This collection of documents provides the API reference for many fundamental user experience features—such as windows, menus, text handling, and event management—used in Carbon applications.

The Carbon framework also includes support for a number of legacy technologies—such as TextEdit and the Event Manager—that have been superseded by newer technologies like Multilingual Text Engine (MLTE) and the Carbon Event Manager.

Managers

Appearance Manager Reference

Framework: Carbon/Carbon.h

Declared in Appearance.h
HITheme.h

Overview

The Appearance Manager coordinates the look of human interface elements in Mac OS X. You can use the Appearance Manager to adapt any nonstandard interface elements in your program to the same coordinated look as the rest of Mac OS X. The Appearance Manager also provides many standard human interface elements, such as focus rings and group boxes, that can eliminate the need to create and maintain your own custom solutions.

In Mac OS X v10.3 and later, the Appearance Manager provides a new API called HITheme for drawing appearance primitives. Currently, this API is documented in the `HITheme.h` interface file. The HITheme API is similar to the legacy Appearance Manager API, but many parameters have been modified to use Quartz 2D types instead of QuickDraw types. For example, HITheme functions draw into a Quartz graphics context instead of the current QuickDraw graphics port. The legacy Appearance Manager API is implemented on top of the HITheme API, so using the new API can provide a significant performance advantage.

Functions by Task

Accessing Theme Information

`CopyThemeIdentifier` (page 28)
Retrieves a string identifying the current theme variant.

`GetTheme` (page 59)
Obtains a collection containing data describing the current theme.

`GetThemeMetric` (page 70)
Retrieves the value of a metric property of a user interface element.

`GetThemeFont` (page 65) Deprecated in Mac OS X v10.5
Obtains information about a system font in the current theme. (Deprecated. Some theme fonts cannot be drawn using QuickDraw; use `HIThemeDrawTextBox` instead.)

`IsValidAppearanceFileType` (page 90) Deprecated in Mac OS X v10.5
Returns whether the system can interpret files of a given file type as appearance files. (Deprecated. There is no replacement function.)

`IterateThemes` (page 91) Deprecated in Mac OS X v10.5
: Iterates over all themes installed on a system. (Deprecated. There is no replacement function.)

`SetTheme` (page 97) Deprecated in Mac OS X v10.5
: Sets a specified collection as the current theme. (Deprecated. There is no replacement function.)

`UseThemeFont` (page 103) Deprecated in Mac OS X v10.5
: Sets the font of the current graphics port to one of the current theme's system fonts. (Deprecated. Use `HIThemeDrawTextBox` instead.)

Drawing Theme-Compliant Controls

`GetThemeCheckBoxStyle` (page 64)
: Obtains the system preference for the type of mark to use in a checkbox.

`GetThemeScrollBarArrowStyle` (page 70)
: Obtains the system preference for the type of scroll bar arrows to be used.

`GetThemeScrollBarThumbStyle` (page 71)
: Obtains the system preference for the type of scroll box to be used.

`DrawThemeButton` (page 31) Deprecated in Mac OS X v10.5
: Draws a button. (Deprecated. Use `HIThemeDrawButton` instead.)

`DrawThemeChasingArrows` (page 33) Deprecated in Mac OS X v10.5
: Draws an asynchronous arrows indicator. (Deprecated. Use `HIThemeDrawChasingArrows` instead.)

`DrawThemeEditTextFrame` (page 34) Deprecated in Mac OS X v10.5
: Draws an editable text frame. (Deprecated. Use `HIThemeDrawFrame` instead.)

`DrawThemeFocusRect` (page 34) Deprecated in Mac OS X v10.5
: Draws or erases a focus ring around a specified rectangle. (Deprecated. Use `HIThemeDrawFocusRect` instead.)

`DrawThemeFocusRegion` (page 35) Deprecated in Mac OS X v10.5
: Draws or erases a focus ring around a specified region. (Deprecated. Use `HIThemeDrawFocusRect` instead.)

`DrawThemeGenericWell` (page 36) Deprecated in Mac OS X v10.5
: Draws an image well frame. (Deprecated. Use `HIThemeDrawGenericWell` instead.)

`DrawThemeListBoxFrame` (page 37) Deprecated in Mac OS X v10.5
: Draws a list box frame. (Deprecated. Use `HIThemeDrawFrame` instead.)

`DrawThemePlacard` (page 42) Deprecated in Mac OS X v10.5
: Draws a placard. (Deprecated. Use `HIThemeDrawPlacard` instead.)

`DrawThemePopupArrow` (page 43) Deprecated in Mac OS X v10.5
: Draws a pop-up arrow. (Deprecated. Use `HIThemeDrawPopupArrow` instead.)

`DrawThemePrimaryGroup` (page 44) Deprecated in Mac OS X v10.5
: Draws a primary group box frame. (Deprecated. Use `HIThemeDrawGroupBox` instead.)

`DrawThemeScrollBarArrows` (page 45) Deprecated in Mac OS X v10.5
: Draws scroll bar arrows consistent with the current system preferences. (Deprecated. Use `HIThemeDrawTrack`, which draws the entire scrollbar including both the track and arrows.)

`DrawThemeSecondaryGroup` (page 46) Deprecated in Mac OS X v10.5
: Draws a secondary group box frame. (Deprecated. Use `HIThemeDrawGroupBox` instead.)

`DrawThemeSeparator` (page 47) Deprecated in Mac OS X v10.5
Draws a separator line. (Deprecated. Use `HIThemeDrawSeparator` instead.)

`DrawThemeTab` (page 50) Deprecated in Mac OS X v10.5
Draws a tab. (Deprecated. Use `HIThemeDrawTab` instead.)

`DrawThemeTabPane` (page 51) Deprecated in Mac OS X v10.5
Draws a tab pane. (Deprecated. Use `HIThemeDrawTabPane` instead.)

`DrawThemeTickMark` (page 53) Deprecated in Mac OS X v10.5
Draws a tick mark. (Deprecated. Use `HIThemeDrawTickMark` instead.)

`DrawThemeTrack` (page 55) Deprecated in Mac OS X v10.5
Draws a track. (Deprecated. Use `HIThemeDrawTrack` instead.)

`DrawThemeTrackTickMarks` (page 56) Deprecated in Mac OS X v10.5
Draws tick marks for a track. (Deprecated. Use `HIThemeDrawTrackTickMarks` instead.)

`GetThemeButtonBackgroundBounds` (page 62) Deprecated in Mac OS X v10.5
Obtains the rectangle that contains a button. (Deprecated. Use `HIThemeGetButtonBackgroundBounds` instead.)

`GetThemeButtonContentBounds` (page 62) Deprecated in Mac OS X v10.5
Obtains the rectangle where content can be drawn for a button. (Deprecated. Use `HIThemeGetButtonContentBounds` instead.)

`GetThemeButtonRegion` (page 63) Deprecated in Mac OS X v10.5
Obtains the region occupied by a button. (Deprecated. Use `HIThemeGetButtonShape` instead.)

`GetThemeScrollBarTrackRect` (page 71) Deprecated in Mac OS X v10.5
Obtains the area containing the track portion of a scroll bar. (Deprecated. Use `HIThemeGetScrollBarTrackRect` instead.)

`GetThemeTabRegion` (page 73) Deprecated in Mac OS X v10.5
Obtains the region occupied by a tab. (Deprecated. Use `HIThemeGetTabDrawShape` instead.)

`GetThemeTrackBounds` (page 76) Deprecated in Mac OS X v10.5
Obtains the bounding rectangle of a track. (Deprecated. Use `HIThemeGetTrackBounds` instead.)

`GetThemeTrackDragRect` (page 77) Deprecated in Mac OS X v10.5
Obtains the area in which the user may drag a track's indicator. (Deprecated. Use `HIThemeGetTrackDragRect` instead.)

`GetThemeTrackLiveValue` (page 78) Deprecated in Mac OS X v10.5
Obtains the current value of a track's indicator, given its relative position. (Deprecated. Use `HIThemeGetTrackLiveValue` instead.)

`GetThemeTrackThumbPositionFromOffset` (page 79) Deprecated in Mac OS X v10.5
Obtains the relative position of a track's indicator, given an offset from its prior position. (Deprecated. Use `HIThemeGetTrackThumbPositionFromOffset` instead.)

`GetThemeTrackThumbPositionFromRegion` (page 79) Deprecated in Mac OS X v10.5
Obtains the relative position of a track's indicator, given its current position. (Deprecated. use `HIThemeGetTrackThumbPositionFromBounds` instead.)

`GetThemeTrackThumbRgn` (page 80) Deprecated in Mac OS X v10.5
Obtains the region containing a track's indicator. (Deprecated. Use `HIThemeGetTrackThumbShape` instead.)

`HitTestThemeScrollBarArrows` (page 83) Deprecated in Mac OS X v10.5
Returns whether the user clicked upon the specified scroll bar's arrows. (Deprecated. Use `HIThemeHitTestScrollBarArrows` instead.)

`HitTestThemeTrack` (page 84) Deprecated in Mac OS X v10.5
Returns whether the user clicked upon the specified track. (Deprecated. Use `HIThemeHitTestTrack` instead.)

Drawing Theme-Compliant Menus

`GetThemeMenuBarHeight` (page 67)
Obtains the height of a menu bar.

`GetThemeMenuItemExtra` (page 68)
Obtains a measurement of the space surrounding a menu item.

`GetThemeMenuSeparatorHeight` (page 68)
Obtains the height of a menu separator line.

`GetThemeMenuTitleExtra` (page 69)
Obtains a measurement of the space to either side of a menu title.

`DrawThemeMenuBackground` (page 37) Deprecated in Mac OS X v10.5
Draws a menu background. (Deprecated. Use `HIThemeDrawMenuBackground` instead.)

`DrawThemeMenuBarBackground` (page 38) Deprecated in Mac OS X v10.5
Draws a menu bar background. (Deprecated. Use `HIThemeDrawMenuBarBackground` instead.)

`DrawThemeMenuItem` (page 38) Deprecated in Mac OS X v10.5
Draws a menu item. (Deprecated. Use `HIThemeDrawMenuItem` instead.)

`DrawThemeMenuSeparator` (page 40) Deprecated in Mac OS X v10.5
Draws a menu item separator line. (Deprecated. Use `HIThemeDrawMenuSeparator` instead.)

`DrawThemeMenuTitle` (page 40) Deprecated in Mac OS X v10.5
Draws a menu title. (Deprecated. Use `HIThemeDrawMenuTitle` instead.)

`GetThemeMenuBackgroundRegion` (page 66) Deprecated in Mac OS X v10.5
Obtains the background region for a menu. (Deprecated. Use `HIThemeGetMenuBackgroundShape` instead.)

Drawing Theme-Compliant Windows

`DrawThemeModelessDialogFrame` (page 42) Deprecated in Mac OS X v10.5
Draws a beveled outline inside the content area of a modeless dialog box. (Deprecated. Use `HIThemeDrawWindowFrame` instead.)

`DrawThemeScrollBarDelimiters` (page 46) Deprecated in Mac OS X v10.5
Outlines a window's scroll bars. (Deprecated. Use `HIThemeDrawScrollBarDelimiters` instead.)

`DrawThemeStandaloneGrowBox` (page 48) Deprecated in Mac OS X v10.5
Draws a size box. (Deprecated. Use `HIThemeDrawGrowBox` instead.)

`DrawThemeStandaloneNoGrowBox` (page 49) Deprecated in Mac OS X v10.5
Draws a fill image for use in the corner space between scroll bars. (Deprecated. Use `HIThemeDrawGrowBox` instead.)

`DrawThemeTitleBarWidget` (page 54) Deprecated in Mac OS X v10.5
Draws a close box, zoom box, or collapse box. (Deprecated. Use `HIThemeDrawTitleBarWidget` instead.)

`DrawThemeWindowFrame` (page 57) Deprecated in Mac OS X v10.5
Draws a window frame. (Deprecated. Use `HIThemeDrawWindowFrame` instead.)

`DrawThemeWindowHeader` (page 58) Deprecated in Mac OS X v10.5
Draws a window header. (Deprecated. Use `HIThemeDrawHeader` instead.)

`DrawThemeWindowListViewHeader` (page 58) Deprecated in Mac OS X v10.5
Draws a window list view header. (Deprecated. Use `HIThemeDrawHeader` instead.)

`GetThemeStandaloneGrowBoxBounds` (page 72) Deprecated in Mac OS X v10.5
Obtains the bounds of a size box. (Deprecated. Use `HIThemeGetGrowBoxBounds` instead.)

`GetThemeWindowRegion` (page 81) Deprecated in Mac OS X v10.5
Obtains the specified window region. (Deprecated. Use `HIThemeGetWindowShape` instead.)

`GetThemeWindowRegionHit` (page 82) Deprecated in Mac OS X v10.5
Obtains the part of the window that the user clicked upon. (Deprecated. Use `HIThemeGetWindowRegionHit` instead.)

Playing Theme Sounds

The theme sound functions do nothing in Mac OS X.

`BeginThemeDragSound` (page 27)
Continuously plays a theme-specific sound associated with the user's movement of a given interface object.

`EndThemeDragSound` (page 59)
Terminates the playing of a sound associated with the user's movement of a given interface object.

`PlayThemeSound` (page 94)
Plays an asynchronous sound associated with the specified state change.

Registering With the Appearance Manager

`IsAppearanceClient` (page 88) Deprecated in Mac OS X v10.5
Returns whether a given process is currently registered as a client of the Appearance Manager. (Deprecated. There is no replacement function.)

`RegisterAppearanceClient` (page 95) Deprecated in Mac OS X v10.5
Registers your program with the Appearance Manager. (Deprecated. There is no replacement function.)

`UnregisterAppearanceClient` (page 103) Deprecated in Mac OS X v10.5
Informs the Appearance Manager that your program is no longer its client. (Deprecated. There is no replacement function.)

Specifying Theme-Compliant Cursors

`SetAnimatedThemeCursor` (page 96)
Animates a version of the specified cursor type that is consistent with the current theme.

`SetThemeCursor` (page 98)
Sets the cursor to a version of the specified cursor type that is consistent with the current theme.

Using Theme-Compliant Colors and Patterns

`DisposeThemeDrawingState` (page 29)
Releases the memory associated with a reference to a graphics port's drawing state.

`GetThemeBrushAsColor` (page 61)
Obtains the color that corresponds to a given theme brush type under the current theme.

`GetThemeDrawingState` (page 65)
Obtains the drawing state of the current graphics port.

`GetThemeTextColor` (page 74)
Obtains the text color used for a specified element under the current theme.

`NormalizeThemeDrawingState` (page 94)
Sets the current graphics port to a default drawing state.

`SetThemeDrawingState` (page 99)
Sets the drawing state of the current graphics port.

`ApplyThemeBackground` (page 26) Deprecated in Mac OS X v10.5
Sets the background color or pattern of the current port to be consistent with that of an embedding object. (Deprecated. Use `HIThemeApplyBackground` instead.)

`GetThemeAccentColors` (page 60) Deprecated in Mac OS X v10.5
Obtains a copy of a theme's accent colors. (Deprecated. There is no replacement function.)

`IsThemeInColor` (page 89) Deprecated in Mac OS X v10.5
Returns whether the current theme would draw in color in the given environment. (Deprecated. There is no replacement function.)

`SetThemeBackground` (page 98) Deprecated in Mac OS X v10.5
Applies a theme-compliant color or pattern to the background of the current port. (Deprecated. Use `HIThemeSetFill` and draw using Quartz 2D.)

`SetThemePen` (page 100) Deprecated in Mac OS X v10.5
Applies a theme-compliant color or pattern to the foreground of the current port. (Deprecated. Use `HIThemeSetStroke` and draw using Quartz 2D.)

`SetThemeTextColor` (page 101) Deprecated in Mac OS X v10.5
Sets the current text color to be consistent with that of a specified element. (Deprecated. Use `HIThemeSetTextFill` and draw with Quartz 2D, ATSUI, or `HIThemeDrawTextBox`.)

Drawing Theme-Compliant Text

`GetThemeTextShadowOutset` (page 76)
Tells you the amount of space taken up by the shadow for a given font and drawing state combination.

`DrawThemeTextBox` (page 51) Deprecated in Mac OS X v10.5
Draws text into the area you specify. (Deprecated. Use `HIThemeDrawTextBox` instead.)

`GetThemeTextDimensions` (page 74) Deprecated in Mac OS X v10.5
Tells you the height, width, and baseline for a string. (Deprecated. Use `HIThemeGetTextDimensions` instead.)

`TruncateThemeText` (page 102) Deprecated in Mac OS X v10.5
Truncates text to fit within the width you specify. (Deprecated. There is no replacement function; use `HIThemeGetTextDimensions` or `HIThemeDrawTextBox` instead.)

Creating and Disposing Universal Procedure Pointers to Appearance Manager Callbacks

`DisposeMenuItemDrawingUPP` (page 28) Deprecated in Mac OS X v10.5
Disposes of the UPP to a menu item drawing function. (Deprecated. There is no replacement function.)

`DisposeMenuTitleDrawingUPP` (page 29) Deprecated in Mac OS X v10.5
Disposes of the UPP to a menu title drawing function. (Deprecated. There is no replacement function.)

`DisposeThemeButtonDrawUPP` (page 29) Deprecated in Mac OS X v10.5
Disposes of the UPP to a button drawing function. (Deprecated. There is no replacement function.)

`DisposeThemeEraseUPP` (page 30) Deprecated in Mac OS X v10.5
Disposes of the UPP to a background drawing callback function. (Deprecated. There is no replacement function.)

`DisposeThemeIteratorUPP` (page 30) Deprecated in Mac OS X v10.5
Disposes of the UPP to a theme iteration callback function. (Deprecated. There is no replacement function.)

`DisposeThemeTabTitleDrawUPP` (page 31) Deprecated in Mac OS X v10.5
Disposes of the UPP to a tab title drawing function. (Deprecated. There is no replacement function.)

`DisposeWindowTitleDrawingUPP` (page 31) Deprecated in Mac OS X v10.5
Disposes of the UPP to a window title drawing function. (Deprecated. There is no replacement function.)

`InvokeMenuItemDrawingUPP` (page 85) Deprecated in Mac OS X v10.5
Invokes your menu item drawing function. (Deprecated. There is no replacement function.)

`InvokeMenuTitleDrawingUPP` (page 85) Deprecated in Mac OS X v10.5
Invokes your menu title drawing function. (Deprecated. There is no replacement function.)

`InvokeThemeButtonDrawUPP` (page 86) Deprecated in Mac OS X v10.5
Invokes your button drawing function. (Deprecated. There is no replacement function.)

`InvokeThemeEraseUPP` (page 86) Deprecated in Mac OS X v10.5
Invokes your background drawing callback function. (Deprecated. There is no replacement function.)

`InvokeThemeIteratorUPP` (page 87) Deprecated in Mac OS X v10.5
Invokes your theme iteration callback function. (Deprecated. There is no replacement function.)

`InvokeThemeTabTitleDrawUPP` (page 87) Deprecated in Mac OS X v10.5
Invokes your tab title drawing function. (Deprecated. There is no replacement function.)

`InvokeWindowTitleDrawingUPP` (page 88) Deprecated in Mac OS X v10.5
Invokes your window title drawing function. (Deprecated. There is no replacement function.)

`NewMenuItemDrawingUPP` (page 91) Deprecated in Mac OS X v10.5
Creates a new universal procedure pointer (UPP) to a menu item drawing function. (Deprecated. There is no replacement function.)

`NewMenuTitleDrawingUPP` (page 92) Deprecated in Mac OS X v10.5
Creates a new universal procedure pointer (UPP) to a menu title drawing function. (Deprecated. There is no replacement function.)

`NewThemeButtonDrawUPP` (page 92) Deprecated in Mac OS X v10.5
Creates a new universal procedure pointer (UPP) to a button drawing function. (Deprecated. There is no replacement function.)

`NewThemeEraseUPP` (page 92) Deprecated in Mac OS X v10.5
Creates a new universal procedure pointer (UPP) to a background drawing callback function. (Deprecated. There is no replacement function.)

`NewThemeIteratorUPP` (page 93) Deprecated in Mac OS X v10.5
: Creates a new universal procedure pointer (UPP) to a theme iteration callback function. (Deprecated. There is no replacement function.)

`NewThemeTabTitleDrawUPP` (page 93) Deprecated in Mac OS X v10.5
: Creates a new universal procedure pointer (UPP) to a tab title drawing function. (Deprecated. There is no replacement function.)

`NewWindowTitleDrawingUPP` (page 94) Deprecated in Mac OS X v10.5
: Creates a new universal procedure pointer (UPP) to a window title drawing function. (Deprecated. There is no replacement function.)

Functions

ApplyThemeBackground

Sets the background color or pattern of the current port to be consistent with that of an embedding object. (Deprecated in Mac OS X v10.5. Use `HIThemeApplyBackground` instead.)

```
OSStatus ApplyThemeBackground (
   ThemeBackgroundKind inKind,
   const Rect *bounds,
   ThemeDrawState inState,
   SInt16 inDepth,
   Boolean inColorDev
);
```

Parameters

inKind
: A value of type `ThemeBackgroundKind`. Pass a constant specifying the type of embedding object. See "Theme Backgrounds" (page 144) for descriptions of possible values.

bounds
: A pointer to a structure of type `Rect`. Before calling `ApplyThemeBackground`, set the rectangle to a size and position that contains the embedding object, in local coordinates.

inState
: A value of type `ThemeDrawState`. Pass a constant specifying the current state of the embedding object. See "Theme Drawing States" (page 126) for descriptions of possible values.

inDepth
: A signed 16-bit integer. Pass a value specifying the bit depth (in bits per pixel) of the current graphics port.

inColorDev
: A value of type `Boolean`. Pass `true` to indicate that you are drawing on a color device, or `false` for a monochrome device.

Return Value

A result code. See "Appearance Manager Result Codes" (page 217).

Discussion
The `ApplyThemeBackground` function sets the background color or pattern of the current port to match the background of an embedding object, such as a placard or tab control. Your application should call `ApplyThemeBackground` before erasing the background of your application's content to ensure that the content background matches that of the object in which it is visually embedded.

`ApplyThemeBackground` aligns patterns based on the rectangle passed in the bounds parameter. This is in contrast to the function `SetThemeBackground` (page 98), which aligns patterns based on the origin of the current port.

You do not need to call `ApplyThemeBackground` if your content is an embedded part within a control hierarchy and is logically as well as visually embedded in its container; in this case, the Control Manager automatically requests the embedding control to set up the background before drawing the embedded control.

If you have a custom control definition function that erases its background before drawing, you should use the Control Manager function `SetUpControlBackground` before erasing. `SetUpControlBackground` calls `ApplyThemeBackground` if necessary.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Appearance.h`

BeginThemeDragSound

Continuously plays a theme-specific sound associated with the user's movement of a given interface object.

```
OSStatus BeginThemeDragSound (
   ThemeDragSoundKind kind
);
```

Parameters
kind
A value of type `ThemeDragSoundKind`. Pass a constant specifying the sound to play; see "Theme Drag Sounds" (page 210) for descriptions of possible values.

Return Value
A result code. See "Appearance Manager Result Codes" (page 217).

Discussion
The Appearance Manager automatically plays drag sounds for standard user interface elements and for Drag Manager drag actions. Your application may call `BeginThemeDragSound`, typically upon detecting a drag initiation, to play a drag sound for a custom element. `BeginThemeDragSound` plays the specified sound in a continuous loop until your application calls the function `EndThemeDragSound` (page 59), typically upon receiving a mouse-up event.

Note that the `BeginThemeDragSound` function automatically tracks the current mouse position and handles any panning or variations in pitch for the sound.

Special Considerations

This function is not implemented in Mac OS X.

Availability

Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In

`Appearance.h`

CopyThemeIdentifier

Retrieves a string identifying the current theme variant.

```
OSStatus CopyThemeIdentifier (
   CFStringRef *outIdentifier
);
```

Parameters

outIdentifier

A pointer to a string that, on output, contains the current theme variant. When you no longer need the string, you should release it.

Return Value

A result code. See "Appearance Manager Result Codes" (page 217).

Availability

Available in Mac OS X v10.1 and later.

Declared In

`Appearance.h`

DisposeMenuItemDrawingUPP

Disposes of the UPP to a menu item drawing function. (Deprecated in Mac OS X v10.5. There is no replacement function.)

```
void DisposeMenuItemDrawingUPP (
   MenuItemDrawingUPP userUPP
);
```

Parameters

userUPP

The UPP to dispose of.

Availability

Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In

`Appearance.h`

DisposeMenuTitleDrawingUPP

Disposes of the UPP to a menu title drawing function. (Deprecated in Mac OS X v10.5. There is no replacement function.)

```
void DisposeMenuTitleDrawingUPP (
   MenuTitleDrawingUPP userUPP
);
```

Parameters

userUPP

The UPP to dispose of.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Declared In

`Appearance.h`

DisposeThemeButtonDrawUPP

Disposes of the UPP to a button drawing function. (Deprecated in Mac OS X v10.5. There is no replacement function.)

```
void DisposeThemeButtonDrawUPP (
   ThemeButtonDrawUPP userUPP
);
```

Parameters

userUPP

The UPP to dispose of.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Declared In

`Appearance.h`

DisposeThemeDrawingState

Releases the memory associated with a reference to a graphics port's drawing state.

```
OSStatus DisposeThemeDrawingState (
   ThemeDrawingState inState
);
```

Parameters

inState

A value of type `ThemeDrawingState`. Pass a value specifying the previous drawing state for the current graphics port. You may obtain this value from the `outState` parameter of `GetThemeDrawingState` (page 65).

Return Value
A result code. See "Appearance Manager Result Codes" (page 217).

Discussion
Also see the function `SetThemeDrawingState` (page 99).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Appearance.h`

DisposeThemeEraseUPP

Disposes of the UPP to a background drawing callback function. (Deprecated in Mac OS X v10.5. There is no replacement function.)

```
void DisposeThemeEraseUPP (
   ThemeEraseUPP userUPP
);
```

Parameters
userUPP
The UPP to dispose of.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In
`Appearance.h`

DisposeThemeIteratorUPP

Disposes of the UPP to a theme iteration callback function. (Deprecated in Mac OS X v10.5. There is no replacement function.)

```
void DisposeThemeIteratorUPP (
   ThemeIteratorUPP userUPP
);
```

Parameters
userUPP
The UPP to dispose of.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In
`Appearance.h`

DisposeThemeTabTitleDrawUPP

Disposes of the UPP to a tab title drawing function. (Deprecated in Mac OS X v10.5. There is no replacement function.)

```
void DisposeThemeTabTitleDrawUPP (
   ThemeTabTitleDrawUPP userUPP
);
```

Parameters

userUPP

The UPP to dispose of.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Declared In

`Appearance.h`

DisposeWindowTitleDrawingUPP

Disposes of the UPP to a window title drawing function. (Deprecated in Mac OS X v10.5. There is no replacement function.)

```
void DisposeWindowTitleDrawingUPP (
   WindowTitleDrawingUPP userUPP
);
```

Parameters

userUPP

The UPP to dispose of.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Declared In

`Appearance.h`

DrawThemeButton

Draws a button. (Deprecated in Mac OS X v10.5. Use `HIThemeDrawButton` instead.)

```
OSStatus DrawThemeButton (
   const Rect *inBounds,
   ThemeButtonKind inKind,
   const ThemeButtonDrawInfo *inNewInfo,
   const ThemeButtonDrawInfo *inPrevInfo,
   ThemeEraseUPP inEraseProc,
   ThemeButtonDrawUPP inLabelProc,
   URefCon inUserData
);
```

Parameters

inBounds

A pointer to a structure of type `Rect`. Pass a rectangle specifying the boundary of the button, in local coordinates.

inKind

A value of type `ThemeButtonKind`. Pass a constant specifying the type of button to draw. See "Theme Buttons" (page 153) for descriptions of possible values.

inNewInfo

A pointer to a structure of type `ThemeButtonDrawInfo`. Before calling `DrawThemeButton`, set the structure to contain the new state, value, and adornment for the button. `DrawThemeButton` uses the information passed in the `inNewInfo` and `inPrevInfo` parameters to apply transitional animation or sound effects as the button state changes, if such are specified under the current theme.

inPrevInfo

A pointer to a structure of type `ThemeButtonDrawInfo`. If the button state is changing, set the structure to contain the previous state, value, and adornment for the button, to allow `DrawThemeButton` to apply any transitional effects. If the button state is not changing, you can pass `NULL`.

inEraseProc

A value of type `ThemeEraseUPP`. If you have a custom background, use this parameter to pass a universal function pointer to an application-defined function such as that described in `ThemeEraseProcPtr` (page 108). `DrawThemeButton` calls this function to erase the background before drawing the button. If you pass `NULL`, `DrawThemeButton`'s default behavior is to erase the background for you.

inLabelProc

A value of type `ThemeButtonDrawUPP`. If you pass a universal function pointer to an application-defined function such as that described in `ThemeButtonDrawProcPtr` (page 107), `DrawThemeButton` calls that function to draw the label of the button. If you pass `NULL`, no label is drawn.

inUserData

An unsigned 32-bit integer. Provide any data to be passed in to the callback functions specified in the `inLabelProc` and `inEraseProc` parameters. Pass `NULL` if you do not wish to provide any data.

Return Value

A result code. See "Appearance Manager Result Codes" (page 217).

Discussion

The `DrawThemeButton` function draws a theme-compliant button. If a `ThemeEraseProcPtr` is specified in the `inEraseProc` parameter, `DrawThemeButton` uses that function to erase the background of the button before drawing the button. After the button is drawn, if a `ThemeButtonDrawProcPtr` is specified in the `inLabelProc` parameter, `DrawThemeButton` calls that function to draw the button's label.

Note that `DrawThemeButton` also draws any appearance adornments for the button and that these can extend beyond the button's basic bounding rectangle, as specified in the `inBounds` parameter, and may be of variable shape. You may therefore wish to call the function `GetThemeButtonBackgroundBounds` (page 62) to obtain the actual rectangle containing the pixels belonging to a button under the current theme.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Appearance.h`

DrawThemeChasingArrows

Draws an asynchronous arrows indicator. (Deprecated in Mac OS X v10.5. Use `HIThemeDrawChasingArrows` instead.)

```
OSStatus DrawThemeChasingArrows (
   const Rect *bounds,
   UInt32 index,
   ThemeDrawState state,
   ThemeEraseUPP eraseProc,
   URefCon eraseData
);
```

Parameters

bounds
A pointer to a structure of type `Rect`. Before calling `DrawThemeChasingArrows`, set the rectangle to contain the asynchronous arrows, in local coordinates.

index
An unsigned 32-bit value. Pass a value specifying the current animation step of the arrows. To animate the arrows, increment the initial value by 1 with each call to `DrawThemeChasingArrows`.

state
A value of type `ThemeDrawState`. Pass a constant specifying the state in which to draw the asynchronous arrows indicator; see "Theme Drawing States" (page 126). The asynchronous arrows indicator can be drawn as active or inactive; passing `kThemeStatePressed` produces an error.

eraseProc
A value of type `ThemeEraseUPP`. If you have a custom background, pass a universal function pointer to an application-defined function such as that described in `ThemeEraseProcPtr` (page 108). `DrawThemeChasingArrows` calls that function to erase the background before drawing the asynchronous arrows. If you pass `NULL`, no erasing occurs.

eraseData
An unsigned 32-bit integer. Provide any data to be passed in to the `eraseData` parameter of the callback function specified in the `eraseProc` parameter.

Return Value
A result code. See "Appearance Manager Result Codes" (page 217).

Discussion
The `DrawThemeChasingArrows` function draws a theme-compliant asynchronous arrows (also known as "chasing arrows") indicator.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Appearance.h`

DrawThemeEditTextFrame

Draws an editable text frame. (Deprecated in Mac OS X v10.5. Use `HIThemeDrawFrame` instead.)

```
OSStatus DrawThemeEditTextFrame (
   const Rect *inRect,
   ThemeDrawState inState
);
```

Parameters

`inRect`

A pointer to a structure of type `Rect`. Before calling `DrawThemeEditTextFrame`, set the rectangle to the position around which to draw the editable text frame, in local coordinates.

`inState`

A value of type `ThemeDrawState`. Pass a constant specifying the state in which to draw the editable text frame; see "Theme Drawing States" (page 126). The frame can be drawn as active or inactive; passing `kThemeStatePressed` produces an error.

Return Value
A result code. See "Appearance Manager Result Codes" (page 217).

Discussion
The `DrawThemeEditTextFrame` function draws a theme-compliant frame for an editable text field. The frame is a maximum of 2 pixels thick and is drawn outside the specified rectangle. You should not use this function to draw frames for items other than editable text fields.

To ensure that you get an appropriate focus ring for your editable text field, you should pass the same rectangle that you use with `DrawThemeEditTextFrame` function to the function `DrawThemeFocusRect` (page 34).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Appearance.h`

DrawThemeFocusRect

Draws or erases a focus ring around a specified rectangle. (Deprecated in Mac OS X v10.5. Use `HIThemeDrawFocusRect` instead.)

```
OSStatus DrawThemeFocusRect (
   const Rect *inRect,
   Boolean inHasFocus
);
```

Parameters

inRect

A pointer to a structure of type `Rect`. Before calling `DrawThemeFocusRect`, set the rectangle to the position around which to draw the focus ring, in local coordinates. The focus ring is drawn outside the rectangle that is passed in, and it can be outset a maximum of 3 pixels.

inHasFocus

A value of type `Boolean`. Pass `true` to draw the focus ring. Pass `false` to erase the focus ring.

Return Value

A result code. See "Appearance Manager Result Codes" (page 217).

Discussion

Your application can use the `DrawThemeFocusRect` function to draw a theme-compliant focus ring. The presence of a focus ring indicates whether an item has keyboard focus.

If you are drawing a focus ring around an element for which you have drawn a frame using `DrawThemeEditTextFrame` (page 34) or `DrawThemeListBoxFrame` (page 37), you must coordinate your drawing sequence to achieve the correct look. When drawing the element, your application should first call `DrawThemeEditTextFrame` or `DrawThemeListBoxFrame` and then call `DrawThemeFocusRect`, passing the same rectangle in the `inRect` parameter. If you use `DrawThemeFocusRect` to erase the focus ring around an editable text frame or list box frame, you must redraw the editable text frame or list box frame after calling `DrawThemeFocusRect`, because there is typically an overlap.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Appearance.h`

DrawThemeFocusRegion

Draws or erases a focus ring around a specified region. (Deprecated in Mac OS X v10.5. Use `HIThemeDrawFocusRect` instead.)

```
OSStatus DrawThemeFocusRegion (
   RgnHandle inRegion,
   Boolean inHasFocus
);
```

Parameters

inRegion

A value of type `RgnHandle`. Before calling `DrawThemeFocusRegion`, set the region to the position around which to draw the focus ring, in local coordinates. The focus ring is drawn outside the region that is passed in, and it can be outset a maximum of 3 pixels.

inHasFocus

A value of type `Boolean`. Pass `true` to draw the focus region. Pass `false` to erase the focus region.

Return Value
A result code. See "Appearance Manager Result Codes" (page 217).

Discussion
Your application can use the `DrawThemeFocusRegion` function to draw a theme-compliant focus ring. The presence of a focus ring indicates whether an item has keyboard focus.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Appearance.h`

DrawThemeGenericWell

Draws an image well frame. (Deprecated in Mac OS X v10.5. Use `HIThemeDrawGenericWell` instead.)

```
OSStatus DrawThemeGenericWell (
   const Rect *inRect,
   ThemeDrawState inState,
   Boolean inFillCenter
);
```

Parameters

inRect
A pointer to a structure of type `Rect`. Before calling `DrawThemeGenericWell`, set the rectangle to the position around which to draw the image well frame, in local coordinates.

inState
A value of type `ThemeDrawState`. Pass a constant specifying the state in which to draw the image well frame; see "Theme Drawing States" (page 126). The well can be drawn as active or inactive; passing `kThemeStatePressed` produces an error.

inFillCenter
A value of type `Boolean`. Set to `true` to fill the image well frame with white; otherwise, `false`.

Return Value
A result code. See "Appearance Manager Result Codes" (page 217).

Discussion
The `DrawThemeGenericWell` function draws a theme-compliant image well frame. You can specify that the center of the well be filled in with white.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Appearance.h`

DrawThemeListBoxFrame

Draws a list box frame. (Deprecated in Mac OS X v10.5. Use `HIThemeDrawFrame` instead.)

```
OSStatus DrawThemeListBoxFrame (
   const Rect *inRect,
   ThemeDrawState inState
);
```

Parameters

inRect

A pointer to a structure of type `Rect`. Before calling `DrawThemeListBoxFrame`, set the rectangle to the position around which to draw the list box frame, in local coordinates.

inState

A value of type `ThemeDrawState`. Pass a constant specifying the state in which to draw the list box frame; see "Theme Drawing States" (page 126). The frame can be drawn as active or inactive; passing `kThemeStatePressed` produces an error.

Return Value

A result code. See "Appearance Manager Result Codes" (page 217).

Discussion

The `DrawThemeListBoxFrame` function draws a theme-compliant list box frame. The frame is a maximum of 2 pixels thick and is drawn outside the specified rectangle. To ensure that you get an appropriate focus ring for your list box, you should pass the same rectangle that you use with the `DrawThemeListBoxFrame` function to the function `DrawThemeFocusRect` (page 34).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Appearance.h`

DrawThemeMenuBackground

Draws a menu background. (Deprecated in Mac OS X v10.5. Use `HIThemeDrawMenuBackground` instead.)

```
OSStatus DrawThemeMenuBackground (
   const Rect *inMenuRect,
   ThemeMenuType inMenuType
);
```

Parameters

inMenuRect

A pointer to a structure of type `Rect`. Before calling `DrawThemeMenuBackground`, set the rectangle to contain the entire menu, in global coordinates.

inMenuType

A value of type `ThemeMenuType`. Pass a constant specifying the type of menu for which to draw a background; see "Theme Menu Types" (page 176) for descriptions of possible values.

Return Value

A result code. See "Appearance Manager Result Codes" (page 217).

Discussion
The `DrawThemeMenuBackground` function draws a theme-compliant menu background in the specified rectangle.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Appearance.h`

DrawThemeMenuBarBackground

Draws a menu bar background. (Deprecated in Mac OS X v10.5. Use `HIThemeDrawMenuBarBackground` instead.)

```
OSStatus DrawThemeMenuBarBackground (
   const Rect *inBounds,
   ThemeMenuBarState inState,
   UInt32 inAttributes
);
```

Parameters

inBounds
A pointer to a structure of type `Rect`. Before calling `DrawThemeMenuBarBackground`, set the rectangle to specify the menu bar's initial size and location, in global coordinates.

inState
A value of type `ThemeMenuBarState`. Pass a constant specifying the state (active or selected) in which to draw the menu bar; see "Theme Menu Bar States" (page 177).

inAttributes
A value indicating the attributes of the menu bar. Pass 0 for a standard menu bar or `kThemeMenuSquareMenuBar` for a menu bar with square corners.

Return Value
A result code. See "Appearance Manager Result Codes" (page 217).

Discussion
The `DrawThemeMenuBarBackground` function draws a theme-compliant menu bar background in the specified rectangle.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Appearance.h`

DrawThemeMenuItem

Draws a menu item. (Deprecated in Mac OS X v10.5. Use `HIThemeDrawMenuItem` instead.)

```
OSStatus DrawThemeMenuItem (
   const Rect *inMenuRect,
   const Rect *inItemRect,
   SInt16 inVirtualMenuTop,
   SInt16 inVirtualMenuBottom,
   ThemeMenuState inState,
   ThemeMenuItemType inItemType,
   MenuItemDrawingUPP inDrawProc,
   URefCon inUserData
);
```

Parameters

inMenuRect

A pointer to a structure of type `Rect`. Before calling `DrawThemeMenuItem`, set the rectangle to contain the entire menu, in global coordinates. This is the actual menu rectangle as used in your menu definition function.

inItemRect

A pointer to a structure of type `Rect`. Before calling `DrawThemeMenuItem`, set the rectangle to contain the menu item, in global coordinates. The menu item's background is drawn in the rectangle passed in the `inItemRect` parameter. You should calculate the size of the menu item's content and then call `GetThemeMenuItemExtra` (page 68) to get the amount of padding surrounding menu items in the current theme; the width and height of the menu item rectangle are determined by adding these values together.

inVirtualMenuTop

A signed 16-bit integer. Pass a value representing the actual top of the menu. Normally this value is the top coordinate of the rectangle supplied in the `inMenuRect` parameter. This value could be different, however, if a menu is scrolled or bigger than can be displayed in the menu rectangle. You typically pass the value of the global variable `TopMenuItem` into this parameter if you are writing a custom menu definition function.

inVirtualMenuBottom

A signed 16-bit integer. Pass a value representing the actual bottom of the menu. Typically this value is the bottom coordinate of the rectangle supplied in the `inMenuRect` parameter. This value could be different, however, if a menu is scrolled or bigger than can be displayed in the menu rectangle. You typically pass the value of the global variable `AtMenuBottom` into this parameter if you are writing a custom menu definition function.

inState

A value of type `ThemeMenuState`. Pass a constant specifying the state (active, selected, or disabled) in which to draw the menu item; see "Theme Menu States" (page 176).

inItemType

A value of type `ThemeMenuItemType`. If you pass `kThemeMenuItemScrollUpArrow` or `kThemeMenuItemScrollDownArrow`, then you should pass `NULL` for the `inDrawProc` parameter, since there is no content to be drawn. If you pass `kThemeMenuItemHierarchical`, the hierarchical arrow is drawn for you. See "Theme Menu Item Types" (page 177) for descriptions of possible values.

inDrawProc

A value of type `MenuItemDrawingUPP`. Pass a universal function pointer to a menu item drawing function such as `MenuItemDrawingProcPtr` (page 104). The value of the `inDrawProc` parameter can be a valid universal function pointer or `NULL`.

inUserData

An unsigned 32-bit integer. Provide any data to be passed in to the `inUserData` parameter of `MenuItemDrawingProcPtr` (page 104).

Return Value
A result code. See "Appearance Manager Result Codes" (page 217).

Discussion
The `DrawThemeMenuItem` function draws a theme-compliant menu item.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Appearance.h`

DrawThemeMenuSeparator

Draws a menu item separator line. (Deprecated in Mac OS X v10.5. Use `HIThemeDrawMenuSeparator` instead.)

```
OSStatus DrawThemeMenuSeparator (
   const Rect *inItemRect
);
```

Parameters

inItemRect
A pointer to a structure of type `Rect`. Before calling `DrawThemeMenuSeparator`, set the rectangle to contain the menu item separator to be drawn, in global coordinates. The rectangle should be the same height as the height returned by the function `GetThemeMenuSeparatorHeight` (page 68).

Return Value
A result code. See "Appearance Manager Result Codes" (page 217).

Discussion
The `DrawThemeMenuSeparator` function draws a theme-compliant menu item separator line.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Appearance.h`

DrawThemeMenuTitle

Draws a menu title. (Deprecated in Mac OS X v10.5. Use `HIThemeDrawMenuTitle` instead.)

```
OSStatus DrawThemeMenuTitle (
   const Rect *inMenuBarRect,
   const Rect *inTitleRect,
   ThemeMenuState inState,
   UInt32 inAttributes,
   MenuTitleDrawingUPP inTitleProc,
   URefCon inTitleData
);
```

Parameters

inMenuBarRect

A pointer to a structure of type `Rect`. Before calling `DrawThemeMenuTitle`, set the rectangle to contain the entire menu bar in which the title is to be drawn, in global coordinates. The menu bar background is drawn in the rectangle passed in the `inMenuBarRect` parameter. Your application can call `GetThemeMenuBarHeight` (page 67) to get the height of the menu bar.

inTitleRect

A pointer to a structure of type `Rect`. Before calling `DrawThemeMenuTitle`, set the rectangle to contain the menu title, in global coordinates. The title background is drawn in the rectangle passed in the `inTitleRect` parameter. The width of this rectangle is determined by calculating the width of the menu title's content and then calling `GetThemeMenuTitleExtra` (page 69) to get the amount of padding between menu titles in the current theme; these two values are added together and added to the left edge of where the title should be drawn. The top and bottom coordinates of this rectangle should be the same as those of the `inMenuBarRect` parameter.

inState

A value of type `ThemeMenuState`. Pass a constant specifying the state (active, selected, or disabled) in which to draw the menu title; see "Theme Menu States" (page 176).

inAttributes

Reserved. Pass 0.

inTitleProc

A value of type `MenuTitleDrawingUPP`. Pass a universal function pointer to a menu title drawing function such as `MenuTitleDrawingProcPtr` (page 105), defining how to draw the contents of the menu title. The value of the `inTitleProc` parameter can be a valid universal function pointer or `NULL`.

inTitleData

An unsigned 32-bit integer. Provide any data to be passed in to the `inUserData` parameter of `MenuTitleDrawingProcPtr` (page 105).

Return Value

A result code. See "Appearance Manager Result Codes" (page 217).

Discussion

The `DrawThemeMenuTitle` function draws a theme-compliant menu title.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Appearance.h`

DrawThemeModelessDialogFrame

Draws a beveled outline inside the content area of a modeless dialog box. (Deprecated in Mac OS X v10.5. Use `HIThemeDrawWindowFrame` instead.)

```
OSStatus DrawThemeModelessDialogFrame (
   const Rect *inRect,
   ThemeDrawState inState
);
```

Parameters

inRect

A pointer to a structure of type `Rect`. Before calling `DrawThemeModelessDialogFrame`, set the rectangle to the boundary of the window's content area (that is, its port rectangle), inset by 1 pixel on each side, in local coordinates.

inState

A value of type `ThemeDrawState`. Pass a constant specifying the state in which to draw the modeless dialog box frame; see "Theme Drawing States" (page 126) for descriptions of possible values. The frame can be drawn as active or inactive; passing `kThemeStatePressed` produces an error.

Return Value

A result code. See "Appearance Manager Result Codes" (page 217).

Discussion

The `DrawThemeModelessDialogFrame` function draws a beveled frame, no more than 2 pixels wide, that bounds the window's content area. You can use this function to make a custom modeless dialog box theme-compliant the Dialog Manager automatically draws the interior frame for standard dialog boxes.

If you use `DrawThemeModelessDialogFrame` to draw a frame for a modeless dialog box, your application must explicitly invalidate and redraw the frame area if the dialog box is resized.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Appearance.h`

DrawThemePlacard

Draws a placard. (Deprecated in Mac OS X v10.5. Use `HIThemeDrawPlacard` instead.)

```
OSStatus DrawThemePlacard (
   const Rect *inRect,
   ThemeDrawState inState
);
```

Parameters

inRect

A pointer to a structure of type `Rect`. Before calling `DrawThemePlacard`, set the rectangle to a size and position that contains the placard, in local coordinates.

inState

A value of type `ThemeDrawState`. Pass a constant specifying the state in which to draw the placard; see "Theme Drawing States" (page 126). The placard can be drawn as active, inactive, or pressed.

Return Value
A result code. See "Appearance Manager Result Codes" (page 217).

Discussion
The `DrawThemePlacard` function draws a theme-compliant placard inside the specified rectangle.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Appearance.h`

DrawThemePopupArrow

Draws a pop-up arrow. (Deprecated in Mac OS X v10.5. Use `HIThemeDrawPopupArrow` instead.)

```
OSStatus DrawThemePopupArrow (
   const Rect *bounds,
   ThemeArrowOrientation orientation,
   ThemePopupArrowSize size,
   ThemeDrawState state,
   ThemeEraseUPP eraseProc,
   URefCon eraseData
);
```

Parameters

bounds

A pointer to a structure of type `Rect`. Before calling `DrawThemePopupArrow`, set the rectangle to contain the arrow, in local coordinates. `DrawThemePopupArrow` positions the arrow relative to the top left corner of the rectangle.

orientation

A value of type `ThemeArrowOrientation`. Pass a constant specifying the direction in which the pop-up arrow points. See "Theme Pop-Up Arrow Orientations" (page 160) for descriptions of possible values.

size

A value of type `ThemePopupArrowSize`. Pass a constant specifying the size of the pop-up arrow to draw. See "Theme Pop-Up Arrow Sizes" (page 161) for descriptions of possible values.

state

A value of type `ThemeDrawState`. Pass a constant specifying the current state of the button containing the pop-up arrow. See "Theme Drawing States" (page 126) for descriptions of possible values.

eraseProc

A value of type `ThemeEraseUPP`. If you have a custom background, pass a universal function pointer to an application-defined function such as that described in `ThemeEraseProcPtr` (page 108). `DrawThemePopupArrow` calls that function to erase the background before drawing the pop-up arrow. If you pass `NULL`, no erasing occurs.

eraseData

An unsigned 32-bit integer. Provide any data to be passed in to the `eraseData` parameter of the callback function specified in the `eraseProc` parameter.

Return Value
A result code. See "Appearance Manager Result Codes" (page 217).

Discussion
The `DrawThemePopupArrow` function draws a theme-compliant pop-up arrow. A pop-up arrow is an image drawn onto another control to indicate that when the control is clicked, you get a pop-up menu. A pop-up arrow is not a separate button itself. Typically, a pop-up arrow is used in conjunction with a button, such as a push button or bevel button. Bevel button controls automatically draw a pop-up arrow if a menu is associated with the control.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Appearance.h`

DrawThemePrimaryGroup

Draws a primary group box frame. (Deprecated in Mac OS X v10.5. Use `HIThemeDrawGroupBox` instead.)

```
OSStatus DrawThemePrimaryGroup (
   const Rect *inRect,
   ThemeDrawState inState
);
```

Parameters

inRect

A pointer to a structure of type `Rect`. Before calling `DrawThemePrimaryGroup`, set the rectangle to the bounds of the primary group box frame, in local coordinates.

inState

A value of type `ThemeDrawState`. Pass a constant specifying the state in which to draw the primary group box frame; see "Theme Drawing States" (page 126). The frame can be drawn as active or inactive; passing `kThemeStatePressed` produces an error.

Return Value
A result code. See "Appearance Manager Result Codes" (page 217).

Discussion
The `DrawThemePrimaryGroup` function draws a theme-compliant primary group box frame. The primary group box frame is drawn inside the specified rectangle and is a maximum of 2 pixels thick.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Appearance.h`

DrawThemeScrollBarArrows

Draws scroll bar arrows consistent with the current system preferences. (Deprecated in Mac OS X v10.5. Use `HIThemeDrawTrack`, which draws the entire scrollbar including both the track and arrows.)

```
OSStatus DrawThemeScrollBarArrows (
   const Rect *bounds,
   ThemeTrackEnableState enableState,
   ThemeTrackPressState pressState,
   Boolean isHoriz,
   Rect *trackBounds
);
```

Parameters

bounds

A pointer to a structure of type `Rect`. Before calling `DrawThemeScrollBarArrows`, set the rectangle to contain the scroll bar for which to draw arrows, in local coordinates. Typically, the rectangle you specify is the entire base control rectangle—that is, the value contained in the `contrlRect` field of the scroll bar's `ControlRecord` structure.

enableState

A value of type `ThemeTrackEnableState`. Pass a constant specifying the current state of the scroll bar; see "Theme Track States" (page 185) for descriptions of possible values.

pressState

A value of type `ThemeTrackPressState`. Pass a constant specifying what is pressed in an active scroll bar or 0 if nothing is pressed. The press state is ignored if the scroll bar is not active. See "Theme Track Press States" (page 187) for descriptions of possible values.

isHoriz

A value of type `Boolean`. Pass `true` if the scroll bar is horizontal; pass `false` if it is vertical.

trackBounds

A pointer to a structure of type `Rect`. On return, the rectangle is set to the bounds of the track portion of the scroll bar; this rectangle excludes the area containing the scroll bar arrows. Pass `NULL` if you do not wish to obtain this information.

Return Value

A result code. See "Appearance Manager Result Codes" (page 217).

Discussion

The `DrawThemeScrollBarArrows` function draws a set of theme-compliant scroll bar arrows for the scroll bar whose position and dimensions are specified in the `bounds` parameter. Depending upon the current system preferences, `DrawThemeScrollBarArrows` draws the arrows in one of the following configurations:

- one arrow at either end of the scroll bar
- two arrows at the same end of the scroll bar

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Appearance.h`

DrawThemeScrollBarDelimiters

Outlines a window's scroll bars. (Deprecated in Mac OS X v10.5. Use `HIThemeDrawScrollBarDelimiters` instead.)

```
OSStatus DrawThemeScrollBarDelimiters (
   ThemeWindowType flavor,
   const Rect *inContRect,
   ThemeDrawState state,
   ThemeWindowAttributes attributes
);
```

Parameters

flavor

A value of type `ThemeWindowType`. Pass a constant specifying the type of window for which to draw scroll bar delimiters. See "Theme Window Types" (page 189) for descriptions of possible values.

inContRect

A pointer to a structure of type `Rect`. Before calling `DrawThemeScrollBarDelimiters`, set the rectangle to the boundary of the content rectangle of the window, in local coordinates.

state

A value of type `ThemeDrawState`. Pass a constant—either `kThemeStateActive` or `kThemeStateInactive`—appropriate to the current state of the window. The scroll bar delimiters can be drawn as active or inactive passing `kThemeStatePressed` produces an error. See "Theme Drawing States" (page 126) for descriptions of these values.

attributes

A value of type `ThemeWindowAttributes`. Pass one or more constants corresponding to the window's current visual attributes. See "Theme Window Attributes" (page 191) for descriptions of possible values. Pass 0 if the window has none of the enumerated attributes.

Return Value

A result code. See "Appearance Manager Result Codes" (page 217).

Discussion

The `DrawThemeScrollBarDelimiters` function draws theme-compliant outlines for both the horizontal and vertical scroll bars in a given window. The scroll bars are each assumed to cover the full length of their respective sides of the window's content region if the scroll bars for which you wish delimiters to be drawn are not full length, or if only one scroll bar exists for a given window, `DrawThemeScrollBarDelimiters` should not be used.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Appearance.h`

DrawThemeSecondaryGroup

Draws a secondary group box frame. (Deprecated in Mac OS X v10.5. Use `HIThemeDrawGroupBox` instead.)

```
OSStatus DrawThemeSecondaryGroup (
   const Rect *inRect,
   ThemeDrawState inState
);
```

Parameters

inRect

A pointer to a structure of type `Rect`. Before calling `DrawThemeSecondaryGroup`, set the rectangle to the bounds of the secondary group box frame to be drawn, in local coordinates.

inState

A value of type `ThemeDrawState`. Pass a constant specifying the state in which to draw the secondary group box frame; see "Theme Drawing States" (page 126). The frame can be drawn as active or inactive; passing `kThemeStatePressed` produces an error.

Return Value

A result code. See "Appearance Manager Result Codes" (page 217).

Discussion

The `DrawThemeSecondaryGroup` function draws a theme-compliant secondary group box frame. The secondary group box frame is drawn inside the specified rectangle and is a maximum of 2 pixels thick. Note that a secondary group box frame is typically nested within a primary group box frame.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Appearance.h`

DrawThemeSeparator

Draws a separator line. (Deprecated in Mac OS X v10.5. Use `HIThemeDrawSeparator` instead.)

```
OSStatus DrawThemeSeparator (
   const Rect *inRect,
   ThemeDrawState inState
);
```

Parameters

inRect

A pointer to a structure of type `Rect`. Before calling `DrawThemeSeparator`, set the rectangle to contain the separator line, in local coordinates. The orientation of the rectangle determines where the separator line is drawn. If the rectangle is wider than it is tall, the separator line is horizontal; otherwise it is vertical.

inState

A value of type `ThemeDrawState`. Pass a constant specifying the state in which to draw the separator line; see "Theme Drawing States" (page 126). The separator line can be drawn as active or inactive; passing `kThemeStatePressed` produces an error.

Return Value

A result code. See "Appearance Manager Result Codes" (page 217).

Discussion
The `DrawThemeSeparator` function draws a theme-compliant separator line. The separator line is a maximum of 2 pixels thick and is drawn inside the specified rectangle.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Appearance.h`

DrawThemeStandaloneGrowBox

Draws a size box. (Deprecated in Mac OS X v10.5. Use `HIThemeDrawGrowBox` instead.)

```
OSStatus DrawThemeStandaloneGrowBox (
   Point origin,
   ThemeGrowDirection growDirection,
   Boolean isSmall,
   ThemeDrawState state
);
```

Parameters

origin
A structure of type `Point`. Pass the origin point of the size box rectangle. For example, the origin point of the size box for an object that can grow downward and to the right is the size box's upper-left corner. Typically, you use the coordinates of the corner of whatever object owns the size box for the `origin` value. For example, if you are drawing a scrolling list that can grow downward and to the right, the `origin` value would be the coordinates of the bottom-right corner of the list.

growDirection
A value of type `ThemeGrowDirection`. Pass a constant specifying the direction(s) in which the resizeable object can grow. See "Theme Size Box Directions" (page 180) for descriptions of possible values. The Appearance Manager uses the `growDirection` parameter to establish which corner of the size box is the origin.

isSmall
A value of type `Boolean`. Pass a value of `true` to specify a small size box (typically for use with small scroll bars) or `false` to specify a standard size box.

state
A value of type `ThemeDrawState`. Pass a constant—either `kThemeStateActive` or `kThemeStateInactive`—appropriate to the current state of the size box the size box cannot be drawn as pressed. See "Theme Drawing States" (page 126) for descriptions of these values.

Return Value
A result code. See "Appearance Manager Result Codes" (page 217).

Discussion
The `DrawThemeStandaloneGrowBox` function draws a theme-compliant size box that is suitable for use inside the content area of a window. The image is designed to fit between scroll bars and does not have to be abutted with the window frame.

Also see the function `DrawThemeStandaloneNoGrowBox` (page 49).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Appearance.h`

DrawThemeStandaloneNoGrowBox

Draws a fill image for use in the corner space between scroll bars. (Deprecated in Mac OS X v10.5. Use `HIThemeDrawGrowBox` instead.)

```
OSStatus DrawThemeStandaloneNoGrowBox (
   Point origin,
   ThemeGrowDirection growDirection,
   Boolean isSmall,
   ThemeDrawState state
);
```

Parameters

origin

A structure of type `Point`. Pass the origin point of the rectangle in which to draw the image. Typically, you use the coordinates of the corner of whatever object owns the image for the `origin` value. For example, if you are drawing the image in the bottom-right corner of a window between the scroll bars of a non-resizeable scrolling list, the `origin` value would be the coordinates of the bottom-right corner of the list.

growDirection

A value of type `ThemeGrowDirection`. See "Theme Size Box Directions" (page 180) for descriptions of possible values. The Appearance Manager uses the `growDirection` parameter to establish which corner of the rectangle that contains the image is the origin.

isSmall

A value of type `Boolean`. Pass a value of `true` to specify a small image (for use with small scroll bars) or `false` to specify a large image (for use with standard scroll bars).

state

A value of type `ThemeDrawState`. Pass a constant—either `kThemeStateActive` or `kThemeStateInactive`—appropriate to the current state of the window containing the fill image the image cannot be drawn as pressed. See "Theme Drawing States" (page 126) for descriptions of these values.

Return Value
A result code. See "Appearance Manager Result Codes" (page 217).

