a setting for the direction text is written on the line. If you pass this constant in the `iControlTags` parameter of the `TXNSetTXNObjectControls` (page 2693) function, you must also pass a value that specifies the line direction in the `iControlData` parameter. See Line Direction Settings (page 2757) for a description of possible values.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNJustificationTag`
Specifies a justification setting. If you pass this constant in the `iControlTags` parameter of the `TXNSetTXNObjectControls` (page 2693) function, you must also pass a value that specifies a justification setting in the `iControlData` parameter. See Justification Settings (page 2755) for a description of possible values.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNIOPrivilegesTag`

Indicates a privileges setting. If you pass this constant in the `iControlTags` parameter of the `TXNSetTXNObjectControls` (page 2693) function, you must also pass a value that specifies a privileges setting in the `iControlData` parameter. See Read and Write Privileges Settings (page 2758) for a description of possible values.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNSelectionStateTag`

Specifies a selection state; that is, whether MLTE displays a cursor and allows selections in a read-only document. If you pass this constant in the `iControlTags` parameter of the `TXNSetTXNObjectControls` (page 2693) function, you must also pass a value that specifies the selection state in the `iControlData` parameter. See Selection State Settings (page 2764) for a description of possible values.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNInlineStateTag`

Specifies an inline state that is, whether text is input through the document's window (inline) or through a small floating window that appears at the bottom of the screen. If you pass this constant in the `iControlTags` parameter of the `TXNSetTXNObjectControls` (page 2693) function, you must also pass a value that specifies the inline state in the `iControlData` parameter. See Inline State Settings (page 2755) for a description of possible values.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNWordWrapStateTag`

Specifies a word-wrap setting. If you pass this constant in the `iControlTags` parameter of the `TXNSetTXNObjectControls` (page 2693) function, you must also pass a value that specifies the line-wrapping state in the `iControlData` parameter. See Line Wrapping Settings (page 2758) for a description of possible values.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNKeyboardSyncStateTag`

Specifies whether to synchronize the keyboard with the font setting. If you pass this constant in the `iControlTags` parameter of the `TXNSetTXNObjectControls` (page 2693) function, you must also pass a value that specifies the keyboard synchronization state in the `iControlData` parameter. See Keyboard Synchronization Settings (page 2756) for a description of possible values.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `MacTextEditor.h`.

`kTXNAutoIndentStateTag`

Specifies an automatic indentation setting. This is available only when word warp is turned off. If you pass this constant in the `iControlTags` parameter of the `TXNSetTXNObjectControls` (page 2693) function, you must also pass a value that specifies the indentation state in the `iControlData` parameter. See Automatic Indentation Settings (page 2726) for a description of possible values.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNTabSettingsTag`

Specifies a tab width setting. If you pass this constant in the `iControlTags` parameter of the `TXNSetTXNObjectControls` (page 2693) function, you must also pass a `TXNTab` (page 2716) structure in the `iControlData` parameter.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNRefConTag`

An application-specific constant you define.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNMarginsTag`

Specifies margin settings. If you pass this constant in the `iControlTags` parameter of the `TXNSetTXNObjectControls` (page 2693) function, you must also pass a pointer to a `TXNMargins` structure in the `iControlData` parameter. You use this structure to specify the top, left, and right margin settings.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNFlattenMoviesTag`

Specifies whether to flattens movies. A flattened movie is self-contained. If you don't flatten a movie, it can't be played unless any external files (such as audio or image files) on which it depends are available. If you pass this constant in the `iControlTags` parameter of the `TXNSetTXNObjectControls` (page 2693) function, you must also pass a `Boolean` value in the `iControlData` parameter that specifies whether to enable (`true`) or disable (`false`) movie flattening.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNDoFontSubstitution`

Specifies a font substitution setting. If you pass this constant in the `iControlTags` parameter of the `TXNSetTXNObjectControls` (page 2693) function, you must also pass a `Boolean` value in the `iControlData` parameter that specifies whether to enable (`true`) or disable (`false`) font substitution. For best performance, don't enable font substitution.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNNoUserIOTag`

Specifies an input setting; that is, whether to prevent input typed by the user, but allows your application to use the `TXNSetData` (page 2683) function. Text objects could have read-only with respect to the application user, but have read-and-write privileges with respect to the application. If you pass this constant in the `iControlTags` parameter of the `TXNSetTXNObjectControls` (page 2693) function, you must also pass a value that specifies a read-write setting in the `iControlData` parameter. See Read and Write Privileges Settings (page 2758) for a description of possible values.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNUseCarbonEvents`

Specifies settings for using Carbon events. (**Deprecated.** Use `TXNGetEventTarget` (page 2651) and `TXNSetEventTarget` (page 2686).)

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNDrawCaretWhenInactiveTag`

Specifies settings for drawing the caret when the text object does not have focus. (**Deprecated.** In Mac OS Xv10.4 and later, MLTE never draws the caret when the text object does not have focus.)

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNDrawSelectionWhenInactiveTag`

Specifies settings for drawing the selection when the text object does not have focus.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNDisableDragAndDropTag`

Specifies settings for drag and drop support.

Available in Mac OS X v10.1 and later.

Declared in `MacTextEditor.h`.

`kTXNSingleLevelUndoTag`

Specifies to use a single level of undo.

Available in Mac OS X v10.2 and later.

Declared in `MacTextEditor.h`.

`kTXNVisibilityTag`

Specifies visibility.

Available in Mac OS X v10.2 and later.

Declared in `MacTextEditor.h`.

`kTXNDisableLayoutAndDrawTag`

Specifies visibility. Equivalent to `kTXNVisibilityTag`. Available in Mac OS X v10.4 and later. Use this tag to disable and re-enable layout and drawing. It optimizes performance when adding data incrementally to a text object.

Available in Mac OS X v10.4 and later.

Declared in `MacTextEditor.h`.

`kTXNAutoScrollBehaviorTag`

Specifies autoscroll behavior. Available in Mac OS X v10.4 and later. For constants that represent the various types of autoscrolling, see Automatic Scrolling Behavior (page 2727).

Available in Mac OS X v10.4 and later.

Declared in `MacTextEditor.h`.

Discussion

You pass formatting and privileges settings in the `iControlTags` parameter of the `TXNSetTXNObjectControls` (page 2693) or `TXNGetTXNObjectControls` (page 2659) functions. If you want to clear a setting associated with a control tag, you can set the value of the `iControlData` parameter to Clearance Settings (page 2729).

Declared In
`MacTextEditor.h`

Frame Option Bits

Specify frame options for a text object.

```
enum {
    kTXNDrawGrowIconBit = 0,
    kTXNShowWindowBit = 1,
    kTXNWantHScrollBarBit = 2,
    kTXNWantVScrollBarBit = 3,
    kTXNNoTSMEverBit = 4,
    kTXNReadOnlyBit = 5,
    kTXNNoKeyboardSyncBit = 6,
    kTXNNoSelectionBit = 7,
    kTXNSaveStylesAsSTYLResourceBit = 8,
    kOutputTextInUnicodeEncodingBit = 9,
    kTXNDoNotInstallDragProcsBit = 10,
    kTXNAlwaysWrapAtViewEdgeBit = 11,
    kTXNDontDrawCaretWhenInactiveBit = 12,
    kTXNDontDrawSelectionWhenInactiveBit = 13,
    kTXNSingleLineOnlyBit = 14,
    kTXNDisableDragAndDropBit = 15,
    kTXNUseQDforImagingBit = 16,
    kTXNMonostyledTextBit = 17
};
```

Constants

`kTXNDrawGrowIconBit`

When this bit is set, it indicates the frame will have a size box. The presence of a size box in the lower right corner of an MLTE pane is only useful for resizing an MLTE pane if the MLTE pane occupies the entire window (a full-window MLTE object). In this case your application would look for a mouse-down event in the size box and call the function `TXNGrowWindow` as appropriate. Note that the size box is not supported as a means of resizing MLTE panes using `TXNGrowWindow` for MLTE pane objects.

Passing the `kTXNDrawGrowIconMask` constant to the function `TXNNewObject` only causes a size box to be drawn in the lower right corner of the MLTE pane. Passing this constant does not create a size box control in the window. The window will not contain an actual size box control. This means the window will not receive events that indicate a mouse-down event in the grow region. For this to happen, when you create the window that contains the MLTE pane, you must create the window to have a size box.

In summary, although you may pass the constants `kTXNDrawGrowIconMask` to the function `TXNNewObject` when you create an MLTE object in a window, this action only causes the visual appearance of a size box in the lower right corner of the MLTE pane. If you want to detect mouse-down events in the size box, you must also provide a size box in the window through the appropriate Window Manager functions or other tools.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNShowWindowBit`

When this bit is set, it indicates MLTE should display a window when a text object is created. If this bit is set, your application no longer needs to call the `ShowWindow` function from the Window Manager; MLTE will do this for you.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNWantHScrollBarBit`

When this bit is set, it indicates the frame should have a horizontal scroll bar.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNWantVScrollBarBit`

When this bit is set, it indicates the frame should have a vertical scroll bar.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNNoTSMEverBit`

When this bit is set, it indicates not to use Text Services Manager. You cannot use this bit when your application accepts Unicode input. (**Deprecated.** You can no longer set this because in Mac OS X, MLTE always uses the Text Services Manager.)

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNReadOnlyBit`

When this bit is set, it indicates the text object is read-only. If you set this bit when you call the function `TXNNewObject`, the text object is put into a state that does not allow user input. However, your application can put data into the text object by calling the function `TXNSetData`. If you want the text object set into a more restrictive read-only state that does not allow user input or your application to put data into the text object programmatically you need to call the function `TXNSetTXNObjectControls`, passing the tag `kTXNIOPrivilegesTag`.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNNoKeyboardSyncBit`

When this bit is set, it indicates no keyboard synchronization.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `MacTextEditor.h`.

`kTXNNoSelectionBit`

When this bit is set, it indicates MLTE should not show the insertion point.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNSaveStylesAsSTYLResourceBit`

When this bit is set, it indicates text style should be saved as a `kTXNMultipleStylesPerTextDocumentResType` resource. You can set this to assure compatibility with SimpleText. If you use `kTXNMultipleStylesPerTextDocumentResType` resources to save style info, your documents can have as many styles as you'd like. However tabs are not saved. If you don't set this bit, plain text files are saved as `kTXNSingleStylePerTextDocumentResType` resources, and only the first style in the document is saved. (Your application is expected to apply all style changes to the entire document.) If you save files with a `kTXNSingleStylePerTextDocumentResType` resource, their output is similar to those output by CodeWarrior, BBEdit, and MPW.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kOutputTextInUnicodeEncodingBit`

When this bit is set, it indicates plain text should be saved as Unicode.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNDoNotInstallDragProcsBit`

When this bit is set, it indicates you want to call your own drag handlers.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNAlwaysWrapAtViewEdgeBit`

When this bit is set, it indicates line wrap at the edge of the view rectangle.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNDontDrawCaretWhenInactiveBit`

When this bit is set, it indicates the caret should not be drawn when the object does not have focus. (**Deprecated.** In Mac OS X v10.4, MLTE never draws the caret when the text object does not have focus.)

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNDontDrawSelectionWhenInactiveBit`

When this bit is set, it indicates the selection should not be drawn when the object does not have focus.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNSingleLineOnlyBit`

When this bit is set, it indicates that the text object will not scroll vertically. Horizontal scrolling will stop when the end of the text is visible, and there will be no limit to the width of the text. In addition, a line break character typed, pasted, or dropped into the text object will be translated into a hyphen (-).

Available in Mac OS X v10.1 and later.

Declared in `MacTextEditor.h`.

`kTXNDisableDragAndDropBit`

When this bit is set, it indicates that drag and drop will not be allowed in the text object.

Available in Mac OS X v10.1 and later.

Declared in `MacTextEditor.h`.

`kTXNUseQDforImagingBit`

When this bit is set, it indicates that QuickDraw will be used for imaging instead of Quartz, which is the default. Available in Mac OS X only. (**Deprecated.** You can no longer set the imaging system to use; MLTE always uses Quartz imaging.)

Available in Mac OS X v10.1 and later.

Declared in `MacTextEditor.h`.

`kTXNMonostyledTextBit`

When this bit is set, it indicates that the text object will have a single style no matter what kind of changes are made to the object.

Available in Mac OS X v10.2 and later.

Declared in `MacTextEditor.h`.

Declared In
`MacTextEditor.h`

Frame Option Masks

Represents information about frame behavior (such as whether there are scroll bars and a size box).

```
typedef OptionBits TXNFrameOptions;
enum {
    kTXNDrawGrowIconMask = 1L << kTXNDrawGrowIconBit,
    kTXNShowWindowMask = 1L << kTXNShowWindowBit,
    kTXNWantHScrollBarMask = 1L << kTXNWantHScrollBarBit,
    kTXNWantVScrollBarMask = 1L << kTXNWantVScrollBarBit,
    kTXNNoTSMEverMask = 1L << kTXNNoTSMEverBit,
    kTXNReadOnlyMask = 1L << kTXNReadOnlyBit,
    kTXNNoKeyboardSyncMask = 1L << kTXNNoKeyboardSyncBit,
    kTXNNoSelectionMask = 1L << kTXNNoSelectionBit,
    kTXNSaveStylesAsSTYLResourceMask = 1L <<
kTXNSaveStylesAsSTYLResourceBit,
    kOutputTextInUnicodeEncodingMask = 1L <<
kOutputTextInUnicodeEncodingBit,
    kTXNDoNotInstallDragProcsMask = 1L << kTXNDoNotInstallDragProcsBit,
    kTXNAlwaysWrapAtViewEdgeMask = 1L << kTXNAlwaysWrapAtViewEdgeBit,
    kTXNDontDrawCaretWhenInactiveMask = 1L <<
kTXNDontDrawCaretWhenInactiveBit,
    kTXNDontDrawSelectionWhenInactiveMask = 1L <<
kTXNDontDrawSelectionWhenInactiveBit,
    kTXNSingleLineOnlyMask = 1L << kTXNSingleLineOnlyBit,
    kTXNDisableDragAndDropMask = 1L << kTXNDisableDragAndDropBit,
    kTXNUseQDforImagingMask = 1L << kTXNUseQDforImagingBit,
    kTXNMonostyledTextMask = 1L << kTXNMonostyledTextBit
};
```

Constants

`kTXNDrawGrowIconMask`

Use to set or test for the `kTXNDrawGrowIconBit` bit.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNShowWindowMask`

Use to set or test for the `kTXNShowWindowBit` bit.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNWantHScrollBarMask`

Use to set or test for the `kTXNWantHScrollBarBit` bit.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNWantVScrollBarMask`

Use to set or test for the `kTXNWantVScrollBarBit` bit.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNNoTSMEverMask`

Use to set or test for the `kTXNNoTSMEverBit` bit. (**Deprecated.** You can no longer set this because in Mac OS X, MLTE always uses the Text Services Manager.)

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNReadOnlyMask`
Use to set or test for the `kTXNReadOnlyBit` bit.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNNoKeyboardSyncMask`
Use to set or test for the `kTXNNoKeyboardSyncBit` bit.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `MacTextEditor.h`.

`kTXNNoSelectionMask`
Use to set or test for the `kTXNNoSelectionBit` bit.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNSaveStylesAsSTYLResourceMask`
Use to set or test for the `kTXNSaveStylesAsSTYLResourceBit` bit.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kOutputTextInUnicodeEncodingMask`
Use to set or test for the `kOutputTextInUnicodeEncodingBit` bit.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNDoNotInstallDragProcsMask`
Use to set or test for the `kTXNDoNotInstallDragProcsBit` bit.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNAlwaysWrapAtViewEdgeMask`
Use to set or test for the `kTXNAlwaysWrapAtViewEdgeBit` bit.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNDontDrawCaretWhenInactiveMask`

Use to set or test for the `kTXNDontDrawCaretWhenInactiveBit` bit. (**Deprecated.** In Mac OS Xv10.4 and later, MLTE never draws the caret when the text object does not have focus.)

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNDontDrawSelectionWhenInactiveMask`
Use to set or test for the `kTXNDontDrawSelectionWhenInactiveBit` bit.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNSingleLineOnlyMask`
Use to set or test for the `kTXNSingleLineOnlyBit` bit.

Available in Mac OS X v10.1 and later.

Declared in `MacTextEditor.h`.

`kTXNDisableDragAndDropMask`
Use to set or test for the `kTXNDisableDragAndDropBit` bit.

Available in Mac OS X v10.1 and later.

Declared in `MacTextEditor.h`.

`kTXNUseQDforImagingMask`
Use to set or test for the `kTXNUseQDforImagingBit` bit. (**Deprecated.** You can no longer set the imaging system; MLTE always uses Quartz imaging.)

Available in Mac OS X v10.1 and later.

Declared in `MacTextEditor.h`.

`kTXNMonostyledTextMask`
Use to set or test for the `kTXNMonostyledTextBit` bit.

Available in Mac OS X v10.2 and later.

Declared in `MacTextEditor.h`.

Discussion
See Frame Option Bits (page 2746).

Declared In
`MacTextEditor.h`

HIObject Class ID

Specifies the HIObject class ID for the HITextView class.

```
#define kHITextViewClassID CFSTR("com.apple.HITextView")
```

Constants
`kHITextViewClassID`
The class ID for the HITextView class.

Discussion
For more information on HIView, see the document *Introducing HIView*, available from the Apple Developer Documentation website.

Declared In
`MacTextEditor.h`

HIObject Control Kind

Specifies the HIObject control kind for the HITextView class.

```
enum {
    kControlKindHITextView  = 'hitx'
};
```

Constants
`kControlKindHITextView`
The control kind for the HITextView class.

Available in Mac OS X v10.3 and later.

Declared in `HITextViews.h`.

Discussion
For more information on HIView, see the document *Introducing HIView*, available from the Apple Developer Documentation website.

Declared In
`MacTextEditor.h`

Initialization Option Bits

Specify initialization options for MLTE.

```
enum {
    kTXNWantMoviesBit = 0,
    kTXNWantSoundBit = 1,
    kTXNWantGraphicsBit = 2,
    kTXNAlwaysUseQuickDrawTextBit = 3,
    kTXNUseTemporaryMemoryBit = 4
};
```

Constants

`kTXNWantMoviesBit`
When this bit is set, it specifies that movie data is supported in a text object.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `MacTextEditor.h`.

`kTXNWantSoundBit`
When this bit is set, it specifies that sound data is supported in a text object.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `MacTextEditor.h`.

`kTXNWantGraphicsBit`
When this bit is set, it specifies that graphics data is supported in a text object.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `MacTextEditor.h`.

`kTXNAlwaysUseQuickDrawTextBit`
When this bit is set, it specifies that MLTE should use QuickDraw for imaging even if ATSUI is available. This is often the best choice for applications that need speed and efficient memory usage.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `MacTextEditor.h`.

`kTXNUseTemporaryMemoryBit`
When this bit is set, it specifies that MLTE should use temporary memory for all memory allocations.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `MacTextEditor.h`.

Declared In
MacTextEditor.h

Initialization Option Masks

Represents MLTE initialization options.

```
typedef OptionBits TXNInitOptions;
enum {
    kTXNWantMoviesMask = 1L << kTXNWantMoviesBit,
    kTXNWantSoundMask = 1L << kTXNWantSoundBit,
    kTXNWantGraphicsMask = 1L << kTXNWantGraphicsBit,
    kTXNAlwaysUseQuickDrawTextMask = 1L << kTXNAlwaysUseQuickDrawTextBit,
    kTXNUseTemporaryMemoryMask = 1L << kTXNUseTemporaryMemoryBit
};
```

Constants

`kTXNWantMoviesMask`
Use to set or test for the `kTXNWantMoviesBit` bit.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `MacTextEditor.h`.

`kTXNWantSoundMask`
Use to set or test for the `kTXNWantSoundBit` bit.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `MacTextEditor.h`.

`kTXNWantGraphicsMask`
Use to set or test for the `kTXNWantGraphicsBit` bit.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `MacTextEditor.h`.

`kTXNAlwaysUseQuickDrawTextMask`
Use to set or test for the `kTXNAlwaysUseQuickDrawTextBit` bit.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `MacTextEditor.h`.

`kTXNUseTemporaryMemoryMask`
Use to set or test for the `kTXNUseTemporaryMemoryBit` bit.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `MacTextEditor.h`.

Discussion
Used in the `iUsageFlags` parameter of the `TXNInitTextension` (page 2662) function.

Declared In
MacTextEditor.h

Inline State Settings

Specify the inline state for a text object.

```
enum {
    kTXNUseInline = false,
    kTXNUseBottomline = true
};
```

Constants

`kTXNUseInline`

Text is entered at the caret insertion point in the text object's window.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNUseBottomline`

Text is entered in a bottom-line window (a small floating window that appears at the bottom of the screen).

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

Discussion

Passed in the `iControlData` parameter of the `TXNSetTXNObjectControls` (page 2693) function when the value of the `iControlTags` parameter is `kTXNInlineStateTag`, or returned in the `oControlData` parameter of the `TXNGetTXNObjectControls` (page 2659) function when the value of the `iControlTags` parameter is `kTXNInlineStateTag`.

Declared In

`MacTextEditor.h`

Justification Settings

Specify the justification setting.

```
enum {
    kTXNFlushDefault = 0,
    kTXNFlushLeft = 1,
    kTXNFlushRight = 2,
    kTXNCenter = 4,
    kTXNFullJust = 8,
    kTXNForceFullJust = 16
};
```

Constants

`kTXNFlushDefault`

Justification is flush according to the line direction.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNFlushLeft`

Justification is flush left.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNFlushRight`
Justification is flush right.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNCenter`
Justification is centered.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNFullJust`
Justification is flush left and right for all lines except the last line in a paragraph.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNForceFullJust`
Justification is flush left and right for all lines.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

Discussion
Passed in the `iControlData` parameter of the `TXNSetTXNObjectControls` (page 2693) function when the value of the `iControlTags` parameter is `kTXNJustificationTag`, or returned in the `oControlData` parameter of the `TXNGetTXNObjectControls` (page 2659) function when the value of the `iControlTags` parameter is `kTXNJustificationTag`.

Declared In
`MacTextEditor.h`

Keyboard Synchronization Settings

Specify the keyboard synchronization setting for a text object.

```
enum {
    kTXNSyncKeyboard = false,
    kTXNNoSyncKeyboard = true
};
```

Constants
`kTXNSyncKeyboard`
Keyboard synchronization is enabled.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `MacTextEditor.h`.

`kTXNNoSyncKeyboard`
Keyboard synchronization is not enabled.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `MacTextEditor.h`.

Discussion
These constants are passed in the `iControlData` parameter of the `TXNSetTXNObjectControls` (page 2693) function when the value of the `iControlTags` parameter is `kTXNKeyboardSyncStateTag`. They are also returned in the `oControlData` parameter of the `TXNGetTXNObjectControls` (page 2659) function when the value of the `iControlTags` parameter is `kTXNKeyboardSyncStateTag`.

Declared In
`MacTextEditor.h`

Layout and Draw Constants

Specify the layout and draw setting for a text object.

```
enum {
    kTXNEnableLayoutAndDraw = false,
    kTXNDisableLayoutAndDraw = true
};
```

Constants
`kTXNEnableLayoutAndDraw`
Layout and draw is enabled.
Available in Mac OS X v10.4 and later.
Declared in `MacTextEditor.h`.

`kTXNDisableLayoutAndDraw`
Layout and draw is disabled.
Available in Mac OS X v10.4 and later.
Declared in `MacTextEditor.h`.

Discussion
These constants are passed in the `iControlData` parameter of the `TXNSetTXNObjectControls` (page 2693) function when the value of the `iControlTags` parameter is `kTXNDisableLayoutAndDrawTag`. They are also are returned in the `oControlData` parameter of the `TXNGetTXNObjectControls` (page 2659) function when the value of the `iControlTags` parameter is `kTXNDisableLayoutAndDrawTag`.

Declared In
`MacTextEditor.h`

Line Direction Settings

Specify the line direction setting.

```
enum {
    kTXNLeftToRight = 0,
    kTXNRightToLeft = 1
};
```

Constants
`kTXNLeftToRight`
Line direction flows from left to right.
Available in Mac OS X v10.0 and later.
Declared in `MacTextEditor.h`.

`kTXNRightToLeft`
Line direction flows from right to left.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

Discussion
Passed in the `iControlData` parameter of the `TXNSetTXNObjectControls` (page 2693) function when the value of the `iControlTags` parameter is `kTXNLineDirectionTag`, or returned in the `oControlData` parameter of the `TXNGetTXNObjectControls` (page 2659) function when the value of the `iControlTags` parameter is `kTXNLineDirectionTag`.

Declared In
`MacTextEditor.h`

Line Wrapping Settings

Specify the line-wrap setting for a text object.

```
enum {
    kTXNAutoWrap = false,
    kTXNNoAutoWrap = true
};
```

Constants
`kTXNAutoWrap`
Automatic line wrapping is enabled.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNNoAutoWrap`
Automatic line wrapping is not enabled.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

Discussion
Passed in the `iControlData` parameter of the `TXNSetTXNObjectControls` (page 2693) function when the value of the `iControlTags` parameter is `kTXNWordWrapStateTag`, or returned in the `oControlData` parameter of the `TXNGetTXNObjectControls` (page 2659) function when the value of the `iControlTags` parameter is `kTXNWordWrapStateTag`.

Declared In
`MacTextEditor.h`

Read and Write Privileges Settings

Specify the privileges setting for a text object.

```
enum {
    kTXNReadWrite = false,
    kTXNReadOnly = true
};
```

Constants

`kTXNReadWrite`
The document has read and write privileges.
Available in Mac OS X v10.0 and later.
Declared in `MacTextEditor.h`.

`kTXNReadOnly`
The document is read-only.
Available in Mac OS X v10.0 and later.
Declared in `MacTextEditor.h`.

Discussion

Passed in the `iControlData` parameter of the `TXNSetTXNObjectControls` (page 2693) function when the value of the `iControlTags` parameter is `kTXNIOPrivilegesTag`, or returned in the `oControlData` parameter of the `TXNGetTXNObjectControls` (page 2659) function when the value of the `iControlTags` parameter is `kTXNIOPrivilegesTag`.

Declared In

`MacTextEditor.h`

Rectangle Keys

Specifies the bounds to use for a text object.

```
typedef UInt32    TXNRectKey;
enum {
    kTXNViewRectKey               = 0,
    kTXNDestinationRectKey        = 1,
    kTXNTextRectKey               = 2,
    kTXNVerticalScrollBarRectKey  = 3,
    kTXNHorizontalScrollBarRectKey = 4
};
```

Constants

`kTXNViewRectKey`
Specifies to use the view rectangle.
Available in Mac OS X v10.3 and later.
Declared in `MacTextEditor.h`.

`kTXNDestinationRectKey`
Specifies to use the destination rectangle.
Available in Mac OS X v10.3 and later.
Declared in `MacTextEditor.h`.

`kTXNTextRectKey`
Specifies to use the text rectangle.
Available in Mac OS X v10.3 and later.
Declared in `MacTextEditor.h`.

`kTXNVerticalScrollBarRectKey`
Specifies to include the vertical scroll bar in the rectangle.

Available in Mac OS X v10.3 and later.

Declared in `MacTextEditor.h`.

`kTXNHorizontalScrollBarRectKey`
Specifies to include the horizontal scroll bar in the rectangle.

Available in Mac OS X v10.3 and later.

Declared in `MacTextEditor.h`.

Discussion
You can pass a rectangle key to the function `TXNGetHIRect` (page 2653).

Declared In
`MacTextEditor.h`

Scroll Bar Orientation

Specifies the orientation of a text window's scroll bar.

```
typedef UInt32 TXNScrollBarOrientation;
enum {
    kTXNHorizontal = 0,
    kTXNVertical = 1
};
```

Constants
`kTXNHorizontal`
Specifies a horizontal scroll bar.

Available in Mac OS X v10.2 and later.

Declared in `MacTextEditor.h`.

`kTXNVertical`
Specifies a vertical scroll bar.

Available in Mac OS X v10.2 and later.

Declared in `MacTextEditor.h`.

Discussion
You use these constants in your `TXNScrollInfoProcPtr` (page 2705) callback function.

Declared In
`MacTextEditor.h`

Scroll Bar States

Represents the scroll bar state for the window attached to a text object.

```
typedef Boolean TXNScrollBarState;
enum {
    kScrollBarsAlwaysActive = true,
    kScrollBarsSyncWithFocus = false
};
```

Constants

`kScrollBarsAlwaysActive`
Indicates that scroll bars should always appear in the active state even then the text area does not have focus.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kScrollBarsSyncWithFocus`
Indicates that scroll bars should be active only if the frame in which they are enclosed is focused.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

Discussion
Used in the `TXNActivate` (page 2618) function.

Declared In
`MacTextEditor.h`

Scroll Units

Specify the unit by which scrolling should occur.

```
typedef UInt32 TXNScrollUnit;
enum {
    kTXNScrollUnitsInPixels = 0,
    kTXNScrollUnitsInLines = 1,
    kTXNScrollUnitsInViewRects = 2
};
```

Constants

`kTXNScrollUnitsInPixels`
Specifies pixels as the scrolling unit.

Available in Mac OS X v10.2 and later.

Declared in `MacTextEditor.h`.

`kTXNScrollUnitsInLines`
Specifies line count as the scrolling unit. Scrolling is slower when you use this unit because each line must be measured by MLTE before the text scrolls.

Available in Mac OS X v10.2 and later.

Declared in `MacTextEditor.h`.

`kTXNScrollUnitsInViewRects`
Specifies the height of the current view rectangle as the scrolling unit.

Available in Mac OS X v10.2 and later.

Declared in `MacTextEditor.h`.

Discussion
These constants are supplied as the `iVerticalScrollUnit` and `iHorizontalScrollUnit` parameters to the `TXNScroll` (page 2679) function. They specifies the units used for each of these parameters.

Declared In
`MacTextEditor.h`

Search Criteria Bits

Specify matching rules to use when searching.

```
enum {
    kTXNIgnoreCaseBit = 0,
    kTXNEntireWordBit = 1,
    kTXNUseEncodingWordRulesBit = 31
};
```

Constants

`kTXNIgnoreCaseBit`
When this bit is set, indicates that case should be ignored.
Available in Mac OS X v10.0 and later.
Declared in `MacTextEditor.h`.

`kTXNEntireWordBit`
When this bit is set, indicates that the entire word must match.
Available in Mac OS X v10.0 and later.
Declared in `MacTextEditor.h`.

`kTXNUseEncodingWordRulesBit`
When this bit is set, indicates that Unicode Utilities should be used to find a word boundary. You need to set this bit if your applications uses 2-byte scripts in which words are not separated by a space.
Available in Mac OS X v10.0 and later.
Declared in `MacTextEditor.h`.

Declared In
`MacTextEditor.h`

Search Criteria Masks

Represents the matching rules to be used in a find operation.

```
typedef OptionBits TXNMatchOptions;
enum {
    kTXNIgnoreCaseMask = 1L << kTXNIgnoreCaseBit,
    kTXNEntireWordMask = 1L << kTXNEntireWordBit,
    kTXNUseEncodingWordRulesMask = 1L << kTXNUseEncodingWordRulesBit
};
```

Constants

`kTXNIgnoreCaseMask`
Use to set or test for the `kTXNIgnoreCaseBit` bit.
Available in Mac OS X v10.0 and later.
Declared in `MacTextEditor.h`.

`kTXNEntireWordMask`
Use to set or test for the `kTXNEntireWordBit` bit.
Available in Mac OS X v10.0 and later.
Declared in `MacTextEditor.h`.

`kTXNUseEncodingWordRulesMask`
Use to set or test for the `kTXNEntireWordBit` bit.
Available in Mac OS X v10.0 and later.
Declared in `MacTextEditor.h`.

Discussion

These constants can be passed in the `iMatchOptions` parameter of the `TXNFind` (page 2641) function or the callback `TXNFindProcPtr` (page 2703).

Declared In

`MacTextEditor.h`

Selection Display Settings

Specify whether the text object should scroll to show the beginning or the end of the selection.

```
enum {
    kTXNShowStart = false,
    kTXNShowEnd = true
};
```

Constants

`kTXNShowStart`
The start of the selection should be shown. The selection scrolls to show the start if necessary.
Available in Mac OS X v10.0 and later.
Declared in `MacTextEditor.h`.

`kTXNShowEnd`
The end of the selection should be shown. The selection scrolls to show the end if necessary.
Available in Mac OS X v10.0 and later.
Declared in `MacTextEditor.h`.

Declared In

`MacTextEditor.h`

Selection State Settings

Specify whether or not MLTE displays a caret and allows selections in text that is read-only.

```
enum {
    kTXNSelectionOn = true,
    kTXNSelectionOff = false
};
```

Constants

`kTXNSelectionOn`

Display a caret and allow a selection in text that is read-only.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNSelectionOff`

Do not display a caret or allow a selection in text that is read-only.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

Discussion

Passed in the `iControlData` parameter of the `TXNSetTXNObjectControls` (page 2693) function when the value of the `iControlTags` parameter is `kTXNSelectionStateTag`, or returned in the `oControlData` parameter of the `TXNGetTXNObjectControls` (page 2659) function when the value of the `iControlTags` parameter is `kTXNSelectionStateTag`.

Declared In

`MacTextEditor.h`

Style Resource Types

Specify the resource type to use to save style information for a plain text document.

```
enum {
    kTXNSingleStylePerTextDocumentResType = 'MPSR',
    kTXNMultipleStylesPerTextDocumentResType = 'styl'
};
```

Constants

`kTXNSingleStylePerTextDocumentResType`

User for a document that contains a single style and should be treated as a BBEdit, MPW, or CodeWarrior document.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNMultipleStylesPerTextDocumentResType`

Use for a document that contains multiple styles and should be treated as a SimpleText document.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

Discussion

Used in the `TXNNewObject` (page 2667) function.

Declared In
MacTextEditor.h

Supported Data Types

Specifies the type of data being requested from or passed to an MLTE function.

```
typedef OSType TXNDataType;
enum {
    kTXNTextData = 'TEXT',
    kTXNPictureData = 'PICT',
    kTXNMovieData = 'moov',
    kTXNSoundData = 'snd ',
    kTXNUnicodeTextData = 'utxt'
};
```

Constants

`kTXNTextData`
Text data.
Available in Mac OS X v10.0 and later.
Declared in `MacTextEditor.h`.

`kTXNPictureData`
Graphics (`PICT`) data.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `MacTextEditor.h`.

`kTXNMovieData`
Movie or sound data.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `MacTextEditor.h`.

`kTXNSoundData`
Sound data.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `MacTextEditor.h`.

`kTXNUnicodeTextData`
Unicode text data.
Available in Mac OS X v10.0 and later.
Declared in `MacTextEditor.h`.

Discussion
Used in the `TXNGetDataEncoded` (page 2650) function.

Declared In
MacTextEditor.h

Supported File Types

Represents a file type.

```
typedef OSType TXNFileType;
enum {
    kTXNTextensionFile = 'txtn',
    kTXNTextFile = 'TEXT',
    kTXNPictureFile = 'PICT',
    kTXNMovieFile = 'MooV',
    kTXNSoundFile = 'sfil',
    kTXNAIFFFile = 'AIFF',
    kTXNUnicodeTextFile = 'utxt'
};
```

Constants

`kTXNTextensionFile`

A file that contains Unicode or Mac OS text. By default, it contains Unicode text. Files are saved in a private format.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNTextFile`

A file that contains plain text data.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNPictureFile`

A file that contains graphics data in `PICT` format.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `MacTextEditor.h`.

`kTXNMovieFile`

A file that contains movie data in `'MooV'` format.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `MacTextEditor.h`.

`kTXNSoundFile`

A file that contains sound data in `'sfil'` format.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `MacTextEditor.h`.

`kTXNAIFFFile`

A file that contains sound data in `'aiff'` format.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNUnicodeTextFile`
A file that contains Unicode text data.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

Declared In
`MacTextEditor.h`

Supported Frame Types

Represents a frame type. (**Deprecated.** No longer needed.)

```
typedef UInt32 TXNFrameType;
enum {
    kTXNTextEditStyleFrameType = 1,
    kTXNPageFrameType = 2,
    kTXNMultipleFrameType = 3
};
```

Constants
`kTXNTextEditStyleFrameType`
A single rectangle that allows text to scroll if the rectangle fills. Although you can pass this as a parameter to the function `TXNNewObject` (page 2667), you should instead use the function `TXNCreateObject` (page 2630), which does not require a frame type.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNPageFrameType`
A single rectangle with a bottom. That is, text moves to a new page if the frame is full. This constant is not supported in Mac OS X version 10.3 and later.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNMultipleFrameType`
Multiple frames. This constant is not supported in Mac OS X version 10.3 and later.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

Special Considerations

This data type is used only by the `TXNNewObject` function, which is deprecated.

Declared In
`MacTextEditor.h`

Tab Types

Defines the tab settings for a text object.

```
typedef SInt8 TXNTabType;
enum {
    kTXNRightTab = -1,
    kTXNLeftTab = 0,
    kTXNCenterTab = 1
};
```

Constants

`kTXNRightTab`
Right tabs are active.
Available in Mac OS X v10.0 and later.
Declared in `MacTextEditor.h`.

`kTXNLeftTab`
Left tabs are active; not available in MLTE version 1.0.
Available in Mac OS X v10.0 and later.
Declared in `MacTextEditor.h`.

`kTXNCenterTab`
Center tabs are active; not available in MLTE version 1.0.
Available in Mac OS X v10.0 and later.
Declared in `MacTextEditor.h`.

Discussion
Used in the `TXNTab` (page 2716) structure.

Declared In
`MacTextEditor.h`

Text Background Types

Represents a background data type used in the `TXNBackground` structure.

```
typedef UInt32 TXNBackgroundType;
enum {
    kTXNBackgroundTypeRGB = 1
};
```

Constants

`kTXNBackgroundTypeRGB`
Indicates color.
Available in Mac OS X v10.0 and later.
Declared in `MacTextEditor.h`.

Discussion
Used in the `TXNBackground` (page 2708) structure. MLTE supports only color as the background type.

Declared In
`MacTextEditor.h`

Text Box Options Bits

Specify how text should be displayed in a Unicode text box.

```
enum {
    kTXNSetFlushnessBit = 0,
    kTXNSetJustificationBit = 1,
    kTXNUseFontFallBackBit = 2,
    kTXNRotateTextBit = 3,
    kTXNUseVerticalTextBit = 4,
    kTXNDontUpdateBoxRectBit = 5,
    kTXNDontDrawTextBit = 6,
    kTXNUseCGContextRefBit = 7,
    kTXNImageWithQDBit = 8,
    kTXNDontWrapTextBit = 9
};
```

Constants

`kTXNSetFlushnessBit`

When this bit is set, indicates MLTE should display text flush according to the line direction.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `MacTextEditor.h`.

`kTXNSetJustificationBit`

When this bit is set, indicates justification. Text is justified in the direction of the display. Horizontal text is justified horizontally, but not vertically. Vertical text is justified vertically, but not horizontally.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `MacTextEditor.h`.

`kTXNUseFontFallBackBit`

When this bit is set, indicates MLTE should use ATSUI transient font matching that searches for a font that has a matching character.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `MacTextEditor.h`.

`kTXNRotateTextBit`

When this bit is set, indicates MLTE should display text rotated clockwise.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `MacTextEditor.h`.

`kTXNUseVerticalTextBit`

When this bit is set, indicates MLTE should display text vertically from top to bottom.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `MacTextEditor.h`.

`kTXNDontUpdateBoxRectBit`
When this bit is set, indicates MLTE should not update the specified rectangle. If you set this bit when you call the `TXNDrawUnicodeTextBox` (page 2639) function, the function does not update the right coordinates of the specified rectangle to accommodate the longest line for text.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `MacTextEditor.h`.

`kTXNDontDrawTextBit`
When this bit is set, indicates MLTE should return the size of the text but should not draw the text box.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `MacTextEditor.h`.

`kTXNUseCGContextRefBit`
When this bit is set, indicates MLTE should the Quartz context (`CGContext`) you provide instead of the temporary `CGContextRef` created internally by MLTE. To do so, you must set the `kTXNUseCGContextRefBit` bit in `TXNTextBoxOptions` and pass a `CGContextRef` in the `options` field of the `TXNTextBoxOptionsData` structure.

Available in Mac OS X v10.1 and later.

Not available to 64-bit applications.

Declared in `MacTextEditor.h`.

`kTXNImageWithQDBit`
When this bit is set, indicates MLTE should use QuickDraw for imaging text. (**Deprecated.** You can no longer set the imaging system; MLTE always uses Quartz imaging.)

Available in Mac OS X v10.1 and later.

Declared in `MacTextEditor.h`.

`kTXNDontWrapTextBit`
When this bit is set, indicates MLTE should not wrap text.

Available in Mac OS X v10.1 and later.

Not available to 64-bit applications.

Declared in `MacTextEditor.h`.

Declared In
`MacTextEditor.h`

Text Box Options Masks

Defines how text appears in a text box.

```
typedef OptionBits TXNTextBoxOptions;
enum {
    kTXNSetFlushnessMask = 1L << kTXNSetFlushnessBit,
    kTXNSetJustificationMask = 1L << kTXNSetJustificationBit,
    kTXNUseFontFallBackMask = 1L << kTXNUseFontFallBackBit,
    kTXNRotateTextMask = 1L << kTXNRotateTextBit,
    kTXNUseVerticalTextMask = 1L << kTXNUseVerticalTextBit,
    kTXNDontUpdateBoxRectMask = 1L << kTXNDontUpdateBoxRectBit,
    kTXNDontDrawTextMask = 1L << kTXNDontDrawTextBit,
    kTXNUseCGContextRefMask = 1L << kTXNUseCGContextRefBit,
    kTXNImageWithQDMask = 1L << kTXNImageWithQDBit,
    kTXNDontWrapTextMask = 1L << kTXNDontWrapTextBit
};
```

Constants

`kTXNSetFlushnessMask`
Use to set or test for the `kTXNSetFlushnessBit` bit.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `MacTextEditor.h`.

`kTXNSetJustificationMask`
Use to set or test for the `kTXNSetJustificationBit` bit.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `MacTextEditor.h`.

`kTXNUseFontFallBackMask`
Use to set or test for the `kTXNUseFontFallBackBit` bit.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `MacTextEditor.h`.

`kTXNRotateTextMask`
Use to set or test for the `kTXNRotateTextBit` bit.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `MacTextEditor.h`.

`kTXNUseVerticalTextMask`
Use to set or test for the `kTXNUseVerticalTextBit` bit.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `MacTextEditor.h`.

`kTXNDontUpdateBoxRectMask`
Use to set or test for the `kTXNDontUpdateBoxRectBit` bit.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `MacTextEditor.h`.

`kTXNDontDrawTextMask`

Use to set or test for the `kTXNDontDrawTextBit` bit.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `MacTextEditor.h`.

`kTXNUseCGContextRefMask`

Use to set or test for `kTXNUseCGContextRefBit` bit.

Available in Mac OS X v10.1 and later.

Not available to 64-bit applications.

Declared in `MacTextEditor.h`.

`kTXNImageWithQDMask`

Use to set or test for `kTXNImageWithQDBit` bit. (**Deprecated.** You can no longer set the imaging system; MLTE always uses Quartz imaging.)

Available in Mac OS X v10.1 and later.

Declared in `MacTextEditor.h`.

`kTXNDontWrapTextMask`

Use to set or test for `kTXNDontWrapTextBit` bit.

Available in Mac OS X v10.1 and later.

Not available to 64-bit applications.

Declared in `MacTextEditor.h`.

Discussion

Used in the `TXNDrawUnicodeTextBox` (page 2639) and `TXNDrawCFStringTextBox` (page 2637) functions.

Declared In

`MacTextEditor.h`

Text Encoding Preferences

Represents how to encode text for your application.

```
typedef UInt32 TXNPermanentTextEncodingType;
enum {
    kTXNSystemDefaultEncoding = 0,
    kTXNMacOSEncoding = 1,
    kTXNUnicodeEncoding = 2
};
```

Constants

`kTXNSystemDefaultEncoding`

Use the encoding that is used internally by MLTE and the system. The preferred encoding is Unicode for a system that has ATSUI.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNMacOSEncoding`

Incoming and outgoing text should be in traditional Mac OS script system encodings even if MLTE uses another format internally. MLTE will use the Text Encoding Convertor (TEC) to convert text and offsets to match your application's preference.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

`kTXNUnicodeEncoding`

Incoming and outgoing text should be in Unicode even on systems that do not have ATSUI. MLTE will use the Text Encoding Convertor (TEC) to convert text and offsets to match the applications preference.

Available in Mac OS X v10.0 and later.

Declared in `MacTextEditor.h`.

Discussion
These convenience constants can be used in the functions `TXNNewObject` (page 2667) and `TXNSave` (page 2677).

Declared In
`MacTextEditor.h`

Result Codes

The most common result codes returned by MLTE are listed below.

Result Code	Value	Description
`kTXNEndIterationErr`	-22000	Function was not able to iterate through the data contained by a text object. Available in Mac OS X v10.0 and later.
`kTXNCannotAddFrameErr`	-22001	Frame was not added. The multiple-frame feature is currently not available in MLTE, so this error is returned any time you try to define an object with multiple frames. Available in Mac OS X v10.0 and later.
`kTXNInvalidFrameIDErr`	-22002	The frame ID is invalid. Available in Mac OS X v10.0 and later.
`kTXNIllegalToCrossDataBoundariesErr`	-22003	Offsets specify a range that crosses a data type boundary. Available in Mac OS X v10.0 and later.
`kTXNUserCanceledOperationErr`	-22004	A user canceled an operation before your application completed processing it. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
kTXNBadDefaultFileTypeWarning	-22005	Text file is not in the format you specified. Available in Mac OS X v10.0 and later.
kTXNCannotSetAutoIndentErr	-22006	Automatic indenting could not be enabled—the document has word wrapping enabled and you tried to enable auto indentation. Available in Mac OS X v10.0 and later.
kTXNRunIndexOutofBoundsErr	-22007	An index you supplied to a function is out of bounds. Available in Mac OS X v10.0 and later.
kTXNNoMatchErr	-22008	Returned by TXNFind (page 2641) when a match is not found. Available in Mac OS X v10.0 and later.
kTXNAttributeTagInvalidForRunErr	-22009	Tag for a specific run is not valid. Available in Mac OS X v10.0 and later.
kTXNSomeOrAllTagsInvalidForRunErr	-22010	Tags supplied to a function are not valid. Available in Mac OS X v10.0 and later.
kTXNInvalidRunIndex	-22011	Index is out of range for that run. Available in Mac OS X v10.0 and later.
kTXNAlreadyInitializedErr	-22012	You already called the TXNInitTextension (page 2662) function. Available in Mac OS X v10.0 and later.
kTXNCannotTurnTSMOffWhenUsingUnicodeErr	-22013	Your application tried to turn off the Text Services Manager while MLTE was set to process Unicode. Available in Mac OS X v10.0 and later.
kTXNCopyNotAllowedInEchoModeErr	-22014	Your application tried to copy text that was in echo mode. Available in Mac OS X v10.0 and later.
kTXNDataTypeNotAllowedErr	-22015	Your applications specifies a data type that MTLE does not allow. Available in Mac OS X v10.0 and later.
kTXNATSUIIsNotInstalledErr	-22016	Indicates ATSUI is not installed on the system. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
kTXNOutsideOfLineErr	-22017	Indicates a value that is beyond the length of the line. Available in Mac OS X v10.0 and later.
kTXNOutsideOfFrameErr	-22018	Indicates a value that is outside of the text object's frame. Available in Mac OS X v10.0 and later.
kTXNDisabledFunctionalityErr	-22019	Indicates the function has been disabled. Available in Mac OS X v10.3 and later.
kTXNOperationNotAllowedErr	-22020	Indicates that the function cannot be called in this context. Available in Mac OS X v10.4 and later.

Open Scripting Architecture Reference

Framework:	Carbon/Carbon.h
Declared in	ASDebugging.h AppleScript.h ASRegistry.h OSAComp.h OSA.h OSAGeneric.h

Overview

The Open Scripting Architecture (OSA) provides a standard and extensible mechanism for interapplication communication in Mac OS X. It provides support for creating scriptable applications and for writing scripting components to implement scripting languages. Every Mac OS X system includes the AppleScript component, which implements AppleScript, the standard scripting language defined by Apple. However, developers can write scripting components for additional scripting languages. For conceptual information on the OSA, see "Open Scripting Architecture" in AppleScript Overview.