Discussion
The `DrawThemeStandaloneNoGrowBox` function draws a theme-compliant image for use as filler in the corner space between scroll bars that

- abut the frame of a window that is not resizeable and which therefore lacks a size box to fill the intervening space
- do not abut the window frame

Also see the function `DrawThemeStandaloneGrowBox` (page 48).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Appearance.h`

DrawThemeTab

Draws a tab. (Deprecated in Mac OS X v10.5. Use `HIThemeDrawTab` instead.)

```
OSStatus DrawThemeTab (
   const Rect *inRect,
   ThemeTabStyle inStyle,
   ThemeTabDirection inDirection,
   ThemeTabTitleDrawUPP labelProc,
   URefCon userData
);
```

Parameters

inRect

A pointer to a structure of type `Rect`. Before calling `DrawThemeTab`, set the rectangle to the bounds of the tab, in local coordinates. There are two standard sizes (or heights) for tabs that should be used in your calculation of the tab rectangle—these are measured by the distance the tabs protrude from the pane. Small tabs have a height of 16 pixels large tabs have a height of 21 pixels. (The widths of tabs are variable.) Additionally, the distance that the tab overlaps the pane must be included in the tab rectangle this overlap distance is always 3 pixels, although the 3-pixel overlap is only drawn for the front tab. The tab rectangle should reflect the orientation of the tab that is specified in the `inDirection` parameter.

inStyle

A value of type `ThemeTabStyle`. Pass a constant specifying the relative position (front or non-front) and state of the tab. See "Theme Tab Styles" (page 183) for descriptions of possible values.

inDirection

A value of type `ThemeTabDirection`. Pass a constant specifying the direction in which to orient the tab. See "Theme Tab Directions" (page 182) for descriptions of possible values.

labelProc

A value of type `ThemeTabTitleDrawUPP`. Pass a universal function pointer to an application-defined function such as that described in `ThemeTabTitleDrawProcPtr` (page 111). `DrawThemeTab` calls your function to draw the title of the tab. If you pass `NULL`, no drawing occurs.

userData

An unsigned 32-bit integer. Provide any data to be passed in to the `userData` parameter of the callback function specified in the `labelProc` parameter.

Return Value
A result code. See "Appearance Manager Result Codes" (page 217).

Discussion
The `DrawThemeTab` function draws a theme-compliant tab. A tab control consists of two basic components: multiple tabs that label the various content pages that can be displayed and a single pane upon which the content for each tab is drawn. Use the function `DrawThemeTabPane` (page 51) to draw the tab pane. The Appearance Manager coordinates the appearance of the pane and frontmost tab automatically.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Appearance.h`

DrawThemeTabPane

Draws a tab pane. (Deprecated in Mac OS X v10.5. Use `HIThemeDrawTabPane` instead.)

```
OSStatus DrawThemeTabPane (
   const Rect *inRect,
   ThemeDrawState inState
);
```

Parameters

inRect

A pointer to a structure of type `Rect`. Before calling `DrawThemeTabPane`, set the rectangle to the bounds of the tab pane, in local coordinates.

inState

A value of type `ThemeDrawState`. Pass a constant specifying the state in which to draw the tab pane; see "Theme Drawing States" (page 126). The tab pane can be drawn as active or inactive; passing `kThemeStatePressed` produces an error.

Return Value
A result code. See "Appearance Manager Result Codes" (page 217).

Discussion
The `DrawThemeTabPane` function draws a theme-compliant tab pane. A tab control consists of two basic components: multiple tabs that label the various content pages that can be displayed and a single pane upon which the content for each tab is drawn. Use the function `DrawThemeTab` (page 50) to draw the tab. The Appearance Manager coordinates the appearance of the pane and frontmost tab automatically.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Appearance.h`

DrawThemeTextBox

Draws text into the area you specify. (Deprecated in Mac OS X v10.5. Use `HIThemeDrawTextBox` instead.)

```
OSStatus DrawThemeTextBox (
   CFStringRef inString,
   ThemeFontID inFontID,
   ThemeDrawState inState,
   Boolean inWrapToWidth,
   const Rect *inBoundingBox,
   SInt16 inJust,
   CGContextRef inContext
);
```

Parameters

inString

A `CFStringRef` containing the unicode characters you wish to render. You must not pass in a `CFStringRef` that was allocated with any of the "NoCopy" CFString creation functions; a string created with a "NoCopy" function has transient storage which is incompatible with `DrawThemeTextBox`'s caches.

inFontID

The `ThemeFontID` describing the font you'd like to render the text with. See "Theme Font IDs" (page 166) for the values you can use here.

inState

The `ThemeDrawState` describing the state of the interface element you are drawing the text for. If, for example, you are drawing text for an inactive window, you would pass `kThemeStateInactive`. The `ThemeDrawState` is generally only used to determine the shadow characteristics for the text on Mac OS X.

See "Theme Drawing States" (page 126) for the values you can use here.

Note that the `ThemeDrawState` does not imply a color. It is not used as a mechanism for graying the text. If you wish to draw grayed text, you must set up the desired gray color and apply it to either the current QuickDraw port or the `CGContextRef`, as appropriate.

inWrapToWidth

A Boolean value indicating whether you want to draw multiple lines of text wrapped to a bounding box. `False` indicates that only one line of text should be drawn without any sort of wrapping.

inBoundingBox

The rectangle, in coordinates relative to the current QuickDraw port, describing the area to draw the text within. The first line of text will be top-justified to this rectangle. Wrapping, if desired, will happen at the horizontal extent of this rectangle. Regardless of the amount of text in your `CFStringRef`, all drawn text will be clipped to this rectangle.

inJust

The horizontal alignment you would like for your text. You can use one of the standard alignment constants from TextEdit.h.

inContext

The `CGContextRef` into which you would like to draw the text. On Mac OS X, all text drawing happens in `CGContextRef`s; if you pass `NULL`, a transient `CGContextRef` will be allocated and deallocated for use within the single function call. Relying on the system behavior if transiently creating `CGContextRef`s may result in performance problems. On Mac OS 9, this parameter is ignored.

Return Value

A result code. See "Appearance Manager Result Codes" (page 217).

Discussion
`DrawThemeTextBox` allows you to draw theme-savvy —that is, Aqua-savvy on Mac OS X— text. It is unicode savvy, although only partially so under CarbonLib, and allows you to customize certain text rendering characteristics such as the font, wrapping behavior, and justification. The text is drawn into the `CGContextRef` you provide, or into the current QuickDraw port if no `CGContextRef` is provided. None of `DrawThemeTextBox`'s parameters imply a color, so you must set up the desired text color separately before calling `DrawThemeTextBox`. If you provide a `CGContextRef`, its fill color will be used to draw the text. If you do not provide a `CGContextRef`, a color based on the current QuickDraw port's foreground color and the `grayishTextOr` mode, if set, will be used to draw the text.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Appearance.h`

DrawThemeTickMark

Draws a tick mark. (Deprecated in Mac OS X v10.5. Use `HIThemeDrawTickMark` instead.)

```
OSStatus DrawThemeTickMark (
   const Rect *bounds,
   ThemeDrawState state
);
```

Parameters

bounds
A pointer to a structure of type `Rect`. Before calling `DrawThemeTickMark`, set the rectangle to the position that contains the tick mark, in local coordinates. Note that tick marks are of a fixed—3 pixel by 8 pixel—size.

state
A value of type `ThemeDrawState`. Pass a constant specifying the state in which to draw the tick mark; see "Theme Drawing States" (page 126). The tick mark can be drawn as active or inactive; passing `kThemeStatePressed` produces an error.

Return Value
A result code. See "Appearance Manager Result Codes" (page 217).

Discussion
The `DrawThemeTickMark` function draws a single theme-compliant tick mark. To draw a complete set of tick marks for a track, call the function `DrawThemeTrackTickMarks` (page 56).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Appearance.h`

DrawThemeTitleBarWidget

Draws a close box, zoom box, or collapse box. (Deprecated in Mac OS X v10.5. Use `HIThemeDrawTitleBarWidget` instead.)

```
OSStatus DrawThemeTitleBarWidget (
   ThemeWindowType flavor,
   const Rect *contRect,
   ThemeDrawState state,
   const ThemeWindowMetrics *metrics,
   ThemeWindowAttributes attributes,
   ThemeTitleBarWidget widget
);
```

Parameters

flavor

A value of type `ThemeWindowType`. Pass a constant specifying the type of window for which to draw a title bar item. See "Theme Window Types" (page 189) for descriptions of possible values.

contRect

A pointer to a structure of type `Rect`. Before calling `DrawThemeTitleBarWidget`, specify the rectangle for which you wish to draw a title bar item, in coordinates local to the current port. This rectangle is typically the content rectangle of a window.

state

A value of type `ThemeDrawState`. Pass a constant— `kThemeStateActive`, `kThemeStateInactive`, or `kThemeStatePressed`—appropriate to the current state of the title bar item. See "Theme Drawing States" (page 126) for descriptions of these values.

metrics

A pointer to a structure of type `ThemeWindowMetrics`. Before calling `DrawThemeTitleBarWidget`, set the structure to contain information describing the window for which you wish to draw a title bar item.

attributes

A value of type `ThemeWindowAttributes`. Pass one or more constants corresponding to the window's current visual attributes. See "Theme Window Attributes" (page 191) for descriptions of possible values. Pass 0 if the window has none of the enumerated attributes.

widget

A value of type `ThemeTitleBarWidget`. Pass a constant—`kThemeWidgetCloseBox`, `kThemeWidgetZoomBox`, or `kThemeWidgetCollapseBox`—appropriate to the type of title bar item you wish to draw. See "Theme Title Bar Items" (page 192) for descriptions of these values.

Return Value

A result code. See "Appearance Manager Result Codes" (page 217).

Discussion

The `DrawThemeTitleBarWidget` function draws theme-compliant title bar items. Your application should not typically need to call this function; `DrawThemeTitleBarWidget` is typically of use only for applications that need to draw title bar items of simulated windows. Note that while the `DrawThemeWindowFrame` function automatically draws all title bar items, your application must call the `DrawThemeTitleBarWidget` function during tracking, to ensure that the title bar items' states are drawn correctly.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In
Appearance.h

DrawThemeTrack

Draws a track. (Deprecated in Mac OS X v10.5. Use HIThemeDrawTrack instead.)

```
OSStatus DrawThemeTrack (
   const ThemeTrackDrawInfo *drawInfo,
   RgnHandle rgnGhost,
   ThemeEraseUPP eraseProc,
   URefCon eraseData
);
```

Parameters

drawInfo

A pointer to a structure of type ThemeTrackDrawInfo. Before calling DrawThemeTrack, set the structure to contain the current visual characteristics of the track.

rgnGhost

A value of type RgnHandle. If the track is of a type that contains an indicator, such as a scroll bar or slider, you may pass a handle to the region where DrawThemeTrack is to draw a ghost image of the track indicator. Your application should only use a ghost image with the indicator when a track does not support live feedback. Pass NULL if you do not want to draw a ghost image.

eraseProc

A value of type ThemeEraseUPP. If you have a custom background, pass a universal function pointer to an application-defined function such as that described in ThemeEraseProcPtr (page 108). DrawThemeTrack calls that function to erase the background before drawing the track. If you pass NULL, no erasing occurs.

eraseData

An unsigned 32-bit integer. Provide any data to be passed in to the callback function specified in the eraseProc parameter.

Return Value
A result code. See "Appearance Manager Result Codes" (page 217).

Discussion
Your application may use the DrawThemeTrack function to draw a theme-compliant slider, progress bar, or scroll bar. If you use DrawThemeTrack to draw a scroll bar, use the function DrawThemeScrollBarArrows (page 45) to draw the scroll bar's arrows. If you use DrawThemeTrack to draw a slider, use DrawThemeTrackTickMarks (page 56) to draw any tick marks for the slider.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
Appearance.h

DrawThemeTrackTickMarks

Draws tick marks for a track. (Deprecated in Mac OS X v10.5. Use `HIThemeDrawTrackTickMarks` instead.)

```
OSStatus DrawThemeTrackTickMarks (
   const ThemeTrackDrawInfo *drawInfo,
   ItemCount numTicks,
   ThemeEraseUPP eraseProc,
   URefCon eraseData
);
```

Parameters

drawInfo

A pointer to a structure of type `ThemeTrackDrawInfo`. Before calling `DrawThemeTrackTickMarks`, set the structure to describe the current visual characteristics of the track. Because, under Appearance Manager 1.1, sliders are the only track type to support tick marks, you should set the `kind` field of the `ThemeTrackDrawInfo` structure to `kThemeSlider` and fill out the remainder of the structure appropriately for a slider track. You should set the `bounds` field of the `ThemeTrackDrawInfo` structure to the boundary of the track itself, not including the area that contains the tick marks; you can obtain the actual bounding rectangle of the track by calling the function `GetThemeTrackBounds` (page 76). `DrawThemeTrackTickMarks` draws the tick marks outside the track's bounding rectangle, above or below the track depending on the thumb direction indicated by the `drawInfo.trackInfo.slider.thumbDir` field.

numTicks

A value of type `ItemCount`. Pass an unsigned 32-bit value specifying the number of tick marks to be drawn.

eraseProc

A value of type `ThemeEraseUPP`. If you have a custom background, pass a universal function pointer to an application-defined function such as that described in `ThemeEraseProcPtr` (page 108). `DrawThemeTrackTickMarks` calls that function to erase the background before drawing tick marks. If you pass `NULL`, no erasing occurs.

eraseData

An unsigned 32-bit integer. Provide any data to be passed in to the callback function specified in the `eraseProc` parameter.

Return Value

A result code. See "Appearance Manager Result Codes" (page 217).

Discussion

Your application can call the `DrawThemeTrackTickMarks` function to draw theme-compliant tick marks for a slider control. (Under Appearance Manager 1.1, sliders are the only track type that supports tick marks.) To draw a track control, call the function `DrawThemeTrack` (page 55). To draw a single tick mark, call the function `DrawThemeTickMark` (page 53).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Appearance.h`

DrawThemeWindowFrame

Draws a window frame. (Deprecated in Mac OS X v10.5. Use `HIThemeDrawWindowFrame` instead.)

```
OSStatus DrawThemeWindowFrame (
   ThemeWindowType flavor,
   const Rect *contRect,
   ThemeDrawState state,
   const ThemeWindowMetrics *metrics,
   ThemeWindowAttributes attributes,
   WindowTitleDrawingUPP titleProc,
   URefCon titleData
);
```

Parameters

flavor

A value of type `ThemeWindowType`. Pass a constant specifying the type of window for which to draw a frame. See "Theme Window Types" (page 189) for descriptions of possible values.

contRect

A pointer to a structure of type `Rect`. Before calling `DrawThemeWindowFrame`, specify the rectangle for which you wish to draw a window frame, in coordinates local to the current port. This rectangle is typically the content rectangle of a window.

state

A value of type `ThemeDrawState`. Pass a constant—either `kThemeStateActive` or `kThemeStateInactive`—appropriate to the current state of the window. See "Theme Drawing States" (page 126) for descriptions of these values.

metrics

A pointer to a structure of type `ThemeWindowMetrics`. Before calling `DrawThemeWindowFrame`, set the structure to describe the window for which to draw a frame.

attributes

A value of type `ThemeWindowAttributes`. Pass one or more constants corresponding to the window's current visual attributes. See "Theme Window Attributes" (page 191) for descriptions of possible values. Pass 0 if the window has none of the enumerated attributes.

titleProc

A value of type `WindowTitleDrawingUPP`. If you pass the value `kThemeWindowHasTitleText` in the `attributes` parameter, you should pass a universal function pointer to an application-defined function such as that described in `WindowTitleDrawingProcPtr` (page 112) in the `titleProc` parameter. `DrawThemeWindowFrame` calls that function to draw the window's title. Pass `NULL` if there is no title to be drawn.

titleData

An unsigned 32-bit integer. Provide any data to be passed in to the `userData` parameter of the callback function specified in the `titleProc` parameter.

Return Value

A result code. See "Appearance Manager Result Codes" (page 217).

Discussion

The `DrawThemeWindowFrame` function draws a window frame appropriate to the specified window type. You may use `DrawThemeWindowFrame` to make a custom window theme-compliant.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In
`Appearance.h`

DrawThemeWindowHeader

Draws a window header. (Deprecated in Mac OS X v10.5. Use `HIThemeDrawHeader` instead.)

```
OSStatus DrawThemeWindowHeader (
   const Rect *inRect,
   ThemeDrawState inState
);
```

Parameters

`inRect`

A pointer to a structure of type `Rect`. Before calling `DrawThemeWindowHeader`, specify the rectangle containing the window header, in local coordinates.

`inState`

A value of type `ThemeDrawState`. Pass a constant specifying the state in which to draw the window header; see "Theme Drawing States" (page 126). The header can be drawn as active or inactive; passing `kThemeStatePressed` produces an error.

Return Value
A result code. See "Appearance Manager Result Codes" (page 217).

Discussion
The `DrawThemeWindowHeader` function draws a theme-compliant window header, such as that used by the Finder.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Appearance.h`

DrawThemeWindowListViewHeader

Draws a window list view header. (Deprecated in Mac OS X v10.5. Use `HIThemeDrawHeader` instead.)

```
OSStatus DrawThemeWindowListViewHeader (
   const Rect *inRect,
   ThemeDrawState inState
);
```

Parameters

`inRect`

A pointer to a structure of type `Rect`. Before calling `DrawThemeWindowListViewHeader`, specify the rectangle in which to draw the window list view header, in local coordinates.

inState

A value of type `ThemeDrawState`. Pass a constant specifying the state in which to draw the window list view header; see "Theme Drawing States" (page 126). The header can be drawn as active or inactive; passing `kThemeStatePressed` produces an error.

Return Value
A result code. See "Appearance Manager Result Codes" (page 217).

Discussion
The `DrawThemeWindowListViewHeader` function draws a theme-compliant window list view header, such as that used by the Finder. A window list view header is drawn without a line on its bottom edge, so that bevel buttons can be placed against it without overlapping.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Appearance.h`

EndThemeDragSound

Terminates the playing of a sound associated with the user's movement of a given interface object.

```
OSStatus EndThemeDragSound (
   void
);
```

Return Value
A result code. See "Appearance Manager Result Codes" (page 217).

Discussion
The Appearance Manager automatically starts and stops drag sounds for standard user interface elements and for Drag Manager drag actions. Your application may call `BeginThemeDragSound` (page 27), typically upon detecting a drag initiation, to play a drag sound for a custom element. Call the `EndThemeDragSound` function to turn off a drag sound when the drag is completed, typically upon receipt of a mouse-up event.

Special Considerations
This function is not implemented in Mac OS X.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Appearance.h`

GetTheme

Obtains a collection containing data describing the current theme.

```
OSStatus GetTheme (
   Collection ioCollection
);
```

Parameters

ioCollection

A value of type `Collection`. Pass a reference to a collection object, such as that created by calling the Collection Manager function `NewCollection`. On return, the collection contains data describing attributes of the current theme.

Return Value

A result code. See "Appearance Manager Result Codes" (page 217).

Discussion

The `GetTheme` function obtains a collection containing a copy of the data for the current theme. The theme data is in the form of collection items, each corresponding to an attribute of the theme. For a given theme, the actual number of collection items may vary, depending upon how fully the theme's attributes are specified. See "Theme Collection Tags" (page 122) for descriptions of the possible theme collection items.

Your application can use theme collection tags, along with various Collection Manager functions, to access the data in the collection.

Also see the function `SetTheme` (page 97).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Appearance.h`

GetThemeAccentColors

Obtains a copy of a theme's accent colors. (Deprecated in Mac OS X v10.5. There is no replacement function.)

```
OSStatus GetThemeAccentColors (
   CTabHandle *outColors
);
```

Parameters

outColors

A pointer to a value of type `CTabHandle`. On return, the handle refers to a `ColorTable` structure containing the current accent colors.

Return Value

A result code. `GetThemeAccentColors` returns the result `appearanceThemeHasNoAccents` if the current theme has no accent colors.

Discussion

Note that the Appearance Manager does not currently define semantics for any indexes into the color table produced by the `GetThemeAccentColors` function.

Special Considerations

In Mac OS X, theme accent colors are not supported.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Appearance.h`

GetThemeBrushAsColor

Obtains the color that corresponds to a given theme brush type under the current theme.

```
OSStatus GetThemeBrushAsColor (
   ThemeBrush inBrush,
   SInt16 inDepth,
   Boolean inColorDev,
   RGBColor *outColor
);
```

Parameters

inBrush
A value of type `ThemeBrush`. Pass a constant specifying the theme brush type for which you wish to obtain a color; see "Theme Brushes" (page 145) for descriptions of possible values.

inDepth
A signed 16-bit integer. Pass a value specifying the bit depth (in bits per pixel) of the current graphics port.

inColorDev
A value of type `Boolean`. Pass `true` to indicate that you are drawing on a color device. Pass `false` for a monochrome device.

outColor
A pointer to a structure of type `RGBColor`. On return, the structure contains a color corresponding to the color or pattern used by the specified theme brush under the current theme.

Return Value
A result code. See "Appearance Manager Result Codes" (page 217).

Discussion
The `GetThemeBrushAsColor` function obtains a color that corresponds to that which is in use for a specified theme brush. If, in the current theme, the specified brush draws with a pattern instead of a color, a theme-specified approximate color is obtained. Your application should call `GetThemeBrushAsColor` only when you must use an `RGBColor` value for a specific operation; typically, your application should call the functions `SetThemeBackground` (page 98) and `SetThemePen` (page 100) for greatest fidelity with the current theme.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Appearance.h`

GetThemeButtonBackgroundBounds

Obtains the rectangle that contains a button. (Deprecated in Mac OS X v10.5. Use `HIThemeGetButtonBackgroundBounds` instead.)

```
OSStatus GetThemeButtonBackgroundBounds (
   const Rect *inBounds,
   ThemeButtonKind inKind,
   const ThemeButtonDrawInfo *inDrawInfo,
   Rect *outBounds
);
```

Parameters

inBounds

A pointer to a structure of type `Rect`. Before calling `GetThemeButtonBackgroundBounds`, set the rectangle to the boundary of the button without any adornments, in local coordinates.

inKind

A value of type `ThemeButtonKind`. Pass a constant specifying the type of button being examined. See "Theme Buttons" (page 153) for descriptions of possible values.

inDrawInfo

A pointer to a structure of type `ThemeButtonDrawInfo`. Before calling `GetThemeButtonBackgroundBounds`, set the structure to contain the state, value, and adornment for the button.

outBounds

A pointer to a structure of type `Rect`. On return, the rectangle contains the actual boundary of the button, including any adornments, in local coordinates.

Return Value

A result code. See "Appearance Manager Result Codes" (page 217).

Discussion

Appearance adornments can extend beyond the basic bounding rectangle of a button and may be of variable shape. Your application may call the `GetThemeButtonBackgroundBounds` function to obtain the actual rectangle containing the pixels belonging to a button under the current theme.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Appearance.h`

GetThemeButtonContentBounds

Obtains the rectangle where content can be drawn for a button. (Deprecated in Mac OS X v10.5. Use `HIThemeGetButtonContentBounds` instead.)

```
OSStatus GetThemeButtonContentBounds (
   const Rect *inBounds,
   ThemeButtonKind inKind,
   const ThemeButtonDrawInfo *inDrawInfo,
   Rect *outBounds
);
```

Parameters

inBounds

A pointer to a structure of type `Rect`. Before calling `GetThemeButtonContentBounds`, set the rectangle to contain the boundary of the button, in local coordinates.

inKind

A value of type `ThemeButtonKind`. Pass a constant specifying the type of button being examined. See "Theme Buttons" (page 153) for descriptions of possible values.

inDrawInfo

A pointer to a structure of type `ThemeButtonDrawInfo`. Before calling `GetThemeButtonContentBounds`, set the structure to contain the state, value, and adornment for the button.

outBounds

A pointer to a structure of type `Rect`. On return, the rectangle contains the actual boundary, in local coordinates, of the area of the button's face in which content can be drawn.

Return Value

A result code. See "Appearance Manager Result Codes" (page 217).

Discussion

The `GetThemeButtonContentBounds` function obtains the rectangle where content can be drawn for a button under the current theme.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Appearance.h`

GetThemeButtonRegion

Obtains the region occupied by a button. (Deprecated in Mac OS X v10.5. Use `HIThemeGetButtonShape` instead.)

```
OSStatus GetThemeButtonRegion (
   const Rect *inBounds,
   ThemeButtonKind inKind,
   const ThemeButtonDrawInfo *inNewInfo,
   RgnHandle outRegion
);
```

Parameters

inBounds

A pointer to a structure of type `Rect`. Before calling `GetThemeButtonRegion`, set the rectangle to the boundary of the button without any adornments, in local coordinates.

inKind

A value of type `ThemeButtonKind`. Pass a constant specifying the type of button being examined. See "Theme Buttons" (page 153) for descriptions of possible values.

inNewInfo

A pointer to a structure of type `ThemeButtonDrawInfo`. Before calling `GetThemeButtonRegion`, set the structure to contain the state, value, and adornment for the button.

outRegion

A value of type `RgnHandle`. On return, the region contains the actual dimensions and position of the button and any adornments, in local coordinates.

Return Value
A result code. See "Appearance Manager Result Codes" (page 217).

Discussion
Appearance adornments can extend beyond the basic bounding rectangle of a button and may be of variable shape. Your application may call the `GetThemeButtonRegion` function to obtain the exact area covered by pixels belonging to a specific button under the current theme.

Special Considerations

This function is available with Appearance Manager 1.1 and later.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In
`Appearance.h`

GetThemeCheckBoxStyle

Obtains the system preference for the type of mark to use in a checkbox.

```
OSStatus GetThemeCheckBoxStyle (
   ThemeCheckBoxStyle *outStyle
);
```

Parameters

outStyle

A pointer to a value of type `ThemeCheckBoxStyle`. On return, the value specifies the type of mark being used. See "Theme Checkbox Styles" (page 161) for descriptions of possible values.

Return Value
A result code. See "Appearance Manager Result Codes" (page 217).

Discussion
Because international systems may specify the use of one type of mark to use in checkboxes over another, your application should call `GetThemeCheckBoxStyle` to obtain the correct type of mark to use on the current system.

Availability
Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In
`Appearance.h`

GetThemeDrawingState

Obtains the drawing state of the current graphics port.

```
OSStatus GetThemeDrawingState (
   ThemeDrawingState *outState
);
```

Parameters

outState

A pointer to a value of type `ThemeDrawingState`. On return, `GetThemeDrawingState` sets the `outState` parameter to point to a copy of the drawing state for the current graphics port.

Return Value
A result code. See "Appearance Manager Result Codes" (page 217).

Discussion
Your application may call the `GetThemeDrawingState` function before performing an operation that modifies the drawing state of a graphics port. To return the graphics port to its previous drawing state and release the memory allocated for the drawing state reference, your application should call `SetThemeDrawingState` (page 99), providing the reference obtained in the `outState` parameter of `GetThemeDrawingState`. You can also call `DisposeThemeDrawingState` (page 29) to release the allocated memory.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Appearance.h`

GetThemeFont

Obtains information about a system font in the current theme. (Deprecated in Mac OS X v10.5. Some theme fonts cannot be drawn using QuickDraw; use `HIThemeDrawTextBox` instead.)

```
OSStatus GetThemeFont (
   ThemeFontID inFontID,
   ScriptCode inScript,
   Str255 outFontName,
   SInt16 *outFontSize,
   Style *outStyle
);
```

Parameters

inFontID

A value of type `ThemeFontID`. Pass a constant specifying the kind of font (that is, the current large, small, or small emphasized system fonts or the views font) for which you wish to retrieve the current font name, size, and style in use.

inScript

A value of type `ScriptCode`. Pass a script code identifying the script system for which you wish obtain font information. You may pass the metascript code `smSystemScript` to specify the system script.

outFontName

A value of type `StringPtr`. Pass a pointer to a Pascal string. On return, the string contains the name of the font in use. Pass `NULL` if you do not wish to obtain this information.

outFontSize

A pointer to a signed 16-bit integer. On return, the integer value specifies the size of the font in use. Pass `NULL` if you do not wish to obtain this information.

outStyle

A pointer to a value of type `Style`. On return, the value specifies the style of the font in use. Pass `NULL` if you do not wish to obtain this information.

Return Value
A result code. See "Appearance Manager Result Codes" (page 217).

Discussion
Your application can call the `GetThemeFont` function to obtain the precise font settings (font name, size, and style) used by a system font under the current theme.

Also see the function `UseThemeFont` (page 103).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Appearance.h`

GetThemeMenuBackgroundRegion

Obtains the background region for a menu. (Deprecated in Mac OS X v10.5. Use `HIThemeGetMenuBackgroundShape` instead.)

```
OSStatus GetThemeMenuBackgroundRegion (
   const Rect *inMenuRect,
   ThemeMenuType menuType,
   RgnHandle region
);
```

Parameters

inMenuRect

A pointer to a structure of type `Rect`. Before calling `GetThemeMenuBackgroundRegion`, set the rectangle to contain the entire menu, in global coordinates.

menuType

A value of type `ThemeMenuType`. Pass a constant specifying the type of menu (pull-down, pop-up, or hierarchical) whose background you wish to obtain; see "Theme Menu Types" (page 176) for descriptions of possible values.

region

A value of type `RgnHandle`. Pass a region handle created by your application. On return, the region is set to that of the rectangle specified in the `inMenuRect` parameter, that is, the menu's background region.

Return Value
A result code. See "Appearance Manager Result Codes" (page 217).

Discussion
The `GetThemeMenuBackgroundRegion` function obtains the background region that a menu occupies under the current theme.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Appearance.h`

GetThemeMenuBarHeight

Obtains the height of a menu bar.

```
OSStatus GetThemeMenuBarHeight (
   SInt16 *outHeight
);
```

Parameters

outHeight

A pointer to a signed 16-bit integer. On return, the integer value represents the height (in pixels) of the menu bar.

Return Value
A result code. See "Appearance Manager Result Codes" (page 217).

Discussion
The `GetThemeMenuBarHeight` function obtains the specified height of a menu bar in the current theme. This is in contrast to the Menu Manager function `GetMBarHeight`, which obtains the actual space that the menu bar is currently occupying on the screen. In most instances, the values produced by these two functions are the same. But, when the menu bar is hidden, `GetMBarHeight` produces a value of 0, and `GetThemeMenuBarHeight` still provides the "ideal" menu bar height.

Special Considerations

Because menu bar heights may vary among appearances by one or more pixels, you should check the current menu bar height after a theme switch. Specifically, your application should respond to the theme-switch Apple event, `kAEAppearanceChanged`, by checking the current menu bar height. See "Appearance Manager Apple Events" (page 120) for more details on `kAEAppearanceChanged`.

It is important to check the menu bar height before positioning any windows. Failure to do so may result in the menu bar overlapping your application's windows.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
Appearance.h

GetThemeMenuItemExtra

Obtains a measurement of the space surrounding a menu item.

```
OSStatus GetThemeMenuItemExtra (
   ThemeMenuItemType inItemType,
   SInt16 *outHeight,
   SInt16 *outWidth
);
```

Parameters

inItemType

A value of type ThemeMenuItemType. Pass a constant identifying the type of menu item for which you are interested in getting a measurement. See "Theme Menu Item Types" (page 177).

outHeight

A pointer to a signed 16-bit integer. On return, the integer value represents the total amount of padding between the content of the menu item and the top and bottom of its frame (in pixels). Your content's height plus the measurement provided by the outHeight parameter equals the total item height.

outWidth

A pointer to a signed 16-bit integer. On return, the integer value represents the total amount of padding between the content of the menu item and the left and right limits of the menu (in pixels). Your content's width plus the measurement provided by the outWidth parameter equals the total item width.

Return Value
A result code. See "Appearance Manager Result Codes" (page 217).

Discussion
Your application should call the GetThemeMenuItemExtra function when you are writing your own menu definition function and wish to be theme-compliant. Once you have determined the height and width of the content of a menu item, call GetThemeMenuItemExtra to get a measurement in pixels of the space surrounding a menu item, including any necessary inter-item spacing, in the current theme. By combining the values for your menu item's content and the extra padding needed by the theme, you can derive the size of the rectangle needed to encompass both the content and the theme element together.

Availability
Available in Mac OS X v10.0 and later.

Declared In
Appearance.h

GetThemeMenuSeparatorHeight

Obtains the height of a menu separator line.

```
OSStatus GetThemeMenuSeparatorHeight (
   SInt16 *outHeight
);
```

Parameters

outHeight

A pointer to a signed 16-bit integer. On return, the integer value represents the height (in pixels) of the menu separator line.

Return Value
A result code. See "Appearance Manager Result Codes" (page 217).

Discussion
The `GetThemeMenuSeparatorHeight` function obtains the height of a menu separator line under the current theme. Your application should call the `GetThemeMenuSeparatorHeight` function when you are writing your own menu definition function and wish to calculate a menu rectangle for a separator to match the current theme.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Appearance.h`

GetThemeMenuTitleExtra

Obtains a measurement of the space to either side of a menu title.

```
OSStatus GetThemeMenuTitleExtra (
   SInt16 *outWidth,
   Boolean inIsSquished
);
```

Parameters

outWidth

A pointer to a signed 16-bit integer. On return, the integer value represents the horizontal distance (in pixels) between the menu title and the bounds of its containing rectangle.

inIsSquished

A value of type `Boolean`. If all the titles do not fit in the menu bar and you wish to condense the menu title's spacing to fit, pass `true`. If you pass `false`, the menu title is not condensed.

Return Value
A result code. See "Appearance Manager Result Codes" (page 217).

Discussion
Once you have determined the height and width of the content of a menu title, call `GetThemeMenuTitleExtra` to get the space surrounding the menu title in the current theme.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Appearance.h`

GetThemeMetric

Retrieves the value of a metric property of a user interface element.

```
OSStatus GetThemeMetric (
   ThemeMetric inMetric,
   SInt32 *outMetric
);
```

Parameters

inMetric

The user interface metric to retrieve. See "Theme Metrics" (page 128) for a list of possible metrics.

outMetric

A pointer to an integer value. On output, contains the value of the specified metric property, generally in points.

Return Value

A result code. See "Appearance Manager Result Codes" (page 217).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Appearance.h`

GetThemeScrollBarArrowStyle

Obtains the system preference for the type of scroll bar arrows to be used.

```
OSStatus GetThemeScrollBarArrowStyle (
   ThemeScrollBarArrowStyle *outStyle
);
```

Parameters

outStyle

A pointer to a value of type `ThemeScrollBarArrowStyle`. On return, the value specifies the type of scroll bar arrows being used. See "Theme Scroll Bar Arrow Styles" (page 179) for descriptions of possible values.

Return Value

A result code. See "Appearance Manager Result Codes" (page 217).

Discussion

Because the user can specify varying types of scroll bar arrows on a theme-specific basis, your application should call `GetThemeScrollBarArrowStyle` to obtain the preferred style under the current theme.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Appearance.h`

GetThemeScrollBarThumbStyle

Obtains the system preference for the type of scroll box to be used.

```
OSStatus GetThemeScrollBarThumbStyle (
   ThemeScrollBarThumbStyle *outStyle
);
```

Parameters

outStyle

A pointer to a value of type `ThemeScrollBarThumbStyle`. On return, the value specifies the type of scroll box being used. See "Theme Scroll Box Styles" (page 180) for descriptions of possible values.

Return Value

A result code. See "Appearance Manager Result Codes" (page 217).

Discussion

Because the user can specify either proportional or fixed-size scroll boxes (also known as "scroll indicators" or "thumbs") on a theme-specific basis, your application should call `GetThemeScrollBarThumbStyle` to obtain the preferred style under the current theme.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Appearance.h`

GetThemeScrollBarTrackRect

Obtains the area containing the track portion of a scroll bar. (Deprecated in Mac OS X v10.5. Use `HIThemeGetScrollBarTrackRect` instead.)

```
OSStatus GetThemeScrollBarTrackRect (
   const Rect *bounds,
   ThemeTrackEnableState enableState,
   ThemeTrackPressState pressState,
   Boolean isHoriz,
   Rect *trackBounds
);
```

Parameters

bounds

A pointer to a structure of type `Rect`. Before calling `GetThemeScrollBarTrackRect`, set the rectangle to the boundary of the scroll bar, in local coordinates. Typically, the rectangle you specify is the entire base control rectangle—that is, the value contained in the `contrlRect` field of the track's `ControlRecord` structure.

enableState

A value of type `ThemeTrackEnableState`. Pass a constant specifying the current state of the scroll bar; see "Theme Track States" (page 185) for descriptions of possible values.

pressState

A value of type `ThemeTrackPressState`. Pass a constant specifying what is pressed in an active scroll bar or 0 if nothing is pressed; the press state is ignored if the scroll bar is not active. See "Theme Track Press States" (page 187) for descriptions of possible values.

isHoriz

A value of type `Boolean`. Pass `true` if the scroll bar is horizontal; pass `false` if it is vertical.

trackBounds

A pointer to a structure of type `Rect`. On return, the structure contains the rectangle that bounds the track portion of the scroll bar. Note that the rectangle produced does not include in its bounds any tick marks that a track (such as a slider) might have; tick marks are drawn outside the track rectangle. Similarly, for a scroll bar, the rectangle produced does not contain the scroll bar arrows, just the track itself.

Return Value
A result code. See "Appearance Manager Result Codes" (page 217).

Discussion
Your application may call the `GetThemeScrollBarTrackRect` function to obtain the actual rectangle containing the track portion of a scroll bar under the current theme.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In
`Appearance.h`

GetThemeStandaloneGrowBoxBounds

Obtains the bounds of a size box. (Deprecated in Mac OS X v10.5. Use `HIThemeGetGrowBoxBounds` instead.)

```
OSStatus GetThemeStandaloneGrowBoxBounds (
   Point origin,
   ThemeGrowDirection growDirection,
   Boolean isSmall,
   Rect *bounds
);
```

Parameters

origin

A structure of type `Point`. Pass the origin point of the size box rectangle. For example, the origin point of the size box for an object that can grow downward and to the right is the size box's upper-left corner. Typically, you use the coordinates of the corner of whatever object owns the size box for the `origin` value; for instance, if you are drawing a scrolling list that can grow downward and to the right, the `origin` value would be the coordinates of the bottom-right corner of the list.

growDirection

A value of type `ThemeGrowDirection`. For a size box, pass a constant specifying the direction(s) in which the window can grow. See "Theme Size Box Directions" (page 180) for descriptions of possible values. The Appearance Manager uses the `growDirection` parameter to establish which corner of the size box is the origin.

isSmall

A value of type `Boolean`. Pass a value of `true` to specify a small size box or fill image. Pass `false` to specify a large size box or fill image.

bounds

A pointer to a structure of type `Rect`. On return, the rectangle contains the boundary of the size box or fill image.

Return Value
A result code. See "Appearance Manager Result Codes" (page 217).

Discussion
The `GetThemeStandaloneGrowBoxBounds` function obtains the bounds of a size box under the current theme. Note that you can also use `GetThemeStandaloneGrowBoxBounds` to obtain the bounds of the fill image drawn by the function `DrawThemeStandaloneNoGrowBox` (page 49).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Appearance.h`

GetThemeTabRegion

Obtains the region occupied by a tab. (Deprecated in Mac OS X v10.5. Use `HIThemeGetTabDrawShape` instead.)

```
OSStatus GetThemeTabRegion (
   const Rect *inRect,
   ThemeTabStyle inStyle,
   ThemeTabDirection inDirection,
   RgnHandle ioRgn
);
```

Parameters

inRect

A pointer to a structure of type `Rect`. Before calling `GetThemeTabRegion`, set the rectangle to the boundary of the tab, in local coordinates.

inStyle

A value of type `ThemeTabStyle`. Pass a constant specifying the relative position (front or non-front) and state of the tab to be examined. See "Theme Tab Styles" (page 183) for descriptions of possible values.

inDirection

A value of type `ThemeTabDirection`. Pass a constant specifying the direction in which the tab is oriented. See "Theme Tab Directions" (page 182) for descriptions of possible values.

ioRgn

A value of type `RgnHandle`. On return, the region contains the actual dimensions and position of the tab, in local coordinates.

Return Value
A result code. See "Appearance Manager Result Codes" (page 217).

Discussion
Because a tab can have a non-rectangular shape, your application should call `GetThemeTabRegion` to get the actual region containing the tab under the current theme, in order to perform accurate hit testing.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Appearance.h`

GetThemeTextColor

Obtains the text color used for a specified element under the current theme.

```
OSStatus GetThemeTextColor (
   ThemeTextColor inColor,
   SInt16 inDepth,
   Boolean inColorDev,
   RGBColor *outColor
);
```

Parameters

inColor
A value of type `ThemeTextColor`. Pass a constant specifying the element for which you wish to obtain the current text color; see "Theme Text Colors" (page 169) for descriptions of possible values.

inDepth
A signed 16-bit integer. Pass a value specifying the bit depth (in bits per pixel) of the current graphics port.

inColorDev
A value of type `Boolean`. Pass `true` to indicate that you are drawing on a color device. Pass `false` for a monochrome device.

outColor
A pointer to a structure of type `RGBColor`. On return, the structure contains the text color used for the specified element under the current theme.

Return Value
A result code. See "Appearance Manager Result Codes" (page 217).

Discussion
Also see the function `SetThemeTextColor` (page 101).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Appearance.h`

GetThemeTextDimensions

Tells you the height, width, and baseline for a string. (Deprecated in Mac OS X v10.5. Use `HIThemeGetTextDimensions` instead.)

```
OSStatus GetThemeTextDimensions (
   CFStringRef inString,
   ThemeFontID inFontID,
   ThemeDrawState inState,
   Boolean inWrapToWidth,
   Point *ioBounds,
   SInt16 *outBaseline
);
```

Parameters

inString

A `CFStringRef` containing the unicode characters you wish to measure. You must not pass in a `CFStringRef` that was allocated with any of the "NoCopy" CFString creation functions, as mentioned in the description of the `DrawThemeTextBox` (page 51) function.

inFontID

The `ThemeFontID` describing the font you'd like to measure the text with. See "Theme Font IDs" (page 166) for the values you can use here.

inState

The `ThemeDrawState` which matches the state you will ultimately render the string with. Drawing state may affect text measurement, so you should be sure the value you pass to `GetThemeTextDimensions` matches the value you will eventually use for drawing. See "Theme Drawing States" (page 126) for the values you can use here.

inWrapToWidth

A Boolean indicating whether you want the measurements based on wrapping the text to a specific width. If you pass `true`, you must specify the desired width in `ioBounds->h`.

ioBounds

On output, `ioBounds->v` contains the height of the text. If you pass `false` in the `inWrapToWidth` parameter, `ioBounds->h` will contain the width of the text on output. If you pass `true` in `inWrapToWidth`, `ioBounds->h` must (on input) contain the desired width for wrapping; on output, `ioBounds->h` contains the same value you specified on input.

outBaseline

On output, `outBaseline` contains the offset (in QuickDraw space) from the bottom edge of the last line of text to the baseline of the first line of text. `outBaseline` will generally be a negative value.

Return Value

A result code. See "Appearance Manager Result Codes" (page 217).

Discussion

`GetThemeTextDimensions` measures the given string using the font and drawing state you specify. It always reports the actual height and baseline. It sometimes reports the actual width. It can measure a string that wraps. It is unicode savvy, although only partially so under CarbonLib.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Appearance.h`

GetThemeTextShadowOutset

Tells you the amount of space taken up by the shadow for a given font and drawing state combination.

```
OSStatus GetThemeTextShadowOutset (
   ThemeFontID inFontID,
   ThemeDrawState inState,
   Rect *outOutset
);
```

Parameters

inFontID

The `ThemeFontID` describing the font you'd like the shadow characteristics of. Font and drawing state both determine the amount of shadow that will be used on rendered text. See "Theme Font IDs" (page 166) for the values you can use here.

inState

The `ThemeDrawState` which matches the drawing state you'd like the shadow characteristics of. Font and state both determine the amount of shadow that will be used on rendered text. See "Theme Drawing States" (page 126) for the values you can use here.

outOutset

On output, this parameter contains the amount of space the shadow will take up beyond each edge of the text bounding rectangle returned by `GetThemeTextDimensions`. The fields of this parameter will either be positive values or zero.

Return Value

A result code. See "Appearance Manager Result Codes" (page 217).

Discussion

`GetThemeTextShadowOutset` passes back the maximum amount of space the shadow will take up for text drawn in the specified font and state. While `GetThemeTextDimensions` tells you how much space is taken up by the character glyphs themselves, it does not incorporate the font or state shadow into its calculations. If you need to know how much total space including the shadow will be taken up, call `GetThemeTextDimensions` followed by `GetThemeTextShadowOutset`.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Appearance.h`

GetThemeTrackBounds

Obtains the bounding rectangle of a track. (Deprecated in Mac OS X v10.5. Use `HIThemeGetTrackBounds` instead.)

```
OSStatus GetThemeTrackBounds (
   const ThemeTrackDrawInfo *drawInfo,
   Rect *bounds
);
```

Parameters

drawInfo

A pointer to a structure of type `ThemeTrackDrawInfo`. Before calling `GetThemeTrackBounds`, set the structure to describe the current visual characteristics of the track. Typically, the rectangle you specify in `ThemeTrackDrawInfo.bounds` is the proposed bounding rectangle for the track. `GetThemeTrackBounds` examines this rectangle to determine the actual bounds that the track would occupy. Depending on the track type, the actual bounding rectangle for a track might contain an absolute or fixed value (as for the height of a progress bar, which is always 14 pixels). Or, the track bounds might scale (as for a scroll bar) to fit the proposed bounds.

bounds

A pointer to a structure of type `Rect`. On return, the rectangle contains the actual boundary of the track, in local coordinates. Note that the rectangle produced does not include in its bounds any tick marks that a track (such as a slider) might have; tick marks are drawn outside the track rectangle. Similarly, for a scroll bar, the rectangle produced does not contain the scroll bar arrows, just the track itself.

Return Value

A result code. See "Appearance Manager Result Codes" (page 217).

Discussion

Your application may call the `GetThemeTrackBounds` function to obtain the actual rectangle containing a track under the current theme.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Appearance.h`

GetThemeTrackDragRect

Obtains the area in which the user may drag a track's indicator. (Deprecated in Mac OS X v10.5. Use `HIThemeGetTrackDragRect` instead.)

```
OSStatus GetThemeTrackDragRect (
   const ThemeTrackDrawInfo *drawInfo,
   Rect *dragRect
);
```

Parameters

drawInfo

A pointer to a structure of type `ThemeTrackDrawInfo`. Before calling `GetThemeTrackDragRect`, set the structure to contain the current visual characteristics of the track.

dragRect

A pointer to a structure of type `Rect`. On return, the rectangle contains the actual boundary of the indicator's drag rectangle, in local coordinates.

Return Value
A result code. See "Appearance Manager Result Codes" (page 217).

Discussion
Because of varying indicator geometries and theme designs, the draggable area for an indicator is not typically exactly the same as the track rectangle. Your application should call `GetThemeTrackDragRect` to obtain the actual area within a track where an indicator can be dragged under the current theme.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Appearance.h`

GetThemeTrackLiveValue

Obtains the current value of a track's indicator, given its relative position. (Deprecated in Mac OS X v10.5. Use `HIThemeGetTrackLiveValue` instead.)

```
OSStatus GetThemeTrackLiveValue (
   const ThemeTrackDrawInfo *drawInfo,
   SInt32 relativePosition,
   SInt32 *value
);
```

Parameters

drawInfo
A pointer to a structure of type `ThemeTrackDrawInfo`. Before calling `GetThemeTrackLiveValue`, set the structure to contain the current visual characteristics of the track.

relativePosition
A signed 32-bit value. Pass the distance, in pixels, between the minimum end of the track and the near side of the indicator. You may obtain this value by calling either of the functions `GetThemeTrackThumbPositionFromOffset` (page 79) or `GetThemeTrackThumbPositionFromRegion` (page 79).

value
A pointer to a signed 32-bit value. On return, this value contains the new value of the indicator.

Return Value
A result code. See "Appearance Manager Result Codes" (page 217).

Discussion
Your application can use the `GetThemeTrackLiveValue` function to respond to the `posCntl` and `kControlMsgCalcValueFromPos` control definition message.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Appearance.h`

GetThemeTrackThumbPositionFromOffset

Obtains the relative position of a track's indicator, given an offset from its prior position. (Deprecated in Mac OS X v10.5. Use `HIThemeGetTrackThumbPositionFromOffset` instead.)

```
OSStatus GetThemeTrackThumbPositionFromOffset (
   const ThemeTrackDrawInfo *drawInfo,
   Point thumbOffset,
   SInt32 *relativePosition
);
```

Parameters

drawInfo

A pointer to a structure of type `ThemeTrackDrawInfo`. Before calling `GetThemeTrackThumbPositionFromOffset`, set the structure to contain the current visual characteristics of the track.

thumbOffset

A structure of type `Point`. Pass the point (in coordinates local to the control's window) that specifies the vertical and horizontal offset, in pixels, by which the indicator has moved from its current position. Typically, this is the offset between the locations where the cursor was when the user pressed and released the mouse button while dragging the indicator.

relativePosition

A pointer to a signed 32-bit value. On return, this value contains the new distance, in pixels, between the minimum end of the track and the near side of the indicator.

Return Value

A result code. See "Appearance Manager Result Codes" (page 217).

Discussion

Your application can use the `GetThemeTrackThumbPositionFromOffset` function to respond to the `posCntl` control definition message.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Appearance.h`

GetThemeTrackThumbPositionFromRegion

Obtains the relative position of a track's indicator, given its current position. (Deprecated in Mac OS X v10.5. use `HIThemeGetTrackThumbPositionFromBounds` instead.)

```
OSStatus GetThemeTrackThumbPositionFromRegion (
   const ThemeTrackDrawInfo *drawInfo,
   RgnHandle thumbRgn,
   SInt32 *relativePosition
);
```

Parameters

drawInfo

A pointer to a structure of type `ThemeTrackDrawInfo`. Before calling `GetThemeTrackThumbPositionFromRegion`, set the structure to contain the current visual characteristics of the track.

thumbRgn

A value of type `RgnHandle`. Before calling `GetThemeTrackThumbPositionFromRegion` set the region to contain the actual dimensions and position of the indicator, in local coordinates.

relativePosition

A pointer to a signed 32-bit value. On return, this value contains the new distance, in pixels, between the minimum end of the track and the near side of the indicator.

Return Value

A result code. See "Appearance Manager Result Codes" (page 217).

Discussion

Your application can use the `GetThemeTrackThumbPositionFromRegion` function to respond to the `kControlMsgCalcValueFromPos` control definition message.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Appearance.h`

GetThemeTrackThumbRgn

Obtains the region containing a track's indicator. (Deprecated in Mac OS X v10.5. Use `HIThemeGetTrackThumbShape` instead.)

```
OSStatus GetThemeTrackThumbRgn (
   const ThemeTrackDrawInfo *drawInfo,
   RgnHandle thumbRgn
);
```

Parameters

drawInfo

A pointer to a structure of type `ThemeTrackDrawInfo`. Before calling `GetThemeTrackThumbRgn`, set the structure to contain the current visual characteristics of the track.

thumbRgn

A value of type `RgnHandle`. On return, the region contains the actual dimensions and position of the indicator, in local coordinates.

Return Value

A result code. See "Appearance Manager Result Codes" (page 217).

Discussion
Your application can use the `GetThemeTrackThumbRgn` function to obtain the indicator region for tracks that have indicators, such as sliders and scroll bars.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Appearance.h`

GetThemeWindowRegion

Obtains the specified window region. (Deprecated in Mac OS X v10.5. Use `HIThemeGetWindowShape` instead.)

```
OSStatus GetThemeWindowRegion (
   ThemeWindowType flavor,
   const Rect *contRect,
   ThemeDrawState state,
   const ThemeWindowMetrics *metrics,
   ThemeWindowAttributes attributes,
   AppearanceRegionCode winRegion,
   RgnHandle rgn
);
```

Parameters

flavor
A value of type `ThemeWindowType`. Pass a constant specifying the type of window to be examined. See "Theme Window Types" (page 189) for descriptions of possible values.

contRect
A pointer to a structure of type `Rect`. Before calling `GetThemeWindowRegion`, set the rectangle to the content area of the window, specified in coordinates local to the current port.

state
A value of type `ThemeDrawState`. Pass a constant—either `kThemeStateActive` or `kThemeStateInactive`—appropriate to the current state of the window. See "Theme Drawing States" (page 126) for descriptions of these values.

metrics
A pointer to a structure of type `ThemeWindowMetrics`. Before calling `GetThemeWindowRegion`, set the structure to contain information describing the window.

attributes
A value of type `ThemeWindowAttributes`. Pass one or more constants corresponding to the window's current visual attributes. See "Theme Window Attributes" (page 191) for descriptions of possible values. Pass 0 if the window has none of the enumerated attributes.

winRegion
A value of type `WindowRegionCode`. Pass a constant specifying the region of the window whose dimensions you wish to obtain.

rgn
A value of type `RgnHandle`. Pass a handle to a valid region. On return, the region represents the actual region requested.

Return Value
A result code. See "Appearance Manager Result Codes" (page 217).

Discussion
The `GetThemeWindowRegion` function obtains the dimensions of the specified window region under the current theme.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Appearance.h`

GetThemeWindowRegionHit

Obtains the part of the window that the user clicked upon. (Deprecated in Mac OS X v10.5. Use `HIThemeGetWindowRegionHit` instead.)

```
Boolean GetThemeWindowRegionHit (
   ThemeWindowType flavor,
   const Rect *inContRect,
   ThemeDrawState state,
   const ThemeWindowMetrics *metrics,
   ThemeWindowAttributes inAttributes,
   Point inPoint,
   AppearanceRegionCode *outRegionHit
);
```

Parameters

flavor
A value of type `ThemeWindowType`. Pass a constant specifying the type of window to be examined. See "Theme Window Types" (page 189) for descriptions of possible values.

inContRect
A pointer to a structure of type `Rect`. Before calling `GetThemeWindowRegionHit`, set rectangle to the content area of the window, specified in coordinates local to the current port.

state
A value of type `ThemeDrawState`. Pass a constant—either `kThemeStateActive` or `kThemeStateInactive`—appropriate to the current state of the window. See "Theme Drawing States" (page 126) for descriptions of these values.

metrics
A pointer to a structure of type `ThemeWindowMetrics`. Before calling `GetThemeWindowRegionHit`, set the structure to contain information describing the window.

inAttributes
A value of type `ThemeWindowAttributes`. Pass one or more constants corresponding to the window's current visual attributes. See "Theme Window Attributes" (page 191) for descriptions of possible values. Pass 0 if the window has none of the enumerated attributes.

inPoint

A structure of type `Point`. Pass the point, specified in specified in coordinates local to the current port, where the mouse-down event occurred. Your application may retrieve this value from the `where` field of the `event` structure.

outRegionHit

A pointer to a value of type `WindowRegionCode`. On return, the value is set to the region code of the window part in which the point passed in the `inPoint` parameter is located.

Return Value
A value of type `Boolean`. If `true`, the mouse-down event occurred inside the window; otherwise, `false`.

Discussion
Your window definition function should call the `GetThemeWindowRegionHit` function to determine where a specified mouse-down event occurred.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In
`Appearance.h`

HitTestThemeScrollBarArrows

Returns whether the user clicked upon the specified scroll bar's arrows. (Deprecated in Mac OS X v10.5. Use `HIThemeHitTestScrollBarArrows` instead.)

```
Boolean HitTestThemeScrollBarArrows (
   const Rect *scrollBarBounds,
   ThemeTrackEnableState enableState,
   ThemeTrackPressState pressState,
   Boolean isHoriz,
   Point ptHit,
   Rect *trackBounds,
   AppearancePartCode *partcode
);
```

Parameters

scrollBarBounds

A pointer to a structure of type `Rect`. Before calling `HitTestThemeScrollBarArrows`, set the rectangle to the boundary of the scroll bar, in local coordinates. Typically, the rectangle you specify is the entire base control rectangle—that is, the value contained in the `contrlRect` field of the scroll bar's `ControlRecord` structure.

enableState

A value of type `ThemeTrackEnableState`. Pass a constant specifying the current state of the scroll bar; see "Theme Track States" (page 185) for descriptions of possible values.

pressState

A value of type `ThemeTrackPressState`. Pass a constant specifying what is pressed in an active scroll bar or 0 if nothing is pressed; the press state is ignored if the scroll bar is not active. See "Theme Track Press States" (page 187) for descriptions of possible values.

isHoriz

A value of type `Boolean`. Pass `true` if the scroll bar is horizontal; pass `false` if it is vertical.

ptHit

A structure of type `Point`. Pass the point, specified in local coordinates, where the mouse-down event occurred. Your application may retrieve this value from the `where` field of the `event` structure.

trackBounds

A pointer to a structure of type `Rect`. On return, the rectangle contains the bounds of the track portion of the scroll bar; this rectangle excludes the area containing the scroll bar arrows. Pass `NULL` if you do not wish to obtain this information.

partcode

A pointer to a value of type `ControlPartCode`. On return, this value specifies the arrow in which the mouse-down event occurred.

Return Value

A value of type `Boolean`. If `true`, the mouse-down event occurred inside the scroll bar arrows; otherwise, `false`.

Discussion

Your application may use the `HitTestThemeScrollBarArrow` function to test whether a given mouse-down event occurred on a scroll bar's arrows. If not, you may then use the rectangle produced in the `trackBounds` parameter of `HitTestThemeScrollBarArrows` as the bounds of the track for the function `HitTestThemeTrack` (page 84), in order to determine whether the mouse-down event occurred in the track part of the scroll bar.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Appearance.h`

HitTestThemeTrack

Returns whether the user clicked upon the specified track. (Deprecated in Mac OS X v10.5. Use `HIThemeHitTestTrack` instead.)

```
Boolean HitTestThemeTrack (
   const ThemeTrackDrawInfo *drawInfo,
   Point mousePoint,
   AppearancePartCode *partHit
);
```

Parameters

drawInfo

A pointer to a structure of type `ThemeTrackDrawInfo`. Before calling `HitTestThemeTrack`, set the structure to contain the current visual characteristics of the track.

mousePoint

A structure of type `Point`. Pass the point, specified in local coordinates, where the mouse-down event occurred. Your application may retrieve this value from the `where` field of the `event` structure.

partHit

A pointer to a value of type `ControlPartCode`. On return, this value specifies the part of the track in which the mouse-down event occurred.

Return Value
A value of type `Boolean`. If `true`, the mouse-down event occurred inside the track; otherwise, `false`.

Discussion
The `HitTestThemeTrack` function checks to see whether a given track contains the specified point at which a mouse-down event occurred.

For a scroll bar–type track, your application should also check to see whether the mouse-down event occurred in the scroll bar's arrows, which are not considered part of the track and are not tested by this function. To do this, your application should first use the function `HitTestThemeScrollBarArrows` (page 83) to test whether a given mouse-down event occurred on a scroll bar's arrows. If not, you may then use the rectangle produced in the `rTrack` parameter of `HitTestThemeScrollBarArrows` as the bounds of the track for `HitTestThemeTrack`, in order to determine whether the mouse-down event occurred in the track part of the scroll bar.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Appearance.h`

InvokeMenuItemDrawingUPP

Invokes your menu item drawing function. (Deprecated in Mac OS X v10.5. There is no replacement function.)

```
void InvokeMenuItemDrawingUPP (
   const Rect *inBounds,
   SInt16 inDepth,
   Boolean inIsColorDevice,
   SRefCon inUserData,
   MenuItemDrawingUPP userUPP
);
```

Discussion
You should not need to use the function `InvokeMenuItemDrawingUPP`, as the system calls your menu item drawing function for you.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In
`Appearance.h`

InvokeMenuTitleDrawingUPP

Invokes your menu title drawing function. (Deprecated in Mac OS X v10.5. There is no replacement function.)

```
void InvokeMenuTitleDrawingUPP (
   const Rect *inBounds,
   SInt16 inDepth,
   Boolean inIsColorDevice,
   SRefCon inUserData,
   MenuTitleDrawingUPP userUPP
);
```

Discussion
You should not need to use the function `InvokeMenuTitleDrawingUPP`, as the system calls your menu title drawing function for you.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In
`Appearance.h`

InvokeThemeButtonDrawUPP

Invokes your button drawing function. (Deprecated in Mac OS X v10.5. There is no replacement function.)

```
void InvokeThemeButtonDrawUPP (
   const Rect *bounds,
   ThemeButtonKind kind,
   const ThemeButtonDrawInfo *info,
   URefCon userData,
   SInt16 depth,
   Boolean isColorDev,
   ThemeButtonDrawUPP userUPP
);
```

Discussion
You should not need to use the function `InvokeThemeButtonDrawUPP`, as the system calls your button drawing function for you.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In
`Appearance.h`

InvokeThemeEraseUPP

Invokes your background drawing callback function. (Deprecated in Mac OS X v10.5. There is no replacement function.)

```
void InvokeThemeEraseUPP (
   const Rect *bounds,
   URefCon eraseData,
   SInt16 depth,
   Boolean isColorDev,
   ThemeEraseUPP userUPP
);
```

Discussion
You should not need to use the function `InvokeThemeEraseUPP`, as the system calls your `ThemeEraseProcPtr` (page 108) callback function for you.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In
`Appearance.h`

InvokeThemeIteratorUPP

Invokes your theme iteration callback function. (Deprecated in Mac OS X v10.5. There is no replacement function.)

```
Boolean InvokeThemeIteratorUPP (
   ConstStr255Param inFileName,
   SInt16 resID,
   Collection inThemeSettings,
   PRefCon inUserData,
   ThemeIteratorUPP userUPP
);
```

Discussion
You should not need to use the function `InvokeThemeIteratorUPP`, as the system calls your `ThemeIteratorProcPtr` (page 109) callback function for you.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In
`Appearance.h`

InvokeThemeTabTitleDrawUPP

Invokes your tab title drawing function. (Deprecated in Mac OS X v10.5. There is no replacement function.)

```
void InvokeThemeTabTitleDrawUPP (
   const Rect *bounds,
   ThemeTabStyle style,
   ThemeTabDirection direction,
   SInt16 depth,
   Boolean isColorDev,
   URefCon userData,
   ThemeTabTitleDrawUPP userUPP
);
```

Discussion
You should not need to use the function `InvokeThemeTabTitleDrawUPP`, as the system calls your tab title drawing function for you.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In
`Appearance.h`

InvokeWindowTitleDrawingUPP

Invokes your window title drawing function. (Deprecated in Mac OS X v10.5. There is no replacement function.)

```
void InvokeWindowTitleDrawingUPP (
   const Rect *bounds,
   SInt16 depth,
   Boolean colorDevice,
   URefCon userData,
   WindowTitleDrawingUPP userUPP
);
```

Discussion
You should not need to use the function `InvokeWindowTitleDrawingUPP`, as the system calls your window title drawing function for you.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In
`Appearance.h`

IsAppearanceClient

Returns whether a given process is currently registered as a client of the Appearance Manager. (Deprecated in Mac OS X v10.5. There is no replacement function.)

```
Boolean IsAppearanceClient (
   const ProcessSerialNumber *process
);
```

Parameters

process

A pointer to a value of type `ProcessSerialNumber`. Pass the serial number of the process to examine.

Return Value

A value of type `Boolean`. If `true`, the specified process is currently registered as a client of the Appearance Manager; otherwise, `false`.

Discussion

Applications typically do not need to call the `IsAppearanceClient` function. A plug-in could call `IsAppearanceClient` to determine whether the process in which it is running is a registered Appearance Manager client. To register with the Appearance Manager, call the function `RegisterAppearanceClient` (page 95).

Special Considerations

This function always returns `true` in Mac OS X.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Appearance.h`

IsThemeInColor

Returns whether the current theme would draw in color in the given environment. (Deprecated in Mac OS X v10.5. There is no replacement function.)

```
Boolean IsThemeInColor (
   SInt16 inDepth,
   Boolean inIsColorDevice
);
```

Parameters

inDepth

A signed 16-bit integer. Pass a value specifying the bit depth (in bits per pixel) of the current graphics port.

inIsColorDevice

A value of type `Boolean`. Pass `true` to indicate that you are drawing on a color device, or `false` for a monochrome device.

Return Value

A value of type `Boolean`. `IsThemeInColor` returns `true` if, given the depth and color device information, the theme would draw in color; otherwise, `false`.

Discussion
To be consistent with the current theme, your application can call the `IsThemeInColor` function to determine whether or not the Appearance Manager is drawing the theme in color or black and white. If the function returns `true`, you should draw in color; if it returns `false`, you should draw in black and white. Note that the Appearance Manager may draw a theme in black and white not only because of the current bit depth or device type, but also because the theme may have defined black-and-white elements, such as the "Black & White" accent color in the platinum appearance.

Special Considerations

In Mac OS X, this function always returns true because the Aqua theme is always drawn in color.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In
`Appearance.h`

IsValidAppearanceFileType

Returns whether the system can interpret files of a given file type as appearance files. (Deprecated in Mac OS X v10.5. There is no replacement function.)

```
Boolean IsValidAppearanceFileType (
   OSType fileType
);
```

Parameters

`fileType`

A four-character code. Pass the file type to be examined.

Return Value
A value of type `Boolean`. If `true`, files of the specified file type can be used as appearance files; otherwise, `false`.

Discussion
Under Appearance Manager 1.1, only the `'thme'` and `'pltn'` file types, described in "Appearance Manager File Types" (page 121), are valid appearance file types. Your application typically does not need to call this function.

Special Considerations

This function always returns false in Mac OS X.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In
`Appearance.h`

IterateThemes

Iterates over all themes installed on a system. (Deprecated in Mac OS X v10.5. There is no replacement function.)

```
OSStatus IterateThemes (
   ThemeIteratorUPP inProc,
   PRefCon inUserData
);
```

Parameters

inProc

A universal function pointer to an application-defined function such as that described in `ThemeIteratorProcPtr` (page 109). `IterateThemes` calls the specified function for each theme found installed in the system.

inUserData

A pointer to data of any type. Provide any data to be passed in to the `inUserData` parameter of the callback function specified in the `inProc` parameter. Pass `NULL`, if you do not wish to provide any data.

Return Value

A result code. See "Appearance Manager Result Codes" (page 217).

Discussion

The `IterateThemes` function continues to iterate until the function specified in the `inProc` parameter returns `false` or until there are no more themes.

Special Considerations

This function does nothing in Mac OS X; it does not call the theme iterator callback function.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Appearance.h`

NewMenuItemDrawingUPP

Creates a new universal procedure pointer (UPP) to a menu item drawing function. (Deprecated in Mac OS X v10.5. There is no replacement function.)

```
MenuItemDrawingUPP NewMenuItemDrawingUPP (
   MenuItemDrawingProcPtr userRoutine
);
```

Return Value

A UPP. See `MenuItemDrawingProcPtr` (page 104) for information on the menu item drawing function. See the description of the `MenuItemDrawingUPP` data type.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Declared In
`Appearance.h`

NewMenuTitleDrawingUPP

Creates a new universal procedure pointer (UPP) to a menu title drawing function. (Deprecated in Mac OS X v10.5. There is no replacement function.)

```
MenuTitleDrawingUPP NewMenuTitleDrawingUPP (
   MenuTitleDrawingProcPtr userRoutine
);
```

Return Value
A UPP. See `MenuTitleDrawingProcPtr` (page 105) for information on the menu title drawing function. See the description of the `MenuTitleDrawingUPP` data type.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In
`Appearance.h`

NewThemeButtonDrawUPP

Creates a new universal procedure pointer (UPP) to a button drawing function. (Deprecated in Mac OS X v10.5. There is no replacement function.)

```
ThemeButtonDrawUPP NewThemeButtonDrawUPP (
   ThemeButtonDrawProcPtr userRoutine
);
```

Return Value
A UPP. See `ThemeButtonDrawProcPtr` (page 107) for information on the button drawing function. See the description of the `ThemeButtonDrawUPP` data type.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In
`Appearance.h`

NewThemeEraseUPP

Creates a new universal procedure pointer (UPP) to a background drawing callback function. (Deprecated in Mac OS X v10.5. There is no replacement function.)

```
ThemeEraseUPP NewThemeEraseUPP (
   ThemeEraseProcPtr userRoutine
);
```

Return Value
A UPP. See the description of the `ThemeEraseUPP` data type.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In
`Appearance.h`

NewThemeIteratorUPP

Creates a new universal procedure pointer (UPP) to a theme iteration callback function. (Deprecated in Mac OS X v10.5. There is no replacement function.)

```
ThemeIteratorUPP NewThemeIteratorUPP (
   ThemeIteratorProcPtr userRoutine
);
```

Return Value
A UPP. See the description of the `ThemeIteratorUPP` data type.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In
`Appearance.h`

NewThemeTabTitleDrawUPP

Creates a new universal procedure pointer (UPP) to a tab title drawing function. (Deprecated in Mac OS X v10.5. There is no replacement function.)

```
ThemeTabTitleDrawUPP NewThemeTabTitleDrawUPP (
   ThemeTabTitleDrawProcPtr userRoutine
);
```

Return Value
A UPP. See `ThemeTabTitleDrawProcPtr` (page 111) for information on the tab title drawing function. See the description of the `ThemeTabTitleDrawUPP` data type.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In
`Appearance.h`

NewWindowTitleDrawingUPP

Creates a new universal procedure pointer (UPP) to a window title drawing function. (Deprecated in Mac OS X v10.5. There is no replacement function.)

```
WindowTitleDrawingUPP NewWindowTitleDrawingUPP (
   WindowTitleDrawingProcPtr userRoutine
);
```

Return Value
A UPP. See `WindowTitleDrawingProcPtr` (page 112) for information on the window title drawing function. See the description of the `WindowTitleDrawingUPP` data type.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In
`Appearance.h`

NormalizeThemeDrawingState

Sets the current graphics port to a default drawing state.

```
OSStatus NormalizeThemeDrawingState (
   void
);
```

Return Value
A result code. See "Appearance Manager Result Codes" (page 217).

Discussion
The `NormalizeThemeDrawingState` function sets the background of a graphics port to white; the pen of the port to a size of 1 pixel by 1 pixel, a pattern mode of `patCopy`, and a pattern of black; and the text mode of the port to `srcOr`. `NormalizeThemeDrawingState` also flushes from memory any color foreground or background patterns saved in the port's `GrafPort.pnPat` or `GrafPort.bkPat` fields, respectively.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Appearance.h`

PlayThemeSound

Plays an asynchronous sound associated with the specified state change.

```
OSStatus PlayThemeSound (
   ThemeSoundKind kind
);
```

Parameters

kind

A value of type `ThemeSoundKind`. Pass a constant specifying the sound to play; see "Theme Sounds" (page 194) for descriptions of possible values.

Return Value

A result code. See "Appearance Manager Result Codes" (page 217).

Discussion

The Appearance Manager automatically plays theme sounds for standard user interface elements. Your application can call the `PlayThemeSound` function to play a theme sound for a custom element. The sound plays asynchronously until complete, stopping automatically.

Special Considerations

This function is not implemented in Mac OS X.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Appearance.h`

RegisterAppearanceClient

Registers your program with the Appearance Manager. (Deprecated in Mac OS X v10.5. There is no replacement function.)

```
OSStatus RegisterAppearanceClient (
   void
);
```

Return Value

A result code. The result code `appearanceProcessRegisteredErr` indicates that your program was already registered when you called the `RegisterAppearanceClient` function.

Discussion

The `RegisterAppearanceClient` function must be called at the beginning of your program, prior to initializing or drawing any onscreen elements or invoking any definition functions, such as the menu bar.

You should call `RegisterAppearanceClient` in order to receive Appearance Manager Apple events. Under Appearance Manager 1.1 and later, when the user changes the current appearance (that is, when a theme switch occurs), the Appearance Manager sends Apple events to all running applications that are registered as clients of the Appearance Manager and which are high-level event aware. Because typical results of a theme switch might include a change in menu bar height or window structure dimensions, as well as changes to the system fonts, colors, and patterns currently in use, you should listen for and respond to the Appearance Manager Apple events under most circumstances. See "Appearance Manager Apple Events" (page 120) for more details.

When your program calls `RegisterAppearanceClient`, the Appearance Manager also automatically maps standard pre–Appearance Manager definition functions to their theme-compliant equivalents for your program, whether or not systemwide appearance is active.

See also the function `UnregisterAppearanceClient` (page 103).

Special Considerations

This function does nothing in Mac OS X.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Appearance.h`

SetAnimatedThemeCursor

Animates a version of the specified cursor type that is consistent with the current theme.

```
OSStatus SetAnimatedThemeCursor (
   ThemeCursor inCursor,
   UInt32 inAnimationStep
);
```

Parameters

inCursor

A value of type `ThemeCursor`. Pass a constant specifying the type of cursor to set; see "Theme Cursors" (page 162) for a description of the possible values. Note that only cursors designated as able to be animated should be used for this function. If you specify an unanimatable cursor type, `SetAnimatedThemeCursor` returns the error `themeBadCursorIndexErr` (–30565).

inAnimationStep

An unsigned 32-bit value. Pass a value specifying the current animation step of the cursor. To animate the cursor, increment the value by 1 with each call to `SetAnimatedThemeCursor`.

Return Value

A result code. See "Appearance Manager Result Codes" (page 217).

Discussion

Appearance Manager 1.1 introduces cursors that can change appearance with a theme change. In order to be theme-compliant, your program should use these theme-specific cursors whenever possible, instead of the classic black-and-white cursors.

Your application should call the `SetAnimatedThemeCursor` function to ensure that its animated cursors are theme-compliant, rather than using any QuickDraw cursor utilities functions such as `SetCursor`, `SetCCursor`, `SpinCursor`, or `RotateCursor`. If you wish a non-animated cursor to be theme-compliant, call the function `SetThemeCursor` (page 98).

Because these are color cursors, they currently cannot be set from interrupt time. Therefore, if you support animated cursors that are changed at interrupt time you should continue to use your own cursors for now.

Special Considerations

Do not call `SetAnimatedThemeCursor` at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Appearance.h`

SetTheme

Sets a specified collection as the current theme. (Deprecated in Mac OS X v10.5. There is no replacement function.)

```
OSStatus SetTheme (
   Collection ioCollection
);
```

Parameters

`ioCollection`

A value of type `Collection`. Pass a reference to a collection object, such as that created by calling the Collection Manager function `NewCollection`. Before calling `SetTheme`, set the collection to contain theme data that you wish to use for the current theme. The theme data is in the form of collection items, each corresponding to an attribute of the theme. For a given theme, the actual number of collection items may vary, depending upon how fully the theme's attributes are specified. Your application can use theme collection tags, along with various Collection Manager functions, to access the data in the collection. See "Theme Collection Tags" (page 122) for descriptions of the possible theme collection items.

Return Value

A result code. See "Appearance Manager Result Codes" (page 217).

Discussion

The `SetTheme` function sets the attributes of the current theme. You may use `SetTheme` to set up a custom theme environment for your application, to be used only when your application is active. You may also use `SetTheme` to create a theme environment that you want to be user-selectable and to have systemwide effect.

Your application can use the `GetTheme` (page 59) function to obtain a collection containing a copy of the data for the current theme.

Special Considerations

This function does not modify the current theme in Mac OS X.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Appearance.h`

SetThemeBackground

Applies a theme-compliant color or pattern to the background of the current port. (Deprecated in Mac OS X v10.5. Use `HIThemeSetFill` and draw using Quartz 2D.)

```
OSStatus SetThemeBackground (
   ThemeBrush inBrush,
   SInt16 inDepth,
   Boolean inIsColorDevice
);
```

Parameters

inBrush

A value of type `ThemeBrush`. Pass a constant specifying the theme brush to which to set the background; see "Theme Brushes" (page 145) for descriptions of possible values.

inDepth

A signed 16-bit integer. Pass a value specifying the bit depth (in bits per pixel) of the current graphics port.

inIsColorDevice

A value of type `Boolean`. Pass `true` to indicate that you are drawing on a color device. Pass `false` for a monochrome device.

Return Value

A result code. The result code `appearanceBadBrushIndexErr` indicates that the brush constant passed was not valid.

Discussion

Your application should call the `SetThemeBackground` function each time you wish to draw in a specified brush type. Note that the `SetThemeBackground` function aligns patterns with 0,0 in the current port. To align a pattern independently of the port origin, use the function `ApplyThemeBackground` (page 26).

Because the constant in the `inBrush` parameter can specify a color or pattern, depending on the current theme, your application must save and restore the current drawing state of the graphics port around calls to `SetThemeBackground`. Under Appearance Manager 1.1 and later, you can use the functions `GetThemeDrawingState` (page 65) and `SetThemeDrawingState` (page 99) to do this.

Prior to Appearance Manager 1.1, you must save and restore the `pnPixPat` and `bkPixPat` fields of your graphics port when saving the text and background colors. Because patterns in the `bkPixPat` field override the background color of the window, call the QuickDraw function `BackPat` to set your background pattern to a normal white pattern. This ensures that you can use `RGBBackColor` to set your background color to white, call the QuickDraw function `EraseRect`, and get the expected results.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Appearance.h`

SetThemeCursor

Sets the cursor to a version of the specified cursor type that is consistent with the current theme.

```
OSStatus SetThemeCursor (
   ThemeCursor inCursor
);
```

Parameters

inCursor

A value of type `ThemeCursor`. Pass a constant specifying the type of cursor to set; see "Theme Cursors" (page 162) for a description of possible values.

Return Value

A result code. See "Appearance Manager Result Codes" (page 217).

Discussion

Appearance Manager 1.1 introduces cursors that can change appearance with a theme change. In order to be theme-compliant, your program should use these theme-specific cursors whenever possible, instead of the classic black-and-white cursors. Because these are color cursors, they currently cannot be set from interrupt time.

Your application should call the `SetThemeCursor` function to ensure that its cursors are theme-compliant, rather than the QuickDraw cursor utilities functions `SetCursor` or `SetCCursor`. If you wish an animatable cursor to be theme-compliant, call the function `SetAnimatedThemeCursor` (page 96).

Special Considerations

Do not call `SetThemeCursor` at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Related Sample Code

CarbonCocoa_PictureCursor

CarbonSketch

QTCarbonShell

Declared In

`Appearance.h`

SetThemeDrawingState

Sets the drawing state of the current graphics port.

```
OSStatus SetThemeDrawingState (
   ThemeDrawingState inState,
   Boolean inDisposeNow
);
```

Parameters

inState

A value of type `ThemeDrawingState`. Pass a `ThemeDrawingState` value such as that produced in the `outState` parameter of `GetThemeDrawingState` (page 65).

inDisposeNow

A value of type `Boolean`. Pass a value of `true` to release the memory allocated for the drawing state reference. Pass `false` if you wish to continue using the drawing state and do not want to dispose of the memory at this time; you must call `DisposeThemeDrawingState` (page 29) to dispose of the memory any time before your application terminates.

Return Value
A result code. See "Appearance Manager Result Codes" (page 217).

Discussion
Your application can save the port state by calling the function `GetThemeDrawingState` (page 65) and restore the port state by calling the function `SetThemeDrawingState`, supplying the value obtained in the `outState` parameter of `GetThemeDrawingState`, after you have completed all of your drawing.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Appearance.h`

SetThemePen

Applies a theme-compliant color or pattern to the foreground of the current port. (Deprecated in Mac OS X v10.5. Use `HIThemeSetStroke` and draw using Quartz 2D.)

```
OSStatus SetThemePen (
   ThemeBrush inBrush,
   SInt16 inDepth,
   Boolean inIsColorDevice
);
```

Parameters

inBrush

A value of type `ThemeBrush`. Pass a constant specifying the theme brush type to which to set the pen; see "Theme Brushes" (page 145) for descriptions of possible values.

inDepth

A signed 16-bit integer. Pass a value specifying the bit depth (in bits per pixel) of the current graphics port.

inIsColorDevice

A value of type `Boolean`. Pass `true` to indicate that you are drawing on a color device. Pass `false` for a monochrome device.

Return Value
A result code. The result code `appearanceBadBrushIndexErr` indicates that the brush constant passed in was not valid.

Discussion
Your application should call the `SetThemePen` function each time you wish to draw an element in a specified brush constant.

Because the constant in the `inBrush` parameter can represent a color or pattern, depending on the current theme, your application must save and restore the current drawing state of the graphics port around calls to `SetThemePen`. Under Appearance Manager 1.1 and later, you can use the functions

GetThemeDrawingState (page 65) and SetThemeDrawingState (page 99) to do this. Prior to Appearance Manager 1.1, you must save and restore the pnPixPat and bkPixPat fields of your graphics port when saving the text and background colors. Because patterns in the pnPixPat field override the foreground color of the window, call the QuickDraw function PenPat to set your foreground pattern to a normal white pattern. This ensures that you can use RGBForeColor to set your foreground color to white, call the QuickDraw function PaintRect, and get the expected results.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
Appearance.h

SetThemeTextColor

Sets the current text color to be consistent with that of a specified element. (Deprecated in Mac OS X v10.5. Use HIThemeSetTextFill and draw with Quartz 2D, ATSUI, or HIThemeDrawTextBox.)

```
OSStatus SetThemeTextColor (
   ThemeTextColor inColor,
   SInt16 inDepth,
   Boolean inIsColorDevice
);
```

Parameters

inColor
A value of type ThemeTextColor. Pass a constant specifying an interface element. SetThemeTextColor sets the current text color to be the same as the color of that element's text. See "Theme Text Colors" (page 169) for descriptions of possible values.

inDepth
A signed 16-bit integer. Pass a value specifying the bit depth (in bits per pixel) of the current graphics port.

inIsColorDevice
A value of type Boolean. Pass true to indicate that you are drawing on a color device. Pass false for a monochrome device.

Return Value
A result code. The result code appearanceBadTextColorIndexErr indicates that the text color index passed was not valid.

Discussion
Your application typically uses the SetThemeTextColor function inside a DeviceLoop drawing function to set the foreground color to a theme-compliant value.

Also see the function GetThemeTextColor (page 74).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Appearance.h`

TruncateThemeText

Truncates text to fit within the width you specify. (Deprecated in Mac OS X v10.5. There is no replacement function; use `HIThemeGetTextDimensions` or `HIThemeDrawTextBox` instead.)

```
OSStatus TruncateThemeText (
   CFMutableStringRef inString,
   ThemeFontID inFontID,
   ThemeDrawState inState,
   SInt16 inPixelWidthLimit,
   TruncCode inTruncWhere,
   Boolean *outTruncated
);
```

Parameters

inString

A `CFMutableStringRef` containing the unicode characters you wish to truncate. On output, this string may have been altered to fit within the specified width.

You must not pass in a CFString that was allocated with any of the "NoCopy" CFString creation functions, as mentioned in the description of the `DrawThemeTextBox` (page 51) function.

inFontID

The `ThemeFontID` to use for text measurements. See "Theme Font IDs" (page 166) for the values you can use here.

inState

The `ThemeDrawState` which matches the state you will ultimately render the string with. This may affect text measurement during truncation, so you should be sure the value you pass to `TruncateThemeText` matches the value you will eventually use for drawing. See "Theme Drawing States" (page 126) for the values you can use here.

inPixelWidthLimit

The maximum width, in pixels, that the resulting truncated string may have.

inTruncWhere

A `TruncCode` indicating where you would like truncation to occur.

outTruncated

On output, this Boolean value indicates whether the string was truncated. `True` means the string was truncated. `False` means the string was not—and did not need to be—truncated.

Return Value
A result code. See "Appearance Manager Result Codes" (page 217).

Discussion
`TruncateThemeText` alters a unicode string to fit within a width that you specify. It is unicode savvy, although only partially so under CarbonLib, and makes its calculations—and any subsequent string alteration—based on the font and drawing state you specify. If the string needs to be truncated, it will be reduced to the maximum number of characters which, with the addition of an ellipsis character, fits within the specified width.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In
`Appearance.h`

UnregisterAppearanceClient

Informs the Appearance Manager that your program is no longer its client. (Deprecated in Mac OS X v10.5. There is no replacement function.)

```
OSStatus UnregisterAppearanceClient (
   void
);
```

Return Value
A result code. The result code `appearanceProcessNotRegisteredErr` indicates that your program was not registered when you called the `UnregisterAppearanceClient` function.

Discussion
The `UnregisterAppearanceClient` function is automatically called for you when your program terminates. While you do not typically need to call this function, you might want to call `UnregisterAppearanceClient` if you are running a plug-in architecture, and you know that a given plug-in is not theme-compliant. In this case you would bracket your use of the plug-in with calls to `UnregisterAppearanceClient` (before the plug-in is used) and `RegisterAppearanceClient` (after the plug-in is used), so that the Appearance Manager is turned off for the duration of the plug-in's usage.

See also the function `RegisterAppearanceClient` (page 95).

Special Considerations

This function does nothing in Mac OS X.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Appearance.h`

UseThemeFont

Sets the font of the current graphics port to one of the current theme's system fonts. (Deprecated in Mac OS X v10.5. Use `HIThemeDrawTextBox` instead.)

```
OSStatus UseThemeFont (
   ThemeFontID inFontID,
   ScriptCode inScript
);
```

Parameters

inFontID

A value of type `ThemeFontID`. Pass a constant specifying the kind of font (that is, the current large, small, or small emphasized system fonts or the views font) to be applied to the current port. See "Theme Font IDs" (page 166) for descriptions of possible values.

inScript

A value of type `ScriptCode`. Pass a script code specifying the script system for which you wish to set the current font; you may pass the metascript code `smSystemScript` to specify the system script.

Return Value

A result code. See "Appearance Manager Result Codes" (page 217).

Discussion

Your application can call the `UseThemeFont` function to draw text in one of the current theme's system fonts.

Also see the function `GetThemeFont` (page 65).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Appearance.h`

Callbacks

MenuItemDrawingProcPtr

Draws a menu item.

```
typedef void ( *MenuItemDrawingProcPtr)
(
    const Rect * inBounds,
    SInt16 inDepth,
    Boolean inIsColorDevice,
    SInt32 inUserData
);
```

If you name your function `MyMenuItemDrawingCallback`, you would declare it like this:

```
void MyMenuItemDrawingCallback (
    const Rect * inBounds,
    SInt16 inDepth,
    Boolean inIsColorDevice,
    SInt32 inUserData
```

```
);
```

Parameters

inBounds

A pointer to a structure of type `Rect`. You are passed a rectangle specifying the dimensions and position in which you should draw your menu item content. Your menu item drawing function is called clipped to the rectangle in which you are allowed to draw your content; do not draw outside this region.

inDepth

A signed 16-bit integer. You are passed the bit depth (in bits per pixel) of the current graphics port.

inIsColorDevice

A value of type `Boolean`. You are passed `true` to indicate that you are drawing on a color device; `inIsColorDevice` is `false` for a monochrome device.

inUserData

You are passed data specifying how to draw the menu item content from the `inUserData` parameter of `DrawThemeMenuItem` (page 38).

Discussion

At the time your menu item drawing function is called, the foreground text color and mode is already set to draw in the correct state (enabled, selected, disabled) and correct color for the theme. You do not need to set the color unless you have special drawing needs. If you do have special drawing needs, you should supply the `inDepth` value and the value of the `inIsColorDevice` parameter to the function `IsThemeInColor` to determine whether or not you should draw the menu item content in color.

Note that the Appearance Manager calls your `MyMenuItemDrawingCallback` function for every device that the `inBounds` rectangle intersects.

You should refer to your `MyMenuItemDrawingCallback` function using a `MenuItemDrawingUPP`, which you can create with `NewMenuItemDrawingUPP`.

You typically use the `NewMenuItemDrawingUPP` function like this:

```
MenuItemDrawingUPP myMenuItemDrawingUPP;
myMenuItemDrawingUPP = NewMenuItemDrawingUPP(MyMenuItemDrawingCallback);
```

Special Considerations

The Appearance Manager draws the background of the menu item prior to calling your menu item drawing function, so you should not erase the item's background from this function.

Version Notes

This function is available with Appearance Manager 1.0.1 and later.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Appearance.h`

MenuTitleDrawingProcPtr

Draws a menu title.

```
typedef void (*MenuTitleDrawingProcPtr)
(
    const Rect * inBounds,
    SInt16 inDepth,
    Boolean inIsColorDevice,
    SInt32 inUserData
);
```

If you name your function `MyMenuTitleDrawingCallback`, you would declare it like this:

```
void MyMenuTitleDrawingCallback (
    const Rect * inBounds,
    SInt16 inDepth,
    Boolean inIsColorDevice,
    SInt32 inUserData
);
```

Parameters

inBounds

A pointer to a structure of type `Rect`. You are passed a rectangle specifying the dimensions and position in which you should draw your menu title content. Your menu title drawing function is called clipped to the rectangle in which you are allowed to draw your content; do not draw outside this region.

inDepth

A signed 16-bit integer. You are passed the bit depth (in bits per pixel) of the current graphics port.

inIsColorDevice

A value of type `Boolean`. You are passed `true` to indicate that you are drawing on a color device; `inIsColorDevice` is `false` for a monochrome device.

inUserData

You are passed data specifying how to draw the menu title content from the `inTitleData` parameter of `DrawThemeMenuTitle` (page 40).

Discussion

At the time your menu title drawing function is called, the foreground text color and mode is already set to draw in the correct state (enabled, selected, disabled) and correct color for the theme. You do not need to set the color unless you have special drawing needs. If you do have special drawing needs, you should supply the `inDepth` value and the value of the `inIsColorDevice` parameter to the function `IsThemeInColor` to determine whether or not you should draw the menu title content in color.

Note that the Appearance Manager calls your `MyMenuTitleDrawingCallback` function for every device that the `inBounds` rectangle intersects.

You should refer to your `MyMenuTitleDrawingCallback` function using a `MenuTitleDrawingUPP`, which you can create with the `NewMenuTitleDrawingUPP` function.

You typically use the `NewMenuTitleDrawingUPP` function like this:

```
MenuTitleDrawingUPP myMenuTitleDrawingUPP;
myMenuTitleDrawingUPP = NewMenuTitleDrawingUPP(MyMenuTitleDrawingCallback);
```

Special Considerations

The Appearance Manager draws the background of the menu title prior to calling your menu title drawing function, so you should not erase the title's background from this function.

Version Notes
This function is available with Appearance Manager 1.0.1 and later.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Appearance.h`

ThemeButtonDrawProcPtr

Draws a button label.

```
typedef void (*ThemeButtonDrawProcPtr)
(
    const Rect * bounds,
    ThemeButtonKind kind,
    const ThemeButtonDrawInfo * info,
    UInt32 userData,
    SInt16 depth,
    Boolean isColorDev
);
```

If you name your function `MyThemeButtonDrawCallback`, you would declare it like this:

```
void MyThemeButtonDrawCallback (
    const Rect * bounds,
    ThemeButtonKind kind,
    const ThemeButtonDrawInfo * info,
    UInt32 userData,
    SInt16 depth,
    Boolean isColorDev
);
```

Parameters

bounds
A pointer to a structure of type `Rect`. The rectangle you are passed is set to the area in which you should draw your content. Your button label drawing function is called clipped to the rectangle in which you are allowed to draw your content; do not draw outside this region. Note that if a right-to-left adornment is specified in the `ThemeButtonDrawInfo` structure passed into the `info` parameter, you may need to accommodate this orientation when placing your content.

kind
A value of type `ThemeButtonKind`. You are passed a constant specifying the button type. See "Theme Buttons" (page 153) for descriptions of possible values.

info
A pointer to a structure of type `ThemeButtonDrawInfo` (page 115). The structure is set to contain the current state, value, and adornment for the button.

userData
An unsigned 32-bit value. You are passed data specifying how to draw the content, from the `inUserData` parameter of `DrawThemeButton` (page 31).

depth
A signed 16-bit value. You are passed the bit depth (in bits per pixel) of the current graphics port.

isColorDev

A value of type `Boolean`. If `true`, indicates that you are drawing on a color device; a value of `false` indicates a monochrome device.

Discussion

At the time your button label drawing function is called, the foreground text color and mode is already set to draw in the correct state (active or inactive) and correct color for the theme. You do not need to set the color unless you have special drawing needs. If you do have special drawing needs, you should supply the `depth` value and the value of the `isColorDevice` parameter to the function `IsThemeInColor` to determine whether or not you should draw your content in color. Note that the Appearance Manager calls your `MyThemeButtonDrawCallback` function for every device that the `bounds` rectangle intersects.

You should refer to your `MyThemeButtonDrawCallback` function using a `ThemeButtonDrawUPP`, which you can create with the `NewThemeButtonDrawUPP` function.

You typically use the `NewThemeButtonDrawUPP` function like this:

```
ThemeButtonDrawUPP myThemeButtonDrawUPP;
myThemeButtonDrawUPP = NewThemeButtonDrawUPP(MyThemeButtonDrawCallback);
```

Special Considerations

The Appearance Manager draws the button background prior to calling your button label drawing function, so you should not erase the button background from your label drawing function.

Version Notes

This function is available with Appearance Manager 1.1 and later.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Appearance.h`

ThemeEraseProcPtr

Draws a background.

```
typedef void (*ThemeEraseProcPtr) (
    const Rect * bounds,
    UInt32 eraseData,
    SInt16 depth,
    Boolean isColorDev
);
```

If you name your function `MyThemeEraseCallback`, you would declare it like this:

```
void MyThemeEraseCallback (
    const Rect * bounds,
    UInt32 eraseData,
    SInt16 depth,
    Boolean isColorDev
);
```

Parameters

bounds

A pointer to a structure of type `Rect`. The rectangle you are passed is set to the area in which you should draw. Your drawing function is called clipped to the rectangle in which you are allowed to draw; do not draw outside this region.

eraseData

An unsigned 32-bit value. You are passed data specifying how to draw, from the `eraseData` parameter of `DrawThemeChasingArrows` (page 33), `DrawThemePopupArrow` (page 43), `DrawThemeTrack` (page 55), or `DrawThemeTrackTickMarks` (page 56) or from the `inUserData` parameter of `DrawThemeButton` (page 31).

depth

A signed 16-bit value. You are passed the bit depth (in bits per pixel) of the current graphics port.

isColorDev

A value of type `Boolean`. If `true`, indicates that you are drawing on a color device; a value of `false` indicates a monochrome device.

Discussion

At the time your drawing function is called, the foreground text color and mode is already set to draw in the correct state (active or inactive) and correct color for the theme. You do not need to set the color unless you have special drawing needs. If you do have special drawing needs, you should supply the `depth` value and the value of the `isColorDevice` parameter to the function `IsThemeInColor` to determine whether or not you should draw in color. Note that the Appearance Manager calls your `MyThemeEraseCallback` function for every device that the `bounds` rectangle intersects, so your application does not need to call the `DeviceLoop` function itself.

You should refer to your `MyThemeEraseCallback` function using a `ThemeEraseUPP`, which you can create with the `NewThemeEraseUPP` function.

You typically use the `NewThemeEraseUPP` function like this:

```
ThemeEraseUPP myThemeEraseUPP;
myThemeEraseUPP = NewThemeEraseUPP(MyThemeEraseCallback);
```

Version Notes

This function is available with Appearance Manager 1.1 and later.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Appearance.h`

ThemeIteratorProcPtr

Performs a custom response to an iteration over themes installed on a system.

```
typedef Boolean (*ThemeIteratorProcPtr)
(
    ConstStr255Param inFileName,
    SInt16 resID,
    Collection inThemeSettings,
    void * inUserData
);
```

If you name your function `MyThemeIteratorCallback`, you would declare it like this:

```
Boolean MyThemeIteratorCallback (
    ConstStr255Param inFileName,
    SInt16 resID,
    Collection inThemeSettings,
    void * inUserData
);
```

Parameters

inFileName

A value of type `ConstStr255Param`. You are passed the name of the file containing the theme being iterated upon.

resID

A signed 16-bit integer. You are passed the resource ID of the theme.

inThemeSettings

A value of type `Collection`. You are passed a reference to a collection that contains data describing attributes of the theme. Note that the Appearance Manager owns this collection, and that your application should not dispose of it.

inUserData

A pointer to data of any type. You are passed the value specified in the `inUserData` parameter of the function `IterateThemes` (page 91).

Return Value

A value of type `Boolean`. If you return `true`, `IterateThemes` continues iterating. Set to `false` to terminate the iteration.

Discussion

You should refer to your `MyThemeIteratorCallback` function using a `ThemeIteratorUPP`, which you can create using the `NewThemeIteratorUPP` function.

You typically use the `NewThemeIteratorUPP` function like this:

```
ThemeIteratorUPP myThemeIteratorUPP;
myThemeIteratorUPP = NewThemeIteratorUPP(MyThemeIteratorCallback);
```

Special Considerations

Your application should not open and close theme files during this call.

Version Notes

This function is available with Appearance Manager 1.1 and later.

Availability

Available in Mac OS X v10.0 and later.

Declared In
`Appearance.h`

ThemeTabTitleDrawProcPtr

Draws a tab title.

```
typedef void (*ThemeTabTitleDrawProcPtr)
(
    const Rect * bounds,
    ThemeTabStyle style,
    ThemeTabDirection direction,
    SInt16 depth,
    Boolean isColorDev,
    UInt32 userData
);
```

If you name your function `MyThemeTabTitleDrawCallback`, you would declare it like this:

```
void MyThemeTabTitleDrawCallback (
    const Rect * bounds,
    ThemeTabStyle style,
    ThemeTabDirection direction,
    SInt16 depth,
    Boolean isColorDev,
    UInt32 userData
);
```

Parameters

bounds
: A pointer to a structure of type `Rect`. The rectangle you are passed is set to the area in which you should draw your tab title content. Your tab title drawing function is called clipped to the rectangle in which you are allowed to draw your content; do not draw outside this region.

style
: A value of type `ThemeTabStyle`. You are passed a constant specifying the relative position (front or non-front) and state of the tab. See "Theme Tab Styles" (page 183) for descriptions of possible values.

direction
: A value of type `ThemeTabDirection`. You are passed a constant specifying the direction in which the tab is oriented. See "Theme Tab Directions" (page 182) for descriptions of possible values.

depth
: A signed 16-bit value. You are passed the bit depth (in bits per pixel) of the current graphics port.

isColorDev
: A value of type `Boolean`. If `true`, indicates that you are drawing on a color device; a value of `false` indicates a monochrome device.

userData
: An unsigned 32-bit value. You are passed data specifying how to draw the tab title content, from the `userData` parameter of `DrawThemeTab` (page 50).

Discussion

At the time your tab title drawing function is called, the foreground text color and mode is already set to draw in the correct state (active or inactive) and correct color for the theme. You do not need to set the color unless you have special drawing needs. If you do have special drawing needs, you should supply the `depth`

value and the value of the `isColorDevice` parameter to the function `IsThemeInColor` to determine whether or not you should draw the tab title content in color. Note that the Appearance Manager calls your `MyThemeTabTitleDrawCallback` function for every device that the `bounds` rectangle intersects.

You should refer to your `MyThemeTabTitleDrawCallback` function using a `ThemeTabTitleDrawUPP`, which you can create with the `NewThemeTabTitleDrawUPP` function.

You typically use the `NewThemeTabTitleDrawUPP` function like this:

```
ThemeTabTitleDrawUPP myThemeTabTitleDrawUPP;
myThemeTabTitleDrawUPP = NewThemeTabTitleDrawUPP(MyThemeTabTitleDrawCallback);
```

Special Considerations

The Appearance Manager draws the tab background prior to calling your tab title drawing function, so you should not erase the tab background from your title drawing function.

Version Notes
This function is available with Appearance Manager 1.1 and later.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Appearance.h`

WindowTitleDrawingProcPtr

Draws a window title.

```
typedef void (*WindowTitleDrawingProcPtr)
(
    const Rect * bounds,
    SInt16 depth,
    Boolean colorDevice,
    UInt32 userData
);
```

If you name your function `MyWindowTitleDrawingCallback`, you would declare it like this:

```
void MyWindowTitleDrawingCallback (
    const Rect * bounds,
    SInt16 depth,
    Boolean colorDevice,
    UInt32 userData
);
```

Parameters

bounds

A pointer to a structure of type `Rect`. The rectangle you are passed is set to the area in which you should draw your window title content. Your window title drawing function is called clipped to the rectangle in which you are allowed to draw your content; do not draw outside this region.

depth

A signed 16-bit value. You are passed the bit depth (in bits per pixel) of the current graphics port.

colorDevice

A value of type `Boolean`. If `true`, indicates that you are drawing on a color device; a value of `false` indicates a monochrome device.

userData

A signed 32-bit value. You are passed data specifying how to draw the window title content, from the `titleData` parameter of `DrawThemeWindowFrame` (page 57).

Discussion

At the time your window title drawing function is called, the foreground text color and mode is already set to draw in the correct window state (active or inactive) and correct color for the theme. You do not need to set the color unless you have special drawing needs. If you do have special drawing needs, you should supply the `depth` value and the value of the `colorDevice` parameter to the function `IsThemeInColor` to determine whether or not you should draw the window title content in color. Note that the Appearance Manager calls your `MyWindowTitleDrawingCallback` function for every device that the `bounds` rectangle intersects.

You should refer to your `MyWindowTitleDrawingCallback` function using a `WindowTitleDrawingUPP`, which you can create with the `NewWindowTitleDrawingUPP` function.

You typically use the `NewWindowTitleDrawingUPP` function like this:

```
WindowTitleDrawingUPP myWindowTitleDrawingUPP;
myWindowTitleDrawingUPP = NewWindowTitleDrawingUPP(MyWindowTitleDrawingCallback);
```

Special Considerations

The Appearance Manager draws the background of the window title prior to calling your window title drawing function, so you should not erase the background from this function.

Version Notes

This function is available with Appearance Manager 1.1 and later.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Appearance.h`

Data Types

ProgressTrackInfo

Describes the progress bar–specific features of a given track control.

```
struct ProgressTrackInfo {
    UInt8 phase;
};
typedef struct ProgressTrackInfo ProgressTrackInfo;
```

Fields

`phase`

A value specifying the current animation phase for an indeterminate progress bar. You can pass any value of type `UInt8`. Increment this value to animate the progress bar. Set this field to 0 for a determinate progress bar.

Discussion
Your application supplies a `ProgressTrackInfo` structure in the `ThemeTrackDrawInfo` (page 116) structure.

Version Notes
The `ProgressTrackInfo` structure is available with Appearance Manager 1.1 and later.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Appearance.h`

ScrollBarTrackInfo

Describes the scroll bar–specific features of a given track control.

```
struct ScrollBarTrackInfo {
    SInt32 viewsize;
    ThemeTrackPressState pressState;
};
typedef struct ScrollBarTrackInfo ScrollBarTrackInfo;
```

Fields

`viewsize`
A signed 32-bit integer, specifying the size of the content being displayed. This value should be expressed in terms of the same units of measurement as are used for the minimum, maximum, and current settings of the scroll bar.

`pressState`
A value of type `ThemeTrackPressState`, specifying what in the scroll bar is currently pressed. See "Theme Track Press States" (page 187) for descriptions of possible values. Pass 0 if nothing is currently pressed.

Discussion
Your application uses the `ScrollBarTrackInfo` structure in the `ThemeTrackDrawInfo` (page 116) structure.

Version Notes
The `ScrollBarTrackInfo` structure is available with Appearance Manager 1.1 and later.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Appearance.h`

SliderTrackInfo

Describes the slider-specific features of a given track control.

```
struct SliderTrackInfo {
    ThemeThumbDirection thumbDir;
    ThemeTrackPressState pressState;
};
typedef struct SliderTrackInfo SliderTrackInfo;
```

Fields

`thumbDir`

A value of type `ThemeThumbDirection`, specifying the direction in which the slider indicator points. See "Theme Thumb Directions" (page 181) for descriptions of possible values.

`pressState`

A value of type `ThemeTrackPressState`, specifying the part of the slider that is currently pressed. See "Theme Track Press States" (page 187) for descriptions of possible values. Pass 0 if nothing is currently pressed.

Discussion

Your application supplies a `SliderTrackInfo` structure to the `ThemeTrackDrawInfo` (page 116) structure.

Version Notes

The `SliderTrackInfo` structure is available with Appearance Manager 1.1 and later.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Appearance.h`

ThemeButtonDrawInfo

Describes the changeable visual characteristics of a button.

```
struct ThemeButtonDrawInfo {
    ThemeDrawState state;
    ThemeButtonValue value;
    ThemeButtonAdornment adornment;
};
typedef struct ThemeButtonDrawInfo ThemeButtonDrawInfo;
```

Fields

`state`

A value of type `ThemeDrawState`, specifying the state of the button, such as whether it is active, inactive, or pressed. See "Theme Drawing States" (page 126) for descriptions of possible values.

`value`

A value of type `ThemeButtonValue`, specifying the value of the button, such as, in the case of checkbox, whether it is drawn as on, off, or mixed. See "Theme Button Values" (page 159) for descriptions of possible values.

`adornment`

A value of type `ThemeButtonAdornment`, specifying any supplementary characteristics of the button, such as whether it is drawn with a focus ring. See "Theme Button Adornments" (page 156) for descriptions of possible values.

Discussion
Your application can use a `ThemeButtonDrawInfo` structure, together with a constant of type `ThemeButtonKind`, to fully describe the visual characteristics of a given button type at a given point in time. See "Theme Buttons" (page 153) for a description of `ThemeButtonKind` values.

Your application uses the `ThemeButtonDrawInfo` structure in the function `DrawThemeButton` (page 31) to draw a theme-compliant button and in the functions `GetThemeButtonRegion` (page 63) and `GetThemeButtonContentBounds` (page 62) to obtain information about a specific button type.

Version Notes
The `ThemeButtonDrawInfo` structure is available with Appearance Manager 1.1 and later.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Appearance.h`

ThemeTrackDrawInfo

Describes a track control.

```
struct ThemeTrackDrawInfo {
    ThemeTrackKind kind
    Rect bounds
    SInt32 min
    SInt32 max
    SInt32 value
    UInt32 reserved
    ThemeTrackAttributes attributes
    ThemeTrackEnableState enableState
    UInt8 filler1
    union {
        ScrollBarTrackInfo scrollbar;
        SliderTrackInfo slider;
        ProgressTrackInfo progress;
    } trackInfo;
};
typedef struct ThemeTrackDrawInfo ThemeTrackDrawInfo;
```

Fields

`kind`
A value of type `ThemeTrackKind`, specifying the type of track to be drawn. See "Theme Track Kinds" (page 186) for descriptions of possible values.

`bounds`
A structure of type `Rect` specifying the dimensions and position of the track, in local coordinates.

`min`
A signed 32-bit integer specifying the minimum value for the track.

`max`
A signed 32-bit integer specifying the maximum value for the track.

`value`
A signed 32-bit integer specifying the current value for the track.

`reserved`
Reserved.

`attributes`
A value of type `ThemeTrackAttributes` specifying additional attributes of the track, such as whether the track has an indicator. See "Theme Track Attributes" (page 184) for descriptions of possible values.

`enableState`
A value of type `ThemeTrackEnableState` specifying the current state of the track control; see "Theme Track States" (page 185) for descriptions of possible values.

`filler1`

`trackInfo`
A union of the `ScrollBarTrackInfo`, `SliderTrackInfo`, and `ProgressTrackInfo` structures. Your application fills in the structure that is appropriate for the kind of track with which you are working. See `ScrollBarTrackInfo` (page 114), `SliderTrackInfo` (page 114), and `ProgressTrackInfo` (page 113) for details on these structures.

Discussion
Your application fills out the applicable fields of a `ThemeTrackDrawInfo` structure to fully describe any given track control.

Version Notes
The `ThemeTrackDrawInfo` structure is available with Appearance Manager 1.1 and later.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Appearance.h`

ThemeWindowMetrics

Describes the dimensions of the parts of a window.

```
struct ThemeWindowMetrics {
    UInt16 metricSize;
    SInt16 titleHeight;
    SInt16 titleWidth;
    SInt16 popupTabOffset;
    SInt16 popupTabWidth;
    UInt16 popupTabPosition;
};
typedef struct ThemeWindowMetrics ThemeWindowMetrics;
```

Fields
`metricSize`
A value specifying the size of the `ThemeWindowMetrics` structure.

`titleHeight`
A measurement in pixels of the height of the title text in the current system font, including any icon that may be present in the title region. Set this field to 0 if the window does not contain a title.

`titleWidth`
A measurement in pixels of the width of the title text in the current system font, including any icon that may be present in the title region. Set this field to 0 if the window does not contain a title.

`popupTabOffset`
: A measurement in pixels of the distance that the left edge of a pop-up window's tab is offset from the left edge of the window. This value is used in conjunction with the value passed in the `popupTabPosition` field to determine the actual position of the tab. Set this field to 0 if the window is not a pop-up window.

`popupTabWidth`
: A measurement in pixels of the width of a pop-up window's tab. Set this field to 0 if the window is not a pop-up window.

`popupTabPosition`
: A value specifying the rule to apply when positioning a pop-up window's tab. Set this field to 0 if the window is not a pop-up window. See "Pop-up Window Tab Positions" (page 193) for the values you can use in this field.

Discussion
Your application uses the `ThemeWindowMetrics` structure to inform the Appearance Manager of the dimensions of specific parts of your window.

Version Notes
The `ThemeWindowMetrics` structure is available with Appearance Manager 1.1 and later.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Appearance.h`

ThemeDrawingState

Defines a reference to a private structure containing information about the current state of a graphics port.

```
typedef struct OpaqueThemeDrawingState * ThemeDrawingState;
```

Discussion
You can use the `ThemeDrawingState` type with the function `GetThemeDrawingState` (page 65) to obtain the current graphics port's drawing state and with the function `SetThemeDrawingState` (page 99) to restore a port's drawing state. You should dispose of the memory allocated to contain a `ThemeDrawingState` reference by calling `DisposeThemeDrawingState` (page 29) or passing a value of `true` in the `inDisposeNow` parameter of `SetThemeDrawingState`.

Version Notes
The `ThemeDrawingState` type is available with Appearance Manager 1.1 and later.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Appearance.h`

MenuItemDrawingUPP

Defines a universal procedure pointer (UPP) to a menu item drawing function.

```
typedef MenuItemDrawingProcPtr MenuItemDrawingUPP;
```

Discussion
See `MenuItemDrawingProcPtr` (page 104) for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Appearance.h`

MenuTitleDrawingUPP

Defines a universal procedure pointer (UPP) to a menu title drawing function.

```
typedef MenuTitleDrawingProcPtr MenuTitleDrawingUPP;
```

Discussion
See `MenuTitleDrawingProcPtr` (page 105) for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Appearance.h`

ThemeButtonDrawUPP

Defines a universal procedure pointer (UPP) to a button drawing function.

```
typedef ThemeButtonDrawProcPtr ThemeButtonDrawUPP;
```

Discussion
See `ThemeButtonDrawProcPtr` (page 107) for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Appearance.h`

ThemeEraseUPP

Defines a universal procedure pointer (UPP) to a background drawing callback function.

```
typedef ThemeEraseProcPtr ThemeEraseUPP;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Appearance.h`

ThemeIteratorUPP

Defines a universal procedure pointer (UPP) to a theme iteration callback function.

```
typedef ThemeIteratorProcPtr ThemeIteratorUPP;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Appearance.h`

ThemeTabTitleDrawUPP

Defines a universal procedure pointer (UPP) to a tab title drawing function.

```
typedef ThemeTabTitleDrawProcPtr ThemeTabTitleDrawUPP;
```

Discussion
See `ThemeTabTitleDrawProcPtr` (page 111) for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Appearance.h`

WindowTitleDrawingUPP

Defines a universal procedure pointer (UPP) to a window title drawing function.

```
typedef WindowTitleDrawingProcPtr WindowTitleDrawingUPP;
```

Discussion
See `WindowTitleDrawingProcPtr` (page 112) for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Appearance.h`

Constants

Appearance Manager Apple Events

Identify Apple events sent to Appearance Manager clients when a change occurs in the current appearance.

```
enum {
    kAppearanceEventClass = 'appr',
    kAEAppearanceChanged = 'thme',
    kAESystemFontChanged = 'sysf',
    kAESmallSystemFontChanged = 'ssfn',
    kAEViewsFontChanged = 'vfnt'
};
```

Constants

`kAppearanceEventClass`
The event class of Appearance Manager Apple events.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kAEAppearanceChanged`
The ID of the event indicating the current appearance has changed.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kAESystemFontChanged`
The ID of the event indicating the current system font has changed.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kAESmallSystemFontChanged`
The ID of the event indicating the current small system font has changed.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kAEViewsFontChanged`
The ID of the event indicating the current views font has changed.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

Discussion

When the user changes the current appearance (that is, when a theme switch occurs), the Appearance Manager may send any of these Apple events to all running applications that are high-level event aware and which are registered as clients of the Appearance Manager. Your application registers itself with the Appearance Manager by calling the function `RegisterAppearanceClient` (page 95).

Because typical results of a theme switch might include a change in menu bar height or window structure dimensions, as well as changes to the system fonts, colors, and patterns that are currently in use, applications should listen for and respond to the Appearance Manager Apple events under most circumstances. Note that none of the Appearance Manager Apple events have parameters and that the return value for each is ignored.

Appearance Manager File Types

Identify the various Appearance Manager file types.

```
enum {
    kThemeDataFileType = 'thme',
    kThemePlatinumFileType = 'pltn',
    kThemeCustomThemesFileType = 'scen',
    kThemeSoundTrackFileType = 'tsnd'
};
```

Constants

`kThemeDataFileType`
The file type of appearances other than the platinum appearance.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemePlatinumFileType`
The file type of the platinum appearance.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeCustomThemesFileType`
The file type of a file that contains user-defined themes. See `SetTheme` (page 97) for a discussion of defining your own theme.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

Theme Collection Tags

Identify items in a collection describing a theme.

```
enum {
    kThemeNameTag = 'name',
    kThemeVariantNameTag = 'varn',
    kThemeVariantBaseTintTag = 'tint',
    kThemeHighlightColorTag = 'hcol',
    kThemeScrollBarArrowStyleTag = 'sbar',
    kThemeScrollBarThumbStyleTag = 'sbth',
    kThemeSoundsEnabledTag = 'snds',
    kThemeDblClickCollapseTag = 'coll'
    kThemeAppearanceFileNameTag = 'thme',
    kThemeSystemFontTag = 'lgsf',
    kThemeSmallSystemFontTag = 'smsf',
    kThemeViewsFontTag = 'vfnt',
    kThemeViewsFontSizeTag = 'vfsz',
    kThemeDesktopPatternNameTag = 'patn',
    kThemeDesktopPatternTag = 'patt',
    kThemeDesktopPictureNameTag = 'dpnm',
    kThemeDesktopPictureAliasTag = 'dpal',
    kThemeDesktopPictureAlignmentTag = 'dpan',
    kThemeHighlightColorNameTag = 'hcnm',
    kThemeExamplePictureIDTag = 'epic',
    kThemeSoundTrackNameTag = 'sndt',
    kThemeSoundMaskTag = 'smsk',
    kThemeUserDefinedTag = 'user',
    kThemeSmoothFontEnabledTag = 'smoo',
    kThemeSmoothFontMinSizeTag = 'smos'
};
```

Constants

`kThemeNameTag`

Identifies a collection item containing the name of the theme, e.g. "Mac OS Default". The Appearance Manager only uses this collection item to identify themes within the Appearance control panel, so the `GetTheme` function does not return this collection item. To specify a theme name, you must create a new collection item of this type before calling the function `SetTheme`.

Collection data type: `Str255`

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeVariantNameTag`

Identifies a collection item containing the color variation used for menus and controls in the theme.

Collection data type: `Str255`

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeHighlightColorTag`

Identifies a collection item containing the text highlight color for the theme.

Collection data type: an `RGBColor` structure

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeScrollBarArrowStyleTag`
Identifies a collection item containing a value of type `ThemeScrollBarArrowStyle` identifying the type of scroll bar arrows used in the theme.

Collection data type: `ThemeScrollBarArrowStyle`

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeScrollBarThumbStyleTag`
Identifies a collection item containing a value of type `ThemeScrollBarThumbStyle` identifying the type of scroll boxes used in the theme.

Collection data type: `ThemeScrollBarThumbStyle`

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundsEnabledTag`
Identifies a collection item specifying whether theme sounds are enabled for the theme.

Collection data type: `Boolean`

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeDblClickCollapseTag`
Identifies a collection item specifying whether the ability to double-click to collapse a window is enabled for the theme.

Collection data type: `Boolean`

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeAppearanceFileNameTag`
Identifies a collection item containing the name of the appearance, e.g. "Apple platinum".

Collection data type: `Str255`

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSystemFontTag`
Identifies a collection item containing the name of the large system font for the theme.

Collection data type: `Str255`

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSmallSystemFontTag`
Identifies a collection item containing the name of the small system font for the theme.

Collection data type: `Str255`

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeViewsFontTag`
Identifies a collection item containing the name of the views font for the theme.

Collection data type: `Str255`

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeViewsFontSizeTag`
Identifies a collection item containing the size of the views font for the theme.
Collection data type: `SInt16`
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeDesktopPatternNameTag`
Identifies a collection item containing the name of the desktop pattern for the theme.
Collection data type: `Str255`
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeDesktopPatternTag`
Identifies a collection item containing a flattened version of the desktop pattern for the theme.
Collection data type: variable-length data
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeDesktopPictureNameTag`
Identifies a collection item containing the name of the desktop picture for the theme.
Collection data type: `Str255`
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeDesktopPictureAliasTag`
Identifies a collection item containing an alias handle for the desktop picture for the theme.
Collection data type: `AliasHandle`
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeDesktopPictureAlignmentTag`
Identifies a collection item containing a value specifying how to position the desktop picture for the theme. Possible values are described in "Desktop Picture Alignments" (page 212).
Collection data type: `UInt32`
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeHighlightColorNameTag`
Identifies a collection item containing the name of the text highlight color for the theme.
Collection data type: `Str255`
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeExamplePictureIDTag`
Identifies a collection item containing the ID of the example picture for the theme.
Collection data type: `SInt16`
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeSoundTrackNameTag`
: Identifies a collection item containing the name of the soundtrack for the theme.

  Collection data type: `Str255`

  Available in Mac OS X v10.0 and later.

  Declared in `Appearance.h`.