You need to use this reference if you are writing a scripting component or if your application needs to interact with scripting components to manipulate and execute scripts. The API described in this document is implemented by the OpenScripting framework, a subframework of the Carbon framework. For information about working with components, see Scripting Components in Inside Macintosh: Interapplication Communication.

Important: Do not rely on the API descriptions in Interapplication Communication—*Open Scripting Architecture Reference* provides the current API documentation.

The Apple Event Manager, another part of the OSA, is implemented primarily by the AE framework, a subframework of the Application Services framework, and is documented in *Apple Event Manager Reference* and *Apple Events Programming Guide*. Applications use the Apple Event Manager to send and respond to Apple events and to make their operations and data available to AppleScript scripts.

Functions by Task

Saving and Loading Script Data

`OSALoad` (page 2832)
Loads script data.

`OSALoadFile` (page 2835)
Loads a script from the specified file into the specified scripting component, compiling the script if the file is a text file.

`OSAStore` (page 2850)
Gets a handle to script data in the form of a storage descriptor record.

`OSAStoreFile` (page 2851)
Stores a script into the specified file.

Executing and Disposing of Scripts

To execute a script, your application must first obtain a valid script ID for a compiled script or script context. You can use either the `OSALoad` function or the optional `OSACompile` function to obtain a script ID.

`OSAExecute` (page 2816)
Executes a compiled script or a script context.

`OSAScriptError` (page 2839)
Gets information about errors that occur during script execution.

`OSADispose` (page 2811)
Reclaims the memory occupied by script data.

Setting and Getting Script Information

`OSASetScriptInfo` (page 2846)
Sets information about script data according to the value you pass in the selector parameter.

`OSAGetScriptInfo` (page 2827)
Obtains information about script data according to the value you pass in the `selector` parameter.

Manipulating the Active Function

`OSASetActiveProc` (page 2840)
Sets the active function that a scripting component calls periodically while executing a script.

`OSAGetActiveProc` (page 2819)
Gets a pointer to the active function that a scripting component is currently using.

Compiling Scripts

Scripting components can provide three optional functions that get the name of a scripting component, compile a script, and update a script ID. A scripting component that supports the functions in this section has the `kOSASupportsCompiling` bit set in the `componentFlags` field of its component description record.

`OSAScriptingComponentName` (page 2840)
Gets the name of a scripting component.

`OSACompile` (page 2799)
Compiles the source data for a script and obtain a script ID for a compiled script or a script context.

`OSACopyID` (page 2802)
Updates script data after editing or recording and to perform undo or revert operations on script data.

Getting Source Data

`OSAGetSource` (page 2830)
Decompiles the script data identified by a script ID and obtains the equivalent source data.

`OSADisplay` (page 2810)
Converts a script value to text. Your application can then use its own functions to display this text to the user.

`OSACopyDisplayString` (page 2801)
Converts a script value to an attributed Unicode text string, which your application can display to the user.

`OSACopySourceString` (page 2804)
Decompiles the script data for the specified script and returns a copy of the equivalent source data as an attributed Unicode text string.

Coercing Script Values

Scripting components can provide support for two optional functions which coerce data in a descriptor record to a script value and coerce a script value to data in a descriptor record. A scripting component that supports the functions in this section has the `kOSASupportsAECoercion` bit set in the `componentFlags` field of its component description record.

`OSACoerceFromDesc` (page 2798)
Obtains the script ID for a script value that corresponds to the data in a descriptor record.

`OSACoerceToDesc` (page 2798)
Coerces a script value to a descriptor record of a desired descriptor type.

Manipulating the Create and Send Functions

Some scripting components provide functions that allow your application to set or get pointers to the create and send functions used by the scripting component when it sends and creates Apple events during script execution. If you do not set the pointers that specify these functions, the scripting component uses the standard `AECreateAppleEvent` and `AESend` functions with default parameters. A scripting component that supports the functions described in this section has the `kOSASupportsAESending` bit set in the `componentFlags` field of its component description record.

`OSASetCreateProc` (page 2841)
Specifies a create function that a scripting component should use instead of the Apple Event Manager's `AECreateAppleEvent` function when creating Apple events.

`OSAGetCreateProc` (page 2820)
Gets a pointer to the create function that a scripting component is currently using to create Apple events.

`OSASetSendProc` (page 2847)
Specifies a send function that a scripting component should use instead of the Apple Event Manger's `AESend` function when sending Apple events.

`OSAGetSendProc` (page 2829)
Gets a pointer to the send function that a scripting component is currently using.

`OSASetDefaultTarget` (page 2843)
Sets the default target application for Apple events.

Recording Scripts

Script editors use these functions to allow users to control recording. Any application can use these functions to provide its own script-recording interface. A scripting component that supports the functions described in this section has the `kOSASupportsRecording` bit set in the `componentFlags` field of its component description record.

`OSAStartRecording` (page 2848)
Turns on Apple event recording and records subsequent Apple events in a compiled script.

`OSAStopRecording` (page 2849)
Turns off Apple event recording.

Executing Scripts in One Step

You can use these functions if you know that the script data to be executed will be executed only once. A scripting component that supports the functions described in this section has the `kOSASupportsConvenience` bit set in the `componentFlags` field of its component description record.

`OSACompileExecute` (page 2800)
Compiles and executes a script in a single step rather than calling `OSACompile` and `OSAExecute`.

`OSADoScript` (page 2813)
Compiles and executes a script and converts the resulting script value to text in a single step rather than calling `OSACompile`, `OSAExecute`, and `OSADisplay`.

`OSADoScriptFile` (page 2815)
Loads a script from the specified file, compiles the script if the file is a text file, executes the script, converts the resulting script value to text, and stores the script back into the file if the script has persistent properties and the file is not a text file.

`OSALoadExecute` (page 2833)
Loads and executes a script in a single step rather than calling `OSALoad` and `OSAExecute`.

`OSALoadExecuteFile` (page 2834)
Loads a script from the specified file into the specified scripting component, compiles the script if the file is a text file, and executes the script.

Copying a Scripting Dictionary as a Scripting Definition File

`OSACopyScriptingDefinition` (page 2803)
Creates a copy of a scripting definition (sdef) from the specified file or bundle.

Manipulating Dialects

Scripting components that provide several dialects may provide five functions that allow you to switch between dialects dynamically and get information about currently available dialects. The codes for specific dialects are provided by the scripting component. A scripting component that supports the functions described in this section has the `kOSASupportsDialects` bit set in the `componentFlags` field of its component description record.

`OSASetCurrentDialect` (page 2842)
: Sets the current dialect for a scripting component.

`OSAGetCurrentDialect` (page 2821)
: Gets the dialect code for the dialect currently being used by a scripting component.

`OSAAvailableDialectCodeList` (page 2796)
: Obtains a descriptor list containing dialect codes for each of a scripting component's currently available dialects.

`OSAGetDialectInfo` (page 2822)
: Gets information about a specified dialect provided by a specified scripting component.

`OSAAvailableDialects` (page 2797)
: Obtains a descriptor list containing information about each of the currently available dialects for a scripting component.

Using Script Contexts to Handle Apple Events

The optional functions described in this section allow your application to use script contexts to handle Apple events. One way to do this is to install a general Apple event handler in your application's special handler dispatch table. The general Apple event handler provides initial handling for every Apple event received by your application. A scripting component that supports the functions described in this section has the `kOSASupportsEventHandling` bit set in the `componentFlags` field of its component description record.

`OSASetResumeDispatchProc` (page 2845)
: Sets the resume dispatch function called by a scripting component during execution of an AppleScript `continue` statement or its equivalent.

`OSAGetResumeDispatchProc` (page 2826)
: Gets the resume dispatch function currently being used by a scripting component instance during execution of an AppleScript `continue` statement or its equivalent

`OSAExecuteEvent` (page 2817)
: Handles an Apple event with the aid of a script context and obtains a script ID for the resulting script value.

`OSADoEvent` (page 2812)
: Handles an Apple event with the aid of a script context and obtains a reply event.

`OSAMakeContext` (page 2836)
: Gets a script ID for a new script context.

Initializing AppleScript

`ASInit` (page 2788)
: Initializes the AppleScript component.

Getting and Setting Styles for Source Data

`ASCopySourceAttributes` (page 2785)
Gets the current text style attributes AppleScript uses to display script text.

`ASSetSourceAttributes` (page 2791)
Sets the text style attributes used by the AppleScript component to display scripts.

`ASGetSourceStyleNames` (page 2787)
Obtains a list of style names that are each formatted according to the script format styles currently used by the AppleScript component.

Getting and Setting the Default Scripting Component

The default scripting component for any instance of the generic scripting component is initially AppleScript, but you can change it if necessary.

`OSAGetDefaultScriptingComponent` (page 2822)
Gets the subtype code for the default scripting component associated with an instance of the generic scripting component.

`OSASetDefaultScriptingComponent` (page 2842)
Sets the default scripting component associated with an instance of the generic scripting component.

Using Component-Specific Routines

You can't use the generic scripting component to call a component-specific routine. Instead, you must use an instance of the specific scripting component that supports the routine.

To facilitate the use of component-specific routines, the generic scripting component allows you to identify the scripting component that created stored script data, get an instance of a specified scripting component, and convert between generic script IDs and component-specific script IDs.

`OSAGetScriptingComponentFromStored` (page 2829)
Gets the subtype code for a scripting component that created a storage descriptor record.

`OSAGetScriptingComponent` (page 2828)
Gets the instance of a scripting component for a specified subtype.

`OSAGenericToRealID` (page 2818)
Converts a generic script ID to the corresponding component-specific script ID.

`OSARealToGenericID` (page 2837)
Converts a component-specific script ID to the corresponding generic script ID.

Manipulating Trailers for Generic Storage Descriptor Records

All scripting components must use the `OSAGetStorageType`, `OSAAddStorageType`, and `OSARemoveStorageType` functions described in this section to add, remove, and inspect the trailers appended to script data in generic storage descriptor records.

`OSAGetStorageType` (page 2831)
Retrieves the scripting component subtype from the script trailer appended to the script data in a generic storage descriptor record.

`OSAAddStorageType` (page 2796)
Adds a trailer to the script data in a generic storage descriptor record.

`OSARemoveStorageType` (page 2838)
Removes a trailer from the script data in a generic storage descriptor record

Miscellaneous

`ASGetAppTerminology` (page 2786)
Deprecated. Use `OSAGetAppTerminology` (page 2820) instead.

`ASGetHandler` (page 2786)
Deprecated. Use `OSAGetHandler` (page 2823) instead.

`ASGetProperty` (page 2787)
Deprecated. Use `OSAGetProperty` (page 2825) instead.

`ASSetHandler` (page 2790)
Deprecated. Use `OSASetHandler` (page 2843) instead.

`ASSetProperty` (page 2790)
Deprecated. Use `OSASetProperty` (page 2844) instead.

`OSAGetHandler` (page 2823)
Gets a script ID for the specified script handler from the specified script.

`OSAGetHandlerNames` (page 2824)
Gets a list of all handler names in the specified script as an `AEDescList` of descriptors of type `typeChar`.

`OSAGetProperty` (page 2825)
Gets the value of a specified script property from a specified script.

`OSAGetPropertyNames` (page 2825)
Gets a list of all property names from the specified script.

`OSAGetSysTerminology` (page 2832)
Gets one or more scripting terminology resources from the OSA system.

`OSASetHandler` (page 2843)
Sets a specified script handler in the specified script to the supplied handler.

`OSASetProperty` (page 2844)
Sets the value of a script property in a specified script, creating the property if it does not already exist.

`OSAGetAppTerminology` (page 2820) Deprecated in Mac OS X v10.5
Gets one or more scripting terminology resources from the specified file. (Deprecated. Use `OSACopyScriptingDefinition` (page 2803) instead.)

Creating, Invoking and Disposing Universal Procedure Pointers

`NewOSAActiveUPP` (page 2795)
Creates a new universal procedure pointer to an application-defined active function.

`NewOSACreateAppleEventUPP` (page 2795)
Creates a new universal procedure pointer to an application-defined Apple event creation function.

`NewOSASendUPP` (page 2795)
Creates a new universal procedure pointer to an application-defined send function.

`DisposeOSAActiveUPP` (page 2792)
Disposes of a universal procedure pointer to an application-defined active function.

`DisposeOSACreateAppleEventUPP` (page 2793)
Disposes of a universal procedure pointer to an application-defined Apple event create function.

`DisposeOSASendUPP` (page 2793)
Disposes of a universal procedure pointer to an application-defined send function.

`InvokeOSAActiveUPP` (page 2793)
Invokes an application-defined active function.

`InvokeOSACreateAppleEventUPP` (page 2794)
Invokes an application-defined Apple event creation function.

`InvokeOSASendUPP` (page 2794)
Invokes an application-defined send function.

Deprecated Functions

Warning: Do not use the OSA debugging functions listed here. They were were not intended for public use, they do not work, and they will return an error.

`OSADebuggerCreateSession` (page 2805)
Do not use.

`OSADebuggerDisposeCallFrame` (page 2805)
Do not use.

`OSADebuggerDisposeSession` (page 2805)
Do not use.

`OSADebuggerGetBreakpoint` (page 2806)
Do not use.

`OSADebuggerGetCallFrameState` (page 2806)
Do not use.

`OSADebuggerGetCurrentCallFrame` (page 2807)
Do not use.

`OSADebuggerGetDefaultBreakpoint` (page 2807)
Do not use.

`OSADebuggerGetPreviousCallFrame` (page 2807)
Do not use.

`OSADebuggerGetSessionState` (page 2808)
Do not use.

`OSADebuggerGetStatementRanges` (page 2808)
Do not use.

`OSADebuggerGetVariable` (page 2809)
Do not use.

`OSADebuggerSessionStep` (page 2809)
Do not use.

`OSADebuggerSetBreakpoint` (page 2809)
Do not use.

`OSADebuggerSetVariable` (page 2810)
Do not use.

`ASGetSourceStyles` (page 2788) Deprecated in Mac OS X v10.5
Gets the script format styles currently used by the AppleScript component to display scripts. (Deprecated. Use `ASGetSourceStyleNames` (page 2787) instead.)

`ASSetSourceStyles` (page 2792) Deprecated in Mac OS X v10.5
Sets the script format styles used by the AppleScript component to display scripts. (Deprecated. Use `ASSetSourceAttributes` (page 2791) instead.)

Functions

ASCopySourceAttributes

Gets the current text style attributes AppleScript uses to display script text.

```
OSAError ASCopySourceAttributes (
    ComponentInstance scriptingComponent,
    CFArrayRef *resultingSourceAttributes
);
```

Parameters

scriptingComponent
A component instance created by a prior call to the Component Manager function `OpenDefaultComponent` or `OpenComponent`.

resultingSourceAttributes
If successful, returns a reference to an array (of type `CFArray`) of dictionaries (of type `CFDictionary`) of text style attributes; otherwise, returns `nil`.

The order of elements in the array corresponds to the constants defined in "Source Style Constants" (page 2882), and therefore also to the names returned by `ASGetSourceStyleNames` (page 2787). For example, the first dictionary in the array (at position `kASSourceStyleUncompiledText`) describes the style for uncompiled text. However, you should not rely on there being any specific number of dictionaries in the returned array—instead, count the number of items in the array before accessing any of them.

This array is a copy and the caller is responsible for releasing it, according to the rules described in Ownership Policy in *Memory Management Programming Guide for Core Foundation*.

Return Value

A result code. See "Result Codes" (page 2885).

Discussion

A text style attribute is typically something that is meaningful to a `CFAttributedString`, such as the one returned by `OSACopyDisplayString` (page 2801) or `OSACopySourceString` (page 2804). However, clients may add other attributes using `ASSetSourceAttributes` (page 2791).

Availability
Available in Mac OS X v10.5 and later.

Declared In
`AppleScript.h`

ASGetAppTerminology

Deprecated. Use `OSAGetAppTerminology` (page 2820) instead.

```
OSAError ASGetAppTerminology (
   ComponentInstance scriptingComponent,
   FSSpec *fileSpec,
   short terminologID,
   Boolean *didLaunch,
   AEDesc *terminologyList
);
```

Return Value
A result code. See "Result Codes" (page 2885).

Version Notes
Provided for backward compatibility only. Use `OSAGetAppTerminology` (page 2820) instead.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ASDebugging.h`

ASGetHandler

Deprecated. Use `OSAGetHandler` (page 2823) instead.

```
OSAError ASGetHandler (
   ComponentInstance scriptingComponent,
   OSAID contextID,
   const AEDesc *handlerName,
   OSAID *resultingCompiledScriptID
);
```

Return Value
A result code. See "Result Codes" (page 2885).

Version Notes
Provided for backward compatibility only. Use `OSAGetHandler` (page 2823) instead.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ASDebugging.h`

ASGetProperty

Deprecated. Use `OSAGetProperty` (page 2825) instead.

```
OSAError ASGetProperty (
   ComponentInstance scriptingComponent,
   OSAID contextID,
   const AEDesc *variableName,
   OSAID *resultingScriptValueID
);
```

Return Value
A result code. See "Result Codes" (page 2885).

Version Notes
Provided for backward compatibility only. Use `OSAGetProperty` (page 2825) instead.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ASDebugging.h`

ASGetSourceStyleNames

Obtains a list of style names that are each formatted according to the script format styles currently used by the AppleScript component.

```
OSAError ASGetSourceStyleNames (
   ComponentInstance scriptingComponent,
   SInt32 modeFlags,
   AEDescList *resultingSourceStyleNamesList
);
```

Parameters

scriptingComponent
A component instance created by a prior call to the Component Manager function `OpenDefaultComponent` or `OpenComponent`.

modeFlags
Reserved for future use. Set to `kOSAModeNull`.

resultingSourceStyleNames
A pointer to a list of style names (for example, "Uncompiled Text," "Normal Text") that are each formatted according to the current script format styles. The order of the names corresponds to the order of the source style constants listed in "Source Style Constants" (page 2882). For example, the first name in the list (at position `kASSourceStyleUncompiledText`) is formatted according to the style for uncompiled text.

Return Value
A result code. See "Result Codes" (page 2885).

Availability
Available in Mac OS X v10.0 and later.

Declared In
AppleScript.h

ASGetSourceStyles

Gets the script format styles currently used by the AppleScript component to display scripts. (Deprecated in Mac OS X v10.5. Use ASGetSourceStyleNames (page 2787) instead.)

```
OSAError ASGetSourceStyles (
    ComponentInstance scriptingComponent,
    STHandle *resultingSourceStyles
);
```

Parameters

scriptingComponent

A component instance created by a prior call to the Component Manager function OpenDefaultComponent or OpenComponent.

resultingSourceStyles

A pointer to a handle to a style element array defined by the TextEdit data type TEStyleTable that defines the styles used for different kinds of AppleScript terms.

Return Value
A result code. See "Result Codes" (page 2885).

Discussion
The ASGetSourceStyles function returns a style element array that defines the styles used for AppleScript terms. You can use the index constants described in "Source Style Constants" (page 2882) to identify individual styles returned in the *resultingSourceStyles* parameter. Other AppleScript dialects may define additional styles. When you have finished using the style element array, you must dispose of it.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In
AppleScript.h

ASInit

Initializes the AppleScript component.

```
OSAError ASInit (
   ComponentInstance scriptingComponent,
   SInt32 modeFlags,
   UInt32 minStackSize,
   UInt32 preferredStackSize,
   UInt32 maxStackSize,
   UInt32 minHeapSize,
   UInt32 preferredHeapSize,
   UInt32 maxHeapSize
);
```

Parameters

scriptingComponent

A component instance created by a prior call to the Component Manager function `OpenDefaultComponent` or `OpenComponent`.

modeFlags

Reserved for future use. Set to `kOSAModeNull`.

minStackSize

The minimum size for the portion of the application's heap used by the AppleScript component's application-specific stack.

preferredStackSize

The preferred size for the portion of the application's heap used by the AppleScript component's application-specific stack.

maxStackSize

The maximum size for the portion of the application's heap used by the AppleScript component's application-specific stack.

minHeapSize

The minimum size for the portion of the application's heap used by the AppleScript component's application-specific heap. (See Version Notes section.)

preferredHeapSize

The preferred size for the portion of the application's heap used by the AppleScript component's application-specific heap. (See Version Notes section.)

maxHeapSize

The maximum size for the portion of the application's heap used by the AppleScript component's application-specific heap. (See Version Notes section.)

Return Value

A result code. See "Result Codes" (page 2885).

Discussion

Your application should set the *modeFlags* parameter to `kOSAModeNull`. You can use the other parameters to specify memory sizes for the portion of your application's heap used by the AppleScript component for its application-specific heap and stack. If your application sets any of these parameters to 0, the AppleScript component uses the corresponding value in your application's `'scsz'` resource. If that value is also set to 0, the AppleScript component uses the default values described in "Default Initialization Values" (page 2863).

If your application doesn't call `ASInit` explicitly, the AppleScript component initializes itself using the values specified in your application's `'scsz'` resource when your application first calls any scripting component routine. If any of these values are set to 0, the AppleScript component uses the corresponding default value.

If your application doesn't call `ASInit` explicitly and doesn't call any scripting component routines, the AppleScript component will not be initialized. For example, if your application opens and closes the AppleScript component or calls Component Manager functions such as `OpenDefaultComponent` or `FindNextComponent` but doesn't call any scripting component routines, the AppleScript component is not initialized.

When the AppleScript component is initialized, it uses your application's high memory to create the blocks that it locks for its own use. If you expect to lock any portion of high memory for a shorter time than you expect the AppleScript component to be available, you should call `ASInit` explicitly.

Version Notes
Starting in Mac OS X version 10.5, heap size parameter values are ignored—AppleScript's heap will grow as large as needed.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`AppleScript.h`

ASSetHandler

Deprecated. Use `OSASetHandler` (page 2843) instead.

```
OSAError ASSetHandler (
   ComponentInstance scriptingComponent,
   OSAID contextID,
   const AEDesc *handlerName,
   OSAID compiledScriptID
);
```

Return Value
A result code. See "Result Codes" (page 2885).

Version Notes
Provided for backward compatibility only. Use `OSASetHandler` (page 2843) instead.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ASDebugging.h`

ASSetProperty

Deprecated. Use `OSASetProperty` (page 2844) instead.

```
OSAError ASSetProperty (
   ComponentInstance scriptingComponent,
   OSAID contextID,
   const AEDesc *variableName,
   OSAID scriptValueID
);
```

Return Value
A result code. See "Result Codes" (page 2885).

Version Notes
Provided for backward compatibility only. Use `OSASetProperty` (page 2844) instead.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ASDebugging.h`

ASSetSourceAttributes

Sets the text style attributes used by the AppleScript component to display scripts.

```
OSAError ASSetSourceAttributes (
    ComponentInstance scriptingComponent,
    CFArrayRef sourceAttributes
);
```

Parameters

`scriptingComponent`

A component instance created by a prior call to the Component Manager function `OpenDefaultComponent` or `OpenComponent`.

`sourceAttributes`

A reference to an array (of type `CFArray`) of dictionaries (of type `CFDictionary`) of text style attributes.

You can pass a `nil` reference for this parameter if you want the AppleScript component to display script text using its default styles.

Return Value
A result code. See "Result Codes" (page 2885).

Discussion
A text style attribute is typically something that is meaningful to a `CFAttributedString`, such as the one returned by `OSACopyDisplayString` (page 2801) or `OSACopySourceString` (page 2804). However, clients may add any attributes they like. Because of this, you should generally call `ASSetSourceAttributes` with a modified copy of the result from `ASCopySourceAttributes` (page 2785), not a built-from-scratch set of attributes.

The order of elements in the array should correspond to the constants defined in "Source Style Constants" (page 2882), and therefore also to the names returned by `ASGetSourceStyleNames` (page 2787). After calling `ASSetSourceAttributes`, you must dispose of the style element array you used to specify the text style attributes.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`AppleScript.h`

ASSetSourceStyles

Sets the script format styles used by the AppleScript component to display scripts. (Deprecated in Mac OS X v10.5. Use `ASSetSourceAttributes` (page 2791) instead.)

```
OSAError ASSetSourceStyles (
    ComponentInstance scriptingComponent,
    STHandle sourceStyles
);
```

Parameters

`scriptingComponent`

A component instance created by a prior call to the Component Manager function `OpenDefaultComponent` or `OpenComponent`.

`sourceStyles`

A handle to a style element array defined by the TextEdit data type `TEStyleTable` that defines the styles used for different kinds of AppleScript terms. The style for each kind of term should be identified according to the index constants listed in "Source Style Constants" (page 2882).

Return Value
A result code. See "Result Codes" (page 2885).

Discussion
The `ASSetSourceStyles` function sets the script format styles used to display scripts. If you pass a `NULL` handle in the *`sourceStyles`* parameter, the AppleScript component uses its default styles.

After you have set the script format styles, you must dispose of the style element array you used to specify them.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In
`AppleScript.h`

DisposeOSAActiveUPP

Disposes of a universal procedure pointer to an application-defined active function.

```
void DisposeOSAActiveUPP (
   OSAActiveUPP userUPP
);
```

Parameters

`userUPP`

The UPP to dispose of.

Availability
Available in Mac OS X v10.0 and later.

Declared In
OSA.h

DisposeOSACreateAppleEventUPP

Disposes of a universal procedure pointer to an application-defined Apple event create function.

```
void DisposeOSACreateAppleEventUPP (
   OSACreateAppleEventUPP userUPP
);
```

Parameters

userUPP
The UPP to dispose of.

Availability
Available in Mac OS X v10.0 and later.

Declared In
OSA.h

DisposeOSASendUPP

Disposes of a universal procedure pointer to an application-defined send function.

```
void DisposeOSASendUPP (
   OSASendUPP userUPP
);
```

Parameters

userUPP
The UPP to dispose of.

Availability
Available in Mac OS X v10.0 and later.

Declared In
OSA.h

InvokeOSAActiveUPP

Invokes an application-defined active function.

```
OSErr InvokeOSAActiveUPP (
   SRefCon refCon,
   OSAActiveUPP userUPP
);
```

Return Value
A result code. See "Result Codes" (page 2885).

Availability
Available in Mac OS X v10.0 and later.

Declared In
OSA.h

InvokeOSACreateAppleEventUPP

Invokes an application-defined Apple event creation function.

```
OSErr InvokeOSACreateAppleEventUPP (
   AEEventClass theAEEventClass,
   AEEventID theAEEventID,
   const AEAddressDesc *target,
   short returnID,
   SInt32 transactionID,
   AppleEvent *result,
   SRefCon refCon,
   OSACreateAppleEventUPP userUPP
);
```

Return Value
A result code. See "Result Codes" (page 2885).

Availability
Available in Mac OS X v10.0 and later.

Declared In
OSA.h

InvokeOSASendUPP

Invokes an application-defined send function.

```
OSErr InvokeOSASendUPP (
   const AppleEvent *theAppleEvent,
   AppleEvent *reply,
   AESendMode sendMode,
   AESendPriority sendPriority,
   SInt32 timeOutInTicks,
   AEIdleUPP idleProc,
   AEFilterUPP filterProc,
   SRefCon refCon,
   OSASendUPP userUPP
);
```

Return Value
A result code. See "Result Codes" (page 2885).

Availability
Available in Mac OS X v10.0 and later.

Declared In
OSA.h

NewOSAActiveUPP

Creates a new universal procedure pointer to an application-defined active function.

```
OSAActiveUPP NewOSAActiveUPP (
   OSAActiveProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to the active function.

Return Value

The new UPP.

Availability

Available in Mac OS X v10.0 and later.

Declared In

OSA.h

NewOSACreateAppleEventUPP

Creates a new universal procedure pointer to an application-defined Apple event creation function.

```
OSACreateAppleEventUPP NewOSACreateAppleEventUPP (
   OSACreateAppleEventProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to the creation function.

Return Value

The new UPP.

Availability

Available in Mac OS X v10.0 and later.

Declared In

OSA.h

NewOSASendUPP

Creates a new universal procedure pointer to an application-defined send function.

```
OSASendUPP NewOSASendUPP (
   OSASendProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to the send function.

Return Value

The new UPP.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OSA.h`

OSAAddStorageType

Adds a trailer to the script data in a generic storage descriptor record.

```
OSErr OSAAddStorageType (
   AEDataStorage scriptData,
   DescType dscType
);
```

Parameters

`scriptData`
A handle to the script data.

`dscType`
The descriptor type to be specified in the trailer added to the script data.

Return Value
A result code. See "Result Codes" (page 2885).

Discussion
The `OSAAddStorageType` function attaches a trailer to a handle (consequently expanding the data to which the handle refers) or updates an existing trailer.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OSAComp.h`

OSAAvailableDialectCodeList

Obtains a descriptor list containing dialect codes for each of a scripting component's currently available dialects.

```
OSAError OSAAvailableDialectCodeList (
   ComponentInstance scriptingComponent,
   AEDesc *resultingDialectCodeList
);
```

Parameters

`scriptingComponent`
A component instance created by a prior call to the Component Manager function `OpenDefaultComponent` or `OpenComponent`.

`resultingDialectCodeList`
A pointer to the returned descriptor list.

Return Value
A result code. See "Result Codes" (page 2885).

Discussion
Each item in the descriptor list returned by `OSAAvailableDialectCodeList` is a descriptor record of descriptor type `typeInteger` containing a dialect code for one of the specified scripting component's currently available dialects. Dialect codes are defined by individual scripting components.

You can pass any dialect code you obtain using `OSAAvailableDialectCodeList` to `OSAGetDialectInfo` to get information about the corresponding dialect.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OSA.h`

OSAAvailableDialects

Obtains a descriptor list containing information about each of the currently available dialects for a scripting component.

```
OSAError OSAAvailableDialects (
   ComponentInstance scriptingComponent,
   AEDesc *resultingDialectInfoList
);
```

Parameters

`scriptingComponent`
A component instance created by a prior call to the Component Manager function `OpenDefaultComponent` or `OpenComponent`.

`resultingDialectInfoList`
A pointer to the returned descriptor list.

Return Value
A result code. See "Result Codes" (page 2885).

Discussion
Each item in the list returned by `OSAAvailableDialects` is an AE record of descriptor type `typeOSADialectInfo`. Each descriptor record in the descriptor list contains, at a minimum, four keyword-specified descriptor records with the keywords described in "Dialect Descriptor Constants" (page 2865).

Rather than calling `OSAAvailableDialects` to obtain complete dialect information for a scripting component, it is usually more convenient to call `OSAAvailableDialectCodeList` to get a list of codes for a scripting component's dialects, then call `OSAGetDialectInfo` to get information about the specific dialect you're interested in.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OSA.h`

OSACoerceFromDesc

Obtains the script ID for a script value that corresponds to the data in a descriptor record.

```
OSAError OSACoerceFromDesc (
   ComponentInstance scriptingComponent,
   const AEDesc *scriptData,
   SInt32 modeFlags,
   OSAID *resultingScriptID
);
```

Parameters

scriptingComponent

A component instance created by a prior call to the Component Manager function `OpenDefaultComponent` or `OpenComponent`.

scriptData

A pointer to a descriptor record containing the script data to be coerced.

modeFlags

Information used by individual scripting components. To avoid setting mode flag values, specify `kOSAModeNull`. If the *scriptData* parameter contains an Apple event, you can use any of the mode flags listed in "Mode Flags" (page 2873).

resultingScriptValueID

A pointer to the resulting script ID for a script value. See the `OSAID` (page 2855) data type.

Return Value

A result code. See "Result Codes" (page 2885).

Discussion

The `OSACoerceFromDesc` function coerces the descriptor record in the *scriptData* parameter to the equivalent script value and returns a script ID for that value.

If you pass `OSACoerceFromDesc` an Apple event in the *scriptData* parameter, it returns a script ID for the equivalent compiled script in the *resultingScriptValueID* parameter. In this case you can specify any of the *modeFlags* values used by `OSACompile` to control the way the compiled script is executed.

If you call `OSACoerceFromDesc` using an instance of the generic scripting component, the generic scripting component uses the default scripting component to perform the coercion.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OSA.h`

OSACoerceToDesc

Coerces a script value to a descriptor record of a desired descriptor type.

```
OSAError OSACoerceToDesc (
   ComponentInstance scriptingComponent,
   OSAID scriptID,
   DescType desiredType,
   SInt32 modeFlags,
   AEDesc *result
);
```

Parameters

scriptingComponent

A component instance created by a prior call to the Component Manager function `OpenDefaultComponent` or `OpenComponent`.

scriptID

The script ID for the script value to coerce. See the `OSAID` (page 2855) data type.

desiredType

The desired descriptor type of the resulting descriptor record.

modeFlags

Information used by individual scripting components. To avoid setting mode flag values, specify `kOSAModeNull`.

result

A pointer to the resulting descriptor record.

Return Value

A result code. See "Result Codes" (page 2885).

Discussion

The `OSACoerceToDesc` function coerces the script value identified by *scriptValueID* to a descriptor record of the type specified by the *desiredType* parameter, if possible. Valid types include all the standard descriptor types, plus any special types supported by the scripting component.

If you want the descriptor type of the descriptor record returned in the result parameter to be the same as the descriptor type returned by a scripting component, use `OSACoerceToDesc` and specify `typeWildCard` as the desired type. If you want to get a script value in a form that you can display for humans to read, use `OSADisplay`.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OSA.h`

OSACompile

Compiles the source data for a script and obtain a script ID for a compiled script or a script context.

```
OSAError OSACompile (
   ComponentInstance scriptingComponent,
   const AEDesc *sourceData,
   SInt32 modeFlags,
   OSAID *previousAndResultingScriptID
);
```

Parameters

scriptingComponent

A component instance created by a prior call to the Component Manager function `OpenDefaultComponent` or `OpenComponent`.

sourceData

A pointer to a descriptor record containing suitable source data for the specified scripting component.

modeFlags

Information used by individual scripting components. To avoid setting mode flag values, specify `kOSAModeNull`. Other possible mode flags are listed in "Mode Flags" (page 2873).

previousAndResultingScriptID

A pointer to the script ID for the resulting compiled script. If the value of this parameter on input is `kOSANullScript`, `OSACompile` returns a new script ID for the compiled script data. If the value of this parameter on input is an existing script ID, `OSACompile` updates the script ID so that it refers to the newly compiled script data. See the `OSAID` (page 2855) data type.

Return Value

A result code. See "Result Codes" (page 2885).

Discussion

You can pass a descriptor record containing source data suitable for a specific scripting component (usually text) to the `OSACompile` function to obtain a script ID for the equivalent compiled script or script context. To compile the source data as a script context for use with `OSAExecuteEvent` or `OSADoEvent`, you must set the `kOSAModeCompileIntoContext` flag, and the source data should include appropriate handlers.

After you have successfully compiled the script, you can use the returned script ID to refer to the compiled script when you call `OSAExecute` and other scripting component routines.

If you use `OSACompile` with an instance of the generic scripting component and pass `kOSANullScript` in the *previousAndResultingScriptID* parameter, the generic scripting component uses the default scripting component to compile the script.

If you're recompiling a script, specify the original script ID in the *previousAndResultingScriptID* parameter. The generic scripting component uses the script ID to determine which scripting component it should use to compile the script.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OSA.h`

OSACompileExecute

Compiles and executes a script in a single step rather than calling `OSACompile` and `OSAExecute`.

```
OSAError OSACompileExecute (
   ComponentInstance scriptingComponent,
   const AEDesc *sourceData,
   OSAID contextID,
   SInt32 modeFlags,
   OSAID *resultingScriptValueID
);
```

Parameters

scriptingComponent

A component instance created by a prior call to the Component Manager function `OpenDefaultComponent` or `OpenComponent`.

sourceData

A pointer to a descriptor record identifying suitable source data for the specified scripting component.

contextID

The script ID for the context to be used during script execution. The constant `kOSANullScript` in this parameter indicates that the scripting component should use its default context. See the `OSAID` (page 2855) data type.

modeFlags

Information used by individual scripting components. To avoid setting mode flag values, specify `kOSAModeNull`. Other possible mode flags are listed in "Mode Flags" (page 2873).

resultingScriptValueID

A pointer to the script ID for the script value returned.

Return Value

A result code. See "Result Codes" (page 2885).

Discussion

The `OSACompileExecute` function compiles source data and executes the resulting compiled script, using the script context identified by the *contextID* parameter to maintain state information such as the binding of variables. After successfully executing the script, `OSACompileExecute` disposes of the compiled script and returns either the script ID for the resulting script value or, if execution does not result in a value, the constant `kOSANullScript`.

If the result c ode returned by `OSACompileExecute` is a general result code, there was some problem in arranging for the script to be run. If the result code is `errOSAScriptError`, an error occurred during script execution. In this case, you can obtain more detailed error information by calling `OSAScriptError`.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OSA.h`

OSACopyDisplayString

Converts a script value to an attributed Unicode text string, which your application can display to the user.

```
OSAError OSACopyDisplayString (
    ComponentInstance scriptingComponent,
    OSAID scriptID,
    SInt32 modeFlags,
    CFAttributedStringRef *result
);
```

Parameters

scriptingComponent

A component instance created by a prior call to the Component Manager function `OpenDefaultComponent` or `OpenComponent`.

scriptID

The script ID for the script value to display. See the `OSAID` (page 2855) data type.

modeFlags

Information used by individual scripting components. To avoid setting any mode flags, specify `kOSAModeNull`. To make the resulting text readable by humans only, so that it can't be recompiled, specify `kOSAModeDisplayForHumans`.

result

If successful, a reference to the script data as an attributed Unicode text string; otherwise not defined.

Because the `result` parameter returns a copy, the caller is responsible for releasing this string object, according to the rules described in Ownership Policy in *Memory Management Programming Guide for Core Foundation*.

Return Value
A result code. See "Result Codes" (page 2885).

Discussion
The `OSACopyDisplayString` function is analogous to `OSADisplay` (page 2810), except that it returns the script text as an attributed Unicode text string. An instance of `CFAttributedString` manages a character string and an associated set of attributes that apply to characters or ranges of characters in the string. You can call `ASCopySourceAttributes` (page 2785) to get the current AppleScript source style attributes.

Availability
Available in Mac OS X v10.5 and later.

Declared In
`OSA.h`

OSACopyID

Updates script data after editing or recording and to perform undo or revert operations on script data.

```
OSAError OSACopyID (
   ComponentInstance scriptingComponent,
   OSAID fromID,
   OSAID *toID
);
```

Parameters

scriptingComponent

A component instance created by a prior call to the Component Manager function `OpenDefaultComponent` or `OpenComponent`.

fromID

The script ID for script data that you want to be associated with the script ID in the *toID* parameter. See the OSAID (page 2855) data type.

toID

A pointer to the script ID for the script data to be replaced. If the value of this parameter is kOSANullScript, the OSACopyID function returns a new script ID. See the OSAID (page 2855) data type.

Return Value
A result code. See "Result Codes" (page 2885).

Discussion
The OSACopyID function replaces the script data identified by the script ID in the *toID* parameter with the script data identified by the script ID in the *fromID* parameter.

Availability
Available in Mac OS X v10.0 and later.

Declared In
OSA.h

OSACopyScriptingDefinition

Creates a copy of a scripting definition (sdef) from the specified file or bundle.

```
OSAError OSACopyScriptingDefinition (
   const FSRef *ref,
   SInt32 modeFlags,
   CFDataRef *sdef
);
```

Parameters

ref

A file reference to the application file or bundle from which to copy the scripting definition.

modeFlags

Reserved for future use. Set to kOSAModeNull.

sdef

On return, the resulting scripting definition, as XML data.

Return Value
A result code. See "Result Codes" (page 2885).

Discussion
If the target application does not have a true scripting definition (sdef) but does have an 'aete' resource or a Cocoa script suite, this function translates the existing information to an sdef. As a result, OSACopyScriptingDefinition works for any scriptable application.

To provide a scripting definition in your application:

1. Put the sdef file in the Resources folder of the application bundle.
2. Add an entry to your information property list (Info.plist) file:
   - key: "OSAScriptingDefinition"

- value: “MyApplication.sdef” (the name of the sdef)

For an introduction to scripting definitions, see “Specifying Scripting Terminology” in AppleScript Overview. See the man page for sdef(5) for details of the sdef format.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`ASDebugging.h`

OSACopySourceString

Decompiles the script data for the specified script and returns a copy of the equivalent source data as an attributed Unicode text string.

```
OSAError OSACopySourceString (
   ComponentInstance scriptingComponent,
   OSAID scriptID,
   SInt32 modeFlags,
   CFAttributedStringRef *result
);
```

Parameters

scriptingComponent

A component instance created by a prior call to the Component Manager function `OpenDefaultComponent` or `OpenComponent`.

scriptID

The script ID for the script data to decompile. If you pass `kOSANullScript` in this parameter, `OSACopySourceString` returns a null source description (such as an empty text string). See the `OSAID` (page 2855) data type.

modeFlags

No mode information is currently supported, so you should specify `kOSAModeNull` for this parameter.

result

If successful, a reference to the script data as an attributed Unicode text string; otherwise not defined.

Because the `result` parameter returns a copy, the caller is responsible for releasing this string object, according to the rules described in Ownership Policy in *Memory Management Programming Guide for Core Foundation*.

Return Value
A result code. See “Result Codes” (page 2885).

Discussion
The `OSACopySourceString` function is analogous to `OSAGetSource` (page 2830), except that it returns the decompiled script data as an attributed Unicode text string (a Core Foundation attributed string object). This data can be displayed to the user or compiled and executed. You can call `ASCopySourceAttributes` (page 2785) to get the current AppleScript source style attributes.

Availability
Available in Mac OS X v10.5 and later.

Declared In
OSA.h

OSADebuggerCreateSession

Do not use.

Unsupported

```
OSAError OSADebuggerCreateSession (
   ComponentInstance scriptingComponent,
   OSAID inScript,

   OSADebugStepKind inKind
);
```

Return Value
A result code. See "Result Codes" (page 2885).

Availability
Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared In
OSA.h

OSADebuggerSetBreakpoint

Do not use.

Unsupported

```
OSAError OSADebuggerSetBreakpoint (
   ComponentInstance scriptingComponent,
   OSADebugSessionRef inSession,
   UInt32 inSrcOffset,
   OSAID inBreakpoint
);
```

Return Value
A result code. See "Result Codes" (page 2885).

Availability
Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared In
OSA.h

OSADebuggerSetVariable

Do not use.

Unsupported

```
OSAError OSADebuggerSetVariable (
   ComponentInstance scriptingComponent,
   OSADebugCallFrameRef inCallFrame,
   const AEDesc *inVariableName,
   OSAID inVariable
);
```

Return Value
A result code. See "Result Codes" (page 2885).

Availability
Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared In
OSA.h

OSADisplay

Converts a script value to text. Your application can then use its own functions to display this text to the user.

```
OSAError OSADisplay (
   ComponentInstance scriptingComponent,
   OSAID scriptValueID,
   DescType desiredType,
   SInt32 modeFlags,
   AEDesc *resultingText
);
```

Parameters

scriptingComponent

A component instance created by a prior call to the Component Manager function `OpenDefaultComponent` or `OpenComponent`.

scriptValueID

The script ID for the script value to coerce. See the `OSAID` (page 2855) data type.

desiredType

The desired text descriptor type, such as `typeChar`, for the resulting descriptor record.

modeFlags

Information used by individual scripting components. To avoid setting any mode flags, specify `kOSAModeNull`. To make the resulting text readable by humans only, so that it can't be recompiled, specify `kOSAModeDisplayForHumans`.

resultingText

A pointer to the resulting descriptor record.

Return Value

A result code. See "Result Codes" (page 2885).

Discussion

The `OSADisplay` function coerces the script value identified by *scriptValueID* to a descriptor record of the text type specified by the *desiredType* parameter, if possible. Valid types include the standard text descriptor types, plus any special types supported by the scripting component.

Unlike `OSAGetSource` (page 2830), `OSADisplay` can coerce only script values and always produces a descriptor record of a text descriptor type. In addition, if you specify the mode flag `kOSAModeDisplayForHumans`, the resulting text cannot be recompiled.

If you want to get a script value in a form that you can display for humans to read, use `OSADisplay`. If you want the descriptor type of the descriptor record returned in the *resultingText* parameter to be the same as the descriptor type returned by a scripting component, use `OSACoerceToDesc` and specify `typeWildCard` as the desired type.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OSA.h`

OSADispose

Reclaims the memory occupied by script data.

```
OSAError OSADispose (
   ComponentInstance scriptingComponent,
   OSAID scriptID
);
```

Parameters

scriptingComponent

A component instance created by a prior call to the Component Manager function `OpenDefaultComponent` or `OpenComponent`.

scriptID

The script ID for the script data to be disposed of. See the `OSAID` (page 2855) data type.

Return Value
A result code. See "Result Codes" (page 2885).

Discussion
The `OSADispose` function releases the memory assigned to the script data identified by the *scriptID* parameter. The script ID passed to the `OSADispose` function is no longer valid if the function returns successfully. A scripting component can then reuse that script ID for other script data.

A call to `OSADispose` returns `noErr` if the script ID is `kOSANullScript`, although it does not dispose of anything.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OSA.h`

OSADoEvent

Handles an Apple event with the aid of a script context and obtains a reply event.

```
OSAError OSADoEvent (
   ComponentInstance scriptingComponent,
   const AppleEvent *theAppleEvent,
   OSAID contextID,
   SInt32 modeFlags,
   AppleEvent *reply
);
```

Parameters

scriptingComponent

A component instance created by a prior call to the Component Manager function `OpenDefaultComponent` or `OpenComponent`.

theAppleEvent

A pointer to the Apple event to be handled.

contextID

The script ID for the script context to be used to handle the Apple event. See the `OSAID` (page 2855) data type.

modeFlags

Information used by individual scripting components. To avoid setting mode flag values, specify `kOSAModeNull`. Other possible mode flags are listed in "Mode Flags" (page 2873).

reply
A pointer to the reply Apple event.

Return Value
A result code. See "Result Codes" (page 2885).

Discussion
The `OSADoEvent` function resembles both `OSADoScript` and `OSAExecuteEvent`. However, unlike `OSADoScript`, the script `OSADoEvent` executes must be in the form of a script context, and execution is initiated by an Apple event. Unlike `OSAExecuteEvent`, `OSADoEvent` returns a reply Apple event rather than the script ID of the resulting script value.

The `OSADoEvent` function, like `OSAExecuteEvent`, attempts to use the script context specified by the *`contextID`* parameter to handle the Apple event specified by the *`theAppleEvent`* parameter. If the scripting component determines that the script context can't handle the event (for example, if a script written in an AppleScript dialect doesn't include statements that handle the event), `OSADoEvent` immediately returns `errAEEventNotHandled` rather than `errOSAScriptError`. This causes the Apple Event Manager to look for an appropriate handler in the application's Apple event dispatch table or elsewhere, using standard Apple event dispatching.

If the scripting component determines that the script context can handle the event, `OSADoEvent` executes the script context's handler for the event and returns the resulting script ID.

The `OSADoEvent` function returns a reply event that contains either the resulting script value or, if an error occurred during script execution, information about the error. If the error `errOSAScriptError` occurs during script execution, `OSADoEvent` calls `OSAScriptError` and returns the appropriate error information in the reply. The `OSADoEvent` function never returns `errOSAScriptError`.

If the script context specifies that the Apple event should be passed to the application's standard handler for that event (for example, with an AppleScript continue statement), `OSADoEvent` passes the event to the resume dispatch function currently being used by the scripting component. The resume dispatch function dispatches the event directly to the application's standard handler for that event (that is, without calling `OSADoEvent` again). If the *`contextID`* parameter is `kOSANullScript`, the `OSADoEvent` function passes the event directly to the resume dispatch function. If the call to the resume dispatch function is successful, execution of the script context proceeds from the point at which the resume dispatch function was called.

Special Considerations

Like `OSAExecuteEvent`, `OSADoEvent` can generate the result code `errAEEventNotHandled` in at least two ways. If the scripting component determines that a script context doesn't declare a handler for a particular event, `OSADoEvent` immediately returns `errAEEventNotHandled`. If a scripting component calls its resume dispatch function during script execution and the application's standard handler for the event fails to handle it, `OSADoEvent` returns `errAEEventNotHandled` in the reply Apple event.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OSA.h`

OSADoScript

Compiles and executes a script and converts the resulting script value to text in a single step rather than calling `OSACompile`, `OSAExecute`, and `OSADisplay`.