`kThemeSoundMaskTag`
: Identifies a collection item containing an unsigned 32-bit integer whose bits are set to reflect the classes of sounds that are enabled for a theme. Possibilities include sounds for menus, windows, controls, and the Finder. See "Theme Sound Masks" (page 193) for descriptions of possible sound mask values.

  Collection data type: `UInt32`

  Available in Mac OS X v10.0 and later.

  Declared in `Appearance.h`.

`kThemeUserDefinedTag`
: Identifies a collection item specifying whether the theme is user-defined; the value contained in a `kThemeUserDefinedTag` collection should always be `true` if the `kThemeUserDefinedTag` collection is present. The Appearance Manager uses this collection item to identify themes that the user can delete. Note that the `GetTheme` function does not return this collection item.

  Collection data type: `Boolean`

  Available in Mac OS X v10.0 and later.

  Declared in `Appearance.h`.

`kThemeSmoothFontEnabledTag`
: Identifies a collection item specifying whether font smoothing is enabled in the theme.

  Collection data type: `Boolean`

  Available in Mac OS X v10.0 and later.

  Declared in `Appearance.h`.

`kThemeSmoothFontMinSizeTag`
: Identifies a collection item containing the minimum point size at which font smoothing may be enabled in the theme. Possible values range from 12 to 24, inclusive.

  Collection data type: `UInt16`

  Available in Mac OS X v10.0 and later.

  Declared in `Appearance.h`.

Discussion
Your application may use these collection tags with the functions `SetTheme` (page 97) and `GetTheme` (page 59) to access aspects of a theme. The data type contained in each of the collection items accessed is noted below.

Theme Drawing States

Specify the state in which human interface elements are drawn.

```
enum {
    kThemeStateInactive = 0,
    kThemeStateActive = 1,
    kThemeStatePressed = 2,
    kThemeStateRollover = 6,
    kThemeStateUnavailable = 7,
    kThemeStateUnavailableInactive = 8,
    kThemeStatePressedUp = 2,
    kThemeStatePressedDown = 3
};
typedef UInt32 ThemeDrawState;
```

Constants

`kThemeStateInactive`
The drawing state of elements in an inactive window.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeStateActive`
The drawing state of elements in an active window.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeStatePressed`
The drawing state of elements in which a mouse click is occurring.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeStateRollover`
The drawing state of elements over which the mouse is positioned.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeStateUnavailable`
The drawing state of elements that are disabled. This state is used to indicate that an element cannot be clicked.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeStateUnavailableInactive`
The drawing state of elements that are disabled and are not in the currently active window.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeStatePressedUp`
For stepper controls, the drawing state of the increment button in which a mouse click is occurring.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeStatePressedDown`
For stepper controls, the drawing state of the decrement button in which a mouse click is occurring.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

Theme Metrics

Specify metric properties of user interface elements in the current environment.

```
typedef UInt32 ThemeMetric;
enum {
    kThemeMetricScrollBarWidth = 0,
    kThemeMetricSmallScrollBarWidth = 1,
    kThemeMetricCheckBoxHeight = 2,
    kThemeMetricRadioButtonHeight = 3,

    kThemeMetricTexturedSmallPushButtonHeight = 140
};
```

Constants

`kThemeMetricScrollBarWidth`

The width of a scroll bar. For horizontal scroll bars, this measurement is actually the scroll bar height.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeMetricSmallScrollBarWidth`

The width of a small scroll bar. For horizontal scroll bars, this measurement is actually the scroll bar height.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeMetricCheckBoxHeight`

The height of the non-label part of a check box control.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeMetricRadioButtonHeight`
The height of the non-label part of a radio button control.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeMetricEditTextWhitespace`
The amount of white space surrounding the text rectangle of the text inside of an Edit Text control. If you select all of the text in an Edit Text control, this white space is visible. The metric is the number of pixels, per side, that the text rectangle is outset to create the whitespace rectangle.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeMetricEditTextFrameOutset`
The thickness of the Edit Text frame that surrounds the whitespace rectangle (which surrounds the text rectangle). The metric is the number of pixels, per side, that the frame rectangle is outset from the whitespace rectangle.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeMetricListBoxFrameOutset`
The number of pixels that the list box frame is outset from the content of the list box.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeMetricFocusRectOutset`
This is a deprecated metric and you should not use it. This metric describes how far from a control the focus rectangle was drawn, but control focus drawing no longer uses this information.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeMetricImageWellThickness`
The thickness of the frame drawn by `DrawThemeGenericWell`.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeMetricScrollBarOverlap`
The number of pixels a scrollbar should overlap any bounding box which surrounds it and scrollable content. This also includes the window frame when a scrollbar is along an edge of the window.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeMetricLargeTabHeight`
The height of the large tab of a tab control.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeMetricLargeTabCapsWidth`
The width of the caps, or end pieces, of the large tabs of a tab control.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeMetricTabFrameOverlap`
The amount you must add to the tab height, `kThemeMetricLargeTabHeight`, to find the rectangle height to use with the various tab drawing primitives. This amount is also the amount that each tab overlaps the tab pane.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeMetricTabIndentOrStyle`
If less than zero, this indicates that the text should be centered on each tab. If greater than zero, the text should be justified, according to the system script direction, and the amount is the offset from the edge at which the text should start drawing.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeMetricTabOverlap`
The amount of space that every tab's drawing rectangle overlapsthat of the tab on either side of it.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeMetricSmallTabHeight`
The height of the small tab of a tab control. This includes the pixels that overlap the tab pane and/or tab pane bar.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeMetricSmallTabCapsWidth`
The width of the caps, or end pieces, of the small tabs of a tab control.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeMetricPushButtonHeight`
The height and the width of the push button control.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeMetricListHeaderHeight`
The height of the list header field of the data browser control.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeMetricDisclosureTriangleHeight`
The height of a disclosure triangle control. This triangle is the not the center of the disclosure button, but its own control.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeMetricDisclosureTriangleWidth`
The width of a disclosure triangle control.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeMetricLittleArrowsHeight`
The height of a little arrows control.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeMetricLittleArrowsWidth`
The width of a little arrows control.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeMetricPopupButtonHeight`
The height of a popup button control.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeMetricSmallPopupButtonHeight`
The height of a small popup button control.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeMetricLargeProgressBarThickness`
The height of the large progress bar, not including its shadow.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeMetricPullDownHeight`
This metric is not used.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeMetricSmallPullDownHeight`
This metric is not used.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeMetricResizeControlHeight`
The height of the window grow box control.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeMetricSmallResizeControlHeight`
The width of the window grow box control.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeMetricHSliderHeight`
The height of the horizontal slider control.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeMetricHSliderTickHeight`
The height of the tick marks for a horizontal slider control.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeMetricVSliderWidth`
The width of the vertical slider control.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeMetricVSliderTickWidth`
The width of the tick marks for a vertical slider control.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeMetricTitleBarControlsHeight`
The height of the title bar widgets (grow, close, and zoom boxes) for a document window.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeMetricCheckBoxWidth`
The width of the non-label part of a check box control.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeMetricRadioButtonWidth`
The width of the non-label part of a radio button control.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeMetricNormalProgressBarThickness`
The height of the normal progress bar, not including its shadow.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeMetricProgressBarShadowOutset`
The number of pixels of shadow depth drawn below the progress bar.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeMetricSmallProgressBarShadowOutset`
The number of pixels of shadow depth drawn below the small progress bar.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeMetricPrimaryGroupBoxContentInset`
The number of pixels that the content of a primary group box is inset from the bounds of the control.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeMetricSecondaryGroupBoxContentInset`
The number of pixels that the content of a secondary group box is from the bounds of the control.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeMetricMenuMarkColumnWidth`
The width allocated to draw the mark character in a menu.

Available in Mac OS X v10.1 and later.

Declared in `Appearance.h`.

`kThemeMetricMenuExcludedMarkColumnWidth`
The width allocated for the mark character in a menu item when the menu has the attribute `kMenuAttrExcludesMarkColumn`.

Available in Mac OS X v10.1 and later.

Declared in `Appearance.h`.

`kThemeMetricMenuMarkIndent`
The indent into the interior of the mark column at which the mark character is drawn.

Available in Mac OS X v10.1 and later.

Declared in `Appearance.h`.

`kThemeMetricMenuTextLeadingEdgeMargin`
The whitespace at the leading edge of menu item text.

Available in Mac OS X v10.1 and later.

Declared in `Appearance.h`.

`kThemeMetricMenuTextTrailingEdgeMargin`
The whitespace at the trailing edge of menu item text.

Available in Mac OS X v10.1 and later.

Declared in `Appearance.h`.

`kThemeMetricMenuIndentWidth`
The width per indent level of a menu item. This indent is set by the `SetMenuItemIndent` function.

Available in Mac OS X v10.1 and later.

Declared in `Appearance.h`.

`kThemeMetricMenuIconTrailingEdgeMargin`
The whitespace at the trailing edge of a menu icon, if the item also has text.

Available in Mac OS X v10.1 and later.

Declared in `Appearance.h`.

`kThemeMetricDisclosureButtonHeight`
The height of a disclosure button.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeMetricRoundButtonSize`
The height and the width of the round button control.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeMetricSmallCheckBoxHeight`
The height of the non-label part of a small check box control.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeMetricDisclosureButtonWidth`
The width of a disclosure button.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeMetricSmallDisclosureButtonHeight`
The height of a small disclosure button.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeMetricSmallDisclosureButtonWidth`
The width of a small disclosure button.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeMetricPaneSplitterHeight`
The height (or width if vertical) of a pane splitter.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeMetricSmallPushButtonHeight`
The height of the small push button control.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeMetricSmallRadioButtonHeight`
The height of the non-label part of a small radio button control.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeMetricRelevanceIndicatorHeight`
The height of the relevance indicator control.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeMetricLargeRoundButtonSize`
The height and the width of the large round button control.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeMetricSmallHSliderHeight`
The height of the small, horizontal slider control.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeMetricSmallHSliderTickHeight`
The height of the tick marks for a small, horizontal slider control.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeMetricSmallVSliderWidth`
The width of the small, vertical slider control.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeMetricSmallVSliderTickWidth`
The width of the tick marks for a small, vertical slider control.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeMetricSmallCheckBoxWidth`
The width of the non-label part of a small check box control.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeMetricSmallRadioButtonWidth`
The width of the non-label part of a small radio button control.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeMetricSmallHSliderMinThumbWidth`
The minimum width of the thumb of a small, horizontal slider control.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeMetricSmallVSliderMinThumbHeight`
The minimum width of the thumb of a small, vertical slider control.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeMetricSmallHSliderTickOffset`
The offset of the tick marks from the appropriate side of a small horizontal slider control.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeMetricSmallVSliderTickOffset`
The offset of the tick marks from the appropriate side of a small vertical slider control.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeMetricComboBoxLargeBottomShadowOffset`
Available in Mac OS X v10.3 and later.
Declared in `Appearance.h`.

`kThemeMetricComboBoxLargeRightShadowOffset`
Available in Mac OS X v10.3 and later.
Declared in `Appearance.h`.

`kThemeMetricComboBoxSmallBottomShadowOffset`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricComboBoxSmallRightShadowOffset`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricComboBoxLargeDisclosureWidth`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricComboBoxSmallDisclosureWidth`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricRoundTextFieldContentInsetLeft`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricRoundTextFieldContentInsetRight`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricRoundTextFieldContentInsetBottom`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricRoundTextFieldContentInsetTop`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricRoundTextFieldContentHeight`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricComboBoxMiniBottomShadowOffset`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricComboBoxMiniDisclosureWidth`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricComboBoxMiniRightShadowOffset`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricLittleArrowsMiniHeight`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricLittleArrowsMiniWidth`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricLittleArrowsSmallHeight`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricLittleArrowsSmallWidth`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricMiniCheckBoxHeight`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricMiniCheckBoxWidth`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricMiniDisclosureButtonHeight`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricMiniDisclosureButtonWidth`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricMiniHSliderHeight`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricMiniHSliderMinThumbWidth`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricMiniHSliderTickHeight`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricMiniHSliderTickOffset`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricMiniPopupButtonHeight`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricMiniPullDownHeight`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricMiniPushButtonHeight`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricMiniRadioButtonHeight`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricMiniRadioButtonWidth`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricMiniTabCapsWidth`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricMiniTabFrameOverlap`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricMiniTabHeight`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricMiniTabOverlap`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricMiniVSliderMinThumbHeight`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricMiniVSliderTickOffset`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricMiniVSliderTickWidth`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricMiniVSliderWidth`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricRoundTextFieldContentInsetWithIconLeft`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricRoundTextFieldContentInsetWithIconRight`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricRoundTextFieldMiniContentHeight`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricRoundTextFieldMiniContentInsetBottom`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricRoundTextFieldMiniContentInsetLeft`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricRoundTextFieldMiniContentInsetRight`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricRoundTextFieldMiniContentInsetTop`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricRoundTextFieldMiniContentInsetWithIconLeft`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricRoundTextFieldMiniContentInsetWithIconRight`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricRoundTextFieldSmallContentHeight`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricRoundTextFieldSmallContentInsetBottom`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricRoundTextFieldSmallContentInsetLeft`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricRoundTextFieldSmallContentInsetRight`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricRoundTextFieldSmallContentInsetTop`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricRoundTextFieldSmallContentInsetWithIconLeft`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricRoundTextFieldSmallContentInsetWithIconRight`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricSmallTabFrameOverlap`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricSmallTabOverlap`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricSmallPaneSplitterHeight`

The height of a small pane splitter. Should only be used in a window with thick borders, such as a textured window.

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeMetricHSliderTickOffset`

The horizontal start offset for the first tick mark on a horizontal slider.

Available in Mac OS X v10.4 and later.

Declared in `Appearance.h`.

`kThemeMetricVSliderTickOffset`

The vertical start offset for the first tick mark on a vertical slider.

Available in Mac OS X v10.4 and later.

Declared in `Appearance.h`.

`kThemeMetricSliderMinThumbHeight`

The minimum height for a thumb on a slider.

Available in Mac OS X v10.4 and later.

Declared in `Appearance.h`.

`kThemeMetricSliderMinThumbWidth`

The minimum width for a thumb on a slider.

Available in Mac OS X v10.4 and later.

Declared in `Appearance.h`.

`kThemeMetricScrollBarMinThumbHeight`

The minimum height for a thumb on a scroll bar.

Available in Mac OS X v10.4 and later.

Declared in `Appearance.h`.

`kThemeMetricScrollBarMinThumbWidth`

The minimum width for a thumb on a scroll bar.

Available in Mac OS X v10.4 and later.

Declared in `Appearance.h`.

`kThemeMetricSmallScrollBarMinThumbHeight`

The minimum height for a thumb on a small scroll bar.

Available in Mac OS X v10.4 and later.

Declared in `Appearance.h`.

`kThemeMetricSmallScrollBarMinThumbWidth`
The minimum width for a thumb on a small scroll bar.

Available in Mac OS X v10.4 and later.

Declared in `Appearance.h`.

`kThemeMetricButtonRoundedHeight`
The height of a round-ended button (for example, the Kind button in a Finder Search query.)

Available in Mac OS X v10.5 and later.

Declared in `Appearance.h`.

`kThemeMetricButtonRoundedRecessedHeight`
The height of the inset round-ended button (for example, the Servers button in a Finder Search query.)

Available in Mac OS X v10.5 and later.

Declared in `Appearance.h`.

`kThemeMetricSeparatorSize`
The height of a horizontal separator, or the width of a vertical separator, drawn with the `HIThemeDrawSeparator` theme primitive.

Available in Mac OS X v10.5 and later.

Declared in `Appearance.h`.

`kThemeMetricTexturedPushButtonHeight`
The height of the push button control designed for use in a textured window.

Available in Mac OS X v10.5 and later.

Declared in `Appearance.h`.

`kThemeMetricTexturedSmallPushButtonHeight`
The height of the small push button control designed for use in a textured window.

Available in Mac OS X v10.5 and later.

Declared in `Appearance.h`.

Theme Backgrounds

Identify theme-compliant backgrounds.

```
enum {
    kThemeBackgroundTabPane = 1,
    kThemeBackgroundPlacard = 2,
    kThemeBackgroundWindowHeader = 3,
    kThemeBackgroundListViewWindowHeader = 4,
    kThemeBackgroundSecondaryGroupBox = 5
};
typedef UInt32 ThemeBackgroundKind;
```

Constants

`kThemeBackgroundTabPane`
The background for a tab pane.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeBackgroundPlacard`
: The background for a placard.

  Available in Mac OS X v10.0 and later.

  Declared in `Appearance.h`.

`kThemeBackgroundWindowHeader`
: The background for a window header.

  Available in Mac OS X v10.0 and later.

  Declared in `Appearance.h`.

`kThemeBackgroundListViewWindowHeader`
: The background for a window list view header.

  Available in Mac OS X v10.0 and later.

  Declared in `Appearance.h`.

Discussion
You can pass a constant of type `ThemeBackgroundKind` to the function `ApplyThemeBackground` (page 26) to specify that an embedded object have a background consistent with the current theme and object in which it is visually embedded.

Theme Brushes

Specify theme-compliant colors and patterns for particular human interface elements.

```
enum {
    kThemeBrushDialogBackgroundActive = 1,
    kThemeBrushDialogBackgroundInactive = 2,
    kThemeBrushAlertBackgroundActive = 3,
    kThemeBrushAlertBackgroundInactive = 4,
    kThemeBrushModelessDialogBackgroundActive = 5,
    kThemeBrushModelessDialogBackgroundInactive = 6,
    kThemeBrushUtilityWindowBackgroundActive = 7,
    kThemeBrushUtilityWindowBackgroundInactive = 8,
    kThemeBrushListViewSortColumnBackground = 9,
    kThemeBrushListViewBackground = 10,
    kThemeBrushIconLabelBackground = 11,
    kThemeBrushListViewSeparator = 12,
    kThemeBrushChasingArrows = 13,
    kThemeBrushDragHilite = 14,
    kThemeBrushDocumentWindowBackground = 15,
    kThemeBrushFinderWindowBackground = 16,
    kThemeBrushScrollBarDelimiterActive = 17,
    kThemeBrushScrollBarDelimiterInactive = 18,
    kThemeBrushFocusHighlight = 19,
    kThemeBrushPopupArrowActive = 20,
    kThemeBrushPopupArrowPressed = 21,
    kThemeBrushPopupArrowInactive = 22,
    kThemeBrushAppleGuideCoachmark = 23,
    kThemeBrushIconLabelBackgroundSelected = 24,
    kThemeBrushStaticAreaFill = 25,
    kThemeBrushActiveAreaFill = 26,
    kThemeBrushButtonFrameActive = 27,
    kThemeBrushButtonFrameInactive = 28,
    kThemeBrushButtonFaceActive = 29,
    kThemeBrushButtonFaceInactive = 30,
    kThemeBrushButtonFacePressed = 31,
    kThemeBrushButtonActiveDarkShadow = 32,
    kThemeBrushButtonActiveDarkHighlight = 33,
    kThemeBrushButtonActiveLightShadow = 34,
    kThemeBrushButtonActiveLightHighlight = 35,
    kThemeBrushButtonInactiveDarkShadow = 36,
    kThemeBrushButtonInactiveDarkHighlight = 37,
    kThemeBrushButtonInactiveLightShadow = 38,
    kThemeBrushButtonInactiveLightHighlight = 39,
    kThemeBrushButtonPressedDarkShadow = 40,
    kThemeBrushButtonPressedDarkHighlight = 41,
    kThemeBrushButtonPressedLightShadow = 42,
    kThemeBrushButtonPressedLightHighlight = 43,
    kThemeBrushBevelActiveLight = 44,
    kThemeBrushBevelActiveDark = 45,
    kThemeBrushBevelInactiveLight = 46,
    kThemeBrushBevelInactiveDark = 47,
    kThemeBrushNotificationWindowBackground = 48,
    kThemeBrushMovableModalBackground = 49,
    kThemeBrushSheetBackgroundOpaque = 50,
    kThemeBrushDrawerBackground = 51,
    kThemeBrushToolbarBackground = 52,
    kThemeBrushSheetBackgroundTransparent = 53,
    kThemeBrushMenuBackground = 54,
    kThemeBrushMenuBackgroundSelected = 55,
    kThemeBrushListViewOddRowBackground = 56,
    kThemeBrushListViewEvenRowBackground = 57,
```

```
    kThemeBrushListViewColumnDivider = 58,
    kThemeBrushSheetBackground = kThemeBrushSheetBackgroundOpaque,
    kThemeBrushBlack = -1,
    kThemeBrushWhite = -2,
    kThemeBrushPrimaryHighlightColor = -3,
    kThemeBrushSecondaryHighlightColor = -4,
    kThemeBrushAlternatePrimaryHighlightColor = -5
};
typedef SInt16 ThemeBrush;
```

Constants

`kThemeBrushDialogBackgroundActive`
An active dialog box's background color or pattern.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeBrushDialogBackgroundInactive`
An inactive dialog box's background color or pattern.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeBrushAlertBackgroundActive`
An active alert box's background color or pattern.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeBrushAlertBackgroundInactive`
An inactive alert box's background color or pattern.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeBrushModelessDialogBackgroundActive`
An active modeless dialog box's background color or pattern.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeBrushModelessDialogBackgroundInactive`
An inactive modeless dialog box's background color or pattern.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeBrushUtilityWindowBackgroundActive`
An active utility window's background color or pattern.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeBrushUtilityWindowBackgroundInactive`
An inactive utility window's background color or pattern.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeBrushListViewSortColumnBackground`
The background color or pattern of the list view column that is being sorted upon.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeBrushListViewBackground`
The background color or pattern of a list view column that is not being sorted upon.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeBrushIconLabelBackground`
An icon label's color or pattern.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeBrushListViewSeparator`
The color or pattern of the horizontal lines that separate rows of items in list view columns.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeBrushChasingArrows`
Asynchronous arrows' color or pattern.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeBrushDragHilite`
The color or pattern used to indicate that an element is a valid drag-and-drop destination

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeBrushDocumentWindowBackground`
A document window's background color or pattern.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeBrushFinderWindowBackground`
A Finder window's background color or pattern. Generally, you should not use this constant unless you are trying to create a window that matches a Finder window.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeBrushScrollBarDelimiterActive`
The color or pattern used to outline the sides of an active scroll bar.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeBrushScrollBarDelimiterInactive`
The color or pattern used to outline the sides of an inactive scroll bar.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeBrushFocusHighlight`
The color or pattern of the focus ring around an element that is selected.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeBrushPopupArrowActive`
The color or pattern of the arrow on an active pop-up menu button.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeBrushPopupArrowPressed`
The color or pattern of the arrow on a pop-up menu button that is being clicked on by the user.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeBrushPopupArrowInactive`
The color or pattern of the arrow on an inactive pop-up menu button.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeBrushAppleGuideCoachmark`
The color or pattern of an Apple Guide coachmark.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeBrushIconLabelBackgroundSelected`
The color or pattern of the background of an icon's label area, when the icon is selected.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeBrushStaticAreaFill`
The background color or pattern of an element that does not support user interaction.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeBrushActiveAreaFill`
The color or pattern of an element that supports user interaction.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeBrushButtonFrameActive`
The color or pattern that outlines an active button. Your application should draw the button outline outside the edge of the button.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeBrushButtonFrameInactive`
The color or pattern that outlines an inactive button. Your application should draw the button outline outside the edge of the button.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeBrushButtonFaceActive`
The color or pattern of the face of an active button.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeBrushButtonFaceInactive`
The color or pattern of the face of an inactive button.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeBrushButtonFacePressed`
The color or pattern of the face of a button that is being clicked on by the user.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeBrushButtonActiveDarkShadow`
For an active button with a 2-pixel-wide edge, the color or pattern of the bottom and right sides of the outer ring of the edge.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeBrushButtonActiveDarkHighlight`
For an active button with a 2-pixel-wide edge, the color or pattern of the top and left sides of the outer ring of the edge.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeBrushButtonActiveLightShadow`
For an active button with a 2-pixel-wide edge, the color or pattern of the bottom and right sides of the inner ring of the edge. For an active button with a 1-pixel-wide edge, the color or pattern of the bottom and right sides of the edge.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeBrushButtonActiveLightHighlight`
For an active button with a 2-pixel-wide edge, the color or pattern of the top and left sides of the inner ring of the edge. For an active button with a 1-pixel-wide edge, the color or pattern of the top and left sides of the edge.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeBrushButtonInactiveDarkShadow`
For an inactive button with a 2-pixel-wide edge, the color or pattern of the bottom and right sides of the outer ring of the edge.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeBrushButtonInactiveDarkHighlight`
For an inactive button with a 2-pixel-wide edge, the color or pattern of the top and left sides of the outer ring of the edge.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeBrushButtonInactiveLightShadow`
: For an inactive button with a 2-pixel-wide edge, the color or pattern of the bottom and right sides of the inner ring of the edge. For an inactive button with a 1-pixel-wide edge, the color or pattern of the bottom and right sides of the edge.

  Available in Mac OS X v10.0 and later.

  Declared in `Appearance.h`.

`kThemeBrushButtonInactiveLightHighlight`
: For an inactive button with a 2-pixel-wide edge, the color or pattern of the top and left sides of the inner ring of the edge. For an inactive button with a 1-pixel-wide edge, the color or pattern of the top and left sides of the edge.

  Available in Mac OS X v10.0 and later.

  Declared in `Appearance.h`.

`kThemeBrushButtonPressedDarkShadow`
: For a button with a 2-pixel-wide edge that is being clicked on by the user, the color or pattern of the bottom and right sides of the outer ring of the edge.

  Available in Mac OS X v10.0 and later.

  Declared in `Appearance.h`.

`kThemeBrushButtonPressedDarkHighlight`
: For a button with a 2-pixel-wide edge that is being clicked on by the user, the color or pattern of the top and left sides of the outer ring of the edge.

  Available in Mac OS X v10.0 and later.

  Declared in `Appearance.h`.

`kThemeBrushButtonPressedLightShadow`
: For a button with a 2-pixel-wide edge that is being clicked on by the user, the color or pattern of the bottom and right sides of the inner ring of the edge. For a button with a 1-pixel-wide edge that is being clicked on by the user, the color or pattern of the bottom and right sides of the edge.

  Available in Mac OS X v10.0 and later.

  Declared in `Appearance.h`.

`kThemeBrushButtonPressedLightHighlight`
: For a button with a 2-pixel-wide edge that is being clicked on by the user, the color or pattern of the top and left sides of the inner ring of the edge. For a button with a 1-pixel-wide edge that is being clicked on by the user, the color or pattern of the top and left sides of the edge.

  Available in Mac OS X v10.0 and later.

  Declared in `Appearance.h`.

`kThemeBrushBevelActiveLight`
: For an active bevel button, the color or pattern of the top and left sides of the bevel.

  Available in Mac OS X v10.0 and later.

  Declared in `Appearance.h`.

`kThemeBrushBevelActiveDark`
: For an active bevel button, the color or pattern of the bottom and right sides of the bevel.

  Available in Mac OS X v10.0 and later.

  Declared in `Appearance.h`.

`kThemeBrushBevelInactiveLight`

For an inactive bevel button, the color or pattern of the top and left sides of the bevel.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeBrushBevelInactiveDark`

For an inactive bevel button, the color or pattern of the bottom and right sides of the bevel.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeBrushNotificationWindowBackground`

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeBrushMovableModalBackground`

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeBrushSheetBackgroundOpaque`

Available in Mac OS X v10.1 and later.

Declared in `Appearance.h`.

`kThemeBrushDrawerBackground`

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeBrushToolbarBackground`

Available in Mac OS X v10.1 and later.

Declared in `Appearance.h`.

`kThemeBrushSheetBackgroundTransparent`

Available in Mac OS X v10.1 and later.

Declared in `Appearance.h`.

`kThemeBrushMenuBackground`

Available in Mac OS X v10.2 and later.

Declared in `Appearance.h`.

`kThemeBrushMenuBackgroundSelected`

Available in Mac OS X v10.2 and later.

Declared in `Appearance.h`.

`kThemeBrushListViewOddRowBackground`

Available in Mac OS X v10.4 and later.

Declared in `Appearance.h`.

`kThemeBrushListViewEvenRowBackground`

Available in Mac OS X v10.4 and later.

Declared in `Appearance.h`.

`kThemeBrushListViewColumnDivider`

Available in Mac OS X v10.4 and later.

Declared in `Appearance.h`.

`kThemeBrushSheetBackground`

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeBrushBlack`

Black; this color does not change from theme to theme. You may use this constant instead of specifying a direct RGB value.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeBrushWhite`

White; this color does not change from theme to theme. You may use this constant instead of specifying a direct RGB value.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeBrushPrimaryHighlightColor`

Available in Mac OS X v10.2 and later.

Declared in `Appearance.h`.

`kThemeBrushSecondaryHighlightColor`

Available in Mac OS X v10.2 and later.

Declared in `Appearance.h`.

`kThemeBrushAlternatePrimaryHighlightColor`

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

Discussion

The Appearance Manager provides the underlying support for RGB color data and overrides System 7 color tables such as `'cctb'` and `'mctb'` with an abstract mechanism that allows colors and patterns to be coordinated with the current theme. You can pass constants of type `ThemeBrush` in the `inBrush` parameter of `SetThemeBackground` (page 98), `SetThemePen` (page 100), and `SetThemeWindowBackground` (page 1933) to specify that the Appearance Manager substitute whatever the appropriate color or pattern is for a given human interface element in the current theme.

Theme Buttons

Identify types of buttons.

```
enum {
    kThemePushButton = 0,
    kThemeCheckBox = 1,
    kThemeRadioButton = 2,
    kThemeBevelButton = 3,
    kThemeArrowButton = 4,
    kThemePopupButton = 5,
    kThemeDisclosureButton = 6,
    kThemeIncDecButton = 7,
    kThemeSmallBevelButton = 8,
    kThemeMediumBevelButton = 3,
    kThemeLargeBevelButton = 9,
    kThemeListHeaderButton = 10,
    kThemeRoundButton = 11,
    kThemeLargeRoundButton = 12,
    kThemeSmallCheckBox = 13,
    kThemeSmallRadioButton = 14,
    kThemeRoundedBevelButton = 15,
    kThemeNormalCheckBox = 1,
    kThemeNormalRadioButton = 2
};
typedef UInt16 ThemeButtonKind;
```

Constants

`kThemePushButton`
Identifies a push button.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeCheckBox`
Identifies a checkbox.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeRadioButton`
Identifies a radio button.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeBevelButton`
Identifies a bevel button with a medium-width bevel; this value is the same as `kThemeMediumBevelButton`.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeArrowButton`
Identifies an arrow button. This button has the appearance of a single button containing small upward- and downward-pointing triangles drawn back to back; the typical use of this button is with an editable text field to create an editable pop-up menu. This button should not be confused with an increment/decrement button.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemePopupButton`
Identifies a pop-up menu button. This button has the appearance of a single button made of two parts: a menu item text part and an arrow part.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeDisclosureButton`
Identifies a disclosure triangle.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeIncDecButton`
Identifies an increment/decrement or "little arrows" button. This button has the appearance of two separate buttons—one containing an upward-pointing triangle and the other containing a downward-pointing triangle—placed back to back. This button should not be confused with the arrow button.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSmallBevelButton`
Identifies a bevel button with a small-width bevel.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeMediumBevelButton`
Identifies a bevel button with a medium-width bevel; this value is the same as `kThemeBevelButton`.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeLargeBevelButton`
Identifies a bevel button with a large-width bevel.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeListHeaderButton`
Identifies a sort button for the top of a list.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeRoundButton`
Identifies a round button.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeLargeRoundButton`
Identifies a large round button.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSmallCheckBox`
Identifies a small checkbox.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeSmallRadioButton`
Identifies a small radio button.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeRoundedBevelButton`
Identifies a rounded bevel button.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeNormalCheckBox`
Identifies a checkbox; this value is the same as `kThemeCheckBox`.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeNormalRadioButton`
Identifies a radio button; this value is the same as `kThemeRadioButton`.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

Discussion
You can pass constants of type `ThemeButtonKind` to the function `DrawThemeButton` (page 31) to draw a theme-compliant button of a specific type. You can also pass `ThemeButtonKind` constants to the functions `GetThemeButtonRegion` (page 63) and `GetThemeButtonContentBounds` (page 62) to retrieve information about a specific button type.

Theme Button Adornments

Specify the visual characteristics of a button control.

```
enum {
    kThemeAdornmentNone = 0,
    kThemeAdornmentDefault = (1 << 0),
    kThemeAdornmentFocus = (1 << 2),
    kThemeAdornmentRightToLeft = (1 << 4),
    kThemeAdornmentDrawIndicatorOnly = (1 << 5),
    kThemeAdornmentHeaderButtonLeftNeighborSelected = (1 <<
6),
    kThemeAdornmentHeaderButtonRightNeighborSelected = (1 <<
7),
    kThemeAdornmentHeaderButtonSortUp = (1 << 8),
    kThemeAdornmentHeaderMenuButton = (1 << 9),
    kThemeAdornmentHeaderButtonNoShadow = (1 << 10),
    kThemeAdornmentHeaderButtonShadowOnly = (1 << 11),
    kThemeAdornmentNoShadow = kThemeAdornmentHeaderButtonNoShadow,
    kThemeAdornmentShadowOnly = kThemeAdornmentHeaderButtonShadowOnly,
    kThemeAdornmentArrowLeftArrow = (1 << 6),
    kThemeAdornmentArrowDownArrow = (1 << 7),
    kThemeAdornmentArrowDoubleArrow = (1 << 8),
    kThemeAdornmentArrowUpArrow = (1 << 9)
};
typedef UInt16 ThemeButtonAdornment;
```

Constants

`kThemeAdornmentNone`

If no bits are set, the button is drawn with no adornment.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeAdornmentDefault`

If the bit specified by this mask is set, a default button ring is drawn. This constant applies to push button controls only.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeAdornmentFocus`

If the bit specified by this mask is set, a focus ring is drawn.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeAdornmentRightToLeft`

If the bit specified by this mask is set, the button is drawn in a right-to-left orientation.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeAdornmentDrawIndicatorOnly`

If the bit specified by this mask is set, only the button is drawn, not its label. This characteristic applies to radio buttons, checkboxes, and disclosure triangles.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeAdornmentHeaderButtonLeftNeighborSelected`
If the bit specified by this mask is set, the left border of the button is drawn as selected (list header button only).

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeAdornmentHeaderButtonRightNeighborSelected`
If the bit specified by this mask is set, the right border of the button is drawn as selected (list header button only).

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeAdornmentHeaderButtonSortUp`
If the bit specified by this mask is set the sort indicator is drawn pointing upward (list header button only).

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeAdornmentHeaderMenuButton`
If the bit specified by this mask is set, the button is drawn as a header menu button (list header button only).

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeAdornmentHeaderButtonNoShadow`
If the bit specified by this mask is set, the non-shadow area of the button is drawn (list header button only).

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeAdornmentHeaderButtonShadowOnly`
If the bit specified by this mask is set, only the shadow area of the button is drawn (list header button only).

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeAdornmentNoShadow`
Use `kThemeAdornmentHeaderButtonNoShadow` instead.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeAdornmentShadowOnly`
Use `kThemeAdornmentHeaderButtonShadowOnly` instead.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeAdornmentArrowLeftArrow`
If the bit specified by this mask is set, a left arrow is drawn on the arrow button.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeAdornmentArrowDownArrow`
If the bit specified by this mask is set, a down arrow is drawn on the arrow button.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeAdornmentArrowDoubleArrow`
If the bit specified by this mask is set, a double arrow is drawn on the arrow button.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeAdornmentArrowUpArrow`
If the bit specified by this mask is set, an up arrow is drawn on the arrow button.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

Discussion
The `ThemeButtonAdornment` enumeration defines masks your application can use in the `ThemeButtonDrawInfo` (page 115) structure to specify that button controls are drawn with the appropriate human interface characteristics.

Theme Button Values

Specify the value of a button.

```
enum {
    kThemeButtonOff = 0,
    kThemeButtonOn = 1,
    kThemeButtonMixed = 2,
    kThemeDisclosureRight = 0,
    kThemeDisclosureDown = 1,
    kThemeDisclosureLeft = 2
};
typedef UInt16 ThemeButtonValue;
```

Constants
`kThemeButtonOff`
Identifies a button that is not selected.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeButtonOn`
Identifies a button that is selected.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeButtonMixed`
Identifies a button that is in the mixed state, indicating that a setting is on for some elements in a selection and off for others. This value typically applies to checkboxes and radio buttons.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeDisclosureRight`
Identifies a disclosure triangle that is pointing to the right.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeDisclosureDown`
Identifies a disclosure triangle that is pointing down.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeDisclosureLeft`
Identifies a disclosure triangle that is pointing to the left.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

Discussion
You can use constants of type `ThemeButtonValue` in the `ThemeButtonDrawInfo` (page 115) structure to specify that button controls are drawn with the correct values.

Theme Pop-Up Arrow Orientations

Specify the direction in which a pop-up arrow is drawn on a button.

```
enum {
    kThemeArrowLeft = 0,
    kThemeArrowDown = 1,
    kThemeArrowRight = 2,
    kThemeArrowUp = 3
};
typedef UInt16 ThemeArrowOrientation;
```

Constants
`kThemeArrowLeft`
A left-pointing arrow.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeArrowDown`
A downward-pointing arrow.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeArrowRight`
A right-pointing arrow.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeArrowUp`
An upward-pointing arrow.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

Discussion
You can use a constant of type `ThemeArrowOrientation` in the function `DrawThemePopupArrow` (page 43).

Theme Pop-Up Arrow Sizes

Specify the size of the pop-up arrow that is drawn on a button.

```
enum {
    kThemeArrow3pt = 0,
    kThemeArrow5pt = 1,
    kThemeArrow7pt = 2,
    kThemeArrow9pt = 3
};
typedef UInt16 ThemePopupArrowSize;
```

Constants

`kThemeArrow3pt`
Identifies a pop-up arrow with a 3-pixel base.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeArrow5pt`
Identifies a pop-up arrow with a 5-pixel base.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeArrow7pt`
Identifies a pop-up arrow with a 7-pixel base.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeArrow9pt`
Identifies a pop-up arrow with a 9-pixel base.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

Discussion
You can use a constant of type `ThemePopupArrowSize` in the function `DrawThemePopupArrow` (page 43).

Theme Checkbox Styles

Specify types of checkbox marks.

```
enum {
    kThemeCheckBoxClassicX = 0,
    kThemeCheckBoxCheckMark = 1
};
typedef UInt16 ThemeCheckBoxStyle;
```

Constants

`kThemeCheckBoxClassicX`

An "X" type of checkbox mark.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeCheckBoxCheckMark`

A checkmark type of checkbox mark.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

Discussion

You can call the function `GetThemeCheckBoxStyle` (page 64) to obtain the type of checkbox mark being used in the current theme.

Theme Cursors

Identify types of cursors.

```
enum {
    kThemeArrowCursor = 0,
    kThemeCopyArrowCursor = 1,
    kThemeAliasArrowCursor = 2,
    kThemeContextualMenuArrowCursor = 3,
    kThemeIBeamCursor = 4,
    kThemeCrossCursor = 5,
    kThemePlusCursor = 6,
    kThemeWatchCursor = 7,
    kThemeClosedHandCursor = 8,
    kThemeOpenHandCursor = 9,
    kThemePointingHandCursor = 10,
    kThemeCountingUpHandCursor = 11,
    kThemeCountingDownHandCursor = 12,
    kThemeCountingUpAndDownHandCursor = 13,
    kThemeSpinningCursor = 14,
    kThemeResizeLeftCursor = 15,
    kThemeResizeRightCursor = 16,
    kThemeResizeLeftRightCursor = 17,
    kThemeNotAllowedCursor = 18,
    kThemeResizeUpCursor = 19,
    kThemeResizeDownCursor = 20,
    kThemeResizeUpDownCursor = 21,
    kThemePoofCursor = 22
};
typedef UInt32 ThemeCursor;
```

Constants

`kThemeArrowCursor`

The cursor identified by this constant is typically used as the standard cursor.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeCopyArrowCursor`

The cursor identified by this constant is typically used when the cursor is over a location where a drag action would initiate a copy.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeAliasArrowCursor`

The cursor identified by this constant is typically used when the cursor is over a location where a drag action would create an alias or link.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeContextualMenuArrowCursor`

The cursor identified by this constant is typically used when the Control key is being pressed and the cursor is over a location where a contextual menu can be activated.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeIBeamCursor`

The cursor identified by this constant is typically used when the cursor is over an area where the user can select text.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeCrossCursor`

The cursor identified by this constant is typically used when the cursor is over an area where the user can draw graphics.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemePlusCursor`

The cursor identified by this constant is typically used when the cursor is over an area where the user can select table cells.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeWatchCursor`

The cursor identified by this constant is typically used to indicate that an operation is in progress. You can animate this cursor so that a hand of the watch appears to move.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeClosedHandCursor`

The cursor identified by this constant is typically used to indicate that an object has been grabbed and is being moved by the user.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeOpenHandCursor`

The cursor identified by this constant is typically used to indicate that an object may be grabbed or moved by the user.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemePointingHandCursor`

The cursor identified by this constant has the appearance of a pointing hand. You would typically use this constant to indicate that the user may select an object by pressing the mouse button.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeCountingUpHandCursor`

The cursor identified by this constant is typically used to indicate that an operation is in progress. You can animate this cursor so that the fingers appear to open from the palm one by one.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeCountingDownHandCursor`
The cursor identified by this constant is typically used to indicate that an operation is in progress. You can animate this cursor so that the fingers appear to fold into the palm one by one.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeCountingUpAndDownHandCursor`
The cursor identified by this constant is typically used to indicate that an operation is in progress. You can animate this cursor so that the fingers appear to alternate between opening from the palm one by one and folding into the palm one by one.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSpinningCursor`
The cursor identified by this constant is typically used to indicate that an operation is in progress.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeResizeLeftCursor`
The cursor identified by this constant is typically used to indicate that an object may be resized by dragging to the left.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeResizeRightCursor`
The cursor identified by this constant is typically used to indicate that an object may be resized by dragging to the right.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeResizeLeftRightCursor`
The cursor identified by this constant is typically used to indicate that an object may be resized in either direction horizontally.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeNotAllowedCursor`
The cursor identified by this constant is typically used to indicate that the current action is not allowed. For example, you could use this cursor to indicate that an object being dragged cannot be dropped at the current mouse position.

Available in Mac OS X v10.2 and later.

Declared in `Appearance.h`.

`kThemeResizeUpCursor`
The cursor identified by this constant is typically used to indicate that an object may be resized by dragging vertically in the up direction.

Available in Mac OS X v10.3 and later.

Declared in `Appearance.h`.

`kThemeResizeDownCursor`
: The cursor identified by this constant is typically used to indicate that an object may be resized by dragging vertically in the down direction.

  Available in Mac OS X v10.3 and later.

  Declared in `Appearance.h`.

`kThemeResizeUpDownCursor`
: The cursor identified by this constant is typically used to indicate that an object may be resized by dragging vertically in either direction.

  Available in Mac OS X v10.3 and later.

  Declared in `Appearance.h`.

`kThemePoofCursor`
: The cursor identified by this constant is typically used to indicate that a dragged object will go away if it is released at the current mouse position. When the object goes away, a poof cloud animation should occur.

  Available in Mac OS X v10.3 and later.

  Declared in `Appearance.h`.

Discussion
You can pass constants of type `ThemeCursor` to the functions `SetThemeCursor` (page 98) and `SetAnimatedThemeCursor` (page 96) to specify the category of cursor to be displayed for your application. The Appearance Manager substitutes the theme-specific instance of the cursor for the cursor category as is appropriate.

Theme Font IDs

Identify types of fonts.

```
enum {
    kThemeSystemFont = 0,
    kThemeSmallSystemFont = 1,
    kThemeSmallEmphasizedSystemFont = 2,
    kThemeViewsFont = 3,
    kThemeEmphasizedSystemFont = 4,
    kThemeApplicationFont = 5,
    kThemeLabelFont = 6,
    kThemeMenuTitleFont = 100,
    kThemeMenuItemFont = 101,
    kThemeMenuItemMarkFont = 102,
    kThemeMenuItemCmdKeyFont = 103,
    kThemeWindowTitleFont = 104,
    kThemePushButtonFont = 105,
    kThemeUtilityWindowTitleFont = 106,
    kThemeAlertHeaderFont = 107,
    kThemeSystemFontDetail = 7,
    kThemeSystemFontDetailEmphasized = 8,
    kThemeCurrentPortFont = 200,
    kThemeToolbarFont = 108
};
typedef UInt16 ThemeFontID;
```

Constants

`kThemeSystemFont`

The current (large) system font. This is the font used to draw most interface elements. If you can't find a more appropriate `ThemeFontID` constant, you should use this one. This font is suitable for drawing titles on most custom widgets and buttons, as well as most static text in dialogs and windows.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSmallSystemFont`

The current small system font. This is the font used to draw interface elements when space is at a premium.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSmallEmphasizedSystemFont`

The current small, emphasized system font. This constant is identical to `kThemeSmallSystemFont`, except it draws bold or otherwise emphasized text, as is appropriate for your application's language and script.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeViewsFont`

The current views font. This is the font used to draw file and folder names in Finder windows or other browsable lists.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeEmphasizedSystemFont`

The current emphasized system font. This constant is identical to `kThemeSystemFont`, except it draws bold or otherwise emphasized text, as is appropriate for your application's language and script.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeApplicationFont`
An analog to the Script Manager's notion of the Application Font. This font is a suitable default choice for your application's document-style text editing areas.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeLabelFont`
Generally smaller than `kThemeSmallSystemFont`, this font is appropriate for drawing text labels next to image content that reinforces the meaning of the text, such as you may use with a bevel button.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeMenuTitleFont`
The font used to draw menu titles in the menu bar.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeMenuItemFont`
The font used to draw menu items in menus.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeMenuItemMarkFont`
The font used to draw menu item marks in menus.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeMenuItemCmdKeyFont`
The font used to draw menu item command key equivalents in menus.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeWindowTitleFont`
The font used to draw text in most window title bars.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemePushButtonFont`
The font used to draw text labels on push buttons.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeUtilityWindowTitleFont`
The font used to draw text in utility window title bars.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeAlertHeaderFont`
The font used to draw the first and most important message of an alert window.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeCurrentPortFont`

Unlike the other `ThemeFontID` constants, `kThemeCurrentPortFont` doesn't map to a font appropriate to your application's language or script. It maps directly to the font, size, and style of the current QuickDraw port. This allows you to get somewhat customized behavior out of the functions that take `ThemeFontID` constants.

Note, however, that `kThemeCurrentPortFont` does not support all QuickDraw styles on all platforms; in particular, outline and shadow style are not supported on Mac OS X. Additionally, `kThemeCurrentPortFont` is not completely unicode savvy; use of `kThemeCurrentPortFont` may result in errors having to do with the current port's font not being appropriate for rendering or measuring all glyphs in a given unicode string.

Because of overhead associated with gathering QuickDraw font information and converting it to the native font format on Mac OS X, using `kThemeCurrentPortFont` may slow down your text drawing and measuring significantly compared to other `ThemeFontID` constants. Use `kThemeCurrentPortFont` only as a last resort.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeToolbarFont`

The font used to draw the label of a toolbar item.

Available in Mac OS X v10.2 and later.

Declared in `Appearance.h`.

Discussion
A `ThemeFontID` constant is a virtual font ID that you can pass to one of the Appearance Manager's text-related functions. Within these functions, the `ThemeFontID` is mapped to the appropriate font or fonts, size, and style based on a number of factors, including:

- the system appearance (Platinum on Mac OS 9 and Aqua on Mac OS X)
- the string to be rendered, if any
- the language or script that the application is running in

The `ThemeFontID` constants allow you to get the correct text appearance for the platform your application is currently running on.

kPublicThemeFontCount

The total number of public `ThemeFontID` constants.

```
enum {
    kPublicThemeFontCount = 17
};
```

Theme Text Colors

Identify the text colors appropriate to the contexts in which text is used.

```
enum {
    kThemeTextColorDialogActive = 1,
    kThemeTextColorDialogInactive = 2,
    kThemeTextColorAlertActive = 3,
    kThemeTextColorAlertInactive = 4,
    kThemeTextColorModelessDialogActive = 5,
    kThemeTextColorModelessDialogInactive = 6,
    kThemeTextColorWindowHeaderActive = 7,
    kThemeTextColorWindowHeaderInactive = 8,
    kThemeTextColorPlacardActive = 9,
    kThemeTextColorPlacardInactive = 10,
    kThemeTextColorPlacardPressed = 11,
    kThemeTextColorPushButtonActive = 12,
    kThemeTextColorPushButtonInactive = 13,
    kThemeTextColorPushButtonPressed = 14,
    kThemeTextColorBevelButtonActive = 15,
    kThemeTextColorBevelButtonInactive = 16,
    kThemeTextColorBevelButtonPressed = 17,
    kThemeTextColorPopupButtonActive = 18,
    kThemeTextColorPopupButtonInactive = 19,
    kThemeTextColorPopupButtonPressed = 20,
    kThemeTextColorIconLabel = 21,
    kThemeTextColorListView = 22

/*Text colors available in Appearance 1.0.1 and later*/
    kThemeTextColorDocumentWindowTitleActive = 23,
    kThemeTextColorDocumentWindowTitleInactive = 24,
    kThemeTextColorMovableModalWindowTitleActive = 25,
    kThemeTextColorMovableModalWindowTitleInactive = 26,
    kThemeTextColorUtilityWindowTitleActive = 27,
    kThemeTextColorUtilityWindowTitleInactive = 28,
    kThemeTextColorPopupWindowTitleActive = 29,
    kThemeTextColorPopupWindowTitleInactive = 30,
    kThemeTextColorRootMenuActive = 31,
    kThemeTextColorRootMenuSelected = 32,
    kThemeTextColorRootMenuDisabled = 33,
    kThemeTextColorMenuItemActive = 34,
    kThemeTextColorMenuItemSelected = 35,
    kThemeTextColorMenuItemDisabled = 36,
    kThemeTextColorPopupLabelActive = 37,
    kThemeTextColorPopupLabelInactive = 38

/* Text colors available in Appearamce 1.1 and later*/
    kThemeTextColorTabFrontActive = 39,
    kThemeTextColorTabNonFrontActive = 40,
    kThemeTextColorTabNonFrontPressed = 41,
    kThemeTextColorTabFrontInactive = 42,
    kThemeTextColorTabNonFrontInactive = 43,
    kThemeTextColorIconLabelSelected = 44,
    kThemeTextColorBevelButtonStickyActive = 45,
    kThemeTextColorBevelButtonStickyInactive = 46

/*Text colors available in Appearance 1.1.1 and later*/
    kThemeTextColorNotification = 47

/*Text colors available later than Mac OS X 10.1.3
    kThemeTextColorSystemDetail = 48
```

```
/*Specific colors that do not change from theme to theme*/
    kThemeTextColorBlack = -1,
    kThemeTextColorWhite = -2
};
typedef SInt16 ThemeTextColor;
```

Constants

`kThemeTextColorDialogActive`
Text color for an active dialog box.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeTextColorDialogInactive`
Text color for an inactive dialog box.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeTextColorAlertActive`
Text color for an active alert box.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeTextColorAlertInactive`
Text color for an inactive alert box.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeTextColorModelessDialogActive`
Text color for an active modeless dialog box.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeTextColorModelessDialogInactive`
Text color for an inactive modeless dialog box.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeTextColorWindowHeaderActive`
Text color for the window header of an active window.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeTextColorWindowHeaderInactive`
Text color for the window header of an inactive window.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeTextColorPlacardActive`
Text color for a placard in an active window.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeTextColorPlacardInactive`
Text color for a placard in an inactive window.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeTextColorPlacardPressed`
Text color for a placard that is being clicked on by the user.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeTextColorPushButtonActive`
Text color for an active push button.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeTextColorPushButtonInactive`
Text color for an inactive push button.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeTextColorPushButtonPressed`
Text color for a push button that is being clicked on by the user.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeTextColorBevelButtonActive`
Text color for an active bevel button.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeTextColorBevelButtonInactive`
Text color for an inactive bevel button.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeTextColorBevelButtonPressed`
Text color for a bevel button that is being clicked on by the user.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeTextColorPopupButtonActive`
Text color for the menu of an active pop-up menu button.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeTextColorPopupButtonInactive`
Text color for the menu of an inactive pop-up menu button.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeTextColorPopupButtonPressed`
Text color for the menu of a pop-up menu button that is being clicked on by the user.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeTextColorIconLabel`
Text color for an icon label.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeTextColorListView`
Text color for the contents of a list view column.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeTextColorDocumentWindowTitleActive`
Text color for the title of an active document window.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeTextColorDocumentWindowTitleInactive`
Text color for the title of an inactive document window.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeTextColorMovableModalWindowTitleActive`
Text color for the title of an active movable modal window.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeTextColorMovableModalWindowTitleInactive`
Text color for the title of inactive movable modal window.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeTextColorUtilityWindowTitleActive`
Text color for the title of an active utility (floating) window.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeTextColorUtilityWindowTitleInactive`
Text color for the title of an inactive utility (floating) window.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeTextColorPopupWindowTitleActive`
Text color for the title of an active pop-up window.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeTextColorPopupWindowTitleInactive`
Text color for the title of an inactive pop-up window.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeTextColorRootMenuActive`
Text color for an active menu bar title.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeTextColorRootMenuSelected`
Text color for a menu bar title that is being selected by the user.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeTextColorRootMenuDisabled`
Text color for a disabled menu bar title.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeTextColorMenuItemActive`
Text color for an active menu item.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeTextColorMenuItemSelected`
Text color for a menu item that is being selected by the user.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeTextColorMenuItemDisabled`
Text color for a disabled menu item.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeTextColorPopupLabelActive`
Text color for the label of an active pop-up menu button.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeTextColorPopupLabelInactive`
Text color for the label of an inactive pop-up menu button.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeTextColorTabFrontActive`
Text color for the front tab of an active tab control.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeTextColorTabNonFrontActive`
Text color for an active tab that is not the frontmost of a tab control.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeTextColorTabNonFrontPressed`
Text color for a tab that is not the frontmost of a tab control, when the tab is being clicked on by the user.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeTextColorTabFrontInactive`
Text color for the front tab of an inactive tab control.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeTextColorTabNonFrontInactive`
Text color for an inactive tab that is not the frontmost of a tab control. The tab may either be inactive because it has been individually disabled or because the tab control as a whole is currently inactive.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeTextColorIconLabelSelected`
Text color for the label of an icon that is currently selected.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeTextColorBevelButtonStickyActive`
Text color for an active bevel button that is currently on.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeTextColorBevelButtonStickyInactive`
Text color for an inactive bevel button that is currently on.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeTextColorBlack`
Black; this color does not change from theme to theme. You may use this constant instead of specifying a direct RGB value.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeTextColorWhite`
White; this color does not change from theme to theme. You may use this constant instead of specifying a direct RGB value.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

Discussion
You can pass a constant of type `ThemeTextColor` to the function `SetThemeTextColor` (page 101) to specify that the Appearance Manager substitute whatever the appropriate text color is for a given context under the current theme. You can use the function `GetThemeTextColor` (page 74) to obtain the actual color in use under the current theme for the specified `ThemeTextColor` constant.

Theme Menu Types

Specify a type of menu.

```
enum {
    kThemeMenuTypePullDown = 0,
    kThemeMenuTypePopUp = 1,
    kThemeMenuTypeHierarchical = 2,
    kThemeMenuTypeInactive = 0x0100
};
typedef UInt16 ThemeMenuType;
```

Constants

`kThemeMenuTypePullDown`
A pull-down menu.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeMenuTypePopUp`
A pop-up menu.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeMenuTypeHierarchical`
A hierarchical menu.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeMenuTypeInactive`
An inactive menu. Add this value to any other menu type if the entire menu is inactive.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

Discussion
You can pass constants of type `ThemeMenuType` in the `inMenuType` parameter of `GetThemeMenuBackgroundRegion` (page 66) and `DrawThemeMenuBackground` (page 37).

Theme Menu States

Specify the state in which theme-compliant menus are drawn.

```
enum {
    kThemeMenuActive = 0,
    kThemeMenuSelected = 1,
    kThemeMenuDisabled = 3
};
typedef UInt16 ThemeMenuState;
```

Constants

`kThemeMenuActive`

Menu is drawn in its active state.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeMenuSelected`

Menu is drawn in its selected state.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

Discussion

You can pass constants of type `ThemeMenuState` in the `inState` parameter of `DrawThemeMenuItem` (page 38) and `DrawThemeMenuTitle` (page 40). The `ThemeMenuState` constants are available with Appearance Manager 1.0.1 and later.

Theme Menu Bar States

Specify whether theme-compliant menu bars are drawn as normal or selected.

```
enum {
    kThemeMenuBarNormal = 0,
    kThemeMenuBarSelected = 1
};
typedef UInt16 ThemeMenuBarState;
```

Constants

`kThemeMenuBarNormal`

Menu bar is drawn in its normal state.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeMenuBarSelected`

Menu bar is drawn in its selected state.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

Discussion

You can pass constants of type `ThemeMenuBarState` in the `inState` parameter of `DrawThemeMenuBarBackground` (page 38). The `ThemeMenuBarState` constants are available with Appearance Manager 1.0.1 and later.

Theme Menu Item Types

Identify types of menu items.

```
enum {
    kThemeMenuItemPlain = 0,
    kThemeMenuItemHierarchical = 1,
    kThemeMenuItemScrollUpArrow = 2,
    kThemeMenuItemScrollDownArrow = 3,
    kThemeMenuItemAtTop = 0x0100,
    kThemeMenuItemAtBottom = 0x0200,
    kThemeMenuItemHierBackground = 0x0400,
    kThemeMenuItemPopUpBackground = 0x0800,
    kThemeMenuItemHasIcon = 0x8000,
    kThemeMenuItemNoBackground = 0x4000
};
typedef UInt16 ThemeMenuItemType;
```

Constants

`kThemeMenuItemPlain`
A plain menu item.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeMenuItemHierarchical`
A hierarchical menu item.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeMenuItemScrollUpArrow`
A scroll-up arrow.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeMenuItemScrollDownArrow`
A scroll-down arrow.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeMenuItemAtTop`
This value may be added to other `ThemeMenuItemType` constants to specify that the item being drawn appears at the top of the menu.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeMenuItemAtBottom`
This value may be added to other `ThemeMenuItemType` constants to specify that the item being drawn appears at the bottom of the menu.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeMenuItemHierBackground`
This value may be added to other `ThemeMenuItemType` constants to specify that the item being drawn is located in a hierarchical menu.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeMenuItemPopUpBackground`
: This value may be added to other `ThemeMenuItemType` constants to specify that the item being drawn is located in a pop-up menu.

  Available in Mac OS X v10.0 and later.

  Declared in `Appearance.h`.

`kThemeMenuItemHasIcon`
: This value may be added to the `kThemeMenuItemPlain` or `kThemeMenuItemHierarchical` constants, to specify that an icon is drawn along with the item text. This value may not be used with the `kThemeMenuItemScrollUpArrow` and `kThemeMenuItemScrollDownArrow` constants.

  Available in Mac OS X v10.0 and later.

  Declared in `Appearance.h`.

`kThemeMenuItemNoBackground`
: This value may be added to other `ThemeMenuItemType` constants to specify that the menu background should not be drawn along with the menu item. Available in Mac OS X.

  Available in Mac OS X v10.1 and later.

  Declared in `Appearance.h`.

Discussion
Your application may pass a `ThemeMenuItemType` constant to the function `DrawThemeMenuItem` (page 38) to draw a menu item of the specified type, or it may pass a `ThemeMenuItemType` constant to the function `GetThemeMenuItemExtra` (page 68) to retrieve spatial information for the given menu item type under the current theme.

kThemeMenuSquareMenuBar

Indicates that the menu bar should be drawn with square corners.

```
enum {
    kThemeMenuSquareMenuBar = (1 << 0)
};
```

Constants
`kThemeMenuSquareMenuBar`
: Menu bar is drawn with square corners.

  Available in Mac OS X v10.0 and later.

  Declared in `Appearance.h`.

Discussion
If you wish the menu bar to be drawn with square upper corners (as for a laptop system) instead of rounded ones (as for a desktop system), your application should set the bit for the attribute `kThemeMenuSquareMenuBar`.

Theme Scroll Bar Arrow Styles

Specify types of scroll bar arrows.

```
enum {
    kThemeScrollBarArrowsSingle = 0,
    kThemeScrollBarArrowsLowerRight = 1
};
typedef UInt16 ThemeScrollBarArrowStyle;
```

Constants

`kThemeScrollBarArrowsSingle`
Specifies the use of a single arrow at each end of a scroll bar.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeScrollBarArrowsLowerRight`
Specifies the use of double arrows at one end of a scroll bar. For vertical scroll bars, the double arrows are located at the lower end of the scroll bar. For horizontal scroll bars, the double arrows are located at the right end of the scroll bar.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

Discussion
You can call the function `GetThemeScrollBarArrowStyle` (page 70) to obtain the type of scroll bar arrows being used in the current theme.

Theme Scroll Box Styles

Specify types of scroll boxes.

```
enum {
    kThemeScrollBarThumbNormal = 0,
    kThemeScrollBarThumbProportional = 1
};
typedef UInt16 ThemeScrollBarThumbStyle;
```

Constants

`kThemeScrollBarThumbNormal`
A classic scroll box.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeScrollBarThumbProportional`
A proportional scroll box.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

Discussion
You can call the function `GetThemeScrollBarThumbStyle` (page 71) to obtain the type of scroll boxes (also known as "scroll indicators" or "thumbs") being used in the current theme.

Theme Size Box Directions

Identify the directions in which a window may be resized.

```
enum {
    kThemeGrowLeft = (1 << 0),
    kThemeGrowRight = (1 << 1),
    kThemeGrowUp = (1 << 2),
    kThemeGrowDown = (1 << 3)
};
typedef UInt16 ThemeGrowDirection;
```

Constants

`kThemeGrowLeft`
If the bit specified by this mask is set, the object can grow to the left.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeGrowRight`
If the bit specified by this mask is set, the object can grow to the right.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeGrowUp`
If the bit specified by this mask is set, the object can grow upward.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeGrowDown`
If the bit specified by this mask is set, the object can grow downward.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

Discussion

The `ThemeGrowDirection` enumeration defines masks your application can use to specify the directions in which a window may be resized. You may use constants of type `ThemeGrowDirection` with the function `DrawThemeStandaloneGrowBox` (page 48) to draw a size box and with the function `GetThemeStandaloneGrowBoxBounds` (page 72) to obtain the bounding rectangle of a size box. The constants may be combined to set more than one direction of growth.

Theme Thumb Directions

Specify the direction in which the indicator points in a slider control.

```
enum {
    kThemeThumbPlain = 0,
    kThemeThumbUpward = 1,
    kThemeThumbDownward = 2
};
typedef UInt8 ThemeThumbDirection;
```

Constants

`kThemeThumbPlain`
A plain indicator; that is, one that does not point in any direction.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeThumbUpward`
For a horizontal slider, an upward-pointing indicator. For a vertical slider, a left-pointing indicator.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeThumbDownward`
For a horizontal slider, a downward-pointing indicator. For a vertical slider, a right-pointing indicator.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

Discussion
You can use constants of type `ThemeThumbDirection` in the `SliderTrackInfo` (page 114) structure. You may use these constants with either horizontal or vertical sliders, and the Appearance Manager interprets the direction of the indicator appropriately.

Theme Tab Directions

Specify the orientation of a tab.

```
enum {
    kThemeTabNorth = 0,
    kThemeTabSouth = 1,
    kThemeTabEast = 2,
    kThemeTabWest = 3
};
typedef UInt16 ThemeTabDirection;
```

Constants
`kThemeTabNorth`
An upward-pointing tab.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeTabSouth`
A downward-pointing tab.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeTabEast`
A right-pointing tab.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeTabWest`
A left-pointing tab.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

Discussion
You can pass constants of type `ThemeTabDirection` to the function `DrawThemeTab` (page 50) to draw theme-compliant tabs that are oriented in various directions. You can also pass a `ThemeTabDirection` constant to the function `GetThemeTabRegion` (page 73) to obtain the region containing a tab oriented in a particular direction.

Theme Tab Styles

Specfiy a type of tab.

```
enum {
    kThemeTabNonFront = 0,
    kThemeTabNonFrontPressed = 1,
    kThemeTabNonFrontInactive = 2,
    kThemeTabFront = 3,
    kThemeTabFrontInactive = 4,
    kThemeTabNonFrontUnavailable = 5,
    kThemeTabFrontUnavailable = 6
};
typedef UInt16 ThemeTabStyle;
```

Constants

`kThemeTabNonFront`
An active tab that is not the frontmost in a tab control.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeTabNonFrontPressed`
A tab that is being clicked on by the user which is not the frontmost tab in a tab control.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeTabNonFrontInactive`
An inactive tab that is not the frontmost in a tab control. The tab may either be inactive because it has been individually disabled or because the tab control as a whole is currently inactive.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeTabFront`
The frontmost tab in an active tab control.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeTabFrontInactive`
The frontmost tab in an inactive tab control.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

Discussion

You can pass a constant of type `ThemeTabStyle` to the function `DrawThemeTab` (page 50) to draw a theme-compliant tab in a specific state. You can also pass a `ThemeTabStyle` constant to the function `GetThemeTabRegion` (page 73) to obtain the region containing a tab in a specific state.

Tab Heights

Specify the height of a tab.

```
enum {
    kThemeSmallTabHeight = 16,
    kThemeLargeTabHeight = 21,
    kThemeTabPaneOverlap = 3,
    kThemeSmallTabHeightMax = 19,
    kThemeLargeTabHeightMax = 24
};
```

Constants

`kThemeSmallTabHeight`
The amount that small tabs protrude from the frame.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeLargeTabHeight`
The amount that large tabs protrude from the frame.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeTabPaneOverlap`
The amount that tabs overlap the frame.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeSmallTabHeightMax`
The small tab height, including the overlap.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeLargeTabHeightMax`
The large tab height, including the overlap.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

Discussion

Use the `kThemeSmallTabHeightMax` and `kThemeLargeTabHeightMax` constants when calculating the rectangles to draw tabs into. This height includes the tab frame overlap. Tabs that are not in the front are only drawn to where they meet the frame, as if the height was just `kThemeLargeTabHeight`, for example. Remember that for east and west tabs, the height referred to is actually the width.

Theme Track Attributes

Specify attributes of a track control.

```
enum {
    kThemeTrackHorizontal = (1 << 0),
    kThemeTrackRightToLeft = (1 << 1),
    kThemeTrackShowThumb = (1 << 2),
    kThemeTrackThumbRgnIsNotGhost = (1 << 3),
    kThemeTrackNoScrollBarArrows = (1 << 4),
    kThemeTrackHasFocus = (1 << 5)
};
typedef UInt16 ThemeTrackAttributes;
```

Constants

`kThemeTrackHorizontal`
If the bit specified by this mask is set, the track is horizontally, not vertically, oriented.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeTrackRightToLeft`
If the bit specified by this mask is set, values for the track increase from right to left if the track is horizontally oriented, or from bottom to top if the track is vertically oriented.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeTrackShowThumb`
If the bit specified by this mask is set, an indicator is drawn for this track.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeTrackThumbRgnIsNotGhost`
If the bit specified by this mask is set, the thumb region is drawn opaque, rather than as a ghost.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeTrackNoScrollBarArrows`
If the bit specified by this mask is set, the track scroll bar is drawn without arrows. This attribute currently has no effect.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeTrackHasFocus`
If the bit specified by this mask is set, the thumb has focus. This attribute currently has effect only on sliders.

Available in Mac OS X v10.2 and later.

Declared in `Appearance.h`.

Discussion

The `ThemeTrackAttributes` enumeration defines masks your application can use in the `ThemeTrackDrawInfo` (page 116) structure to specify various attributes of track controls.

Theme Track States

Specify the state of a track control.

```
enum {
    kThemeTrackActive = 0,
    kThemeTrackDisabled = 1,
    kThemeTrackNothingToScroll = 2,
    kThemeTrackInactive = 3
};
typedef UInt8 ThemeTrackEnableState;
```

Constants

`kThemeTrackActive`

A track in the active state.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeTrackDisabled`

A track in the disabled state.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeTrackNothingToScroll`

For scroll bars, the window containing the track is expanded to a sufficiently large state such that all the content is viewable and there is nothing remaining to scroll.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

Discussion

You can use constants of type `ThemeTrackEnableState` in the `ThemeTrackDrawInfo` (page 116) structure and in the functions `GetThemeScrollBarTrackRect` (page 71) and `HitTestThemeScrollBarArrows` (page 83).

Theme Track Kinds

Identify specific kinds of track-based controls to the Appearance Manager.

```
enum {
    kThemeMediumScrollBar = 0,
    kThemeSmallScrollBar = 1,
    kThemeMediumSlider = 2,
    kThemeMediumProgressBar = 3,
    kThemeMediumIndeterminateBar = 4,
    kThemeRelevanceBar = 5,
    kThemeSmallSlider = 6,
    kThemeLargeProgressBar = 7,
    kThemeLargeIndeterminateBar = 8
};
typedef UInt16 ThemeTrackKind;
```

Constants

`kThemeMediumScrollBar`

A scroll bar.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSmallScrollBar`
A small scroll bar.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeMediumSlider`
A slider bar.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeMediumProgressBar`
A progress bar.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeMediumIndeterminateBar`
An indeterminate progress bar.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

Theme Track Press States

Identify what is pressed in an active scroll bar or slider.

```
enum {
    kThemeLeftOutsideArrowPressed = 0x01,
    kThemeLeftInsideArrowPressed = 0x02,
    kThemeLeftTrackPressed = 0x04,
    kThemeThumbPressed = 0x08,
    kThemeRightTrackPressed = 0x10,
    kThemeRightInsideArrowPressed = 0x20,
    kThemeRightOutsideArrowPressed = 0x40,
    kThemeTopOutsideArrowPressed = 0x01,
    kThemeTopInsideArrowPressed = 0x02,
    kThemeTopTrackPressed = 0x04,
    kThemeBottomTrackPressed = 0x10,
    kThemeBottomInsideArrowPressed = 0x20,
    kThemeBottomOutsideArrowPressed = 0x40
};
typedef UInt8 ThemeTrackPressState;
```

Constants

`kThemeLeftOutsideArrowPressed`
For a horizontal scroll bar containing a single pair of arrows, this constant indicates that the arrow on the left is selected.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeLeftInsideArrowPressed`
For a horizontal scroll bar containing a single pair of arrows, this constant should not be used. For a horizontal scroll bar containing two pairs of arrows with one pair at each end, this constant indicates that the inner arrow at the left end of the scroll bar is selected.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeLeftTrackPressed`
For a horizontal scroll bar or slider, indicates that the end of the track to the left of the scroll box or indicator is selected.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeThumbPressed`
Indicates that the scroll box or indicator is selected.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeRightTrackPressed`
For a horizontal scroll bar or slider, indicates that the end of the track to the right of the scroll box or indicator is selected.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeRightInsideArrowPressed`
For a horizontal scroll bar containing a single pair of arrows, this constant should not be used. For a horizontal scroll bar containing two pairs of arrows with one pair at each end, this constant indicates that the inner arrow at the right end of the scroll bar is selected.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeRightOutsideArrowPressed`
For a horizontal scroll bar containing a single pair of arrows, this constant indicates that the arrow on the right is selected.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeTopOutsideArrowPressed`
For a vertical scroll bar containing a single pair of arrows, this constant indicates that the arrow on the top is selected.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeTopInsideArrowPressed`
For a vertical scroll bar containing a single pair of arrows, this constant should not be used. For a vertical scroll bar containing two pairs of arrows with one pair at each end, this constant indicates that the inner arrow at the top end of the scroll bar is selected.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeTopTrackPressed`
For a vertical scroll bar or slider, indicates that the end of the track above the scroll box or indicator is selected.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeBottomTrackPressed`
For a vertical scroll bar or slider, indicates that the end of the track beneath the scroll box or indicator is selected.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeBottomInsideArrowPressed`
For a vertical scroll bar containing a single pair of arrows, this constant should not be used. For a vertical scroll bar containing two pairs of arrows with one pair at each end, this constant indicates that the inner arrow at the bottom end of the scroll bar is selected.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeBottomOutsideArrowPressed`
For a vertical scroll bar containing a single pair of arrows, this constant indicates that the arrow on the bottom is selected.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

Discussion
You can use constants of type `ThemeTrackPressState` in structures of type `ScrollBarTrackInfo` (page 114) and `SliderTrackInfo` (page 114) to identify what is pressed in an active scroll bar or slider; the press state is ignored if the control is not active.

Note that some constants are undefined when the corresponding arrows do not exist in the current visual appearance. Prior to using the `ThemeTrackPressState` constants, your application should call the function `GetThemeScrollBarArrowStyle` (page 70) to obtain the type of scroll bar arrows currently being used.

Theme Window Types

Identify windows of specific visual categories.

```
enum {
    kThemeDocumentWindow = 0,
    kThemeDialogWindow = 1,
    kThemeMovableDialogWindow = 2,
    kThemeAlertWindow = 3,
    kThemeMovableAlertWindow = 4,
    kThemePlainDialogWindow = 5,
    kThemeShadowDialogWindow = 6,
    kThemePopupWindow = 7,
    kThemeUtilityWindow = 8,
    kThemeUtilitySideWindow = 9,
    kThemeSheetWindow = 10,
    kThemeDrawerWindow = 11
};
typedef UInt16 ThemeWindowType;
```

Constants

`kThemeDocumentWindow`
A document window.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeDialogWindow`
A modal dialog box.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeMovableDialogWindow`
A movable modal dialog box.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeAlertWindow`
An alert box.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeMovableAlertWindow`
A movable alert box.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemePlainDialogWindow`
A plain modal dialog box. This window visually corresponds to that produced by the `plainDBox` pre–Appearance Manager window definition ID and does not change appearance by theme.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeShadowDialogWindow`
A dialog box with shadowing.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemePopupWindow`
A pop-up window.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeUtilityWindow`
A utility window.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeUtilitySideWindow`
A utility window with a side title bar.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

Theme Window Attributes

Specify interface elements in a window.

```
enum {
    kThemeWindowHasGrow = (1 << 0),
    kThemeWindowHasHorizontalZoom = (1 << 3),
    kThemeWindowHasVerticalZoom = (1 << 4),
    kThemeWindowHasFullZoom = kThemeWindowHasHorizontalZoom +
kThemeWindowHasVerticalZoom,
    kThemeWindowHasCloseBox = (1 << 5),
    kThemeWindowHasCollapseBox = (1 << 6),
    kThemeWindowHasTitleText = (1 << 7),
    kThemeWindowIsCollapsed = (1 << 8),
    kThemeWindowHasDirty = (1 << 9)
};
typedef UInt32 ThemeWindowAttributes;
```

Constants

`kThemeWindowHasGrow`
If the bit specified by this mask is set, the window contains a size box.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeWindowHasHorizontalZoom`
If the bit specified by this mask is set, the window contains a horizontal zoom box.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeWindowHasVerticalZoom`
If the bit specified by this mask is set, the window contains a vertical zoom box.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeWindowHasFullZoom`
If the bit specified by this mask is set, the window contains a full (horizontal and vertical) zoom box.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeWindowHasCloseBox`
If the bit specified by this mask is set, the window contains a close box.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeWindowHasCollapseBox`
If the bit specified by this mask is set, the window contains a collapse box.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeWindowHasTitleText`
If the bit specified by this mask is set, the window contains a title.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeWindowIsCollapsed`
If the bit specified by this mask is set, the window is currently collapsed.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

Discussion
The `ThemeWindowAttributes` enumeration defines masks your application can use to specify the various interface elements that a given window contains.

Theme Title Bar Items

Identify specific types of window title bar items.

```
enum {
    kThemeWidgetCloseBox = 0,
    kThemeWidgetZoomBox = 1,
    kThemeWidgetCollapseBox = 2,
    kThemeWidgetDirtyCloseBox = 6
};
typedef UInt16 ThemeTitleBarWidget;
```

Constants
`kThemeWidgetCloseBox`
Identifies a close box.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeWidgetZoomBox`
Identifies a zoom box.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeWidgetCollapseBox`
Identifies a collapse box.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

Discussion
You may pass constants of type `ThemeTitleBarWidget` to the function `DrawThemeTitleBarWidget` (page 54) to draw specific types of window title bar items. The Appearance Manager draws a theme-compliant version of the title bar item type, as is appropriate.

Pop-up Window Tab Positions

Indicate how a pop-up window's tab is positioned.

```
enum {
    kThemePopupTabNormalPosition = 0,
    kThemePopupTabCenterOnWindow = 1,
    kThemePopupTabCenterOnOffset = 2
};
```

Constants
`kThemePopupTabNormalPosition`
Specifies that the left edge of the tab is to be drawn at the position indicated by the `popupTabOffset` field of the `ThemeWindowMetrics` structure.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemePopupTabCenterOnWindow`
Specifies that the tab is to be drawn centered on the window; the `popupTabOffset` field is ignored.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemePopupTabCenterOnOffset`
Specifies that the tab is to be drawn centered at the position indicated by the `popupTabOffset` field.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

Discussion
You can use these constants in the `popupTabPosition` field of the `ThemeWindowMetrics` structure.

Theme Sound Masks

Define masks that are used to specify the classes of sounds that are enabled for a theme.

```
enum {
    kThemeNoSounds = 0,
    kThemeWindowSoundsMask = (1 << 0),
    kThemeMenuSoundsMask = (1 << 1),
    kThemeControlSoundsMask = (1 << 2),
    kThemeFinderSoundsMask = (1 << 3)
};
```

Constants

`kThemeNoSounds`
If no bits are set, no theme sounds are enabled.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeWindowSoundsMask`
If the bit specified by this mask is set, window sounds are enabled.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeMenuSoundsMask`
If the bit specified by this mask is set, menu sounds are enabled.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeControlSoundsMask`
If the bit specified by this mask is set, control sounds are enabled.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeFinderSoundsMask`
If the bit specified by this mask is set, Finder sounds are enabled.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

Discussion

You can use these masks to operate upon the unsigned 32-bit integer contained in the `kThemeSoundMaskTag` collection item, which is described in "Theme Collection Tags" (page 122).

Theme Sounds

Identify theme-specific sounds played when an interface object changes state.

```
enum {
    kThemeSoundNone = 0,
    kThemeSoundMenuOpen = 'mnuo',
    kThemeSoundMenuClose = 'mnuc',
    kThemeSoundMenuItemHilite = 'mnui',
    kThemeSoundMenuItemRelease = 'mnus',
    kThemeSoundWindowClosePress = 'wclp',
    kThemeSoundWindowCloseEnter = 'wcle',
    kThemeSoundWindowCloseExit = 'wclx',
    kThemeSoundWindowCloseRelease = 'wclr',
    kThemeSoundWindowZoomPress = 'wzmp',
    kThemeSoundWindowZoomEnter = 'wzme',
    kThemeSoundWindowZoomExit = 'wzmx',
    kThemeSoundWindowZoomRelease = 'wzmr',
    kThemeSoundWindowCollapsePress = 'wcop',
    kThemeSoundWindowCollapseEnter = 'wcoe',
    kThemeSoundWindowCollapseExit = 'wcox',
    kThemeSoundWindowCollapseRelease = 'wcor',
    kThemeSoundWindowDragBoundary = 'wdbd',
    kThemeSoundUtilWinClosePress = 'uclp',
    kThemeSoundUtilWinCloseEnter = 'ucle',
    kThemeSoundUtilWinCloseExit = 'uclx',
    kThemeSoundUtilWinCloseRelease = 'uclr',
    kThemeSoundUtilWinZoomPress = 'uzmp',
    kThemeSoundUtilWinZoomEnter = 'uzme',
    kThemeSoundUtilWinZoomExit = 'uzmx',
    kThemeSoundUtilWinZoomRelease = 'uzmr',
    kThemeSoundUtilWinCollapsePress = 'ucop',
    kThemeSoundUtilWinCollapseEnter = 'ucoe',
    kThemeSoundUtilWinCollapseExit = 'ucox',
    kThemeSoundUtilWinCollapseRelease = 'ucor',
    kThemeSoundUtilWinDragBoundary = 'udbd',
    kThemeSoundWindowOpen = 'wopn',
    kThemeSoundWindowClose = 'wcls',
    kThemeSoundWindowZoomIn = 'wzmi',
    kThemeSoundWindowZoomOut = 'wzmo',
    kThemeSoundWindowCollapseUp = 'wcol',
    kThemeSoundWindowCollapseDown = 'wexp',
    kThemeSoundWindowActivate = 'wact',
    kThemeSoundUtilWindowOpen = 'uopn',
    kThemeSoundUtilWindowClose = 'ucls',
    kThemeSoundUtilWindowZoomIn = 'uzmi',
    kThemeSoundUtilWindowZoomOut = 'uzmo',
    kThemeSoundUtilWindowCollapseUp = 'ucol',
    kThemeSoundUtilWindowCollapseDown = 'uexp',
    kThemeSoundUtilWindowActivate = 'uact',
    kThemeSoundDialogOpen = 'dopn',
    kThemeSoundDialogClose = 'dlgc',
    kThemeSoundAlertOpen = 'aopn',
    kThemeSoundAlertClose = 'altc',
    kThemeSoundPopupWindowOpen = 'pwop',
    kThemeSoundPopupWindowClose = 'pwcl',
    kThemeSoundButtonPress = 'btnp',
    kThemeSoundButtonEnter = 'btne',
    kThemeSoundButtonExit = 'btnx',
    kThemeSoundButtonRelease = 'btnr',
    kThemeSoundDefaultButtonPress = 'dbtp',
    kThemeSoundDefaultButtonEnter = 'dbte',
```

```
    kThemeSoundDefaultButtonExit = 'dbtx',
    kThemeSoundDefaultButtonRelease = 'dbtr',
    kThemeSoundCancelButtonPress = 'cbtp',
    kThemeSoundCancelButtonEnter = 'cbte',
    kThemeSoundCancelButtonExit = 'cbtx',
    kThemeSoundCancelButtonRelease = 'cbtr',
    kThemeSoundCheckboxPress = 'chkp',
    kThemeSoundCheckboxEnter = 'chke',
    kThemeSoundCheckboxExit = 'chkx',
    kThemeSoundCheckboxRelease = 'chkr',
    kThemeSoundRadioPress = 'radp',
    kThemeSoundRadioEnter = 'rade',
    kThemeSoundRadioExit = 'radx',
    kThemeSoundRadioRelease = 'radr',
    kThemeSoundScrollArrowPress = 'sbap',
    kThemeSoundScrollArrowEnter = 'sbae',
    kThemeSoundScrollArrowExit = 'sbax',
    kThemeSoundScrollArrowRelease = 'sbar',
    kThemeSoundScrollEndOfTrack = 'sbte',
    kThemeSoundScrollTrackPress = 'sbtp',
    kThemeSoundSliderEndOfTrack = 'slte',
    kThemeSoundSliderTrackPress = 'sltp',
    kThemeSoundBalloonOpen = 'blno',
    kThemeSoundBalloonClose = 'blnc',
    kThemeSoundBevelPress = 'bevp',
    kThemeSoundBevelEnter = 'beve',
    kThemeSoundBevelExit = 'bevx',
    kThemeSoundBevelRelease = 'bevr',
    kThemeSoundLittleArrowUpPress = 'laup',
    kThemeSoundLittleArrowDnPress = 'ladp',
    kThemeSoundLittleArrowEnter = 'lare',
    kThemeSoundLittleArrowExit = 'larx',
    kThemeSoundLittleArrowUpRelease = 'laur',
    kThemeSoundLittleArrowDnRelease = 'ladr',
    kThemeSoundPopupPress = 'popp',
    kThemeSoundPopupEnter = 'pope',
    kThemeSoundPopupExit = 'popx',
    kThemeSoundPopupRelease = 'popr',
    kThemeSoundDisclosurePress = 'dscp',
    kThemeSoundDisclosureEnter = 'dsce',
    kThemeSoundDisclosureExit = 'dscx',
    kThemeSoundDisclosureRelease = 'dscr',
    kThemeSoundTabPressed = 'tabp',
    kThemeSoundTabEnter = 'tabe',
    kThemeSoundTabExit = 'tabx',
    kThemeSoundTabRelease = 'tabr',
    kThemeSoundDragTargetHilite = 'dthi',
    kThemeSoundDragTargetUnhilite = 'dtuh',
    kThemeSoundDragTargetDrop = 'dtdr',
    kThemeSoundEmptyTrash = 'ftrs',
    kThemeSoundSelectItem = 'fsel',
    kThemeSoundNewItem = 'fnew',
    kThemeSoundReceiveDrop = 'fdrp',
    kThemeSoundCopyDone = 'fcpd',
    kThemeSoundResolveAlias = 'fral',
    kThemeSoundLaunchApp = 'flap',
    kThemeSoundDiskInsert = 'dski',
    kThemeSoundDiskEject = 'dske',
```

```
    kThemeSoundFinderDragOnIcon = 'fdon',
    kThemeSoundFinderDragOffIcon = 'fdof'
};
typedef OSType ThemeSoundKind;
```

Constants

`kThemeSoundNone`
Specifies that no sound is played.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeSoundMenuOpen`
Identifies a sound to be played when the user opens a menu.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeSoundMenuClose`
Identifies a sound to be played when the user closes a menu.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeSoundMenuItemHilite`
Identifies a sound to be played when the user highlights a menu item.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeSoundMenuItemRelease`
Identifies a sound to be played when the user selects a menu item.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeSoundWindowClosePress`
Identifies a sound to be played when the user presses the mouse button while the cursor is over a window's close box.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeSoundWindowCloseEnter`
Identifies a sound to be played when the user moves the cursor over a window's close box after having moved the cursor away from the close box without releasing the mouse button.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeSoundWindowCloseExit`
Identifies a sound to be played when the user moves the cursor away from a position over a window's close box, while the mouse button remains pressed.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeSoundWindowCloseRelease`
Identifies a sound to be played when the user releases the mouse button while the cursor is over a window's close box.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundWindowZoomPress`
Identifies a sound to be played when the user presses the mouse button while the cursor is over a window's zoom box.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundWindowZoomEnter`
Identifies a sound to be played when the user moves the cursor over a window's zoom box after having moved the cursor away from the zoom box without releasing the mouse button.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundWindowZoomExit`
Identifies a sound to be played when the user moves the cursor away from a position over a window's zoom box, while the mouse button remains pressed.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundWindowZoomRelease`
Identifies a sound to be played when the user releases the mouse button while the cursor is over a window's zoom box.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundWindowCollapsePress`
Identifies a sound to be played when the user presses the mouse button while the cursor is over a window's collapse box.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundWindowCollapseEnter`
Identifies a sound to be played when the user moves the cursor over a window's collapse box after having moved the cursor away from the collapse box without releasing the mouse button.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundWindowCollapseExit`
Identifies a sound to be played when the user moves the cursor away from a position over a window's collapse box, while the mouse button remains pressed.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundWindowCollapseRelease`
Identifies a sound to be played when the user releases the mouse button while the cursor is over a window's collapse box.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundWindowDragBoundary`
Identifies a sound to be played when the user drags a window to the edge of the area where it can be dragged. Note: This functionality is not available under Appearance Manager 1.1 or prior versions of Appearance.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundUtilWinClosePress`
Identifies a sound to be played when the user presses the mouse button while the cursor is over a utility (floating) window's close box.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundUtilWinCloseEnter`
Identifies a sound to be played when the user moves the cursor over a utility (floating) window's close box after having moved the cursor away from the close box without releasing the mouse button.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundUtilWinCloseExit`
Identifies a sound to be played when the user moves the cursor away from a position over a utility (floating) window's close box, while the mouse button remains pressed.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundUtilWinCloseRelease`
Identifies a sound to be played when the user releases the mouse button while the cursor is over a utility (floating) window's close box.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundUtilWinZoomPress`
Identifies a sound to be played when the user presses the mouse button while the cursor is over a utility (floating) window's zoom box.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundUtilWinZoomEnter`
Identifies a sound to be played when the user moves the cursor over a utility (floating) window's zoom box after having moved the cursor away from the zoom box without releasing the mouse button.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundUtilWinZoomExit`
Identifies a sound to be played when the user moves the cursor away from a position over a utility (floating) window's zoom box, while the mouse button remains pressed.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundUtilWinZoomRelease`
Identifies a sound to be played when the user releases the mouse button while the cursor is over a utility (floating) window's zoom box.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundUtilWinCollapsePress`
Identifies a sound to be played when the user presses the mouse button while the cursor is over a utility (floating) window's collapse box.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundUtilWinCollapseEnter`
Identifies a sound to be played when the user moves the cursor over a utility (floating) window's collapse box after having moved the cursor away from the collapse box without releasing the mouse button.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundUtilWinCollapseExit`
Identifies a sound to be played when the user moves the cursor away from a position over a utility (floating) window's collapse box, while the mouse button remains pressed.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundUtilWinCollapseRelease`
Identifies a sound to be played when the user releases the mouse button while the cursor is over a utility (floating) window's collapse box.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundUtilWinDragBoundary`
Identifies a sound to be played when the user drags a utility (floating) window to the edge of the area where it can be dragged.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundWindowOpen`
Identifies a sound to be played when the user opens a window.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundWindowClose`
Identifies a sound to be played when the user closes a window.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundWindowZoomIn`
Identifies a sound to be played when the user zooms a window in, that is, to the user state.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundWindowZoomOut`
Identifies a sound to be played when the user zooms a window out, that is, to the standard state.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundWindowCollapseUp`
Identifies a sound to be played when the user collapses a window.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundWindowCollapseDown`
Identifies a sound to be played when the user uncollapses a window.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundWindowActivate`
Identifies a sound to be played when the user presses the mouse button while the cursor is over an inactive window, thus activating it.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundUtilWindowOpen`
Identifies a sound to be played when the user opens a utility (floating) window.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundUtilWindowClose`
Identifies a sound to be played when the user closes a utility (floating) window.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundUtilWindowZoomIn`
Identifies a sound to be played when the user zooms a utility (floating) window in, that is, to the user state.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundUtilWindowZoomOut`
Identifies a sound to be played when the user zooms a utility (floating) window out, that is, to the standard state.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundUtilWindowCollapseUp`
Identifies a sound to be played when the user collapses a utility (floating) window.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundUtilWindowCollapseDown`
Identifies a sound to be played when the user uncollapses a utility (floating) window.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundUtilWindowActivate`
Identifies a sound to be played when the user presses the mouse button while the cursor is over an inactive utility (floating) window, thus activating it.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundDialogOpen`
Identifies a sound to be played when a dialog box opens.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundDialogClose`
Identifies a sound to be played when a dialog box closes.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundAlertOpen`
Identifies a sound to be played when an alert box opens.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundAlertClose`
Identifies a sound to be played when an alert box closes.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundPopupWindowOpen`
Identifies a sound to be played when a pop-up window opens.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundPopupWindowClose`
Identifies a sound to be played when a pop-up window closes.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundButtonPress`
Identifies a sound to be played when the user presses the mouse button while the cursor is over a push button.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundButtonEnter`
Identifies a sound to be played when the user moves the cursor over a push button after having moved the cursor away from the button without releasing the mouse button.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundButtonExit`
Identifies a sound to be played when the user moves the cursor away from a position over a push button, while the mouse button remains pressed.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundButtonRelease`
Identifies a sound to be played when the user releases the mouse button while the cursor is over a push button.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundDefaultButtonPress`
Identifies a sound to be played when the user presses the mouse button while the cursor is over a default button.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundDefaultButtonEnter`
Identifies a sound to be played when the user moves the cursor over a default button after having moved the cursor away from the button without releasing the mouse button.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundDefaultButtonExit`
Identifies a sound to be played when the user moves the cursor away from a position over a default button, while the mouse button remains pressed.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundDefaultButtonRelease`
Identifies a sound to be played when the user releases the mouse button while the cursor is over a default button.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundCancelButtonPress`
Identifies a sound to be played when the user presses the mouse button while the cursor is over a Cancel button.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundCancelButtonEnter`
Identifies a sound to be played when the user moves the cursor over a Cancel button after having moved the cursor away from the button without releasing the mouse button.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundCancelButtonExit`
Identifies a sound to be played when the user moves the cursor away from a position over a Cancel button, while the mouse button remains pressed.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundCancelButtonRelease`
Identifies a sound to be played when the user releases the mouse button while the cursor is over a Cancel button.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundCheckboxPress`
Identifies a sound to be played when the user presses the mouse button while the cursor is over a checkbox.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundCheckboxEnter`
Identifies a sound to be played when the user moves the cursor over a checkbox after having moved the cursor away from the checkbox without releasing the mouse button.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundCheckboxExit`
Identifies a sound to be played when the user moves the cursor away from a position over a checkbox, while the mouse button remains pressed.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundCheckboxRelease`
Identifies a sound to be played when the user releases the mouse button while the cursor is over a checkbox.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundRadioPress`
Identifies a sound to be played when the user presses the mouse button while the cursor is over a radio button.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundRadioEnter`
Identifies a sound to be played when the user moves the cursor over a radio button after having moved the cursor away from the radio button without releasing the mouse button.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundRadioExit`
: Identifies a sound to be played when the user moves the cursor away from a position over a radio button, while the mouse button remains pressed.

  Available in Mac OS X v10.0 and later.

  Declared in `Appearance.h`.

`kThemeSoundRadioRelease`
: Identifies a sound to be played when the user releases the mouse button while the cursor is over a radio button.

  Available in Mac OS X v10.0 and later.

  Declared in `Appearance.h`.

`kThemeSoundScrollArrowPress`
: Identifies a sound to be played when the user presses the mouse button while the cursor is over a scroll bar arrow.

  Available in Mac OS X v10.0 and later.

  Declared in `Appearance.h`.

`kThemeSoundScrollArrowEnter`
: Identifies a sound to be played when the user moves the cursor over a scroll bar arrow after having moved the cursor away from the arrow without releasing the mouse button.

  Available in Mac OS X v10.0 and later.

  Declared in `Appearance.h`.

`kThemeSoundScrollArrowExit`
: Identifies a sound to be played when the user moves the cursor away from a position over a scroll bar arrow, while the mouse button remains pressed.

  Available in Mac OS X v10.0 and later.

  Declared in `Appearance.h`.

`kThemeSoundScrollArrowRelease`
: Identifies a sound to be played when the user releases the mouse button while the cursor is over a scroll bar arrow.

  Available in Mac OS X v10.0 and later.

  Declared in `Appearance.h`.

`kThemeSoundScrollEndOfTrack`
: Identifies a sound to be played when a scroll box arrives at the end of a scroll bar and can go no further.

  Available in Mac OS X v10.0 and later.

  Declared in `Appearance.h`.

`kThemeSoundScrollTrackPress`
: Identifies a sound to be played when the user presses the mouse button while the cursor is over the track part of a scroll bar (this area does not include the scroll box or scroll bar arrows).

  Available in Mac OS X v10.0 and later.

  Declared in `Appearance.h`.

`kThemeSoundSliderEndOfTrack`
: Identifies a sound to be played when a slider indicator arrives at the end of a slider track and can go no further. Note: This functionality is not available under Appearance Manager 1.1 or prior versions of Appearance.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundSliderTrackPress`
: Identifies a sound to be played when the user presses the mouse button while the cursor is over the track part of a slider (this area does not include the slider indicator).

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundBalloonOpen`
: Identifies a sound to be played when a help balloon appears.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundBalloonClose`
: Identifies a sound to be played when a help balloon disappears.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundBevelPress`
: Identifies a sound to be played when the user presses the mouse button while the cursor is over a bevel button.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundBevelEnter`
: Identifies a sound to be played when the user moves the cursor over a bevel button after having moved the cursor away from the bevel button without releasing the mouse button.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundBevelExit`
: Identifies a sound to be played when the user moves the cursor away from a position over a bevel button, while the mouse button remains pressed.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundBevelRelease`
: Identifies a sound to be played when the user releases the mouse button while the cursor is over a bevel button.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundLittleArrowUpPress`
: Identifies a sound to be played when the user presses the mouse button while the cursor is over the upward-pointing arrow of an increment/decrement button.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundLittleArrowDnPress`
: Identifies a sound to be played when the user presses the mouse button while the cursor is over the downward-pointing arrow of an increment/decrement button.

  Available in Mac OS X v10.0 and later.

  Declared in `Appearance.h`.

`kThemeSoundLittleArrowEnter`
: Identifies a sound to be played when the user moves the cursor over an increment/decrement button after having moved the cursor away from the button without releasing the mouse button.

  Available in Mac OS X v10.0 and later.

  Declared in `Appearance.h`.

`kThemeSoundLittleArrowExit`
: Identifies a sound to be played when the user moves the cursor away from a position over an increment/decrement button, while the mouse button remains pressed.

  Available in Mac OS X v10.0 and later.

  Declared in `Appearance.h`.

`kThemeSoundLittleArrowUpRelease`
: Identifies a sound to be played when the user releases the mouse button while the cursor is over the upward-pointing arrow of an increment/decrement button.

  Available in Mac OS X v10.0 and later.

  Declared in `Appearance.h`.

`kThemeSoundLittleArrowDnRelease`
: Identifies a sound to be played when the user releases the mouse button while the cursor is over the downward-pointing arrow of an increment/decrement button.

  Available in Mac OS X v10.0 and later.

  Declared in `Appearance.h`.

`kThemeSoundPopupPress`
: Identifies a sound to be played when the user presses the mouse button while the cursor is over a pop-up menu button.

  Available in Mac OS X v10.0 and later.

  Declared in `Appearance.h`.

`kThemeSoundPopupEnter`
: Identifies a sound to be played when the user moves the cursor over a pop-up menu button after having moved the cursor away from the button without releasing the mouse button.

  Available in Mac OS X v10.0 and later.

  Declared in `Appearance.h`.

`kThemeSoundPopupExit`
: Identifies a sound to be played when the user moves the cursor away from a position over a pop-up menu button, while the mouse button remains pressed.

  Available in Mac OS X v10.0 and later.

  Declared in `Appearance.h`.

`kThemeSoundPopupRelease`
Identifies a sound to be played when the user releases the mouse button while the cursor is over a pop-up menu button.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundDisclosurePress`
Identifies a sound to be played when the user presses the mouse button while the cursor is over a disclosure triangle.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundDisclosureEnter`
Identifies a sound to be played when the user moves the cursor over a disclosure triangle after having moved the cursor away from the disclosure triangle without releasing the mouse button.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundDisclosureExit`
Identifies a sound to be played when the user moves the cursor away from a position over a disclosure triangle, while the mouse button remains pressed.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundDisclosureRelease`
Identifies a sound to be played when the user releases the mouse button while the cursor is over a disclosure triangle.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundTabPressed`
Identifies a sound to be played when the user presses the mouse button while the cursor is over a tab.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundTabEnter`
Identifies a sound to be played when the user places the cursor over a tab.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundTabExit`
Identifies a sound to be played when the user moves the cursor over a tab after having moved the cursor away from the tab without releasing the mouse button.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundTabRelease`
Identifies a sound to be played when the user releases the mouse button while the cursor is over a tab.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundDragTargetHilite`
Identifies a sound to be played when the user drags an object over a valid drag-and-drop destination.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundDragTargetUnhilite`
Identifies a sound to be played when the user drags an object away from a valid drag-and-drop destination.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundDragTargetDrop`
Identifies a sound to be played when the user drops an object on a valid drag-and-drop destination.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundEmptyTrash`
Identifies a sound to be played when the Finder completes emptying the Trash directory.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundSelectItem`
Identifies a sound to be played when the user presses the mouse button while the cursor is over an item in the Finder.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundNewItem`
Identifies a sound to be played when the user creates a new item.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundReceiveDrop`
Identifies a sound to be played when a Finder object changes parents, such as when the user drops an icon on a folder.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundCopyDone`
Identifies a sound to be played when the Finder completes a copy operation.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundResolveAlias`
Identifies a sound to be played when the Finder resolves an alias.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundLaunchApp`
Identifies a sound to be played when the Finder launches an application.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeSoundDiskInsert`
Identifies a sound to be played when a disk is inserted.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeSoundDiskEject`
Identifies a sound to be played when a disk is ejected.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeSoundFinderDragOnIcon`
Identifies a sound to be played when the user drags an object over an icon.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeSoundFinderDragOffIcon`
Identifies a sound to be played when the user drags an object off of an icon.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

Discussion
Your application can pass constants of type `ThemeSoundKind` to the function `PlayThemeSound` (page 94) to play a theme-specific sound for an interface object when it changes state. Each sound plays asynchronously until complete, then stops automatically.

Theme Drag Sounds

Identify theme-specific sounds played when the user performs a drag.

```
enum {
    kThemeDragSoundNone = 0,
    kThemeDragSoundMoveWindow = 'wmov',
    kThemeDragSoundGrowWindow = 'wgro',
    kThemeDragSoundMoveUtilWindow = 'umov',
    kThemeDragSoundGrowUtilWindow = 'ugro',
    kThemeDragSoundMoveDialog = 'dmov',
    kThemeDragSoundMoveAlert = 'amov',
    kThemeDragSoundMoveIcon = 'imov',
    kThemeDragSoundSliderThumb = 'slth',
    kThemeDragSoundSliderGhost = 'slgh',
    kThemeDragSoundScrollBarThumb = 'sbth',
    kThemeDragSoundScrollBarGhost = 'sbgh',
    kThemeDragSoundScrollBarArrowDecreasing = 'sbad',
    kThemeDragSoundScrollBarArrowIncreasing = 'sbai',
    kThemeDragSoundDragging = 'drag'
};
typedef OSType ThemeDragSoundKind;
```

Constants
`kThemeDragSoundNone`
Specifies that no drag sound is used.
Available in Mac OS X v10.0 and later.
Declared in `Appearance.h`.

`kThemeDragSoundMoveWindow`
Specifies a sound to be played when the user moves a document window.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeDragSoundGrowWindow`
Specifies a sound to be played when the user resizes a window by dragging the size box.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeDragSoundMoveUtilWindow`
Specifies a sound to be played when the user moves a utility window.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeDragSoundGrowUtilWindow`
Specifies a sound to be played when the user resizes a utility window by dragging the size box.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeDragSoundMoveDialog`
Specifies a sound to be played when the user moves a dialog box.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeDragSoundMoveAlert`
Specifies a sound to be played when the user moves an alert box.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeDragSoundMoveIcon`
Specifies a sound to be played when the user moves an icon.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeDragSoundSliderThumb`
Specifies a sound to be played when the user drags the indicator of a slider control that supports live feedback.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeDragSoundSliderGhost`
Specifies a sound to be played when the user drags the indicator of a slider control that does not support live feedback.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeDragSoundScrollBarThumb`
Specifies a sound to be played when the user drags a scroll box belonging to a scroll bar that supports live feedback.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeDragSoundScrollBarGhost`
Specifies a sound to be played when the user drags a scroll box belonging to a scroll bar that does not support live feedback.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeDragSoundScrollBarArrowDecreasing`
Specifies a sound to be played when the user presses and holds the mouse button while the cursor is over the scroll bar arrow that decreases the scroll bar's value.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeDragSoundScrollBarArrowIncreasing`
Specifies a sound to be played when the user presses and holds the mouse button while the cursor is over the scroll bar arrow that increases the scroll bar's value.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

`kThemeDragSoundDragging`
Specifies a sound to be played during a Drag Manager drag.

Available in Mac OS X v10.0 and later.

Declared in `Appearance.h`.

Discussion
Your application can pass constants of type `ThemeDragSoundKind` to the function `BeginThemeDragSound` (page 27) to play a theme-specific sound when a user drags an interface object or otherwise holds the mouse button down for an extended action. Dragging sounds are looped for the duration of the drag and cease when your application calls `EndThemeDragSound` (page 59) when the drag has finished. Only one drag sound may occur at a time.

Desktop Picture Alignments

Represent picture alignments that might be reported in the data for the `kThemeDesktopPictureAlignmentTag` theme collection tag.

```
enum {
    kTiledOnScreen = 1,
    kCenterOnScreen = 2,
    kFitToScreen = 3,
    kFillScreen = 4,
    kUseBestGuess = 5
};
```

Constants
`kTiledOnScreen`
The picture draws repeatedly.

Available in Mac OS X v10.2 and later.

Declared in `Appearance.h`.

`kCenterOnScreen`
The picture is its actual size, or clipped if necessary, with the desktop pattern showing to the side of the picture if it is smaller than the desktop

Available in Mac OS X v10.2 and later.

Declared in `Appearance.h`.

`kFitToScreen`
The picture is reduced if necessary.

Available in Mac OS X v10.2 and later.

Declared in `Appearance.h`.

`kFillScreen`
The picture's aspect ratio is altered if necessary.

Available in Mac OS X v10.2 and later.

Declared in `Appearance.h`.

`kUseBestGuess`
The picture is automatically positioned, based on picture and monitor sizes.

Available in Mac OS X v10.2 and later.

Declared in `Appearance.h`.

appearanceBadBrushIndexErr

Obsolete error codes. Use the result codes listed in the section "Appearance Manager Result Codes" (page 217) instead.

```
enum {
    appearanceBadBrushIndexErr = -30560,
    appearanceProcessRegisteredErr = -30561,
    appearanceProcessNotRegisteredErr = -30562,
    appearanceBadTextColorIndexErr = -30563,
    appearanceThemeHasNoAccents = -30564,
    appearanceBadCursorIndexErr = -30565
};
```

kAEThemeSwitch

Obsolete. Use `kAEAppearanceChanged` , described in "Appearance Manager Apple Events," instead.

```
enum {
    kAEThemeSwitch = kAEAppearanceChanged
};
```

kThemeActiveDialogBackgroundBrush

Obsolete. Use the constants described in "Theme Brushes" instead.

```
enum {
    kThemeActiveDialogBackgroundBrush = kThemeBrushDialogBackgroundActive,
    kThemeInactiveDialogBackgroundBrush =
            kThemeBrushDialogBackgroundInactive,
    kThemeActiveAlertBackgroundBrush = kThemeBrushAlertBackgroundActive,
    kThemeInactiveAlertBackgroundBrush = kThemeBrushAlertBackgroundInactive,
    kThemeActiveModelessDialogBackgroundBrush =
            kThemeBrushModelessDialogBackgroundActive,
    kThemeInactiveModelessDialogBackgroundBrush =
        kThemeBrushModelessDialogBackgroundInactive,
    kThemeActiveUtilityWindowBackgroundBrush =
        kThemeBrushUtilityWindowBackgroundActive,
    kThemeInactiveUtilityWindowBackgroundBrush =
        kThemeBrushUtilityWindowBackgroundInactive,
    kThemeListViewSortColumnBackgroundBrush =
        kThemeBrushListViewSortColumnBackground,
    kThemeListViewBackgroundBrush = kThemeBrushListViewBackground,
    kThemeIconLabelBackgroundBrush = kThemeBrushIconLabelBackground,
    kThemeListViewSeparatorBrush = kThemeBrushListViewSeparator,
    kThemeChasingArrowsBrush = kThemeBrushChasingArrows,
    kThemeDragHiliteBrush = kThemeBrushDragHilite,
    kThemeDocumentWindowBackgroundBrush =
        kThemeBrushDocumentWindowBackground,
    kThemeFinderWindowBackgroundBrush = kThemeBrushFinderWindowBackground
};
```

kThemeActiveScrollBarDelimiterBrush

Obsolete. Use the constants described in "Theme Brushes" instead.

```
enum {
    kThemeActiveScrollBarDelimiterBrush =
        kThemeBrushScrollBarDelimiterActive,
    kThemeInactiveScrollBarDelimiterBrush =
        kThemeBrushScrollBarDelimiterInactive,
    kThemeFocusHighlightBrush     = kThemeBrushFocusHighlight,
    kThemeActivePopupArrowBrush   = kThemeBrushPopupArrowActive,
    kThemePressedPopupArrowBrush  = kThemeBrushPopupArrowPressed,
    kThemeInactivePopupArrowBrush = kThemeBrushPopupArrowInactive,
    kThemeAppleGuideCoachmarkBrush = kThemeBrushAppleGuideCoachmark
};
```

kThemeBrushPassiveAreaFill

Obsolete. Use the `kThemeBrushStaticAreaFill` constant, described in "Theme Brushes," instead.

```
enum {
    kThemeBrushPassiveAreaFill = kThemeBrushStaticAreaFill
};
```

kThemeActiveDialogTextColor

Obsolete. Use the constants described in "Theme Text Colors" instead.

```
enum {
    kThemeActiveDialogTextColor   = kThemeTextColorDialogActive,
    kThemeInactiveDialogTextColor = kThemeTextColorDialogInactive,
    kThemeActiveAlertTextColor    = kThemeTextColorAlertActive,
    kThemeInactiveAlertTextColor  = kThemeTextColorAlertInactive,
    kThemeActiveModelessDialogTextColor =
        kThemeTextColorModelessDialogActive,
    kThemeInactiveModelessDialogTextColor =
        kThemeTextColorModelessDialogInactive,
    kThemeActiveWindowHeaderTextColor = kThemeTextColorWindowHeaderActive,
    kThemeInactiveWindowHeaderTextColor =
        kThemeTextColorWindowHeaderInactive,
    kThemeActivePlacardTextColor  = kThemeTextColorPlacardActive,
    kThemeInactivePlacardTextColor = kThemeTextColorPlacardInactive,
    kThemePressedPlacardTextColor = kThemeTextColorPlacardPressed,
    kThemeActivePushButtonTextColor = kThemeTextColorPushButtonActive,
    kThemeInactivePushButtonTextColor = kThemeTextColorPushButtonInactive,
    kThemePressedPushButtonTextColor = kThemeTextColorPushButtonPressed,
    kThemeActiveBevelButtonTextColor = kThemeTextColorBevelButtonActive,
    kThemeInactiveBevelButtonTextColor = kThemeTextColorBevelButtonInactive,
    kThemePressedBevelButtonTextColor = kThemeTextColorBevelButtonPressed,
    kThemeActivePopupButtonTextColor = kThemeTextColorPopupButtonActive,
    kThemeInactivePopupButtonTextColor = kThemeTextColorPopupButtonInactive,
    kThemePressedPopupButtonTextColor = kThemeTextColorPopupButtonPressed,
    kThemeIconLabelTextColor      = kThemeTextColorIconLabel,
    kThemeListViewTextColor       = kThemeTextColorListView
};
```

kThemeActiveDocumentWindowTitleTextColor

Obsolete. Use the constants described in "Theme Text Colors" instead.

```
enum {
    kThemeActiveDocumentWindowTitleTextColor =
        kThemeTextColorDocumentWindowTitleActive,
    kThemeInactiveDocumentWindowTitleTextColor =
        kThemeTextColorDocumentWindowTitleInactive,
    kThemeActiveMovableModalWindowTitleTextColor =
        kThemeTextColorMovableModalWindowTitleActive,
    kThemeInactiveMovableModalWindowTitleTextColor =
        kThemeTextColorMovableModalWindowTitleInactive,
    kThemeActiveUtilityWindowTitleTextColor =
        kThemeTextColorUtilityWindowTitleActive,
    kThemeInactiveUtilityWindowTitleTextColor =
        kThemeTextColorUtilityWindowTitleInactive,
    kThemeActivePopupWindowTitleColor =
        kThemeTextColorPopupWindowTitleActive,
    kThemeInactivePopupWindowTitleColor =
        kThemeTextColorPopupWindowTitleInactive,
    kThemeActiveRootMenuTextColor = kThemeTextColorRootMenuActive,
    kThemeSelectedRootMenuTextColor = kThemeTextColorRootMenuSelected,
    kThemeDisabledRootMenuTextColor = kThemeTextColorRootMenuDisabled,
    kThemeActiveMenuItemTextColor = kThemeTextColorMenuItemActive,
    kThemeSelectedMenuItemTextColor = kThemeTextColorMenuItemSelected,
    kThemeDisabledMenuItemTextColor = kThemeTextColorMenuItemDisabled,
    kThemeActivePopupLabelTextColor = kThemeTextColorPopupLabelActive,
    kThemeInactivePopupLabelTextColor = kThemeTextColorPopupLabelInactive
};
```

kThemeScrollBar

Obsolete. Use the constants described in "Theme Track Kinds" instead.

```
enum {
    kThemeScrollBar              = kThemeMediumScrollBar,
    kThemeSlider                 = kThemeMediumSlider,
    kThemeProgressBar            = kThemeMediumProgressBar,
    kThemeIndeterminateBar       = kThemeMediumIndeterminateBar
};
```

kThemeMetricCheckBoxGlyphHeight

Obsolete. Use the constants described in "Theme Metrics" instead.

```
enum {
    kThemeMetricCheckBoxGlyphHeight = kThemeMetricCheckBoxHeight,
    kThemeMetricRadioButtonGlyphHeight = kThemeMetricRadioButtonHeight,
    kThemeMetricDisclosureButtonSize = kThemeMetricDisclosureButtonHeight,
    kThemeMetricBestListHeaderHeight = kThemeMetricListHeaderHeight,
    kThemeMetricSmallProgressBarThickness =
        kThemeMetricNormalProgressBarThickness,
    kThemeMetricProgressBarThickness = kThemeMetricLargeProgressBarThickness };
```

kThemeNoAdornment

Obsolete. Use the constants described in "Theme Button Adornments" instead.

```
enum {
    kThemeNoAdornment             = kThemeAdornmentNone,
    kThemeDefaultAdornment        = kThemeAdornmentDefault,
    kThemeFocusAdornment          = kThemeAdornmentFocus,
    kThemeRightToLeftAdornment    = kThemeAdornmentRightToLeft,
    kThemeDrawIndicatorOnly       = kThemeAdornmentDrawIndicatorOnly
};
```

kThemeStateDisabled

Obsolete. Use the constants described in "Theme Drawing States" instead.

```
enum {
    kThemeStateDisabled = 0
};
```

kThemeWidgetABox

Obsolete. Use the constants described in "Theme Title Bar Items" instead.

```
enum {
    kThemeWidgetABox = 3,
    kThemeWidgetBBox = 4,
    kThemeWidgetBOffBox = 5
};
```

Result Codes

The most common result codes returned by Appearance Manager are listed below.

Result Code	Value	Description
`themeInvalidBrushErr`	-30560	Invalid brush color constant Available in Mac OS X v10.0 and later.

Result Code	Value	Description
themeProcessRegisteredErr	-30561	Application already registered as an Appearance Manager client. Available in Mac OS X v10.0 and later.
themeProcessNotRegisteredErr	-30562	Application not registered as Appearance Manager client. Available in Mac OS X v10.0 and later.
themeBadTextColorErr	-30563	Invalid text color constant Available in Mac OS X v10.0 and later.
themeHasNoAccentsErr	-30564	Theme does not support accent colors Available in Mac OS X v10.0 and later.
themeBadCursorIndexErr	-30565	Invalid cursor constant Available in Mac OS X v10.0 and later.
themeScriptFontNotFoundErr	-30566	No font record for specified script. Available in Mac OS X v10.0 and later.
themeMonitorDepthNotSupportedErr	-30567	Theme cannot be supported on all monitors at their current bit depth Available in Mac OS X v10.0 and later.
themeNoAppropriateBrushErr	-30568	Theme brush has no corresponding theme text color Available in Mac OS X v10.2 and later.

Gestalt Constants

You can check for version and feature availability information by using the Appearance Manager selectors defined in the Gestalt Manager. For more information, see *Gestalt Manager Reference*.

Application Manager Reference

Framework: Carbon/Carbon.h

Declared in MacApplication.h

Overview

Note: This document was previously titled *Dock Manager Reference*.

The Application Manager provides a set of functions that Mac OS X applications can use to perform various application-level tasks. For example, you can use the Application Manager to:

- Control the display of system-provided user interface elements such as the menu bar and Dock while your application is in the foreground
- Customize your application's Dock tile by modifying the Dock icon and adding items to the contextual menu displayed for your application
- Display a Spotlight search window
- Display a custom about box for your application
- Retrieve the current application object (HIObject)

Functions by Task

Drawing in the Application Dock Tile

`HIApplicationCreateDockTileContext` (page 227)
Returns a Quartz graphics context for drawing in the application Dock tile.

`BeginCGContextForApplicationDockTile` (page 221)
Returns a Quartz graphics context for drawing in the application Dock tile.

`EndCGContextForApplicationDockTile` (page 223)
Releases the Quartz graphics context for an application Dock tile.

`BeginQDContextForApplicationDockTile` (page 221) Deprecated in Mac OS X v10.5
Returns a QuickDraw graphics port for drawing in the application Dock tile. (Deprecated. Use `BeginCGContextForApplicationDockTile` (page 221) or `HIApplicationCreateDockTileContext` (page 227) instead.)

`EndQDContextForApplicationDockTile` (page 223) Deprecated in Mac OS X v10.5
Releases the QuickDraw graphics port for an application Dock tile. (Deprecated. Use `EndCGContextForApplicationDockTile` (page 223) instead.)

Working With the Dock Menu

`GetApplicationDockTileMenu` (page 224)
Returns the menu containing items added to the contextual menu for your application Dock tile.

`SetApplicationDockTileMenu` (page 231)
Adds items to the contextual menu for your application Dock tile.

Working With the Dock Icon

`SetApplicationDockTileImage` (page 230)
Replaces an application Dock icon.

`OverlayApplicationDockTileImage` (page 229)
Composites an image with your application's Dock icon.

`RestoreApplicationDockTileImage` (page 230)
Restores your application Dock icon to the application icon.

`CreateCGImageFromPixMaps` (page 222)
Creates a Quartz image from an image and a mask.

Getting Scripts and Encodings

`GetApplicationScript` (page 224)
Returns the application script.

`GetApplicationTextEncoding` (page 225)
Returns the application text encoding for Resource Manager resources.

Displaying an About Box

`HIAboutBox` (page 226)
Displays a generic, HI-compliant about box.

Controlling System-Provided User Interface Elements

`SetSystemUIMode` (page 232)
Sets the presentation mode of the calling application.

`GetSystemUIMode` (page 225)
Gets the presentation mode of the calling application.

`HISearchWindowShow` (page 229)
Displays a Spotlight search window.