```
OSAError OSADoScript (
   ComponentInstance scriptingComponent,
   const AEDesc *sourceData,
   OSAID contextID,
   DescType desiredType,
   SInt32 modeFlags,
   AEDesc *resultingText
);
```

Parameters

scriptingComponent

A component instance created by a prior call to the Component Manager function `OpenDefaultComponent` or `OpenComponent`.

sourceData

A pointer to a descriptor record identifying suitable source data for the specified scripting component.

contextID

The script ID for the context to be used during script execution. The constant `kOSANullScript` in this parameter indicates that the scripting component should use its default context. See the `OSAID` (page 2855) data type.

desiredType

The desired text descriptor type, such as `typeChar`, for the resulting descriptor record.

modeFlags

Information used by individual scripting components. To avoid setting mode flag values, specify `kOSAModeNull`. Other possible mode flags are listed in "Mode Flags" (page 2873).

resultingText

A pointer to the resulting descriptor record.

Return Value

A result code.

If the result code returned by `OSADoScript` is a general result code, there was some problem in arranging for the script to be run. If an error occurs during script execution, the error message of the error is stored in `resultingText`, and the function returns `errOSAScriptError`. You can use `OSAScriptError` (page 2839) to obtain more information about the particular error.

For additional information on result codes, see "Result Codes" (page 2885).

Discussion

Calling the `OSADoScript` function is equivalent to calling `OSACompile` followed by `OSAExecute` and `OSADisplay`. After compiling the source data, executing the compiled script using the script context identified by the *contextID* parameter, and returning the text equivalent of the resulting script value in the *resultingText* parameter, `OSADoScript` disposes of both the compiled script and the resulting script value.

Special Considerations

Prior to Mac OS X version 10.5, if an error occurred during script execution, the error message of the error was not returned in `resultingText`.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OSA.h`

OSADoScriptFile

Loads a script from the specified file, compiles the script if the file is a text file, executes the script, converts the resulting script value to text, and stores the script back into the file if the script has persistent properties and the file is not a text file.

```
OSAError OSADoScriptFile (
   ComponentInstance scriptingComponent,
   const FSRef *scriptFile,
   OSAID contextID,
   DescType desiredType,
   SInt32 modeFlags,
   AEDesc *resultingText
);
```

Parameters

scriptingComponent

A component instance created by a prior call to the Component Manager function `OpenDefaultComponent` or `OpenComponent`. See the Component Manager documentation for a description of the `ComponentInstance` data type.

scriptFile

Identifies the file to load the script from and to save the script back to (if the script has persistent properties and the file is not a text file). See the File Manager documentation for a description of the `FSRef` data type.

File format is determined by inspection. If the file is a text file, `OSADoScriptFile` uses the following steps to determine the text encoding:

- If a Unicode BOM is present, that determines the encoding—one of UTF-16BE, UTF-16LE, or UTF-8
- Otherwise, if the file is valid UTF-8, it is assumed to be UTF-8.
- Otherwise, it is assumed to be in the primary encoding.

contextID

The script ID for the context to be used during script execution. The constant `kOSANullScript` in this parameter indicates that the scripting component should use its default context. See the `OSAID` (page 2855) data type.

desiredType

The desired text descriptor type, such as `typeChar`, for the resulting descriptor record.

modeFlags

Information for use by the scripting component. Can include any of the mode flags that would normally be sent to the `OSACompile` (page 2799) (if the file is a text file), `OSADisplay` (page 2810), `OSAExecute` (page 2816), and `OSALoad` (page 2832) functions. For descriptions of the mode flag usage of those functions, see the chapter "Scripting Components" in "Interapplication Communication" at http://developer.apple.com/documentation/mac/IAC/IAC-2.html.

resultingText

The descriptor record for the resulting script value. The `AEDesc` data type is described in Apple Event Manager Reference.

Return Value

A result code. See "Result Codes" (page 2885).

Discussion
This routine is effectively equivalent to calling `OSALoadFile` (page 2835), followed by `OSAExecute` (page 2816), `OSADisplay` (page 2810), and then `OSAStoreFile` (page 2851) if the script has persistent properties. After execution, the compiled source and the resulting value are disposed. Only the `resultingText` descriptor is retained. If an error occurs during script execution, the error message of the error is stored in `resultingText`, and the function returns `errOSAScriptError`. You can use `OSAScriptError` (page 2839) to obtain more information about the particular error.

Special Considerations

Prior to Mac OS X version 10.5, if an error occurred during script execution, the error message of the error was not returned in `resultingText`.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`OSA.h`

OSAExecute

Executes a compiled script or a script context.

```
OSAError OSAExecute (
   ComponentInstance scriptingComponent,
   OSAID compiledScriptID,
   OSAID contextID,
   SInt32 modeFlags,
   OSAID *resultingScriptValueID
);
```

Parameters

scriptingComponent
A component instance created by a prior call to the Component Manager function `OpenDefaultComponent` or `OpenComponent`.

compiledScriptID
The script ID for the compiled script to be executed. See the `OSAID` (page 2855) data type.

contextID
The script ID for the context to be used during script execution. The constant `kOSANullScript` in this parameter indicates that the scripting component should use its default context. See the `OSAID` (page 2855) data type.

modeFlags
Information used by individual scripting components. To avoid setting mode flag values, specify `kOSAModeNull`. Other possible mode flags are listed in the description that follows.

resultingScriptValueID
A pointer to the script ID for the script value returned. See the `OSAID` (page 2855) data type.

Return Value
A result code. See "Result Codes" (page 2885). If the result code returned by `OSAExecute` is a general result code, there was some problem in arranging for the script to be run. If the result code is `errOSAScriptError`, an error occurred during script execution. In this case, you can obtain more detailed error information by calling `OSAScriptError`.

Discussion
The `OSAExecute` function executes the compiled script identified by the *`compiledScriptID`* parameter, using the script context identified by the *`contextID`* parameter to maintain state information, such as the binding of variables, for the compiled script. After successfully executing a script, `OSAExecute` returns the script ID for a resulting script value, or, if execution does not result in a value, the constant `kOSANullScript`. You can use the `OSACoerceToDesc` function to coerce the resulting script value to a descriptor record of a desired descriptor type, or the `OSADisplay` (page 2810) function to obtain the equivalent source data for the script value. You can control the way in which the scripting component executes a script by adding any of the flags described in "Mode Flags" (page 2873).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OSA.h`

OSAExecuteEvent

Handles an Apple event with the aid of a script context and obtains a script ID for the resulting script value.

```
OSAError OSAExecuteEvent (
   ComponentInstance scriptingComponent,
   const AppleEvent *theAppleEvent,
   OSAID contextID,
   SInt32 modeFlags,
   OSAID *resultingScriptValueID
);
```

Parameters

`scriptingComponent`
A component instance created by a prior call to the Component Manager function `OpenDefaultComponent` or `OpenComponent`.

`theAppleEvent`
A pointer to the Apple event to be handled.

`contextID`
The script ID for the script context to be used to handle the Apple event. See the `OSAID` (page 2855) data type.

`modeFlags`
Information used by individual scripting components. To avoid setting mode flag values, specify `kOSAModeNull`. Other possible mode flags are listed in "Mode Flags" (page 2873).

`resultingScriptValueID`
A pointer to the script ID for the resulting script value.

Return Value
A result code. See "Result Codes" (page 2885).

Discussion
The `OSAExecuteEvent` function attempts to use the script context specified by the *`contextID`* parameter to handle the Apple event specified by the *`theAppleEvent`* parameter. If the scripting component determines that the script context can't handle the event (for example, if a script written in AppleScript doesn't include

statements that handle the event), `OSAExecuteEvent` immediately returns `errAEEventNotHandled` rather than `errOSAScriptError`. This causes the Apple Event Manager to look for an appropriate handler in the application's Apple event dispatch table or elsewhere, using standard Apple event dispatching.

If the scripting component determines that the script context can handle the event, `OSAExecuteEvent` executes the script context's handler and returns the resulting script ID. If execution of the script context's handler for the event generates an error, `OSAExecuteEvent` returns `errOSAScriptError`, and you can get more detailed error information by calling the `OSAScriptError` function.

If the script context identified by the *`contextID`* parameter specifies that the Apple event should be passed to the application's default handler for that event (for example, with an AppleScript `continue` statement), `OSAExecuteEvent` passes the event to the resume dispatch function currently being used by the scripting component. The resume dispatch function dispatches the event directly to the application's standard handler for that event (that is, without calling `OSAExecuteEvent` again). If the *`contextID`* parameter is `kOSANullScript`, the `OSAExecuteEvent` function passes the event directly to the resume dispatch function. If a call to the resume dispatch function is successful, execution of the script context proceeds from the point at which the resume dispatch function was called.

Special Considerations

The `OSAExecuteEvent` function can generate the result code `errAEEventNotHandled` in at least two ways. If the scripting component determines that a script context doesn't declare a handler for a particular event, `OSAExecuteEvent` immediately returns `errAEEventNotHandled`. If a scripting component calls its resume dispatch function during script execution and the application's standard handler for the event fails to handle it, `OSAExecuteEvent` returns `errOSAScriptError` and a call to `OSAScriptError` with `kOSAErrorNumber` in the *`selector`* parameter returns `errAEEventNotHandled` as the resulting error description.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OSA.h`

OSAGenericToRealID

Converts a generic script ID to the corresponding component-specific script ID.

```
OSAError OSAGenericToRealID (
   ComponentInstance genericScriptingComponent,
   OSAID *theScriptID,
   ComponentInstance *theExactComponent
);
```

Parameters

`genericScriptingComponent`

A component instance for the generic scripting component, created by a prior call to the Component Manager function `OpenDefaultComponent` or `OpenComponent`.

`theScriptID`

A pointer to the generic script ID that you want to convert. The `OSAGenericToRealID` function returns, in this parameter, the component-specific script ID that corresponds to the generic script ID that you pass in this parameter. See the `OSAID` (page 2855) data type.

theExactComponent
On return, a pointer to the component instance that created the script ID returned in the *theScriptID* parameter.

Return Value
A result code. See "Result Codes" (page 2885).

Discussion
You can't use the generic scripting component and a generic script ID with component-specific routines. Instead, you can use the component instance and script ID returned by `OSAGenericToRealID`.

Given a generic script ID (that is, a script ID returned by a call to a standard component routine via the generic scripting component), the `OSAGenericToRealID` function returns the equivalent component-specific script ID and the component instance that created that script ID. The `OSAGenericToRealID` function modifies the script ID in place, changing the generic script ID you pass in the *theScriptID* parameter to the corresponding component-specific script ID.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OSAGeneric.h`

OSAGetActiveProc

Gets a pointer to the active function that a scripting component is currently using.

```
OSAError OSAGetActiveProc (
   ComponentInstance scriptingComponent,
   OSAActiveUPP *activeProc,
   SRefCon *refCon
);
```

Parameters
scriptingComponent
A component instance created by a prior call to the Component Manager function `OpenDefaultComponent` or `OpenComponent`.

activeProc
On return, a pointer a UPP to the active function currently set for the specified scripting component.

refCon
On return, a pointer to the reference constant associated with the active function for the specified scripting component.

Return Value
A result code. See "Result Codes" (page 2885).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OSA.h`

OSAGetAppTerminology

Gets one or more scripting terminology resources from the specified file. (Deprecated in Mac OS X v10.5. Use `OSACopyScriptingDefinition` (page 2803) instead.)

```
OSAError OSAGetAppTerminology (
   ComponentInstance scriptingComponent,
   SInt32 modeFlags,
   FSSpec *fileSpec,
   short terminologyID,
   Boolean *didLaunch,
   AEDesc *terminologyList
);
```

Parameters

scriptingComponent

Identifies the current scripting component. See the Component Manager documentation for a description of the `ComponentInstance` data type.

modeFlags

Information for use by the scripting component. No mode flags are applicable for this function, so pass the value `kOSAModeNull`.

fileSpec

Specifies the file to search. See the File Manager documentation for a description of the `FSSpec` data type.

terminologyID

A dialect code obtained from a previous call to the `OSAGetDialectInfo` function or the `OSAGetCurrentDialect` function.

didLaunch

On return, has the value `true` if the application's scripting size resource or plist flags indicate that it has a dynamic terminology (in which case, the application will have been launched).

terminologyList

On return, a descriptor list containing zero or more terminology resources. See Apple Event Manager Reference for a description of the `AEDesc` data type.

Return Value

A result code. See "Result Codes" (page 2885).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`ASDebugging.h`

OSAGetCreateProc

Gets a pointer to the create function that a scripting component is currently using to create Apple events.

```
OSAError OSAGetCreateProc (
   ComponentInstance scriptingComponent,
   OSACreateAppleEventUPP *createProc,
   SRefCon *refCon
);
```

Parameters

scriptingComponent

A component instance created by a prior call to the Component Manager function `OpenDefaultComponent` or `OpenComponent`.

createProc

On return, a pointer to the UPP to the create function currently set for the specified scripting component.

refCon

On return, a pointer to the reference constant associated with the create function for the specified scripting component.

Return Value
A result code. See "Result Codes" (page 2885).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OSA.h`

OSAGetCurrentDialect

Gets the dialect code for the dialect currently being used by a scripting component.

```
OSAError OSAGetCurrentDialect (
   ComponentInstance scriptingComponent,
   short *resultingDialectCode
);
```

Parameters

scriptingComponent

A component instance created by a prior call to the Component Manager function `OpenDefaultComponent` or `OpenComponent`.

resultingDialectCode

On return, a pointer to the code for the current dialect of the specified scripting component.

Return Value
A result code. See "Result Codes" (page 2885).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OSA.h`

OSAGetDefaultScriptingComponent

Gets the subtype code for the default scripting component associated with an instance of the generic scripting component.

```
OSAError OSAGetDefaultScriptingComponent (
   ComponentInstance genericScriptingComponent,
   ScriptingComponentSelector *scriptingSubType
);
```

Parameters

genericScriptingComponent

A component instance for the generic scripting component, created by a prior call to the Component Manager function `OpenDefaultComponent` or `OpenComponent`.

scriptingSubType

On return, a pointer to the subtype code for the default scripting component associated with the instance of the generic scripting component specified in the *genericScriptingComponent* parameter.

Return Value

A result code. See "Result Codes" (page 2885).

Discussion

The `OSAGetDefaultScriptingComponent` function returns the subtype code for the default scripting component. This is the scripting component that will be used by `OSAStartRecording`, `OSACompile`, or `OSACompileExecute` if no existing script ID is specified. From the user's point of view, the default scripting component corresponds to the scripting language selected in the Script Editor application when the user first creates a new script.

Each instance of the generic scripting component has its own default scripting component, which is initially AppleScript. You can use `OSASetDefaultScriptingComponent` to change the default scripting component.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OSAGeneric.h`

OSAGetDialectInfo

Gets information about a specified dialect provided by a specified scripting component.

```
OSAError OSAGetDialectInfo (
   ComponentInstance scriptingComponent,
   short dialectCode,
   OSType selector,
   AEDesc *resultingDialectInfo
);
```

Parameters

scriptingComponent

A component instance created by a prior call to the Component Manager function `OpenDefaultComponent` or `OpenComponent`.

dialectCode

A code for the dialect about which you want information. You can obtain a list of a scripting component's dialect codes by calling `OSAAvailableDialectCodeList`.

selector

A constant that indicates what kind of information you want `OSAGetDialectInfo` to return in the result parameter. This constant determines the descriptor type for the descriptor record returned. See the description in "Dialect Descriptor Constants" (page 2865) for a list of the standard constants you can specify in this parameter.

resultingDialectInfo

A pointer to a descriptor record containing the requested information. The descriptor record's descriptor type corresponds to the constant specified in the `selector` parameter.

Return Value
A result code. See "Result Codes" (page 2885).

Discussion
After you obtain a list of dialect codes by calling `OSAAvailableDialectCodeList`, you can pass any of those codes to `OSAGetDialectInfo` to get information about the corresponding dialect. The descriptor type of the descriptor record returned by `OSAGetDialectInfo` depends on the constant specified in the *selector* parameter. All scripting components support the "Dialect Descriptor Constants" (page 2865) constants for this parameter. Individual scripting components may allow you to specify additional constants.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OSA.h`

OSAGetHandler

Gets a script ID for the specified script handler from the specified script.

```
OSAError OSAGetHandler (
   ComponentInstance scriptingComponent,
   SInt32 modeFlags,
   OSAID contextID,
   const AEDesc *handlerName,
   OSAID *resultingCompiledScriptID
);
```

Parameters

scriptingComponent

Identifies the current scripting component. See the Component Manager documentation for a description of the `ComponentInstance` data type.

modeFlags

Information for use by the scripting component. No mode flags are applicable for this function, so pass the value `kOSAModeNull`.

contextID

Specifies the script to get the script handler for. See the `OSAID` (page 2855) data type.

handlerName

A descriptor record that specifies the name of the handler to get. The descriptor must be of type `typeChar`, or of a type that can be coerced to `typeChar`. The handler name is case-sensitive and must exactly match the case of the handler name as supplied by the `OSAGetHandlerNames` function or the `OSAGetSource` (page 2830) function. See Apple Event Manager Reference for a description of the `AEDesc` data type.

resultingCompiledScriptID

On return, the `OSAID` for the specified handler, or `kOSANullScript` if the handler does not exist. If the handler has no input parameters, it may be executed by calling `OSAExecute`; if it requires input parameters, you can create an Apple event that supplies the handler parameters and execute it with `OSAExecuteEvent`. You may also copy it to another script with the `OSASetHandler` function or get its source code with the `OSAGetSource` function. See the `OSAID` (page 2855) data type.

Return Value
A result code. See "Result Codes" (page 2885).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ASDebugging.h`

OSAGetHandlerNames

Gets a list of all handler names in the specified script as an `AEDescList` of descriptors of type `typeChar`.

```
OSAError OSAGetHandlerNames (
   ComponentInstance scriptingComponent,
   SInt32 modeFlags,
   OSAID contextID,
   AEDescList *resultingHandlerNames
);
```

Parameters

scriptingComponent

Identifies the current scripting component. See the Component Manager documentation for a description of the `ComponentInstance` data type.

modeFlags

Information for use by the scripting component. No mode flags are applicable for this function, so pass the value `kOSAModeNull`.

contextID

See the `OSAID` (page 2855) data type.

resultingHandlerNames

On return, a list of all handler names, as an `AEDescList` of descriptors of type `typeChar`. See Apple Event Manager Reference for a description of the `AEDescList` data type.

Return Value
A result code. See "Result Codes" (page 2885).

Availability
Available in Mac OS X v10.0 and later.

Declared In
ASDebugging.h

OSAGetProperty

Gets the value of a specified script property from a specified script.

```
OSAError OSAGetProperty (
   ComponentInstance scriptingComponent,
   SInt32 modeFlags,
   OSAID contextID,
   const AEDesc *variableName,
   OSAID *resultingScriptValueID
);
```

Parameters

scriptingComponent
Identifies the current scripting component. See the Component Manager documentation for a description of the ComponentInstance data type.

modeFlags
Information for use by the scripting component. No mode flags are applicable for this function, so pass the value kOSAModeNull.

contextID
Specifies the script to get the script property from. See the OSAID (page 2855) data type.

variableName
A descriptor record that specifies the name of the property to get. The descriptor must be of type typeChar, or of a type that can be coerced to typeChar. The variable name is case-sensitive and must exactly match the case of the variable name as supplied by the OSAGetPropertyNames function or the OSAGetSource (page 2830) function. See Apple Event Manager Reference for a description of the AEDesc data type.

resultingScriptValueID
On return, a script ID whose associated data supplies the value for the property specified by the variableName parameter. Note that the value is returned as an OSAID, not an AEDesc. To get it as an AEDesc, use the OSACoerceToDesc function; to get it as user-readable text, use OSADisplay (page 2810). See the OSAID (page 2855) data type.

Return Value
A result code. See "Result Codes" (page 2885).

Availability
Available in Mac OS X v10.0 and later.

Declared In
ASDebugging.h

OSAGetPropertyNames

Gets a list of all property names from the specified script.

```
OSAError OSAGetPropertyNames (
   ComponentInstance scriptingComponent,
   SInt32 modeFlags,
   OSAID contextID,
   AEDescList *resultingPropertyNames
);
```

Parameters

scriptingComponent

Identifies the current scripting component. See the Component Manager documentation for a description of the `ComponentInstance` data type.

modeFlags

Information for use by the scripting component. No mode flags are applicable for this function, so pass the value `kOSAModeNull`.

contextID

Specifies the script to get the property names from. See the `OSAID` (page 2855) data type.

resultingPropertyNames

On return, a list of all property names, as an `AEDescList` of descriptors of type `typeChar`. You can extract these descriptors from the list and use them as input values to the `OSAGetProperty` function or the `OSASetProperty` (page 2844) function. See Apple Event Manager Reference for a description of the `AEDescList` data type.

Return Value

A result code. See "Result Codes" (page 2885).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`ASDebugging.h`

OSAGetResumeDispatchProc

Gets the resume dispatch function currently being used by a scripting component instance during execution of an AppleScript `continue` statement or its equivalent

```
OSAError OSAGetResumeDispatchProc (
   ComponentInstance scriptingComponent,
   AEEventHandlerUPP *resumeDispatchProc,
   SRefCon *refCon
);
```

Parameters

scriptingComponent

A component instance created by a prior call to the Component Manager function `OpenDefaultComponent` or `OpenComponent`.

resumeDispatchProc

On return, a pointer to a UPP to the resume dispatch function for the specified scripting component. If no resume dispatch function has been registered, `OSAGetResumeDispatchProc` returns `kOSAUseStandardDispatch` (the default).

refCon

On return, a pointer to the reference constant associated with the resume dispatch function.

Return Value
A result code. See "Result Codes" (page 2885).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OSA.h`

OSAGetScriptInfo

Obtains information about script data according to the value you pass in the `selector` parameter.

```
OSAError OSAGetScriptInfo (
   ComponentInstance scriptingComponent,
   OSAID scriptID,
   OSType selector,
   long *result
);
```

Parameters

`scriptingComponent`
A component instance created by a prior call to the Component Manager function `OpenDefaultComponent` or `OpenComponent`.

`scriptID`
The script ID for the script data about which to obtain information. See the `OSAID` (page 2855) data type.

`selector`
A value that determines what kind of information `OSAGetScriptInfo` returns. The value can be one of the constants described in "Script Information Selectors" (page 2880). In addition to the standard constants, the AppleScript component also supports the `kASHasOpenHandler` constant. For additional information, see the Version Notes section below.

`result`
On return, a pointer to the requested information, which you can coerce to the appropriate descriptor type for the value specified in the *`selector`* parameter.

Return Value
A result code. See "Result Codes" (page 2885).

Version Notes
In Mac OS X, if you specify `kOSAScriptIsModified` for the value of the *`selector`* parameter, `OSAGetScriptInfo` returns `true` if the script has been modified and `false` if it has not.

The following information describes the behavior of `OSAGetScriptInfo` in versions of the Mac OS prior to Mac OS X: Although you can specify `kOSAScriptIsModified` when you are using the AppleScript component without generating an error, the current version of AppleScript interprets this request conservatively. The AppleScript component stores script data in a network of interlocking structures, and running a script can cause any of these structures to be modified. If you pass a script ID is to `OSAGetScriptInfo` with `kOSAScriptIsModified` as the value of the *`selector`* parameter, the AppleScript component returns 1 if there is any possibility that the script data or related structures may have been modified, and 0 if there is no possibility that they have been modified.

Availability
Available in Mac OS X v10.0 and later.

Declared In
OSA.h

OSAGetScriptingComponent

Gets the instance of a scripting component for a specified subtype.

```
OSAError OSAGetScriptingComponent (
   ComponentInstance genericScriptingComponent,
   ScriptingComponentSelector scriptingSubType,
   ComponentInstance *scriptingInstance
);
```

Parameters

genericScriptingComponent
A component instance for the generic scripting component, created by a prior call to the Component Manager function OpenDefaultComponent or OpenComponent.

scriptingSubType
A subtype code for a scripting component.

scriptingInstance
On return, a pointer to a component instance for the scripting component identified by the *scriptingSubType* parameter.

Return Value
A result code. See "Result Codes" (page 2885).

Discussion
You can't use the generic scripting component with component-specific routines. Instead, use an instance of the specific scripting component, which you can obtain with OSAGetScriptingComponent.

The OSAGetScriptingComponent function returns, in the *scriptingInstance* parameter, an instance of the scripting component identified by the *scriptingSubType* parameter. Each instance of the generic scripting component keeps track of a single instance of each component subtype, so OSAGetScriptingComponent always returns the same instance of a specified scripting component that the generic scripting component uses for standard scripting component routines.

For example, you can use OSAGetScriptingComponent to get the subtype code for the default scripting component (that is, the scripting component used by the generic scripting component for new scripts). You can then get an instance of the default scripting component by passing its subtype code to OSAGetScriptingComponent. Finally, you can pass that instance to OSAScriptingComponentName to obtain the default scripting component's name so you can display it to the user.

Similarly, you can pass kAppleScriptSubtype in the *scriptingSubType* parameter to obtain an instance of the AppleScript component. This is necessary, for example, to call AppleScript-specific routines such as ASGetSourceStyles (which is deprecated in Mac OS X version 10.5 in favor of ASCopySourceAttributes (page 2785)).

Availability
Available in Mac OS X v10.0 and later.

Declared In
OSAGeneric.h

OSAGetScriptingComponentFromStored

Gets the subtype code for a scripting component that created a storage descriptor record.

```
OSAError OSAGetScriptingComponentFromStored (
   ComponentInstance genericScriptingComponent,
   const AEDesc *scriptData,
   ScriptingComponentSelector *scriptingSubType
);
```

Parameters

genericScriptingComponent
A component instance for the generic scripting component, created by a prior call to the Component Manager function OpenDefaultComponent or OpenComponent.

scriptData
A pointer to either a generic storage descriptor record or a component-specific storage descriptor record.

scriptingSubType
On return, a pointer to a subtype code identifying the scripting component that created the descriptor record specified by the *scriptData* parameter.

Return Value
A result code. See "Result Codes" (page 2885).

Discussion
The OSAGetScriptingComponentFromStored function returns, in the *scriptingSubType* parameter, the subtype code for the scripting component that created the script data specified by the *scriptData* parameter.

The generic scripting component automatically identifies the appropriate scripting component for you when you use it to call OSALoad. By calling OSAGetScriptingComponentFromStored, you can determine, without loading a script, which scripting component created the script data.

Availability
Available in Mac OS X v10.0 and later.

Declared In
OSAGeneric.h

OSAGetSendProc

Gets a pointer to the send function that a scripting component is currently using.

```
OSAError OSAGetSendProc (
   ComponentInstance scriptingComponent,
   OSASendUPP *sendProc,
   SRefCon *refCon
);
```

Parameters

scriptingComponent

A component instance created by a prior call to the Component Manager function `OpenDefaultComponent` or `OpenComponent`.

sendProc

On return, a pointer to the UPP to the send function currently set for the specified scripting component.

refCon

On return, a pointer to the reference constant associated with the send function for the specified scripting component.

Return Value
A result code. See "Result Codes" (page 2885).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OSA.h`

OSAGetSource

Decompiles the script data identified by a script ID and obtains the equivalent source data.

```
OSAError OSAGetSource (
   ComponentInstance scriptingComponent,
   OSAID scriptID,
   DescType desiredType,
   AEDesc *resultingSourceData
);
```

Parameters

scriptingComponent

A component instance created by a prior call to the Component Manager function `OpenDefaultComponent` or `OpenComponent`

scriptID

The script ID for the script data to decompile. If you pass `kOSANullScript` in this parameter, `OSAGetSource` returns a null source description (such as an empty text string). See the `OSAID` (page 2855) data type.

desiredType

The desired descriptor type of the resulting descriptor record, or `typeBest` if any type will do.

resultingSourceData

A pointer to the resulting descriptor record.

Return Value
A result code. See "Result Codes" (page 2885).

Discussion
The `OSAGetSource` function decompiles the script data identified by the specified script ID and returns a descriptor record containing the equivalent source data. The source data returned need not be exactly the same as the source data originally passed to `OSACompile`—for example, white space and formatting might be different—but it should be a reasonable equivalent suitable for user viewing and editing.

The difference between `OSACoerceToDesc` and `OSAGetSource` is that `OSAGetSource` creates source data that can be displayed to a user or compiled and executed to generate an appropriate value, whereas `OSACoerceToDesc` actually returns the value. For example, if you call `OSAGetSource` and specify a string value, it returns the text surrounded by quotation marks (so that it can be properly compiled). If you call `OSACoerceToDesc` and specify a string value, it simply returns the text.

The main difference between `OSADisplay` and `OSAGetSource` is that `OSAGetSource` can coerce any form of script data using a variety of descriptor types, whereas `OSADisplay` can coerce only script values and always produces a descriptor record of a text descriptor type.

A scripting component that supports the `OSAGetSource` function has the `kOSASupportsGetSource` bit set in the `componentFlags` field of its component description record.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OSA.h`

OSAGetStorageType

Retrieves the scripting component subtype from the script trailer appended to the script data in a generic storage descriptor record.

```
OSErr OSAGetStorageType (
   AEDataStorage scriptData,
   DescType *dscType
);
```

Parameters

`scriptData`
A handle to the script data.

`dscType`
A pointer to the descriptor type specified in the script data trailer.

Return Value
A result code. See "Result Codes" (page 2885).

Discussion
The `OSAGetStorageType` function retrieves the scripting component subtype from the trailer. If no trailer can be found, `OSAGetStorageType` returns the error `errOSABadStorageType`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OSAComp.h`

OSAGetSysTerminology

Gets one or more scripting terminology resources from the OSA system.

```
OSAError OSAGetSysTerminology (
   ComponentInstance scriptingComponent,
   SInt32 modeFlags,
   short terminologyID,
   AEDesc *terminologyList
);
```

Parameters

scriptingComponent

Identifies the current scripting component. See the Component Manager documentation for a description of the `ComponentInstance` data type.

modeFlags

Information for use by the scripting component. No mode flags are applicable for this function, so pass the value `kOSAModeNull`.

terminologyID

terminologyList

On return, one or more terminology resources from the OSA system. These include the built-in terminology for AppleScript as well as the standard suites, but not the terminology for installed scripting additions. The terminology may be returned as a single `AEDesc` of type `typeAEUT` or as a list of such descriptors. The internal format of the `typeAEUT` descriptor is the resource format described in AEUserTermTypes.r. See Apple Event Manager Reference Apple Event Manager Reference for a description of the `AEDesc` data type.

Return Value

A result code. See "Result Codes" (page 2885).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`ASDebugging.h`

OSALoad

Loads script data.

```
OSAError OSALoad (
   ComponentInstance scriptingComponent,
   const AEDesc *scriptData,
   SInt32 modeFlags,
   OSAID *resultingScriptID
);
```

Parameters

scriptingComponent

A component instance created by a prior call to the Component Manager function `OpenDefaultComponent` or `OpenComponent`.

scriptData

A pointer to the descriptor record containing the script data to be loaded.

modeFlags
: Information used by individual scripting components. To avoid setting any mode flags, specify `kOSAModeNull`. To indicate that only the minimum script data required to run the script should be loaded, pass `kOSAModePreventGetSource` in this parameter.

resultingScriptID
: On return, a pointer to the script ID for the compiled script. See the `OSAID` (page 2855) data type.

Return Value
A result code. See "Result Codes" (page 2885).

Discussion
The `OSALoad` function loads script data and returns a script ID. The generic scripting component uses the descriptor record in the *scriptData* parameter to determine which scripting component should load the script. If the descriptor record is of type `typeOSAGenericStorage`, the generic scripting component uses the trailer at the end of the script data to identify the scripting component. If the descriptor record's type is the subtype value for another scripting component, the generic scripting component uses the descriptor type to identify the scripting component.

If you want the script ID returned by `OSALoad` to identify only the minimum script data required to run the script and you are sure that you won't need to display the source data to the user, specify the `kOSAModePreventGetSource` flag in the *modeFlags* parameter.

Scripting components other than the generic scripting component can load script data only if it has been saved in a descriptor record whose descriptor type matches the scripting component's subtype.

Script data may change after it has been loaded—for example, if your application allows the user to edit a script's source data. To test whether script data has been modified, pass its script ID to `OSAGetScriptInfo`. If it has changed, you can call `OSAStore` again to obtain a handle to the modified script data and save it.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OSA.h`

OSALoadExecute

Loads and executes a script in a single step rather than calling `OSALoad` and `OSAExecute`.

```
OSAError OSALoadExecute (
   ComponentInstance scriptingComponent,
   const AEDesc *scriptData,
   OSAID contextID,
   SInt32 modeFlags,
   OSAID *resultingScriptValueID
);
```

Parameters

scriptingComponent
: A component instance created by a prior call to the Component Manager function `OpenDefaultComponent` or `OpenComponent`.

scriptData
: A pointer to the descriptor record identifying the script data to be loaded and executed.

contextID
The script ID for the context to be used during script execution. The constant `kOSANullScript` in this parameter indicates that the scripting component should use its default context. See the `OSAID` (page 2855) data type.

modeFlags
Information used by individual scripting components. To avoid setting mode flag values, specify `kOSAModeNull`. Other possible mode flags are listed in "Mode Flags" (page 2873).

resultingScriptValueID
A pointer to the script ID for the script value returned. See the `OSAID` (page 2855) data type.

Return Value
A result code. See "Result Codes" (page 2885).

Discussion
The `OSALoadExecute` function loads script data and executes the resulting compiled script, using the script context identified by the *contextID* parameter to maintain state information such as the binding of variables. After successfully executing the script, `OSALoadExecute` disposes of the compiled script and returns either the script ID for the resulting script value or, if execution does not result in a value, the constant `kOSANullScript`.

You can control the way in which the scripting component executes a script by adding any of the "Mode Flags" (page 2873) flags to the *modeFlags* parameter.

If the result code returned by `OSALoadExecute` is a general result code, there was some problem in arranging for the script to be run. If the result code is `errOSAScriptError`, an error occurred during script execution. In this case, you can obtain more detailed error information by calling `OSAScriptError`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OSA.h`

OSALoadExecuteFile

Loads a script from the specified file into the specified scripting component, compiles the script if the file is a text file, and executes the script.

```
OSAError OSALoadExecuteFile (
   ComponentInstance scriptingComponent,
   const FSRef *scriptFile,
   OSAID contextID,
   SInt32 modeFlags,
   OSAID *resultingScriptValueID
);
```

Parameters

scriptingComponent
A component instance created by a prior call to the Component Manager function `OpenDefaultComponent` or `OpenComponent`. See the Component Manager documentation for a description of the `ComponentInstance` data type.

scriptFile

Identifies the file to load the script from. See the File Manager documentation for a description of the `FSRef` data type.

File format is determined by inspection. If the file is a text file, `OSALoadExecuteFile` uses the following steps to determine the text encoding:

- If a Unicode BOM is present, that determines the encoding—one of UTF-16BE, UTF-16LE, or UTF-8
- Otherwise, if the file is valid UTF-8, it is presumed to be UTF-8.
- Otherwise, it is assumed to be in the primary encoding.

contextID

The script ID for the context to be used during script execution. The constant `kOSANullScript` in this parameter indicates that the scripting component should use its default context. See the `OSAID` (page 2855) data type.

modeFlags

Information for use by the scripting component. Can include any of the mode flags that would normally be sent to the `OSACompileExecute` (page 2800) (if the file is a text file) and `OSALoadExecute` (page 2833) functions. For descriptions of the mode flag usage of those functions, see the chapter "Scripting Components" in "Interapplication Communication" at http://developer.apple.com/documentation/mac/IAC/IAC-2.html.

resultingScriptValueID

The script ID for the resulting script value. See the `OSAID` (page 2855) data type.

Return Value
A result code. See "Result Codes" (page 2885).

Discussion
This routine is effectively equivalent to calling `OSALoadFile` (page 2835) followed by `OSAExecute` (page 2816). After execution, the compiled source is disposed. Only the resulting value ID is retained.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`OSA.h`

OSALoadFile

Loads a script from the specified file into the specified scripting component, compiling the script if the file is a text file.

```
OSAError OSALoadFile (
   ComponentInstance scriptingComponent,
   const FSRef *scriptFile,
   Boolean *storable,
   SInt32 modeFlags,
   OSAID *resultingScriptID
);
```

Parameters

scriptingComponent

A component instance created by a prior call to the Component Manager function `OpenDefaultComponent` or `OpenComponent`. See the Component Manager documentation for a description of the `ComponentInstance` data type.

scriptFile

Identifies the file to load the script from. See the File Manager documentation for a description of the `FSRef` data type.

File format is determined by inspection. If the file is a text file, `OSALoadFile` uses the following steps to determine the text encoding:

- If a Unicode BOM is present, that determines the encoding—one of UTF-16BE, UTF-16LE, or UTF-8
- Otherwise, if the file is valid UTF-8, it is presumed to be UTF-8.
- Otherwise, it is assumed to be in the primary encoding.

storable

If `storable` is not `NULL`, on return it is set to indicate whether a compiled script can be stored into the script file using `OSAStoreFile` (page 2851).

modeFlags

Information for use by the scripting component. Can include any of the mode flags that would normally be sent to the `OSACompile` (page 2799) (if the file is a text file) and `OSALoad` (page 2832) functions. For descriptions of the mode flag usage of those functions, see the chapter "Scripting Components" in "Interapplication Communication" at http://developer.apple.com/documentation/mac/IAC/IAC-2.html.

resultingScriptID

The returned script ID for the compiled script. See the `OSAID` (page 2855) data type.

Return Value

A result code. See "Result Codes" (page 2885).

Availability

Available in Mac OS X v10.3 and later.

Declared In

`OSA.h`

OSAMakeContext

Gets a script ID for a new script context.

```
OSAError OSAMakeContext (
   ComponentInstance scriptingComponent,
   const AEDesc *contextName,
   OSAID parentContext,
   OSAID *resultingContextID
);
```

Parameters

scriptingComponent

A component instance created by a prior call to the Component Manager function `OpenDefaultComponent` or `OpenComponent`.

contextName

A pointer to the name of the new context. Some scripting components may use context names for semantic purposes. If the value of this parameter is `typeNull`, `OSAMakeContext` creates an unnamed context.

parentContext

The existing context from which the new context inherits bindings. If the value of this parameter is `kOSANullScript`, the new context does not inherit bindings from any other context.

resultingContextID

A pointer to the script ID for the resulting script context. See the `OSAID` (page 2855) data type.

Return Value
A result code. See "Result Codes" (page 2885).

Discussion
The `OSAMakeContext` function creates a new script context that you may pass to `OSAExecute` or `OSAExecuteEvent`. The new script context inherits the bindings of the script context specified in the *parentContext* parameter.

If you call `OSAMakeContext` using an instance of the generic scripting component, the generic scripting component uses the default scripting component to create the new script context.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OSA.h`

OSARealToGenericID

Converts a component-specific script ID to the corresponding generic script ID.

```
OSAError OSARealToGenericID (
   ComponentInstance genericScriptingComponent,
   OSAID *theScriptID,
   ComponentInstance theExactComponent
);
```

Parameters

genericScriptingComponent

A component instance for the generic scripting component, created by a prior call to the Component Manager function `OpenDefaultComponent` or `OpenComponent`.

theScriptID

A pointer to the component-specific script ID that you want to convert. You must have obtained this script ID from the scripting component instance passed in the *theExactComponent* parameter. The OSARealToGenericID function returns, in this parameter, the generic script ID that corresponds to the component-specific script ID that you pass in this parameter. See the OSAID (page 2855) data type.

theExactComponent

A scripting component instance returned by a generic scripting component routine.

Return Value
A result code. See "Result Codes" (page 2885).

Discussion
The OSARealToGenericID function performs the reverse of the task performed by OSAGenericToRealID. Given a component-specific script ID and an exact scripting component instance (that is, the component instance that created the component-specific script ID), the OSARealToGenericID function returns the corresponding generic script ID. The OSARealToGenericID function modifies the script ID in place, changing the component-specific script ID passed in the *theScriptID* parameter to the corresponding generic script ID.

You'll need to do this if you have obtained a component-specific script ID using an exact scripting component instance and you want to refer to the same script in calls that use an instance of the generic scripting component. You can't use a component-specific script ID with the generic scripting component.

The script ID you pass in the *theScriptID* parameter must be a component-specific script ID obtained from a scripting component instance known to the generic scripting component. You can obtain such an instance by calling either OSAGetScriptingComponent or OSAGenericToRealID.

Availability
Available in Mac OS X v10.0 and later.

Declared In
OSAGeneric.h

OSARemoveStorageType

Removes a trailer from the script data in a generic storage descriptor record

```
OSErr OSARemoveStorageType (
   AEDataStorage scriptData
);
```

Parameters

scriptData

A handle to the script data.

Return Value
A result code. See "Result Codes" (page 2885).

Discussion
The OSARemoveStorageType function removes an existing trailer (reducing the handle's size). If no trailer can be found, then the handle is not modified, and noErr is returned.

Availability
Available in Mac OS X v10.0 and later.

Declared In
OSAComp.h

OSAScriptError

Gets information about errors that occur during script execution.

```
OSAError OSAScriptError (
   ComponentInstance scriptingComponent,
   OSType selector,
   DescType desiredType,
   AEDesc *resultingErrorDescription
);
```

Parameters

scriptingComponent
A component instance created by a prior call to the Component Manager function OpenDefaultComponent or OpenComponent.

selector
A value that determines what OSAScriptError returns. The value can be one of the constants described in "OSAScriptError Selectors" (page 2877).

desiredType
The desired descriptor type of the resulting descriptor record. The description that follows explains how this is determined by the value passed in the selector parameter.

resultingErrorDescription
On return, a pointer to the resulting descriptor record.

Return Value
A result code. See "Result Codes" (page 2885).

Discussion
Whenever the OSAExecute function returns the error errOSAScriptError, you can use the OSAScriptError function to get more specific information about the error from the scripting component that encountered it. (This information remains available only until the next call to the same scripting component.) The information returned by OSAScriptError depends on the value passed in the *selector* parameter, which also determines the descriptor type you should specify in the desiredType parameter.

Every scripting component should support calls to OSAScriptError that pass kOSAErrorNumber, kOSAErrorMessage, or kOSAErrorPartialResult in the *selector* parameter.

Some scripting components may also support calls that pass other values in the selector parameter, including kOSAErrorRange, which provides start and end positions delimiting the errant expression in the source data. If the value of the *selector* parameter is kOSAErrorRange, the value of *desiredType* must be typeOSAErrorRange.

If the value of the selector parameter is kOSAErrorNumber, scripting components may return, in the *resultingErrorDescription* parameter, one of the general error codes described in "Result Codes" (page 2885).

If you call OSAScriptError using an instance of the generic scripting component, the generic scripting component uses the same instance of a scripting component that it used for the previous call.

Availability
Available in Mac OS X v10.0 and later.

Declared In
OSA.h

OSAScriptingComponentName

Gets the name of a scripting component.

```
OSAError OSAScriptingComponentName (
   ComponentInstance scriptingComponent,
   AEDesc *resultingScriptingComponentName
);
```

Parameters

scriptingComponent
A component instance created by a prior call to the Component Manager function OpenDefaultComponent or OpenComponent.

resultingScriptingComponentName
On return, a pointer to the name of the scripting component; or, if the component is the generic scripting component, the name of the default scripting component.

Return Value
A result code. See "Result Codes" (page 2885).

Discussion
The OSAScriptingComponentName function returns a descriptor record that you can coerce to a text descriptor type such as typeChar. This can be useful if you want to display the name of the scripting language in which the user should write a new script.

Availability
Available in Mac OS X v10.0 and later.

Declared In
OSA.h

OSASetActiveProc

Sets the active function that a scripting component calls periodically while executing a script.

```
OSAError OSASetActiveProc (
   ComponentInstance scriptingComponent,
   OSAActiveUPP activeProc,
   SRefCon refCon
);
```

Parameters

scriptingComponent
A component instance created by a prior call to the Component Manager function OpenDefaultComponent or OpenComponent.

activeProc

A pointer to the active function to set. If the value of this parameter is `NULL`, `OSASetActiveProc` sets the scripting component's default active function.

refCon

A reference constant to be associated with the active function. This parameter can be used for many purposes; for example, it could contain a handle to data used by the active function.

Return Value
A result code. See "Result Codes" (page 2885).

Discussion
The `OSASetActiveProc` function allows your application to set a pointer to the active function called periodically by the scripting component during script execution. To get time periodically during script execution for its own purposes, your application can substitute its own active function for use by the scripting component. If you do not specify an active function, the scripting component uses its default active function, which allows a user to cancel script execution.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OSA.h`

OSASetCreateProc

Specifies a create function that a scripting component should use instead of the Apple Event Manager's `AECreateAppleEvent` function when creating Apple events.

```
OSAError OSASetCreateProc (
   ComponentInstance scriptingComponent,
   OSACreateAppleEventUPP createProc,
   SRefCon refCon
);
```

Parameters

scriptingComponent

A component instance created by a prior call to the Component Manager function `OpenDefaultComponent` or `OpenComponent`.

createProc

A universal procedure pointer to the create function to set.

refCon

A reference constant.

Return Value
A result code. See "Result Codes" (page 2885).

Discussion
To gain control over the creation and addressing of Apple events, your application can provide its own create function for use by scripting components. To set a new create function, call the `OSASetCreateProc` function; to get the current create function, call `OSAGetCreateProc`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
OSA.h

OSASetCurrentDialect

Sets the current dialect for a scripting component.

```
OSAError OSASetCurrentDialect (
   ComponentInstance scriptingComponent,
   short dialectCode
);
```

Parameters

scriptingComponent

A component instance created by a prior call to the Component Manager function OpenDefaultComponent or OpenComponent.

dialectCode

The code for the dialect to be set.

Return Value
A result code. See "Result Codes" (page 2885).

Availability
Available in Mac OS X v10.0 and later.

Declared In
OSA.h

OSASetDefaultScriptingComponent

Sets the default scripting component associated with an instance of the generic scripting component.

```
OSAError OSASetDefaultScriptingComponent (
   ComponentInstance genericScriptingComponent,
   ScriptingComponentSelector scriptingSubType
);
```

Parameters

genericScriptingComponent

A component instance for the generic scripting component, created by a prior call to the Component Manager function OpenDefaultComponent or OpenComponent.

scriptingSubType

The subtype code for the scripting component you want to set as the default.

Return Value
A result code. See "Result Codes" (page 2885).

Discussion
The OSASetDefaultScriptingComponent function sets the default scripting component for the specified instance of the generic scripting component to the scripting component identified by the *scriptingSubType* parameter.

Each instance of the generic scripting component has its own default scripting component, which is initially AppleScript. You can use `OSAGetDefaultScriptingComponent` to get the current default scripting component for an instance of the generic scripting component.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OSAGeneric.h`

OSASetDefaultTarget

Sets the default target application for Apple events.

```
OSAError OSASetDefaultTarget (
   ComponentInstance scriptingComponent,
   const AEAddressDesc *target
);
```

Parameters

`scriptingComponent`
A component instance created by a prior call to the Component Manager function `OpenDefaultComponent` or `OpenComponent`.

`target`
The address of the application that is being made the default application. If you pass a null descriptor record in this parameter, the scripting component treats the current process as the default target.

Return Value
A result code. See "Result Codes" (page 2885).

Discussion
Scripting components that support manipulation of the create and send functions also support the `OSASetDefaultTarget` function. The `OSASetDefaultTarget` function establishes the default target application for Apple event sending and the default application from which the scripting component should obtain terminology information. For example, AppleScript statements that refer to the default application do not need to be enclosed in `tell/end tell` statements.

If your application doesn't call this function, or if you pass a null descriptor record in the target parameter, the scripting component treats the current process (that is, the application that calls `OSAExecute` or related functions) as the default target application.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OSA.h`

OSASetHandler

Sets a specified script handler in the specified script to the supplied handler.

```
OSAError OSASetHandler (
   ComponentInstance scriptingComponent,
   SInt32 modeFlags,
   OSAID contextID,
   const AEDesc *handlerName,
   OSAID compiledScriptID
);
```

Parameters

scriptingComponent

Identifies the current scripting component. See the Component Manager documentation for a description of the `ComponentInstance` data type.

modeFlags

Information for use by the scripting component. Pass the value `kOSAModeDontDefine` to prevent a handler from being created if it doesn't already exist. Otherwise, pass `kOSAModeNull` to avoid setting mode flag values (no other flags are applicable for this function).

contextID

Specifies the script to set the script handler for. See `OSAID` (page 2855) for a description of the `OSAID` data type.

handlerName

A descriptor record that specifies the handler to set. The descriptor must be of type `typeChar`, or of a type that can be coerced to `typeChar`. If the handler does not already exist, it is created, unless you pass the value `kOSAModeDontDefine` for the `modeFlags` parameter. The handler name is case-sensitive and must exactly match the case of the handler name as supplied by the `OSAGetHandlerNames` function or the `OSAGetSource` (page 2830) function. See Apple Event Manager Reference for a description of the `AEDesc` data type.

compiledScriptID

The `OSAID` value to set the handler to, normally obtained by a previous call to `OSAGetHandler`. Any other value will return an error value of `errOSAInvalidID`. Note that a script compiled by `OSACompile` is not itself a handler. See the `OSAID` (page 2855) data type.

Return Value

A result code. See "Result Codes" (page 2885).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`ASDebugging.h`

OSASetProperty

Sets the value of a script property in a specified script, creating the property if it does not already exist.

```
OSAError OSASetProperty (
   ComponentInstance scriptingComponent,
   SInt32 modeFlags,
   OSAID contextID,
   const AEDesc *variableName,
   OSAID scriptValueID
);
```

Parameters

scriptingComponent

See the Component Manager documentation for a description of the `ComponentInstance` data type.

modeFlags

Information for use by the scripting component. Pass the value `kOSAModeDontDefine` to prevent a property from being created if it doesn't already exist in the specified script. Otherwise, pass `kOSAModeNull` to avoid setting mode flag values (no other flags are applicable for this function).

contextID

Specifies the script to set the script property for. See the `OSAID` (page 2855) data type.

variableName

A descriptor record that specifies the name of the property to set. The descriptor must be of type `typeChar`, or of a type that can be coerced to `typeChar`. The variable name is case-sensitive and must exactly match the case of the variable name as supplied by the `OSAGetPropertyNames` function or the `OSAGetSource` (page 2830) function. See Apple Event Manager Reference for a description of the `AEDesc` data type.

scriptValueID

A script ID whose associated data should be used to set the value for the property specified by `variableName`. Note that the value is specified by an `OSAID`, not an `AEDesc`. You can set a property to a value returned from script execution (from the `OSAExecute` function), extracted from another property (with the `OSAGetProperty` function), or converted from an `AEDesc` (by the `OSACoerceFromDesc` function). See the `OSAID` (page 2855) data type.

Return Value
A result code. See "Result Codes" (page 2885).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ASDebugging.h`

OSASetResumeDispatchProc

Sets the resume dispatch function called by a scripting component during execution of an AppleScript `continue` statement or its equivalent.

```
OSAError OSASetResumeDispatchProc (
   ComponentInstance scriptingComponent,
   AEEventHandlerUPP resumeDispatchProc,
   SRefCon refCon
);
```

Parameters

scriptingComponent

A component instance created by a prior call to the Component Manager function `OpenDefaultComponent` or `OpenComponent`.

resumeDispatchProc

A UPP to the resume dispatch function. You can specify one of the following in this parameter:

- a pointer to a resume dispatch function
- the `kOSAUseStandardDispatch` constant, which causes the Apple Event Manager to dispatch the event using standard Apple event dispatching (the handler registered in the application with AEInstallEventHandler is used)
- the `kOSANoDispatch` constant, which tells the Apple Event Manager that the processing of the Apple event is complete and that no dispatching should occur

refCon

A reference constant. You can pass the constant `kOSADontUsePhac` in this parameter, as described in the Discussion section below.

Return Value
A result code. See "Result Codes" (page 2885).

Discussion
The `OSASetResumeDispatchProc` function sets the resume dispatch function that the specified instance of a scripting component calls during execution of an AppleScript continue statement or its equivalent. The resume dispatch function should dispatch the event to the application's standard handler for that event.

If you are using a general handler for preliminary processing of Apple events, and if you can rely on standard Apple event dispatching to dispatch the event correctly, you don't need to provide a resume dispatch function. Instead, you can specify `kOSAUseStandardDispatch` as the value of the *resumeDispatchProc* parameter and the constant `kOSADontUsePhac` as the value of the *refCon* parameter. This causes the Apple Event Manager to use standard Apple event dispatching except that it bypasses your application's special handler dispatch table and thus won't call your predispatch Apple event handler recursively. (A predispatch handler is called immediately before the Apple Event Manager dispatches an event.)

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OSA.h`

OSASetScriptInfo

Sets information about script data according to the value you pass in the selector parameter.

```
OSAError OSASetScriptInfo (
   ComponentInstance scriptingComponent,
   OSAID scriptID,
   OSType selector,
   long value
);
```

Parameters

scriptingComponent

A component instance created by a prior call to the Component Manager function `OpenDefaultComponent` or `OpenComponent`.

scriptID

The script ID for the script data whose information is to be set. See the `OSAID` (page 2855) data type.

selector

A value that determines which information `OSASetScriptInfo` sets.

The value can be one of the constants described in "Script Information Selectors" (page 2880). For more information, see the Version Notes section below.

In Mac OS X, the AppleScript component does not set a value.

value

The value to set.

In Mac OS X, the AppleScript component does not set a value.

Return Value
A result code. See "Result Codes" (page 2885).

Version Notes
In Mac OS X, if you specify `kOSAScriptIsModified` for the value of the *selector* parameter, it is ignored, and no value is set.

The following information describes the behavior of `OSASetScriptInfo` in versions of the Mac OS prior to Mac OS X: The `OSASetScriptInfo` function sets script information according to the value you pass in the *selector* parameter. If you use the `kOSAScriptIsModified` constant, `OSASetScriptInfo` sets a value that indicates whether the script data has been modified since it was created or passed to `OSALoad`. Some scripting components may provide additional constants.

For related information, see the `OSAGetScriptInfo` (page 2827) function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OSA.h`

OSASetSendProc

Specifies a send function that a scripting component should use instead of the Apple Event Manger's `AESend` function when sending Apple events.

```
OSAError OSASetSendProc (
   ComponentInstance scriptingComponent,
   OSASendUPP sendProc,
   SRefCon refCon
);
```

Parameters

scriptingComponent

A component instance created by a prior call to the Component Manager function `OpenDefaultComponent` or `OpenComponent`.

sendProc

A universal procedure pointer (UPP) to the send function to set.

refCon

A reference constant.

Return Value
A result code. See "Result Codes" (page 2885).

Discussion
The send function provided by your application can perform almost any action instead of or in addition to sending Apple events; for example, it can be used to facilitate concurrent script execution. To set a new send function, call the `OSASetSendProc` function; to get the current send function, call `OSAGetSendProc`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OSA.h`

OSAStartRecording

Turns on Apple event recording and records subsequent Apple events in a compiled script.

```
OSAError OSAStartRecording (
   ComponentInstance scriptingComponent,
   OSAID *compiledScriptToModifyID
);
```

Parameters

scriptingComponent

A component instance created by a prior call to the Component Manager function `OpenDefaultComponent` or `OpenComponent`.

compiledScriptToModifyID

A pointer to the script ID for the compiled script in which to record. See the `OSAID` (page 2855) data type.

Return Value
A result code. See "Result Codes" (page 2885).

Discussion
The `OSAStartRecording` function turns on Apple event recording. Subsequent Apple events are recorded (that is, appended to any existing statements) in the compiled script specified by the *compiledScriptToModifyID* parameter. If the source data for the compiled script is currently displayed in a script editor's window, the script editor's handler for the Recorded Text event should display each new

statement in the window as it is recorded. Users should not be able to change a script that is open in a script editor window while it is being recorded into. Recording continues until a call to `OSAStopRecording` turns recording off.

To record into a new compiled script, pass the constant `kOSANullScript` in the *`compiledScriptToModifyID`* parameter. The scripting component should respond by creating a new compiled script and recording into that.

The generic scripting component uses its default scripting component to create and record into a new compiled script.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OSA.h`

OSAStopRecording

Turns off Apple event recording.

```
OSAError OSAStopRecording (
   ComponentInstance scriptingComponent,
   OSAID compiledScriptID
);
```

Parameters

`scriptingComponent`

A component instance created by a prior call to the Component Manager function `OpenDefaultComponent` or `OpenComponent`.

`compiledScriptID`

A script ID for the compiled script into which Apple events are being recorded. See the `OSAID` (page 2855) data type.

Return Value
A result code. See "Result Codes" (page 2885).

Discussion
The `OSAStopRecording` function turns off recording. If the script is not currently open in a script editor window, the *`compiledScriptToModifyID`* parameter supplied to `OSAStartRecording` is then augmented to contain the newly recorded statements. If the script is currently open in a script editor window, the script data that corresponds to the *`compiledScriptToModifyID`* parameter supplied to `OSAStartRecording` is updated continuously until the client application calls `OSAStopRecording`.

If the compiled script identified by the script ID in the *`compiledScriptID`* parameter is not being recorded into or recording is not currently on, `OSAStopRecording` returns `noErr`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OSA.h`

OSAStore

Gets a handle to script data in the form of a storage descriptor record.

```
OSAError OSAStore (
   ComponentInstance scriptingComponent,
   OSAID scriptID,
   DescType desiredType,
   SInt32 modeFlags,
   AEDesc *resultingScriptData
);
```

Parameters

scriptingComponent

A component instance created by a prior call to the Component Manager function `OpenDefaultComponent` or `OpenComponent`.

scriptID

The script ID for the script data for which to obtain a data handle.

desiredType

The desired type of the descriptor record to be returned. If you want to store the script data in the form used by a generic storage descriptor record, specify `typeOSAGenericStorage`.

modeFlags

Information used by individual scripting components. To avoid setting any mode flags, specify `kOSAModeNull`. To indicate that only the minimum script data required to run the script should be returned, pass `kOSAModePreventGetSource` in this parameter. (In this case the script data returned is not identical to the compiled script data and can't be used to generate source data.) If the `scriptID` parameter identifies a script context, you can pass `kOSAModeDontStoreParent` in this parameter to store the script context without storing its parent context.

resultingScriptData

On return, a pointer to the resulting descriptor record.

Return Value

A result code. See "Result Codes" (page 2885).

Discussion

The `OSAStore` function writes script data to a descriptor record so that the data can later be saved in a resource or written to the data fork of a document. You can then reload the data for the descriptor record as a compiled script (although possibly with a different script ID) by passing the descriptor record to `OSALoad`.

If you want the returned script data to be as small as possible and you are sure that you won't need to display the source data to the user, specify the `kOSAModePreventGetSource` flag in the `modeFlags` parameter. If the `scriptID` parameter identifies a script context and you don't want the returned script data to include the associated parent context, specify the `kOSAModeDontStoreParent` flag in the `modeFlags` parameter.

The desired type is either `typeOSAGenericStorage` (for a generic storage descriptor record) or a specific scripting component subtype value (for a component-specific storage descriptor record).

To store either a generic storage descriptor record or a component-specific storage descriptor record with your application's resources, use `'scpt'` as the resource type. The generic scripting component subtype, the generic storage descriptor type, and the resource type for stored script data all have the same value, though they serve different purposes.

Availability

Available in Mac OS X v10.0 and later.

Declared In
OSA.h

OSAStoreFile

Stores a script into the specified file.

```
OSAError OSAStoreFile (
   ComponentInstance scriptingComponent,
   OSAID scriptID,
   DescType desiredType,
   SInt32 modeFlags,
   const FSRef *scriptFile
);
```

Parameters

scriptingComponent
A component instance created by a prior call to the Component Manager function OpenDefaultComponent or OpenComponent. See the Component Manager documentation for a description of the ComponentInstance data type.

scriptID
Specifies the script to store. See the OSAID (page 2855) data type.

desiredType
Specifies how the script should be stored. The desired type is either typeOSAGenericStorage (for a generic storage descriptor record) or a specific scripting component subtype value (for a component-specific storage descriptor record).

modeFlags
Information used by individual scripting components. To avoid setting any mode flags, specify kOSAModeNull. To indicate that only the minimum script data required to run the script should be stored, pass kOSAModePreventGetSource in this parameter. (In this case the stored script data is not identical to the compiled script data and can't be used to generate source data.) If the scriptID parameter identifies a script context, you can pass kOSAModeDontStoreParent in this parameter to store the script context without storing its parent context.

scriptFile
Identifies the file to store the script into. See the File Manager documentation for a description of the FSRef data type.

Return Value
A result code. See "Result Codes" (page 2885).

Availability
Available in Mac OS X v10.3 and later.

Declared In
OSA.h

Callbacks

Your application can provide alternative active, send, and create functions for use by scripting components during script execution. All scripting components support routines that allow you to set and get the current active function called periodically by the scripting component during script execution. Some scripting components also support routines that allow you to set and get the current send and create functions used by the scripting component when it creates and sends Apple events during script execution.

OSAActiveProcPtr

Defines a pointer to an application-defined active function that performs periodic tasks during script compilation such as checking for Command-period, spinning the cursor, and checking for system-level errors.

```
typedef OSErr (*OSAActiveProcPtr) (
    long refCon
);
```

If you name your function `MyOSAActiveProc`, you would declare it like this:

```
OSErr MyOSAActiveProc (
    long refCon
);
```

Parameters

refCon

A reference constant.

Return Value

A result code. See "Result Codes" (page 2885).

Discussion

Every scripting component calls an active function periodically during script compilation and execution and provides routines that allow your application to set or get the pointer to the active function.

If you don't set an alternative active function for a scripting component, it uses its own default active function. A scripting component's default active function allows a user to cancel script execution by pressing Command-period and calls `WaitNextEvent` to give other processes time.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`OSA.h`

OSACreateAppleEventProcPtr

Defines a pointer to an application-defined create function that allows you to gain control over the creation and addressing of Apple events.

```
typedef OSErr (*OSACreateAppleEventProcPtr)
(
    AEEventClass theAEEventClass,
    AEEventID theAEEventID,
    const AEAddressDesc * target,
    short returnID,
    long transactionID,
    AppleEvent * result,
    long refCon
);
```

If you name your function `MyOSACreateAppleEventProc`, you would declare it like this:

```
OSErr MyOSACreateAppleEventProc (
    AEEventClass theAEEventClass,
    AEEventID theAEEventID,
    const AEAddressDesc * target,
    short returnID,
    long transactionID,
    AppleEvent * result,
    long refCon
);
```

Parameters

`theAEEventClass`

The event class of the Apple event to create.

`theAEEventID`

The event ID of the Apple event to create.

`target`

A pointer to an address descriptor. This descriptor identifies the target (or server) application for the Apple event.

`returnID`

The return ID for the created Apple event.

`transactionID`

The transaction ID for this Apple event. A transaction is a series of Apple events that are sent back and forth between the client and server applications, beginning with the client's initial request for a service. All Apple events that are part of a transaction must have the same transaction ID. The constant `kAnyTransactionID` specifies that the Apple event is not one of a series of interdependent Apple events.

`result`

A pointer to an Apple event. On successful return, this parameter should point to the new Apple event. On error, this should be a `NULL` descriptor.

`refCon`

A reference constant.

Return Value

A result code. See "Result Codes" (page 2885).

Discussion

Every scripting component calls a create function whenever it creates an Apple event during script execution and provides routines that allow you to set or get the pointer to the create function.

Providing your own create function can be useful, for example, if your application needs to add its own transaction code to the event. An alternative create function takes the same parameters as the `AECreateAppleEvent` function plus a reference constant.

If you don't set an alternative create function for a scripting component, it uses the standard Apple Event Manager function `AECreateAppleEvent`, which it calls with its own default parameters.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OSA.h`

OSASendProcPtr

Defines a pointer to an application-defined send function that performs almost any action instead of or in addition to sending Apple events.

```
typedef OSErr (*OSASendProcPtr) (
    const AppleEvent * theAppleEvent,
    AppleEvent * reply,
    AESendMode sendMode,
    AESendPriority sendPriority,
    long timeOutInTicks,
    AEIdleUPP idleProc,
    AEFilterUPP filterProc,
    long refCon
);
```

If you name your function `MyOSASendProc`, you would declare it like this:

```
OSErr MyOSASendProc (
    const AppleEvent * theAppleEvent,
    AppleEvent * reply,
    AESendMode sendMode,
    AESendPriority sendPriority,
    long timeOutInTicks,
    AEIdleUPP idleProc,
    AEFilterUPP filterProc,
    long refCon
);
```

Parameters

theAppleEvent
A pointer to the Apple event.

reply
A pointer to a reply Apple event.

sendMode
Specifies various options for how the Apple event should be handled.

sendPriority
A value that specifies the priority for processing the Apple event.

timeOutInTicks

If the reply mode specified in the *sendMode* parameter is `kAEWaitReply`, or if a return receipt is requested, this parameter specifies the length of time (in ticks) that the client application is willing to wait for the reply or return receipt before timing out. If this parameter is `kNoTimeOut`, the Apple event never times out.

idleProc

A universal procedure pointer to a function that handles events (such as update, operating-system, activate, and null events) received while waiting for a reply.

filterProc

A universal procedure pointer to a function that determines which incoming Apple events should be received while the handler waits for a reply or a return receipt. This parameter may be `NULL`.

refCon

A reference constant.

Return Value
A result code. See "Result Codes" (page 2885).

Discussion
Every scripting component calls a send function whenever it sends an Apple event during script execution and provides routines that allow you to set or get the pointer to the send function.

For example, before sending an Apple event, an alternative send function can modify the event or save a copy of the event. An alternative send function takes the same parameters as the `AESend` function plus a reference constant.

If you don't set an alternative send function for a scripting component, it uses the standard Apple Event Manager function `AESend`, which it calls with its own default parameters.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`OSA.h`

Data Types

OSAID

Used by a scripting component to keep track of script data in memory.

```
typedef unsigned long OSAID;
```

Discussion
A scripting component assigns a script ID when it creates the associated script data (that is, a compiled script, a script value, a script context, or other kinds of script data supported by a scripting component) or loads it into memory. The scripting routines that create, load, compile, and execute scripts all return script IDs, and your application must pass valid script IDs to the other routines that manipulate scripts. A script ID remains valid until a client application calls `OSADispose` to reclaim the memory used for the corresponding script data.

    kOSASupportsCompiling = 0x0002,
    kOSASupportsGetSource = 0x0004,
    kOSASupportsAECoercion = 0x0008,
    kOSASupportsAESending = 0x0010,
    kOSASupportsRecording = 0x0020,
    kOSASupportsConvenience = 0x0040,
    kOSASupportsDialects = 0x0080,
    kOSASupportsEventHandling = 0x0100
};
```

Constants

`kOSASupportsCompiling`
Set if the scripting component supports the functions described in "Compiling Scripts" (page 2778).
Available in Mac OS X v10.0 and later.
Declared in `OSA.h`.

`kOSASupportsGetSource`
Set if the scripting component supports the `OSAGetSource` function.
Available in Mac OS X v10.0 and later.
Declared in `OSA.h`.

`kOSASupportsAECoercion`
Set if the scripting component supports the `OSACoerceFromDesc` and `OSACoerceToDesc` functions.
Available in Mac OS X v10.0 and later.
Declared in `OSA.h`.

`kOSASupportsAESending`
Set if the scripting component supports the functions described in "Manipulating the Create and Send Functions" (page 2779).
Available in Mac OS X v10.0 and later.
Declared in `OSA.h`.

`kOSASupportsRecording`
Set if the scripting component supports the `OSAStartRecording` (page 2848)and `OSAStopRecording` (page 2849) functions.
Available in Mac OS X v10.0 and later.
Declared in `OSA.h`.

`kOSASupportsConvenience`
Set if the script component supports the `OSALoadExecute` (page 2833), `OSACompileExecute` (page 2800), and `OSADoScript` (page 2813) functions.
Available in Mac OS X v10.0 and later.
Declared in `OSA.h`.

`kOSASupportsDialects`
: Set if the scripting component supports the `OSASetCurrentDialect` (page 2842), `OSAGetCurrentDialect` (page 2821), `OSAAvailableDialectCodeList` (page 2796), `OSAGetDialectInfo` (page 2822), and `OSAAvailableDialects` (page 2797) functions.

Available in Mac OS X v10.0 and later.

Declared in `OSA.h`.

`kOSASupportsEventHandling`
: Set if the scripting component supports the event handling functions described in "Using Script Contexts to Handle Apple Events" (page 2781).

Available in Mac OS X v10.0 and later.

Declared in `OSA.h`.

Discussion
Your application can use the Component Manager to find a scripting component that supports a specific group of functions or to determine whether a particular scripting component supports a specific group of functions. Each of these flags identifies one of these groups of functions. To specify one or more groups of functions for the Component Manager, use these constants to set the equivalent bits in the `componentFlags` field of a component description record.

Declared In
`OSA.h`

Considerations Flags

```
enum {
  kAECase                       = 'case',
  kAEDiacritic                  = 'diac',
  kAEWhiteSpace                 = 'whit',
  kAEHyphens                    = 'hyph',
  kAEExpansion                  = 'expa',
  kAEPunctuation                = 'punc',
  kAEZenkakuHankaku             = 'zkhk',
  kAESmallKana                  = 'skna',
  kAEKataHiragana               = 'hika',
  kASConsiderReplies            = 'rmte',
  kASNumericStrings             = 'nume',
  enumConsiderations            = 'cons'
};
```

Constants
`kASNumericStrings`
: Should strings be considered as numbers?

Available in Mac OS X v10.4 and later.

Declared in `ASRegistry.h`.

Version Notes
The constant `kASNumericStrings` is available starting with Mac OS X version 10.4.

Declared In
`ASRegistry.h`

Considerations Bit Masks

Specify settings for string comparisons.

```
enum {
  kAECaseConsiderMask           = 0x00000001,
  kAEDiacriticConsiderMask      = 0x00000002,
  kAEWhiteSpaceConsiderMask     = 0x00000004,
  kAEHyphensConsiderMask        = 0x00000008,
  kAEExpansionConsiderMask      = 0x00000010,
  kAEPunctuationConsiderMask    = 0x00000020,
  kASConsiderRepliesConsiderMask = 0x00000040,
  kASNumericStringsConsiderMask = 0x00000080,
  kAECaseIgnoreMask             = 0x00010000,
  kAEDiacriticIgnoreMask        = 0x00020000,
  kAEWhiteSpaceIgnoreMask       = 0x00040000,
  kAEHyphensIgnoreMask          = 0x00080000,
  kAEExpansionIgnoreMask        = 0x00100000,
  kAEPunctuationIgnoreMask      = 0x00200000,
  kASConsiderRepliesIgnoreMask  = 0x00400000,
  kASNumericStringsIgnoreMask   = 0x00800000,
  enumConsidsAndIgnores         = 'csig'
};
```

Constants

`kASNumericStringsConsiderMask`

If bit at this position is set, consider strings to represent numerical values for comparison. For example, compare the string "1.01" as if it were the number 1.01.

Available in Mac OS X v10.4 and later.

Declared in `ASRegistry.h`.

`kASNumericStringsIgnoreMask`

If bit at this position is set, do not compare strings as numeric values.

Available in Mac OS X v10.4 and later.

Declared in `ASRegistry.h`.

Discussion

AppleScript has various settings for string comparisons, such as whether to consider or ignore capitalization. When your application receives an Apple event from AppleScript, it contains an attribute with the keyword `enumConsidsAndIgnores`. You can extract the consideration bit information from that attribute as `typeSInt32`, then use the bit masks in this enum to determine which considering and ignoring flags are currently set. You can use that information to conduct comparisons with the same criteria currently in use by AppleScript.

Version Notes

The constants `kASNumericStringsConsiderMask` and `kASNumericStringsIgnoreMask` are available starting with Mac OS X version 10.4.

Declared In

`ASRegistry.h`

cString

```
enum {
    cString = cStringClass
};
```

Current Dialect Constants

```
enum {
    kOSASelectSetCurrentDialect = 0x0701,
    kOSASelectGetCurrentDialect = 0x0702,
    kOSASelectAvailableDialects = 0x0703,
    kOSASelectGetDialectInfo = 0x0704,
    kOSASelectAvailableDialectCodeList = 0x0705
};
```

Discussion
AppleScript is designed so that scripts can be displayed in different dialects, which are representations of AppleScript that resemble human languages or programming languages. While dialects are supported, they are not particularly useful because no currently available OSA language supports dialects other than English.

Date and Time Constants

```
enum {
    pASWeekday = 'wkdy',
    pASMonth = 'mnth',
    pASDay = 'day ',
    pASYear = 'year',
    pASTime = 'time',
    pASDateString = 'dstr',
    pASTimeString = 'tstr',
    cMonth = pASMonth,
    cJanuary = 'jan ',
    cFebruary = 'feb ',
    cMarch = 'mar ',
    cApril = 'apr ',
    cMay = 'may ',
    cJune = 'jun ',
    cJuly = 'jul ',
    cAugust = 'aug ',
    cSeptember = 'sep ',
    cOctober = 'oct ',
    cNovember = 'nov ',
    cDecember = 'dec '
};
```

Default Initialization Values

Initialization constants passed to `ASInit` function.

```
enum {
    kASDefaultMinStackSize = 4 * 1024,
    kASDefaultPreferredStackSize = 16 * 1024,
    kASDefaultMaxStackSize = 16 * 1024,
    kASDefaultMinHeapSize = 4 * 1024,
    kASDefaultPreferredHeapSize = 16 * 1024,
    kASDefaultMaxHeapSize = 32L * 1024 * 1024
};
```

Constants

`kASDefaultMinStackSize`

Represents the default value for the minimum size for the portion of the application's heap used by the AppleScript component's application-specific stack.

Available in Mac OS X v10.0 and later.

Declared in `AppleScript.h`.

`kASDefaultPreferredStackSize`

Represents the default value for the preferred size for the portion of the application's heap used by the AppleScript component's application-specific stack.

Available in Mac OS X v10.0 and later.

Declared in `AppleScript.h`.

`kASDefaultMaxStackSize`

Represents the default value for the maximum size for the portion of the application's heap used by the AppleScript component's application-specific stack.

Available in Mac OS X v10.0 and later.

Declared in `AppleScript.h`.

`kASDefaultMinHeapSize`

Represents the default value for the minimum size for the portion of the application's heap used by the AppleScript component's application-specific heap. (See Version Notes section.)

Available in Mac OS X v10.0 and later.

Declared in `AppleScript.h`.

`kASDefaultPreferredHeapSize`

Represents the default value for the preferred size for the portion of the application's heap used by the AppleScript component's application-specific heap. (See Version Notes section.)

Available in Mac OS X v10.0 and later.

Declared in `AppleScript.h`.

`kASDefaultMaxHeapSize`

Represents the default value for the maximum size for the portion of the application's heap used by the AppleScript component's application-specific heap. (See Version Notes section.)

Available in Mac OS X v10.0 and later.

Declared in `AppleScript.h`.

Discussion

You can pass these constants to the `ASInit` (page 2788) function to use the default values when initializing the AppleScript component. These values are also used if `ASInit` is not called explicitly, or if any of `ASInit`'s parameters are zero.

Version Notes

Starting in Mac OS X version 10.5, heap size parameter values are ignored—AppleScript's heap will grow as large as needed.

Declared In
AppleScript.h

Dialect Descriptor Constants

Define the descriptor type and keywords for descriptor records describing the dialects supported by a scripting component.

```
enum {
    typeOSADialectInfo = 'difo',
    keyOSADialectName = 'dnam',
    keyOSADialectCode = 'dcod',
    keyOSADialectLangCode = 'dlcd',
    keyOSADialectScriptCode = 'dscd'
};
```

Constants

`typeOSADialectInfo`
The descriptor type for each item in list returned by `OSAAvailableDialects`.
Available in Mac OS X v10.0 and later.
Declared in `OSA.h`.

`keyOSADialectName`
Used with a descriptor record of any text type, such as type `typeChar`.
Available in Mac OS X v10.0 and later.
Declared in `OSA.h`.

`keyOSADialectCode`
Used with a descriptor record of type `typeShortInteger`.
Available in Mac OS X v10.0 and later.
Declared in `OSA.h`.

`keyOSADialectLangCode`
Used with a descriptor record of type `typeShortInteger`.
Available in Mac OS X v10.0 and later.
Declared in `OSA.h`.

`keyOSADialectScriptCode`
Used with a descriptor record of type `typeShortInteger`.
Available in Mac OS X v10.0 and later.
Declared in `OSA.h`.

Discussion
These constants define the descriptor type for each item in the list returned by `OSAAvailableDialects` and the keywords for descriptor records of that type. The keyword constants can also be used in the *`selector`* parameter of `OSAGetDialectInfo` to obtain information about the dialects supported by a scripting component.

Generic Scripting Component Selectors

```
enum {
    kGSSSelectGetDefaultScriptingComponent = 0x1001,
    kGSSSelectSetDefaultScriptingComponent = 0x1002,
    kGSSSelectGetScriptingComponent = 0x1003,
    kGSSSelectGetScriptingComponentFromStored = 0x1004,
    kGSSSelectGenericToRealID = 0x1005,
    kGSSSelectRealToGenericID = 0x1006,
    kGSSSelectOutOfRange = 0x1007
};
```

Global Properties

```
enum {
    pASIt = 'it  ',
    pASMe = 'me  ',
    pASResult = 'rslt',
    pASSpace = 'spac',
    pASReturn = 'ret ',
    pASTab = 'tab ',
    pASPi = 'pi  ',
    pASParent = 'pare',
    kASInitializeEventCode = 'init',
    pASPrintLength = 'prln',
    pASPrintDepth = 'prdp',
    pASTopLevelScript = 'ascr'
};
```

kASAdd

```
enum {
    kASAdd = '+   ',
    kASSubtract = '-   ',
    kASMultiply = '*   ',
    kASDivide = '/   ',
    kASQuotient = 'div ',
    kASRemainder = 'mod ',
    kASPower = '^   ',
    kASEqual = kAEEquals,
    kASNotEqual = '   ',
    kASGreaterThan = kAEGreaterThan,
    kASGreaterThanOrEqual = kAEGreaterThanEquals,
    kASLessThan = kAELessThan,
    kASLessThanOrEqual = kAELessThanEquals,
    kASComesBefore = 'cbfr',
    kASComesAfter = 'cafr',
    kASConcatenate = 'ccat',
    kASStartsWith = kAEBeginsWith,
    kASEndsWith = kAEEndsWith,
    kASContains = kAEContains
};
```

kASAnd

```
enum {
    kASAnd = kAEAND,
    kASOr = kAEOR,
    kASNot = kAENOT,
    kASNegate = 'neg ',
    keyASArg = 'arg '
};
```

kASErrorEventCode

```
enum {
    kASErrorEventCode = 'err ',
    kOSAErrorArgs = 'erra',
    keyAEErrorObject = 'erob',
    pLength = 'leng',
    pReverse = 'rvse',
    pRest = 'rest',
    pInherits = 'c@#^',
    pProperties = 'pALL',
    keyASUserRecordFields = 'usrf',
    typeUserRecordFields = typeAEList
};
```

kASStartLogEvent

```
enum {
    kASStartLogEvent = 'log1',
    kASStopLogEvent = 'log0',
    kASCommentEvent = 'cmnt'
};
```

kDialectBundleResType

```
enum {
    kDialectBundleResType = 'Dbdl',
    cConstant = typeEnumerated,
    cClassIdentifier = pClass,
    cObjectBeingExamined = typeObjectBeingExamined,
    cList = typeAEList,
    cSmallReal = typeSMFloat,
    cReal = typeFloat,
    cRecord = typeAERecord,
    cReference = cObjectSpecifier,
    cUndefined = 'undf',
    cMissingValue = 'msng',
    cSymbol = 'symb',
    cLinkedList = 'llst',
    cVector = 'vect',
    cEventIdentifier = 'evnt',
    cKeyIdentifier = 'kyid',
    cUserIdentifier = 'uid ',
```

```
    cPreposition = 'prep',
    cKeyForm = enumKeyForm,
    cScript = 'scpt',
    cHandler = 'hand',
    cProcedure = 'proc'
};
```

keyAETarget

```
enum {
    keyAETarget = 'targ',
    keySubjectAttr = 'subj',
    keyASReturning = 'Krtn',
    kASAppleScriptSuite = 'ascr',
    kASScriptEditorSuite = 'ToyS',
    kASTypeNamesSuite = 'tpnm',
    typeAETE = 'aete',
    typeAEUT = 'aeut',
    kGetAETE = 'gdte',
    kGetAEUT = 'gdut',
    kUpdateAEUT = 'udut',
    kUpdateAETE = 'udte',
    kCleanUpAEUT = 'cdut',
    kASComment = 'cmnt',
    kASLaunchEvent = 'noop',
    keyScszResource = 'scsz',
    typeScszResource = 'scsz',
    kASSubroutineEvent = 'psbr',
    keyASSubroutineName = 'snam',
    kASPrepositionalSubroutine = 'psbr',
    keyASPositionalArgs = 'parg'
};
```

keyAppHandledCoercion

```
enum {
    keyAppHandledCoercion = 'idas'
};
```

keyASPrepositionAt

```
enum {
    keyASPrepositionAt = 'at  ',
    keyASPrepositionIn = 'in  ',
    keyASPrepositionFrom = 'from',
    keyASPrepositionFor = 'for ',
    keyASPrepositionTo = 'to  ',
    keyASPrepositionThru = 'thru',
    keyASPrepositionThrough = 'thgh',
    keyASPrepositionBy = 'by  ',
    keyASPrepositionOn = 'on  ',
    keyASPrepositionInto = 'into',
    keyASPrepositionOnto = 'onto',
```

```
    keyASPrepositionBetween = 'btwn',
    keyASPrepositionAgainst = 'agst',
    keyASPrepositionOutOf = 'outo',
    keyASPrepositionInsteadOf = 'isto',
    keyASPrepositionAsideFrom = 'asdf',
    keyASPrepositionAround = 'arnd',
    keyASPrepositionBeside = 'bsid',
    keyASPrepositionBeneath = 'bnth',
    keyASPrepositionUnder = 'undr'
};
```

keyASPrepositionOver

```
enum {
    keyASPrepositionOver = 'over',
    keyASPrepositionAbove = 'abve',
    keyASPrepositionBelow = 'belw',
    keyASPrepositionApartFrom = 'aprt',
    keyASPrepositionGiven = 'givn',
    keyASPrepositionWith = 'with',
    keyASPrepositionWithout = 'wout',
    keyASPrepositionAbout = 'abou',
    keyASPrepositionSince = 'snce',
    keyASPrepositionUntil = 'till'
};
```

keyOSASourceEnd

Specifies the end of an error range.

```
enum {
    keyOSASourceEnd = 'srce'
};
```

Constants

`keyOSASourceEnd`

Field of a `typeOSAErrorRange` record of `typeShortInteger`. This field specifies the end of the error range.

Available in Mac OS X v10.0 and later.

Declared in `OSA.h`.

Declared In

`OSA.h`

keyOSASourceStart

Specifies the start of an error range.

```
enum {
    keyOSASourceStart = 'srcs'
};
```

Constants

`keyOSASourceStart`

Field of a `typeOSAErrorRange` record of `typeShortInteger`. This field specifies the start of the error range.

Available in Mac OS X v10.0 and later.

Declared in `OSA.h`.

Declared In

`OSA.h`

keyProcedureName

```
enum {
    keyProcedureName = 'dfnm',
    keyStatementRange = 'dfsr',
    keyLocalsNames = 'dfln',
    keyGlobalsNames = 'dfgn',
    keyParamsNames = 'dfpn'
};
```

keyProgramState

```
enum {
    keyProgramState = 'dsps'
};
```

kGenericComponentVersion

Specifies the generic component version.

```
enum {
    kGenericComponentVersion = 0x0100
};
```

Constants

`kGenericComponentVersion`

Indicates the component version this header file describes.

Available in Mac OS X v10.0 and later.

Declared in `OSAGeneric.h`.

Declared In

`OSAGeneric.h`

kOSAComponentType

Defines the Component Manager type code for components that support the standard scripting component routines.

```
enum {
    kOSAComponentType = 'osa '
};
```

Constants

`kOSAComponentType`

Specifies the standard OSA component type.

Available in Mac OS X v10.0 and later.

Declared in `OSA.h`.

Declared In

`OSA.h`

kOSAGenericScriptingComponentSubtype

Defines the subtype code for the generic scripting component.

```
enum {
    kOSAGenericScriptingComponentSubtype = 'scpt'
};
```

kOSAModeDontDefine

```
enum {
    kOSAModeDontDefine = 0x0001
};
```

Constants

`kOSAModeDontDefine`

This mode flag can be passed to `OSASetProperty` (page 2844) or `OSASetHandler` (page 2843) and will prevent properties or handlers from being defined in a context that doesn't already have bindings for them. An error is returned if a current binding doesn't already exist.

Available in Mac OS X v10.0 and later.

Declared in `ASDebugging.h`.

kOSANullScript

Defines a null script ID.

```
enum {
    kOSANullScript = 0
};
```

Discussion
If the execution of a script does not result in a value, `OSAExecute` returns the constant `kOSANullScript` as the script ID. If a client application passes `kOSANullScript` to the `OSAGetSource` function instead of a valid script ID, the scripting component should display a null source description (possibly an empty text string). If a client application passes `kOSANullScript` to `OSAStartRecording`, the scripting component creates a new compiled script for editing or recording.

kOSARecordedText

Defines the event code for the Recorded Text event.

```
enum {
    kOSARecordedText = 'recd'
};
```

kOSAScriptResourceType

Defines the resource type for stored script data.

```
enum {
    kOSAScriptResourceType = kOSAGenericScriptingComponentSubtype
};
```

Constants
`kOSAScriptResourceType`
Resource type for scripts.
Available in Mac OS X v10.0 and later.
Declared in `OSA.h`.

kOSASelectComponentSpecificStart

```
enum {
    kOSASelectComponentSpecificStart = 0x1001
};
```

Constants
`kOSASelectComponentSpecificStart`
Scripting component specific selectors are added beginning with this value.
Available in Mac OS X v10.0 and later.
Declared in `OSA.h`.

kOSASelectCopyScript

```
enum {
    kOSASelectCopyScript = 0x0105
};
```

kOSASuite

Defines the suite for the Recorded Text event.

```
enum {
    kOSASuite = 'ascr'
};
```

Mode Flags

Specify information used by the scripting component.

```
enum {
    kOSAModePreventGetSource = 0x00000001
};
enum {
    kOSAModeNeverInteract = kAENeverInteract,
    kOSAModeCanInteract = kAECanInteract,
    kOSAModeAlwaysInteract = kAEAlwaysInteract,
    kOSAModeDontReconnect = kAEDontReconnect
};
enum {
    kOSAModeCantSwitchLayer = 0x00000040
};
enum {
    kOSAModeDoRecord = 0x00001000
};
enum {
    kOSAModeCompileIntoContext = 0x00000002
};
enum {
    kOSAModeAugmentContext = 0x00000004
};
enum {
    kOSAModeDisplayForHumans = 0x00000008
};
enum {
    kOSAModeDontStoreParent = 0x00010000
};
enum {
    kOSAModeDispatchToDirectObject = 0x00020000
};
enum {
    kOSAModeDontGetDataForArguments = 0x00040000
};
enum {
kOSAModeFullyQualifyDescriptors = 0x00080000
};
```

Constants

`kOSAModePreventGetSource`

This mode flag may be passed to `OSALoad` (page 2832), `OSAStore` (page 2850), or `OSACompile` (page 2799) to instruct the scripting component to not retain the "source" of an expression. This will cause a call to `OSAGetSource` (page 2830) to return the error `errOSASourceNotAvailable` if used. However, some scripting components may not retain the source anyway. This is mainly used when either space efficiency is desired, or a script is to be "locked" so that its implementation may not be viewed.

Available in Mac OS X v10.0 and later.

Declared in `OSA.h`.

`kOSAModeNeverInteract`

This mode flag may be passed to the functions `OSACompile` (page 2799), `OSAExecute` (page 2816), `OSALoadExecute` (page 2833), `OSACompileExecute` (page 2800), `OSADoScriptFile` (page 2815), `OSAExecuteEvent` (page 2817), and `OSADoEvent` (page 2812) to indicate whether or not the script may interact with the user if necessary. Adds `kAENeverInteract` to the `sendMode` parameter of `AESend` for events sent when the script is executed.

Available in Mac OS X v10.0 and later.

Declared in `OSA.h`.

`kOSAModeCanInteract`

This mode flag may be passed to the functions `OSACompile` (page 2799), `OSAExecute` (page 2816), `OSALoadExecute` (page 2833), `OSACompileExecute` (page 2800), `OSADoScriptFile` (page 2815), `OSAExecuteEvent` (page 2817), and `OSADoEvent` (page 2812) to indicate whether or not the script may interact with the user. Adds `kAECanInteract` to the `sendMode` parameter of `AESend` for events sent when the script is executed.

Available in Mac OS X v10.0 and later.

Declared in `OSA.h`.

`kOSAModeAlwaysInteract`

This mode flag may be passed to the functions `OSACompile` (page 2799), `OSAExecute` (page 2816), `OSALoadExecute` (page 2833), `OSACompileExecute` (page 2800), `OSADoScriptFile` (page 2815), `OSAExecuteEvent` (page 2817), and `OSADoEvent` (page 2812) to indicate whether or not the script may interact with the user. Adds `kAEAlwaysInteract` to the `sendMode` parameter of `AESend` for events sent when the script is executed.

Available in Mac OS X v10.0 and later.

Declared in `OSA.h`.

`kOSAModeDontReconnect`

This mode flag may be passed to the functions `OSACompile` (page 2799), `OSAExecute` (page 2816), `OSALoadExecute` (page 2833), `OSACompileExecute` (page 2800), `OSADoScriptFile` (page 2815), `OSAExecuteEvent` (page 2817), and `OSADoEvent` (page 2812) to indicate whether or not the script may reconnect if necessary. Adds `kAEDontReconnect` to the `sendMode` parameter of `AESend` for events sent when the script is executed.

Available in Mac OS X v10.0 and later.

Declared in `OSA.h`.

`kOSAModeCantSwitchLayer`

This mode flag may be passed to the functions `OSACompile` (page 2799), `OSAExecute` (page 2816), `OSALoadExecute` (page 2833), `OSACompileExecute` (page 2800), `OSADoScriptFile` (page 2815), `OSAExecuteEvent` (page 2817), and `OSADoEvent` (page 2812) to indicate whether Apple events should be sent with the `kAECanSwitchLayer` mode flag sent. This flag is exactly the opposite of the Apple event flag `kAECanSwitchLayer`. This is to provide a more convenient default, such as not supplying any mode (see `kOSANullMode` in the "Null Mode Flags" (page 2877)) means to send events with `kAECanSwitchLayer`. Supplying the `kOSAModeCantSwitchLayer` mode flag will cause `AESend` to be called without `kAECanSwitchLayer`.

Available in Mac OS X v10.0 and later.

Declared in `OSA.h`.

`kOSAModeDoRecord`

This mode flag may be passed to the functions `OSACompile` (page 2799), `OSAExecute` (page 2816), `OSALoadExecute` (page 2833), `OSACompileExecute` (page 2800), `OSADoScriptFile` (page 2815), `OSAExecuteEvent` (page 2817), and `OSADoEvent` (page 2812) to indicate whether Apple events should be sent with the `kAEDontRecord` mode flag. This flag is exactly the opposite the Apple event flag `kAEDontRecord`. This is to provide a more convenient default, such as not supplying any mode (see `kOSANullMode` in the "Null Mode Flags" (page 2877)) means to send events with `kAEDontRecord`. Supplying the kOSAModeDoRecord mode flag will cause `AESend` to be called without `kAEDontRecord`.

Available in Mac OS X v10.0 and later.

Declared in `OSA.h`.

`kOSAModeCompileIntoContext`

This is a mode flag for `OSACompile` (page 2799) that indicates that a context should be created as the result of compilation. All handler definitions are inserted into the new context, and variables are initialized by evaluating their initial values in a null context (for example, they must be constant expressions).

Available in Mac OS X v10.0 and later.

Declared in `OSA.h`.

`kOSAModeAugmentContext`

This is a mode flag for `OSACompile` (page 2799) that indicates that the previous script ID (input to `OSACompile`) should be augmented with any new definitions in the `sourceData` parameter rather than replaced with a new script. This means that the previous script ID must designate a context. The presence of this flag causes the kOSAModeCompileIntoContext flag to be implicitly used, causing any new definitions to be initialized in a null context.

Available in Mac OS X v10.0 and later.

Declared in `OSA.h`.

`kOSAModeDisplayForHumans`

This mode flag may be passed to `OSADisplay` (page 2810) or `OSADoScriptFile` (page 2815) to indicate that output only need be human-readable, not re-compilable by `OSACompile` (page 2799). If used, output may be arbitrarily "beautified", for example, quotes may be left off of string values, and long lists may have ellipses.

Available in Mac OS X v10.0 and later.

Declared in `OSA.h`.

`kOSAModeDontStoreParent`

This mode flag may be passed to `OSAStore` (page 2850) in the case where the `scriptID` parameter is a context. This causes the context to be saved, but not the context's parent context. When the stored context is loaded back in, the parent will be `kOSANullMode` (see the "Null Mode Flags" (page 2877)).

Available in Mac OS X v10.0 and later.

Declared in `OSA.h`.

`kOSAModeDispatchToDirectObject`

This mode flag may be passed to `OSAExecuteEvent` (page 2817) to cause the event to be dispatched to the direct object of the event. The direct object (or subject attribute if the direct object is a non-object specifier) will be resolved, and the resulting script object will be the recipient of the message. The context argument to `OSAExecuteEvent` will serve as the root of the lookup/resolution process.

Available in Mac OS X v10.0 and later.

Declared in `OSA.h`.

`kOSAModeDontGetDataForArguments`

This mode flag may be passed to `OSAExecuteEvent` (page 2817) to indicate that components do not have to get the data of object specifier arguments.

Available in Mac OS X v10.0 and later.

Declared in `OSA.h`.

`kOSAModeFullyQualifyDescriptors`

This mode flag may be passed to `OSACoerceToDesc` (page 2798) to indicate that the resulting descriptor should be fully qualified (i.e. should include the root application reference).

Available in Mac OS X v10.3 and later.

Declared in `OSA.h`.

Null Mode Flags

Indicate a function's default mode settings are to be used.

```
enum {
    kOSANullMode = 0,
    kOSAModeNull = 0
};
```

OSADebugStepKind

```
typedef UInt32 OSADebugStepKind;
enum {
    eStepOver = 0,
    eStepIn = 1,
    eStepOut = 2,
    eRun = 3
};
```

OSAProgramState

```
typedef UInt32 OSAProgramState;
enum {
    eNotStarted = 0,
    eRunnable = 1,
    eRunning = 2,
    eStopped = 3,
    eTerminated = 4
};
```

OSAScriptError Selectors

Define selectors used to retrieve information about script errors from the `OSAScriptError` function.

```
enum {
    kOSAErrorNumber = keyErrorNumber
};
enum {
    kOSAErrorMessage = keyErrorString
};
enum {
    kOSAErrorBriefMessage = 'errb'
};
enum {
    kOSAErrorApp = 'erap'
};
enum {
    kOSAErrorPartialResult = 'ptlr'
};
enum {
    kOSAErrorOffendingObject = 'erob'
};
enum {
    kOSAErrorExpectedType = 'errt'
};
enum {
    kOSAErrorRange = 'erng'
};
```

Constants

`kOSAErrorNumber`

This selector is used to determine the error number of a script error. These error numbers may be either system error numbers, or error numbers that are scripting component specific. The value of `desiredType` must be `typeShortInteger`.

Available in Mac OS X v10.0 and later.

Declared in `OSA.h`.

`kOSAErrorMessage`

This selector is used to determine the full error message associated with the error number. It should include the name of the application which caused the error, as well as the specific error that occurred. This selector is sufficient for simple error reporting (but see kOSAErrorBriefMessage). The value of `desiredType` must be `typeChar` or another text descriptor type.

Available in Mac OS X v10.0 and later.

Declared in `OSA.h`.

`kOSAErrorBriefMessage`

This selector is used to determine a brief error message associated with the error number. This message should not mention the name of the application which caused the error, any partial results or offending object (see kOSAErrorApp, kOSAErrorPartialResult , and kOSAErrorOffendingObject). The value of `desiredType` must be `typeChar` or another text descriptor type.

Available in Mac OS X v10.0 and later.

Declared in `OSA.h`.

`kOSAErrorApp`

This selector is used to determine which application actually got the error (if it was the result of an `AESend`). The value of `desiredType` must be `typeProcessSerialNumber` (for the PSN) or a text descriptor type such as `typeChar` (for the name).

Available in Mac OS X v10.0 and later.

Declared in `OSA.h`.

`kOSAErrorPartialResult`
: This selector is used to determine any partial result returned by an operation. If an `AESend` call failed, but a partial result was returned, then the partial result may be returned as an `AEDesc`. The value of `desiredType` must be `typeBest` (for the best type) or `typeWildCard` (for the default type).

  Available in Mac OS X v10.0 and later.

  Declared in `OSA.h`.

`kOSAErrorOffendingObject`
: This selector is used to determine any object which caused the error that may have been indicated by an application. The result is an `AEDesc`. The value of `desiredType` must be `typeObjectSpecifier`, `typeBest`, or `typeWildCard`. For some scripting components, including AppleScript, these three values are equivalent.