Getting the Application Object

`HIApplicationGetCurrent` (page 228)
Returns the currently running Carbon application object.

Getting the Focused Window

`HIApplicationGetFocus` (page 228)
Returns either the modeless or effective focused window.

Functions

BeginCGContextForApplicationDockTile

Returns a Quartz graphics context for drawing in the application Dock tile.

```
CGContextRef BeginCGContextForApplicationDockTile (
   void
);
```

Return Value
A graphics context you can use to draw in the application Dock tile with Quartz 2D.

Discussion
This function makes it possible to draw into the application Dock tile at a resolution of 128x128, which is the size of all Dock tiles prior to Mac OS X v10.5. If the user interface scale factor is not 1.0, the drawing will be scaled to the actual size of the tile.

This function locks the application Dock tile to prevent the Dock from drawing in the tile. When you are finished using the context, you must call the function `EndCGContextForApplicationDockTile` to release the context and the lock. Do not use `CGEndContext` or `CFRelease` for this purpose. To ensure that drawing to the context appears onscreen, you should call `CGContextFlush` before releasing the context.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

See Also
`EndCGContextForApplicationDockTile` (page 223)

Declared In
`MacApplication.h`

BeginQDContextForApplicationDockTile

Returns a QuickDraw graphics port for drawing in the application Dock tile. (Deprecated in Mac OS X v10.5. Use `BeginCGContextForApplicationDockTile` (page 221) or `HIApplicationCreateDockTileContext` (page 227) instead.)

```
CGrafPtr BeginQDContextForApplicationDockTile (
   void
);
```

Return Value
A pointer to a graphics port. You can use this port to draw into your application Dock tile with QuickDraw.

Discussion
This function locks the application Dock tile to prevent the Dock from drawing in the tile. When you are finished using the graphics port, you must call the function `EndQDContextForApplicationDockTile` to release the port and the lock. Do not use `DisposePort` for this purpose.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

See Also
`EndQDContextForApplicationDockTile` (page 223)

Declared In
`MacApplication.h`

CreateCGImageFromPixMaps

Creates a Quartz image from an image and a mask.

```
OSStatus CreateCGImageFromPixMaps (
   PixMapHandle inImage,
   PixMapHandle inMask,
   CGImageRef *outImage
);
```

Parameters

inImage
A handle to the image you want to use to create the Quartz image. The image should be the same size as the mask. For use in the Dock, the image should be 128 pixels square. Otherwise, the image can be any size.

inMask
A handle to the mask to use as the alpha channel. The mask should be the same size as the image.

outImage
On return, a Quartz image.

Return Value
A result code.

Discussion
The function `CreateCGImageFromPixMaps` uses the mask as the alpha channel for the resulting image. This allows you to have any level of transparency in the resulting image. You can pass the Quartz image as a parameter to any Quartz 2D drawing function, as well as to Dock tile functions such as the functions `SetApplicationDockTileImage` and `OverlayApplicationDockTileImage`. You can use `CreateCGImageFromPixMaps` to create an image for a badge, and then apply the badge to your application Dock icon.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacApplication.h`

EndCGContextForApplicationDockTile

Releases the Quartz graphics context for an application Dock tile.

```
void EndCGContextForApplicationDockTile (
   CGContextRef inContext
);
```

Parameters

inContext

A Quartz graphics context created by calling `BeginCGContextForApplicationDockTile` or `HIApplicationCreateDockTileContext`. On output, the context is invalid and should no longer be used.

Discussion
This function also releases the lock on the application Dock tile, signaling the Dock that you are done drawing in the tile.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

See Also
`HIApplicationCreateDockTileContext` (page 227)
`BeginCGContextForApplicationDockTile` (page 221)

Declared In
`MacApplication.h`

EndQDContextForApplicationDockTile

Releases the QuickDraw graphics port for an application Dock tile. (Deprecated in Mac OS X v10.5. Use `EndCGContextForApplicationDockTile` (page 223) instead.)

```
void EndQDContextForApplicationDockTile (
   CGrafPtr inContext
);
```

Parameters

inContext

A QuickDraw graphics port acquired by calling `BeginQDContextForApplicationDockTile`. On output, the port is invalid and should no longer be used.

Discussion
This function also releases the lock on the application Dock tile, signaling the Dock that you are done drawing in the tile.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

See Also
`BeginQDContextForApplicationDockTile` (page 221)

Declared In
`MacApplication.h`

GetApplicationDockTileMenu

Returns the menu containing items added to the contextual menu for your application Dock tile.

```
MenuRef GetApplicationDockTileMenu (
   void
);
```

Return Value
The menu containing items added to your application Dock tile menu using the function `SetApplicationDockTileMenu` (page 231), or `NULL` if there are no additional menu items.

Availability
Available in Mac OS X v10.1 and later.
Not available to 64-bit applications.

See Also
`SetApplicationDockTileMenu` (page 231)

Declared In
`MacApplication.h`

GetApplicationScript

Returns the application script.

```
ScriptCode GetApplicationScript (
   void
);
```

Return Value
The application script.

Discussion
Your application needs to get the application script when it uses a function, such as `UseThemeFont`, that takes a script code as a parameter.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacApplication.h`

GetApplicationTextEncoding

Returns the application text encoding for Resource Manager resources.

```
TextEncoding GetApplicationTextEncoding (
   void
);
```

Return Value
The application text encoding.

Discussion
Your application needs to use the application text encoding when it creates a CFString from text stored in Resource Manager resources. Typically the text uses a Mac encoding such as MacRoman or MacJapanese. For more information, see *Programming With the Text Encoding Conversion Manager*.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
QTCarbonShell

Declared In
`MacApplication.h`

GetSystemUIMode

Gets the presentation mode of the calling application.

```
void GetSystemUIMode (
   SystemUIMode *outMode,
   SystemUIOptions *outOptions
);
```

Parameters

outMode

On output, the caller's presentation mode. Pass `NULL` if you don't need this information. For a list of possible modes, see "Presentation Modes" (page 235). The presentation mode of an application determines which system-provided user interface elements are visible on the screen.

outOptions

On output, the options for the caller's presentation mode. Pass `NULL` if you don't need this information. For a list of possible options, see "Presentation Options" (page 236). Presentation options are used to inhibit or allow certain user interface elements and commands.

Discussion
This function returns information about the presentation mode of the calling application, not the presentation mode of the current login session. The login session mode may be different, since the login session mode is determined by the presentation mode of the frontmost application. If the calling application is not currently the frontmost application, then its presentation mode will not be in use. To track changes in the login session's presentation mode, you may handle the `kEventAppSystemUIModeChanged` Carbon event.

Availability
Available in Mac OS X v10.2 and later.

SetSystemUIMode (page 232)

Declared In
MacApplication.h

HIAboutBox

Displays a generic, HI-compliant about box.

```
OSStatus HIAboutBox (
   CFDictionaryRef inOptions
);
```

Parameters

inOptions

A dictionary of standard strings, a dictionary with the name of a localized strings file from which to retrieve the strings, or NULL to retrieve the strings from the Info.plist file. See the discussion for details.

Return Value
A result code.

Discussion
When this function is called, it displays a window called an about box that contains your application icon, name, software version, and other optional information. In a Carbon event–based application, the standard application event handler responds to the kHICommandAbout command by calling the function HIAboutBox for you. If your application menu has an About menu item, you will get this behavior for free. You don't need to call this function unless you want to customize the contents of the about box.

In addition to the application name and version, this function is designed to display two additional strings in the about box, a copyright string and a description string. You can customize what this function displays by passing in various options in the inOptions parameter:

- You can pass NULL to display application information defined in the Info.plist file or your bundle resource (not recommended). This function looks the Info.plist file for three keys to get the name, version, and copyright strings: CFBundleName, CFBundleVersion, and CFBundleGetInfoString.
- You can pass a dictionary with replacement values for one or more strings. See "About Box Keys" (page 233) for a list of valid keys in this dictionary. If a replacement string is not passed, the default behavior applies. For example, you could pass some variant of your application name in the dictionary, but not pass a replacement version string or copyright string. The function would display your replacement string, and fall back to looking in the Info.plist file for the other strings.
- You can pass a dictionary with a single entry, the name of a localized strings file that contains replacement values for one or more strings. The dictionary key is kHIAboutBoxStringFileKey, and the value is the name of the strings file without the .strings extension. This function automatically uses that file to find the strings for the about box. This example shows the key-value pairs in a typical strings file:

  ```
  HIAboutBoxName = "AboutBox";
  HIAboutBoxVersion = "v1.0";
  HIAboutBoxCopyright = "© Apple Computer, 2006";
  ```

```
HIAboutBoxDescription = "An Example Application";
```

Again, if a string is not found in that file, this function falls back to looking for a string in the dictionary, and then finally the `Info.plist` file.

Note that the description string can only be specified in an options dictionary or a strings file; this function does not check your `Info.plist` file for a description string.

Availability
Available in Mac OS X v10.3 and later.
Not available to 64-bit applications.

Declared In
`MacApplication.h`

HIApplicationCreateDockTileContext

Returns a Quartz graphics context for drawing in the application Dock tile.

```
CGContextRef HIApplicationCreateDockTileContext (
   HISize *outContextSize
);
```

Parameters

outContextSize
On output, the size of the graphics context in which the application should draw.

Return Value
A Quartz graphics context you can use to draw in the application Dock tile. For more information about this context, see the Discussion below.

Discussion
This function makes it possible to draw into the application Dock tile at a resolution other than 128x128, which is the size of all Dock tiles prior to Mac OS X v10.5. In Mac OS X v10.5 and later, dock tiles may use different sizes when the user interface scale factor is not 1.0.

Unlike `BeginCGContextForApplicationDockTile` (page 221), this function returns a context that has no transform applied to it; user space and device space are 1:1. Your application must use the output context size to determine the area in which you should draw in the context.

Because the Dock's tile size can change dynamically, applications that use this function should be prepared to redraw their Dock tile as necessary. A `kEventAppUpdateDockTile` Carbon event is sent when the application needs to redraw its Dock tile.

This function locks the application Dock tile to prevent the Dock from drawing in the tile. When you are finished using the context, you must call the function `EndCGContextForApplicationDockTile` to release the context and the lock. Do not use `CGEndContext` or `CFRelease` for this purpose. To ensure that drawing to the context appears onscreen, you should call `CGContextFlush` before releasing the context.

Availability
Available in Mac OS X v10.5 and later.
Not available to 64-bit applications.

See Also
EndCGContextForApplicationDockTile (page 223)

Declared In
MacApplication.h

HIApplicationGetCurrent

Returns the currently running Carbon application object.

```
HIObjectRef HIApplicationGetCurrent (
   void
);
```

Return Value
The current application object.

Discussion
In Mac OS X v10.5 and later, you can use this function to install your own HIObject delegates on the application object.

The function GetApplicationEventTarget (page 260) returns the event target associated with the application object.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
MacApplication.h

HIApplicationGetFocus

Returns either the modeless or effective focused window.

```
WindowRef HIApplicationGetFocus (
   Boolean inConsideringModalFocus
);
```

Parameters
inConsideringModalFocus
A Boolean value that specifies whether to return the effective focus (true) or the modeless focus (false).

Return Value
The focused window, or NULL if there is no focused window.

Discussion
With the introduction of the modal focus stack in Mac OS X v10.5, an application may have two different focused windows: the modeless focus (the window most recently passed to the function SetUserFocusWindow (page 1934)), and the effective focus (either the modeless focus or, if there is a non-empty modal focus stack, the topmost window in the focus stack). This function returns either window.

Applications can use this function to determine if the modeless focus and effective focus are different windows. An application with a custom HIView can also use this function to determine if the application should show an insertion point. The insertion point should only be visible if the view is inside the effective focus.

Note that the function `GetUserFocusWindow` (page 1841) returns the modeless focus—the same window returned when you pass `false` to `HIApplicationGetFocus`.

Availability
Available in Mac OS X v10.5 and later.
Not available to 64-bit applications.

Declared In
`MacApplication.h`

HISearchWindowShow

Displays a Spotlight search window.

```
OSStatus HISearchWindowShow (
   CFStringRef inSearchString,
   OptionBits inFlags
);
```

Parameters

inSearchString
An initial query string. Pass `NULL` to open the search window with no initial query string.

inFlags
Optional flags. Currently, you should pass `kNilOptions`.

Return Value
A result code.

Discussion
This function displays a window with the standard Spotlight search interface. For more information, see *Spotlight Query Programming Guide*.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`MacApplication.h`

OverlayApplicationDockTileImage

Composites an image with your application's Dock icon.

```
OSStatus OverlayApplicationDockTileImage (
   CGImageRef inImage
);
```

Parameters

inImage
The image to overlay onto your application Dock icon.

Return Value
A result code.

Discussion
You can overlay an image, such as a badge, to indicate the application's status to the user.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacApplication.h`

RestoreApplicationDockTileImage

Restores your application Dock icon to the application icon.

```
OSStatus RestoreApplicationDockTileImage (
   void
);
```

Return Value
A result code.

Discussion
If you've called the functions `SetApplicationDockTileImage` or `OverlayApplicationDockTileImage`, you can use the function `RestoreApplicationDockTileImage` to restore the Dock icon to the original application icon.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacApplication.h`

SetApplicationDockTileImage

Replaces an application Dock icon.

```
OSStatus SetApplicationDockTileImage (
   CGImageRef inImage
);
```

Parameters

inImage
The image to use for your application Dock tile.

Return Value
A result code.

Discussion
When an application starts up, by default the application icon is always used as the application Dock tile. You can use the function `SetApplicationDockTileImage` to replace the application icon with another image. This can be useful to indicate the state of the application to the user. If you set the image, it will not revert back to its original image when your application terminates. You need to manually restore it before quitting using the function `RestoreApplicationDockTileImage`.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`MacApplication.h`

SetApplicationDockTileMenu

Adds items to the contextual menu for your application Dock tile.

```
OSStatus SetApplicationDockTileMenu (
   MenuRef inMenu
);
```

Parameters

inMenu
A menu containing the additional items, or `NULL` to remove the current menu.

Return Value
A result code.

Discussion
When you position the cursor over an application Dock tile and hold down the mouse button, a contextual menu automatically displays a list of the application's document windows and standard application Dock menu items such as Open at Login and Show in Finder. You can use the function `SetApplicationDockTileMenu` to add menu items to the contextual menu displayed for your application Dock tile. The items in the menu you pass to this function are inserted into your application Dock tile menu, between the list of document windows and the standard items.

This function increments the reference count of the menu you pass to it. Before the menu is displayed, it receives the Carbon events `kEventMenuPopulate`, `kEventMenuOpening`, and `kEventMenuEnableItems`, so any event handlers for these events can update the menu appropriately. You can receive notifications of and handle selections from the menu using `kEventCommandProcess` Carbon event handlers installed in the application event target. You must make sure each menu item has a command ID, as the `kEventCommandProcess` event sent to your application provides the menu item's command ID.

When you use this function to pass a menu to the Dock, the following state of each menu item is preserved:

- Information about whether the item is a text item or a separator
- The item text (if the item is not a separator)
- The item command ID
- The item command key modifiers (but not the command key itself)
- The item mark
- The item indent

- The item style
- The item icon, if the icon was specified with `kMenuSystemIconSelectorType` or `kMenuIconResourceType`
- The item's submenu
- These menu item attributes:
  - `kMenuItemAttrNotPreviousAlternate`
  - `kMenuItemAttrSectionHeader`
  - `kMenuItemAttrDisabled`
  - `kMenuItemAttrIconDisabled`
  - `kMenuItemAttrSubmenuParentChoosable`
  - `kMenuItemAttrDynamic`

No other menu or menu item state is preserved when the menu is displayed by the Dock. For example, you can set a custom font for the menu or a menu item, but the menu as displayed by the Dock will not use that font.

Availability
Available in Mac OS X v10.1 and later.
Not available to 64-bit applications.

See Also
`GetApplicationDockTileMenu` (page 224)

Declared In
`MacApplication.h`

SetSystemUIMode

Sets the presentation mode of the calling application.

```
OSStatus SetSystemUIMode (
   SystemUIMode inMode,
   SystemUIOptions inOptions
);
```

Parameters

inMode

The new presentation mode. Pass one of the constants listed in "Presentation Modes" (page 235). The presentation mode of an application determines which system-provided user interface elements are visible on the screen.

inOptions

A mask that specifies options controlling how the specified presentation mode behaves. Pass one or more of the flags listed in "Presentation Options" (page 236), or zero to indicate that no options are needed. Presentation options are used to inhibit or allow certain user interface elements and commands.

Return Value
A result code.

Discussion
The purpose of this function is to make it easier to implement a dedicated kiosk system, in which the user is not permitted access to certain elements and features in the system user interface. This function gives your application control over the visibility of the Dock and the menu bar, and over various other system-provided user interface features such as process switching, logout, restart, and shutdown.

If your application is frontmost and you call this function to request a new presentation mode, your presentation mode will take effect immediately. If another application becomes frontmost, the presentation mode you requested will no longer be in effect. If your application becomes frontmost again, the presentation mode you previously established will come back into effect.

When the frontmost application uses this function to change its presentation mode, a `kEventAppSystemUIModeChanged` Carbon event is sent to all applications that have registered for the event. This event is also sent when an application is activated; it contains the newly active application's presentation mode.

In addition to using this function, an application may also specify an initial presentation mode when it is launched by using the `LSUIPresentationMode` key in its `Info.plist` file. This key should be of type `Number` and should have the value of one of the presentation mode constants listed in "Presentation Modes" (page 235).

Special Considerations

If your application uses the `LSUIElement` or `LSBackgroundOnly` key in its `Info.plist` file, you should not use this function. The presentation mode of the current login session is determined by the presentation mode of the frontmost application, and applications that use these keys generally do not become the frontmost application.

Availability
Available in Mac OS X v10.2 and later.

See Also
`GetSystemUIMode` (page 225)

Declared In
`MacApplication.h`

Constants

About Box Keys

Constants that specify keys used in an options dictionary passed to the function `HIAboutBox` (page 226).

```
#define kHIAboutBoxNameKey CFSTR("HIAboutBoxName")
#define kHIAboutBoxVersionKey CFSTR("HIAboutBoxVersion")
#define kHIAboutBoxCopyrightKey CFSTR("HIAboutBoxCopyright")
#define kHIAboutBoxDescriptionKey CFSTR("HIAboutBoxDescription")
#define kHIAboutBoxStringFileKey CFSTR("HIAboutBoxStringFile")
```

Constants

`kHIAboutBoxNameKey`
Key for the application name that replaces the name specified by the `CFBundleName` key in the `Info.plist` file.

Available in Mac OS X v10.3 and later.

Declared in `MacApplication.h`.

`kHIAboutBoxVersionKey`
Key for the application software version number that replaces the version number specified by the `CFBundleVersion` key in the `Info.plist` file.

Available in Mac OS X v10.3 and later.

Declared in `MacApplication.h`.

`kHIAboutBoxCopyrightKey`
Key for the application copyright notice that replaces the text specified by the `CFBundleGetInfoString` key in the `Info.plist` file.

Available in Mac OS X v10.3 and later.

Declared in `MacApplication.h`.

`kHIAboutBoxDescriptionKey`
Key for a short description of the application.

Available in Mac OS X v10.3 and later.

Declared in `MacApplication.h`.

`kHIAboutBoxStringFileKey`
Key for the name of a localized strings file that contains about-box strings for the application.

Available in Mac OS X v10.3 and later.

Declared in `MacApplication.h`.

Discussion
The values associated with the keys in an options dictionary are all strings.

HIToolbox Version Number

Constant that specifies the current version number of HIToolbox.

```
const float kHIToolboxVersionNumber;
```

Constants

`kHIToolboxVersionNumber`
The current HIToolbox version number, which is incremented each time that HIToolbox is rebuilt during the course of a Mac OS X release.

Available in Mac OS X v10.3 and later.

Declared in `MacApplication.h`.

Discussion
You can use this constant to check for the presence of bug fixes documented in HIToolbox release notes. For example, to test for the HIToolbox included in Mac OS X 10.4.2, check that `kHIToolboxVersionNumber` is at least 220. See the header file `MacApplication.h` for a list of the version numbers for specific releases.

Presentation Modes

Constants used to control the presentation of user interface elements provided by Mac OS X, such as the menu bar and Dock.

```
enum {
    kUIModeNormal = 0,
    kUIModeContentSuppressed = 1,
    kUIModeContentHidden = 2,
    kUIModeAllSuppressed = 4,
    kUIModeAllHidden = 3,
};
typedef UInt32 SystemUIMode;
```

Constants

`kUIModeNormal`
All standard system UI elements are visible.
Available in Mac OS X v10.2 and later.
Declared in `MacApplication.h`.

`kUIModeContentSuppressed`
System UI elements positioned in the content area of the screen (the area other than the menu bar) are hidden. However, these elements may automatically show themselves in response to mouse movements or other user activity.
Available in Mac OS X v10.2 and later.
Declared in `MacApplication.h`.

`kUIModeContentHidden`
System UI elements positioned in the content area of the screen (the area other than the menu bar) are hidden.
Available in Mac OS X v10.2 and later.
Declared in `MacApplication.h`.

`kUIModeAllSuppressed`
All system UI elements (including the menu bar) are hidden. However, these elements may automatically show themselves in response to mouse movements or other user activity.
Available in Mac OS X v10.3 and later.
Declared in `MacApplication.h`.

`kUIModeAllHidden`
All system UI elements (including the menu bar) are hidden.
Available in Mac OS X v10.2 and later.
Declared in `MacApplication.h`.

Discussion
The presentation mode of an application determines which system-provided user interface elements are visible on the screen. Your application can specify its presentation mode using the function `SetSystemUIMode` (page 232).

Presentation Options

Flags used to control optional behavior of system-provided user interface elements and features.

```
enum {
    kUIOptionAutoShowMenuBar = 1 << 0,
    kUIOptionDisableAppleMenu = 1 << 2,
    kUIOptionDisableProcessSwitch = 1 << 3,
    kUIOptionDisableForceQuit = 1 << 4,
    kUIOptionDisableSessionTerminate = 1 << 5,
    kUIOptionDisableHide = 1 << 6
};
typedef OptionBits SystemUIOptions;
```

Constants

`kUIOptionAutoShowMenuBar`
: This flag specifies that the menu bar automatically shows itself when the user moves the mouse into the screen area that would ordinarily be occupied by the menu bar. Only valid for the presentation mode `kUIModeAllHidden`.

  Available in Mac OS X v10.2 and later.

  Declared in `MacApplication.h`.

`kUIOptionDisableAppleMenu`
: This flag disables all items in the Apple menu. Valid for all presentation modes.

  Available in Mac OS X v10.2 and later.

  Declared in `MacApplication.h`.

`kUIOptionDisableProcessSwitch`
: This flag disables the Command-Tab and Command-Shift-Tab key sequences to switch the active process, and the global window rotation key sequence selected by the user in the Keyboard preference pane. The function `SetFrontProcess` may still be used to explicitly switch the active process. Only valid with presentation modes other than `kUIModeNormal`.

  Available in Mac OS X v10.2 and later.

  Declared in `MacApplication.h`.

`kUIOptionDisableForceQuit`
: This flag disables the Command-Option-Escape key sequence and the Force Quit menu item in the Apple menu to open the Force Quit window. Only valid with presentation modes other than `kUIModeNormal`.

  Available in Mac OS X v10.2 and later.

  Declared in `MacApplication.h`.

`kUIOptionDisableSessionTerminate`
: This flag disables the Power key (if present) and the Restart, Shut Down, and Log Out menu items in the Apple menu. Only valid with modes other than `kUIModeNormal`.

  Available in Mac OS X v10.2 and later.

  Declared in `MacApplication.h`.

`kUIOptionDisableHide`
: This flag disables the Hide menu item in the Application menu. Note that this option does not prevent this application from being hidden if Hide Others is selected in some other application.

  Available in Mac OS X v10.3 and later.

  Declared in `MacApplication.h`.

Discussion
Presentation mode options are used to inhibit or allow certain user interface elements and commands. Your application can specify these options using the function `SetSystemUIMode` (page 232).

Carbon Event Manager Reference

Framework:	Carbon/Carbon.h
Declared in	CarbonEventsCore.h CarbonEvents.h

Overview

The Carbon Event Manager is the preferred API for handling events in Carbon applications. You can use this interface to handle events generated in response to user input as well as to create your own custom events. Because event handling is so fundamental to all applications, this document is relevant for everyone writing Carbon applications. To use this document, you should be familiar with Macintosh terminology and understand the basics of creating and manipulating the Mac OS user interface (windows, controls, menus, and so on).

For more information about HIObjects and the HIView subclass, see *HIView Programming Guide*.

Functions by Task

Creating and Manipulating Event Handlers

`InstallEventHandler` (page 274)
Installs an event handler on a specified event target.

`InstallStandardEventHandler` (page 278)
Installs the standard event handler for the specified target.

`RemoveEventHandler` (page 294)
Removes the specified event handler.

`AddEventTypesToHandler` (page 246)
Adds events to an installed handler.

`RemoveEventTypesFromHandler` (page 295)
Removes events from an installed event handler.

`CallNextEventHandler` (page 247)
Calls the next handler in the handler chain.

`RegisterEventHotKey` (page 290)
Registers a global hot key.

`UnregisterEventHotKey` (page 306)
Unregisters a global hot key.

`RegisterToolboxObjectClass` (page 291) Deprecated in Mac OS X v10.4
Registers events to be associated with a toolbox object. (Deprecated. Use the HIObject function `HIObjectRegisterSubclass` (page 2335) instead.)

`UnregisterToolboxObjectClass` (page 307) Deprecated in Mac OS X v10.4
Unregisters events for a given toolbox object class (Deprecated. Use the HIObject function `HIObjectUnregisterClass` (page 2340) instead.)

Creating and Manipulating Event Timers

`InstallEventLoopTimer` (page 276)
Installs a timer.

`InstallEventLoopIdleTimer` (page 275)
Installs a timer that fires only when there is no user activity.

`RemoveEventLoopTimer` (page 295)
Removes the specified timer.

`SetEventLoopTimerNextFireTime` (page 300)
Sets the next time that the specified timer will fire.

Creating and Manipulating Events

`GetEventClass` (page 264)
Returns the class of an event (for example, window, mouse, or keyboard).

`GetEventKind` (page 265)
Returns the event kind for the specified event.

`GetEventParameter` (page 266)
Obtains a parameter from the specified event.

`SetEventParameter` (page 300)
Sets a parameter associated with a particular event.

`CreateEvent` (page 252)
Creates an event.

`CopyEvent` (page 250)
Copies an event.

`CopyEventAs` (page 250)
Copies an existing event, allowing you to change the class and kind of the event.

`RetainEvent` (page 296)
Increments the reference count of an event.

`ReleaseEvent` (page 292)
Releases, and possibly disposes of, the specified event.

`GetEventRetainCount` (page 268)
Returns the reference count of an event.

`ConvertEventRefToEventRecord` (page 249)
Converts an event reference into an event record.

`IsEventInMask` (page 280)
Determines whether an event reference matches a `WaitNextEvent`-style event mask.

GetEventMonitorTarget (page 266)
Obtains an event monitor target.

Dispatching Events

SendEventToEventTarget (page 299)
Sends an event to the specified event target.

SendEventToEventTargetWithOptions (page 299)
Sends an event to the specified event target with propagation options.

GetControlEventTarget (page 261)
Obtains the event target reference for the specified control.

GetWindowEventTarget (page 273)
Obtains the event target reference for a specified window.

GetMenuEventTarget (page 270)
Obtains an event target reference for the specified menu.

GetApplicationEventTarget (page 260)
Obtains the event target reference for the application.

GetEventDispatcherTarget (page 264)
Obtains the event target reference for the standard toolbox dispatcher.

GetUserFocusEventTarget (page 272)
Obtains the event target reference for the user focus.

ProcessHICommand (page 287)
Sends a command to the command chain.

Managing Secure Event Input

EnableSecureEventInput (page 257)
Enables secure event input mode.

DisableSecureEventInput (page 255)
Disables secure event input mode.

IsSecureEventInputEnabled (page 282)
Determines whether secure event input mode is enabled.

Managing Event Queues

GetCurrentEventQueue (page 263)
Obtains the current event queue.

GetMainEventQueue (page 269)
Obtains the main event queue.

PostEventToQueue (page 286)
Adds an event to the specified event queue.

RemoveEventFromQueue (page 294)
Removes an event from the event queue.

`IsEventInQueue` (page 281)
Determines whether an event is in a particular queue.

`AcquireFirstMatchingEventInQueue` (page 245)
Obtains the first event that matches the specified list of event classes and kinds.

`FlushEventsMatchingListFromQueue` (page 259)
Removes events from the event queue by kind and class.

`FindSpecificEventInQueue` (page 258)
Finds a specific event in the event queue.

`FlushSpecificEventsFromQueue` (page 260)
Removes specified events from the event queue.

`FlushEventQueue` (page 259)
Removes all events from the event queue.

`GetNumEventsInQueue` (page 271)
Returns the number of events in the event queue.

Managing the Event Loop

`RunApplicationEventLoop` (page 297)
Runs the application event loop.

`QuitApplicationEventLoop` (page 288)
Terminates the application event loop.

`GetMainEventLoop` (page 269)
Obtains a reference to the main event loop.

`GetCurrentEventLoop` (page 263)
Obtains a reference to the current event loop.

`GetCFRunLoopFromEventLoop` (page 261)
Obtains a Core Foundation `CFRunLoop` from an Carbon event loop reference.

`RunCurrentEventLoop` (page 298)
Executes the event loop in the current thread.

`QuitEventLoop` (page 289)
Causes a specific event loop to terminate.

`ReceiveNextEvent` (page 289)
Waits for the next event of a specified type.

Manipulating Event Time

`GetCurrentEventTime` (page 263)
Returns the current time since last system startup, in seconds.

`GetEventTime` (page 268)
Returns the time a specific event occurred.

`SetEventTime` (page 301)
Sets the event time for a given event.

GetLastUserEventTime (page 268)
Returns the last time a user input event arrived in the main event queue of the application.

Implementing Modal Windows

RunAppModalLoopForWindow (page 298)
Puts the window in an application-modal state.

QuitAppModalLoopForWindow (page 288)
Quits the application-modal state for a window.

BeginAppModalStateForWindow (page 247)
Puts the window in an application-modal state, but does not process events.

EndAppModalStateForWindow (page 258)
Ends the application-modal state entered using the function BeginAppModalStateForWindow.

Tracking the Mouse

TrackMouseLocation (page 303)
Tracks the mouse, blocking your application when there is no activity.

TrackMouseLocationWithOptions (page 304)
Tracks the mouse with additional options.

TrackMouseRegion (page 305)
Tracks the mouse within a region.

ChangeMouseTrackingRegion (page 248)
(Deprecated. Use HIViewChangeTrackingArea (page 2445) instead.)

ClipMouseTrackingRegion (page 248)
(Deprecated. No replacement function. Use HIView-based mouse tracking areas instead.)

GetMouseTrackingRegionID (page 270)
(Deprecated. Use HIViewGetTrackingAreaID (page 2465) instead.)

MoveMouseTrackingRegion (page 283)
(Deprecated. No replacement function. Use HIView-based tracking areas instead.)

SetMouseTrackingRegionEnabled (page 302)
(Deprecated. No replacement function. Use HIView-based tracking areas instead.)

ClipWindowMouseTrackingRegions (page 249)
(Deprecated. No replacement function. Use HIView-based tracking areas instead.)

MoveWindowMouseTrackingRegions (page 283)
(Deprecated. No replacement function. Use HIView-based tracking areas instead.)

SetWindowMouseTrackingRegionsEnabled (page 303)
(Deprecated. Use HIView-based tracking areas instead.)

ReleaseWindowMouseTrackingRegions (page 293)
(Deprecated. No replacement function. Use HIView-based tracking areas instead.)

HIMouseTrackingGetParameters (page 273)
Obtains information about how mouse tracking loops should behave.

`CreateMouseTrackingRegion` (page 253) Deprecated in Mac OS X v10.4
Creates a mouse tracking region. (Deprecated. Use the HIView function `HIViewNewTrackingArea` (page 2473) instead.)

`GetMouseTrackingRegionRefCon` (page 271) Deprecated in Mac OS X v10.4
Obtains the reference constant for a mouse tracking region. (Deprecated. No replacement function. Use HIView-based mouse tracking areas instead.)

`ReleaseMouseTrackingRegion` (page 293) Deprecated in Mac OS X v10.4
Releases a mouse tracking region. (Deprecated. Use `HIViewDisposeTrackingArea` (page 2450) instead.)

`RetainMouseTrackingRegion` (page 296) Deprecated in Mac OS X v10.4
Retains a mouse tracking region. (Deprecated. No replacement function. Use HIView-based tracking areas instead.)

Working with Hot Keys

`CopySymbolicHotKeys` (page 252)
Obtains information about symbolic hot keys in the Keyboard preferences pane.

`PushSymbolicHotKeyMode` (page 287)
Sets a new mode for enabling and disabling symbolic hot keys.

`PopSymbolicHotKeyMode` (page 286)
Removes a hot key mode request from the hot key mode stack.

`GetSymbolicHotKeyMode` (page 272)
Obtains the current hot key mode.

Callback-Related Functions

`NewEventComparatorUPP` (page 284)
Creates an event comparator UPP.

`InvokeEventComparatorUPP` (page 278)
Calls an event comparator function through a UPP.

`DisposeEventComparatorUPP` (page 256)
Disposes of an event comparator UPP.

`NewEventHandlerUPP` (page 284)
Creates an event handler UPP.

`DisposeEventHandlerUPP` (page 256)
Disposes of an event handler UPP.

`InvokeEventHandlerUPP` (page 279)
Calls an event handler through a UPP.

`NewEventLoopTimerUPP` (page 285)
Creates an event loop timer UPP.

`InvokeEventLoopTimerUPP` (page 280)
Calls an event loop timer through a UPP.

`DisposeEventLoopTimerUPP` (page 257)
Disposes of an event loop timer.

`NewEventLoopIdleTimerUPP` (page 285)
Creates an event loop idle timer UPP.

`InvokeEventLoopIdleTimerUPP` (page 280)
Calls an event loop idle timer through a UPP.

`DisposeEventLoopIdleTimerUPP` (page 257)
Disposes of an event loop idle timer.

Miscellaneous

`CopyServicesMenuCommandKeys` (page 251)
Obtains information about command key shortcuts in an application's Services menu.

`CreateTypeStringWithOSType` (page 255)
Converts an `OSType` string to a Core Foundation string.

`GetCurrentEventKeyModifiers` (page 262)
Obtains the queue-synchronized keyboard modifier state.

`IsMouseCoalescingEnabled` (page 281)
Indicates whether mouse coalescing is enabled.

`SetMouseCoalescingEnabled` (page 302)
Turns mouse coalescing on or off.

`IsUserCancelEventRef` (page 282)
Returns whether the specified event indicates the user wishes to cancel an operation.

Functions

AcquireFirstMatchingEventInQueue

Obtains the first event that matches the specified list of event classes and kinds.

```
EventRef AcquireFirstMatchingEventInQueue (
   EventQueueRef inQueue,
   ItemCount inNumTypes,
   const EventTypeSpec *inList,
   OptionBits inOptions
);
```

Parameters

inQueue
The queue to check.

inNumTypes
The number of event kinds for which to search. You may pass `0` if you also pass `NULL` for `inList`.

inList
The list of event classes and kinds to search for in the queue. You may pass `NULL` if `inNumTypes` is `0`. Doing so effectively matches *any* event in the queue and causes this function to return the first event in the queue.

inOptions
Must be `kEventQueueOptionsNone`.

Return Value
An event reference, or `NULL` if no events match. The reference count for the event has been incremented (that is, it has been retained), so you must release the event reference.

Discussion
This function does not remove the event from the queue. To remove the event, call `RemoveEventFromQueue` (page 294).

This function does not call the run loop, so no timers fire as a result of calling this function. This function does not cause any window flushing to occur, but it does get new events from the window server.

This function should have better performance characteristics than the older `EventAvail` API.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`CarbonEventsCore.h`

AddEventTypesToHandler

Adds events to an installed handler.

```
OSStatus AddEventTypesToHandler (
   EventHandlerRef inHandlerRef,
   ItemCount inNumTypes,
   const EventTypeSpec *inList
);
```

Parameters

inHandlerRef
The event handler to add events to.

inNumTypes
The number of events to add.

inList
A pointer to an array of `EventTypeSpec` structures.

Return Value
A result code. See "Carbon Event Manager Result Codes" (page 452).

Discussion
You can use this function to dynamically change which events you want your handler to respond to.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CarbonEventsCore.h`

BeginAppModalStateForWindow

Puts the window in an application-modal state, but does not process events.

```
OSStatus BeginAppModalStateForWindow (
   WindowRef inWindow
);
```

Parameters

inWindow

The window you wish to behave modally. See the Window Manager documentation for a description of the `WindowRef` data type.

Return Value

A result code. See "Carbon Event Manager Result Codes" (page 452).

Discussion

This function is a lower level function than `RunAppModalLoopForWindow` (page 298). You use it if you want to enter an application modal state for a window but need to control the event loop yourself. Once you begin your application modal state, the menu bar will disable and prepare for the modal situation. You can then call low-level functions (such as `ReceiveNextEvent`) to run the event loop and process events.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`CarbonEvents.h`

CallNextEventHandler

Calls the next handler in the handler chain.

```
OSStatus CallNextEventHandler (
   EventHandlerCallRef inCallRef,
   EventRef inEvent
);
```

Parameters

inCallRef

The event handler call reference passed into your event handler.

inEvent

The event you want to pass to the next handler.

Return Value

A result code. See "Carbon Event Manager Result Codes" (page 452).

Discussion

Calls through to the event handlers below you in the event handler stack of the target to which your handler is bound. You might use this to call through to the default toolbox handling in order to post-process the event. You can only call this routine from within an event handler.

Availability

Available in Mac OS X v10.0 and later.

`CarbonEventsCore.h`

ChangeMouseTrackingRegion

(Deprecated in Mac OS X v10.4. Use `HIViewChangeTrackingArea` (page 2445) instead.)

```
OSStatus ChangeMouseTrackingRegion (
   MouseTrackingRef inMouseRef,
   RgnHandle inRegion,
   RgnHandle inClip
);
```

Special Considerations

Tracking areas are HIView-based rather than window-based. HIViews support compositing and Quartz, and provide a much easier way to handle user elements in windows. For more details about tracking areas, see the mouse tracking region section in *Carbon Event Manager Programming Guide*. For details about HIViews, see *HIView Programming Guide*.

Availability
Available in Mac OS X v10.2 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`CarbonEvents.h`

ClipMouseTrackingRegion

(Deprecated in Mac OS X v10.4. No replacement function. Use HIView-based mouse tracking areas instead.)

```
OSStatus ClipMouseTrackingRegion (
   MouseTrackingRef inMouseRef,
   RgnHandle inRegion
);
```

Special Considerations

Tracking areas are HIView-based rather than window-based. HIViews support compositing and Quartz, and provide a much easier way to handle user elements in windows. You generally don't need to modify the clipping of a tracking area. For more details about tracking areas, see the mouse tracking region section in *Carbon Event Manager Programming Guide*. For details about HIViews, see *HIView Programming Guide*.

Availability
Available in Mac OS X v10.2 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`CarbonEvents.h`

ClipWindowMouseTrackingRegions

(Deprecated in Mac OS X v10.4. No replacement function. Use HIView-based tracking areas instead.)

```
OSStatus ClipWindowMouseTrackingRegions (
   WindowRef inWindow,
   OSType inSignature,
   RgnHandle inClip
);
```

Special Considerations

Tracking areas are HIView-based rather than window-based. HIViews support compositing and Quartz, and provide a much easier way to handle user elements in windows. You generally don't need to modify the clipping of a tracking area. For more details about tracking areas, see the mouse tracking region section in *Carbon Event Manager Programming Guide*. For details about HIViews, see *HIView Programming Guide*.

Availability
Available in Mac OS X v10.2 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`CarbonEvents.h`

ConvertEventRefToEventRecord

Converts an event reference into an event record.

```
Boolean ConvertEventRefToEventRecord (
   EventRef inEvent,
   EventRecord *outEvent
);
```

Parameters

`inEvent`
The event reference to convert.

`outEvent`
The event record to fill out. See the Event Manager documentation for a description of the `EventRecord` data type.

Return Value
A Boolean value indicating whether the conversion was successful (`true`) or not (`false`).

Discussion
This function helps you when you need an `EventRecord` structure and all you have is a Carbon event reference. If the event can be converted, `outEvent` is filled in and the function returns `true`. If not, the function returns `false` and `outEvent` contains `nullEvent`.

This function can convert the following events:

- kEventMouseDown, kEventMouseUp, kEventMouseMoved, and kEventMouseDragged (kEventClassMouse)
- kEventRawKeyDown, kEventRawKeyUp, and kEventRawKeyRepeat (kEventClassKeyboard)
- kEventWindowUpdate, kEventWindowActivate, kEventWindowDeactivate, and kEventWindowCursorChange (kEventClassWindow)
- kEventAppActivated and kEventAppDeactivate (kEventClassApplication)
- kEventAppleEvent (kEventClassAppleEvents)
- kEventControlTrack (kEventClassControl) is converted to a mouse down event in Mac OS X v10.4 and later

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
CarbonEvents.h

CopyEvent

Copies an event.

```
EventRef CopyEvent (
   EventRef inOther
);
```

Parameters

inOther
The event to copy.

Return Value
A new event reference for the specified event.

Discussion
The CopyEvent function makes an exact duplicate of an existing event reference. The reference count for the duplicate event reference is set to 1.

Availability
Available in Mac OS X v10.0 and later.

Declared In
CarbonEventsCore.h

CopyEventAs

Copies an existing event, allowing you to change the class and kind of the event.

```
EventRef CopyEventAs (
   CFAllocatorRef inAllocator,
   EventRef inOther,
   OSType inEventClass,
   UInt32 inEventKind
);
```

Parameters

inOther

The allocator to use to allocate the event data. Pass `NULL` or `kCFAllocatorDefault` to use the standard allocator.

inOther

The event to copy.

inEventClass

The new event class for the copy of the event.

inEventKind

The new event kind for the copy of the event.

Return Value
A new event reference or `NULL` if the `inOther` was `NULL` or memory for the new event could not be allocated.

Discussion
The `CopyEventAs` is useful during event flow and transformation. For example, this function is used when upgrading a raw mouse down to a window click event, to ensure that the window click event has exactly the same parameters as the original mouse down event.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`CarbonEventsCore.h`

CopyServicesMenuCommandKeys

Obtains information about command key shortcuts in an application's Services menu.

```
OSStatus CopyServicesMenuCommandKeys (
   CFArrayRef *outCommandKeyArray
);
```

Parameters

outCommandKeyArray

On return, an array of items in the Services menu that have command key shortcuts associated with them.

Return Value
A result code. See "Carbon Event Manager Result Codes" (page 452).

Discussion
Each array entry is a reference to a CFDictionary, and each dictionary contains information about a single command key shortcut for items in the application's Services menu. Each dictionary contains the following keys: `kHIServicesMenuProviderName`, `kHIServicesMenuItemName`, `kHIServicesMenuCharCode`, and `kHIServicesMenuKeyModifiers`. The array must be released by the caller. The dictionaries do not need to be released because they are released automatically when the array is released.

Availability
Available in Mac OS X v10.4 and later.
Not available to 64-bit applications.

Declared In
`CarbonEvents.h`

CopySymbolicHotKeys

Obtains information about symbolic hot keys in the Keyboard preferences pane.

```
OSStatus CopySymbolicHotKeys (
   CFArrayRef *outHotKeyArray
);
```

Parameters

`outHotKeyArray`

An array of dictionaries containing information about the systemwide symbolic hot keys defined in the Keyboard preferences pane, such as the Screen Capture, Universal Access, and Keyboard Navigation keys. The array does not include information about custom, application-specific command keys. You must release the array when you no longer need it. The dictionaries are automatically released when you release the array.

Return Value
A result code. See "Carbon Event Manager Result Codes" (page 452).

Discussion
Each array entry is a reference for a CFDictionary, and each dictionary contains information about a single hot key. There is currently no way to determine which hot key in the Keyboards preference pane corresponds to a specific dictionary. Each dictionary contains the following keys: `kHISymbolicHotKeyCode`, `kHISymbolicHotKeyModifiers`, and `kHISymbolicHotKeyEnabled`. For details, see "Symbolic Hot Key Definitions" (page 376).

The number of hot keys will increase in the future, so do not call this function unnecessarily or in highly performance-sensitive code.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`CarbonEvents.h`

CreateEvent

Creates an event.

```
OSStatus CreateEvent (
    CFAllocatorRef inAllocator,
    UInt32 inClassID,
    UInt32 kind,
    EventTime when,
    EventAttributes flags,
    EventRef * outEvent
);
```

Parameters

inAllocator

A reference to the desired memory allocator to use to allocate memory for the event. Pass `NULL` to use the default allocator. See the Base Services documentation for a description of the `CFAllocatorRef` data type.

inClassID

The event class of the event to create.

kind

The event kind of the event to create.

when

The time the event occurred. Pass `0` to specify the current event time (as returned by the `GetCurrentEventTime` (page 263) function).

flags

The event attributes to set. Currently you can pass `kEventAttributeNone` or `kEventAttributeUserEvent`.

outEvent

On return, a reference to the newly created event.

Return Value

A result code. See "Carbon Event Manager Result Codes" (page 452).

Discussion

You can use this function to create your own custom events or to simulate existing events. If you are creating custom events, you must make sure that the event signature (the combination of event class and event kind) does not conflict with any existing events.

Availability

Available in Mac OS X v10.0 and later.

Related Sample Code

CarbonSketch

QTCarbonShell

Declared In

`CarbonEventsCore.h`

CreateMouseTrackingRegion

Creates a mouse tracking region. (Deprecated in Mac OS X v10.4. Use the HIView function `HIViewNewTrackingArea` (page 2473) instead.)

```
OSStatus CreateMouseTrackingRegion (
   WindowRef inWindow,
   RgnHandle inRegion,
   RgnHandle inClip,
   MouseTrackingOptions inOptions,
   MouseTrackingRegionID inID,
   void *inRefCon,
   EventTargetRef inTargetToNotify,
   MouseTrackingRef *outTrackingRef
);
```

Parameters

inWindow

The window to contain the tracking region.

inRegion

The region for which you want to receive mouse entered/exited events.

inClip

The clip region for the `inRegion` region (can be `NULL`).

inOptions

Tracking options that define whether the `inRegion` region is in local or global coordinates.

inID

A signature and ID to uniquely define this tracking region. See `MouseTrackingRegionID` (page 318) for information about the structure of this ID.

inRefCon

A pointer to an application-defined value. You can obtain this value by calling `GetMouseTrackingRegionRefCon` (page 271).

inTargetToNotify

The event target to send the mouse tracking event. If you pass `NULL`, the event target is the owning window specified in `inWindow`.

outTrackingRef

On return, a pointer to the new mouse tracking region.

Return Value

A result code. See "Carbon Event Manager Result Codes" (page 452).

Discussion

`CreateMouseTrackingRegion` allows you to define regions in your window, and the specified event target is notified (using `kEventMouseEntered` or `kEventMouseExited` events) when the mouse cursor interacts with the region. Your application can define any number of regions as long as each has a unique ID. This function is especially useful for creating rollover effects without having to constantly poll the mouse.

If you need to keep track of the state of the mouse (down or up) in a region, you should use `TrackMouseRegion` (page 305), either instead of, or in conjunction with, mouse tracking regions.

Special Considerations

Tracking areas are HIView-based rather than window-based. HIViews support compositing and Quartz, and provide a much easier way to handle user elements in windows. For more details about tracking areas, see the mouse tracking region section in *Carbon Event Manager Programming Guide*. For details about HIViews, see *HIView Programming Guide*.

Availability

Available in Mac OS X v10.2 and later.

Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Related Sample Code
QTCarbonShell

Declared In
`CarbonEvents.h`

CreateTypeStringWithOSType

Converts an `OSType` string to a Core Foundation string.

```
CFStringRef CreateTypeStringWithOSType (
   OSType inType
);
```

Return Value
The Core Foundation string version of the `OSType` string. A return value of `NULL` indicates that an error occurred. See the Base Services documentation for a description of the `CFStringRef` data type.

Discussion
You can use this function to create `CFString` versions of `OSType` data types to pass to the Services Manager. As this is a creation function, you must call `CFRelease` on your Core Foundation string when you no longer need it.

Availability
Available in Mac OS X v10.1 and later.
Not available to 64-bit applications.

Declared In
`CarbonEvents.h`

DisableSecureEventInput

Disables secure event input mode.

```
OSStatus DisableSecureEventInput (
   void
);
```

Return Value
A result code. See "Carbon Event Manager Result Codes" (page 452).

Discussion
When secure event input mode is enabled, keyboard input goes only to the application with keyboard focus and is not echoed to other applications that might be using the event monitor target to watch keyboard input. The `EditText` and `EditUnicodeText` controls automatically enter secure input mode when a password control has focus. If your application implements its own password entry, you should enable secure event input while the user enters text.

This function maintains a count of the number of times that it has been called. Secure event input is not disabled until DisableSecureEventInput has been called the same number of times. Be sure to disable secure event input if your application becomes inactive. If your application crashes, secure event input is automatically disabled if no other application has enabled it.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`CarbonEventsCore.h`

DisposeEventComparatorUPP

Disposes of an event comparator UPP.

```
void DisposeEventComparatorUPP (
   EventComparatorUPP userUPP
);
```

Parameters

userUPP
The UPP you want to destroy.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CarbonEventsCore.h`

DisposeEventHandlerUPP

Disposes of an event handler UPP.

```
void DisposeEventHandlerUPP (
   EventHandlerUPP userUPP
);
```

Parameters

userUPP
The event handler UPP you want to destroy.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CarbonEventsCore.h`

DisposeEventLoopIdleTimerUPP

Disposes of an event loop idle timer.

```
void DisposeEventLoopIdleTimerUPP (
   EventLoopIdleTimerUPP userUPP
);
```

Availability
Available in Mac OS X v10.2 and later.

Declared In
`CarbonEventsCore.h`

DisposeEventLoopTimerUPP

Disposes of an event loop timer.

```
void DisposeEventLoopTimerUPP (
   EventLoopTimerUPP userUPP
);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CarbonEventsCore.h`

EnableSecureEventInput

Enables secure event input mode.

```
OSStatus EnableSecureEventInput (
   void
);
```

Return Value
A result code. See "Carbon Event Manager Result Codes" (page 452).

Discussion
When secure event input mode is enabled, keyboard input goes only to the application with keyboard focus and is not echoed to other applications that might be using the event monitor target to watch keyboard input. The `EditText` and `EditUnicodeText` controls automatically enter secure input mode when a password control has focus. If your application implements its own password entry, you should enable secure event input while the user enters text.

This function maintains a count of the number of times that it has been called. Secure event input is not disabled until `DisableSecureEventInput` (page 255) has been called the same number of times. Be sure to disable secure event input if your application becomes inactive. If your application crashes, secure event input is automatically disabled if no other application has enabled it.

Availability
Available in Mac OS X v10.3 and later.

Declared In
CarbonEventsCore.h

EndAppModalStateForWindow

Ends the application-modal state entered using the function BeginAppModalStateForWindow.

```
OSStatus EndAppModalStateForWindow (
   WindowRef inWindow
);
```

Parameters

inWindow

The window you wish to stop acting as application- modal. See the Window Manager documentation for a description of the WindowRef data type.

Return Value
A result code. See "Carbon Event Manager Result Codes" (page 452).

Discussion
This routine ends an app modal state started with BeginAppModalStateForWindow (page 247).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
CarbonEvents.h

FindSpecificEventInQueue

Finds a specific event in the event queue.

```
EventRef FindSpecificEventInQueue (
   EventQueueRef inQueue,
   EventComparatorUPP inComparator,
   void *inCompareData
);
```

Parameters

inQueue

The event queue to search.

inComparator

The comparison function to invoke for each event in the queue. See EventComparatorProcPtr (page 307) for the required format of your comparison function A return value of true from the comparator indicates a match.

inCompareData

The data you wish to pass to your comparison function.

Return Value
An event reference.

Discussion
Returns the first event that matches a comparator function, or `NULL` if no events match.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CarbonEventsCore.h`

FlushEventQueue

Removes all events from the event queue.

```
OSStatus FlushEventQueue (
   EventQueueRef inQueue
);
```

Parameters

inQueue
The event queue to flush.

Return Value
A result code. See "Carbon Event Manager Result Codes" (page 452).

Discussion
Flushes all events from an event queue.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CarbonEventsCore.h`

FlushEventsMatchingListFromQueue

Removes events from the event queue by kind and class.

```
OSStatus FlushEventsMatchingListFromQueue (
   EventQueueRef inQueue,
   ItemCount inNumTypes,
   const EventTypeSpec *inList
);
```

Parameters

inQueue
The event queue to flush events from.

inNumTypes
The number of event kinds to flush.

inList
The list of event classes and kinds to flush from the queue.

Return Value
A result code. See "Carbon Event Manager Result Codes" (page 452).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CarbonEventsCore.h`

FlushSpecificEventsFromQueue

Removes specified events from the event queue.

```
OSStatus FlushSpecificEventsFromQueue (
   EventQueueRef inQueue,
   EventComparatorUPP inComparator,
   void *inCompareData
);
```

Parameters

inQueue
The event queue to flush events from.

inComparator
The comparison function to invoke for each event in the queue. See `EventComparatorProcPtr` (page 307) for the required format of your comparison function. A return value of `true` from the comparator indicates that the event should be flushed.

inCompareData
The data you wish to pass to your comparison function.

Return Value
A result code. See "Carbon Event Manager Result Codes" (page 452).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CarbonEventsCore.h`

GetApplicationEventTarget

Obtains the event target reference for the application.

```
EventTargetRef GetApplicationEventTarget (
   void
);
```

Return Value
An event target reference.

Discussion
Once you obtain this reference, you can send events to the target and install event handlers on it.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
QTCarbonShell
QTMetaData

Declared In
`CarbonEvents.h`

GetCFRunLoopFromEventLoop

Obtains a Core Foundation `CFRunLoop` from an Carbon event loop reference.

```
CFTypeRef GetCFRunLoopFromEventLoop (
   EventLoopRef inEventLoop
);
```

Parameters

`inEventLoop`
The event loop reference to translate.

Return Value
A reference to the CFRunLoop.

Discussion
There isn't necessarily a one-to-one correspondence between Carbon event loops and Core Foundation event loops, so you should use this function instead of simply calling the Core Foundation function `CFRunLoopGetCurrent`.

Availability
Available in Mac OS X v10.1 and later.

Declared In
`CarbonEventsCore.h`

GetControlEventTarget

Obtains the event target reference for the specified control.

```
EventTargetRef GetControlEventTarget (
   ControlRef inControl
);
```

Parameters

`inControl`
The control to return the target for. See the Control Manager documentation for a description of the `ControlRef` data type.

Return Value
An event target reference.

Discussion
Once you obtain this reference, you can send events to the target and install event handlers on it.

Availability
Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Related Sample Code
CarbonSketch

Declared In
`CarbonEvents.h`

GetCurrentEventKeyModifiers

Obtains the queue-synchronized keyboard modifier state.

```
UInt32 GetCurrentEventKeyModifiers (
   void
);
```

Return Value
A bit field indicating the queue-synchronized keyboard modifier state. This field is the same as the modifiers field returned in an Event Manager `EventRecord` structure, but it includes only the keyboard modifier flags.

Discussion
The queue-synchronized keyboard modifier state indicates the modifier state according to the event most recently dispatched through an event target. This state may be different from the hardware state obtained using `GetCurrentKeyModifiers` (page 994). For example, say the user invokes a Control-click with the mouse. If the user releases or changes a modifier key before the mouse down event is dispatched, the hardware state reflects the new modifier state, not the one that generated the original mouse event.

The most recently dispatched event may not necessarily be the event that your event handler is handling. For example, if a mouse-down event occurs, and you have a handler for the `kEventWindowHandleContentClick` event that is generated from the mouse-down, then the keyboard modifiers will be those that were attached to the mouse-down. The content-click event itself has a `kEventParamKeyModifiers` parameter, which is copied from the mouse-down event, but `GetCurrentEventKeyModifiers` returns the modifiers from the mouse-down, not from the content-click event, because it was the mouse-down event that was most recently dispatched through the event dispatcher.

Events that are not sent through the event dispatcher target will not update the current event key modifiers. Also, events arriving from outside the application, such as an AppleEvent or an Accessibility event, also will not update the modifiers. If your application modifies its behavior based on modifier state, you should parameterize your core code with the event modifiers, and determine the modifiers based on the origin of the behavior request. For a request that originates directly from user input, you can use `GetCurrentEventKeyModifiers`, but for a request that originates from an AppleEvent or Accessibility event, you would probably use no modifiers. `GetCurrentEventKeyModifiers` gives a more consistent user experience when the user input queue is being remote controlled or manipulated via non-hardware event sources such as speech or AppleEvents; using `GetCurrentEventKeyModifiers` is also much faster than using EventAvail(0, &eventRecord) or GetCurrentKeyModifiers.

`GetCurrentEventKeyModifiers` returns a valid modifier state only if your application is the active application. If your application is not active, then user input events are not flowing through the event dispatcher and the queue-synchronized state is not updated.

Availability
Available in Mac OS X v10.2 and later.

Declared In
CarbonEventsCore.h

GetCurrentEventLoop

Obtains a reference to the current event loop.

```
EventLoopRef GetCurrentEventLoop (
   void
);
```

Return Value
An event loop reference.

Discussion
This function returns the event loop for the current thread. If the current thread is a cooperative thread, the main event loop is returned.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
HID Config Save
HID Explorer

Declared In
CarbonEventsCore.h

GetCurrentEventQueue

Obtains the current event queue.

```
EventQueueRef GetCurrentEventQueue (
   void
);
```

Return Value
An event queue reference.

Discussion
This function obtains the event queue for the current thread. If the current thread is a cooperative thread, the main event queue is returned.

Availability
Available in Mac OS X v10.0 and later.

Declared In
CarbonEventsCore.h

GetCurrentEventTime

Returns the current time since last system startup, in seconds.

```
EventTime GetCurrentEventTime (
   void
);
```

Return Value
EventTime.

Discussion
Returns the current time since last system startup in seconds.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
CarbonSketch
QTCarbonShell

Declared In
`CarbonEventsCore.h`

GetEventClass

Returns the class of an event (for example, window, mouse, or keyboard).

```
OSType GetEventClass (
   EventRef inEvent
);
```

Parameters

inEvent
The event in question.

Return Value
The class ID of the event. See "Event Class Constants" (page 322) for more details.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
CarbonSketch
HID Calibrator
HID Config Save
HID Explorer
QTCarbonShell

Declared In
`CarbonEventsCore.h`

GetEventDispatcherTarget

Obtains the event target reference for the standard toolbox dispatcher.