  Available in Mac OS X v10.0 and later.

  Declared in `OSA.h`.

`kOSAErrorRange`
: This selector is used to determine the source text range (start and end positions) of where the error occurred. The value of `desiredType` must be `typeOSAErrorRange`.

  Available in Mac OS X v10.0 and later.

  Declared in `OSA.h`.

`kOSAErrorExpectedType`
: This selector is used to determine the type expected by a coercion operation if a type error occurred.

  Available in Mac OS X v10.0 and later.

  Declared in `OSA.h`.

Recording Constants

```
enum {
    kOSASelectStartRecording = 0x0501,
    kOSASelectStopRecording = 0x0502
};
```

Resume Dispatch Function Constants

Define constants used with the `OSASetResumeDispatchProc` function.

```
enum {
    kOSAUseStandardDispatch = kAEUseStandardDispatch
};
enum {
    kOSANoDispatch = kAENoDispatch
};
enum {
    kOSADontUsePhac = 0x0001
};
```

Constants

`kOSAUseStandardDispatch`
Used in the `resumeDispatchProc` parameter of `OSASetResumeDispatchProc` (page 2845) and `OSAGetResumeDispatchProc` (page 2826) to indicate that the event is dispatched using standard Apple event dispatching (the handler registered in the application with `AEInstallEventHandler` should be used).

Available in Mac OS X v10.0 and later.

Declared in `OSA.h`.

`kOSANoDispatch`
Used in the `resumeDispatchProc` parameter of `OSASetResumeDispatchProc` (page 2845) to tell the Apple Event Manager that the processing of the Apple event is complete and that no dispatching should occur.

Available in Mac OS X v10.0 and later.

Declared in `OSA.h`.

`kOSADontUsePhac`
Used in the `refCon` parameter of `OSASetResumeDispatchProc` (page 2845) to dispatch the event using standard Apple event dispatching, except that the predispatch handler should not be called. Used only in conjunction with `kOSAUseStandardDispatch`. This is useful when the predispatch handler is used to lookup a context associated with an event's direct parameter and call `OSAExecuteEvent` (page 2817) or `OSADoEvent` (page 2812). Failure to bypass the predispatch handler when resuming an event in this case would result in an infinite loop. (A predispatch handler is called immediately before the Apple Event Manager dispatches an event.)

Available in Mac OS X v10.0 and later.

Declared in `OSA.h`.

Declared In
`OSA.h`

Script Document File Type

Defines the file type of script document files.

```
enum {
    kOSAFileType = 'osas'
};
```

Script Information Selectors

Specify which script information is set or returned.

```
enum {
    kOSAScriptIsModified = 'modi'
};
enum {
    kOSAScriptIsTypeCompiledScript = 'cscr'
};
enum {
    kOSAScriptIsTypeScriptValue = 'valu'
};
enum {
    kOSAScriptIsTypeScriptContext = 'cntx'
};
enum {
    kOSAScriptBestType = 'best'
};
enum {
    kOSACanGetSource = 'gsrc'
};
enum {
    kASHasOpenHandler = 'hsod'
};
```

Constants

`kOSAScriptIsModified`
This selector is used to determine whether there have been any changes since the script data was loaded or created. In Mac OS X, the AppleScript component returns a value of `false` if no changes have been made, and a value of `true` if changes may have been made. For more information, see the Version Notes section for the `OSAGetScriptInfo` (page 2827) function.

Available in Mac OS X v10.0 and later.

Declared in `OSA.h`.

`kOSAScriptIsTypeCompiledScript`
This selector is used to determine whether or not the script data is a compiled script. The selector returns a boolean.

Available in Mac OS X v10.0 and later.

Declared in `OSA.h`.

`kOSAScriptIsTypeScriptValue`
This selector is used to determine whether or not the script data is a script value. The selector returns a boolean.

Available in Mac OS X v10.0 and later.

Declared in `OSA.h`.

`kOSAScriptIsTypeScriptContext`
This selector is used to determine whether or not the script data is a script context. The selector returns a boolean.

Available in Mac OS X v10.0 and later.

Declared in `OSA.h`.

`kOSAScriptBestType`
A descriptor type that you can pass to `OSACoerceToDesc`.

Available in Mac OS X v10.0 and later.

Declared in `OSA.h`.

`kOSACanGetSource`
: This selector is used to determine whether a script has source associated with it that when given to `OSAGetSource`, the call will not fail. The selector returns a boolean.

  Available in Mac OS X v10.0 and later.

  Declared in `OSA.h`.

`kASHasOpenHandler`
: This selector is used to query a context as to whether it contains a handler for the `kAEOpenDocuments` event. This allows "applets" to be distinguished from "droplets." `OSAGetScriptInfo` (page 2827) returns false if there is no `kAEOpenDocuments` handler, and returns the error value `errOSAInvalidAccess` if the input is not a context.

  Available in Mac OS X v10.0 and later.

  Declared in `AppleScript.h`.

Source Constants

```
enum {
    kOSASelectGetSource = 0x0201
};
```

Source Style Constants

Identify script format styles used by the AppleScript component to display scripts.

```
enum {
    kASSourceStyleUncompiledText = 0,
    kASSourceStyleNormalText = 1,
    kASSourceStyleLanguageKeyword = 2,
    kASSourceStyleApplicationKeyword = 3,
    kASSourceStyleComment = 4,
    kASSourceStyleLiteral = 5,
    kASSourceStyleUserSymbol = 6,
    kASSourceStyleObjectSpecifier = 7,
    kASNumberOfSourceStyles = 8
};
```

Constants

`kASSourceStyleUncompiledText`
: Script format style for uncompiled text.

  Available in Mac OS X v10.0 and later.

  Declared in `AppleScript.h`.

`kASSourceStyleNormalText`
: Script format style for normal text.

  Available in Mac OS X v10.0 and later.

  Declared in `AppleScript.h`.

`kASSourceStyleLanguageKeyword`
: Script format style for keywords of the AppleScript Language.

  Available in Mac OS X v10.0 and later.

  Declared in `AppleScript.h`.

`kASSourceStyleApplicationKeyword`
Script format style for keywords of a scriptable application.

Available in Mac OS X v10.0 and later.

Declared in `AppleScript.h`.

`kASSourceStyleComment`
Script format style for comment text.

Available in Mac OS X v10.0 and later.

Declared in `AppleScript.h`.

`kASSourceStyleLiteral`
Script format style for literal text.

Available in Mac OS X v10.0 and later.

Declared in `AppleScript.h`.

`kASSourceStyleUserSymbol`
A user-defined symbol, such as a variable or custom handler name.

Available in Mac OS X v10.0 and later.

Declared in `AppleScript.h`.

`kASSourceStyleObjectSpecifier`
Deprecated.

Available in Mac OS X v10.0 and later.

Declared in `AppleScript.h`.

`kASNumberOfSourceStyles`
Deprecated. (The number of different format styles available.)

See the Discussion section for why you should not use this constant.

Available in Mac OS X v10.0 and later.

Declared in `AppleScript.h`.

Discussion
These constants are used to access specific styles in the style information used by the `ASCopySourceAttributes` (page 2785), `ASSetSourceAttributes` (page 2791), and `ASGetSourceStyleNames` (page 2787) functions (and the deprecated functions `ASGetSourceStyles` (page 2788) and `ASSetSourceStyles` (page 2792)).

The order of the style information corresponds to the order of the constants. For example, the first dictionary in the array returned by `ASCopySourceAttributes` (page 2785) (at position `kASSourceStyleUncompiledText`) describes the style for uncompiled text. However, you should not rely on there being any specific number of dictionaries (such as `kASNumberOfSourceStyles`) in the returned array—instead, count the number of items in the array before accessing any of them.

Declared In
`AppleScript.h`

typeAppleScript

Define descriptor types for the AppleScript instance of the Open Scripting Architecture type.

```
enum {
    typeAppleScript = 'ascr',
    kAppleScriptSubtype = typeAppleScript,
    typeASStorage = typeAppleScript
};
```

Constants

`kAppleScriptSubtype`

Defines the Component Manager subtype for the AppleScript component.

Available in Mac OS X v10.0 and later.

Declared in `AppleScript.h`.

`typeASStorage`

Defines the AppleScript constant for storage descriptor records.

Available in Mac OS X v10.0 and later.

Declared in `AppleScript.h`.

typeOSAErrorRange

Defines the descriptor type for an error range.

```
enum {
    typeOSAErrorRange = 'erng'
};
```

typeOSAGenericStorage

Defines the descriptor type for generic storage descriptor records.

```
enum {
    typeOSAGenericStorage = kOSAScriptResourceType
};
```

Constants

`typeOSAGenericStorage`

Default type given to `OSAStore` (page 2850), which creates "generic" loadable script data descriptors.

Available in Mac OS X v10.0 and later.

Declared in `OSA.h`.

Declared In

`OSA.h`

typeStatementRange

```
enum {
    typeStatementRange = 'srng'
};
```

Weekdays

```
enum {
    cWeekday = pASWeekday,
    cSunday = 'sun ',
    cMonday = 'mon ',
    cTuesday = 'tue ',
    cWednesday = 'wed ',
    cThursday = 'thu ',
    cFriday = 'fri ',
    cSaturday = 'sat ',
    pASQuote = 'quot',
    pASSeconds = 'secs',
    pASMinutes = 'min ',
    pASHours = 'hour',
    pASDays = 'days',
    pASWeeks = 'week',
    cWritingCodeInfo = 'citl',
    pScriptCode = 'pscd',
    pLangCode = 'plcd',
    kASMagicTellEvent = 'tell',
    kASMagicEndTellEvent = 'tend'
};
```

Result Codes

The most common result codes returned by Open Scripting Architecture are listed in Table 1-1. Open Scripting Architecture may also return the result codes `noErr` (0), and `badComponentInstance` (-2147450879).

Result Code	Value	Description
`errOSACantCoerce`	-1700	A value can't be coerced to the desired type. Available in Mac OS X v10.0 and later.
`OSAMissingParameter`	-1701	A parameter is missing for a function invocation. Available in Mac OS X v10.0 and later.
`errOSACorruptData`	-1702	Some data could not be read. Available in Mac OS X v10.0 and later.
`errOSATypeError`	-1703	Same as `errAEWrongDataType`; wrong descriptor type. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
`OSAMessageNotUnderstood`	-1708	A message was sent to an object that didn't handle it. Available in Mac OS X v10.0 and later.
`OSAUndefinedHandler`	-1717	A function to be returned doesn't exist. Available in Mac OS X v10.0 and later.
`OSAIllegalIndex`	-1719	An index was out of range. Specialization of `errOSACantAccess`. Available in Mac OS X v10.0 and later.
`OSAIllegalRange`	-1720	The specified range is illegal. Specialization of `errOSACantAccess`. Available in Mac OS X v10.0 and later.
`OSAParameterMismatch`	-1721	The wrong number of parameters were passed to the function, or a parameter pattern cannot be matched. Available in Mac OS X v10.0 and later.
`OSAIllegalAccess`	-1723	A container can not have the requested object. Available in Mac OS X v10.0 and later.
`errOSACantAccess`	-1728	An object is not found in a container. Available in Mac OS X v10.0 and later.
`errOSARecordingIsAlreadyOn`	-1732	Recording is already on. Available in Mac OS X v10.0 and later.
`errOSASystemError`	-1750	Scripting component error. Available in Mac OS X v10.0 and later.
`errOSAInvalidID`	-1751	Invalid script id. Available in Mac OS X v10.0 and later.
`errOSABadStorageType`	-1752	Script doesn't seem to belong to AppleScript. Available in Mac OS X v10.0 and later.
`errOSAScriptError`	-1753	Script error. Available in Mac OS X v10.0 and later.
`errOSABadSelector`	-1754	Invalid selector given. Available in Mac OS X v10.0 and later.
`errOSASourceNotAvailable`	-1756	Invalid access. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
errOSANoSuchDialect	-1757	Source not available. Available in Mac OS X v10.0 and later.
errOSADataFormatObsolete	-1758	No such dialect. Available in Mac OS X v10.0 and later.
errOSADataFormatTooNew	-1759	Data couldn't be read because its format is obsolete. Available in Mac OS X v10.0 and later.
errOSAComponentMismatch	-1761	Parameters are from two different components. Available in Mac OS X v10.0 and later.
errOSACantOpenComponent	-1762	Can't connect to system with that ID. Available in Mac OS X v10.0 and later.
errOSAGeneralError	-2700	No actual error code is to be returned. Available in Mac OS X v10.0 and later.
errOSADivideByZero	-2701	An attempt to divide by zero was made. Available in Mac OS X v10.0 and later.
errOSANumericOverflow	-2702	An integer or real value is too large to be represented. Available in Mac OS X v10.0 and later.
errOSACantLaunch	-2703	An application can't be launched, or when it is, remote and program linking is not enabled. Available in Mac OS X v10.0 and later.
errOSAAppNotHighLevelEventAware	-2704	An application can't respond to Apple events. Available in Mac OS X v10.0 and later.
errOSACorruptTerminology	-2705	An application's terminology resource is not readable. Available in Mac OS X v10.0 and later.
errOSAStackOverflow	-2706	The runtime stack overflowed. Available in Mac OS X v10.0 and later.
errOSAInternalTableOverflow	-2707	A runtime internal data structure overflowed. Available in Mac OS X v10.0 and later.
errOSADataBlockTooLarge	-2708	An intrinsic limitation is exceeded for the size of a value or data structure. Available in Mac OS X v10.0 and later.
errOSACantGetTerminology	-2709	Can't get the event dictionary. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
errOSACantCreate	-2710	Can't make class <class identifier>. Available in Mac OS X v10.0 and later.
OSASyntaxError	-2740	A syntax error occurred. Available in Mac OS X v10.0 and later.
OSASyntaxTypeError	-2741	Another form of syntax was expected. Available in Mac OS X v10.0 and later.
OSATokenTooLong	-2742	A name or number is too long to be parsed. Available in Mac OS X v10.0 and later.
OSADuplicateParameter	-2750	A formal parameter, local variable, or instance variable is specified more than once. Available in Mac OS X v10.0 and later.
OSADuplicateProperty	-2751	A formal parameter, local variable, or instance variable is specified more than once. Available in Mac OS X v10.0 and later.
OSADuplicateHandler	-2752	More than one handler is defined with the same name in a scope where the language doesn't allow it. Available in Mac OS X v10.0 and later.
OSAUndefinedVariable	-2753	A variable is accessed that has no value. Available in Mac OS X v10.0 and later.
OSAInconsistentDeclarations	-2754	A variable is declared inconsistently in the same scope, such as both local and global. Available in Mac OS X v10.0 and later.
OSAControlFlowError	-2755	An illegal control flow occurs in an application. For example, there is no catcher for the throw, or there was a non-lexical loop exit. Available in Mac OS X v10.0 and later.
OSAIllegalAssign	-10003	An object can never be set in a container Available in Mac OS X v10.0 and later.
errOSACantAssign	-10006	An object cannot be set in a container. Available in Mac OS X v10.0 and later.

Printing Plug-in Interfaces Reference

Framework:	ApplicationServices/ApplicationServices.h, Carbon/Carbon.h
Declared in	PMIOModule.h PMPluginHeader.h PMPrinterBrowsers.h PMPrinterModule.h PMPrintingDialogExtensions.h

Overview

As printer vendors and application developers extend the printing capabilities of their hardware and software products, they need a way to extend the Mac OS X printing system to make new printing features available to their customers. To address this need, Mac OS X has introduced the **printing plug-in** —a component architecture based on Core Foundation Plug-in Services. There are four types of printing plug-ins in Mac OS X:

- **I/O modules** are used by the printing system to communicate with a printer using a standard transport-layer interface, such as AppleTalk or TCP/IP.
- **Printer browsers** provide a way for people to discover available local and network printers.
- **Printer modules** are used by the printing system to convert the graphics content in a print job for output to a specific printer or family of printers.
- **Printing dialog extensions** provide a way for people to view and change the settings for a set of related printing features. The user interface of a printing dialog extension is a pane in one of the printing dialogs.

This reference document is relevant for anyone writing a plug-in that provides support for printing.

If you're writing a printing dialog extension, you should refer to this document as you implement the required callback functions. For conceptual information about printing dialog extensions, see *Extending Printing Dialogs*.

Functions

PMCreateLocalizedPaperSizeCFString

Returns a text description of the physical dimensions of the paper specified in a paper information ticket. The unit of measure is based on the current language and script system.

```
CFStringRef PMCreateLocalizedPaperSizeCFString (
   PMTicketRef listofPaperTickets,
   UInt16 paperToUse
);
```

Parameters

listofPaperTickets

A ticket that contains a list of paper information tickets. Typically you would obtain this list ticket from a printer module template ticket.

paperToUse

A one-based index that specifies an entry in a list ticket.Upon entering, this parameter should specify a valid entry in `listofPaperTickets`.

Return Value

A text description of the physical dimensions of the paper specified in a paper information ticket. Numeric values are localized to English or metric measure, based on the current language and script system. The caller assumes ownership of the string and is responsible for releasing it. The return value `NULL` indicates that the function failed to create the string.

Discussion

The name `PMCreateLocalizedPaperSizeCFString` suggests that this function does some additional localization, but that is misleading. This function takes an array of paper information tickets and an index, finds the desired paper information ticket, and simply calls `PMCreatePaperSizeCFString` to get the physical paper size.

Availability

Available in Mac OS X version 10.0 and later.

Not available to 64-bit applications.

Declared In

`PMPrintingDialogExtensionsDeprecated.h`

PMCreatePaperSizeCFString

Returns a text description of the physical dimensions of the paper specified in a paper information ticket. The unit of measure is based on the current language and script system.

```
CFStringRef PMCreatePaperSizeCFString (
   PMTicketRef selectedPaper
);
```

Parameters

selectedPaper

A paper information ticket. Typically you would obtain this ticket from a page format ticket, or possibly from a printer module template ticket.

Return Value

A text description of the physical dimensions of the paper specified in a paper information ticket. Numeric values are localized to English or metric measure, based on the current language and script system. The caller assumes ownership of the string, and is responsible for releasing it. The return value `NULL` indicates that the function failed to create the string.

Availability

Available in Mac OS X version 10.0 and later.

Not available to 64-bit applications.

Declared In
`PMPrintingDialogExtensionsDeprecated.h`

Callbacks by Task

Printing Plug-in Callbacks

The three callback functions described in this section are used by the printing system to manage a printing plug-in after it is loaded. Printing plug-ins (except for printer browsers) are required to implement these functions.

`PMPluginRetainProcPtr` (page 2916)

`PMPluginReleaseProcPtr` (page 2915)
Defines a pointer to the retain function in a printing plug-in interface. Your custom retain function increments the reference count of an instance of one of these interfaces.

`PMPluginGetAPIVersionProcPtr` (page 2915)

Printing Dialog Extension Callbacks

The callback functions described in this section must be implemented by all printing dialog extensions.

`PMPDEPrologueProcPtr` (page 2911)

`PMPDEInitializeProcPtr` (page 2909)

`PMPDESyncProcPtr` (page 2913)

`PMPDEGetSummaryTextProcPtr` (page 2908)

`PMPDEOpenProcPtr` (page 2911)

`PMPDECloseProcPtr` (page 2908)

`PMPDETerminateProcPtr` (page 2914)

Printer Module Callbacks

The callback functions described in this section must be implemented by all printer modules.

PMPrintJobProcPtr (page 2921)

PMPrintPageProcPtr (page 2921)

PMTerminateProcPtr (page 2922)

Printer Browser Module Callbacks

The callback functions described in this section must be implemented by all printer browser modules.

PMCOMAddRefProcPtr (page 2895)

PMCOMQueryInterfaceProcPtr (page 2896)

PMCOMReleaseProcPtr (page 2896)

PMPrBrowserAPIVersionProcPtr (page 2916)

PMPrBrowserGetLookupSpecProcPtr (page 2916)

PMPrBrowserGetSelectedPrintersProcPtr (page 2917)

PMPrBrowserInitializeProcPtr (page 2917)

PMPrBrowserPrologueProcPtr (page 2918)

PMPrBrowserResizeProcPtr (page 2918)

PMPrBrowserSelectionStatusProcPtr (page 2919)

PMPrBrowserSyncProcPtr (page 2919)

PMPrBrowserSyncRequestProcPtr (page 2920)

PMPrBrowserTerminateProcPtr (page 2920)

PMPrBrowserWorksetPrintersProcPtr (page 2920)

I/O Module Callbacks

The callback functions described in this section must be implemented by all I/O modules.

Callbacks

GetConnInfoProcPtr

```
typedef OSStatus(* GetConnInfoProcPtr) (
    const void *jobContext,
    CFStringRef *connectionType,
    CFStringRef *pbmPath
);
```

If you name your function `MyGetConnInfoCallback`, you would declare it like this:

```
OSStatus MyGetConnInfoCallback (
   const void *jobContext,
   CFStringRef *connectionType,
   CFStringRef *pbmPath
);
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`PMPrinterModuleDeprecated.h`

PMBeginJobProcPtr

```
typedef OSStatus(* PMBeginJobProcPtr) (
    PMContext printerModuleContext,
    const void *jobContext,
    PMTicketRef jobTicket,
    PMTicketRef *converterSetup
);
```

If you name your function `MyPMBeginJobCallback`, you would declare it like this:

```
OSStatus MyPMBeginJobCallback (
   PMContext printerModuleContext,
   const void *jobContext,
   PMTicketRef jobTicket,
   PMTicketRef *converterSetup
);
```

PMCancelJobProcPtr

```
typedef OSStatus(* PMCancelJobProcPtr) (
    PMContext printerModuleContext,
    const void *jobContext
);
```

If you name your function `MyPMCancelJobCallback`, you would declare it like this:

```
OSStatus MyPMCancelJobCallback (
   PMContext printerModuleContext,
   const void *jobContext
);
```

PMCOMAddRefProcPtr

```
typedef UInt32(* PMCOMAddRefProcPtr) (
    void *thisPointer
);
```

If you name your function `MyPMCOMAddRefCallback`, you would declare it like this:

```
UInt32 MyPMCOMAddRefCallback (
void *thisPointer
);
```

PMCOMQueryInterfaceProcPtr

```
typedef SInt32(* PMCOMQueryInterfaceProcPtr) (
    void *thisPointer,
    CFUUIDBytes iid,
    void **ppv
);
```

If you name your function `MyPMCOMQueryInterfaceCallback`, you would declare it like this:

```
SInt32 MyPMCOMQueryInterfaceCallback (
void *thisPointer,
CFUUIDBytes iid,
void **ppv
);
```

PMCOMReleaseProcPtr

```
typedef UInt32(* PMCOMReleaseProcPtr) (
    void *thisPointer
);
```

If you name your function `MyPMCOMReleaseCallback`, you would declare it like this:

```
UInt32 MyPMCOMReleaseCallback (
void *thisPointer
);
```

PMCreatePrinterBrowserModuleInfoProcPtr

```
typedef OSStatus(* PMCreatePrinterBrowserModuleInfoProcPtr) (
    CFStringRef connectionType,
    CFArrayRef *printerBrowserInfo
);
```

If you name your function `MyPMCreatePrinterBrowserModuleInfoCallback`, you would declare it like this:

```
OSStatus MyPMCreatePrinterBrowserModuleInfoCallback (
   CFStringRef connectionType,
   CFArrayRef *printerBrowserInfo
);
```

PMCreatePrinterTicketsProcPtr

```
typedef OSStatus(* PMCreatePrinterTicketsProcPtr) (
    PMContext printerModuleContext,
    PMTicketRef *printerInfo,
    PMTemplateRef *jobTemplate
);
```

If you name your function `MyPMCreatePrinterTicketsCallback`, you would declare it like this:

```
OSStatus MyPMCreatePrinterTicketsCallback (
   PMContext printerModuleContext,
   PMTicketRef *printerInfo,
   PMTemplateRef *jobTemplate
);
```

PMCreatePrintingDialogExtensionsPathsProcPtr

```
typedef OSStatus(* PMCreatePrintingDialogExtensionsPathsProcPtr)  (
    PMContext printerModuleContext,
    CFArrayRef *pdePaths
);
```

If you name your function `MyPMCreatePrintingDialogExtensionsPathsCallback`, you would declare it like this:

```
OSStatus MyPMCreatePrintingDialogExtensionsPathsCallback (
   PMContext printerModuleContext,
   CFArrayRef *pdePaths
);
```

PMEndJobProcPtr

```
typedef OSStatus(* PMEndJobProcPtr) (
    PMContext printerModuleContext,
    const void *jobContext
);
```

If you name your function `MyPMEndJobCallback`, you would declare it like this:

```
OSStatus MyPMEndJobCallback (
   PMContext printerModuleContext,
   const void *jobContext
);
```

PMImageAccessProcPtr

```
typedef OSStatus(* PMImageAccessProcPtr) (
    PMContext printerModuleContext,
    const void *jobContext,
    CFStringRef grafBase,
    PMDrawingCtx drawingCtx,
    PMImageRef imageRef,
    PMImageRef *outImageRefPtr
);
```

If you name your function `MyPMImageAccessCallback`, you would declare it like this:

```
OSStatus MyPMImageAccessCallback (
   PMContext printerModuleContext,
   const void *jobContext,
   CFStringRef grafBase,
   PMDrawingCtx drawingCtx,
   PMImageRef imageRef,
   PMImageRef *outImageRefPtr
);
```

PMInitializeProcPtr

```
typedef OSStatus(* PMInitializeProcPtr) (
    CFDataRef printerAddress,
    const void *jobContext,
    const PMIOProcs *pmIOProcs,
   const PMNotificationProcPtr pmNotificationProc,
    PMContext *printerModuleContext
);
```

If you name your function `MyPMInitializeCallback`, you would declare it like this:

```
OSStatus MyPMInitializeCallback (
   CFDataRef printerAddress,
   const void *jobContext,
   const PMIOProcs *pmIOProcs,
   const PMNotificationProcPtr pmNotificationProc,
   PMContext *printerModuleContext
);
```

PMIOCloseProcPtr

```
typedef OSStatus(* PMIOCloseProcPtr) (
    const void *jobContext
);
```

If you name your function `MyPMIOCloseCallback`, you would declare it like this:

```
OSStatus MyPMIOCloseCallback (
   const void *jobContext
```

```
);
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`PMPrinterModuleDeprecated.h`

PMIOGetAttributeProcPtr

```
typedef OSStatus(* PMIOGetAttributeProcPtr) (
    const void *jobContext,
    CFStringRef attribute,
    CFTypeRef *result
);
```

If you name your function `MyPMIOGetAttributeCallback`, you would declare it like this:

```
OSStatus MyPMIOGetAttributeCallback (
   const void *jobContext,
   CFStringRef attribute,
   CFTypeRef *result
);
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`PMPrinterModuleDeprecated.h`

PMIOModuleCloseProcPtr

```
typedef OSStatus(* PMIOModuleCloseProcPtr) (
    IOMContext ioModuleContext,
    Boolean abort
);
```

If you name your function `MyCallback`, you would declare it like this:

```
OSStatus MyCallback (
IOMContext ioModuleContext,
Boolean abort
);
```

PMIOModuleGetAttributeProcPtr

```
typedef OSStatus(* PMIOModuleGetAttributeProcPtr) (
    IOMContext ioModuleContext,
    CFStringRef attribute,
    CFTypeRef *result
);
```

If you name your function `MyCallback`, you would declare it like this:

```
OSStatus MyCallback (
IOMContext ioModuleContext,
CFStringRef attribute,
CFTypeRef *result
);
```

PMIOModuleGetConnectionInfoProcPtr

```
typedef OSStatus(* PMIOModuleGetConnectionInfoProcPtr) (
    CFStringRef *connectionType,
    CFStringRef *pbmPath
);
```

If you name your function `MyCallback`, you would declare it like this:

```
OSStatus MyCallback (
CFStringRef *connectionType,
CFStringRef *pbmPath
);
```

PMIOModuleInitializeProcPtr

```
typedef OSStatus(* PMIOModuleInitializeProcPtr) (
    CFDataRef printerAddress,
    IOMContext *ioModuleContextPtr
);
```

If you name your function `MyCallback`, you would declare it like this:

```
OSStatus MyCallback (
CFDataRef printerAddress,
IOMContext *ioModuleContextPtr
);
```

PMIOModuleOpenProcPtr

```
typedef OSStatus(* PMIOModuleOpenProcPtr) (
    IOMContext ioModuleContext,
    PMTicketRef jobTicket,
    UInt32 *bufferSize
);
```

If you name your function `MyCallback`, you would declare it like this:

```
OSStatus MyCallback (
IOMContext ioModuleContext,
PMTicketRef jobTicket,
UInt32 *bufferSize
);
```

PMIOModuleReadProcPtr

```
typedef OSStatus(* PMIOModuleReadProcPtr) (
    IOMContext ioModuleContext,
    Ptr buffer,
    UInt32 *size,
    Boolean *eoj
);
```

If you name your function `MyCallback`, you would declare it like this:

```
OSStatus MyCallback (
IOMContext ioModuleContext,
Ptr buffer,
UInt32 *size,
Boolean *eoj
);
```

PMIOModuleSetAttributeProcPtr

```
typedef OSStatus(* PMIOModuleSetAttributeProcPtr) (
    IOMContext ioModuleContext,
    CFStringRef attribute,
    CFTypeRef data
);
```

If you name your function `MyCallback`, you would declare it like this:

```
OSStatus MyCallback (
IOMContext ioModuleContext,
CFStringRef attribute,
CFTypeRef data
);
```

PMIOModuleStatusProcPtr

```
typedef OSStatus(* PMIOModuleStatusProcPtr) (
    IOMContext ioModuleContext,
    CFStringRef *status
);
```

If you name your function `MyCallback`, you would declare it like this:

```
OSStatus MyCallback (
IOMContext ioModuleContext,
CFStringRef *status
);
```

PMIOModuleTerminateProcPtr

```
typedef OSStatus(* PMIOModuleTerminateProcPtr) (
    IOMContext *ioModuleContextPtr
);
```

If you name your function `MyCallback`, you would declare it like this:

```
OSStatus MyCallback (
IOMContext *ioModuleContextPtr
);
```

PMIOModuleWriteProcPtr

```
typedef OSStatus(* PMIOModuleWriteProcPtr) (
    IOMContext ioModuleContext,
    Ptr buffer,
    UInt32 *size,
    Boolean eoj
);
```

If you name your function `MyCallback`, you would declare it like this:

```
OSStatus MyCallback (
IOMContext ioModuleContext,
Ptr buffer,
UInt32 *size,
Boolean eoj
);
```

PMIOOpenProcPtr

```
typedef OSStatus(* PMIOOpenProcPtr) (
    const void *jobContext
);
```

If you name your function `MyPMIOOpenCallback`, you would declare it like this:

```
OSStatus MyPMIOOpenCallback (
   const void *jobContext
);
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`PMPrinterModuleDeprecated.h`

PMIOReadProcPtr

```
typedef OSStatus(* PMIOReadProcPtr) (
    const void *jobContext,
    Ptr buffer,
    UInt32 *size,
    Boolean *eoj
);
```

If you name your function `MyPMIOReadCallback`, you would declare it like this:

```
OSStatus MyPMIOReadCallback (
   const void *jobContext,
   Ptr buffer,
   UInt32 *size,
   Boolean *eoj
);
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`PMPrinterModuleDeprecated.h`

PMIOSetAttributeProcPtr

```
typedef OSStatus(* PMIOSetAttributeProcPtr) (
    const void *jobContext,
    CFStringRef attribute,
    CFTypeRef data
);
```

If you name your function `MyPMIOSetAttributeCallback`, you would declare it like this:

```
OSStatus MyPMIOSetAttributeCallback (
   const void *jobContext,
   CFStringRef attribute,
   CFTypeRef data
);
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`PMPrinterModuleDeprecated.h`

PMIOStatusProcPtr

```
typedef OSStatus(* PMIOStatusProcPtr) (
    const void *jobContext,
    CFStringRef *status
);
```

If you name your function `MyPMIOStatusCallback`, you would declare it like this:

```
OSStatus MyPMIOStatusCallback (
   const void *jobContext,
   CFStringRef *status
);
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`PMPrinterModuleDeprecated.h`

PMIOWriteProcPtr

```
typedef OSStatus(* PMIOWriteProcPtr) (
    const void *jobContext,
    Ptr buffer,
    UInt32 *size,
    Boolean eoj
);
```

If you name your function `MyPMIOWriteCallback`, you would declare it like this:

```
OSStatus MyPMIOWriteCallback (
   const void *jobContext,
   Ptr buffer,
   UInt32 *size,
   Boolean eoj
);
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`PMPrinterModuleDeprecated.h`

PMJobStreamGetNextBandProcPtr

```
typedef OSStatus(* PMJobStreamGetNextBandProcPtr) (
    const void *jobContext,
    PMRasterBand *pmRasterBand
);
```

If you name your function `MyPMJobStreamGetNextBandCallback`, you would declare it like this:

```
OSStatus MyPMJobStreamGetNextBandCallback (
   const void *jobContext,
   PMRasterBand *pmRasterBand
);
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`PMPrinterModuleDeprecated.h`

PMJobStreamGetPosProcPtr

```
typedef OSStatus(* PMJobStreamGetPosProcPtr) (
    const void *jobContext,
    UInt32 *markerPos
);
```

If you name your function `MyPMJobStreamGetPosCallback`, you would declare it like this:

```
OSStatus MyPMJobStreamGetPosCallback (
   const void *jobContext,
   UInt32 *markerPos
);
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`PMPrinterModuleDeprecated.h`

PMJobStreamOpenProcPtr

```
typedef OSStatus(* PMJobStreamOpenProcPtr) (
    const void *jobContext
);
```

If you name your function `MyPMJobStreamOpenCallback`, you would declare it like this:

```
OSStatus MyPMJobStreamOpenCallback (
   const void *jobContext
);
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`PMPrinterModuleDeprecated.h`

PMJobStreamReadWriteProcPtr

```
typedef OSStatus(* PMJobStreamReadWriteProcPtr) (
    const void *jobContext,
    void *buffPtr,
    UInt32 *size
);
```

If you name your function `MyPMJobStreamReadWriteCallback`, you would declare it like this:

```
OSStatus MyPMJobStreamReadWriteCallback (
```

```
    const void *jobContext,
    void *buffPtr,
    UInt32 *size
);
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`PMPrinterModuleDeprecated.h`

PMJobStreamSetPosProcPtr

```
typedef OSStatus(* PMJobStreamSetPosProcPtr) (
    const void *jobContext,
    SInt16 posMode,
    UInt32 markerPos
);
```

If you name your function `MyPMJobStreamSetPosCallback`, you would declare it like this:

```
OSStatus MyPMJobStreamSetPosCallback (
    const void *jobContext,
    SInt16 posMode,
    UInt32 markerPos
);
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`PMPrinterModuleDeprecated.h`

PMNotificationProcPtr

```
typedef OSStatus(* PMNotificationProcPtr) (
    const void *jobContext,
    CFDictionaryRef notificationDict,
    CFDictionaryRef *notificationReplyDict
);
```

If you name your function `MyPMNotificationCallback`, you would declare it like this:

```
OSStatus MyPMNotificationCallback (
    const void *jobContext,
    CFDictionaryRef notificationDict,
    CFDictionaryRef *notificationReplyDict
);
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`PMPrinterModuleDeprecated.h`

PMPDECloseProcPtr

```
typedef OSStatus(* PMPDECloseProcPtr) (
    PMPDEContext context
);
```

If you name your function `MyPMPDEClose`, you would declare it like this:

```
OSStatus MyPMPDEClose (
   PMPDEContext context
);
```

Parameters

context

A pointer to a custom data structure that contains state information shared among the functions in a printing dialog extension. This is the same context defined by the prologue function—see `PMPDEPrologueProcPtr` (page 2911).

Return Value
A result code.

Discussion
If your pane is visible, your close function is called when the user

- switches to another pane (including the Summary pane)
- changes printers
- dismisses the dialog by clicking Preview, Print, or Save

If your pane is visible and the user cancels the dialog, your close function is not called. The close function is not required to provide any services, and does not return any information to the caller.

PMPDEGetSummaryTextProcPtr

```
typedef OSStatus(* PMPDEGetSummaryTextProcPtr) (
    PMPDEContext context,
    CFArrayRef *titleArray,
    CFArrayRef *summaryArray
);
```

If you name your function `MyPMPDEGetSummary`, you would declare it like this:

```
OSStatus MyPMPDEGetSummary (
   PMPDEContext context,
   CFArrayRef *titleArray,
   CFArrayRef *summaryArray
```

```
);
```

Parameters

context

A pointer to a custom data structure that contains state information shared among the functions in a printing dialog extension. This is the same context defined by the prologue function—see `PMPDEPrologueProcPtr` (page 2911).

titleArray

A pointer to an array of strings that contain brief, localized descriptions of the settings in your user interface. The array and strings must be Core Foundation types.

On entry, the array is undefined. Before returning, you should assign an array of type `CFArrayRef`. The printing system assumes ownership of the array and is responsible for releasing it.

If your printing dialog extension does not supply summary text—or your user interface does not have any settings—you should assign `NULL` before returning.

summaryArray

A pointer to an array of strings that contain brief, localized descriptions of the current values of the settings in your user interface. The array and strings must be Core Foundation types.

On entry, the array is undefined. Before returning, you should assign an array of type `CFArrayRef`. The printing system assumes ownership of the array and is responsible for releasing it.

If your printing dialog extension does not supply summary text—or your user interface does not have any settings—you should assign `NULL` before returning.

Return Value
A result code.

Discussion
Whenever a user switches to the Summary pane in a printing dialog, the printing system calls the summary function of each active printing dialog extension.

The printing system expects *titleArray* and *summaryArray* to be in a one-to-one correspondence. Here's a formal description of what that means. Your user interface has associated with it *n* pairs of strings, each pair consisting of textual descriptions of a single setting and its current value. The two arrays are in a one-to-one correspondence if for all *k* from 0 to *n*-1, the strings *titleArray[k]* and *summaryArray[k]* form a valid pair.

PMPDEInitializeProcPtr

```
typedef OSStatus(* PMPDEInitializeProcPtr) (
    PMPDEContext context,
    PMPDEFlags *flags,
    PMPDERef ref,
    ControlRef embedderUserPane,
    PMPrintSession printSession
);
```

If you name your function `MyPMPDEInitialize`, you would declare it like this:

```
OSStatus MyPMPDEInitialize (
   PMPDEContext context,
   PMPDEFlags *flags,
   PMPDERef ref,
```

```
    ControlRef embedderUserPane,
    PMPrintSession printSession
);
```

Parameters

context

A pointer to a custom data structure that contains state information shared among the functions in a printing dialog extension. This is the same context defined by the prologue function—see `PMPDEPrologueProcPtr` (page 2911).

flags

A pointer to an integer flag that provides information about the capabilities of your printing dialog extension. On entry, the flag is undefined. Before returning, your initialization function should assign a valid feature request flag. For information about the defined flags, see "PDE Feature Flags" (page 2933).

ref

Reserved for future use.

embedderUserPane

The control provided by the printing system to host the user interface of your printing dialog extension. This parameter is a standard Carbon user pane—a root control into which your printing dialog extension embeds the various controls and other elements in your user interface.

Before returning, your initialization function should create static user interface elements—such as controls, icons, and images—and embed them in the user pane provided by the printing system. You should position the user interface elements with respect to the coordinate system of the dialog window, and make them visible. You should also set the initial values of your controls, based on either your default settings or previous settings saved by the user. Do not modify the user pane itself.

If any user interface elements require special handling, you can install Carbon event handlers for them. For example, the Duplex pane in the Print dialog uses an event handler to enable or disable the two binding selection buttons, based on the current checkbox setting.

Do not do any custom drawing at this time, since the user pane is still invisible. If the user decides to display your user interface, the printing system makes it visible and the Control Manager automatically draws your static elements.

printSession

A pointer to a print session object. This is the same print session created by the application prior to displaying the dialog. You can use this parameter to gain access to one of the specialized printing tickets, such as page format or print settings.

Return Value

A result code.

Discussion

If the printing system calls your initialization function, you can safely assume that your prologue function was called first.

If your initialization function returns a nonzero status code, the printing system does not call your summary function.

PMPDEOpenProcPtr

```
typedef OSStatus(* PMPDEOpenProcPtr) (
    PMPDEContext context
);
```

If you name your function `MyPMPDEOpen`, you would declare it like this:

```
OSStatus MyPMPDEOpen (
   PMPDEContext context
);
```

Parameters

context

A pointer to a custom data structure that contains state information shared among the functions in a printing dialog extension. This is the same context defined by the prologue function—see `PMPDEPrologueProcPtr` (page 2911).

Return Value

A result code.

Discussion

If the user selects your pane for display in the dialog, your open function is called immediately before the pane is made visible.

An open function is not required to provide any services, and does not return any information to the caller.

PMPDEPrologueProcPtr

```
typedef OSStatus(* PMPDEPrologueProcPtr) (
    PMPDEContext *context,
    OSType *creator,
    CFStringRef *userOptionKind,
    CFStringRef *title,
    UInt32 *maxH,
    UInt32 *maxV
);
```

If you name your function `MyPMPDEPrologue`, you would declare it like this:

```
OSStatus MyPMPDEPrologue (
   PMPDEContext *context,
   OSType *creator,
   CFStringRef *userOptionKind,
   CFStringRef *title,
   UInt32 *maxH,
   UInt32 *maxV
);
```

Parameters

context

A pointer to a custom data structure that contains state information shared among the functions in a printing dialog extension. On entry, the caller's `PMPDEContext` variable is undefined. Before returning, your prologue function should assign a new context, or `NULL` to indicate that no context exists.

The printing system does not assume ownership of memory used for a context, so your printing dialog extension should release it when it is no longer needed. Typically this is done in your termination function.

creator

Reserved for future use.

userOptionKind

A pointer to a string that contains a unique identifier for the pane implemented by your printing dialog extension. The printing system uses this identifier to determine whether your printing dialog extension implements an Apple-defined pane, or a custom pane defined by you. On entry, the string is undefined. Before returning, your prologue function should assign the appropriate identifier.

If your printing dialog extension implements or overrides an Apple-defined pane, assign one of the identifiers listed in "PDE Pane Kind Identifiers" (page 2935). If your printing dialog extension implements a custom pane, assign a Core Foundation string that contains your own custom identifier.

By convention, a custom identifier takes the form `<domain>.print.pde.<signature>`, where `<domain>` is your vendor-specific domain and `<signature>` is a short name or signature for the pane you are implementing.

The printing system does not assume ownership of this string, so your printing dialog extension should release it when it is no longer needed.

title

A pointer to a string that contains the localized title of the pane implemented by your printing dialog extension. The printing system displays this title in two places—the pane selection pop-up menu and the Summary pane.

On entry, the string is undefined. Before returning, your prologue function should assign a Core Foundation string containing the localized title.

If you are implementing an Apple-defined pane, the printing system may ignore your localized title and use an Apple-defined title instead.

Your printing dialog extension retains ownership of the string, and you should release it when it is no longer needed. Typically this is done in your terminate function.

maxH

A pointer to a value that represents the maximum number of horizontal pixels your user interface requires. When your user interface is made visible, the printing system might use this value to adjust the width of the dialog.

On entry, the value is undefined. Before returning, your prologue function should assign the maximum horizontal extent of your user interface in pixels.

maxV

A pointer to a value that represents the maximum number of vertical pixels your user interface requires. When your user interface is made visible, the printing system uses this value to adjust the height of the dialog.

On entry, the value is undefined. Before returning, your prologue function should assign the maximum vertical extent of your user interface in pixels.

Return Value

A result code.

Discussion
When the printing system displays a printing dialog, it calls the prologue function for each registered dialog extension.

If your prologue function returns a nonzero status code, the printing system does not include your pane in the dialog, and does not call your terminate function. In this circumstance, your prologue function should release any allocated memory or resources before exiting.

While the dialog is open, if some user action causes the printing system to scan for plug-ins again—choosing a different printer, for example—then your prologue function is called again.

PMPDESyncProcPtr

```
typedef OSStatus(* PMPDESyncProcPtr) (
    PMPDEContext context,
    PMPrintSession printSession,
    Boolean reinitializePlugIn
);
```

If you name your function `MyPMPDESync`, you would declare it like this:

```
OSStatus MyPMPDESync (
   PMPDEContext context,
   PMPrintSession printSession,
   Boolean reinitializePlugIn
);
```

Parameters

context

A pointer to a custom data structure that contains state information shared among the functions in a printing dialog extension. This is the same context defined by the prologue function—see `PMPDEPrologueProcPtr` (page 2911).

printSession

A pointer to a printing session object. Your synchronization function should use this parameter to gain access to the job ticket its uses to save user interface settings. These settings are stored as extended data in either the print settings ticket (for Print dialog extensions) or the page format ticket (for Page Setup dialog extensions).

reinitializePlugIn

A `Boolean` value that indicates which synchronization operation to perform. If the value is `true`, you should locate and retrieve the ticket settings and use them to update your user interface settings. If the value is `false`, you should use your current user interface settings to update the ticket settings.

Return Value
A result code.

Discussion
The printing system calls your synchronization function at certain times—in response to user actions—to update either the user interface or the ticket. Also, your printing dialog extension can call your synchronization function directly. For example, your initialization function may need to synchronize your user interface to its default settings.

Here are some calling conditions where the *reinitializePlugin* parameter might be `true`:

- Your own intialization function wants to synchronize your user interface to its default settings.
- The printing system wants you to initialize your user interface from the print settings ticket associated with a different printer.

Here are some calling conditions where the *reinitializePlugin* parameter might be `false`:

- Your user interface is visible, and the user tries to switch to another pane.
- The user saves the current dialog settings.
- The user clicks the Preview button or the Print button.

You may want to check the validity of the current settings in your pane at this time, to avoid recording invalid or inconsistent settings in a job ticket. To prevent the user from switching to another pane until a problem is corrected, return the result code `kPMDontSwitchPDEError`.

PMPDETerminateProcPtr

```
typedef OSStatus(* PMPDETerminateProcPtr) (
    PMPDEContext context,
    OSStatus status
);
```

If you name your function `MyPMPDETerminate`, you would declare it like this:

```
OSStatus MyPMPDETerminate (
   PMPDEContext context,
   OSStatus status
);
```

Parameters

context

A pointer to a custom data structure that contains state information shared among the functions in a printing dialog extension. This is the same context defined by the prologue function—see `PMPDEPrologueProcPtr` (page 2911).

status

Reserved for future use to indicate the conditions under which the user dismissed the dialog.

Return Value

A result code.

Discussion

The printing system calls your termination function when the printing system decides to tear down or rebuild the dialog, or when your pane is no longer needed.

Unless your prologue function returns a nonzero status code, your termination function is always called when the user dismisses the dialog.

Your termination function is also called if your printing feature is no longer relevant—for example, if your feature applies only to postscript printers and the user switches to a raster printer from within the dialog.

Your termination function should release Core Foundation objects, deallocate your context block, and perform any other actions necessary before your user interface is reinitialized or unloaded.

PMPluginGetAPIVersionProcPtr

```
typedef OSStatus(* PMPluginGetAPIVersionProcPtr) (
   PMPlugInHeaderInterface *obj,
   PMPlugInAPIVersion *versionPtr
);
```

If you name your function `MyPMPluginGetAPIVersion`, you would declare it like this:

```
OSStatus MyPMPluginGetAPIVersion (
   PMPlugInHeaderInterface *obj,
   PMPlugInAPIVersion *versionPtr
);
```

Parameters

obj

A pointer to a generic instance of a plug-in interface. You may ignore this parameter, as it isn't useful here.

versionPtr

A pointer to a data structure supplied by the caller for version information about your printing plug-in. Before returning, you should provide the correct version information for your plug-in by assigning version constants to the fields in this structure.

Return Value
A result code.

PMPluginReleaseProcPtr

Defines a pointer to the retain function in a printing plug-in interface. Your custom retain function increments the reference count of an instance of one of these interfaces.

```
typedef OSStatus (*PMPluginReleaseProcPtr) (
   PMPlugInHeaderInterface **objPtr
);
```

If you name your function `MyPMPluginRelease`, you would declare it like this:

```
OSStatus MyPMPluginRelease (
   PMPlugInHeaderInterface **objPtr
);
```

Parameters

objPtr

The address of a pointer to a generic instance of a plug-in interface. Before returning, your retain function should decrement the reference count of the instance, and assign `NULL` to the pointer whose address is provided by this parameter. If the reference count reaches zero, you should delete the instance and any related storage.

Return Value
A result code.

PMPluginRetainProcPtr

```
typedef OSStatus (*PMPluginRetainProcPtr) (
    PMPlugInHeaderInterface *obj
);
```

If you name your function `MyPMPluginRetain`, you would declare it like this:

```
OSStatus MyPMPluginRetain (
    PMPlugInHeaderInterface *obj
);
```

Parameters

obj

A pointer to a generic instance of a plug-in interface. Before returning, your retain function should increment the reference count of the instance.

Return Value

A result code.

PMPrBrowserAPIVersionProcPtr

```
typedef UInt32(* PMPrBrowserAPIVersionProcPtr) ();
```

If you name your function `MyPMPrBrowserAPIVersionCallback`, you would declare it like this:

```
UInt32 MyPMPrBrowserAPIVersionCallback ();
```

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`PMPrinterBrowsers.h`

PMPrBrowserGetLookupSpecProcPtr

```
typedef OSStatus(* PMPrBrowserGetLookupSpecProcPtr) (
    PMPrBrowserRef ref,
    UInt32 specIndex,
    CFDictionaryRef *lookupSpec
);
```

If you name your function `MyPMPrBrowserGetLookupSpecCallback`, you would declare it like this:

```
OSStatus MyPMPrBrowserGetLookupSpecCallback) (
    PMPrBrowserRef ref,
    UInt32 specIndex,
    CFDictionaryRef *lookupSpec
);
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`PMPrinterBrowsers.h`

PMPrBrowserGetSelectedPrintersProcPtr

```
typedef OSStatus(* PMPrBrowserGetSelectedPrintersProcPtr) (
    PMPrBrowserContext context,
    CFArrayRef *printers
);
```

If you name your function `MyPMPrBrowserGetSelectedPrintersCallback`, you would declare it like this:

```
OSStatus MyPMPrBrowserGetSelectedPrintersCallback (
PMPrBrowserContext context,
CFArrayRef *printers
);
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`PMPrinterBrowsers.h`

PMPrBrowserInitializeProcPtr

```
typedef OSStatus(* PMPrBrowserInitializeProcPtr) (
    PMPrBrowserContext context,
    PMPrBrowserRef ref,
    PMPrBrowserCallbacks *callbacks,
    ControlRef pbUserPaneCtlHdl,
    UInt32 numLookupSpecs
);
```

If you name your function `MyPMPrBrowserInitializeCallback`, you would declare it like this:

```
OSStatus MyPMPrBrowserInitializeCallback (
PMPrBrowserContext context,
PMPrBrowserRef ref,
PMPrBrowserCallbacks *callbacks,
ControlRef pbUserPaneCtlHdl,
UInt32 numLookupSpecs
);
```

Availability
Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In
PMPrinterBrowsers.h

PMPrBrowserPrologueProcPtr

```
typedef OSStatus(* PMPrBrowserPrologueProcPtr) (
    PMPrBrowserContext *context,
    PMPrBrowserFlags prologueFlags,
    CFStringRef *title,
    UInt32 *minH,
    UInt32 *minV,
    UInt32 *maxH,
    UInt32 *maxV
);
```

If you name your function `MyPMPrBrowserPrologueCallback`, you would declare it like this:

```
OSStatus MyPMPrBrowserPrologueCallback (
PMPrBrowserContext *context,
PMPrBrowserFlags prologueFlags,
CFStringRef *title,
UInt32 *minH,
UInt32 *minV,
UInt32 *maxH,
UInt32 *maxV
);
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
PMPrinterBrowsers.h

PMPrBrowserResizeProcPtr

```
typedef OSStatus(* PMPrBrowserResizeProcPtr) (
    PMPrBrowserContext context,
    const Rect *frameRect
);
```

If you name your function `MyPMPrBrowserResizeCallback`, you would declare it like this:

```
OSStatus MyPMPrBrowserResizeCallback (
PMPrBrowserContext context,
const Rect *frameRect
);
```

Availability
Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In
PMPrinterBrowsers.h

PMPrBrowserSelectionStatusProcPtr

```
typedef OSStatus(* PMPrBrowserSelectionStatusProcPtr) (
    PMPrBrowserRef ref,
    Boolean selected,
    Boolean addNow
);
```

If you name your function `MyPMPrBrowserSelectionStatusCallback`, you would declare it like this:

```
OSStatus MyPMPrBrowserSelectionStatusCallback (
PMPrBrowserRef ref,
Boolean selected,
Boolean addNow
);
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
PMPrinterBrowsers.h

PMPrBrowserSyncProcPtr

```
typedef OSStatus(* PMPrBrowserSyncProcPtr) (
    PMPrBrowserContext context
);
```

If you name your function `MyPMPrBrowserSyncCallback`, you would declare it like this:

```
OSStatus MyPMPrBrowserSyncCallback (
PMPrBrowserContext context
);
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
PMPrinterBrowsers.h

PMPrBrowserSyncRequestProcPtr

```
typedef OSStatus(* PMPrBrowserSyncRequestProcPtr) (
    PMPrBrowserRef ref
);
```

If you name your function `MyPMPrBrowserSyncRequestCallback`, you would declare it like this:

```
OSStatus MyPMPrBrowserSyncRequestCallback (
PMPrBrowserRef ref
);
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`PMPrinterBrowsers.h`

PMPrBrowserTerminateProcPtr

```
typedef OSStatus(* PMPrBrowserTerminateProcPtr) (
    PMPrBrowserContext context,
    OSStatus status
);
```

If you name your function `MyPMPrBrowserTerminateCallback`, you would declare it like this:

```
OSStatus MyPMPrBrowserTerminateCallback (
PMPrBrowserContext context,
OSStatus status
);
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`PMPrinterBrowsers.h`

PMPrBrowserWorksetPrintersProcPtr

```
typedef OSStatus(* PMPrBrowserWorksetPrintersProcPtr) (
    PMPrBrowserContext context,
    CFArrayRef printers
);
```

If you name your function `MyPMPrBrowserWorksetPrintersCallback`, you would declare it like this:

```
OSStatus MyPMPrBrowserWorksetPrintersCallback (
PMPrBrowserContext context,
```

```
CFArrayRef printers
);
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`PMPrinterBrowsers.h`

PMPrintJobProcPtr

```
typedef OSStatus(* PMPrintJobProcPtr) (
    PMContext printerModuleContext,
    const void *jobContext,
    PMTicketRef jobTicket,
    const PMJobStreamProcs *inDataProcs
);
```

If you name your function `MyPMPrintJobCallback`, you would declare it like this:

```
OSStatus MyPMPrintJobCallback (
   PMContext printerModuleContext,
   const void *jobContext,
   PMTicketRef jobTicket,
   const PMJobStreamProcs *inDataProcs
);
```

PMPrintPageProcPtr

```
typedef OSStatus(* PMPrintPageProcPtr) (
    PMContext printerModuleContext,
    const void *jobContext,
    PMTicketRef jobTicket,
   const PMJobStreamGetNextBandProcPtr pmJobStreamGetNextBandProc
);
```

If you name your function `MyPMPrintPageCallback`, you would declare it like this:

```
OSStatus MyPMPrintPageCallback (
   PMContext printerModuleContext,
   const void *jobContext,
   PMTicketRef jobTicket,
   const PMJobStreamGetNextBandProcPtr pmJobStreamGetNextBandProc
);
```

PMTerminateProcPtr

```
typedef OSStatus(* PMTerminateProcPtr) (
    PMContext *printerModuleContext,
    const void *jobContext
);
```

If you name your function `MyPMTerminateCallback`, you would declare it like this:

```
OSStatus MyPMTerminateCallback (
   PMContext *printerModuleContext,
   const void *jobContext
);
```

Data Types

Printing Plug-in Data Types

PMPlugInHeader

Defines the table of callback functions in the printing plug-in interface.

```
struct PMPlugInHeader
{
    OSStatus (*Retain) (
        PMPlugInHeaderInterface *obj
    );

    OSStatus (*Release) (
        PMPlugInHeaderInterface **objPtr
    );

    OSStatus (*GetAPIVersion) (
        PMPlugInHeaderInterface *obj,
        PMPlugInAPIVersion *versionPtr
    );
};
typedef struct PMPlugInHeader PMPlugInHeader;
```

Fields

`Retain`
: A pointer to a function that satisfies the requirements for a printing plug-in retain function, as described in `PMPluginRetainProcPtr` (page 2916).

`Release`
: A pointer to a function that satisfies the requirements for a printing plug-in release function, as described in `PMPluginReleaseProcPtr` (page 2915).

`GetAPIVersion`
: A pointer to a function that satisfies the requirements for a printing plug-in version function, as described in `PMPluginGetAPIVersionProcPtr` (page 2915).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`PMPluginHeader.h`

PMPlugInHeaderInterface

Defines a generic instance of the `PMPlugInHeader` interface—the printing system passes a parameter of this type when calling the three interface functions.

```
struct PMPlugInHeaderInterface {
    const PMPlugInHeader *vtable;
};
typedef struct PMPlugInHeaderInterface PMPlugInHeaderInterface;
```

Fields
`vtable`
A pointer to the function table for an implementation of the `PMPlugInHeader` interface.

Discussion
When the printing system calls one of the three functions in the `PMPlugInHeader` interface, a pointer to this generic data type is supplied as a parameter. It's really the address of the plug-in instance supplied by your query interface function (see *Core Foundation Plug-in Services*).

To gain access to your instance data—including the field that holds the reference count—you need to cast this pointer to the actual instance type defined in your plug-in.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`PMPluginHeader.h`

PMPlugInAPIVersion

Contains `PMPlugInHeader` interface version information that printing plug-ins must provide to the printing system.

```
struct PMPlugInAPIVersion {
    UInt32 buildVersionMajor;
    UInt32 buildVersionMinor;
    UInt32 baseVersionMajor;
    UInt32 baseVersionMinor;
};
```

Fields
`buildVersionMajor`
An integer value that specifies the major component of the API version with which the plug-in was compiled.

`buildVersionMinor`
An integer value that specifies the minor component of the API version with which the plug-in was compiled.

`baseVersionMajor`
: An integer value that specifies the major component of the base API version with which this plug-in is forward compatible.

`baseVersionMinor`
: An integer value that specifies the minor component of the base API version with which this plug-in is forward compatible.

Printing Dialog Extension Data Types

PlugInIntfVTable

Defines the table of callback functions in the printing dialog extension plug-in interface.

```
struct PlugInIntfVTable
{
    PMPlugInHeader plugInHeader;

    OSStatus (*Prologue) (
        PMPDEContext *context,
        OSType *creator,
        CFStringRef *userOptionKind,
        CFStringRef *title,
        UInt32 *maxH,
        UInt32 *maxV
    );

    OSStatus (*Initialize) (
        PMPDEContext context,
        PMPDEFlags *flags,
        PMPDERef ref,
        ControlRef embedderUserPane,
        PMPrintSession printSession
    );

    OSStatus (*Sync) (
        PMPDEContext context,
        PMPrintSession printSession,
        Boolean reinitializePlugIn
    );

    OSStatus (*GetSummaryText) (
        PMPDEContext context,
        CFArrayRef *titleArray,
        CFArrayRef *summaryArray
    );

    OSStatus (*Open) (
        PMPDEContext context
    );

    OSStatus (*Close) (
        PMPDEContext context
    );
```

```
    OSStatus (*Terminate) (
        PMPDEContext context,
        OSStatus status
    );
};
typedef struct PlugInIntfVTable PlugInIntfVTable;
```

Fields

`plugInHeader`
A table of pointers to the three functions in the printing plug-in interface.

`Prologue`
A pointer to a function that satisfies the requirements for the prologue function in a printing dialog extension, as described in `PMPDEPrologueProcPtr` (page 2911).

`Initialize`
A pointer to a function that satisfies the requirements for the initialization function in a printing dialog extension, as described in `PMPDEInitializeProcPtr` (page 2909).

`Sync`
A pointer to a function that satisfies the requirements for the synchronization function in a printing dialog extension, as described in `PMPDESyncProcPtr` (page 2913).

`GetSummaryText`
A pointer to a function that satisfies the requirements for the summary function in a printing dialog extension, as described in `PMPDEGetSummaryTextProcPtr` (page 2908).

`Open`
A pointer to a function that satisfies the requirements for the open function in a printing dialog extension, as described in `PMPDEOpenProcPtr` (page 2911).

`Close`
A pointer to a function that satisfies the requirements for the close function in a printing dialog extension, as described in `PMPDECloseProcPtr` (page 2908).

`Terminate`
A pointer to a function that satisfies the requirements for the termination function in a printing dialog extension, as described in `PMPDETerminateProcPtr` (page 2914).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`PMPrintingDialogExtensionsDeprecated.h`

PlugInIntf

Defines a generic instance of the printing dialog extension plug-in interface.

```
struct PlugInIntf {
    PlugInIntfVTable *vtable;
};
```

Fields

`vtable`
A pointer to the table of callback functions in a printing dialog extension.

PMPDEContext

Defines a generic private context for a printing dialog extension—the printing system passes a parameter of this type when calling functions in the `PlugInIntfVTable` interface.

```
typedef struct OpaquePMPDEContext* PMPDEContext;
```

Discussion
A **context** is a pointer to a custom data structure shared by the functions in a printing dialog extension. In Mac OS X, Carbon applications can open the same printing dialog in several document windows concurrently. Printing dialog extensions must support this possibility, which means they must be reentrant.

To ensure reentrancy, your printing dialog extension uses dynamically allocated memory for state information specific to one dialog window. Your prologue function allocates this memory and supplies its address—called a context—to the printing system. The printing system makes sure that the context associated with the current session (the active dialog) is passed in to your other functions as a calling parameter.

The context you provide is a generic pointer of type `PMPDEContext`. You can gain access to your actual context data by casting this parameter to the actual context type defined in your printing dialog extension.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`PMPrintingDialogExtensionsDeprecated.h`

PMPDEFlags

Defines an integer flag that provides additional information about a printing dialog extension to the printing system. A value of this data type is passed back to the printing system by the initialize function.

```
typedef UInt32 PMPDEFlags;
enum {
    kPMPDENoFlags = 0,
    kPMPDENoSummary = 1,
    kPMPDEAllFlags = -1
};
```

Discussion
The printing system examines this integer flag to learn more about its capabilities. For a description of the initialize function, see `PMPDEInitializeProcPtr` (page 2909).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`PMPrintingDialogExtensionsDeprecated.h`

PMPDERef

Defines a generic instance of the printing dialog extension plug-in interface.

```
typedef struct OpaquePMPDERef* PMPDERef;
```

Discussion
A value of this type is passed to the initialize function. For a description of the initialize function, see `PMPDEInitializeProcPtr` (page 2909).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`PMPrintingDialogExtensionsDeprecated.h`

Printer Module Data Types

PMProcs

Defines the table of callback functions in the printer module plug-in interface.

```
struct PMProcs
{
    PMPlugInHeader                  pluginHeader;
    PMCreatePBMInfoProcPtr          CreatePBMInfo;
    PMInitializeProcPtr             Initialize;
    PMCreatePDEPathsProcPtr         CreatePDEPaths;
    PMCreatePrinterTicketsProcPtr   CreatePrinterTickets;
    PMBeginJobProcPtr               BeginJob;
    PMPrintJobProcPtr               PrintJob;
    PMPrintPageProcPtr              PrintPage;
    PMImageAccessProcPtr            ImageAccess;
    PMCancelJobProcPtr              CancelJob;
    PMEndJobProcPtr                 EndJob;
    PMTerminateProcPtr              Terminate;
};
```

PMInterface

Defines a generic instance of the printer module plug-in interface.

```
struct PMInterface {
    const PMProcs *vtable;
};
typedef struct PMInterface PMInterface;
```

Fields
`vtable`
A pointer to the table of callback functions in a printer module.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
PMPrinterModuleDeprecated.h

PMInterfaceRef

Defines a pointer to a generic instance of the printer module plug-in interface.

```
typedef PMInterface* PMInterfaceRef;
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
PMPrinterModuleDeprecated.h

PMIOProcs

Defines the table of callback functions in the `PMIOProcs` interface.

```
struct PMIOProcs
{
    CFIndex                 version;
    GetConnInfoProcPtr      GetConnInfoProc;
    PMIOOpenProcPtr         PMIOOpenProc;
    PMIOReadProcPtr         PMIOReadProc;
    PMIOWriteProcPtr        PMIOWriteProc;
    PMIOStatusProcPtr       PMIOStatusProc;
    PMIOGetAttributeProcPtr PMIOGetAttributeProc;
    PMIOSetAttributeProcPtr PMIOSetAttributeProc;
    PMIOCloseProcPtr        PMIOCloseProc;
};
```

PMJobStreamProcs

Defines the table of callback functions in the printer module data access interface.

```
struct PMJobStreamProcs
{
    CFIndex                         version;
    PMJobStreamOpenProcPtr          PMJobStreamOpenProc;
    PMJobStreamReadWriteProcPtr     PMJobStreamReadProc;
    PMJobStreamReadWriteProcPtr     PMJobStreamWriteProc;
    PMJobStreamGetPosProcPtr        PMJobStreamGetPosProc;
    PMJobStreamSetPosProcPtr        PMJobStreamSetPosProc;
    PMJobStreamGetPosProcPtr        PMJobStreamGetEOFProc;
};
```

PMContext

Defines an opaque type for a private context in a printer module.

```
typedef struct OpaquePMContext* PMContext;
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`PMPrinterModuleDeprecated.h`

PMDrawingCtx

Defines an opaque type for a drawing context in a printer module.

```
typedef struct OpaquePMDrawingCtx* PMDrawingCtx;
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`PMPrinterModuleDeprecated.h`

PMImageRef

Defines an opaque type for an image in a printer module.

```
typedef struct OpaquePMImageRef* PMImageRef;
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`PMPrinterModuleDeprecated.h`

Printer Browser Module Data Types

PMInterfacePrBrowser

Defines the table of callback functions in the printer browser module plug-in interface.

```
struct PMInterfacePrBrowser
{
    IUnknownVTbl                            u;
    PMPrBrowserGetSelectedPrintersProcPtr   getSelectedPrinters;
    PMPrBrowserInitializeProcPtr            initialize;
    PMPrBrowserPrologueProcPtr              prologue;
    PMPrBrowserResizeProcPtr                resize;
    PMPrBrowserSyncProcPtr                  sync;
    PMPrBrowserTerminateProcPtr             terminate;
    PMPrBrowserWorksetPrintersProcPtr       worksetPrinters;
};
```

PMInterfacePrBrowserPtr

Defines a pointer to a function table for the `PMInterfacePrBrowser` interface.

```
typedef PMInterfacePrBrowser* PMInterfacePrBrowserPtr;
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`PMPrinterBrowsers.h`

PMPrBrowserCallbacks

Defines the table of Print Center callback routines for printer browser modules.

```
struct PMPrBrowserCallbacks
{
    CFIndex                             version;
    PMPrBrowserGetLookupSpecProcPtr     getLookupSpec;
    PMPrBrowserSyncRequestProcPtr       syncRequest;
    PMPrBrowserSelectionStatusProcPtr   selStatus;
};
```

PMPrBrowserCallbacksPtr

Defines a pointer to a table of Print Center callbacks for printer browser modules.

```
typedef PMPrBrowserCallbacks* PMPrBrowserCallbacksPtr;
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`PMPrinterBrowsers.h`

PMPrBrowserContext

Defines an opaque type for a private context in a printer browser module.

```
typedef struct OpaquePMPrBrowserContext* PMPrBrowserContext;
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`PMPrinterBrowsers.h`

PMPrBrowserFlags

Defines an integer flag that provides additional information about a printer browser module to the printing system.

```
typedef UInt32 PMPrBrowserFlags;
enum {
    kPMPrBrowserPCNoFlags = 0,
    kPMPrBrowserPCNoUI = 1,
    kPMPrBrowserPCAllFlags = -1
};
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`PMPrinterBrowsers.h`

PMPrBrowserRef

Defines an opaque type for an instance of the printer browser module plug-in interface.

```
typedef struct OpaquePMPrBrowserRef* PMPrBrowserRef;
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`PMPrinterBrowsers.h`

PMInterfaceAPIVersion

Defines the table of callback functions in the `PMInterfaceAPIVersion` interface.

```
struct PMInterfaceAPIVersion
{
    IUnknownVTbl                    u;
    PMPrBrowserAPIVersionProcPtr    apiVersion;
};
```

PMInterfaceAPIVersionPtr

Defines a pointer to a function table for the `PMInterfaceAPIVersion` interface.

```
typedef PMInterfaceAPIVersion* PMInterfaceAPIVersionPtr;
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`PMPrinterBrowsers.h`

I/O Module Data Types

IOMContext

Defines an opaque type for a private context in an I/O module.

```
typedef struct OpaqueIOMContext* IOMContext;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`PMIOModule.h`

IOMInterface

Defines a generic instance of the I/O module plug-in interface.

```
struct IOMInterface {
    const IOMProcs *vtable;
};
```

Fields
`vtable`
A pointer to the table of callback functions in an I/O module.

IOMInterfaceRef

Defines a pointer to a generic instance of the I/O module plug-in interface.

```
typedef const IOMInterface* IOMInterfaceRef;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
PMIOModule.h

IOMProcs

Defines the table of callback functions in the I/O module plug-in interface.

```
struct IOMProcs
{
    PMPlugInHeader pluginHeader;

    PMIOModuleGetConnectionInfoProcPtr  GetConnectionInfo;
    PMIOModuleInitializeProcPtr         Initialize;
    PMIOModuleOpenProcPtr               Open;
    PMIOModuleReadProcPtr               Read;
    PMIOModuleWriteProcPtr              Write;
    PMIOModuleStatusProcPtr             Status;
    PMIOModuleGetAttributeProcPtr       GetAttribute;
    PMIOModuleSetAttributeProcPtr       SetAttribute;
    PMIOModuleCloseProcPtr              Close;
    PMIOModuleTerminateProcPtr          Terminate;
};
typedef struct IOMProcs IOMProcs;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
PMIOModule.h

Constants

PDE Feature Flags

Specify the flags returned by a printing dialog extension in its initialization function.

```
typedef UInt32 PMPDEFlags;
enum {
    kPMPDENoFlags = 0,
    kPMPDENoSummary = 1,
    kPMPDEAllFlags = -1
};
```

Constants

`kPMPDENoFlags`

Specifies that a printing dialog extension does not have any special capabilities to report to the printing system.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `PMPrintingDialogExtensionsDeprecated.h`.

`kPMPDENoSummary`

Specifies that a printing dialog extension does not provide summary information. Your initialization function can indicate this to the printing system by using the `flags` parameter to pass back this constant. For more information about the initialization function, see `PMPDEInitializeProcPtr` (page 2909). For more information about providing summary information, see `PMPDEGetSummaryTextProcPtr` (page 2908).

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `PMPrintingDialogExtensionsDeprecated.h`.

`kPMPDEAllFlags`

Not used.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `PMPrintingDialogExtensionsDeprecated.h`.

PDE Interface Identifier

Specifies the unique identifier for the printing dialog extension plug-in interface.

```
#define kDialogExtensionIntfIDStr
CFSTR("A996FD7E-B738-11D3-8519-0050E4603277")
```

Constants

`kDialogExtensionIntfIDStr`

A UUID that a printing dialog extension should use in its query interface function to verify that the caller wants an instance of a printing dialog extension plug-in interface, and not some other plug-in interface.

Discussion

For more information about the query interface function, see *Core Foundation Plug-in Services*..

PDE Interface Version

Specify the major and minor components of the version numbers for the interface supported by your printing dialog extension.

```
#define kPDEBuildVersionMajor   1
#define kPDEBuildVersionMinor   0
#define kPDEBaseVersionMajor    1
#define kPDEBaseVersionMinor    0
```

Constants

`kPDEBuildVersionMajor`
Specifies that Apple has designated the current release of the printing dialog extension plug-in interface to be major version 1, as in 1.0.

`kPDEBuildVersionMinor`
Specifies that Apple has designated the current release of the printing dialog extension plug-in interface to be minor version 0, as in 1.0.

`kPDEBaseVersionMajor`
Specifies that Apple has designated the first release of the printing dialog extension plug-in interface to be major version 1, as in 1.0.

`kPDEBaseVersionMinor`
Specifies that Apple has designated the first release of the printing dialog extension plug-in interface to be minor version 0, as in 1.0.

PDE Pane Kind Identifiers

Identifiers associated with the Apple-defined panes in a printing dialog.

```
#define kPMColorPDEKindID                   CFSTR("com.apple.print.pde.ColorKind")
#define kPMCopiesAndPagesPDEKindID
CFSTR("com.apple.print.pde.CopiesAndPagesKind")
#define kPMCoverPagePDEKindID
CFSTR("com.apple.print.pde.CoverPageKind")
#define kPMDuplexPDEKindID                 CFSTR("com.apple.print.pde.DuplexKind")
#define kPMLayoutPDEKindID
CFSTR("com.apple.print.pde.LayoutUserOptionKind")
#define kPMOutputOptionsPDEKindID
CFSTR("com.apple.print.pde.OutputOptionsKind")
#define kPMPageAttributesKindID
CFSTR("com.apple.print.pde.PageAttributesKind")
#define kPMPaperFeedPDEKindID
CFSTR("com.apple.print.pde.PaperFeedKind")
#define kPMPriorityPDEKindID
CFSTR("com.apple.print.pde.PriorityKind")
#define kPMRotationScalingPDEKindID
CFSTR("com.apple.print.pde.RotationScalingKind")
```

Constants

`kPMColorPDEKindID`
Identifies the Print dialog pane named Color Option.

`kPMCopiesAndPagesPDEKindID`
Identifies the Print dialog pane named Copies & Pages.

`kPMCoverPagePDEKindID`
Identifies the Print dialog pane named Cover Page.

`kPMDuplexPDEKindID`
Identifies the Print dialog pane named Duplex.

`kPMLayoutPDEKindID`
Identifies the Print dialog pane named Layout.

`kPMOutputOptionsPDEKindID`
Identifies the Print dialog pane named Output Options.

`kPMPageAttributesKindID`
Identifies the Page Setup dialog pane named Page Attributes.

`kPMPaperFeedPDEKindID`
Identifies the Print dialog pane named Paper Feed.

`kPMPriorityPDEKindID`
Identifies the Print dialog pane named Priority.

`kPMRotationScalingPDEKindID`
Identifies the Print dialog pane named Rotation & Scaling.

PDE Ticket Identifiers

Specify the types of printing job tickets used by printing dialog extensions.

```
#define kPDE_PMPrintSettingsRef     CFSTR("PMPrintSettingsTicket")
#define kPDE_PMPageFormatRef        CFSTR("PMPageFormatTicket")
#define kPDE_PMJobTemplateRef       CFSTR("PMJobTemplateTicket")
#define kPDE_PMPrinterInfoRef       CFSTR("PMPrinterInfoTicket")
```

Constants

`kPDE_PMPrintSettingsRef`
Specifies a print settings ticket.

`kPDE_PMPageFormatRef`
Specifies a page format ticket.

`kPDE_PMJobTemplateRef`
Specifies a job template ticket.

`kPDE_PMPrinterInfoRef`
Specifies a printer info ticket.

PDE Type Identifiers

Specify the different types of printing dialog extensions.

```
#define kAppPageSetupDialogTypeIDStr
CFSTR("B9A0DA98-E57F-11D3-9E83-0050E4603277")
#define kAppPrintDialogTypeIDStr
CFSTR("BCB07250-E57F-11D3-8CA6-0050E4603277")
#define kPrinterModuleTypeIDStr
CFSTR("BDB091F4-E57F-11D3-B5CC-0050E4603277")
```

Constants

`kAppPageSetupDialogTypeIDStr`
The identifier for a Page Setup dialog extension supplied with an application.

`kAppPrintDialogTypeIDStr`
The identifier for a Print dialog extension supplied with an application.

`kPrinterModuleTypeIDStr`
The identifier for a Print dialog extension supplied with a printer module.

Discussion
Apple associates each type of printing dialog extension with a UUID, represented as a constant Core Foundation string.

One or more of these constants is used in the `CFPlugInTypes` property list entry of a printing dialog extension, to declare a supported type and associate the type with a factory function that implements it.

For more information about factory functions, see *Core Foundation Plug-in Services*.

I/O Module Interface Version

Specify the major and minor components of the version numbers for the interface supported by your I/O module.

```
enum {
    kIOMBuildVersionMajor = 1,
    kIOMBuildVersionMinor = 0,
    kIOMBaseVersionMajor = 1,
    kIOMBaseVersionMinor = 0
};
```

Printer Module Interface Version

Specify the major and minor components of the version numbers for the interface supported by your printer module.

```
enum {
    kPMBuildVersionMajor = 1,
    kPMBuildVersionMinor = 0,
    kPMBaseVersionMajor = 1,
    kPMBaseVersionMinor = 0
};
```

Printer Module Status Codes

Specify the status and error event codes and keys reported by the printer module (used in PMNotificationProc).

```
enum {
    kPMEventPrinterStatus = 4000,
    kPMEventErrorOccurred = 4001,
    kPMEventRecoverableErrorOccurred = 4002,
    kPMEventRecoverableErrorCleared = 4003
};
```

Other Printer Module Constants

Defined in PMPrinterModule.h.

```
enum {
    kPMBrowserInfoNumValues = 4
};
```

Print Center Feature Flags

Specify the flags returned by Print Center in its prologue function.

```
typedef UInt32 PMPrBrowserFlags;
enum {
    kPMPrBrowserPCNoFlags = 0,
    kPMPrBrowserPCNoUI = 1,
    kPMPrBrowserPCAllFlags = -1
};
```

Print Center Signatures

Specify the Print Center creator code and icon signatures.

```
enum {
    kPMPrBrowserPCCreator = 'pctr',
    kPMPrBrowserWorksetPrinterIconType = 'wspr',
    kPMPrBrowserUnknownPrinterIconType = '?ptr'
};
```

Result Codes

The table below lists the result codes defined in the Carbon Printing Manager for functions in the printing plug-in interfaces.

Result Code	Value	Description
`kPMCloseFailed`	-9785	A file or connection could not be closed. Available in Mac OS X v10.0 and later.
`kPMDontSwitchPDEError`	-9531	Tells the printing system not to switch out of the current pane. Available in Mac OS X v10.0 and later.
`kPMEditRequestFailed`	-9544	Error handling request to update Edit menu. Available in Mac OS X v10.0 and later.
`kPMInvalidLookupSpec`	-9542	Error retrieving lookup specification. Available in Mac OS X v10.0 and later.
`kPMInvalidPBMRef`	-9540	Invalid printer browser module. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
kPMInvalidPDEContext	-9530	Invalid printing dialog extension context. Available in Mac OS X v10.0 and later.
kPMInvalidPrinterAddress	-9780	Invalid printer address. NetInfo printcap entry not found.Unable to open USB interface. Available in Mac OS X v10.0 and later.
kPMIOAttrNotAvailable	-9787	I/O attribute not available on current connection type. Available in Mac OS X v10.0 and later.
kPMNoSelectedPrinters	-9541	No selected printers or error getting selection. Available in Mac OS X v10.0 and later.
kPMOpenFailed	-9781	A file or connection could not be opened. Available in Mac OS X v10.0 and later.
kPMPrBrowserNoUI	-9545	User interface function call with no user interface present. Available in Mac OS X v10.0 and later.
kPMReadFailed	-9782	A file or connection read operation failed. Available in Mac OS X v10.0 and later.
kPMReadGotZeroData	-9788	A file or connection read operation returned no data. Available in Mac OS X v10.1 and later.
kPMStatusFailed	-9784	Connection status failed. Available in Mac OS X v10.0 and later.
kPMSyncRequestFailed	-9543	Error handling sync request. Available in Mac OS X v10.0 and later.
kPMUnsupportedConnection	-9786	Connection type not supported. Available in Mac OS X v10.0 and later.
kPMWriteFailed	-9783	A file or connection write operation failed. Available in Mac OS X v10.0 and later.

TextEdit Reference (Not Recommended)

Framework: Carbon/Carbon.h

Declared in TextEdit.h
TSMTE.h

Important: The information in this document is obsolete and should not be used for new development.

Overview

TextEdit was originally designed to handle editable text items in dialog boxes and other parts of the Mac OS system software. Although TextEdit was enhanced to provide more text-handling support, especially in its handling of multi-script text, it retained some of its original limitations. TextEdit was never intended to manipulate lengthy documents or text requiring more than rudimentary formatting.

TextEdit has been deprecated for deployment targets Mac OS X version 10.4 and later. The replacement API is Multilingual Text Engine (MLTE). MLTE offers additional features such as Unicode text editing, document-wide tabs, full justification of text, support for more than 32 KB of text, built-in scroll bar handling, built-in printing support, support for inline input, support for the advanced font features of Apple Type Services for Unicode Imaging (ATSUI), and support for multiple levels of undo.

You should use MLTE to replace TextEdit functions in your existing applications. With MLTE, you can significantly reduce the number of lines in your code because MLTE handles most of the low-level tasks you had to code in the past. MLTE provides a quick and easy solution for static display of Unicode text and for creating Unicode-compliant text-editing fields within an application. For more information, see *Handling Unicode Text Editing With MLTE*.

Functions by Task

Activating and Deactivating an Edit Structure

`TEActivate` (page 2968) Deprecated in Mac OS X v10.4

Activates the specified edit structure. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`TEDeactivate` (page 2974) Deprecated in Mac OS X v10.4

Deactivates the specified edit structure. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

Using Additional TextEdit Features

`TEFeatureFlag` (page 2976) Deprecated in Mac OS X v10.4
Turns a specified feature on or off or returns the current status of that feature. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

Checking, Setting, and Replacing Styles

`TEContinuousStyle` (page 2970) Deprecated in Mac OS X v10.4
Determines whether a given character attribute is continuous over the current selection range. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`TEGetStyle` (page 2981) Deprecated in Mac OS X v10.4
Gets character attributes for the specified text. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`TEGetStyleScrapHandle` (page 2983) Deprecated in Mac OS X v10.4
Creates a style scrap structure, copies the character attributes associated with the current selection range into it, and returns a handle to it. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`TENumStyles` (page 2987) Deprecated in Mac OS X v10.4
Returns the number of character attribute changes contained in the specified range, counting one for the start of the range. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`TEReplaceStyle` (page 2989) Deprecated in Mac OS X v10.4
Replaces any character attributes in the current selection range that match the specified existing character attributes with the specified new character attributes. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`TESetStyle` (page 2996) Deprecated in Mac OS X v10.4
Sets new character attributes, in the specified edit structure, for the current selection range. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`TEStyleInsert` (page 2998) Deprecated in Mac OS X v10.4
Inserts the specified text immediately before the selection range or the insertion point in the edit structure's text and applies the specified character attributes to the text, redrawing the text if necessary. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`TEUseStyleScrap` (page 3002) Deprecated in Mac OS X v10.4
Assigns new character attributes to the specified range of text in the designated edit structure. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

Customizing TextEdit

`TECustomHook` (page 2972) Deprecated in Mac OS X v10.4
Replaces a default TextEdit hook function with a customized function and returns the address of the replaced function. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`TEGetDoTextHook` (page 2977) Deprecated in Mac OS X v10.4
Obtains a universal procedure pointer to your do-text-hook callback. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`TEGetFindWordHook` (page 2977) Deprecated in Mac OS X v10.4

Obtains a universal procedure pointer to your set-find-word-hook callback. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`TEGetRecalcHook` (page 2980) Deprecated in Mac OS X v10.4

Obtains a universal procedure pointer to your recalculation callback. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`TESetClickLoop` (page 2992) Deprecated in Mac OS X v10.4

Installs the address of the application-supplied click loop function in the `clikLoop` field of the edit structure. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`TESetDoTextHook` (page 2993) Deprecated in Mac OS X v10.4

Sets your do-text-hook callback to be used by TextEdit. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`TESetFindWordHook` (page 2993) Deprecated in Mac OS X v10.4

Sets your set-find-word-hook callback to be used by TextEdit. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`TESetRecalcHook` (page 2994) Deprecated in Mac OS X v10.4

Sets your recalculation callback to be used by TextEdit. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

Displaying and Scrolling Text

`TEAutoView` (page 2968) Deprecated in Mac OS X v10.4

Enables and disables automatic scrolling of the text in the specified edit structure. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`TECalText` (page 2969) Deprecated in Mac OS X v10.4

Recalculates the beginnings of all lines of text in the specified edit structure. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`TEGetHeight` (page 2978) Deprecated in Mac OS X v10.4

Returns the total height of all of the lines in the text between and including the specified starting and ending lines. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`TEPinScroll` (page 2988) Deprecated in Mac OS X v10.4

Scrolls the text within the view rectangle of the specified edit structure by the designated number of pixels. Scrolling stops when the last line of text is scrolled into view. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`TEScroll` (page 2990) Deprecated in Mac OS X v10.4

Scrolls the text within the view rectangle of the specified edit structure by the designated number of pixels. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`TESelView` (page 2991) Deprecated in Mac OS X v10.4

Ensures, once automatic scrolling has been enabled by a call to the `TEAutoView` function or through the `TEFeatureFlag` function, that the selection range is visible, scrolling it into the view rectangle if necessary. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`TESetAlignment` (page 2992) Deprecated in Mac OS X v10.4
Sets the alignment of the specified text in an edit structure so that it is centered, right aligned, or left aligned, or aligned according to the line direction. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`TETextBox` (page 3000) Deprecated in Mac OS X v10.4
Draws the indicated text in a given rectangle, with the specified alignment. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`TEUpdate` (page 3002) Deprecated in Mac OS X v10.4
Draws the specified text within a given update rectangle. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

Initializing TextEdit, Creating an Edit Structure, and Disposing of an Edit Structure

`TEDispose` (page 2975) Deprecated in Mac OS X v10.4
Removes a specified edit structure and releases all memory associated with it. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`TENew` (page 2986) Deprecated in Mac OS X v10.4
Creates and initializes a monostyled edit structure and allocates a handle to it. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`TEStyleNew` (page 2999) Deprecated in Mac OS X v10.4
Creates a multistyled edit structure and allocates a handle to it. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

Managing the TextEdit Private Scrap

`TEGetScrapHandle` (page 2980) Deprecated in Mac OS X v10.4
Returns a handle to the TextEdit private scrap. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`TEGetScrapLength` (page 2981) Deprecated in Mac OS X v10.4
Returns the size of the TextEdit private scrap, in bytes. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`TEScrapHandle` (page 2990) Deprecated in Mac OS X v10.4
Returns a handle to the TextEdit private scrap. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`TESetScrapHandle` (page 2994) Deprecated in Mac OS X v10.4
Sets a handle to the TextEdit private scrap. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`TESetScrapLength` (page 2994) Deprecated in Mac OS X v10.4
Sets the size of the TextEdit private scrap to the specified number of bytes. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

Modifying the Text of an Edit Structure

`TECopy` (page 2971) Deprecated in Mac OS X v10.4

Copies the text selection range from the edit structure, leaving the selection range intact. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`TECut` (page 2973) Deprecated in Mac OS X v10.4

Removes the current selection range from the text of the designated edit structure, redrawing the text as necessary. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`TEDelete` (page 2974) Deprecated in Mac OS X v10.4

Removes the selected range of text from the designated edit structure, redrawing the remaining text as necessary. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`TEFromScrap` (page 2976) Deprecated in Mac OS X v10.4

Copies the contents of the desk scrap to the TextEdit private scrap. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`TEInsert` (page 2985) Deprecated in Mac OS X v10.4

Inserts the specified text immediately before the selection range or the insertion point in the text of the designated edit structure, redrawing the text as necessary. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`TEPaste` (page 2988) Deprecated in Mac OS X v10.4

Replaces the edit structure's selected text with the contents of the private scrap and leaves an insertion point after the inserted text. If the selection range is an insertion point, `TEPaste` inserts the contents of the private scrap there. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`TEStylePaste` (page 3000) Deprecated in Mac OS X v10.4

Pastes text and its associated character attribute information from the desk scrap into the edit structure's text at the insertion point—if the current selection range is an insertion point—or it replaces the current selection range. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`TEToScrap` (page 3001) Deprecated in Mac OS X v10.4

Copies the contents of the TextEdit private scrap to the desk scrap. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

Setting and Getting an Edit Structure's Text and Character Attribute Information

`TEGetStyleHandle` (page 2982) Deprecated in Mac OS X v10.4

Returns the style handle stored in the designated edit structure's `txFont` and `txFace` fields. The style handle points to the associated style structure, not to a copy of it. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`TEGetText` (page 2983) Deprecated in Mac OS X v10.4

Returns a handle to the text of the specified edit structure. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`TEKey` (page 2985) Deprecated in Mac OS X v10.4
Replaces the selection range in the text of the specified edit structure with the input character and positions the insertion point just past the inserted character. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`TESetStyleHandle` (page 2997) Deprecated in Mac OS X v10.4
Sets an edit structure's style handle, which is stored in the `txFont` and `txFace` fields. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`TESetText` (page 2997) Deprecated in Mac OS X v10.4
Incorporates a copy of the specified text into the designated edit structure. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

Setting the Caret and Selection Range

`TEClick` (page 2969) Deprecated in Mac OS X v10.4
Controls placement and highlighting of the selection range as determined by mouse events. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`TEGetHiliteRgn` (page 2978) Deprecated in Mac OS X v10.4
Obtains the highlight region for the specified edit structure. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`TEIdle` (page 2984) Deprecated in Mac OS X v10.4
When called repeatedly, displays a blinking caret at the insertion point, if any exists, in the text of the specified edit structure of an active window. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`TESetSelect` (page 2995) Deprecated in Mac OS X v10.4
Sets the selection range (or denotes the insertion point) within the text of the specified edit structure. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

Using Byte Offsets and Corresponding Points

`TEGetOffset` (page 2979) Deprecated in Mac OS X v10.4
Finds the byte offset of a character in an edit structure's text that corresponds to the specified point. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`TEGetPoint` (page 2979) Deprecated in Mac OS X v10.4
Determines the point that corresponds to the specified byte offset of a character and returns the coordinates of that point. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

Handling TSM Dialogs

`GetTSMTEDialogDocumentID` (page 2954) Deprecated in Mac OS X v10.4
Returns a TSM document ID for the specified dialog. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`GetTSMTEDialogTSMTERecHandle` (page 2954) Deprecated in Mac OS X v10.4
Returns a handle to a TSM record for the specified dialog. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`IsTSMTEDialog` (page 2961) Deprecated in Mac OS X v10.4
Checks to see if the specified dialog is a TSMTE dialog. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`SetTSMTEDialogDocumentID` (page 2967) Deprecated in Mac OS X v10.4
Sets the document ID for the specified dialog. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`SetTSMTEDialogTSMTERecHandle` (page 2967) Deprecated in Mac OS X v10.4
Sets a handle to a TSMTE record for the specified dialog. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

Working With UPPs for TextEdit Callback Functions

`DisposeCaretHookUPP` (page 2950) Deprecated in Mac OS X v10.4
Disposes of a universal procedure pointer (UPP) to a caret-hook callback. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`DisposeDrawHookUPP` (page 2950) Deprecated in Mac OS X v10.4
Disposes of a universal procedure pointer (UPP) to a draw-hook callback. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`DisposeEOLHookUPP` (page 2950) Deprecated in Mac OS X v10.4
Disposes of a universal procedure pointer (UPP) to an EOL-hook callback. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`DisposeHighHookUPP` (page 2951) Deprecated in Mac OS X v10.4
Disposes of a universal procedure pointer (UPP) to a high-hook callback. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`DisposeHitTestHookUPP` (page 2951) Deprecated in Mac OS X v10.4
Disposes of a universal procedure pointer (UPP) to a hit-test hook callback. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`DisposeNWidthHookUPP` (page 2951) Deprecated in Mac OS X v10.4
Disposes of a universal procedure pointer (UPP) to a width-hook callback. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`DisposeTEClickLoopUPP` (page 2952) Deprecated in Mac OS X v10.4
Disposes of a universal procedure pointer (UPP) to a click-loop callback. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`DisposeTEDoTextUPP` (page 2952) Deprecated in Mac OS X v10.4
Disposes of a universal procedure pointer (UPP) to a do-text callback. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`DisposeTEFindWordUPP` (page 2952) Deprecated in Mac OS X v10.4
Disposes of a universal procedure pointer (UPP) to a find-word callback. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`DisposeTERecalcUPP` (page 2952) Deprecated in Mac OS X v10.4
Disposes of a universal procedure pointer (UPP) to a recaluclation callback. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`DisposeTextWidthHookUPP` (page 2953) Deprecated in Mac OS X v10.4
Disposes of a universal procedure pointer (UPP) to a text-width-hook callback. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`DisposeTSMTEPostUpdateUPP` (page 2953) Deprecated in Mac OS X v10.4

Disposes of a universal procedure pointer (UPP) to a post-update callback. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`DisposeTSMTEPreUpdateUPP` (page 2953) Deprecated in Mac OS X v10.4

Disposes of a universal procedure pointer (UPP) to a pre-update callback. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`DisposeWidthHookUPP` (page 2954) Deprecated in Mac OS X v10.4

Disposes of a universal procedure pointer (UPP) to a width-hook callback. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`InvokeCaretHookUPP` (page 2955) Deprecated in Mac OS X v10.4

Calls a caret-hook callback. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`InvokeDrawHookUPP` (page 2955) Deprecated in Mac OS X v10.4

Calls a draw-hook callback. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`InvokeEOLHookUPP` (page 2956) Deprecated in Mac OS X v10.4

Calls an EOL-hook callback. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`InvokeHighHookUPP` (page 2956) Deprecated in Mac OS X v10.4

Calls a high-hook callback. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`InvokeHitTestHookUPP` (page 2957) Deprecated in Mac OS X v10.4

Calls a hit-test hook callback. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`InvokeNWidthHookUPP` (page 2957) Deprecated in Mac OS X v10.4

Calls a width-hook callback. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`InvokeTEClickLoopUPP` (page 2958) Deprecated in Mac OS X v10.4

Calls a click-loop callback. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`InvokeTEDoTextUPP` (page 2958) Deprecated in Mac OS X v10.4

Calls a do-text callback. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`InvokeTEFindWordUPP` (page 2959) Deprecated in Mac OS X v10.4

Calls a find-word callback. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`InvokeTERecalcUPP` (page 2959) Deprecated in Mac OS X v10.4

Calls a recalculation callback. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`InvokeTextWidthHookUPP` (page 2959) Deprecated in Mac OS X v10.4

Calls a text-width-hook callback. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`InvokeTSMTEPostUpdateUPP` (page 2960) Deprecated in Mac OS X v10.4

Calls a post-update callback. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`InvokeTSMTEPreUpdateUPP` (page 2960) Deprecated in Mac OS X v10.4

Calls a pre-update callback. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`InvokeWidthHookUPP` (page 2961) Deprecated in Mac OS X v10.4

Calls a width-hook callback. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`NewCaretHookUPP` (page 2962) Deprecated in Mac OS X v10.4

Creates a new universal procedure pointer (UPP) to a caret-hook callback. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`NewDrawHookUPP` (page 2962) Deprecated in Mac OS X v10.4

Creates a new universal procedure pointer (UPP) to a draw-hook callback. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`NewEOLHookUPP` (page 2962) Deprecated in Mac OS X v10.4

Creates a new universal procedure pointer (UPP) to an EOL-hook callback. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`NewHighHookUPP` (page 2963) Deprecated in Mac OS X v10.4

Creates a new universal procedure pointer (UPP) to a high-hook callback. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`NewHitTestHookUPP` (page 2963) Deprecated in Mac OS X v10.4

Creates a new universal procedure pointer (UPP) to a hit-test hook callback. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`NewNWidthHookUPP` (page 2964) Deprecated in Mac OS X v10.4

Creates a new universal procedure pointer (UPP) to a width-hook callback. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`NewTEClickLoopUPP` (page 2964) Deprecated in Mac OS X v10.4

Creates a new universal procedure pointer (UPP) to a click-loop callback. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`NewTEDoTextUPP` (page 2964) Deprecated in Mac OS X v10.4

Creates a new universal procedure pointer (UPP) to a do-text callback. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`NewTEFindWordUPP` (page 2965) Deprecated in Mac OS X v10.4

Creates a new universal procedure pointer (UPP) to a find-word callback. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`NewTERecalcUPP` (page 2965) Deprecated in Mac OS X v10.4

Creates a new universal procedure pointer (UPP) to a recalculation callback. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`NewTextWidthHookUPP` (page 2965) Deprecated in Mac OS X v10.4

Creates a new universal procedure pointer (UPP) to a text-width-hook callback. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`NewTSMTEPostUpdateUPP` (page 2966) Deprecated in Mac OS X v10.4

Creates a new universal procedure pointer (UPP) to a post-update callback. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`NewTSMTEPreUpdateUPP` (page 2966) Deprecated in Mac OS X v10.4

Creates a new universal procedure pointer (UPP) to a pre-update callback. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

`NewWidthHookUPP` (page 2966) Deprecated in Mac OS X v10.4
Creates a new universal procedure pointer (UPP) to a width-hook callback. (Deprecated. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

Functions

DisposeCaretHookUPP

Disposes of a universal procedure pointer (UPP) to a caret-hook callback. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void DisposeCaretHookUPP (
   CaretHookUPP userUPP
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`TextEdit.h`

DisposeDrawHookUPP

Disposes of a universal procedure pointer (UPP) to a draw-hook callback. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void DisposeDrawHookUPP (
   DrawHookUPP userUPP
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`TextEdit.h`

DisposeEOLHookUPP

Disposes of a universal procedure pointer (UPP) to an EOL-hook callback. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void DisposeEOLHookUPP (
   EOLHookUPP userUPP
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
TextEdit.h

DisposeHighHookUPP

Disposes of a universal procedure pointer (UPP) to a high-hook callback. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void DisposeHighHookUPP (
   HighHookUPP userUPP
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
TextEdit.h

DisposeHitTestHookUPP

Disposes of a universal procedure pointer (UPP) to a hit-test hook callback. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void DisposeHitTestHookUPP (
   HitTestHookUPP userUPP
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
TextEdit.h

DisposeNWidthHookUPP

Disposes of a universal procedure pointer (UPP) to a width-hook callback. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void DisposeNWidthHookUPP (
   NWidthHookUPP userUPP
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
TextEdit.h

DisposeTEClickLoopUPP

Disposes of a universal procedure pointer (UPP) to a click-loop callback. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void DisposeTEClickLoopUPP (
   TEClickLoopUPP userUPP
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`TextEdit.h`

DisposeTEDoTextUPP

Disposes of a universal procedure pointer (UPP) to a do-text callback. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void DisposeTEDoTextUPP (
   TEDoTextUPP userUPP
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`TextEdit.h`

DisposeTEFindWordUPP

Disposes of a universal procedure pointer (UPP) to a find-word callback. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void DisposeTEFindWordUPP (
   TEFindWordUPP userUPP
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`TextEdit.h`

DisposeTERecalcUPP

Disposes of a universal procedure pointer (UPP) to a recaluclation callback. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void DisposeTERecalcUPP (
   TERecalcUPP userUPP
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
TextEdit.h

DisposeTextWidthHookUPP

Disposes of a universal procedure pointer (UPP) to a text-width-hook callback. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void DisposeTextWidthHookUPP (
   TextWidthHookUPP userUPP
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
TextEdit.h

DisposeTSMTEPostUpdateUPP

Disposes of a universal procedure pointer (UPP) to a post-update callback. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void DisposeTSMTEPostUpdateUPP (
   TSMTEPostUpdateUPP userUPP
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
TSMTE.h

DisposeTSMTEPreUpdateUPP

Disposes of a universal procedure pointer (UPP) to a pre-update callback. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void DisposeTSMTEPreUpdateUPP (
   TSMTEPreUpdateUPP userUPP
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`TSMTE.h`

DisposeWidthHookUPP

Disposes of a universal procedure pointer (UPP) to a width-hook callback. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void DisposeWidthHookUPP (
   WidthHookUPP userUPP
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`TextEdit.h`

GetTSMTEDialogDocumentID

Returns a TSM document ID for the specified dialog. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
TSMDocumentID GetTSMTEDialogDocumentID (
   DialogRef dialog
);
```

Return Value
See the Text Services Manager documentation for a description of the `TSMDocumentID` data type.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TSMTE.h`

GetTSMTEDialogTSMTERecHandle

Returns a handle to a TSM record for the specified dialog. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
TSMTERecHandle GetTSMTEDialogTSMTERecHandle (
   DialogRef dialog
);
```

Return Value
See the description of the `TSMTERecHandle` data type.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TSMTE.h`

InvokeCaretHookUPP

Calls a caret-hook callback. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void InvokeCaretHookUPP (
   const Rect *r,
   TEPtr pTE,
   CaretHookUPP userUPP
);
```

Discussion
You should not need to use this function, as the system invokes your callback for you.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`TextEdit.h`

InvokeDrawHookUPP

Calls a draw-hook callback. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void InvokeDrawHookUPP (
   unsigned short textOffset,
   unsigned short drawLen,
   void *textBufferPtr,
   TEPtr pTE,
   TEHandle hTE,
   DrawHookUPP userUPP
);
```

Discussion
You should not need to use this function, as the system invokes your callback for you.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`TextEdit.h`

InvokeEOLHookUPP

Calls an EOL-hook callback. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
Boolean InvokeEOLHookUPP (
   char theChar,
   TEPtr pTE,
   TEHandle hTE,
   EOLHookUPP userUPP
);
```

Return Value
See the Mac Types documentation for a description of the `Boolean` data type.