```
EventTargetRef GetEventDispatcherTarget (
   void
);
```

Return Value
An event target reference.

Discussion
The standard toolbox dispatcher is the default mechanism for dispatching events to the appropriate event targets. You typically don't need to call this, but some applications may need to pick events off the event queue and call the dispatcher themselves. This allows you to do just that instead of calling `RunApplicationEventLoop` to handle it all.

If desired, you can attach event handlers to the event dispatcher target. Doing so allows you to intercept any events before they can be sent to the appropriate event targets.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CarbonEvents.h`

GetEventKind

Returns the event kind for the specified event.

```
UInt32 GetEventKind (
   EventRef inEvent
);
```

Parameters

`inEvent`
The event in question.

Return Value
The kind of the event.

Discussion
Event kind values overlap in different event classes. For example, `kEventMouseDown` and `kEventAppActivated` both have the same value (`1`). The combination of class and kind determines a unique event signature.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
CarbonSketch
HID Calibrator
HID Config Save
HID Explorer
QTCarbonShell

Declared In
`CarbonEventsCore.h`

GetEventMonitorTarget

Obtains an event monitor target.

```
EventTargetRef GetEventMonitorTarget (
   void
);
```

Return Value
An event monitor target.

Discussion
The event monitor target is a special event target used to monitor user input events across all processes. When an event handler is installed on the event monitor target, the Carbon Event Manager examines the EventTypeSpec for user input event types, such as mouse-down, mouse-up, and key-down. It then requests that the WindowServer make copies of any of these events that are sent to any process, and delivers them to the current process. These events are queued into the main thread's event queue and are sent directly to the event handlers installed on the event monitor target during normal event dispatching. Monitored events are not sent through the normal event dispatching path for the current process. Instead, they pass through the event dispatcher target and are sent directly to the event monitor target.Handlers installed on the event monitor target receive events only when the current application is inactive. When the current application is active, all events flow through the event dispatcher target, and no events are sent to the event monitor target. Currently, the event monitor supports the following event kinds: `kEventRawKeyDown`, `kEventRawKeyUp`, `kEventRawKeyRepeat`, `kEventRawKeyModifiersChange`, `kEventMouseDown`, `kEventMouseUp`, `kEventMouseMoved`, `kEventMouseDragged`, `kEventMouseWheelMoved`, `kEventTabletPoint`, and `kEventTabletProximity`.To prevent keyboard events from being passed to other applications, Carbon and Cocoa password-edit-text controls enable a secure input mode while the focus is on the control. Their password-edit-text controls prevent the monitoring event target from being used to capture password keystrokes. For added security, `GetEventMonitorTarget` requires that "Enable access for assistive devices" be checked in the Universal Access preference pane in order to monitor `kEventRawKeyDown`, `kEventRawKeyUp`, and `kEventRawKeyRepeat` events. If this control is not checked, you can still install handlers for these events on the event monitor target, but no events of these types will be sent to your handler. Administrator privileges are required to enable this feature. You can determine whether this control is checked using the `AXAPIEnabled` function in `AXUIElement.h`.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`CarbonEvents.h`

GetEventParameter

Obtains a parameter from the specified event.

```
OSStatus GetEventParameter (
   EventRef inEvent,
   EventParamName inName,
   EventParamType inDesiredType,
   EventParamType *outActualType,
   ByteCount inBufferSize,
   ByteCount *outActualSize,
   void *outData
);
```

Parameters

inEvent

The event to get the parameter from.

inName

The symbolic name of the parameter (for example, `kEventParamDirectObject`). The Carbon Event Manager defines a number of constants defining possible parameters.

inDesiredType

The desired type of the parameter (for example, `typeWindowRef`). The Carbon Event Manager automatically uses AppleEvent coercion handlers to convert the data in the event into the desired type, if possible. The Carbon Event Manager defines a number of constants to indicate possible parameter types. Pass `typeWildCard` to request that the data be returned in its original format.

outActualType

The actual type of the parameter (can be `NULL` if you are not interested in receiving this information).

inBufferSize

The size of the output buffer.

outActualSize

The actual size of the data, or `NULL` if you don't want this information.

outData

The pointer to the buffer receiving the parameter data.

Return Value

A result code. See "Carbon Event Manager Result Codes" (page 452).

Discussion

Events often contain additional useful pieces of data, such as the location of a mouse-down event or the window in which an event occurred.

Availability

Available in Mac OS X v10.0 and later.

Related Sample Code

HID Calibrator

HID Config Save

HID Explorer

QTCarbonShell

Declared In

`CarbonEventsCore.h`

GetEventRetainCount

Returns the reference count of an event.

```
ItemCount GetEventRetainCount (
   EventRef inEvent
);
```

Return Value
The current reference count for the specified event.

Discussion
When an event is created, its reference count is 1. Calls to `RetainEvent` increment this count; calls to `ReleaseEvent` decrement the count.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CarbonEventsCore.h`

GetEventTime

Returns the time a specific event occurred.

```
EventTime GetEventTime (
   EventRef inEvent
);
```

Parameters

`inEvent`
The event in question.

Return Value
The time the event occurred.

Discussion
Returns the time the event specified occurred, specified as an `EventTime` value, which is a floating point number representing seconds since the last system startup.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
QTCarbonShell

Declared In
`CarbonEventsCore.h`

GetLastUserEventTime

Returns the last time a user input event arrived in the main event queue of the application.

```
EventTime GetLastUserEventTime (
   void
);
```

Return Value
The time of the last user event.

Discussion
A user input event is something generated by the user, typically a hardware event such as a mouse-click or key-down event.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`CarbonEvents.h`

GetMainEventLoop

Obtains a reference to the main event loop.

```
EventLoopRef GetMainEventLoop (
   void
);
```

Return Value
An event loop reference.

Discussion
The main loop is the event loop for the main application thread.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
BSDLLCTest
QTCarbonShell

Declared In
`CarbonEventsCore.h`

GetMainEventQueue

Obtains the main event queue.

```
EventQueueRef GetMainEventQueue (
   void
);
```

Return Value
An event queue reference.

Discussion
The main queue is the event queue for the main application thread.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
QTCarbonShell

Declared In
`CarbonEventsCore.h`

GetMenuEventTarget

Obtains an event target reference for the specified menu.

```
EventTargetRef GetMenuEventTarget (
   MenuRef inMenu
);
```

Parameters

inMenu
The menu to return the target for. See the Menu Manager documentation for a description of the `MenuRef` data type.

Return Value
An event target reference.

Discussion
Once you obtain this reference, you can send events to the target and install event handlers on it.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`CarbonEvents.h`

GetMouseTrackingRegionID

(Deprecated in Mac OS X v10.4. Use `HIViewGetTrackingAreaID` (page 2465) instead.)

```
OSStatus GetMouseTrackingRegionID (
   MouseTrackingRef inMouseRef,
   MouseTrackingRegionID *outID
);
```

Special Considerations

Tracking areas are HIView-based rather than window-based. HIViews support compositing and Quartz, and provide a much easier way to handle user elements in windows. For more details about tracking areas, see the mouse tracking region section in *Carbon Event Manager Programming Guide*. For details about HIViews, see *HIView Programming Guide*.

Availability
Available in Mac OS X v10.2 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
CarbonEvents.h

GetMouseTrackingRegionRefCon

Obtains the reference constant for a mouse tracking region. (Deprecated in Mac OS X v10.4. No replacement function. Use HIView-based mouse tracking areas instead.)

```
OSStatus GetMouseTrackingRegionRefCon (
   MouseTrackingRef inMouseRef,
   void **outRefCon
);
```

Parameters

inMouseRef
The mouse tracking region whose reference count you want to obtain.

outRefCon
On return, a handler for the mouse tracking region.

Return Value
A result code. See "Carbon Event Manager Result Codes" (page 452).

Discussion
You use this function to obtain the reference constant you set in the `CreateMouseTrackingRegion` (page 253) function.

Special Considerations

Tracking areas are HIView-based rather than window-based. HIViews support compositing and Quartz, and provide a much easier way to handle user elements in windows. Mouse tracking areas do not support a reference constant. Instead, you can obtain the tracking area ID (using `HIViewGetTrackingAreaID` (page 2465)) and use that as a key to look up extended data in your own tables. For more details about tracking areas, see the mouse tracking region section in *Carbon Event Manager Programming Guide*. For details about HIViews, see *HIView Programming Guide*.

Availability
Available in Mac OS X v10.2 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
CarbonEvents.h

GetNumEventsInQueue

Returns the number of events in the event queue.

```
ItemCount GetNumEventsInQueue (
   EventQueueRef inQueue
);
```

Parameters

inQueue

The event queue to query.

Return Value
The number of items in the queue.

Discussion
Returns the number of events in an event queue.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CarbonEventsCore.h`

GetSymbolicHotKeyMode

Obtains the current hot key mode.

```
OptionBits GetSymbolicHotKeyMode (
   void
);
```

Return Value
The mode request at the top of the hot key mode stack. If there are no mode requests on the stack, this function returns `0` to indicate that hot keys are currently enabled.

Discussion
Unless the "Enable access for assistive devices" checkbox is checked in the Universal Access preference pane, all hot keys are enabled, even if this function returns a nonzero value. This means that hot keys enabled by the caller may be disabled for the current user session if they were disabled by another process.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CarbonEvents.h`

GetUserFocusEventTarget

Obtains the event target reference for the user focus.

```
EventTargetRef GetUserFocusEventTarget (
   void
);
```

Return Value
An event target reference.

Discussion
This event target always references the current user focus. For example, if you install a handler on this target, then your handler will be called whenever an event is sent to the user focus. Keyboard events are always sent to this target.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`CarbonEvents.h`

GetWindowEventTarget

Obtains the event target reference for a specified window.

```
EventTargetRef GetWindowEventTarget (
   WindowRef inWindow
);
```

Parameters

inWindow
The window to return the event target for. See the QuickDraw Manager documentation for a description of the `WindowRef` data type.

Return Value
An event target reference.

Discussion
Once you obtain this reference, you can send events to the target and install an event handler on it.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
QTCarbonShell

Declared In
`CarbonEvents.h`

HIMouseTrackingGetParameters

Obtains information about how mouse tracking loops should behave.

```
OSStatus HIMouseTrackingGetParameters (
   OSType inSelector,
   EventTime *outTime,
   HISize *outDistance
);
```

Parameters

inSelector
The type of information to obtain. Currently, the only supported selector is `kMouseParamsSticky`.

outTime

When sticky mode is select, on return, the maximum time between mouse-down and mouse-up. If the time between events is longer than this value, sticky mode should not be invoked. Pass `NULL` if you don't need this information.

outDistance

When sticky mode is select, on return, the maximum distance between mouse-down and mouse-up. If the distance between events is longer than this value, sticky mode should not be invoked. Pass `NULL` if you don't need this information.

Return Value
A result code. See "Carbon Event Manager Result Codes" (page 452).

Discussion
Mouse tracking loops use different timeouts and wander distances to determine their behavior. This function provides a generic service for requesting this information.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`CarbonEvents.h`

InstallEventHandler

Installs an event handler on a specified event target.

```
OSStatus InstallEventHandler (
   EventTargetRef inTarget,
   EventHandlerUPP inHandler,
   ItemCount inNumTypes,
   const EventTypeSpec *inList,
   void *inUserData,
   EventHandlerRef *outRef
);
```

Parameters

inTarget

The event target to register your handler with.

inHandler

A pointer to your event handler function.

inNumTypes

The number of events you are registering for.

inList

A pointer to an array of `EventTypeSpec` entries representing the events you are interested in.

inUserData

The value you pass in this parameter is passed to your event handler function when it is called.

outRef

On return, an event handler reference, which you can use later to remove the handler. You can pass `NULL` if you don't want the reference—when the target is disposed, the handler is disposed as well.

Return Value
A result code. See "Carbon Event Manager Result Codes" (page 452).

Discussion
After being installed, your handler will be called when an event you registered for is sent to the specified event target. Note that CarbonEvents.h defines several macros which you can use for particular event classes. These macros simply combine the appropriate `GetxxxEventTarget` call with `InstallEventHandler`.

- `InstallApplicationEventHandler`
- `InstallWindowEventHandler`
- `InstallControlEventHandler`
- `InstallMenuEventHandler`
- `InstallHIObjectEventHandler` (in Mac OS X v10.2 and later)
- `HIViewInstallEventHandler` (in Mac OS X v10.2 and later)

Be sure to remove the event handler when you no longer need it by calling `RemoveEventHandler` (page 294). Doing so is especially important if the handler calls code that may disappear. For example, if a plugin installs an event handler and is later removed without removing the handler, the system may attempt to call back to the now nonexistent plugin code.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
QTCarbonShell
QTMetaData

Declared In
`CarbonEventsCore.h`

InstallEventLoopIdleTimer

Installs a timer that fires only when there is no user activity.

```
OSStatus InstallEventLoopIdleTimer (
   EventLoopRef inEventLoop,
   EventTimerInterval inDelay,
   EventTimerInterval inInterval,
   EventLoopIdleTimerUPP inTimerProc,
   void *inTimerData,
   EventLoopTimerRef *outTimer
);
```

Parameters

inEventLoop
The event loop to add the timer.

inFireDelay
The delay before first firing this timer, in seconds. In Mac OS X v10.3 and earlier, this delay must be greater than zero. In Mac OS X v10.4 and later, the delay must be greater than or equal to zero. You cannot pass `kEventDurationForever`.

inInterval
The timer interval, in seconds. Pass `0` or `kEventDurationForever` for a one-shot timer.

inTimerProc
The function to call when the timer fires.

inTimerData
Data to pass to the timer function when called.

outTimer
A reference to the newly installed timer.

Return Value
A result code. See "Carbon Event Manager Result Codes" (page 452).

Discussion
An idle timer is the same as a standard event timer except that it fires only when no user events are being received. That is, if the system receives no user events for the `inFireDelay` delay time, the idle timer fires, and will continue to fire at the rate specified by `inInterval`. If the user begins activity again, the timer stops and resets. For example, you could use an idle timer in a search engine to begin a search 2 seconds after the user stops typing in the search text field.

The callback function for idle timers takes an additional parameter that tells the callback the user status. See `EventLoopIdleTimerProcPtr` (page 309) and "Idle Timer Event Constants" (page 416) for more information.

Be sure to dispose of the timer when you no longer need it by calling `RemoveEventLoopTimer` (page 295). Doing so is especially important if your timer calls code that may no longer exist. For example, if a plugin creates a timer that calls back to it, the timer will attempt to call it even after the plugin is removed.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`CarbonEventsCore.h`

InstallEventLoopTimer

Installs a timer.

```
OSStatus InstallEventLoopTimer (
   EventLoopRef inEventLoop,
   EventTimerInterval inFireDelay,
   EventTimerInterval inInterval,
   EventLoopTimerUPP inTimerProc,
   void *inTimerData,
   EventLoopTimerRef *outTimer
);
```

Parameters

inEventLoop
The event loop to add the timer.

inFireDelay

The delay before first firing this timer, in seconds. In Mac OS X v10.3 and earlier, the delay must be greater than zero. In Mac OS X v10.4, the delay can be greater than or equal to zero.

In Mac OS X and CarbonLib 1.5 and later, you may pass `kEventDurationForever` to stop the timer from firing at all until `SetEventLoopTimerNextFireTime` is used to start it; in earlier versions of CarbonLib, to achieve the same effect, just pass zero and then immediately call `SetEventLoopTimerNextFireTime( timer, (kEventDurationForever )` before returning control to your event loop.

inInterval

The timer interval, in seconds. Pass `0` or (in Mac OS X and CarbonLib 1.5 and later) `kEventDurationForever` for a one-shot timer.

inTimerProc

The function to call when the timer fires.

inTimerData

Data to pass to the timer function when called.

outTimer

A reference to the newly installed timer.

Return Value
A result code. See "Carbon Event Manager Result Codes" (page 452).

Discussion
Installs a timer onto the event loop specified. The timer can either fire once or repeatedly at a specified interval depending on the parameters passed to this function. It executes at task level and should not be confused with Time Manager tasks or any other interrupt-level callback. This means you can call toolbox functions, allocate memory, and draw without worrying about consequences. When a timer fires, it calls the callback you specified when the timer was installed.

Timers in general have two uses: as a timeout mechanism and as a periodic task. An everyday example of using a timer for a timeout might be a light that goes out if no motion is detected in a room for 5 minutes. For this, you might install a timer which will fire in 5 minutes. If motion is detected, you would reset the timer fire time and let the clock start over. If no motion is detected for the full 5 minutes, the timer will fire and you could power off the light. A periodic timer is one that fires at regular intervals (say every second or so). You might use such a timer to blink the insertion point in your editor, and so on.

One advantage of timers is that you can install the timer right from the code that wants the time. For example, the standard editable text control can install a timer to blink the cursor when it's active, meaning that the Control Manager function `IdleControls` is a no-op for that control and doesn't need to be called. When the control is inactive, it removes its timer and doesn't waste CPU time in that state.

Currently, if you do decide to draw when your timer is called, be sure to save and restore the current port so that calling your timer doesn't inadvertently change the port out from under someone.

Be sure to dispose of the timer when you no longer need it by calling `RemoveEventLoopTimer` (page 295). Doing so is especially important if your timer calls code that may no longer exist. For example, if a plugin creates a timer that calls back to it, the timer will attempt to call it even after the plugin is removed.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
BSDLLCTest

QTCarbonShell

Declared In
`CarbonEventsCore.h`

InstallStandardEventHandler

Installs the standard event handler for the specified target.

```
OSStatus InstallStandardEventHandler (
   EventTargetRef inTarget
);
```

Parameters

inTarget

The event target for which you want to install the standard handler.

Return Value
A result code. See "Carbon Event Manager Result Codes" (page 452).

Discussion
Currently you can install the standard handler only for window event targets. To install the standard application handler, you must call `RunApplicationEventLoop` (page 297).

Note that events may also have default behaviors or standard definitions which define how an event is handled if you choose not to handle it yourself. Default behavior is the response that occurs whenever you choose not to handle the event, whether or not you have a standard handler installed. Standard definition behavior defines how an event is handled based on that element's standard definition. For example, the standard menu definition provides some default responses for menu events you do not handle. However if you are using your own custom definition, you cannot assume that these default responses will occur.

You can also install the standard handler for a window event target by calling `ChangeWindowAttributes` to set the `kWindowStandardHandlerAttribute` window attribute on the window.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`CarbonEventsCore.h`

InvokeEventComparatorUPP

Calls an event comparator function through a UPP.

```
Boolean InvokeEventComparatorUPP (
   EventRef inEvent,
   void *inCompareData,
   EventComparatorUPP userUPP
);
```

Parameters

inEvent

The event to compare against.

inCompareData

Application-specific data. Typically this is the data you passed when calling `FindSpecificEventInQueue` (page 258) or `FlushSpecificEventsFromQueue` (page 260).

userUPP

A UPP to the comparator function you want to invoke.

Return Value
Returns `true` if the comparator function indicates a match with the specified event, `false` otherwise.

Discussion
You call this function only if you need to invoke your event comparator callback yourself. In most cases you don't need to call this function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CarbonEventsCore.h`

InvokeEventHandlerUPP

Calls an event handler through a UPP.

```
OSStatus InvokeEventHandlerUPP (
   EventHandlerCallRef inHandlerCallRef,
   EventRef inEvent,
   void *inUserData,
   EventHandlerUPP userUPP
);
```

Return Value
A result code. See "Carbon Event Manager Result Codes" (page 452).

Discussion
You use this function only if you need to invoke an event handler yourself. In most cases you don't need to call this function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CarbonEventsCore.h`

InvokeEventLoopIdleTimerUPP

Calls an event loop idle timer through a UPP.

```
void InvokeEventLoopIdleTimerUPP (
   EventLoopTimerRef inTimer,
   EventLoopIdleTimerMessage inState,
   void *inUserData,
   EventLoopIdleTimerUPP userUPP
);
```

Discussion
You use this function only if you need to invoke an idle event timer callback yourself. In most cases you don't need to call this function.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`CarbonEventsCore.h`

InvokeEventLoopTimerUPP

Calls an event loop timer through a UPP.

```
void InvokeEventLoopTimerUPP (
   EventLoopTimerRef inTimer,
   void *inUserData,
   EventLoopTimerUPP userUPP
);
```

Discussion
You use this function only if you need to invoke an event timer callback yourself. In most cases you don't need to call this function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CarbonEventsCore.h`

IsEventInMask

Determines whether an event reference matches a `WaitNextEvent`-style event mask.

```
Boolean IsEventInMask (
   EventRef inEvent,
   EventMask inMask
);
```

Parameters

inEvent

The event reference to check against the event mask.

inMask
The mask to consider. See the Event Manager documentation for a description of the `EventMask` data type.

Return Value
A Boolean whose value is `TRUE` if the event was in the mask; otherwise, `FALSE`.

Discussion
This is a companion function for `ConvertEventRefToEventRecord` (page 249), and is provided as a convenience function to help you if there are places in your application where you want to check an `EventRef` to see if it matches a classic `EventMask` bitfield. If the event matches, the function returns true.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`CarbonEvents.h`

IsEventInQueue

Determines whether an event is in a particular queue.

```
Boolean IsEventInQueue (
   EventQueueRef inQueue,
   EventRef inEvent
);
```

Parameters
inQueue
The queue to check.
inEvent
The event in question.

Return Value
Returns true if the specified event is posted to a queue.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CarbonEventsCore.h`

IsMouseCoalescingEnabled

Indicates whether mouse coalescing is enabled.

```
Boolean IsMouseCoalescingEnabled (
   void
);
```

Return Value
A Boolean whose value is `TRUE` if mouse coalescing is on; otherwise, `FALSE`.

Discussion
If mouse coalescing is enabled, intermediate mouse movement events are merged into the most recent event, so that only one mouse moved or mouse dragged event is in the event queue at any time. For example, when the user moves the mouse across the screen, more mouse moved events are generated than most applications care about. Rather than place all these events in the queue (which would probably slow down the application), the Carbon Event Manager first checks to see if a mouse moved event already exists. If a mouse moved event already exists, that event is updated with the position and delta information from the more recently-generated event.

Availability
Available in Mac OS X v10.1 and later.
Not available to 64-bit applications.

Declared In
`CarbonEvents.h`

IsSecureEventInputEnabled

Determines whether secure event input mode is enabled.

```
Boolean IsSecureEventInputEnabled (
   void
);
```

Return Value
A Boolean whose value is `TRUE` if secure event input mode is enabled; otherwise, `FALSE`.

Discussion
This function determines whether secure event input is enabled by *any* process, not just the current process. Secure event input may be disabled in the current process but enabled in another process, in which case, this function returns `TRUE`.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`CarbonEventsCore.h`

IsUserCancelEventRef

Returns whether the specified event indicates the user wishes to cancel an operation.

```
Boolean IsUserCancelEventRef (
   EventRef event
);
```

Return Value
A Boolean value indicating whether the event is a user cancel event.

Discussion
Tests the event given to see whether the event represents a user cancel event. Currently this is defined to be either the escape key being pressed or command-period being pressed.

Availability
Available in Mac OS X v10.0 and later.

Declared In
CarbonEvents.h

MoveMouseTrackingRegion

(Deprecated in Mac OS X v10.4. No replacement function. Use HIView-based tracking areas instead.)

```
OSStatus MoveMouseTrackingRegion (
   MouseTrackingRef inMouseRef,
   SInt16 deltaH,
   SInt16 deltaV,
   RgnHandle inClip
);
```

Special Considerations

Tracking areas are HIView-based rather than window-based. HIViews support compositing and Quartz, and provide a much easier way to handle user elements in windows. HIView-based mouse tracking areas move automatically when the HIView moves. For more details about tracking areas, see the mouse tracking region section in *Carbon Event Manager Programming Guide*. For details about HIViews, see *HIView Programming Guide*.

Availability
Available in Mac OS X v10.2 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
CarbonEvents.h

MoveWindowMouseTrackingRegions

(Deprecated in Mac OS X v10.4. No replacement function. Use HIView-based tracking areas instead.)

```
OSStatus MoveWindowMouseTrackingRegions (
   WindowRef inWindow,
   OSType inSignature,
   SInt16 deltaH,
   SInt16 deltaV,
   RgnHandle inClip
);
```

Special Considerations

Tracking areas are HIView-based rather than window-based. HIViews support compositing and Quartz, and provide a much easier way to handle user elements in windows. HIView-based mouse tracking areas move automatically when the HIView moves. For more details about tracking areas, see the mouse tracking region section in *Carbon Event Manager Programming Guide*. For details about HIViews, see *HIView Programming Guide*.

Availability
Available in Mac OS X v10.2 and later.

Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
CarbonEvents.h

NewEventComparatorUPP

Creates an event comparator UPP.

```
EventComparatorUPP NewEventComparatorUPP (
   EventComparatorProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your event comparator callback function.

Return Value
The UPP for your callback function.

Discussion
When calling FindSpecificEventInQueue (page 258) or FlushSpecificEventsFromQueue (page 260), you must pass a universal procedure pointer (UPP) to your event comparator instead of a standard procedure pointer.

Availability
Available in Mac OS X v10.0 and later.

Declared In
CarbonEventsCore.h

NewEventHandlerUPP

Creates an event handler UPP.

```
EventHandlerUPP NewEventHandlerUPP (
   EventHandlerProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your event handler.

Return Value
The UPP for your event handler.

Discussion
When registering your event handler with InstallEventHandler (page 274), you must pass a universal procedure pointer (UPP) to your event handler instead of a standard procedure pointer.

Availability
Available in Mac OS X v10.0 and later.

QTMetaData

Declared In
`CarbonEventsCore.h`

NewEventLoopIdleTimerUPP

Creates an event loop idle timer UPP.

```
EventLoopIdleTimerUPP NewEventLoopIdleTimerUPP (
   EventLoopIdleTimerProcPtr userRoutine
);
```

Parameters

`userRoutine`
A pointer to your idle event timer callback function.

Return Value
The UPP for your event loop idle timer callback function.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`CarbonEventsCore.h`

NewEventLoopTimerUPP

Creates an event loop timer UPP.

```
EventLoopTimerUPP NewEventLoopTimerUPP (
   EventLoopTimerProcPtr userRoutine
);
```

Parameters

`userRoutine`
A pointer to your event timer callback function.

Return Value
The UPP for your event timer callback function.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
BSDLLCTest
HID Config Save
HID Explorer

Declared In
CarbonEventsCore.h

PopSymbolicHotKeyMode

Removes a hot key mode request from the hot key mode stack.

```
void PopSymbolicHotKeyMode (
   void *inToken
);
```

Parameters

inToken

The hot key mode token that was returned by a previous call to PushSymbolicHotKeyMode (page 287).

Discussion
If the request is the topmost request on the stack, the hot key mode changes to the next request on the stack. If there are other mode requests on top of this request on the stack, the mode does not change.

Availability
Available in Mac OS X v10.4 and later.

Declared In
CarbonEvents.h

PostEventToQueue

Adds an event to the specified event queue.

```
OSStatus PostEventToQueue (
   EventQueueRef inQueue,
   EventRef inEvent,
   EventPriority inPriority
);
```

Parameters

inQueue

The event queue to post the event onto.

inEvent

The event to post.

inPriority

The priority of the event. See "Event Priority Constants" (page 326) for a list of possible constants to pass.

Return Value
A result code. See "Carbon Event Manager Result Codes" (page 452).

Discussion
Posts an event to the queue specified and increments its retain count. This automatically wakes up the event loop of the thread the queue belongs to.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
QTCarbonShell

Declared In
`CarbonEventsCore.h`

ProcessHICommand

Sends a command to the command chain.

```
OSStatus ProcessHICommand (
   const HICommand *inCommand
);
```

Return Value
A result code. See "Carbon Event Manager Result Codes" (page 452)

Discussion
`ProcessHICommand` is a convenience function for sending a "process command" event through the command chain (for example, from menu to user focus to application). The command event is sent initially to either a menu (if the command represents a menu command) or the current user focus. If the function returns `eventNotHandledErr`, the command was not handled by any element in the chain.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`CarbonEvents.h`

PushSymbolicHotKeyMode

Sets a new mode for enabling and disabling symbolic hot keys.

```
void * PushSymbolicHotKeyMode (
   OptionBits inOptions
);
```

Parameters
inOptions
The requested symbolic hot key mode. For details, see "Hot Key Constants" (page 376).

Return Value
A token that is passed to `PopSymbolicHotKeyMode` (page 286) to remove this mode request when it is no longer needed.

Discussion
The Event Manager maintains a stack of hot key modes that have been requested by calls to this function. The most recently pushed mode is the mode that is currently in use.

Disabling hot keys can significantly affect the usability of Mac OS X. For this reason, applications are allowed to disable hot keys only if the "Enable access for assistive devices" checkbox is checked in the Universal Access preference pane. If this checkbox is not checked when this function is called, the requested hot key mode is pushed onto the mode stack and a valid token is returned but the actual hot key mode is unchanged.

If the frontmost application pushes a new hot key mode that disables any hot keys, the new mode is active only while the application remains the frontmost application. If the application is deactivated or exits without re-enabling hot keys, the hot key mode automatically reverts to the previous mode.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`CarbonEvents.h`

QuitApplicationEventLoop

Terminates the application event loop.

```
void QuitApplicationEventLoop (
   void
);
```

Discussion
This function is used to quit the `RunApplicationEventLoop` (page 297) function. Typically, your application doesn't need to call this. If your application has the Quit menu item tagged with the `kHICommandQuit` menu command ID, the toolbox will automatically call this for your application, automatically terminating your event loop. If your application wants to do pre-processing before the event loop exits, it should intercept either the `kHICommandQuit` menu command, or the `kEventAppQuit` event.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
QTCarbonShell

Declared In
`CarbonEvents.h`

QuitAppModalLoopForWindow

Quits the application-modal state for a window.

```
OSStatus QuitAppModalLoopForWindow (
   WindowRef inWindow
);
```

Parameters

inWindow
The window that is leaving the modal state. See the Window Manager documentation for a description of the `WindowRef` data type.

Return Value
A result code. See "Carbon Event Manager Result Codes" (page 452).

Discussion
This function is used to quit a currently running call to `RunAppModalLoopForWindow` (page 298) (that is, it terminates a modal loop). Typically you call this from a handler you have installed on the modal window in question when the user clicks the appropriate button (Ok, Cancel, and so on).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`CarbonEvents.h`

QuitEventLoop

Causes a specific event loop to terminate.

```
OSStatus QuitEventLoop (
   EventLoopRef inEventLoop
);
```

Parameters
inEventLoop
The event loop to terminate.

Return Value
A result code. See "Carbon Event Manager Result Codes" (page 452).

Discussion
Usage of this is similar to `WakeUpProcess`, in that it causes the event loop specified to return immediately (as opposed to timing out). Typically you use this call in conjunction with `RunCurrentEventLoop` (page 298).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CarbonEventsCore.h`

ReceiveNextEvent

Waits for the next event of a specified type.

```
OSStatus ReceiveNextEvent (
   ItemCount inNumTypes,
   const EventTypeSpec *inList,
   EventTimeout inTimeout,
   Boolean inPullEvent,
   EventRef *outEvent
);
```

Parameters
inNumTypes
The number of event types to wait for (0 if any event should cause this function to return).

inList
The list of event types we are waiting for (pass `NULL` if any event should cause this function to return).

inTimeout
The time to wait before returning (passing `kEventDurationForever` is preferred).

inPullEvent
Pass `true` for this parameter to remove the next matching event from the queue.

outEvent
A pointer to the next event that matches the list passed in. If you passed `true` in the `inPullEvent` parameter, the event is owned by you, and you should release it when done.

Return Value
A result indicating whether an event was received, the timeout expired, or the current event loop was quit. See "Carbon Event Manager Result Codes" (page 452) for possible values.

Discussion
This function tries to fetch the next event of a specified type. If no events in the event queue match, this function will run the current event loop until an event that matches arrives, or the timeout expires. Except for timers firing, your application is blocked waiting for events to arrive when inside this function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CarbonEventsCore.h`

RegisterEventHotKey

Registers a global hot key.

```
OSStatus RegisterEventHotKey (
   UInt32 inHotKeyCode,
   UInt32 inHotKeyModifiers,
   EventHotKeyID inHotKeyID,
   EventTargetRef inTarget,
   OptionBits inOptions,
   EventHotKeyRef *outRef
);
```

Parameters

inHotKeyCode
The virtual key code of the hot key you want to register.

inHotKeyModifiers
The keyboard modifiers to look for. In Mac OS X v10.2 and earlier, if you do not specify a modifier key, this function returns `paramErr`. In Mac OS X v10.3 and later, passing `0` does not cause an error.

inHotKeyID
The application-specified hot key ID. You will receive this ID in the `kEventHotKeyPressed` event as the direct object parameter.

inTarget
The target to notify when the hot key is pressed.

inOptions
Currently unused. You must pass `0`.

outRef

On return, a reference to the new hot key. You need this reference if you later wish to unregister it.

Return Value
A result code. See "Carbon Event Manager Result Codes" (page 452).

Discussion
This function registers a global hot key based on the virtual key code and modifiers you pass in. When the user enters the hot-key combination, a `kEventHotKeyPressed` event is sent to the target you specified. Only one such combination can exist for the current application (that is, multiple entities in the same application cannot register for the same hot key combination). The same hot key can, however, be registered by multiple applications. This means that multiple applications can potentially be notified when a particular hot key is requested. This might not necessarily be desirable, but it is how it works at present.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CarbonEvents.h`

RegisterToolboxObjectClass

Registers events to be associated with a toolbox object. (Deprecated in Mac OS X v10.4. Use the HIObject function `HIObjectRegisterSubclass` (page 2335) instead.)

```
OSStatus RegisterToolboxObjectClass (
   CFStringRef inClassID,
   ToolboxObjectClassRef inBaseClass,
   ItemCount inNumEvents,
   const EventTypeSpec *inEventList,
   EventHandlerUPP inEventHandler,
   void *inEventHandlerData,
   ToolboxObjectClassRef *outClassRef
);
```

Parameters

inClassID

The class ID of the toolbox object you want to register. This value should be a Core Foundation string in the form `com.myCorp.myApp.myWidget`.

inBaseClass

The class reference of this toolbox object's base class. Pass `NULL` if there is no base class.

inNumEvents

The number of events to register for this object class.

inEventList

An array of events you want to register for this object class. You define these events just as you would for any other Carbon event handler.

inEventHandler

A universal procedure pointer to the event handler for this object class.

inEventHandlerData

Any application-specific data you want passed to your event handler when it is called.

outClassRef

On return, `outClassRef` contains a reference to the new object class. You use this value in your custom definition specification (such as a `ControlDefSpec` or `WindowDefSpec`) to define your new object class.

Return Value
A result code. See "Carbon Event Manager Result Codes" (page 452).

Discussion
You use this function to register event handlers to implement what were formerly called defproc messages; that is, you can use toolbox objects in place of older custom window, menu, and control definitions.

Special Considerations

HIObject allows you to create subclasses that you can use for creating custom HIViews. HIViews support compositing and Quartz and provide an easier way to handle user elements in windows. Use `HIObjectRegisterSubclass` to create custom HIObjects and HIViews. See *HIView Programming Guide* for more details.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In
`CarbonEvents.h`

ReleaseEvent

Releases, and possibly disposes of, the specified event.

```
void ReleaseEvent (
   EventRef inEvent
);
```

Parameters

inEvent

The event to release.

Discussion
This function decrements the reference count of an event. If the reference count reaches 0, the event is disposed.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
CarbonSketch

QTCarbonShell

Declared In
`CarbonEventsCore.h`

ReleaseMouseTrackingRegion

Releases a mouse tracking region. (Deprecated in Mac OS X v10.4. Use `HIViewDisposeTrackingArea` (page 2450) instead.)

```
OSStatus ReleaseMouseTrackingRegion (
   MouseTrackingRef inMouseRef
);
```

Parameters

inMouseRef

The mouse tracking region to release.

Return Value

A result code. See "Carbon Event Manager Result Codes" (page 452).

Discussion

`ReleaseMouseTrackingRegion` decreases the reference count for the region. If the reference count drops to zero, the mouse tracking region is disposed.

Special Considerations

Tracking areas are HIView-based rather than window-based. HIViews support compositing and Quartz, and provide a much easier way to handle user elements in windows. For more details about tracking areas, see the mouse tracking region section in *Carbon Event Manager Programming Guide*. For details about HIViews, see *HIView Programming Guide*.

Availability

Available in Mac OS X v10.2 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Related Sample Code

QTCarbonShell

Declared In

`CarbonEvents.h`

ReleaseWindowMouseTrackingRegions

(Deprecated in Mac OS X v10.4. No replacement function. Use HIView-based tracking areas instead.)

```
OSStatus ReleaseWindowMouseTrackingRegions (
   WindowRef inWindow,
   OSType inSignature
);
```

Special Considerations

Tracking areas are HIView-based rather than window-based. HIViews support compositing and Quartz, and provide a much easier way to handle user elements in windows. If you need to release multiple tracking areas at once, you should keep track of them in your own data structures and release each one. For more details about tracking areas, see the mouse tracking region section in *Carbon Event Manager Programming Guide*. For details about HIViews, see *HIView Programming Guide*.

Availability

Available in Mac OS X v10.2 and later.

Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`CarbonEvents.h`

RemoveEventFromQueue

Removes an event from the event queue.

```
OSStatus RemoveEventFromQueue (
   EventQueueRef inQueue,
   EventRef inEvent
);
```

Parameters

inQueue
The queue to remove the event from.

inEvent
The event to remove.

Return Value
A result code. See "Carbon Event Manager Result Codes" (page 452).

Discussion
Removes the given event from the queue on which it was posted and decrements its retain count.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CarbonEventsCore.h`

RemoveEventHandler

Removes the specified event handler.

```
OSStatus RemoveEventHandler (
   EventHandlerRef inHandlerRef
);
```

Parameters

inHandlerRef
The handler ref to remove (returned in a call to `InstallEventHandler`). After you call this function, the handler reference is considered invalid and can no longer be used.

Return Value
A result code. See "Carbon Event Manager Result Codes" (page 452).

Discussion
Removes an event handler from the event target to which it was bound.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
QTCarbonShell

Declared In
`CarbonEventsCore.h`

RemoveEventLoopTimer

Removes the specified timer.

```
OSStatus RemoveEventLoopTimer (
   EventLoopTimerRef inTimer
);
```

Parameters

inTimer
The timer to remove.

Return Value
A result code. See "Carbon Event Manager Result Codes" (page 452).

Discussion
Removes a timer that was previously installed by a call to `InstallEventLoopTimer` (page 276) or `InstallEventLoopIdleTimer` (page 275). You call this function when you are done using a timer.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
BSDLLCTest
HID Config Save
HID Explorer
QTCarbonShell

Declared In
`CarbonEventsCore.h`

RemoveEventTypesFromHandler

Removes events from an installed event handler.

```
OSStatus RemoveEventTypesFromHandler (
   EventHandlerRef inHandlerRef,
   ItemCount inNumTypes,
   const EventTypeSpec *inList
);
```

Parameters

inHandlerRef
The event handler to remove the events from.

inNumTypes
The number of events to remove.

inList
A pointer to an array of `EventTypeSpec` structures.

Return Value
A result code. See "Carbon Event Manager Result Codes" (page 452).

Discussion
You can use this function dynamically change which events you want your handler to respond to.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CarbonEventsCore.h`

RetainEvent

Increments the reference count of an event.

```
EventRef RetainEvent (
   EventRef inEvent
);
```

Parameters
inEvent
The event to retain.

Return Value
The event reference you passed in the `inEvent` parameter. A value of `NULL` indicates an error condition.

Discussion
The `RetainEvent` function increments an event's reference count by 1. You can use this function to ensure that an event is never disposed of by another event handler. However, if the event system or some other event handler changes the event, those changes are reflected in your reference. To create a separate, unique copy of an event, use `CopyEvent` (page 250) instead.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CarbonEventsCore.h`

RetainMouseTrackingRegion

Retains a mouse tracking region. (Deprecated in Mac OS X v10.4. No replacement function. Use HIView-based tracking areas instead.)

```
OSStatus RetainMouseTrackingRegion (
   MouseTrackingRef inMouseRef
);
```

Parameters
inMouseRef
The mouse tracking region to retain.

Return Value
A result code. See "Carbon Event Manager Result Codes" (page 452).

Discussion
`RetainMouseTrackingRegion` increases the reference count for the region.

Special Considerations

Tracking areas are HIView-based rather than window-based. HIViews support compositing and Quartz, and provide a much easier way to handle user elements in windows. Mouse tracking areas do not have a retain/release semantic, so there is no direct replacement for `RetainMouseTrackingRegion`. For more details about tracking areas, see the mouse tracking region section in *Carbon Event Manager Programming Guide*. For details about HIViews, see *HIView Programming Guide*.

Availability
Available in Mac OS X v10.2 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`CarbonEvents.h`

RunApplicationEventLoop

Runs the application event loop.

```
void RunApplicationEventLoop (
   void
);
```

Discussion
This function is used as the main event loop for a Carbon Event-based application. Once entered, this function waits for events to arrive and dispatches them to your event handlers automatically.

Note that calling `RunApplicationEventLoop` also installs the standard application handler, which provides standard handler responses for menu and application events.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
BSDLLCTest
HID Config Save
HID Explorer
QTCarbonShell
QTMetaData

Declared In
`CarbonEvents.h`

RunAppModalLoopForWindow

Puts the window in an application-modal state.

```
OSStatus RunAppModalLoopForWindow (
   WindowRef inWindow
);
```

Parameters

inWindow

The window you wish to behave modally. See the Window Manager documentation for a description of the `WindowRef` data type.

Return Value

A result code. See "Carbon Event Manager Result Codes" (page 452).

Discussion

This function is used as a replacement for the Dialog Manager function `ModalDialog` to drive a Carbon Event-based modal dialog. Once called, this function will not exit until `QuitAppModalLoopForWindow` (page 288) is called.

While in the modal state, the standard toolbox dispatcher processes events only for the modal window and any that are above it (that is, closer to the front). This feature allows you to create stacked modal dialogs, if desired.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`CarbonEvents.h`

RunCurrentEventLoop

Executes the event loop in the current thread.

```
OSStatus RunCurrentEventLoop (
   EventTimeout inTimeout
);
```

Parameters

inTimeout

The time to wait until returning (can be `kEventDurationForever`).

Return Value

A result code. See "Carbon Event Manager Result Codes" (page 452).

Discussion

This function "runs" the event loop, returning only if aborted or the timeout specified is reached. The event loop is mostly blocked while in this function, occasionally waking up to fire timers or pick up events. The typical use of this function is to cause the current thread to wait for some operation to complete, most likely on another thread of execution.

Availability

Available in Mac OS X v10.0 and later.

Declared In
CarbonEventsCore.h

SendEventToEventTarget

Sends an event to the specified event target.

```
OSStatus SendEventToEventTarget (
   EventRef inEvent,
   EventTargetRef inTarget
);
```

Parameters

inEvent
The event to send.

inTarget
The target to send it to.

Return Value
A result code. See "Carbon Event Manager Result Codes" (page 452).

Discussion
If you are creating your own events, you can dispatch them immediately to an event target by calling this function.

Availability
Available in Mac OS X v10.0 and later.

Related Sample Code
CarbonSketch
QTCarbonShell

Declared In
CarbonEventsCore.h

SendEventToEventTargetWithOptions

Sends an event to the specified event target with propagation options.

```
OSStatus SendEventToEventTargetWithOptions (
   EventRef inEvent,
   EventTargetRef inTarget,
   OptionBits inOptions
);
```

Parameters

inEvent
The event to send.

inTarget
The target to send it to.

inOptions

Options indicating how the event should be propagated. See "Event Target Propagation Options" (page 326) for a list of possible values.

Return Value
A result code. See "Carbon Event Manager Result Codes" (page 452).

Discussion
This function is identical to `SendEventToEventTarget` (page 299) except that you can specify how the event is propagated using options.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`CarbonEventsCore.h`

SetEventLoopTimerNextFireTime

Sets the next time that the specified timer will fire.

```
OSStatus SetEventLoopTimerNextFireTime (
   EventLoopTimerRef inTimer,
   EventTimerInterval inNextFire
);
```

Parameters

inTimer

The timer whose firing time you want to set.

inNextFire

The interval from the current time to wait until firing the timer again.

Return Value
A result code. See "Carbon Event Manager Result Codes" (page 452).

Discussion
This function is used to "reset" a timer. It controls the next time the timer fires. This will override any interval you might have set. For example, if you have a timer that fires every second, and you call this function setting the next time to 5 seconds from now, the timer will sleep for 5 seconds, then fire. The timer will then resume its one second interval. This function acts as if you removed the timer and reinstalled it with a new first-fire delay.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CarbonEventsCore.h`

SetEventParameter

Sets a parameter associated with a particular event.

```
OSStatus SetEventParameter (
   EventRef inEvent,
   EventParamName inName,
   EventParamType inType,
   ByteCount inSize,
   const void *inDataPtr
);
```

Parameters

inEvent

The event to set the data for.

inName

The symbolic name of the parameter.

inType

The symbolic type of the parameter.

inSize

The size of the parameter data.

inDataPtr

A pointer to the parameter data.

Return Value

A result code. See "Carbon Event Manager Result Codes" (page 452).

Discussion

When creating events, you may want to specify additional event-related information, such as the mouse location or the window in which the event occurred. To set these you call `SetEventParameter`, specifying the type and value for the desired parameter.

Availability

Available in Mac OS X v10.0 and later.

Related Sample Code

CarbonCocoa_PictureCursor

CarbonSketch

HID Calibrator

QTCarbonShell

Declared In

`CarbonEventsCore.h`

SetEventTime

Sets the event time for a given event.

```
OSStatus SetEventTime (
   EventRef inEvent,
   EventTime inTime
);
```

Parameters

inEvent

The event in question.

inTime
The new time.

Return Value
A result code. See "Carbon Event Manager Result Codes" (page 452).

Discussion
This function allows you to set the time of a given event, if you so desire. In general, you would never use this function, except for those special cases where you reuse an event from time to time instead of creating a new event each time.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CarbonEventsCore.h`

SetMouseCoalescingEnabled

Turns mouse coalescing on or off.

```
OSStatus SetMouseCoalescingEnabled (
   Boolean inNewState,
   Boolean *outOldState
);
```

Parameters
inNewState
Pass `true` to turn mouse coalescing on, `false` otherwise.

outOldState
A Boolean value indicating the previous mouse coalescing state (that is, before you called this function to set it). You can use this value if you want to save the previous state for later restoration. If you don't need this state information, pass `NULL`.

Return Value
A result code. See "Carbon Event Manager Result Codes" (page 452).

Discussion
See `IsMouseCoalescingEnabled` (page 281) for a definition of mouse coalescing.

Availability
Available in Mac OS X v10.1 and later.
Not available to 64-bit applications.

Declared In
`CarbonEvents.h`

SetMouseTrackingRegionEnabled

(Deprecated in Mac OS X v10.4. No replacement function. Use HIView-based tracking areas instead.)

```
OSStatus SetMouseTrackingRegionEnabled (
   MouseTrackingRef inMouseRef,
   Boolean inEnabled
);
```

Special Considerations

Tracking areas are HIView-based rather than window-based. HIViews support compositing and Quartz, and provide a much easier way to handle user elements in windows. To disable tracking areas, you can either delete the tracking area or ignore kEventControlTrackingAreaEntered events. For more details about tracking areas, see the mouse tracking region section in *Carbon Event Manager Programming Guide*. For details about HIViews, see *HIView Programming Guide*.

Availability
Available in Mac OS X v10.2 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`CarbonEvents.h`

SetWindowMouseTrackingRegionsEnabled

(Deprecated in Mac OS X v10.4. Use HIView-based tracking areas instead.)

```
OSStatus SetWindowMouseTrackingRegionsEnabled (
   WindowRef inWindow,
   OSType inSignature,
   Boolean inEnabled
);
```

Special Considerations

Tracking areas are HIView-based rather than window-based. HIViews support compositing and Quartz, and provide a much easier way to handle user elements in windows. To disable tracking areas, you can either delete the tracking area or ignore kEventControlTrackingAreaEntered events. For more details about tracking areas, see the mouse tracking region section in *Carbon Event Manager Programming Guide*. For details about HIViews, see *HIView Programming Guide*.

Availability
Available in Mac OS X v10.2 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`CarbonEvents.h`

TrackMouseLocation

Tracks the mouse, blocking your application when there is no activity.

```
OSStatus TrackMouseLocation (
   GrafPtr inPort,
   Point *outPt,
   MouseTrackingResult *outResult
);
```

Parameters

inPort

The graphics port to consider for mouse coordinates. You can pass `NULL` for this parameter to indicate the current port. The mouse location is returned in terms of local coordinates of this port. See the QuickDraw Manager documentation for a description of the `GrafPtr` data type.

outPt

On exit, a pointer to the mouse location from the last mouse event that caused this function to exit.

outResult

On exit, a pointer to a value representing what kind of event was received that cause the function to exit, such as `kMouseTrackingMouseReleased`.

Return Value

A result code. See "Carbon Event Manager Result Codes" (page 452).

Discussion

Once entered, this function waits for certain mouse events (move, mouse down, mouse up). When one of these events occurs, the function returns and tells the caller what happened and where the mouse is currently located. While there is no activity, the current event loop is run, effectively blocking the current thread (save for any timers that fire). This helps to minimize CPU usage when there is nothing going on.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`CarbonEvents.h`

TrackMouseLocationWithOptions

Tracks the mouse with additional options.

```
OSStatus TrackMouseLocationWithOptions (
   GrafPtr inPort,
   OptionBits inOptions,
   EventTimeout inTimeout,
   Point *outPt,
   UInt32 *outModifiers,
   MouseTrackingResult *outResult
);
```

Parameters

inPort

The graphics port (`GrafPort`) to consider for mouse coordinates. You can pass `NULL` for this parameter to indicate the current port. The mouse location is returned in global coordinates. See the QuickDraw Manager documentation for a description of the `GrafPtr` data type.

inOptions

The only option supported by this function at present is the option to have the toolbox leave mouse up events in the queue, rather than pulling them (which is the default). See "Mouse Tracking Option Constant" (page 397) for more information.

inTimeout

The amount of time to wait for an event. If no events arrive within this time, `kMouseTrackingTimedOut` is returned in `outResult`.

outPt

On return, a pointer to the mouse location from the last mouse event that caused this function to exit. If a timeout or key modifiers changed event caused this function to exit, the current mouse position at the time is returned.

outModifiers

On return, a pointer to the most recent state of the keyboard modifiers.

outResult

On return, a pointer to a value indicating the kind of event that caused the function to exit, such as `kMouseTrackingMouseReleased`.

Return Value
A result code. See "Carbon Event Manager Result Codes" (page 452).

Discussion
Once entered, this function waits for certain mouse events (move, mouse down, mouse up). When one of these events occurs, the function returns and tells the caller what happened and where the mouse is currently located. While there is no activity, the current event loop is run, effectively blocking the current thread (save for any timers that fire). This helps to minimize CPU usage when there is nothing going on.

Availability
Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Related Sample Code
CarbonSketch

Declared In
`CarbonEvents.h`

TrackMouseRegion

Tracks the mouse within a region.

```
OSStatus TrackMouseRegion (
   GrafPtr inPort,
   RgnHandle inRegion,
   Boolean *ioWasInRgn,
   MouseTrackingResult *outResult
);
```

Parameters

inPort

The graphics port to consider for mouse coordinates. You can pass `NULL` for this parameter to indicate the current port. See the QuickDraw Manager documentation for a description of the `GrafPtr` data type.

inRegion

The region to consider. This should be in the coordinates of the port you passed to `inPort`. See the QuickDraw Manager documentation for a description of the `RgnHandle` data type.

ioWasInRgn

On entering the region, this parameter should be set to `true` if the mouse is currently inside the region passed in `inRegion`, or `false` if the mouse is currently outside the region. On exit, this parameter is updated to reflect the current reality. For example, if the `outResult` parameter returns `kMouseTrackingMouseExited`, `ioWasInRgn` will be set to `false` when this function exits. Because it is updated from within, you should only need to set this yourself before the first call to this function in your tracking loop.

outResult

On exit, a pointer to a value indicating the kind of event that caused the function to exit, such as `kMouseTrackingMouseEntered`.

Return Value
A result code. See "Carbon Event Manager Result Codes" (page 452).

Discussion
This function is largely identical to `TrackMouseLocation` (page 303). The difference between `TrackMouseLocation` and `TrackMouseRegion` is that `TrackMouseRegion` only returns when the mouse enters or exits a specified region that you pass in to the function, as opposed to whenever the mouse moves (it also returns for mouse up/down events). This is useful if you don't need to know intermediate mouse events, but rather just if the mouse enters or leaves an area.

Note that in some cases you may prefer to register one or more special mouse tracking regions and receive events when the mouse enters or exits the region. However, this alternative method does not automatically inform you about mouse up and mouse down actions. See `CreateMouseTrackingRegion` (page 253) for more details.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`CarbonEvents.h`

UnregisterEventHotKey

Unregisters a global hot key.

```
OSStatus UnregisterEventHotKey (
   EventHotKeyRef inHotKey
);
```

Parameters

inHotKey

The event hot key reference of the hot key you want to unregister.

Return Value
A result code. See "Carbon Event Manager Result Codes" (page 452).

Discussion
Unregisters a global hot key that was previously registered with the function `RegisterEventHotKey` (page 290). You do not need to unregister a hot key when your application terminates; the system takes care of that for you. You can use this function if the user changes a hot key for something in your application—you would unregister the previous key and register your new key.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CarbonEvents.h`

UnregisterToolboxObjectClass

Unregisters events for a given toolbox object class (Deprecated in Mac OS X v10.4. Use the HIObject function `HIObjectUnregisterClass` (page 2340) instead.)

```
OSStatus UnregisterToolboxObjectClass (
   ToolboxObjectClassRef inClassRef
);
```

Parameters
inClassRef
A reference to the toolbox object class you want to unregister.

Return Value
A result code. See "Carbon Event Manager Result Codes" (page 452).

Special Considerations

HIObject allows you to create subclasses that you can use for creating custom HIViews. HIViews support compositing and Quartz and provide an easier way to handle user elements in windows. Use `HIObjectUnregisterClass` to unregister custom HIObjects and HIViews. See *HIView Programming Guide* for more details.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`CarbonEvents.h`

Callbacks

EventComparatorProcPtr

Defines the format of your event comparator callback function.

```
typedef Boolean (*EventComparatorProcPtr) (
   EventRef inEvent,
   void * inCompareData
);
```

If you name your function `MyEventComparatorProc`, you would declare it like this:

```
Boolean MyEventComparatorProc (
   EventRef inEvent,
   void * inCompareData
);
```

Parameters

inEvent

The event to compare.

inCompareData

The data you passed to `FindSpecificEventInQueue` (page 258) or `FlushSpecificEventsFromQueue` (page 260).

Return Value

A Boolean value indicating whether the event matches (`true`) or not (`false`).

Discussion

You use this callback function when searching the event queue using functions such as `FindSpecificEventInQueue` (page 258).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CarbonEventsCore.h`

EventHandlerProcPtr

Defines the format of your event handler.

```
typedef OSStatus (*EventHandlerProcPtr) (
   EventHandlerCallRef inHandlerCallRef,
   EventRef inEvent,
   void * inUserData
);
```

If you name your function `MyEventHandlerProc`, you would declare it like this:

```
OSStatus MyEventHandlerProc (
   EventHandlerCallRef inHandlerCallRef,
   EventRef inEvent,
   void * inUserData
);
```

Parameters

inHandlerCallRef

A reference to the current handler call chain. This is passed to your handler so that you can call `CallNextEventHandler` if you need to.

inEvent

The event that triggered this call.

inUserData

The application-specific data you passed in to `InstallEventHandler` (page 274).

Return Value

A result code. See "Carbon Event Manager Result Codes" (page 452). Returning `noErr` indicates you handled the event. Returning `eventNotHandledErr` indicates you did not handle the event and perhaps other handlers in the calling chain should take action.

Discussion

Callback to install on an event target.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CarbonEventsCore.h`

EventLoopIdleTimerProcPtr

Defines the format of your idle timer callback function.

```
typedef void (*EventLoopIdleTimerProcPtr) (
   EventLoopTimerRef inTimer,
   EventLoopIdleTimerMessage inState,
   void * inUserData
);
```

If you name your function `MyEventLoopTimerProc`, you would declare it like this:

```
void MyEventLoopTimerProc (
   EventLoopTimerRef inTimer,
   EventLoopIdleTimerMessage inState,
   void * inUserData
);
```

Parameters

inTimer

The timer that fired.

inState

The state of the idle period. See "Idle Timer Event Constants" (page 416) for a list of possible constants you can receive.

inUserData

The application-specific data you passed into `InstallEventLoopIdleTimer` (page 275).

Discussion

Called when an idle timer fires.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`CarbonEventsCore.h`

EventLoopTimerProcPtr

Defines the format of your event loop timer callback function.

```
typedef void (*EventLoopTimerProcPtr) (
   EventLoopTimerRef inTimer,
   void * inUserData
);
```

If you name your function `MyEventLoopTimerProc`, you would declare it like this:

```
void MyEventLoopTimerProc (
   EventLoopTimerRef inTimer,
   void * inUserData
);
```

Parameters

inTimer
The timer that fired.

inUserData
The data you passed into `InstallEventLoopTimer` (page 276).

Discussion
Called when a timer fires.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CarbonEventsCore.h`

Data Types

EventClassID

Represents an event class ID.

```
typedef UInt32 EventClassID;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CarbonEvents.h`

EventComparatorUPP

Represents a universal procedure pointer to an event comparator callback function.

```
typedef EventComparatorProcPtr EventComparatorUPP
```

EventHandlerCallRef

Indicates the next handler in the event handler calling hierarchy.

```
typedef struct OpaqueEventHandlerCallRef * EventHandlerCallRef;
```

Discussion
This structure is passed to your event handler, which can then choose to pass control to the next handler in the calling hierarchy (such as a standard event handler). Doing so is a convenient way to add pre- or post-processing to the standard event handler. See the `CallNextEventHandler` (page 247) function for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CarbonEventsCore.h`

EventHandlerUPP

Represents a universal procedure pointer for an event handler callback function.

```
typedef EventHandlerProcPtr EventHandlerUPP;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CarbonEventsCore.h`

EventLoopTimerUPP

Represents a universal procedure pointer for an event timer callback function.

```
typedef EventLoopTimerProcPtr EventLoopTimerUPP;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CarbonEventsCore.h`

EventLoopIdleTimerUPP

Represents a universal procedure pointer for an idle event timer callback function.

```
typedef EventLoopIdleTimerProcPtr EventLoopIdleTimerUPP;
```

Availability
Available in Mac OS X v10.2 and later.