Discussion
You should not need to use this function, as the system invokes your callback for you.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`TextEdit.h`

InvokeHighHookUPP

Calls a high-hook callback. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void InvokeHighHookUPP (
   const Rect *r,
   TEPtr pTE,
   HighHookUPP userUPP
);
```

Discussion
You should not need to use this function, as the system invokes your callback for you.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`TextEdit.h`

InvokeHitTestHookUPP

Calls a hit-test hook callback. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
Boolean InvokeHitTestHookUPP (
   unsigned short styleRunLen,
   unsigned short styleRunOffset,
   unsigned short slop,
   void *textBufferPtr,
   TEPtr pTE,
   TEHandle hTE,
   unsigned short *pixelWidth,
   unsigned short *charOffset,
   Boolean *pixelInChar,
   HitTestHookUPP userUPP
);
```

Return Value
See the Mac Types documentation for a description of the `Boolean` data type.

Discussion
You should not need to use this function, as the system invokes your callback for you.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`TextEdit.h`

InvokeNWidthHookUPP

Calls a width-hook callback. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
unsigned short InvokeNWidthHookUPP (
   unsigned short styleRunLen,
   unsigned short styleRunOffset,
   short slop,
   short direction,
   void *textBufferPtr,
   short *lineStart,
   TEPtr pTE,
   TEHandle hTE,
   NWidthHookUPP userUPP
);
```

Discussion
You should not need to use this function, as the system invokes your callback for you.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`TextEdit.h`

InvokeTEClickLoopUPP

Calls a click-loop callback. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
Boolean InvokeTEClickLoopUPP (
   TEPtr pTE,
   TEClickLoopUPP userUPP
);
```

Return Value
See the Mac Types documentation for a description of the `Boolean` data type.

Discussion
You should not need to use this function, as the system invokes your callback for you.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`TextEdit.h`

InvokeTEDoTextUPP

Calls a do-text callback. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void InvokeTEDoTextUPP (
   TEPtr pTE,
   unsigned short firstChar,
   unsigned short lastChar,
   short selector,
   GrafPtr *currentGrafPort,
   short *charPosition,
   TEDoTextUPP userUPP
);
```

Discussion
You should not need to use this function, as the system invokes your callback for you.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`TextEdit.h`

InvokeTEFindWordUPP

Calls a find-word callback. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void InvokeTEFindWordUPP (
   unsigned short currentPos,
   short caller,
   TEPtr pTE,
   TEHandle hTE,
   unsigned short *wordStart,
   unsigned short *wordEnd,
   TEFindWordUPP userUPP
);
```

Discussion
You should not need to use this function, as the system invokes your callback for you.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
TextEdit.h

InvokeTERecalcUPP

Calls a recalculation callback. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void InvokeTERecalcUPP (
   TEPtr pTE,
   unsigned short changeLength,
   unsigned short *lineStart,
   unsigned short *firstChar,
   unsigned short *lastChar,
   TERecalcUPP userUPP
);
```

Discussion
You should not need to use this function, as the system invokes your callback for you.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
TextEdit.h

InvokeTextWidthHookUPP

Calls a text-width-hook callback. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
unsigned short InvokeTextWidthHookUPP (
   unsigned short textLen,
   unsigned short textOffset,
   void *textBufferPtr,
   TEPtr pTE,
   TEHandle hTE,
   TextWidthHookUPP userUPP
);
```

Discussion
You should not need to use this function, as the system invokes your callback for you.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`TextEdit.h`

InvokeTSMTEPostUpdateUPP

Calls a post-update callback. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void InvokeTSMTEPostUpdateUPP (
   TEHandle textH,
   long fixLen,
   long inputAreaStart,
   long inputAreaEnd,
   long pinStart,
   long pinEnd,
   long refCon,
   TSMTEPostUpdateUPP userUPP
);
```

Discussion
You should not need to use this function, as the system invokes your callback for you.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`TSMTE.h`

InvokeTSMTEPreUpdateUPP

Calls a pre-update callback. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void InvokeTSMTEPreUpdateUPP (
   TEHandle textH,
   long refCon,
   TSMTEPreUpdateUPP userUPP
);
```

Discussion
You should not need to use this function, as the system invokes your callback for you.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`TSMTE.h`

InvokeWidthHookUPP

Calls a width-hook callback. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
unsigned short InvokeWidthHookUPP (
   unsigned short textLen,
   unsigned short textOffset,
   void *textBufferPtr,
   TEPtr pTE,
   TEHandle hTE,
   WidthHookUPP userUPP
);
```

Discussion
You should not need to use this function, as the system invokes your callback for you.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`TextEdit.h`

IsTSMTEDialog

Checks to see if the specified dialog is a TSMTE dialog. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
Boolean IsTSMTEDialog (
   DialogRef dialog
);
```

Return Value
See the Mac Types documentation for a description of the `Boolean` data type.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TSMTE.h`

NewCaretHookUPP

Creates a new universal procedure pointer (UPP) to a caret-hook callback. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
CaretHookUPP NewCaretHookUPP (
   CaretHookProcPtr userRoutine
);
```

Return Value
See the description of the `CaretHookUPP` data type.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`TextEdit.h`

NewDrawHookUPP

Creates a new universal procedure pointer (UPP) to a draw-hook callback. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
DrawHookUPP NewDrawHookUPP (
   DrawHookProcPtr userRoutine
);
```

Return Value
See the description of the `DrawHookUPP` data type.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`TextEdit.h`

NewEOLHookUPP

Creates a new universal procedure pointer (UPP) to an EOL-hook callback. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
EOLHookUPP NewEOLHookUPP (
   EOLHookProcPtr userRoutine
);
```

Return Value
See the description of the `EOLHookUPP` data type.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`TextEdit.h`

NewHighHookUPP

Creates a new universal procedure pointer (UPP) to a high-hook callback. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
HighHookUPP NewHighHookUPP (
   HighHookProcPtr userRoutine
);
```

Return Value
See the description of the `HighHookUPP` data type.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`TextEdit.h`

NewHitTestHookUPP

Creates a new universal procedure pointer (UPP) to a hit-test hook callback. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
HitTestHookUPP NewHitTestHookUPP (
   HitTestHookProcPtr userRoutine
);
```

Return Value
See the description of the `HitTestHookUPP` data type.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`TextEdit.h`

NewNWidthHookUPP

Creates a new universal procedure pointer (UPP) to a width-hook callback. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
NWidthHookUPP NewNWidthHookUPP (
   NWidthHookProcPtr userRoutine
);
```

Return Value
See the description of the `NWidthHookUPP` data type.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`TextEdit.h`

NewTEClickLoopUPP

Creates a new universal procedure pointer (UPP) to a click-loop callback. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
TEClickLoopUPP NewTEClickLoopUPP (
   TEClickLoopProcPtr userRoutine
);
```

Return Value
See the description of the `TEClickLoopUPP` data type.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`TextEdit.h`

NewTEDoTextUPP

Creates a new universal procedure pointer (UPP) to a do-text callback. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
TEDoTextUPP NewTEDoTextUPP (
   TEDoTextProcPtr userRoutine
);
```

Return Value
See the description of the `TEDoTextUPP` data type.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
TextEdit.h

NewTEFindWordUPP

Creates a new universal procedure pointer (UPP) to a find-word callback. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
TEFindWordUPP NewTEFindWordUPP (
   TEFindWordProcPtr userRoutine
);
```

Return Value
See TEFindWordUPP (page 3020) for a description of the TEFindWordUPP data type.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
TextEdit.h

NewTERecalcUPP

Creates a new universal procedure pointer (UPP) to a recalculation callback. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
TERecalcUPP NewTERecalcUPP (
   TERecalcProcPtr userRoutine
);
```

Return Value
See the description of the TERecalcUPP data type.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
TextEdit.h

NewTextWidthHookUPP

Creates a new universal procedure pointer (UPP) to a text-width-hook callback. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
TextWidthHookUPP NewTextWidthHookUPP (
   TextWidthHookProcPtr userRoutine
);
```

Return Value
See the description of the TextWidthHookUPP data type.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`TextEdit.h`

NewTSMTEPostUpdateUPP

Creates a new universal procedure pointer (UPP) to a post-update callback. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
TSMTEPostUpdateUPP NewTSMTEPostUpdateUPP (
   TSMTEPostUpdateProcPtr userRoutine
);
```

Return Value
See `TSMTEPostUpdateUPP` (page 3029) for a description of the `TSMTEPostUpdateUPP` data type.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`TSMTE.h`

NewTSMTEPreUpdateUPP

Creates a new universal procedure pointer (UPP) to a pre-update callback. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
TSMTEPreUpdateUPP NewTSMTEPreUpdateUPP (
   TSMTEPreUpdateProcPtr userRoutine
);
```

Return Value
See the description of the `TSMTEPreUpdateUPP` data type.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`TSMTE.h`

NewWidthHookUPP

Creates a new universal procedure pointer (UPP) to a width-hook callback. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
WidthHookUPP NewWidthHookUPP (
   WidthHookProcPtr userRoutine
);
```

Return Value
See the description of the `WidthHookUPP` data type.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.

Declared In
`TextEdit.h`

SetTSMTEDialogDocumentID

Sets the document ID for the specified dialog. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void SetTSMTEDialogDocumentID (
   DialogRef dialog,
   TSMDocumentID documentID
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TSMTE.h`

SetTSMTEDialogTSMTERecHandle

Sets a handle to a TSMTE record for the specified dialog. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void SetTSMTEDialogTSMTERecHandle (
   DialogRef dialog,
   TSMTERecHandle tsmteRecHandle
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TSMTE.h`

TEActivate

Activates the specified edit structure. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void TEActivate (
   TEHandle hTE
);
```

Parameters

hTE

A handle to the specified edit structure.

Discussion

When your application receives notification of an activate event, it can call the `TEActivate` function, which activates an edit structure and highlights the selection range. If the selection range is an insertion point, `TEActivate` simply displays a caret there. Call this function every time the Event Manager function `WaitNextEvent` reports that the window containing the edit structure has become active.

If you do not call `TEActivate` before you call `TEClick`, `TEIdle`, or `TESetSelect`, the selection range is not highlighted, or, if the selection range is set to an insertion point, a caret is not displayed at the insertion point. However, if you have turned on outline highlighting through the `TEFeatureFlag` function for the edit structure, the text of the selection range is framed or a dimmed or an unblinking caret is displayed at the insertion point.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`TextEdit.h`

TEAutoView

Enables and disables automatic scrolling of the text in the specified edit structure. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void TEAutoView (
   Boolean fAuto,
   TEHandle hTE
);
```

Parameters

fAuto

A flag indicating whether to enable or disable automatic scrolling. A value of `TRUE` enables automatic scrolling; a value of `FALSE` disables automatic scrolling.

hTE

A handle to the edit structure for which automatic scrolling is to be enabled or disabled.

Discussion

The `TEAutoView` function does not actually scroll the text automatically: `TESelView` does. However, when `fAuto` is set to `FALSE` , a call to `TESelView` has no effect.

If there is a scroll bar associated with the edit structure, your application must manage scrolling of it. You can replace the default click loop function, which scrolls the text only, with a customized version that also updates the scroll bar.

You can also enable or disable automatic scrolling for an edit structure through the `teFAutoScroll` feature of the `TEFeatureFlag` function. For more information, see `TEFeatureFlag` (page 2976).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextEdit.h`

TECalText

Recalculates the beginnings of all lines of text in the specified edit structure. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void TECalText (
   TEHandle hTE
);
```

Parameters

hTE

A handle to the edit structure whose text lines are to be recalculated.

Discussion
The `TECalText` function updates elements of the `lineStarts` array in an edit structure. Call `TECalText` if you've changed the destination rectangle, the `hText` field, or any other property of the edit structure that pertains to line breaks and the number of characters per line—for example, font, size, style, and so on.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextEdit.h`

TEClick

Controls placement and highlighting of the selection range as determined by mouse events. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void TEClick (
   Point pt,
   Boolean fExtend,
   TEHandle h
);
```

Parameters

pt

The mouse location in local coordinates at the time the mouse button was pressed, obtainable from the event structure (in global coordinates).

fExtend

A flag denoting the state of the Shift key at the time of the click as indicated by the Event Manager. If the Shift key was held down at the time of the click to extend the selection, pass a value of `TRUE`.

h

A handle to the edit structure whose text is displayed in the view rectangle where the click occurred.

Discussion

Call `TEClick` whenever a mouse-down event occurs in the view rectangle of the edit structure and the window associated with that edit structure is active. The `TEClick` function keeps control until the mouse button is released. Use the QuickDraw function `GlobalToLocal` to convert the global coordinates of the mouse location given in the event structure to the local coordinate system for `pt`.

The `TEClick` function removes highlighting of the old selection range unless the selection range is being extended. If the mouse moves, meaning that a drag is occurring, `TEClick` expands or shortens the selection range accordingly a character at a time. In the case of a double-click, the word where the cursor is positioned becomes the selection range.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`TextEdit.h`

TEContinuousStyle

Determines whether a given character attribute is continuous over the current selection range. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
Boolean TEContinuousStyle (
   short *mode,
   TextStyle *aStyle,
   TEHandle hTE
);
```

Parameters

mode

On input, a pointer to a selector specifying the attributes to be checked. On output, `mode` identifies only those attributes determined to be continuous over the selection range. Possible values for the `mode` parameter are defined in "Text Styling Constants" (page 3036).

aStyle

On input, a pointer to a text style structure. On output, this structure contains the values for the `mode` attributes determined to be continuous over the selection.

hTE

A handle to the edit structure containing the selected text whose attributes are to be checked. If the value of `hTE` is a handle to a monostyled edit structure, `TEContinuousStyle` returns the set of character attributes that are consistent for the entire structure.

Return Value
`TRUE` if all of the attributes to be checked are continuous; `FALSE` if none or some are continuous. See the Mac Types documentation for a description of the `Boolean` data type.

Discussion
This function does not modify the text selection. If the current selection range is an insertion point, `TEContinuousStyle` first checks the null scrap. If the null scrap contains character attributes, then they are used based on the value of the `mode` parameter. Otherwise, if the null scrap is empty, `TEContinuousStyle` returns the attributes of the character preceding the insertion point. The `TEContinuousStyle` function always returns `TRUE` in this case, and each field of the text style structure is set if the corresponding bit in the `mode` parameter is set.

Note that fields in the text style structure specified by `aStyle` are only valid if the corresponding bits are set in the `mode` variable.

How the `tsFace` field of the `aStyle` structure is used requires some consideration. For example, if `TEContinuousStyle` returns a `mode` parameter that contains `doFace` and the text style structure `tsFace` field is bold, it means that the selected text is all bold, but may contain other text styles, such as italic, as well. Italic does not apply to all of the selected text, or it would have been included in the `tsFace` field. If the `tsFace` field is an empty set, then all of the selected text is plain.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextEdit.h`

TECopy

Copies the text selection range from the edit structure, leaving the selection range intact. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void TECopy (
   TEHandle hTE
);
```

Parameters

hTE

A handle to the edit structure containing the text to be copied.

Discussion
The `TECopy` function copies the text to the private scrap. For text of a monostyled edit structure, the text is written to the private scrap only. For text of a multistyled edit structure, the text is written to the TextEdit private scrap, the character attribute information is written to the TextEdit style scrap, and both are written to the Scrap Manager's desk scrap. Anything previously in the private scrap is deleted before the copied text is written to it.

For both multistyled and monostyled text, if the selection range is an insertion point, `TECopy` empties the TextEdit private scrap. When the selection range is an insertion point and the text is multistyled, `TECopy` has no effect on the null scrap, the style scrap, or the Scrap Manager's desk scrap.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextEdit.h`

TECustomHook

Replaces a default TextEdit hook function with a customized function and returns the address of the replaced function. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void TECustomHook (
   TEIntHook which,
   UniversalProcPtr *addr,
   TEHandle hTE
);
```

Parameters

which
The hook whose default function is to be replaced.

addr
On input, the address of your customized function.
On output, the `addr` parameter contains the address of the function that was previously installed in the field identified by the `which` parameter. This address is returned so that you can daisy-chain functions.

hTE
A handle to the edit structure to be modified.

Discussion
The `TECustomHook` function lets you alter the behavior of TextEdit to better suit your application's requirements and those of the script systems installed. If you replace a default hook function with a customized version that you write in a high-level language, such as Pascal or C, you need to provide assembly-language glue code that utilizes the registers for your high-level language function.

The end-of-line hook, width measurement hook, new width measurement hook, text width measurement hook, draw hook, and hit test hook fields are hook fields in the TextEdit dispatch structure. The `which` parameter identifies the hook whose default function is to be replaced. You use the constants described in "Text Custom Hook Constants" (page 3033) to specify a value for this parameter.

Certain precautions are critical in replacing default functions. Before placing the address of your function in the TextEdit dispatch structure, strip the addresses, using the Operating System Utilities `StripAddress` function, to guarantee that your application is 32-bit clean.

Before replacing a TextEdit function with a customized one, determine whether more than one script system is installed, and if so, ensure that your customized function accommodates all of the installed script systems. This avoids the problem of your customized function producing results that are incompatible with the Script Manager.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextEdit.h`

TECut

Removes the current selection range from the text of the designated edit structure, redrawing the text as necessary. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void TECut (
   TEHandle hTE
);
```

Parameters

hTE
A handle to the edit structure containing the text to be cut.

Discussion
For monostyled text, the `TECut` function writes the cut text to the private scrap.

For multistyled text, `TECut` writes the cut text to the private scrap and its character attributes to the style scrap it also writes both to the Scrap Manager's desk scrap. For multistyled text, the `TECut` function removes the character attributes from the style structure's style table when the text is cut.

For both monostyled and multistyled text, if the selection range is an insertion point, TextEdit deletes everything from the private scrap. When the selection range is an insertion point and the text is multistyled, `TECut` has no effect on the style scrap or the Scrap Manager's desk scrap.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextEdit.h`

TEDeactivate

Deactivates the specified edit structure. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void TEDeactivate (
   TEHandle hTE
);
```

Parameters

hTE

A handle to the specified edit structure.

Discussion

When the activate event flag is set to deactivate the window, your application can call the `TEDeactivate` function, which changes an edit structure's status from active to inactive and removes the selection range highlighting or the caret.

However, if you turned on outline highlighting through the `TEFeatureFlag` function for the edit structure, the text of the selection range is framed or a dimmed or an unblinking caret is displayed at the insertion point when the structure is deactivated.

Call this function every time the Event Manager function `WaitNextEvent` reports that the window containing the edit structure has become inactive.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`TextEdit.h`

TEDelete

Removes the selected range of text from the designated edit structure, redrawing the remaining text as necessary. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void TEDelete (
   TEHandle hTE
);
```

Parameters

hTE

A handle to the edit structure containing the text to be deleted.

Discussion

When the `TEDelete` function deletes a selected range of text, it does not transfer the text to either the private scrap or the Scrap Manager's desk scrap.

For multistyled structures, when you use `TEDelete` to delete a selected range of text, the associated character attributes are saved in the null scrap to be applied to characters entered after the text is deleted. When the user clicks in some other area of the text, the character attributes are removed from the null scrap. You can use `TEDelete` to implement the Clear command. The `TEDelete` function recalculates line starts and line heights.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextEdit.h`

TEDispose

Removes a specified edit structure and releases all memory associated with it. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void TEDispose (
   TEHandle hTE
);
```

Parameters

hTE

A handle to the edit structure for which the allocated memory should be released.

Discussion
Call the `TEDispose` function only when you're completely through with an edit structure.

Note that if your program retains a handle to text associated with the edit structure that you are destroying with `TEDispose`, the handle becomes invalid because the `TEDispose` function disposes of it, as well as the dispatch structure handle. If the structure is multistyled, `TEDispose` also disposes all of the style-related handles: `STHandle`, `LHHandle`, `STScrpHandle`, `nullSTHandle`, and `TEStyleHandle`.

To continue to refer to the text after you've destroyed the edit structure, you need to make a copy of the handle in the `hText` field of the edit structure using the Operating System Utilities `HandToHand` function before you call `TEDispose`.

In addition to disposing of the edit structure, the edit structure handle, and the dispatch structure handle, the `TEDispose` function destroys the null scrap associated with the edit structure and releases the memory used for it.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextEdit.h`

TEFeatureFlag

Turns a specified feature on or off or returns the current status of that feature. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
short TEFeatureFlag (
   short feature,
   short action,
   TEHandle hTE
);
```

Parameters

feature

The feature for which the action is to be performed. See "Text Feature Constants" (page 3035) for a description of the available values.

action

A selector stipulating that the feature, specified by the `feature` parameter, is to be turned on or off, or that the current status of the feature is to be returned. See "Text Feature Action Constants" (page 3034) for a description of the available values.

hTE

A handle to the edit structure for which the action should be performed.

Return Value

The status of the specified feature (if the selector is set to `teBitTest`).

Discussion

You can use the `TEFeatureFlag` function to check the status of additional TextEdit features—automatic scrolling, outline highlighting, and text buffering—and to enable or disable the feature. You can also use this function to disable inline input in a particular edit structure and to enable several features that have been provided so that inline input works correctly with TextEdit.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`TextEdit.h`

TEFromScrap

Copies the contents of the desk scrap to the TextEdit private scrap. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
OSErr TEFromScrap (
   void
);
```

Return Value

A result code. See "TextEdit Result Codes" (page 3037).

Discussion

You use this function to move monostyled text across applications or between an application and a desk accessory.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextEdit.h`

TEGetDoTextHook

Obtains a universal procedure pointer to your do-text-hook callback. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
TEDoTextUPP TEGetDoTextHook (
   void
);
```

Return Value
See the description of the `TEDoTextUPP` data type.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextEdit.h`

TEGetFindWordHook

Obtains a universal procedure pointer to your set-find-word-hook callback. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
TEFindWordUPP TEGetFindWordHook (
   void
);
```

Return Value
See the description of the `TEFindWordUPP` data type.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextEdit.h`

TEGetHeight

Returns the total height of all of the lines in the text between and including the specified starting and ending lines. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
long TEGetHeight (
   long endLine,
   long startLine,
   TEHandle hTE
);
```

Parameters

endLine

The number of the last line of text whose height is to be included in the total height. You can specify a value that is greater than or equal to 1 for this parameter.

startLine

The number of the first line of text whose height is to be included in the total height. You can specify a value that is greater than or equal to 1 for this parameter.

hTE

A handle to the edit structure containing the lines of text whose height is to be returned.

Return Value

The total height of all of the designated text lines.

Discussion

For monostyled text, the `TEGetHeight` function uses the value of the edit structure's `lineHeight` field. For multistyled text, it uses the line height element (`LHElement`) of the line height table (`LHTable`). Note that `TEGetHeight` does not take into account the height of any blank lines at the end of the text. You need to consider this when scrolling text.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`TextEdit.h`

TEGetHiliteRgn

Obtains the highlight region for the specified edit structure. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
OSErr TEGetHiliteRgn (
   RgnHandle region,
   TEHandle hTE
);
```

Return Value

A result code. See "TextEdit Result Codes" (page 3037).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextEdit.h`

TEGetOffset

Finds the byte offset of a character in an edit structure's text that corresponds to the specified point. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
short TEGetOffset (
   Point pt,
   TEHandle hTE
);
```

Parameters

pt

A point in the displayed text of the specified edit structure.

hTE

A handle to the edit structure containing the text.

Return Value
The byte offset of the character at the specified point. In the case of a 2-byte character, the function returns the byte offset of the first byte.

Discussion
The `TEGetOffset` function works for both monostyled and multistyled edit structures.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextEdit.h`

TEGetPoint

Determines the point that corresponds to the specified byte offset of a character and returns the coordinates of that point. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
Point TEGetPoint (
   short offset,
   TEHandle hTE
);
```

Parameters

offset

A byte offset into the text buffer of an edit structure.

hTE

A handle to the edit structure containing the text.

Return Value
The coordinates of the point that corresponds to the specified byte offset. The `TEGetPoint` function returns a valid result even when the edit structure does not contain any text. The point returned is based on the values in the structure's destination rectangle.

In the case of an offset being equal to a line end, which is also the start of the next line, `TEGetPoint` returns a point corresponding to the line start of the next line. In the case of a dual caret, the primary caret position, the one corresponding to the primary line direction, is returned.

See the Mac Types documentation for a description of the `Point` data type.

Discussion
The line height, taken either from the `lineHeight` field for a monostyled edit structure or from the line-height array, `LHElement` , for a multistyled edit structure, is also used to determine the vertical component. Both the text direction and the primary line direction are used to determine the horizontal component.

The `TEGetPoint` function works for both monostyled and multistyled edit structures.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextEdit.h`

TEGetRecalcHook

Obtains a universal procedure pointer to your recalculation callback. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
TERecalcUPP TEGetRecalcHook (
   void
);
```

Return Value
See the description of the `TERecalcUPP` data type.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextEdit.h`

TEGetScrapHandle

Returns a handle to the TextEdit private scrap. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
Handle TEGetScrapHandle (
   void
);
```

Return Value
See the Mac Types documentation for a description of the `Handle` data type.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextEdit.h`

TEGetScrapLength

Returns the size of the TextEdit private scrap, in bytes. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
long TEGetScrapLength (
   void
);
```

Return Value
The size of the TextEdit private scrap, in bytes.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextEdit.h`

TEGetStyle

Gets character attributes for the specified text. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void TEGetStyle (
   short offset,
   TextStyle *theStyle,
   short *lineHeight,
   short *fontAscent,
   TEHandle hTE
);
```

Parameters
offset
The offset to the text whose character attributes you want to obtain.

theStyle
On output, points to a structure of type TextStyle that contains the character attributes for the current selection range.

lineHeight
A pointer to a value that specifies the line height.

fontAscent
A pointer to a value that specifies the font ascent.

hTE
A handle to the multistyled edit structure containing the text whose character attributes you want to obtain.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextEdit.h`

TEGetStyleHandle

Returns the style handle stored in the designated edit structure's `txFont` and `txFace` fields. The style handle points to the associated style structure, not to a copy of it. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
TEStyleHandle TEGetStyleHandle (
   TEHandle hTE
);
```

Parameters

hTE
A handle to the multistyled edit structure containing the style handle to be returned.

Return Value
A handle to the style structure contained in the specified edit structure (of type `TEStyleRec`). Because only multistyled edit structures have style structures, `TEGetStyleHandle` returns `NULL` when used with a monostyled edit structure. See the description of the `TEStyleHandle` data type.

Discussion
To ensure future compatibility, your application should always use this function rather than manipulate the fields of the edit structure directly.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextEdit.h`

TEGetStyleScrapHandle

Creates a style scrap structure, copies the character attributes associated with the current selection range into it, and returns a handle to it. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
StScrpHandle TEGetStyleScrapHandle (
   TEHandle hTE
);
```

Parameters

hTE

The handle to the edit structure containing the text selection range whose character attributes are to be copied.

Return Value

A handle to the created style scrap structure, or `NULL` if called with a handle to a monostyled structure. See the description of the `StScrpHandle` data type.

Discussion

The `TEGetStyleScrapHandle` function creates a style scrap structure of type `StScrpRec` and copies the character attributes associated with the current selection range of the designated edit structure into it. If the current selection range is an insertion point, `TEGetStyleScrapHandle` first checks the null scrap. If the null scrap contains character attributes, they are written to the newly created style scrap structure. If the null scrap is empty, the attributes associated with the character preceding the insertion point are copied to the style scrap structure.

The `TEGetStyleScrapHandle` function has no impact on the Scrap Manager's desk scrap.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`TextEdit.h`

TEGetText

Returns a handle to the text of the specified edit structure. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
CharsHandle TEGetText (
   TEHandle hTE
);
```

Parameters

hTE

A handle to the edit structure containing the text whose handle you want returned. You pass this handle as an input parameter.

Return Value

A handle to the text contained in the specified edit structure. See page 82 for a description of the `CharsHandle` data type.

Discussion
Given an edit structure that contains text, you can use the `TEGetText` function to get a handle to the text itself. The `TEGetText` function doesn't make a copy of the text. Rather, it returns the handle to the text which is stored as a packed array of characters. (This handle belongs to TextEdit your application must not destroy it.) The `teLength` field of the edit structure contains the length of the text whose handle is returned.

The handle of type `CharsHandle` that is returned by `TEGetText` corresponds to the `hText` field of the `TERec` (page 3021) structure.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextEdit.h`

TEIdle

When called repeatedly, displays a blinking caret at the insertion point, if any exists, in the text of the specified edit structure of an active window. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void TEIdle (
   TEHandle hTE
);
```

Parameters
hTE
A handle to the edit structure.

Discussion
You need to call `TEIdle` only when the window containing the text is active; the caret is blinked only then. TextEdit observes a minimum blink interval, initially set to 32 ticks. No matter how often you call `TEIdle`, the time between blinks is never less than the minimum interval. (The user can adjust the minimum interval setting with the General Controls control panel.)

To maintain a constant frequency of blinking, you need to call `TEIdle` at least once each time through your main event loop. Call it more than once if your application does an unusually large amount of processing each time through the loop.

Call the Event Manager's `GetCaretTime` function to get the blink rate.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextEdit.h`

TEInsert

Inserts the specified text immediately before the selection range or the insertion point in the text of the designated edit structure, redrawing the text as necessary. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void TEInsert (
   const void *text,
   long length,
   TEHandle hTE
);
```

Parameters

text

A pointer to the text to be inserted.

length

The number of characters to be inserted.

hTE

A handle to the edit structure containing the text buffer into which the new text is to be inserted.

Discussion

When you call the `TEInsert` function and a range of text is selected, `TEInsert` doesn't affect the selection range. The `TEInsert` function does not check for a 32 KB limit, so your application must ensure that the inserted text does not exceed this text size limit of 32 KB. The `TEInsert` function recalculates line starts and line heights to adjust for the inserted text.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`TextEdit.h`

TEKey

Replaces the selection range in the text of the specified edit structure with the input character and positions the insertion point just past the inserted character. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void TEKey (
   CharParameter key,
   TEHandle hTE
);
```

Parameters

key

The input character.

hTE

A handle to the edit structure in whose text the character is to be entered.

Discussion
The TextEdit function `TEKey` allows you to handle key-down events and enter text input through the keyboard. If the selection range is an insertion point, `TEKey` inserts the character. (Two-byte characters are passed one byte at a time.)

If the `key` parameter contains a backspace character, the selection range or the character immediately before the insertion point is deleted. When the primary line direction is right-to-left, the character to the right of the insertion point is deleted. When the primary line direction is left-to-right, the character to the left of the insertion point is deleted.

When the user deletes text up to the beginning of a set of character attributes, `TEKey` saves the attributes in the null scrap's style scrap structure. The attributes are saved temporarily to be applied to characters inserted after the deletion. As soon as the user clicks in another area of the text, `TEKey` removes the attributes. `TEKey` redraws the text as necessary.

Call `TEKey` every time the Event Manager function `WaitNextEvent` reports a keyboard event that your application determines should be handled by TextEdit.

Because `TEKey` inserts every character passed in the `key` parameter, your application must filter all characters which aren't actual text, such as keys typed in conjunction with the Command key.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextEdit.h`

TENew

Creates and initializes a monostyled edit structure and allocates a handle to it. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
TEHandle TENew (
   const Rect *destRect,
   const Rect *viewRect
);
```

Parameters

destRect
A pointer to the destination rectangle for the new edit structure, specified in the local coordinates of the current graphics port. This is the area in which text is laid out.

viewRect
A pointer to the view, or visible, rectangle for the new edit structure, specified in the local coordinates of the current graphics port. This is the area of the window in which text is actually displayed.

Return Value
A handle to the newly created edit structure. Your application needs to store the handle to the edit structure that is returned; many functions require it as an input parameter. See the description of the `TEHandle` data type.

Discussion
A monostyled edit structure is one in which all text is restricted to a single font, size, and style. Use the `TENew` function when the text is to be rendered in attributes that are consistent from character to character. Otherwise, use the `TEStyleNew` (page 2999) function.

Call `TENew` once for every edit structure you want allocated. Your application should store the handle to the edit structure that is returned; many functions require it as an input parameter. The edit structure assumes the drawing environment of the graphics port.

If your application contains more than one window where text editing occurs, you need to create an edit structure for each window.

Before this function is called, the window must be in the current graphics port.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextEdit.h`

TENumStyles

Returns the number of character attribute changes contained in the specified range, counting one for the start of the range. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
long TENumStyles (
   long rangeStart,
   long rangeEnd,
   TEHandle hTE
);
```

Parameters

rangeStart
The beginning of the range of text for which the number of style runs (sets of character attributes) or changes is counted and returned.

rangeEnd
The end of the range of text for which the number of style runs (sets of character attributes) or changes is counted and returned.

hTE
A handle to the edit structure containing the range of text.

Return Value
The number of character attribute changes contained in the specified range. This does not necessarily represent the number of unique sets of attributes for the range, because some sets of attributes may be repeated. For monostyled edit structures, `TENumStyles` always returns 1.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextEdit.h`

TEPaste

Replaces the edit structure's selected text with the contents of the private scrap and leaves an insertion point after the inserted text. If the selection range is an insertion point, `TEPaste` inserts the contents of the private scrap there. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void TEPaste (
   TEHandle hTE
);
```

Parameters

hTE

A handle to the edit structure into which the text is to be pasted.

Discussion
When you call `TEPaste`, after it pastes the text from the private scrap, it redraws all of the text as necessary. If the private scrap is empty, `TEPaste` deletes the selection range. If you call `TEPaste` for a multistyled edit structure, it pastes only the text in the private scrap. In this case, `TEPaste` ignores any associated character attribute information stored in the style scrap; instead, it applies the character attributes of the first character of the selection range being replaced to the text. If the selection range is an insertion point, `TEPaste` applies the character attributes of the character preceding the insertion point.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextEdit.h`

TEPinScroll

Scrolls the text within the view rectangle of the specified edit structure by the designated number of pixels. Scrolling stops when the last line of text is scrolled into view. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void TEPinScroll (
   short dh,
   short dv,
   TEHandle hTE
);
```

Parameters

dh

The distance in pixels that the text is to be scrolled horizontally. A positive value moves the text to the right; a negative value moves the text to the left.

dv

The distance in pixels that the text is to be scrolled vertically. A positive value moves the text down; a negative value moves the text up.

hTE

A handle to the edit structure whose text is to be scrolled.

Discussion

The `TEPinScroll` function updates the text on the screen automatically to reflect the new scroll position, as does the `TEScroll` function. The destination rectangle is offset by the amount scrolled. When the edit structure is longer than the text it contains, `TEPinScroll` displays up to the last line of text inclusive, and not beyond it.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`TextEdit.h`

TEReplaceStyle

Replaces any character attributes in the current selection range that match the specified existing character attributes with the specified new character attributes. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void TEReplaceStyle (
   short mode,
   const TextStyle *oldStyle,
   const TextStyle *newStyle,
   Boolean fRedraw,
   TEHandle hTE
);
```

Parameters

mode

A selector that specifies which attributes to replace. It corresponds to any additive combination of the "Text Styling Constants" (page 3036) for font, character style, type size, color, and so forth.

oldStyle

A pointer to a text style structure that specifies the current character attributes to search for in the selected text.

newStyle

A pointer to a text style structure that specifies the new attributes to be set. This structure contains the character attributes to be applied to the current selection range based on the value of `mode`.

fRedraw

A flag that specifies whether or not TextEdit should immediately redraw the text to reflect the attribute changes. A value of `FALSE` delays redrawing until another event forces the update. A value of `TRUE` causes the text to be redrawn immediately using the new character attributes.

hTE

A handle to the multistyled edit structure containing the text selection whose character attributes are to be changed.

Discussion
The `TEReplaceStyle` function replaces any attribute in the current selection range that matches the attribute specified by `oldStyle` with that given by `newStyle`. Only the character attributes specified by `mode` are affected.

Attribute changes are made directly to the style elements (`STElement`) within the style table itself (`TEStyleTable`). If you specify the value `doAll` for the `mode` parameter, `newStyle` replaces `oldStyle` outright. The `TEReplaceStyle` function has no effect on a monostyled edit structure.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextEdit.h`

TEScrapHandle

Returns a handle to the TextEdit private scrap. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
Handle TEScrapHandle (
   void
);
```

Return Value
A handle to the TextEdit private scrap. See the Mac Types documentation for a description of the `Handle` data type.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextEdit.h`

TEScroll

Scrolls the text within the view rectangle of the specified edit structure by the designated number of pixels. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void TEScroll (
   short dh,
   short dv,
   TEHandle hTE
);
```

Parameters

dh

The distance in pixels that the text is to be scrolled horizontally. A positive value moves the text to the right; a negative value moves the text to the left.

dv

The distance in pixels that the text is to be scrolled vertically. A positive value moves the text down; a negative value moves the text up.

hTE

A handle to the edit structure whose text is to be scrolled.

Discussion

The `TEScroll` function updates the text on the screen automatically to reflect the new scroll position. The destination rectangle is offset by the amount scrolled. The `TEScroll` and `TEPinScroll` functions behave the same, except that `TEPinScroll` stops scrolling when the last line of text is scrolled into view.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`TextEdit.h`

TESelView

Ensures, once automatic scrolling has been enabled by a call to the `TEAutoView` function or through the `TEFeatureFlag` function, that the selection range is visible, scrolling it into the view rectangle if necessary. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void TESelView (
   TEHandle hTE
);
```

Parameters

hTE

A handle to the edit structure containing the text selection range.

Discussion

The top left part of the selection range is scrolled into view. If the text is displayed in a rectangle that is not high enough, automatic scrolling can cause text to appear to flicker. If automatic scrolling is disabled, `TESelView` has no effect. For more information, see `TEFeatureFlag` (page 2976).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`TextEdit.h`

TESetAlignment

Sets the alignment of the specified text in an edit structure so that it is centered, right aligned, or left aligned, or aligned according to the line direction. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void TESetAlignment (
   short just,
   TEHandle hTE
);
```

Parameters

just

The alignment for the specified text.The default value of the `just` field of the edit structure is `teFlushDefault`. This means that text alignment is based on the primary line direction which is set by default according to the system script.

For a description of the values you can use in this parameter, see "Text Alignment Constants" (page 3032).

hTE

A handle to the edit structure containing the text.

Discussion
For languages that are read from right to left, text is right aligned by default. For languages that are read from left to right, text is left aligned by default. If you change the alignment, call the Window Manager function `InvalRect` after `TESetAlignment` to redraw the text with the new alignment.

TextEdit does not support justified alignment. To draw justified text, use the QuickDraw Text functions.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextEdit.h`

TESetClickLoop

Installs the address of the application-supplied click loop function in the `clikLoop` field of the edit structure. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void TESetClickLoop (
   TEClickLoopUPP clikProc,
   TEHandle hTE
);
```

Parameters

clikProc

A universal procedure pointer to the customized click loop function.

hTE

A handle to the edit structure whose `clikLoop` field is to be modified.

Discussion

The `TESetClickLoop` function lets you replace the default click loop function. The `TEClick` function repeatedly calls the function that the click loop field points to as long as the user holds down the mouse button within the text of the view rectangle. The default click loop function scrolls only the text. However, you can provide a customized click loop function that scrolls the text and the scroll bars in tandem.

If automatic scrolling is enabled, the default click loop function checks to see if the mouse has been dragged out of the view rectangle; if it has, the function scrolls the text using `TEPinScroll` (page 2988). The amount by which `TEPinScroll` scrolls the text vertically is determined by the `lineHeight` field of the edit structure for monostyled text and the `LHTable` for multistyled text.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`TextEdit.h`

TESetDoTextHook

Sets your do-text-hook callback to be used by TextEdit. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void TESetDoTextHook (
   TEDoTextUPP value
);
```

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`TextEdit.h`

TESetFindWordHook

Sets your set-find-word-hook callback to be used by TextEdit. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void TESetFindWordHook (
   TEFindWordUPP value
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextEdit.h`

TESetRecalcHook

Sets your recalculation callback to be used by TextEdit. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void TESetRecalcHook (
   TERecalcUPP value
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextEdit.h`

TESetScrapHandle

Sets a handle to the TextEdit private scrap. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void TESetScrapHandle (
   Handle value
);
```

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextEdit.h`

TESetScrapLength

Sets the size of the TextEdit private scrap to the specified number of bytes. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void TESetScrapLength (
   long length
);
```

Parameters

length

The size of the private scrap, in bytes.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`TextEdit.h`

TESetSelect

Sets the selection range (or denotes the insertion point) within the text of the specified edit structure. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void TESetSelect (
   long selStart,
   long selEnd,
   TEHandle hTE
);
```

Parameters

selStart

The byte offset at the start of the text selection range. The `selStart` field can range from 0 to 32767.

If `selStart` equals `selEnd`, the new selection range is an insertion point, and a caret is displayed. If `selEnd` is anywhere beyond the last character of the text, `TESetSelect` uses the first position past the last character.

selEnd

The byte offset at the end of the text selection range. The `selEnd` field can range from 0 to 32767.

hTE

A handle to the edit structure.

Discussion

The `TESetSelect` function removes highlighting of the old selection range and highlights the new one.

When only the Roman script system is used, the selection range is always displayed and highlighted as a continuous range of text. However, when one or more script systems requiring mixed-directional display of text are installed, a continuous sequence of characters in memory may appear as a discontinuous selection when displayed.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`TextEdit.h`

TESetStyle

Sets new character attributes, in the specified edit structure, for the current selection range. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void TESetStyle (
   short mode,
   const TextStyle *newStyle,
   Boolean fRedraw,
   TEHandle hTE
);
```

Parameters

mode

A selector that specifies which character attributes are to be changed. The value for `mode` can be any additive combination of the `mode` constants for font, style, type size, color, and so forth. It corresponds to any additive combination of the "Text Styling Constants" (page 3036) for font, character style, type size, color, and so forth.

The value of `mode` specifies which existing character attributes are to be changed to the new character attributes specified by `newStyle`. If `doToggle` is specified along with `doFace` and if an attribute specified in the given `newStyle` parameter exists across the entire selected range of text, then `TESetStyle` removes that attribute. Otherwise, if the attribute doesn't exist across the entire selection range, all of the selected text is set to include that character attribute.

newStyle

A pointer to a structure of type `TextStyle` that specifies the new attributes to be set. This structure contains the character attributes to be applied to the current selection range based on the value of `mode`.

fRedraw

A flag that specifies whether or not TextEdit should immediately redraw the affected text to reflect the new character attribute changes. A value of `TRUE` causes the text to be redrawn immediately. Line breaks, line heights, and line ascents are recalculated. A value of `FALSE` delays redrawing until another event forces the update.

If the `fRedraw` parameter is set to `TRUE`, TextEdit redraws the current selection range using the new character attributes, recalculating line breaks, line heights, and line ascents.

If the `fRedraw` parameter is set to `FALSE`, TextEdit does not redraw the text or recalculate line breaks, line heights, and line ascents. Consequently, when you call a function that uses any of this information, such as `TEGetHeight` (which returns a total height between two specified lines), it does not reflect the new character attributes set with `TESetStyle`. Instead, the function uses the information that was available before `TESetStyle` was called. To update this information, call the `TECalText` (page 2969) function. To be certain that the new information is always reflected, call `TESetStyle` with the `fRedraw` parameter set to `TRUE`.

hTE

A handle to the multistyled edit structure containing the selected text.

Discussion
The `TESetStyle` function has no effect on a monostyled structure.

If you call the `TESetStyle` function when the value of the `selStart` field of an edit structure equals the value of the `selEnd` field (specifying an insertion point), TextEdit stores the input character attributes in the null scrap structure pointed to by the null style handle.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextEdit.h`

TESetStyleHandle

Sets an edit structure's style handle, which is stored in the `txFont` and `txFace` fields. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void TESetStyleHandle (
   TEStyleHandle theHandle,
   TEHandle hTE
);
```

Parameters

`theHandle`
The style handle to be set in the combined `txFont` and `txFace` fields of the specified edit structure.

`hTE`
A handle to the edit structure.

Discussion
The `TESetStyleHandle` function has no effect on monostyled edit structures.

Your application should always use `TESetStyleHandle` rather than manipulate the fields of the edit structure directly.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextEdit.h`

TESetText

Incorporates a copy of the specified text into the designated edit structure. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void TESetText (
   const void *text,
   long length,
   TEHandle hTE
);
```

Parameters

text

A pointer to the text to be copied and incorporated.

length

The number of characters in the text to be incorporated.

hTE

A handle to the edit structure into which the text is to be copied.

Discussion

The function `TESetText` lets you incorporate existing text into the text buffer of an edit structure. The function copies the specified text into the existing `hText` handle of the edit structure, resizing the buffer, if necessary it doesn't bring in the original text. The copied text is wrapped to the destination rectangle, and its `lineStarts` and `nLines` fields are calculated accordingly. The selection range is set to an insertion point at the end of the incorporated text. The `TESetText` function does not display the copied text on the screen. To do this, call `TEUpdate`.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`TextEdit.h`

TEStyleInsert

Inserts the specified text immediately before the selection range or the insertion point in the edit structure's text and applies the specified character attributes to the text, redrawing the text if necessary. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void TEStyleInsert (
   const void *text,
   long length,
   StScrpHandle hST,
   TEHandle hTE
);
```

Parameters

text

A pointer to the text to be inserted.

length

The length, in bytes, of the text to be inserted.

hST

A handle to the style scrap structure containing the character attribute information to be applied to the inserted text.

hTE

A handle to the edit structure into which the text is to be inserted.

Discussion
You should create your own style scrap structure, specifying the character attributes to be inserted and applied to the text, and pass its handle to `TEStyleInsert` as the value of the `hST` parameter. The character attributes are copied directly into the style structure's (`TEStyleRec`) style table.

The `TEStyleInsert` function does not affect the current selection range.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextEdit.h`

TEStyleNew

Creates a multistyled edit structure and allocates a handle to it. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
TEHandle TEStyleNew (
   const Rect *destRect,
   const Rect *viewRect
);
```

Parameters

destRect

A pointer to the destination rectangle for the new edit structure, specified in the local coordinates of the current graphics port. This is the area in which text is laid out.

viewRect

A pointer to the view rectangle for the new edit structure, specified in the local coordinates of the current graphics port. This is the area of the window in which text is actually displayed.

Return Value
A handle to the newly created edit structure. Your application needs to store the handle to the edit structure that is returned; many functions require it as an input parameter. See the description of the `TEHandle` data type.

Discussion
A multistyled edit structure contains text whose attributes, including font, size, and style, can vary from character to character. Always use the `TEStyleNew` function to create an edit structure for text that uses varying character attributes. The `TEStyleNew` function sets the `txSize`, `lineHeight`, and `fontAscent` fields of the edit structure to –1, allocates a style structure, and stores a handle to the style structure in the `txFont` and `txFace` fields. The `TEStyleNew` function creates and initializes a null scrap that is used by TextEdit functions throughout the life of the edit structure.

Call `TEStyleNew` once for every edit structure you want allocated. Your application needs to store the handle to the edit structure that is returned; many functions require it as an input parameter.

If your application contains more than one window where text editing occurs, you need to create an edit structure for each window.

Before this function is called, the window must be in the current graphics port.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextEdit.h`

TEStylePaste

Pastes text and its associated character attribute information from the desk scrap into the edit structure's text at the insertion point—if the current selection range is an insertion point—or it replaces the current selection range. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void TEStylePaste (
   TEHandle hTE
);
```

Parameters

hTE

A handle to the edit structure into which the text is to be pasted.

Discussion
When you call `TEStylePaste` and there is no character attribute information associated with text in the desk scrap, `TEStylePaste` first checks the null scrap. If the null scrap contains character attribute information, this is used. If the null scrap is empty, `TEStylePaste` gives the text the same attributes as those of the first character of the replaced selection range or that of the preceding character if the selection is an insertion point.

For a monostyled edit structure, `TEStylePaste` pastes the text only; there is no associated character attribute information because all the text uses the same attributes.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextEdit.h`

TETextBox

Draws the indicated text in a given rectangle, with the specified alignment. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void TETextBox (
   const void *text,
   long length,
   const Rect *box,
   short just
);
```

Parameters

text

A pointer to the text to be drawn.

length

The number of bytes comprising the text.

box

A pointer to the rectangle where the text is to be drawn. The rectangle is specified in local coordinates (of the current graphics port) and must be at least as wide as the first character drawn. (A good rule of thumb is to make the rectangle at least 20 pixels wide.

just

The kind of justification (alignment) used for the specified text.

Discussion

The `TETextBox` function provides you with an easy way to display static text to a user. It creates its own monostyled edit structure, which it deletes when finished with it, so you cannot edit the text it draws. The `TETextBox` function breaks a line of text correctly. You can specify how text is aligned in the box using any of the "Text Alignment Constants" (page 3032).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`TextEdit.h`

TEToScrap

Copies the contents of the TextEdit private scrap to the desk scrap. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
OSErr TEToScrap (
   void
);
```

Return Value

A result code. See "TextEdit Result Codes" (page 3037).

Discussion

You use the `TEToScrap` function to move monostyled text across applications or between an application and a desk accessory. Call the Scrap Manager function `ZeroScrap` to initialize the desk scrap or clear its contents before calling `TEToScrap`.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`TextEdit.h`

TEUpdate

Draws the specified text within a given update rectangle. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void TEUpdate (
   const Rect *rUpdate,
   TEHandle hTE
);
```

Parameters

rUpdate

The update rectangle, given in the coordinates of the current graphics port, where the specified text is to be drawn.

hTE

A handle to the edit structure containing the text to be drawn.

Discussion
Call `TEUpdate` every time the Event Manager function `WaitNextEvent` reports an update event for a text editing window—after you call the Window Manager function `BeginUpdate` , and before you call the `EndUpdate` function. You also need to erase the update region with the `EraseRect` function. If you don't, the caret can sometimes remain visible when the window is deactivated.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`TextEdit.h`

TEUseStyleScrap

Assigns new character attributes to the specified range of text in the designated edit structure. (Deprecated in Mac OS X v10.4. Use Multilingual Text Engine instead; see *Handling Unicode Text Editing With MLTE*.)

```
void TEUseStyleScrap (
   long rangeStart,
   long rangeEnd,
   StScrpHandle newStyles,
   Boolean fRedraw,
   TEHandle hTE
);
```

Parameters

rangeStart

The offset of the first character in the text of the edit structure to which the character attributes are to be applied.

rangeEnd

The offset of the last character in the text of the edit structure to which the character attributes are to be applied.

newStyles

A handle to a style scrap structure. The style scrap structure contains the attributes to be applied to the specified range of text. If the value of `newStyles` is `NULL`, no action is performed. Each element in the style scrap structure contains a field that is the offset of the beginning of the element's character attributes. This field (`scrpStartChar`) defines the boundaries for the scrap's style runs.

Depending on the requirements of your application, you can create a style scrap structure directly and pass its handle to `TEUseStyleScrap` as the value of `newStyles` or you can use a style scrap structure created by `TEGetStyleScrapHandle`.

fRedraw

A flag that specifies whether TextEdit should immediately redraw the selection range using the new character attributes. If the `fRedraw` parameter is set to `TRUE`, the attributes are applied immediately to the specified range of text, and line breaks, line heights, and line ascents are recalculated. If `fRedraw` is set to `FALSE`, the new character attributes are not reflected in the view rectangle until the next update event occurs.

hTE

A handle to the edit structure containing the range of text to which the character attributes are to be applied. If the handle points to a monostyled edit structure (created using `TENew`), no action is performed.

Discussion

The `TEUseStyleScrap` function writes the character attribute information into the style structure's style table and updates the style run table.

Regardless of whether the text is redrawn, the current selection range is not changed; if characters are highlighted before `TEUseStyleScrap` is called, they remain highlighted after it is called. However, if characters within the current selection range also fall within the specified range of text, they are rendered in the new character attributes when the text is redrawn.

The `TEUseStyleScrap` function applies the first element's attributes to the characters from `rangeStart` up to the `scrpStartChar` field of the next element. The function terminates without error if it prematurely reaches the end of the range or if there are not enough scrap style elements to cover the whole range. In the latter case, the function applies the last set of character attributes in the style scrap structure to the remainder of the range.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Callbacks

CaretHookProcPtr

Defines a pointer to a caret-hook callback.

```
typedef void (*CaretHookProcPtr) (
    const Rect * r,
    TEPtr pTE
);
```

If you name your function `MyCaretHookProc`, you would declare it like this:

```
void CaretHookProcPtr (
    const Rect * r,
    TEPtr pTE
);
```

Availability

Available in Mac OS X v10.0 and later.

Declared In

`TextEdit.h`

DrawHookProcPtr

Defines a pointer to a draw-hook callback.

```
typedef void (*DrawHookProcPtr) (
    unsigned short textOffset,
    unsigned short drawLen,
    void * textBufferPtr,
    TEPtr pTE,
    TEHandle hTE
);
```

If you name your function `MyDrawHookProc`, you would declare it like this:

```
void DrawHookProcPtr (
    unsigned short textOffset,
    unsigned short drawLen,
    void * textBufferPtr,
    TEPtr pTE,
    TEHandle hTE
);
```

Availability

Available in Mac OS X v10.0 and later.

Declared In

`TextEdit.h`

EOLHookProcPtr

Defines a pointer to an EOL-hook callback.

```
typedef Boolean (*EOLHookProcPtr) (
    char theChar,
    TEPtr pTE,
    TEHandle hTE
);
```

If you name your function `MyEOLHookProc`, you would declare it like this:

```
Boolean EOLHookProcPtr (
    char theChar,
    TEPtr pTE,
    TEHandle hTE
);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextEdit.h`

HighHookProcPtr

Defines a pointer to a high-hook callback.

```
typedef void (*HighHookProcPtr) (
    const Rect * r,
    TEPtr pTE
);
```

If you name your function `MyHighHookProc`, you would declare it like this:

```
void HighHookProcPtr (
    const Rect * r,
    TEPtr pTE
);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextEdit.h`

HitTestHookProcPtr

Defines a pointer to a hit-test hook callback.

```
typedef Boolean (*HitTestHookProcPtr) (
    unsigned short styleRunLen,
    unsigned short styleRunOffset,
    unsigned short slop,
    void * textBufferPtr,
    TEPtr pTE,
    TEHandle hTE,
    unsigned short * pixelWidth,
    unsigned short * charOffset,
    Boolean * pixelInChar
);
```

If you name your function `MyHitTestHookProc`, you would declare it like this:

```
Boolean HitTestHookProcPtr (
    unsigned short styleRunLen,
    unsigned short styleRunOffset,
    unsigned short slop,
    void * textBufferPtr,
    TEPtr pTE,
    TEHandle hTE,
    unsigned short * pixelWidth,
    unsigned short * charOffset,
    Boolean * pixelInChar
);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextEdit.h`

NWidthHookProcPtr

Defines a pointer to a width-hook callback.

```
typedef unsigned short (*NWidthHookProcPtr) (
    unsigned short styleRunLen,
    unsigned short styleRunOffset,
    short slop,
    short direction,
    void * textBufferPtr,
    short * lineStart,
    TEPtr pTE,
    TEHandle hTE
);
```

If you name your function `MyNWidthHookProc`, you would declare it like this:

```
unsigned short NWidthHookProcPtr (
    unsigned short styleRunLen,
    unsigned short styleRunOffset,
    short slop,
    short direction,
    void * textBufferPtr,
    short * lineStart,
```

```
    TEPtr pTE,
    TEHandle hTE
);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextEdit.h`

TEClickLoopProcPtr

Defines a pointer to a click-loop callback.

```
typedef Boolean (*TEClickLoopProcPtr) (
    TEPtr pTE
);
```

If you name your function `MyTEClickLoopProc`, you would declare it like this:

```
Boolean TEClickLoopProcPtr (
    TEPtr pTE
);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextEdit.h`

TEDoTextProcPtr

Defines a pointer to a do-text callback.

```
typedef void (*TEDoTextProcPtr) (
    TEPtr pTE,
    unsigned short firstChar,
    unsigned short lastChar,
    short selector,
    GrafPtr * currentGrafPort,
    short * charPosition
);
```

If you name your function `MyTEDoTextProc`, you would declare it like this:

```
void TEDoTextProcPtr (
    TEPtr pTE,
    unsigned short firstChar,
    unsigned short lastChar,
    short selector,
    GrafPtr * currentGrafPort,
    short * charPosition
```

```
);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextEdit.h`

TEFindWordProcPtr

Defines a pointer to a find-word callback.

```
typedef void (*TEFindWordProcPtr) (
    unsigned short currentPos,
    short caller,
    TEPtr pTE,
    TEHandle hTE,
    unsigned short * wordStart,
    unsigned short * wordEnd
);
```

If you name your function `MyTEFindWordProc`, you would declare it like this:

```
void TEFindWordProcPtr (
    unsigned short currentPos,
    short caller,
    TEPtr pTE,
    TEHandle hTE,
    unsigned short * wordStart,
    unsigned short * wordEnd
);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextEdit.h`

TERecalcProcPtr

Defines a pointer to a recalculation callback.

```
typedef void (*TERecalcProcPtr) (
    TEPtr pTE,
    unsigned short changeLength,
    unsigned short * lineStart,
    unsigned short * firstChar,
    unsigned short * lastChar
);
```

If you name your function `MyTERecalcProc`, you would declare it like this:

```
void TERecalcProcPtr (
```

```
    TEPtr pTE,
    unsigned short changeLength,
    unsigned short * lineStart,
    unsigned short * firstChar,
    unsigned short * lastChar
);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextEdit.h`

TextWidthHookProcPtr

Defines a pointer to a width-hook callback.

```
typedef unsigned short (*TextWidthHookProcPtr) (
    unsigned short textLen,
    unsigned short textOffset,
    void * textBufferPtr,
    TEPtr pTE,
    TEHandle hTE
);
```

If you name your function `MyTextWidthHookProc`, you would declare it like this:

```
unsigned short TextWidthHookProcPtr (
    unsigned short textLen,
    unsigned short textOffset,
    void * textBufferPtr,
    TEPtr pTE,
    TEHandle hTE
);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextEdit.h`

TSMTEPostUpdateProcPtr

Defines a pointer to a post-update callback.

```
typedef void (*TSMTEPostUpdateProcPtr) (
    TEHandle textH,
    long fixLen,
    long inputAreaStart,
    long inputAreaEnd,
    long pinStart,
    long pinEnd,
    long refCon
);
```

If you name your function `MyTSMTEPostUpdateProc`, you would declare it like this:

```
void TSMTEPostUpdateProcPtr (
    TEHandle textH,
    long fixLen,
    long inputAreaStart,
    long inputAreaEnd,
    long pinStart,
    long pinEnd,
    long refCon
);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TSMTE.h`

TSMTEPreUpdateProcPtr

Defines a pointer to a pre-udate callback.

```
typedef void (*TSMTEPreUpdateProcPtr) (
    TEHandle textH,
    long refCon
);
```

If you name your function `MyTSMTEPreUpdateProc`, you would declare it like this:

```
void TSMTEPreUpdateProcPtr (
    TEHandle textH,
    long refCon
);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TSMTE.h`

WidthHookProcPtr

Defines a pointer to a width-hook callback.

```
typedef unsigned short (*WidthHookProcPtr) (
    unsigned short textLen,
    unsigned short textOffset,
    void * textBufferPtr,
    TEPtr pTE,
    TEHandle hTE
);
```

If you name your function `MyWidthHookProc`, you would declare it like this:

```
unsigned short WidthHookProcPtr (
    unsigned short textLen,
    unsigned short textOffset,
    void * textBufferPtr,
    TEPtr pTE,
    TEHandle hTE
);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextEdit.h`

Data Types

CaretHookUPP

Defines a universal procedure pointer (UPP) to a caret-hook callback.

```
typedef CaretHookProcPtr CaretHookUPP;
```

Discussion
For more information, see the description of the CaretHookUPP () callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextEdit.h`

Chars

Defines an array of characters.

```
typedef  char Chars[32001];
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextEdit.h`

CharsPtr

Defines a data type for a character pointer.

```
typedef char* CharsPtr;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
TextEdit.h

CharsHandle

Defines a handle to a character pointer.

```
typedef CharsPtr* CharsHandle;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
TextEdit.h

DrawHookUPP

Defines a universal procedure pointer (UPP) to a draw-hook callback.

```
typedef DrawHookProcPtr DrawHookUPP;
```

Discussion
For more information, see the description of the DrawHookUPP () callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
TextEdit.h

EOLHookUPP

Defines a universal procedure pointer (UPP) to an EOL-hook callback.

```
typedef EOLHookProcPtr EOLHookUPP;
```

Discussion
For more information, see the description of the EOLHookUPP () callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
TextEdit.h

HighHookUPP

Defines a universal procedure pointer (UPP) to a high-hook callback.

```
typedef HighHookProcPtr HighHookUPP;
```

Discussion
For more information, see the description of the HighHookUPP () callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextEdit.h`

HitTestHookUPP

Defines a universal procedure pointer (UPP) to a hit-test hook callback.

```
typedef HitTestHookProcPtr HitTestHookUPP;
```

Discussion
For more information, see the description of the HitTestHookUPP () callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextEdit.h`

LHHandle

Defines a handle to a line-height table pointer.

```
typedef LHPtr *     LHHandle;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextEdit.h`

LHElement

Contains height and ascent information.

```
struct LHElement {
    short lhHeight;
    short lhAscent;
};
typedef struct LHElement LHElement;
typedef LHElement * LHPtr;
```

Fields

`lhHeight`

The line height, in points. This is the maximum value for any individual character attribute in the line.

`lhAscent`

The font ascent, in points; this is the maximum value for any individual character attribute in a line.

Discussion

The line-height table, defined by the `LHTable` data type, provides an array of line heights to hold the vertical spacing information for a given edit structure. It also contains line ascent information. The null style structure, defined by the `NullStRec` data type, contains the null scrap which is used to store character attribute information for a null selection.

The line height table holds vertical spacing information for the text of an edit structure. This table parallels the `lineStarts` array in the edit structure itself. Its length equals the edit structure's `nLines` field plus 1 for a dummy entry at the end, just as the `lineStarts` array ends with a dummy entry that has the same value as the length of the text. The table's contents are recalculated whenever the line starting values are themselves recalculated with the `TECalText` function or whenever an editing action causes recalibration.

The line height table is used only if the `lineHeight` and `fontAscent` fields in the edit structure are negative; positive values in those fields specify fixed vertical spacing, overriding the information in the table. The line height table is of type `LHTable`, which is an array of elements of `LHElement`.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`TextEdit.h`

LHTable

Defines an array of line-height elements.

```
typedef LHElement LHTable[8001];
```

Availability

Available in Mac OS X v10.0 and later.

Declared In

`TextEdit.h`

NullStHandle

Defines a handle to a null scrap record pointer.

```
typedef NullStPtr *      NullStHandle;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextEdit.h`

NullStRec

Contains the null scrap.

```
struct NullStRec {
    long teReserved;
    StScrpHandle nullScrap;
};
typedef struct NullStRec NullStRec;
typedef NullStRec * NullStPtr;
```

Fields

`teReserved`
This field is reserved for future expansion.

`nullScrap`
A handle to the style scrap structure.

Discussion
The `NullSTRec` data type defines the null style structure.

The null style structure contains the null scrap, which is used to store the character attribute information for a null selection (insertion point). A number of functions either write this character attribute information to the null scrap or read it from this scrap (to be applied to inserted text). The null scrap is created and initialized when an application calls `TEStyleNew` to create a multistyled edit structure. The null scrap is retained for the life of the edit structure; it is destroyed when `TEDispose` destroys the edit structure and releases the memory allocated for it.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextEdit.h`

NWidthHookUPP

Defines a universal procedure pointer (UPP) to a width-hook callback.

```
typedef NWidthHookProcPtr NWidthHookUPP;
```

Discussion
For more information, see the description of the NWidthHookUPP () callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
TextEdit.h

ScrpSTElement

Contains the scrap style table.

```
struct ScrpSTElement {
    long scrpStartChar;
    short scrpHeight;
    short scrpAscent;
    short scrpFont;
    StyleField scrpFace;
    short scrpSize;
    RGBColor scrpColor;
};
typedef struct ScrpSTElement ScrpSTElement;
typedef ScrpSTElement ScrpSTTable[1601];
```

Fields

`scrpStartChar`
The offset to the beginning of a style structure in the scrap.

`scrpHeight`
The line height. You can determine the line height and the font ascent using the QuickDraw function `GetFontInfo`.

`scrpAscent`
The font ascent. See `scrpHeight`.

`scrpFont`
The font family ID.

`scrpFace`
The character style (such as plain, bold, underline).

`scrpSize`
The size, in points.

`scrpColor`
The RGB (red, green, blue) color for the style scrap.

Discussion
The style scrap structure contains the scrap style table. Unlike the main style table for an edit structure, the scrap style table may contain duplicate elements; the entries in the table correspond one-to-one with the style runs in the text. The `scrpStartChar` field of each entry gives the starting position for the run.

The `scrpStyleTab` data type defines the scrap style table data structure, which is an array of scrap style element structures. The `ScrpSTElement` data type defines each scrap style element structure.

Availability
Available in Mac OS X v10.0 and later.

Declared In
TextEdit.h

ScrpSTTable

Contains an array of scrap style elements.

```
typedef ScrpSTElement ScrpSTTable[1601];
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextEdit.h`

STElement

Contains one entry for each distinct set of character attributes used in the text of an edit structure.

```
struct STElement {
    short stCount;
    short stHeight;
    short stAscent;
    short stFont;
    StyleField stFace;
    short stSize;
    RGBColor stColor;
};
typedef struct STElement STElement;
typedef STElement * STPtr;
```

Fields

`stCount`
A reference count of character runs using this set of character attributes.

`stHeight`
The line height for this run, in points.

`stAscent`
The font ascent for this run, in points.

`stFont`
The font family ID.

`stFace`
The character style (bold, italic, and so forth). This field consists of two bytes. The low-order byte contains the character style. TextEdit uses the high bit (bit 15) of the high-order byte to store the style run direction: it uses 0 for left-to-right text, and 1 for right-to-left text.

`stSize`
The text size, in points.

`stColor`
The RGB (red, green, blue) color.

Discussion
The style table contains one entry for each distinct set of character attributes used in the text of an edit structure. Each entry is defined in a style element structure. The size of the table is given by the `nStyles` field of the style structure. There is no duplication; each set of character attributes appears exactly once in the table. A reference count tells how many times each set of attributes is used in the table. The `TEStyleTable` data type defines the style table. Th `eSTElement` data type defines the style element structure.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextEdit.h`

STHandle

Defines a handle to a style table pointer.

```
typedef STPtr *     STHandle;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextEdit.h`

StScrpHandle

Defines a handle to a scrap style table pointer.

```
typedef StScrpPtr *     StScrpHandle;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextEdit.h`

StScrpRec

Contains information used by functions to store character attribute information temporarily.

```
struct StScrpRec {
    short scrpNStyles;
    ScrpSTTable scrpStyleTab;
};
typedef struct StScrpRec StScrpRec;
typedef StScrpRec * StScrpPtr;
```

Fields

`scrpNStyles`
The number of style runs (sets of character attributes) used in the text. This determines the size of the style table. When character attribute information is written to the null scrap, this field is set to 1; when the character attribute information is removed, this field is set to 0.

`scrpStyleTab`
The scrap style table containing an element for each style run (set of character attributes).

Discussion
The style scrap structure, defined by the `StScrpRec` data type, is used by functions to store character attribute information temporarily. The scrap style table, defined by the `scrpStyleTab` data type, is contained in the style scrap structure. The scrap style element structure, defined by the `ScrpSTElement` data type, contains the character attribute information for an element in the scrap style table. One scrap style element structure exists for each sequential attribute change in the associated text.

The style scrap is used for storing character attribute information associated with the current text selection or insertion point, character attribute information to be applied to text, or multistyled text that is cut or copied. When multistyled text is cut or copied, the character attribute information is written to both the style scrap and the desk scrap.

In most cases, the style scrap is created dynamically as needed by functions. However, a style scrap structure can be created directly without using the `TEGetStyleScrapHandle` function; the character attribute information written to it can be applied to inserted text through `TEStyleInsert` or to existing text through `TEUseStyleScrap`.

The format of the style scrap is defined by a style scrap structure of type `STScrpRec`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextEdit.h`

StyleRun

Contains information for a style run.

```
struct StyleRun {
    short startChar;
    short styleIndex;
};
typedef struct StyleRun StyleRun;
```

Fields
`startChar`
The starting character position.
`styleIndex`
The run's index in the style table.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextEdit.h`

TEClickLoopUPP

Defines a universal procedure pointer (UPP) to a click-loop callback.

```
typedef TEClickLoopProcPtr TEClickLoopUPP;
```

Discussion
For more information, see the description of the TEClickLoopUPP () callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextEdit.h`

TEDoTextUPP

Defines a universal procedure pointer (UPP) to a do-text callback.

```
typedef TEDoTextProcPtr TEDoTextUPP;
```

Discussion
For more information, see the description of the TEDoTextUPP () callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextEdit.h`

TEFindWordUPP

Defines a universal procedure pointer (UPP) to a find-word callback.

```
typedef TEFindWordProcPtr TEFindWordUPP;
```

Discussion
For more information, see the description of the TEFindWordUPP () callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextEdit.h`

TEHandle

Defines a handle to a TextEdit record pointer.

```
typedef TEPtr* TEHandle;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextEdit.h`

TEIntHook

Defines a data type for a TextEdit integer hook.

```
typedef  short TEIntHook;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextEdit.h`

TEPtr

Defines a pointer to a TextEdit record.

```
typedef TTERec* TEPtr;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextEdit.h`

TERec

Stores display and editing information for TextEdit.

```
struct TERec {
    Rect destRect;
    Rect viewRect;
    Rect selRect;
    short lineHeight;
    short fontAscent;
    Point selPoint;
    short selStart;
    short selEnd;
    short active;
    WordBreakUPP wordBreak;
    TEClickLoopUPP clickLoop;
    long clickTime;
    short clickLoc;
    long caretTime;
    short caretState;
    short just;
    short teLength;
    Handle hText;
    long hDispatchRec;
    short clikStuff;
    short crOnly;
    short txFont;
    StyleField txFace;
    short txMode;
    short txSize;
    GrafPtr inPort;
    HighHookUPP highHook;
    CaretHookUPP caretHook;
    short nLines;
    short lineStarts[16001];
};
typedef struct TERec TERec;
typedef TERec * TEPtr;
```

Fields

`destRect`

The destination rectangle, in local coordinates.

`viewRect`

The view rectangle, in local coordinates.

`selRect`

The selection rectangle, whose boundaries are defined in local coordinates. This value is the current selection range or insertion point.

`lineHeight`

The vertical spacing of lines of text. Vertical spacing may be fixed or it may vary from line to line, depending upon specific text attributes. If the value of `lineHeight` is greater than 0, this field specifies the fixed vertical distance from the ascent line of one line of text down to the ascent line of the next.

If the value of `lineHeight` is less than 1, then this field specifies the vertical distance from the ascent line of one line of text down to the ascent line of the next calculated independently for each line, based on the maximum value for any individual character attribute on that line.

`fontAscent`

The font ascent line. If the value of `fontAscent` is greater than 0, this field specifies how far above the base line the pen is positioned to begin drawing the caret or highlighting.

For single-spaced text, this is the height of the text in pixels (the height of the tallest characters in the font from the base line). If the value of `fontAscent` is less than 1, this field specifies the font ascent calculated independently for each line, based on maximum value for any individual character attribute on that line.

`selPoint`

The point selected with the mouse, in the local coordinates of the current graphics port. The assembly-language offset for this field is named `teSelPoint`.

`selStart`

The byte offset of the beginning of a selection range. Note that byte offset 0 refers to the first byte in the text buffer.

`selEnd`

The byte offset of the end of a selection range. To include that byte, this value must be 1 greater than the position of the last byte offset of the text.

`active`

This field is used internally by TextEdit. It is set when an edit structure is activated through `TEActivate` and then reset when the edit structure is rendered inactive through `TEDeactivate`. To ensure future compatibility, use `TEActivate` or `TEDeactivate` to access this field.

`wordBreak`

A universal procedure pointer to the structure's word selection break function. This function determines the word that is highlighted when the user double-clicks in the text and the position at which text is wrapped at the end of a line.

`clickLoop`

A universal procedure pointer to the click loop function.The specified click loop function is called repeatedly by the `TEClick` function as long as the mouse button is held down within the text.

`clickTime`

This field is for internal use only.

`clickLoc`

This field is for internal use only.

`caretTime`

This field is for internal use only.

`caretState`

This field is for internal use only.

`just`

The type of text alignment: default (according to primary line direction), left, center, or right.

`teLength`

The number of bytes in the text to be edited. For two-byte systems, potentially twice the number of characters. Initially set to zero. The maximum length is 32767 bytes.

`hText`

A handle to the text. Initially, it points to a zero-length block of text in the heap.

`hDispatchRec`

A handle to the TextEdit dispatch structure. This field is for internal use only; do not modify this field, or copy it to another edit structure. Each edit structure has its own dispatch structure. Attempting to use the dispatch structure of one edit structure with another edit structure can cause TextEdit to crash.

`clikStuff`

This field is for internal use only. TextEdit sets this field to reflect whether the most recent mouse-down event occurred on the leading or trailing edge of a glyph. TextEdit uses this value in determining a caret position.

`crOnly`

A value specifying whether or not text wraps at the right edge of the destination rectangle. If `crOnly` is positive, text does wrap. Otherwise, new lines are displayed only at Carriage Returns.

If `crOnly` is negative, new lines are specified explicitly by `Return` characters only; text does not wrap at the edge of the destination rectangle. (This is useful in an application similar to a programming-language editor, where you may not want a single line of code to be split onto two lines.

`txFont`

The font of all the text in the edit structure, if the `txSize` field of this edit structure 0. If you change this value, the entire text of this edit structure has the new characteristic when it is redrawn also remember to change the `lineHeight` and `fontAscent` fields.

If the `txSize` field is –1, this field combines with `txFace` to hold a handle to the associated style structure.

`txFace`

The character attributes of all the text in an edit structure, if the `txSize` field of this edit structure 0. If you change this value, the entire text of this edit structure has the new characteristic when it is redrawn also, remember to change the `lineHeight` and `fontAscent` fields as well.

If the `txSize` field is –1, this field combines with `txFont` to hold a handle to the associated style structure.

`txMode`

The pen mode of all the text in the edit structure. If you change this value, the entire text of this edit structure has the new characteristic when it is redrawn; also, remember to change the `lineHeight` and `fontAscent` fields as well.

`txSize`

Depending on its value, `txSize` either contains the point size of all of the text or it acts as a flag indicating whether or not there is associated character attribute information. If `txSize` 0, this is a monostyled edit structure, that is, all text is set in a single font, size, and face, and the value of `txSize` is the size of the text. If `txSize` is –1, the edit structure contains associated character attribute information and the `txFont` and `txFace` fields combine to form a handle to the style structure.

`inPort`

A pointer to the graphics port associated with this edit structure.

`highHook`

A pointer to the function that deals with text highlighting. In assembly language, the `highHook` field is located at the offset `teHiHook`.

`caretHook`

A pointer to the function that controls the appearance of the caret. In assembly language, the `caretHook` field is located at the offset `teCarHook`.

`nLines`

The number of lines in the text.

`lineStarts`

An array containing the character position of the first character in each line. It is declared to have 16001 elements to comply with Pascal range checking. This is a dynamic data structure, having only as many elements as needed. TextEdit calculates these values internally, so do not change the elements of the `lineStarts` array. Because this data structure grows and shrinks, the size of the edit structure changes.

Discussion
The edit structure, defined by the `TERec` data type, stores the display and editing information for TextEdit. Along with various subsidiary data structures, the style structure, defined by the `TEStyleRec` data type, stores the character attribute information for the text of the edit structure.

The edit structure contains display, storage, styling, and other information. Although some fields are used differently for multistyled edit structures and monostyled edit structures, the structure of an edit structure is the same whether the text is multistyled or monostyled.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextEdit.h`

TERecalcUPP

Defines a universal procedure pointer (UPP) to a recalculation callback.

```
typedef TERecalcProcPtr TERecalcUPP;
```

Discussion
For more information, see the description of the TERecalcUPP () callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextEdit.h`

TEStyleRec

Stores the character attribute information for the text of a multistyled edit structure.

```
struct TEStyleRec {
    short nRuns;
    short nStyles;
    STHandle styleTab;
    LHHandle lhTab;
    long teRefCon;
    NullStHandle nullStyle;
    StyleRun runs[8001];
};
typedef struct TEStyleRec TEStyleRec;
typedef TEStyleRec * TEStylePtr;
```

Fields

`nRuns`
The number of style runs in the text.

`nStyles`
The number of distinct sets of character attributes used in the text; this forms the size of the style table.

`styleTab`
A handle to the style table.

`lhTab`
A handle to the line height table.

`teRefCon`
A reference constant for use by applications. The application can use this 32-bit field to suit its needs.

`nullStyle`
A handle to the style scrap structure used to store the character attribute information for a null selection.

`runs`
A table of style runs that is of indefinite length.

Discussion

The style structure stores the character attribute information for the text of a multistyled edit structure. If an edit structure has associated character attribute information, its `txFont` and `txFac` e fields combine to hold a style handle, of type `TEStyleHandle`, to its style structure. The text is divided into style runs, summarized in the style run table, of type `StyleRun`, which is part of the style structure. Each entry in the style run table gives the starting character position of a run and an index into the style table, of type `TEStyleTable`.

The style table element pointed to by the style run index describes the character attributes for that run.

To determine the length of a run, you subtract its start position from that of the next entry in the style run table. A dummy entry at the end of the style run table delimits the length of the last run; its start position is equal to the overall number of characters in the text, plus 1. The `TEStyleRec` data type defines the style structure.

The style run table, defined by the `StyleRun` data type, is an array that contains the boundaries of each style run and an index to its character attribute information in the style element array. The style table, defined by the `TEStyleTable` data type, contains one entry for each distinct set of character attributes used in the text of the edit structure.

Availability

Available in Mac OS X v10.0 and later.

Declared In
TextEdit.h

TEStyleTable

Defines and array of style elements.

```
typedef STElement TEStyleTable[1777];
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
TextEdit.h

TextStyle

Contains text style information.

```
struct TextStyle {
    short tsFont;
    StyleField tsFace;
    short tsSize;
    RGBColor tsColor;
};
typedef struct TextStyle TextStyle;
typedef TextStyle * TextStylePtr;
```

Fields

`tsFont`
The font family number.

`tsFace`
The character style (bold, italic, plain, and so forth).

`tsSize`
The text size in points.

`tsColor`
The RGB (red, green, blue) color.

`tsColor`

Discussion
Text style structures, which are passed as variables or reference parameters, are used for communicating character attribute information between the application and several TextEdit functions, such as `TEContinuousStyle` and `TEReplaceStyle`. They carry the same information as the style element structures in the style table, but without the reference count, line height, and font ascent.

Availability
Available in Mac OS X v10.0 and later.

Declared In
TextEdit.h

TextWidthHookUPP

Defines a universal procedure pointer (UPP) to a width-hook callback.

```
typedef TextWidthHookProcPtr TextWidthHookUPP;
```

Discussion
For more information, see the description of the TextWidthHookUPP () callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextEdit.h`

TSMDialogPeek

Defines a data type for a TSM dialog pointer.

```
typedef TSMDialogPtr TSMDialogPeek;
```

Availability
Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared In
`TSMTE.h`

TSMDialogPtr

Defines a pointer to a TSM dialog record.

```
typedef TSMDialogRecord* TSMDialogPtr;
```

Availability
Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared In
`TSMTE.h`

TSMDialogRecord

Contains information for a TSM dialog record.

```
struct TSMDialogRecord {
  DialogRecord        fDialog;
  TSMDocumentID       fDocID;
  TSMTERecHandle      fTSMTERecH;
  long                fTSMTERsvd[3];
};
typedef struct TSMDialogRecord  TSMDialogRecord;
```

Availability
Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared In
TSMTE.h

TSMTEPostUpdateUPP

Defines a universal procedure pointer (UPP) to a post-update callback.

```
typedef TSMTEPostUpdateProcPtr TSMTEPostUpdateUPP;
```

Discussion
For more information, see the description of the TSMTEPostUpdateUPP () callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
TSMTE.h

TSMTEPreUpdateUPP

Defines a universal procedure pointer (UPP) to a pre-update callback.

```
typedef TSMTEPreUpdateProcPtr TSMTEPreUpdateUPP;
```

Discussion
For more information, see the description of the TSMTEPreUpdateUPP () callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
TSMTE.h

TSMTERec

Defines a TSMTE record structure.

```
struct TSMTERec {
    TEHandle textH;
    TSMTEPreUpdateUPP preUpdateProc;
    TSMTEPostUpdateUPP postUpdateProc;
    long updateFlag;
    long refCon;
};
typedef struct TSMTERec TSMTERec;
typedef TSMTERec * TSMTERecPtr;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
TSMTE.h

TSMTERecHandle

Defines a handle to a TSMTE record pointer.

```
typedef TSMTERecPtr * TSMTERecHandle;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TSMTE.h`

WidthHookUPP

Defines a universal procedure pointer (UPP) to a width-hook callback.

```
typedef WidthHookProcPtr WidthHookUPP;
```

Discussion
For more information, see the description of the WidthHookUPP () callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`TextEdit.h`

Constants

Auto Idling Flag

Enables automatic idling in an event loop.

```
enum {
    teFIdleWithEventLoopTimer = 7
};
```

Auto Scroll Constant

Specifies automatic scrolling

```
enum {
        kTSMTEAutoScroll = 1
};
```

Do Text Selectors

Specify constants for identifying `TEDoTextSelectors`.

```
enum {
    teFind = 0,
    teHighlight = 1,
    teDraw = -1,
    teCaret = -2
};
```

Find Word Identification Constants

Specify constants for identifying the routine that called `FindWord`.

```
enum {
    teWordSelect = 4,
    teWordDrag = 8,
    teFromFind = 12,
    teFromRecal = 16
};
```

Hook Constants

Specify offsets into the `TEDispatchRec` data structure.

```
enum {
    EOLHook = 0,
    DRAWHook = 4,
    WIDTHHook = 8,
    HITTESTHook = 12,
    nWIDTHHook = 24,
    TextWidthHook = 28
};
```

Inline Input Flag

Specifies to use inline input service.

```
enum {
    teFUseTextServices = 4
};
```

Constants

`teFUseTextServices`

Use inline input service. This flag is no longer in use.

Available in Mac OS X v10.0 and later.

Declared in `TextEdit.h`.

Signature and Interface Constants

Specify a TSM TextEdit signature or interface.

```
enum {
    kTSMTESignature = 'tmTE',
    kTSMTEInterfaceType = 'tmTE'
};
```

Style Mode Constants

Used to set and replace style modes.

```
enum {
    fontBit = 0,
    faceBit = 1,
    sizeBit = 2,
    clrBit = 3,
    addSizeBit = 4,
    toggleBit = 5
};
```

Text Alignment Constants

Specify justification (word alignment) styles.

```
enum {
    teJustLeft = 0,
    teJustCenter = 1,
    teJustRight = -1,
    teForceLeft = -2,
    teFlushDefault = 0,
    teCenter = 1,
    teFlushRight = -1,
    teFlushLeft = -2
};
```

Constants

`teFlushDefault`
Align according to primary line direction
Available in Mac OS X v10.0 and later.
Declared in `TextEdit.h`.

`teCenter`
Centered for all scripts
Available in Mac OS X v10.0 and later.
Declared in `TextEdit.h`.

`teFlushRight`
Right aligned for all scripts
Available in Mac OS X v10.0 and later.
Declared in `TextEdit.h`.

`teFlushLeft`
Left aligned for all scripts
Available in Mac OS X v10.0 and later.
Declared in `TextEdit.h`.

Discussion
You can use these constants to specify the text alignment through the `align` parameter of the `TESetAlignment` (page 2992) and `TETextBox` (page 3000) functions. For compatibility, the previous names of these constants (`teJustLeft` , `teJustCenter` , `teJustRight` , and `teForceLeft`) are still supported.

Text Custom Hook Constants

Specify a selector for a TextEdit hook function.

```
enum {
    intEOLHook = 0,
    intDrawHook = 1,
    intWidthHook = 2,
    intHitTestHook = 3,
    intNWidthHook = 6,
    intTextWidthHook = 7,
    intInlineInputTSMTEPreUpdateHook = 8,
    intInlineInputTSMTEPostUpdateHook = 9
};
```

Constants

`intEOLHook`
End-of-line hook
Available in Mac OS X v10.0 and later.
Declared in `TextEdit.h`.

`intDrawHook`
Draw hook
Available in Mac OS X v10.0 and later.
Declared in `TextEdit.h`.

`intWidthHook`
Width measurement hook
Available in Mac OS X v10.0 and later.
Declared in `TextEdit.h`.

`intHitTestHook`
Hit test hook
Available in Mac OS X v10.0 and later.
Declared in `TextEdit.h`.

`intNWidthHook`
New width measurement hook
Available in Mac OS X v10.0 and later.
Declared in `TextEdit.h`.

`intTextWidthHook`
Text width measurement hook (low-memory global width measurement hook)
Available in Mac OS X v10.0 and later.
Declared in `TextEdit.h`.

`intInlineInputTSMTEPreUpdateHook`
Specifies a `TSMTEPreUpdateProcPtr` callback.

Available in Mac OS X v10.0 and later.

Declared in `TextEdit.h`.

`intInlineInputTSMTEPostUpdateHook`
Specifies a `TSMTEPostUpdateProcPtr` callback.

Available in Mac OS X v10.0 and later.

Declared in `TextEdit.h`.

Discussion
To specify a default TextEdit hook function with a customized function, you specify one of the following constants as the value of the `which` parameter to the `TECustomHook` (page 2972) function.

Text Feature Action Constants

Specify the action to be performed on a feature.

```
enum {
    teBitClear = 0,
    teBitSet = 1,
    teBitTest = -1
};
```

Constants
`teBitClear`
Disables the specified feature

Available in Mac OS X v10.0 and later.

Declared in `TextEdit.h`.

`teBitSet`
Enables the specified feature. If `teBitTest` returns `teBitSet`, the feature is enabled; if it returns `teBitClear`, it is disabled.

Available in Mac OS X v10.0 and later.

Declared in `TextEdit.h`.

`teBitTest`
Returns the current setting of the specified feature

Available in Mac OS X v10.0 and later.

Declared in `TextEdit.h`.

Discussion
To specify the action to be performed on a feature, you specify one of these constants as the value of the `action` parameter to the `TEFeatureFlag` (page 2976) function.

To test for the availability of these features, you can call the `Gestalt` function with the `gestaltTextEditVersion` selector. A result of `gestaltTE4` or greater returned in the response parameter indicates that outline highlighting and text buffering are available. A result of `gestaltTE5` or greater returned in the response parameter indicates that the two inline input features are available.

Version Notes
The inline input features are also available on version 6.0.7 systems with non-Roman script systems installed. However, there is no Gestalt constant that indicates this availability.

Text Feature Constants

Specify feature or bit definitions for the function `TEFeatureFlag`.

```
enum {
    teFAutoScroll = 0,
    teFTextBuffering = 1,
    teFOutlineHilite = 2,
    teFInlineInput = 3,
    teFUseWhiteBackground = 4,
    teFUseInlineInput = 5,
    teFInlineInputAutoScroll = 6
};
```

Constants

`teFAutoScroll`

Automatic scrolling. You can use the `TEFeatureFlag` function to turn automatic scrolling on and off as an alternative to calling `TEAutoView`. The effect is the same.

Available in Mac OS X v10.0 and later.

Declared in `TextEdit.h`.

`teFTextBuffering`

Text buffering. The `teFTextBuffering` selector enables or disables text buffering for performance improvements of 2-byte scripts. This is a global buffer, as opposed to the `TEKey` function's internal 2-byte buffer, and it is used across all active edit structures.

Exercise care when you enable the text-buffering capability in more than one active structure; otherwise, the bytes that are buffered from one edit structure may appear in another edit structure.

Ensure that buffering is not turned off in the middle of processing a 2-byte character. To guarantee the integrity of your structure, it is important that you wait for an idle event before you disable buffering or enable buffering in a second edit structure.

When text buffering is enabled, ensure that the `TEIdle` (page 2984) function is called before any pause of more than a few ticks—for example, before the Event Manager function `WaitNextEvent`. A possibility of a long delay before characters appear on the screen exists, especially in non-Roman systems. If you do not call `TEIdle`, the characters can end up in the edit structure of another application.

If text buffering is enabled on a non-Roman script system and the keyboard has changed, TextEdit flushes the text of the current script from the buffer before bringing characters of the new script into the buffer.

Available in Mac OS X v10.0 and later.

Declared in `TextEdit.h`.

`teFOutlineHilite`

Outline highlighting. The `teFOutlineHilite` selector specifies outline highlighting as the feature for which an action is to be performed. If a highlighted region exists in an edit structure and the window is inactive, then the highlighted region is outlined or framed.

In the case that outline highlighting is enabled and the current selection range is an insertion point, the caret is then drawn in a gray pattern so that it appears dimmed. To do the framing and caret dimming, TextEdit temporarily replaces the current address in the `highHook` and `caretHook` fields of the edit structure, redraws the caret or the highlighted region, and then immediately restores the hooks to their previous addresses.

Available in Mac OS X v10.0 and later.

Declared in `TextEdit.h`.

`teFInlineInput`

Inline input. You must deactivate an edit structure (using `TEDeactivate`) before changing the state of the feature bits or any fields in the edit structure.

In the future, other text services may use this same mechanism. If you follow the guidelines specified here, your application should also work with future text services. When an inline edit session begins, inline input also sets the `teFInlineInput` bit to provide the following features so that inline input works correctly with TextEdit: disabling font and keyboard synchronization, forcing a multiple-line selection to be highlighted line by line using a separate rectangle for each line rather than using a minimum number of rectangles for optimization, and highlighting a line only to the edge of the text rather than beyond the text to the edge of the view rectangle.

The `teFInlineInput` bit is cleared by inline input when an inline session ends. Use the `teFInlineInput` constant in the feature parameter of `TEFeatureFlag` to include these features in your application even when inline input is not installed. Be careful about changing the state of this bit if the `teFUseTextServices` bit is set. Again, the edit structure should always be deactivated before you change the state of the `teFInlineInput` bit. If you clear the `teFUseTextServices` bit and you set the `teFInlineInput` bit, inline input is disabled, but your application retains the features listed above.

Available in Mac OS X v10.0 and later.

Declared in `TextEdit.h`.

Discussion
To identify or adjust a feature, you specify one of these constants as the value of the `feature` parameter to the `TEFeatureFlag` (page 2976) function.

Text Styling Constants

Specify character attributes.

```
enum {
    doFont = 1,
    doFace = 2,
    doSize = 4,
    doColor = 8,
    doAll = 15,
    addSize = 16,
    doToggle = 32
};
```

Constants
`doFont`

Sets the font family ID

Available in Mac OS X v10.0 and later.

Declared in `TextEdit.h`.

`doFace`

Sets the character style

Available in Mac OS X v10.0 and later.

Declared in `TextEdit.h`.

`doSize`
Sets the type size
Available in Mac OS X v10.0 and later.
Declared in `TextEdit.h`.

`doColor`
Sets the color
Available in Mac OS X v10.0 and later.
Declared in `TextEdit.h`.

`doAll`
Sets all attributes
Available in Mac OS X v10.0 and later.
Declared in `TextEdit.h`.

`addSize`
Increases or decreases the current type size
Available in Mac OS X v10.0 and later.
Declared in `TextEdit.h`.

`doToggle`
Modifies the mode
Available in Mac OS X v10.0 and later.
Declared in `TextEdit.h`.

Discussion
You can use these constants (singly or in combination) to specify character attributes, through the `mode` parameter of the `TEContinuousStyle` (page 2970) , `TESetStyle` (page 2996) , and `TEReplaceStyle` (page 2989) functions.

Result Codes

In addition to `noErr`, the most common result code returned by TextEdit is listed below.

Result Code	Value	Description
`noScrapErr`	-100	Scrap does not exist (not initalized). Available in Mac OS X v10.0 and later.

Document Revision History

This table describes the changes to *Carbon Framework Reference*.

Date	Notes
2007-10-31	Added three reference documents (HIGeometry, Carbon Printing, Control Manager) and removed two (Carbon Printing Manager, ColorSync Manager).
2006-05-23	First publication of this content as a collection of previously published documents.