Declared In
`CarbonEventsCore.h`

EventHandlerRef

Represents an installed event handler.

```
typedef struct OpaqueEventHandlerRef * EventHandlerRef;
```

Discussion
You receive an event handler reference when you install your handler using `InstallEventHandler` (page 274). You can use this reference when calling functions such as `RemoveEventHandler` (page 294) and `AddEventTypesToHandler` (page 246).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CarbonEventsCore.h`

EventHotKeyID

Represents the ID of a global hot key.

```
struct EventHotKeyID {
    OSType signature;
    UInt32 id;
};
typedef struct EventHotKeyID EventHotKeyID;
```

Discussion
You register a hot key using the `RegisterEventHotKey` (page 290) function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CarbonEvents.h`

EventHotKeyRef

Represents a registered global hot key.

```
typedef struct OpaqueEventHotKeyRef * EventHotKeyRef;
```

Discussion
You register a hot key using the `RegisterEventHotKey` (page 290) function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CarbonEvents.h`

EventLoopIdleTimerMessage

Represents an idle timer message.

```
typedef UInt16 EventLoopIdleTimerMessage;
```

Discussion
Sent to idle timer callback functions to indicate the current idle status. See "Idle Timer Event Constants" (page 416) for a list of possible values.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`CarbonEventsCore.h`

EventLoopRef

Represents an event loop.

```
typedef struct OpaqueEventLoopRef * EventLoopRef;
```

Discussion
The `EventLoopRef` type represents an event loop, which is the conceptual entity that you run to fetch events from hardware and other sources and also fires timers that might be installed with `InstallEventLoopTimer` (page 276) or `InstallEventLoopIdleTimer` (page 275). The term "run" is a bit of a misnomer, as the event loop's goal is to stay as blocked as possible to minimize CPU usage for the current application. The event loop is run implicitly through calls to functions like `ReceiveNextEvent` (page 289), `RunApplicationEventLoop` (page 297), or even the Classic Event Manager function `WaitNextEvent`. It can also be run explicitly through a call to `RunCurrentEventLoop` (page 298). Each preemptive thread can have an event loop. Cooperative threads share the main thread's event loop.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CarbonEventsCore.h`

EventLoopTimerRef

Represents an installed event timer.

```
typedef struct __EventLoopTimer * EventLoopTimerRef;
```

Discussion
The `EventLoopTimerRef` type represents a timer function that is called either once or at regular intervals. See `InstallEventLoopTimer` (page 276) and `InstallEventLoopIdleTimer` (page 275) for more information about event timers.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CarbonEventsCore.h`

EventParamName

Represents an event parameter constant.

```
typedef OSType EventParamName;
```

Discussion
You specify an event parameter name when calling `GetEventParameter` (page 266) or `SetEventParameter` (page 300). Parameter names indicate what kind of event parameter you want to set or obtain (such as `kEventParamDirectObject`). For specific types, see the tables of event parameters and types associated with each class of events (for example, Table 3-8 (page 392)).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CarbonEventsCore.h`

EventParamType

Represents an event parameter type constant.

```
typedef OSType EventParamType;
```

Discussion
You specify an event parameter type when calling `GetEventParameter` (page 266) or `SetEventParameter` (page 300). Event parameter types indicate the data type of the parameter you want to set or obtain (such as `typeBoolean`). For specific types, see the tables of event parameters and types associated with each class of events (for example, Table 3-11 (page 424)).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CarbonEventsCore.h`

EventQueueRef

Represents an event queue.

```
typedef struct OpaqueEventQueueRef * EventQueueRef;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CarbonEventsCore.h`

EventRef

Represents an opaque data structure that identifies individual events.

```
typedef struct OpaqueEventRef * EventRef;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CarbonEventsCore.h`

EventTargetRef

Represents an event target (such as a window or control).

```
typedef struct OpaqueEventTargetRef * EventTargetRef;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CarbonEventsCore.h`

EventTime

Represents a time value in seconds. An absolute `EventTime` value is seconds since boot time.

```
typedef double EventTime;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CarbonEventsCore.h`

EventTimeout

Represents a timeout interval, in seconds.

```
typedef EventTime EventTimeout;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
CarbonEventsCore.h

EventTimerInterval

Specifies the period of an event timer, in seconds.

```
typedef EventTime EventTimerInterval;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
CarbonEventsCore.h

EventType

Represents an event type.

```
typedef UInt32 EventType;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
cssmspi.h

EventTypeSpec

Describes the class and kind of an event.

```
struct EventTypeSpec {
    UInt32 eventClass;
    UInt32 eventKind;
};
typedef struct EventTypeSpec EventTypeSpec;
```

Discussion
This structure is used to specify an event. Typically, you pass a static array of `EventTypeSpec` structures into functions such as `InstallEventHandler` (page 274), as well as functions such as `FlushEventsMatchingListFromQueue` (page 259).

Availability
Available in Mac OS X v10.0 and later.

Declared In
CarbonEventsCore.h

HICommand

Represents a command event; this structure has been superseded by the `HICommandExtended` structure.

```
struct HICommand {
    UInt32 attributes
    UInt32 commandID
    struct {
        MenuRef menuRef;
        MenuItemIndex menuItemIndex;
    } menu;
};
typedef struct HICommand HICommand;
```

Fields

`attributes`
Attributes of the command event.

`commandID`
The command ID of the command event.

`menuRef`
A reference to the menu containing the HICommand.

`menuItemIndex`
The index number of the menu item containing the HICommand.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CarbonEvents.h`

HICommandExtended

Represents an extended command event.

```
struct HICommandExtended {
    UInt32 attributes;
    UInt32 commandID;
    union {
        controlRef control;
        windowRef window;
        struct {
            MenuRef menuRef;
            MenuItemIndex menuItemIndex;
        } menu;
    } source;
};
typedef struct HICommandExtended HICommandExtended;
```

Fields

`attributes`
Attributes of the command event. The value of this field (indicating whether the source of the command event is a control, window, or menu) determines what reference is stored in the union. See "Command Event Source Constants" (page 350) for a list of possible values.

`commandID`
The command ID of the command event.

`controlRef`
The control that produced the command event.

`windowRef`
The window that produced the command event.

`menuRef`
A reference to the menu containing the command event.

`menuItemIndex`
The index number of the menu item containing the command event.

Discussion
The `HICommandExtended` structure was introduced in Mac OS X v10.2 and CarbonLib 1.6. Because the `HICommand` and `HICommandExtended` structures are exactly the same size and have the same fields at the same offsets, you can use an `HICommandExtended` structure at runtime while running on any version of CarbonLib or Mac OS X. The only difference is that the `HICommandExtended` structure has a union that allows you to get type-safe access to the source object. The originator of the command determines whether the structure actually contains a ControlRef, WindowRef, MenuRef, or nothing at all. You can determine what is in the command by checking the `attributes` field.

For example, in Mac OS X v10.2 and later, when a push button is clicked, the Control Manager sends a command event containing the push button's command ID, sets the `kHICommandFromControl` bit in the `attributes` field, and stores the button's ControlRef in the `source.control` field. In Mac OS X v10.0 and v10.1, the same command event is sent, but the `kHICommandFromControl`, `kHICommandFromMenu`, and `kHICommandFromWindow` attributes are not set, and the `source.controlRef`, `source.menu.menuRef` and `source.windowRef` fields are not initialized, respectively. Your code can use an `HICommandExtended` structure when running on Mac OS X v10.0 and v10.1 as long as it first checks the `kHICommandFromControl`, `kHICommandFromMenu`, and `kHICommandFromWindow` attributes before accessing the `source.control`, `menu.control`, and `window.control` fields.

Availability
Available in Mac OS X v10.2 and later.

Declared In
`CarbonEvents.h`

MouseTrackingRef

Represents a mouse tracking region

```
typedef struct OpaqueMouseTrackingRef * MouseTrackingRef;
```

Discussion
Use `CreateMouseTrackingRegion` (page 253) to create a mouse tracking region.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`CarbonEvents.h`

MouseTrackingRegionID

Represents a mouse tracking region identifier.

```
struct MouseTrackingRegionID {
    OSType signature;
    SInt32 id;
};
typedef struct MouseTrackingRegionID MouseTrackingRegionID;
```

Fields

`signature`

A four-character code (such as `'moof'`)that uniquely identifies the application that owns this mouse tracking region.

`id`

An integer that identifies the mouse tracking region in this application.

Discussion

Each application can register multiple mouse tracking regions as long as each region has a unique ID. Use `CreateMouseTrackingRegion` (page 253) to create a mouse tracking region.

Availability

Available in Mac OS X v10.2 and later.

Not available to 64-bit applications.

Declared In

`CarbonEvents.h`

TabletPointRec

Defines a tablet point structure.

```
struct TabletPointRec {
    SInt32 absX;
    SInt32 absY;
    SInt32 absZ;
    UInt16 buttons;
    UInt16 pressure;
    SInt16 tiltX;
    SInt16 tiltY;
    UInt16 rotation;
    SInt16 tangentialPressure;
    UInt16 deviceID;
    SInt16 vendor1;
    SInt16 vendor2;
    SInt16 vendor3;
};
typedef struct TabletPointRec TabletPointRec;
typedef TabletPointRec TabletPointerRec;
```

Fields

`absX`

The x-coordinate of the pointer, in tablet space (at full tablet resolution).

`absY`

The y-coordinate of the pointer, in tablet space (at full tablet resolution).

`absZ`

The z-coordinate of the pointer, in tablet space (at full tablet resolution).

`buttons`
: The buttons that are pressed. This integer is interpreted as a bit field, with bit 0 indicating the first button, bit 1 the second button, and so on. A value of `1` indicates that the button is down.

`pressure`
: The scaled pressure value. The pressure value is in the range 0 to 65535.

`tiltX`
: The scaled tilt x value. The tilt value is in the range -32767 to 32767.

`tiltY`
: The scaled tilt y value. The tilt value is in the range -32767 to 32767.

`rotation`
: The device rotation as a fixed-point value in a 10.6 format.

`tangentialPressure`
: The tangential pressure on the device. This pressure is in the range -32767 to 32767.

`deviceID`
: A unique system-assigned device ID. This ID matches the device ID you receive for the `kEventTabletProximity` event.

`vendor1`
: A vendor-defined value.

`vendor2`
: A vendor-defined value.

`vendor3`
: A vendor-defined value.

Discussion
You receive this structure in the `kEventParamTabletPointRec` parameter for the `kEventTabletPoint` event.

Availability
Available in Mac OS X v10.1 and later.

Declared In
`CarbonEvents.h`

TabletProximityRec

Defines a tablet proximity structure.

```
struct TabletProximityRec {
    UInt16 vendorID;
    UInt16 tabletID;
    UInt16 pointerID;
    UInt16 deviceID;
    UInt16 systemTabletID;
    UInt16 vendorPointerType;
    UInt32 pointerSerialNumber;
    UInt64 uniqueID;
    UInt32 capabilityMask;
    UInt8 pointerType;
    UInt8 enterProximity;
};
typedef struct TabletProximityRec TabletProximityRec;
```

Fields

`vendorID`
A vendor-defined ID. This value is typically the USB vendor ID.

`tabletID`
A vendor-defined ID for the tablet. This value is typically the USB product ID for the tablet.

`pointerID`
A vendor-defined ID for the pointing device (for example, a pen).

`deviceID`
A unique system-assigned device ID. This ID matches the device ID you receive for the `kEventTabletPoint` event.

`systemTabletID`
A system-assigned unique tablet ID.

`vendorPointerType`
A vendor-defined pointer type.

`pointerSerialNumber`
A vendor-defined serial number for the pointing device.

`uniqueID`
A vendor-defined ID for this pointer.

`capabilityMask`
A bit mask representing the capabilities of this device.

`pointerType`
The type of pointing device.

`enterProximity`
The proximity value. A nonzero value indicates that the pointer is entering the tablet proximity; zero indicates that it is leaving.

Discussion

You receive this structure in the `kEventParamTabletProximityRec` parameter for the `kEventTabletProximity` event.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`CarbonEvents.h`

ToolboxObjectClassRef

Represents a toolbox object class.

```
typedef struct OpaqueToolboxObjectClassRef * ToolboxObjectClassRef;
```

Discussion
Typically you use toolbox object classes to specify custom user interface elements. See `RegisterToolboxObjectClass` (page 291) for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CarbonEvents.h`

Constants

Basic Event Constants

Event Class Constants

Define constants for specifying event classes.

```
typedef UInt32 EventClass;
enum {
    kEventClassMouse = 'mous',
    kEventClassKeyboard = 'keyb',
    kEventClassTextInput = 'text',
    kEventClassApplication = 'appl',
    kEventClassAppleEvent = 'eppc',
    kEventClassMenu = 'menu',
    kEventClassWindow = 'wind',
    kEventClassControl = 'cntl',
    kEventClassCommand = 'cmds',
    kEventClassTablet = 'tblt',
    kEventClassVolume = 'vol ',
    kEventClassAppearance = 'appm',
    kEventClassService = 'serv',
    kEventClassToolbar = 'tbar',
    kEventClassToolbarItem = 'tbit',
    kEventClassToolbarItemView = 'tbiv',
    kEventClassAccessibility = 'acce'.
    kEventClassSystem = 'macs',
    kEventClassInk = 'ink ',
    kEventClassTSMDocumentAccess = 'tdac'
};
```

Constants

`kEventClassMouse`
Events related to the mouse (mouse down/up/moved).
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventClassKeyboard`
Events related to the keyboard.
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventClassTextInput`
Events related to text input (by keyboard or by input method).
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventClassApplication`
Application-level events (launch, quit, and so on).
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventClassAppleEvent`
Apple Events.
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventClassMenu`
Menu-related events.
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventClassWindow`
Window-related events.
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventClassControl`
Control-related events.
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventClassCommand`
Command events (HICommands).
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventClassTablet`
Events related to tablet input.
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventClassVolume`
Events related to File Manager volumes.
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventClassAppearance`
Events related to the Appearance Manager.
Available in Mac OS X v10.1 and later.
Declared in `CarbonEvents.h`.

`kEventClassService`
Events related to the Services Manager.
Available in Mac OS X v10.1 and later.
Declared in `CarbonEvents.h`.

`kEventClassToolbar`
Events related to the toolbar (not the toolbar window class).
Available in Mac OS X v10.2 and later.
Declared in `CarbonEvents.h`.

`kEventClassToolbarItem`
Events related to toolbar items.
Available in Mac OS X v10.2 and later.
Declared in `CarbonEvents.h`.

`kEventClassToolbarItemView`
Events related to toolbar item views.
Available in Mac OS X v10.3 and later.
Declared in `CarbonEvents.h`.

`kEventClassAccessibility`
Events related to application accessibility features.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`kEventClassSystem`
Events related to the system.

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

`kEventClassInk`
Events related to ink.

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

`kEventClassTSMDocumentAccess`
Events related to Text Services Manager document access.

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

Discussion
Event classes specify broad categories of events, grouped according to the object they are associated with. Within an event class are specific event types.

Event Attributes

Define constants for special attributes of an event.

```
typedef UInt32 EventAttributes;
enum {
    kEventAttributeNone = 0,
    kEventAttributeUserEvent = (1 << 0),
    kEventAttributeMonitored= 1 << 3
};
```

Constants
`kEventAttributeNone`
No attributes.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEventsCore.h`.

`kEventAttributeUserEvent`
An event generated in response to a user action.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEventsCore.h`.

`kEventAttributeMonitored`
An event that was not originally targeted to this process but has been provided to this process because an event handler for this event type has been installed on the event monitoring target. The event dispatcher sends events with this attribute directly to the event monitor target.

Available in Mac OS X v10.3 and later.

Declared in `CarbonEventsCore.h`.

Discussion
You use these attributes only if you are creating your own events.

Event Priority Constants

Define event priority constants.

```
typedef SInt16 EventPriority;
enum {
    kEventPriorityLow = 0,
    kEventPriorityStandard = 1,
    kEventPriorityHigh = 2
};
```

Constants

`kEventPriorityLow`
Lowest priority. Currently only window update events are posted at this priority.
Available in Mac OS X v10.0 and later.
Declared in `CarbonEventsCore.h`.

`kEventPriorityStandard`
Normal priority of events. Most events are standard priority.
Available in Mac OS X v10.0 and later.
Declared in `CarbonEventsCore.h`.

`kEventPriorityHigh`
Highest priority.
Available in Mac OS X v10.0 and later.
Declared in `CarbonEventsCore.h`.

Discussion
These values define the relative priority of an event, and are used when posting events with `PostEventToQueue` (page 286). In general events are pulled from the queue in order of first posted to last posted. These priorities are a way to alter that behavior when posting events. You can post a standard priority event and then a high priority event, and the high priority event will be pulled from the queue first.

Event Target Propagation Options

Define options for the `SendEventToEventTargetWithOptions` function.

```
enum {
    kEventTargetDontPropagate = (1 << 0),
    kEventTargetSendToAllHandlers = (1 << 1)
};
```

Constants

`kEventTargetDontPropagate`

Do not propagate this event to any other event target. That is, even if the handler returns `eventNotHandledErr`, the event is not propagated up the handler chain. When passed an event sent with this option, `CallNextEventHandler` only calls other event handlers installed on the current event target; it does not propagate the event to other event targets.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEventsCore.h`.

`kEventTargetSendToAllHandlers`

Send this event to all event targets in the handler chain, regardless of any handler's return value. For example, if sent to a control, after returning, the event is sent to the owning window and then to the application. Note that the Carbon Event Manager keeps track of the strongest result code when progressing up the handler chain. That is, if the first handler returns `noErr`, and the second handler returns `eventNotHandledErr`, the result returned is `noErr`.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEventsCore.h`.

Event Queue Constants

Define constants for specifying how events should be handled on the queue.

```
enum {
    kEventLeaveInQueue = false,
    kEventRemoveFromQueue = true
};
```

Constants

`kEventLeaveInQueue`

Leave the event on the queue after examining.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEventsCore.h`.

`kEventRemoveFromQueue`

Remove the event from the queue after examining.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEventsCore.h`.

Discussion

When calling a function such as `ReceiveNextEvent` (page 289), you can specify whether to leave the event on the queue (peeking at it to determine its class, type, and so on), or to pull it before dispatching it to an event handler.

Direct Object Parameter

Define the direct object parameter.

```
enum {
    kEventParamDirectObject = '----'
};
```

Constants

`kEventParamDirectObject`

Type varies depending on event.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEventsCore.h`.

Discussion

The direct object parameter is usable for a wide variety of events. It defines the "object the event acted upon or within." For example, for window events, the direct object parameter returns a reference (that is a `WindowRef`) to the window in which the event occurred.

Event Target Parameter

Define constants for a special event target parameter and its type, that you can set for any created event.

```
enum {
    kEventParamPostTarget = 'ptrg',
    typeEventTargetRef = 'etrg'
};
```

Constants

`kEventParamPostTarget`

Specifies the target the event should be sent to. Instead of sending an event directly to a given target, you can set this parameter and post the event onto the event queue.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`typeEventTargetRef`

The parameter type for `kEventParamPostTarget`.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

Object Reference Parameters and Types

Define constants for parameters that specify various objects and their types.

```
enum {
    kEventParamWindowRef = 'wind',
    kEventParamGrafPort = 'graf',
    kEventParamDragRef = 'drag',
    kEventParamMenuRef = 'menu',
    kEventParamEventRef = 'evnt',
    kEventParamControlRef = 'ctrl',
    kEventParamRgnHandle = 'rgnh',
    kEventParamEnabled = 'enab',
    kEventParamDimensions = 'dims',
    kEventParamBounds = 'boun',
    kEventParamAvailableBounds = 'avlb',
    kEventParamAEEventID = keyAEEventID,
    kEventParamAEEventClass = keyAEEventClass,
    kEventParamCGContextRef = 'cntx',
    kEventParamDeviceDepth = 'devd',
    kEventParamDeviceColor = 'devc',
    kEventParamMutableArray = 'marr',
    kEventParamResult = 'ansr',
    kEventParamMinimumSize = 'mnsz',
    kEventParamMaximumSize = 'mxsz',
    kEventParamAttributes = 'attr',
    kEventParamReason = 'why?',
    kEventParamTransactionID = 'trns',
    kEventParamGDevice = 'gdev',
    kEventParamIndex = 'indx',
    kEventParamUserData = 'usrd',
    kEventParamShape = 'shap',
    typeWindowRef = 'wind',
    typeGrafPtr = 'graf',
    typeGWorldPtr = 'gwld',
    typeDragRef = 'drag',
    typeMenuRef = 'menu',
    typeControlRef = 'ctrl',
    typeCollection = 'cltn',
    typeQDRgnHandle = 'rgnh',
    typeOSStatus = 'osst',
    typeCFIndex = 'cfix',
    typeCGContextRef = 'cntx',
    typeHIPoint = 'hipt',
    typeHISize = 'hisz',
    typeHIRect = 'hirc',
    typeHIShapeRef = 'shap',
    typeVoidPtr = 'void',
    typeGDHandle = 'gdev'
};
```

Constants

`kEventParamWindowRef`

A window reference. (typeWindowRef)

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventParamGrafPort`

typeGrafPtr

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventParamDragRef`
typeDragRef
Available in Mac OS X v10.0 and later.
Declared in `CarbonEventsCore.h`.

`kEventParamMenuRef`
typeMenuRef
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamEventRef`
typeEventRef
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamControlRef`
typeControlRef
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamRgnHandle`
typeQDRgnHandle
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamEnabled`
typeBoolean
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamDimensions`
typeQDPoint
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamBounds`
typeQDRectangle
Available in Mac OS X v10.3 and later.
Declared in `CarbonEvents.h`.

`kEventParamAvailableBounds`
typeQDRectangle
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamAEEventID`
typeType
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamAEEventClass`
typeType
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamCGContextRef`
typeCGContextRef
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamDeviceDepth`
typeShortInteger
Available in Mac OS X v10.1 and later.
Declared in `CarbonEvents.h`.

`kEventParamDeviceColor`
typeBoolean
Available in Mac OS X v10.1 and later.
Declared in `CarbonEvents.h`.

`kEventParamMutableArray`
typeCFMutableArrayRef
Available in Mac OS X v10.2 and later.
Declared in `CarbonEvents.h`.

`kEventParamResult`
Any type, depending on the event
Available in Mac OS X v10.2 and later.
Declared in `CarbonEvents.h`.

`kEventParamMinimumSize`
typeHISize
Available in Mac OS X v10.2 and later.
Declared in `CarbonEvents.h`.

`kEventParamMaximumSize`
typeHISize
Available in Mac OS X v10.2 and later.
Declared in `CarbonEvents.h`.

`kEventParamAttributes`
typeUInt32
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamReason`
typeUInt32
Available in Mac OS X v10.3 and later.
Declared in `CarbonEvents.h`.

`kEventParamTransactionID`
typeUInt32
Available in Mac OS X v10.3 and later.
Declared in `CarbonEvents.h`.

`kEventParamGDevice`
typeGDHandle
Available in Mac OS X v10.3 and later.
Declared in `CarbonEvents.h`.

`kEventParamIndex`
typeCFIndex
Available in Mac OS X v10.3 and later.
Declared in `CarbonEvents.h`.

`kEventParamUserData`
typeVoidPtr
Available in Mac OS X v10.3 and later.
Declared in `CarbonEvents.h`.

`kEventParamShape`
typeHIShapeRef
Available in Mac OS X v10.4 and later.
Declared in `CarbonEvents.h`.

`typeWindowRef`
WindowRef
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`typeGrafPtr`
CGrafPtr
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`typeGWorldPtr`
GWorldPtr
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`typeDragRef`
DragRef
Available in Mac OS X v10.0 and later.
Declared in `CarbonEventsCore.h`.

`typeMenuRef`
MenuRef
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`typeControlRef`
ControlRef
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`typeCollection`
Collection
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`typeQDRgnHandle`
RgnHandle
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`typeOSStatus`
OSStatus
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`typeCFIndex`
CFIndex
Available in Mac OS X v10.2 and later.
Declared in `CarbonEvents.h`.

`typeCGContextRef`
CGContextRef
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`typeHIPoint`
HIPoint
Available in Mac OS X v10.1 and later.
Declared in `CarbonEvents.h`.

`typeHISize`
HISize
Available in Mac OS X v10.2 and later.
Declared in `CarbonEvents.h`.

`typeHIRect`
HIRect
Available in Mac OS X v10.2 and later.
Declared in `CarbonEvents.h`.

`typeHIShapeRef`
HIShapeRef
Available in Mac OS X v10.4 and later.
Declared in `CarbonEvents.h`.

`typeVoidPtr`
Void

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`typeGDHandle`
GDHandle

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

Discussion
You specify these parameters to obtain references to various objects such as windows, controls, graphics ports, and so on. See the various event kinds to determine the parameters available for each event. For example, Table 3-8 (page 392) in "Mouse Events" (page 390) lists the various parameters used in mouse events.

Core Foundation Object Types

Define type constants for Carbon event parameters that refer to Core Foundation objects.

```
enum {
    typeCFAttributedStringRef = 'cfas',
    typeCFMutableAttributedStringRef = 'cfaa',
    typeCFStringRef = 'cfst',
    typeCFMutableStringRef = 'cfms',
    typeCFArrayRef = 'cfar',
    typeCFMutableArrayRef = 'cfma',
    typeCFDictionaryRef = 'cfdc',
    typeCFMutableDictionaryRef = 'cfmd',
    typeCFNumberRef = 'cfnb',
    typeCFBooleanRef = 'cftf',
    typeCFTypeRef = 'cfty'
};
```

Constants
`typeCFAttributedStringRef`
A Core Foundation attributed string.

Available in Mac OS X v10.5 and later.

Declared in `AEDataModel.h`.

`typeCFMutableAttributedStringRef`
A Core Foundation mutable attributed string.

Available in Mac OS X v10.5 and later.

Declared in `AEDataModel.h`.

`typeCFStringRef`
A Core Foundation string.

Available in Mac OS X v10.1 and later.

Declared in `AEDataModel.h`.

`typeCFMutableStringRef`
A Core Foundation mutable string.

Available in Mac OS X v10.2 and later.

Declared in `AEDataModel.h`.

`typeCFArrayRef`
A Core Foundation array.
Available in Mac OS X v10.3 and later.
Declared in `AEDataModel.h`.

`typeCFMutableArrayRef`
A Core Foundation mutable array.
Available in Mac OS X v10.1 and later.
Declared in `AEDataModel.h`.

`typeCFDictionaryRef`
A Core Foundation dictionary.
Available in Mac OS X v10.3 and later.
Declared in `AEDataModel.h`.

`typeCFMutableDictionaryRef`
A Core Foundation mutable dictionary.
Available in Mac OS X v10.3 and later.
Declared in `AEDataModel.h`.

`typeCFNumberRef`
A Core Foundation number.
Available in Mac OS X v10.5 and later.
Declared in `AEDataModel.h`.

`typeCFBooleanRef`
A Core Foundation Boolean value.
Available in Mac OS X v10.5 and later.
Declared in `AEDataModel.h`.

`typeCFTypeRef`
A Core Foundation type.
Available in Mac OS X v10.2 and later.
Declared in `AEDataModel.h`.

Declared In
`AEDataModel.h`

Apple Event Constants

AppleEvent Constant

Define a constant related to events from `kEventClassAppleEvent`.

```
enum {
    kEventAppleEvent = 1
};
```

Constants

`kEventAppleEvent`

An AppleEvent event was received.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

Discussion

The standard application handler automatically calls the Apple Event Manager function `AEProcessAppleEvent` to handle Apple events.

Table 3-1 shows the parameter associated with AppleEvent events.

Table 3-1 Parameter names and types for AppleEvent kinds

Event kind	Parameter name	Parameter type
`kEventAppleEvent`	`kEventParamAEEventID`	`typeType`

Deprecated AppleEvent Event Constants

Define constants for older names for AppleEvent event constants.

```
enum {
    kEventClassEPPC = kEventClassAppleEvent,
    kEventHighLevelEvent = kEventAppleEvent
};
```

Constants

`kEventClassEPPC`

Equivalent to `kEventClassAppleEvent`.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventHighLevelEvent`

Equivalent to `kEventAppleEvent`.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

Appearance Manager Event Constants

Appearance Manager Events

Define a constant related to events from `kEventClassAppearance`.

```
enum {
    kEventAppearanceScrollBarVariantChanged = 1
};
```

Constants

`kEventAppearanceScrollBarVariantChanged`

The scroll bar variant has changed.

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

Appearance Manager Event Parameter

Define a constant for the parameter to Appearance Manager events.

```
enum {
    kEventParamNewScrollBarVariant = 'nsbv'
};
```

Constants

`kEventParamNewScrollBarVariant`

typeShortInteger

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

Application Event Constants

Application Event Constants

Define constants related to events from `kEventClassApplication`.

```
enum {
    kEventAppActivated = 1,
    kEventAppDeactivated = 2,
    kEventAppQuit = 3,
    kEventAppLaunchNotification = 4,
    kEventAppLaunched = 5,
    kEventAppTerminated = 6,
    kEventAppFrontSwitched = 7,
    kEventAppFocusMenuBar = 8,
    kEventAppFocusNextDocumentWindow = 9,
    kEventAppFocusNextFloatingWindow = 10,
    kEventAppFocusToolbar = 11,
    kEventAppFocusDrawer = 12,
    kEventAppGetDockTileMenu = 20,
    kEventAppIsEventInInstantMouser = 104,
    kEventAppHidden = 107,
    kEventAppShown = 108,
    kEventAppSystemUIModeChanged = 109,
    kEventAppAvailableWindowBoundsChanged = 110,
    kEventAppActiveWindowChanged = 111
};
```

Constants

`kEventAppActivated`
The application was activated (resumed, in old parlance).
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventAppDeactivated`
The application was deactivated (suspended, in old parlance).
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventAppQuit`
The application is quitting.
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventAppLaunchNotification`
Response to asynchronous application launch.
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventAppLaunched`
Some other application was launched. (CarbonLib 1.3 or later)
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventAppTerminated`
Some other application was terminated. (CarbonLib 1.3 or later)
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventAppFrontSwitched`
The frontmost application has changed. (CarbonLib 1.3 or later)

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventAppFocusMenuBar`
Request to switch the keyboard focus to the menu bar. The Carbon Event Manager handles this event by default.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`kEventAppFocusNextDocumentWindow`
Request to shift keyboard focus to the next or previous document window (depending on the state of the Shift key). If there are no more document windows in the current process, focus should shift to the document window in the next (or previous) process.

If something other than a document window currently has keyboard focus, you should shift focus to the frontmost document window without changing the ordering of the windows.

If the document window does not have a focused area, you should set the focus to the main control within the window.

The Carbon Event Manager handles this event by default; if you handle this event, you should only check if the user focus is somewhere other than a document window, and if so, set the focus on the active document window. If the focus is already on a document window, your handler should always return `eventNotHandledErr` so that the default handler can rotate to the next window across all processes.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`kEventAppFocusNextFloatingWindow`
Request to shift keyboard focus to the next or previous floating window (depending on the state of the Shift key).

If something other than a floating window currently has keyboard focus, you should shift focus to the frontmost floating window without changing the ordering of the windows.

If the floating window does not have a focused area, you should set the focus to the main control within the window.

The default behavior for this event is to send a `kEventCommandProcess` event containing `kHICommandRotateFloatingWindowsForward` or `kHICommandRotateFloatingWindowsBackward`.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`kEventAppFocusToolbar`
Request to shift keyboard focus to the toolbar.

The default behavior for this event is to move the keyboard focus to the first item in the toolbar (assuming you are using the standard toolbar).

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`kEventAppFocusDrawer`

Request to shift keyboard focus to the drawer in the focused window.

The default behavior for this event is to move the focus to the first control in the drawer in the focused window if a drawer is present. If multiple drawers are present, focus is moved in clockwise order from one drawer to the next, starting with the top drawer, if any. If the modifiers parameter contains the shift key, focus is moved in reverse (counterclockwise) order.

Available in Mac OS X v10.4 and later.

Declared in `CarbonEvents.h`.

`kEventAppGetDockTileMenu`

Request to display a pop-up menu by the application's dock tile. You should return the menu reference of the menu to display in the `kEventParamMenuRef` parameter. The sender of this event releases this menu after the Dock displays it, so if you supply a permanently allocated menu reference, you should call the Menu Manager function `RetainMenu` on it before returning from your handler.

The default behavior for this event is to return the menu (if any) supplied by the `SetApplicationDockTileMenu` function (described in the Dock Manager Reference). Note that for most functions, it's easier to set a menu using `SetApplicationDockTileMenu` rather than installing a handler for this event.

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

`kEventAppIsEventInInstantMouser`

The given event's global mouse location is over an "instant mousing" area. An instant mousing area is an area where a mouse down should not generate ink but should be interpreted as a click.

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

`kEventAppHidden`

The application was hidden.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`kEventAppShown`

The application was shown.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`kEventAppSystemUIModeChanged`

The system user interface mode of the frontmost application has changed.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`kEventAppAvailableWindowBoundsChanged`

The available window positioning bounds have changed. This event is currently sent when the Dock has changed position or size and when the display configuration has changed. A separate copy of this event is sent to each affected GDevice.

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

`kEventAppActiveWindowChanged`

The active window in the current process has changed. The Window Manager uses `ActiveNonFloatingWindow` to track the active window. When `SelectWindow` is called on a window, that window is made the new active window. At that time, the Window Manager also posts a `kEventAppActiveWindowChanged` event to the main event queue.

If more than one window is activated sequentially before the event loop is run, a single `kEventAppActiveWindowChanged` event is left in the event queue. Its `PreviousActiveWindow` parameter will be the window that was originally active, and its `CurrentActiveWindow` parameter will be the window that was finally active.

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

Discussion
You can pass any of these constants when registering an event handler. You can also pass these constants to the `CreateEvent` (page 252) function to specify the type of application event you want to create.

Table 3-2 shows the event parameters associated with application events.

Table 3-2 Parameter names and types for application event kinds

Event kind	Parameter name	Parameter type
`kEventAppActivated`	`kEventParamWindowRef`	`typeWindowRef`
`kEventAppDeactivated`	*None*	
`kEventAppQuit`	*None*	
`kEventAppLaunchNotification`	`kEventParamProcessID`	`typeProcessSerialNumber`
	`kEventParamLaunchRefCon`	`typeUInt32`
	`kEventParamLaunchErr`	`typeOSStatus`
`kEventAppLaunched`	`kEventParamProcessID`	`typeProcessSerialNumber`
`kEventAppTerminated`	`kEventParamProcessID`	`typeProcessSerialNumber`
`kEventAppFrontSwitched`	`kEventParamProcessID`	`typeProcessSerialNumber`
`kEventAppFocusMenuBar`	`kEventParamKeyModifiers`	`typeUInt32`
`kEventAppFocusNextDocumentWindow`	`kEventParamKeyModifiers`	`typeUInt32`
`kEventAppFocusNextFloatingWindow`	`kEventParamKeyModifiers`	`typeUInt32`
`kEventAppFocusToolbar`	`kEventParamKeyModifiers`	`typeUInt32`
`kEventAppGetDockTileMenu`	`kEventParamMenuRef`	`typeMenuRef`
`kEventAppHidden`	*None*	
`kEventAppShown`	*None*	
`kEventAppSystemUIModeChanged`	`kEventParamSystemUIMode`	`typeUInt32`

Application Event Parameters

Define constants for parameters to application events.

```
enum {
    kEventParamProcessID = 'psn ',
    kEventParamLaunchRefCon = 'lref',
    kEventParamLaunchErr = 'err ',
    kEventParamSystemUIMode = 'uimd'
};
```

Constants

`kEventParamProcessID`
typeProcessSerialNumber
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamLaunchRefCon`
typeWildcard
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamLaunchErr`
typeOSStatus
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamSystemUIMode`
typeUInt32
Available in Mac OS X v10.2 and later.
Declared in `CarbonEvents.h`.

Command Events

Command Event Constants

Define constants related to events from `kEventClassCommand`.

```
enum {
    kEventProcessCommand = 1,
    kEventCommandProcess = 1,
    kEventCommandUpdateStatus = 2
};
```

Constants

`kEventProcessCommand`

A command has been invoked and the application should handle it. This event is sent when the user chooses a menu item or when a control with a command is pressed. Some senders of this event will also include the modifier keys that were pressed by the user when the command was invoked, but this parameter is optional.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventCommandProcess`

Same as `kEventProcessCommand`.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventCommandUpdateStatus`

Sent when updates related to the command event may be required. When you receive this event, you should update the necessary user interface elements in your application to reflect the current status of the command. For example, if the command has the `kHICommandFromMenu` bit set, you should update the menu item state, text, and so on, to reflect the current state of your application.

Note that the standard handler for `kEventMenuEnableItems` automatically sends this event to your menu commands. As this can cause a performance hit if you have many menu items, you can choose to bypass these updates by installing a no-op handler for `kEventMenuEnableItems` that simply returns `noErr`.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

Discussion

You pass this constant to the `CreateEvent` (page 252) function to indicate the type of command event you want to create. Future releases of the Carbon Event Manager will provide additional command event types.

Table 3-3 shows the parameters associated with command events.

Table 3-3 Parameter names and types for command event kinds

Event kind	Parameter name	Parameter type
`kEventCommandProcess`	`kEventParamDirectObject`	`typeHICommand`
	`kEventParamKeyModifiers` (Optional)	`typeUInt32`
	`kEventParamMenuContext` (Optional)	`typeUInt32`
`kEventCommand-UpdateStatus`	`kEventParamDirectObject`	`typeHICommand`
	`kEventParamMenuContext` (Optional)	`typeUInt32`

Standard Command ID Constants

Define command IDs for common menu commands and controls.

```
enum {
    kHICommandOK = 'ok  ',
    kHICommandCancel = 'not!',
    kHICommandQuit = 'quit',
    kHICommandUndo = 'undo',
    kHICommandRedo = 'redo',
    kHICommandCut = 'cut ',
    kHICommandCopy = 'copy',
    kHICommandPaste = 'past',
    kHICommandClear = 'clea',
    kHICommandSelectAll = 'sall',
    kHICommandHide = 'hide',
    kHICommandHideOthers = 'hido',
    kHICommandShowAll = 'shal',
    kHICommandPreferences = 'pref',
    kHICommandZoomWindow = 'zoom',
    kHICommandMinimizeWindow = 'mini',
    kHICommandMinimizeAll = 'mina',
    kHICommandMaximizeWindow = 'maxi',
    kHICommandMaximizeAll = 'maxa',
    kHICommandArrangeInFront = 'frnt',
    kHICommandBringAllToFront = 'bfrt',
    kHICommandWindowListSeparator = 'wldv',
    kHICommandWindowListTerminator = 'wlst',
    kHICommandSelectWindow = 'swin',
    kHICommandRotateWindowsForward = 'rotw',
    kHICommandRotateWindowsBackward = 'rotb',
    kHICommandRotateFloatingWindowsForward = 'rtfw',
    kHICommandRotateFloatingWindowsBackward = 'rtfb',
    kHICommandAbout = 'abou',
    kHICommandNew = 'new ',
    kHICommandOpen = 'open',
    kHICommandClose = 'clos',
    kHICommandSave = 'save',
    kHICommandSaveAs = 'svas',
    kHICommandRevert = 'rvrt',
    kHICommandPrint = 'prnt',
    kHICommandPageSetup = 'page',
    kHICommandAppHelp = 'ahlp',
    kHICommandShowCharacterPalette = 'chrp',
    kHICommandShowSpellingPanel = 'shsp',
    kHICommandCheckSpelling = 'cksp',
    kHICommandChangeSpelling = 'chsp',
    kHICommandCheckSpellingAsYouType = 'chsp',
    kHICommandIgnoreSpelling = 'igsp',
    kHICommandLearnWord = 'lrwd'
};
```

Constants

`kHICommandOK`

The OK button in a dialog or alert.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kHICommandCancel`
The Cancel button in a dialog or alert.
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kHICommandQuit`
The application should quit.
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kHICommandUndo`
The last editing operation should be undone.
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kHICommandRedo`
The last editing operation should be redone.
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kHICommandCut`
The selected items should be cut.
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kHICommandCopy`
The selected items should be copied.
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kHICommandPaste`
The contents of the clipboard should be pasted.
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kHICommandClear`
The selected items should be deleted.
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kHICommandSelectAll`
All items in the active window should be selected.
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kHICommandHide`
The application should be hidden. The Menu Manager responds to this command automatically; your application does not need to handle it.
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kHICommandHideOthers`
Other applications should be hidden. The Menu Manager responds to this command automatically; your application does not need to handle it.

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

`kHICommandShowAll`
All applications should become visible. The Menu Manager responds to this command automatically; your application does not need to handle it.

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

`kHICommandPreferences`
The Preferences menu item has been selected.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kHICommandZoom`
The active window should be zoomed in or out. The default application handler responds to this event automatically. Your application does not need to handle this event, but you may want to install a Carbon event handler for `kEventWindowGetIdealSize` to return the ideal size for your document windows.

`kHICommandMinimizeWindow`
The active window should be minimized. The default application handler will respond to this event automatically; your application does not need to handle it.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kHICommandMinimizeAll`
All collapsable windows should be minimized. The default application handler responds to this event automatically; your application does not need to handle it.

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

`kHICommandMaximizeWindow`
The active window should be maximized. Sent only on Mac OS 9. The default application handler will respond to this event automatically; your application does not need to handle it.

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

`kHICommandMaximizeAll`
All collapsible windows should be maximized. This event is not sent or handled on Mac OS X.

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

`kHICommandArrangeInFront`
All document-class windows should be arranged in a stack. The default application handler responds to this event automatically; your application does not need to handle it.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kHICommandBringAllToFront`

All windows of this application should be brought in front of windows from other applications. Sent only on Mac OS X. The default application handler responds to this event automatically; your application does not need to handle it.

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

`kHICommandWindowListSeparator`

A placeholder to mark the separator item dividing the Zoom/Minimize/Maximize/Arrange menu items in the standard Window menu from the menu items listing the visible windows. If you need to add your own menu items to the standard Window menu before the window list section, you can use `GetIndMenuItemWithCommandID` (described in the Menu Manager Reference in the User Experience section of the Carbon documentation) to look for the menu item with this command ID and insert your menu items before the item with this ID.

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

`kHICommandWindowListTerminator`

Used as a placeholder to mark the end of the window list section of the standard Window menu. If you need to add your own menu items to the standard Window menu after the window list section, you can use `GetIndMenuItemWithCommandID` (described in the Menu Manager Reference in the User Experience section of the Carbon documentation) to look for the menu item with this command ID and insert your items after the item with this ID.

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

`kHICommandSelectWindow`

A window in the standard Window menu has been selected and should be activated. In Mac OS X v10.3, this command is also sent by the toolbox whenever it needs to activate a window in your application. For example, it is used when a window is selected from the application's Dock menu, and when a window that uses the standard window event handler is clicked. The default application handler responds to this event automatically; your application does not need to handle it.

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

`kHICommandRotateWindowsForward`

The Rotate Windows hot key (cmd-~ by default) has been pressed. Non-floating windows should be rotated so that the window after the active window is activated. The default application handler responds to this event automatically; your application does not need to handle it.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`kHICommandRotateWindowsBackward`

The Rotate Windows hot key (cmd-~ by default) has been pressed. Non-floating windows should be rotated so that the window before the active window is activated. The default application handler responds to this event automatically; your application does not need to handle it.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`kHICommandRotateFloatingWindowsForward`
: The floating window focus hot key (ctl-F6 by default) has been pressed, and floating windows should be rotated so that the window after the focused window is activated. The default application handler responds to this event automatically; your application does not need to handle it.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`kHICommandRotateFloatingWindowsBackward`
: The floating window focus hot key (ctl-F6 by default) has been pressed, and floating windows should be rotated so that the window before the focused window is activated. The default application handler responds to this event automatically; your application does not need to handle it.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`kHICommandAbout`
: The About menu item has been selected. In Mac OS X v10.3 and later, `RunApplicationEventLoop` installs a handler for this command ID on the application target that handles this event automatically by calling `HIAboutBox`. Your application can install its own handler if you want to display a customized about box.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kHICommandNew`
: A new document or item should be created.

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

`kHICommandOpen`
: The user wants to open an existing document.

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

`kHICommandClose`
: The active window should be closed. This command is typically be generated by a Close menu item. In Mac OS X v10.3 and later, the default application handler responds to this command by sending a `kEventWindowClose` event; on earlier systems, only the standard window event handler responded to this event.

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

`kHICommandSave`
: The active document should be saved.

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

`kHICommandSaveAs`
: The user wants to save the active document under a new name.

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

`kHICommandRevert`
The contents of the active document should be reverted to the last saved version.

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

`kHICommandPrint`
The active window should be printed.

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

`kHICommandPageSetup`
The user wants to configure the current page margins, formatting, and print options.

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

`kHICommandAppHelp`
The application's help book should be displayed. The Help Manager installs a handler for this command ID on the Help menu returned by `HMGetHelpMenu` and responds to this event automatically. Your application does not need to handle it. In Mac OS X v10.4, the Help Manager installs a handler for this event on the application event target rather than on the Help menu.

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

`kHICommandShowCharacterPalette`
The character palette needs to be shown. Events with this command ID are only generated in Mac OS X v10.3 and later. The toolbox will respond to this event automatically; your application does not need to handle it.

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

`kHICommandShowSpellingPanel`
Display the spelling panel if it is not already visible. Events with this command ID are only generated in Mac OS X v10.4 and later. If spell checking has been enabled in the Multilingual Text Engine (MLTE) or an HITextView, this command is handled automatically.

Available in Mac OS X v10.4 and later.

Declared in `CarbonEvents.h`.

`kHICommandCheckSpelling`
Spell check the document now. Events with this command ID are only generated in Mac OS X v10.4 and later. If spell checking has been enabled in MLTE or an HITextView, this command is handled automatically.

Available in Mac OS X v10.4 and later.

Declared in `CarbonEvents.h`.

`kHICommandChangeSpelling`
Change the spelling. Events with this command ID are only generated in Mac OS X v10.4 and later. If spell checking has been enabled in MLTE or an HITextView, this command is handled automatically.

Available in Mac OS X v10.4 and later.

Declared in `CarbonEvents.h`.

`kHICommandCheckSpellingAsYouType`
Begin interactive spell checking. Events with this command ID are only generated in Mac OS X v10.4 and later. If spell checking has been enabled in MLTE or an HITextView, this command is handled automatically.

Available in Mac OS X v10.4 and later.

Declared in `CarbonEvents.h`.

`kHICommandIgnoreSpelling`
Ignore this word while spell checking this text view. Events with this command ID are only generated in Mac OS X v10.4 and later. If spell checking has been enabled in MLTE or an HITextView, this command is handled automatically.

Available in Mac OS X v10.4 and later.

Declared in `CarbonEvents.h`.

`kHICommandLearnWord`
Learn this spelling for all documents. Events with this command ID are generated only in Mac OS X v10.4 and later. If spell checking has been enabled in MLTE or an HITextView, this command is handled automatically.

Available in Mac OS X v10.4 and later.

Declared in `CarbonEvents.h`.

Discussion
You should use these values for standard menu and control commands rather than defining your own.

Command Event Source Constants

Define constants for the user interface element that produced an HICommand event.

```
enum {
    kHICommandFromMenu = (1L << 0),
    kHICommandFromControl = (1L << 1),
    kHICommandFromWindow = (1L << 2)
};
```

Constants
`kHICommandFromMenu`
This bit is set for commands generated from menu items in all versions of CarbonLib and Mac OS X.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kHICommandFromControl`
The command event originated from a control. This bit was introduced in Mac OS X v10.2 and CarbonLib 1.6; it is never set in earlier versions of Mac OS X or CarbonLib.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`kHICommandFromWindow`
The command event originated from a window. This bit was introduced in Mac OS X v10.2 and CarbonLib 1.6; it is never set in earlier versions of Mac OS X or CarbonLib.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

Control Events

Control Event Constants

Define constants related to events from `kEventClassControl`.

```
enum {
    kEventControlInitialize = 1000,
    kEventControlDispose = 1001,
    kEventControlGetOptimalBounds = 1003,
    kEventControlDefInitialize = kEventControlInitialize,
    kEventControlDefDispose = kEventControlDispose,

    kEventControlEnabledStateChanged = 161,
    kEventControlArbitraryMessage = 201
};
```

Constants

`kEventControlInitialize`

Sent when a control is created. Allows the control to initialize private data.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventControlDispose`
Sent when a control is disposed. Allows the control to dispose of private data.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventControlGetOptimalBounds`
Allows the control to report its best size and its text baseline based on its current settings. You should set the `kEventParamControlOptimalBounds` parameter to an appropriate rectangle. You should also set the `kEventParamControlOptimalBaselineOffset` parameter to be the offset from the top of your optimal bounds of a text baseline, if any. (Mac OS X only)

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventControlDefInitialize`
Same as `kEventControlInitialize`. You can use this event when creating custom control definitions.

Available in Mac OS X v10.0 through Mac OS X v10.2.

Declared in `CarbonEvents.h`.

`kEventControlDefDispose`
Same as `kEventControlDispose`. You can use this event when creating custom control definitions.

Available in Mac OS X v10.0 through Mac OS X v10.2.

Declared in `CarbonEvents.h`.

`kEventControlHit`
Sent by the Control Manager functions `TrackControl` and `HandleControlClick` after handling a click in a control. If you do not handle this event, and the control has a command ID associated with it, then the Control Manager sends a `kEventCommandProcess` event to the control.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventControlSimulateHit`
Sent when your control should simulate a click in response to some other action, such as a return key for a default button. The default behavior is to use the Control Manager function `HiliteControl` to highlight and unhighlight the part specified in the `kEventParamControlPart` parameter (simulating the hit) and then call the control's action callback function. (Mac OS X only)

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventControlHitTest`
Sent when someone wants to find out what part of your control is at a given point in local coordinates. You should set the `kEventParamControlPart` parameter to the appropriate part. (Mac OS X only)

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventControlDraw`
Sent when your control should draw itself. The event can optionally contain parameters indicating which port to draw into and which part to constrain drawing to. (Mac OS X only)

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventControlApplyBackground`
Sent when your control should apply its background color/pattern to the port specified so the subcontrol can properly erase. The port is optional; if it does not exist you should apply the background to the current port. Note that if you don't handle this event, the event is propagated to the control's parent. (Mac OS X only)

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CarbonEvents.h`.

`kEventControlApplyTextColor`
Sent when your control should apply a color/pattern to the specified port and context so a subcontrol can draw text which looks appropriate for your control's background. The port is optional; if it does not exist, you should apply the text color to the current port. The context is also optional. (Mac OS X only)

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventControlSetFocusPart`
Sent when your control is gaining, losing, or changing the focus. Set the focus to the part indicated by the `kEventParamControlPart` parameter. (Mac OS X only)

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventControlGetFocusPart`
Sent when your the Control Manager wants to know what part of your control is currently focused. Set the `kEventParamControlPart` parameter to your currently focused part. If you don't handle this event, the Control Manager sets the part parameter to the last part that was focused (or no part if the control lost focus). (Mac OS X only)

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventControlActivate`
Sent when your control becomes active as a result of a call to `ActivateControl`. (Mac OS X only)

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventControlDeactivate`
Sent when your control becomes inactive as a result of a call to `DeactivateControl`. (Mac OS X only)

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventControlSetCursor`
Sent when your control is asked to change the cursor as a result of a call to the Control Manager function `HandleControlSetCursor`. (Mac OS X only)

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventControlContextualMenuClick`

Sent when your control is asked to display a contextual menu as a result of a call to the Control Manager function `HandleControlContextualMenuClick`. (Mac OS X only)

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventControlClick`

A mouse down occurred in a control. The standard window handler sets the keyboard focus to the control if it takes focus on clicks, and calls the Control Manager function `HandleControlClick`.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventControlGetNextFocusCandidate`

Sent to allow a control to customize the focus order of its subcontrols. The current subcontrol with focus is stored in the `kEventParamStartControl` parameter. The desired focus direction is indicated by the `kControlFocusNextPart` or `kControlFocusPrevPart` constants, passed to you in the `kEventParamControlPart` parameter. The handler should return the next subcontrol in the `kEventParamNextControl` parameter. If the `kEventParamStartControl` parameter is `NULL`, return the first subcontrol in the specified focus direction. If no next subcontrol exists in the desired focus direction, return `NULL` or omit the `kEventParamNextControl` parameter.

The default behavior is to return the "most appropriate" peer control, which currently means the previous control in the ordering scheme.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`kEventControlGetAutoToggleValue`

Sent when the system wants to auto-toggle a control. You can specify the value to use based on the current value of your control.

If the control has the `kControlAutoToggles` feature bit set, then the default behavior is as follows:

- If the control does not behave like a radio button (the `kControlHasRadioBehavior` feature bit is not set), and its value is 1, then the `kEventParamControlValue` parameter is set to 0.
- If the control's value is anything other than 1, the `kEventParamControlValue` parameter is set to 0.

Otherwise, there is no default behavior.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`kEventControlInterceptSubviewClick`

Sent when the `HIViewGetViewForMouseClick` function is called (typically by the Control Manager before it descends into subviews). A view can use this event to intercept mouse clicks that would normally be destined for one of its subviews. For example, the Toolbar control uses this event to intercept command-clicks so that it can handle dragging of its children. If the command key is down, the user wants to drag, so the handler returns `noErr` to indicate that this view (the Toolbar) should receive the click, not the child that was actually under the mouse.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`kEventControlGetClickActivation`

Sent when a mouse click occurs in a background (inactive) control. This event is essentially the control version of `kEventWindowGetClickActivation`. The only differences are that the mouse location is view-relative and no window part parameter is passed to you.

This event is sent only when the standard window handler is installed. The default behavior is to activate the view and absorb the mouse click (that is, the click is not passed on to the view).

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`kEventControlDragEnter`

Sent when a drag item enters a view's bounds. If you want to respond to the drag, your drag entered handler must return `noErr` If you return `eventNotHandledErr` then you will not receive further drag events, nor will you be able to receive the drag item.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`kEventControlDragWithin`

Sent when a drag item has moved while in the view's bounds (but not within any of its subviews). If the drag subsequently enters a subview, all additional drag events are directed to that subview.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`kEventControlDragLeave`

Sent when a drag item leaves your view. You can use this event to unhighlight your view, and so on. (Available in Mac OS X v10.2 and later.)

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`kEventControlDragReceive`

Sent when a drag item is dropped within your view.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`kEventControlTrack`

Sent to allow your control to completely replace the normal tracking that is part of a call to the Control Manager functions `TrackControl` or `HandleControlClick`. Set the `kEventParamControlPart` to the part hit during tracking.

This event is sent only to controls that return a non-zero control part code from `kEventControlHitTest`. If you are implementing a custom HIView and you need to receive this event, you must also handle `kEventControlHitTest`. The hit-test handler must place a valid control part code into the `kEventParamControlPart` parameter and return `noErr`.

The default behavior is to implement indicator tracking (if the mouse is down in an indicator part, such as for a scroll bar) or one-part tracking (if the mouse is down in a button or similar part). If the tracking is successful, the Control Manager passes back the part that was hit.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventControlGetScrollToHereStartPoint`
Sent so your control can support "Scroll To Here" behavior during tracking. Set the `kEventParamMouseLocation` parameter to the mouse location in local coordinates which represents where a click would have needed to be to cause your indicator to be dragged to the incoming mouse location. (Mac OS X only)

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventControlGetIndicatorDragConstraint`
Sent so your control can constrain the movement of its indicator during tracking. Set the `kEventParamControlIndicatorDragConstraint` parameter to the appropriate constraint. (Mac OS X only)

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventControlIndicatorMoved`
Sent during live-tracking of the indicator so your control can update its value based on the new indicator position. During non-live tracking, this event lets you redraw the indicator ghost at the appropriate place. (Mac OS X only)

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventControlGhostingFinished`
Sent at the end of non-live indicator tracking so your control can update its value based on the final ghost location. (Mac OS X only)

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventControlGetActionProcPart`
Sent during tracking so your control can alter the part that is passed to its action callback based on modifier keys, etc. Set the `kEventParamControlPart` to the part you want to have sent. (Mac OS X only)

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventControlGetPartRegion`
Sent when a client wants to get a particular region of your control. See the `GetControlRegion` function in the Control Manager. The `kEventParamControlRegion` contains a region for you to modify.

If the requested part is `kControlStructureMetaPart`, the default behavior is to pass back a region equal to the control's bounds. Otherwise, there is no default behavior.

(Mac OS X only)

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventControlGetPartBounds`
Sent when a client wants to get a particular rectangle of your control when it may be more efficient than asking for a region. Set the `kEventParamControlPartBounds` parameter to the appropriate rectangle. (Mac OS X only)

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventControlSetData`
Sent when a client wants to change an arbitrary setting of your control. See the `SetControlData` function in the Control Manager. (Mac OS X only)

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventControlGetData`
Sent when a client wants to get an arbitrary setting of your control. See the Control Manager function `GetControlData`. (Mac OS X only)

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventControlGetSizeConstraints`
Sent when the `HIViewGetSizeContraints` function is called. You use this to let your custom view indicate its maximum and minimum size. A parent view can use this information to help it lay out subviews.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`kEventControlValueFieldChanged`
Sent when your control's value, minimum, maximum, or view size has changed. Useful so other entities can watch for your control's value to change. If the window does not have compositing enabled, the default behavior is to redraw the control (but not its subcontrols). (Mac OS X only)

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventControlAddedSubControl`
Sent when a control is embedded within your control.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventControlRemovingSubControl`
Sent when one of your child controls will be removed from your control.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventControlBoundsChanged`
Sent when your control's bounding rectangle has changed. Note that the `kEventParamOriginalBounds` and `kEventParamPreviousBounds` parameters for this event contain the same value.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventControlTitleChanged`
Sent when your control's title changes.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`kEventControlOwningWindowChanged`
Sent when one your control's owning window has changed. Useful to update any dependencies that your control has on its owning window. (Mac OS X only)

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventControlHiliteChanged`
Sent when a control's highlight state changes.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`kEventControlEnabledStateChanged`
Sent when a control's enabled state changes (that is, when a control is enabled or disabled).

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`kEventControlArbitraryMessage`
Sent when someone tries to send an old-style CDEF message to your control. In most cases, you should implement Carbon event replacements for CDEF messages instead. If you do handle this event, but do not explicitly handle a particular CDEF message, you should propagate this event up the handler chain (either explicitly by calling `CallNextEventHandler` (page 247) or implicitly by returning `eventNotHandledErr`), as some default behavior may be implemented for compatibility purposes. (Mac OS X only)

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CarbonEvents.h`.

Discussion
You can specify any of these events when installing an event handler. You can also pass these constants to the `CreateControlEvent` function to specify the type of control event you want to create.

Note that many control events are not sent as a request for you to take action; rather they provide a way for the application to override default behavior. Because this is the case, most control events do not have a standard handler associated with them. Their default behavior occurs whether or not you have the standard window handler installed.

Table 3-4 shows the parameters available for control events.

Table 3-4 Parameter names and types for common control event kinds

Event kind	Parameter name	Parameter type
`kEventControl-Initialize`	`kEventParamDirectObject`	`typeControlRef`
	`kEventParamInitCollection`	`typeCollection`
	`kEventParamControlFeatures`	`typeUInt32`
`kEventControlDispose`	`kEventParamDirectObject`	`typeControlRef`
`kEventControlGet-OptimalBounds`	`kEventParamDirectObject`	`typeControlRef`

	kEventParamControlOptimalBounds	typeQDRectangle
	kEventParamControlOptimalBaseline-Offset (Optional)	typeShortInteger
kEventControlHit	kEventParamDirectObject	typeControlRef
	kEventParamControlPart	typeControlPartCode
	kEventParamKeyModifiers	typeUInt32
kEventControl-SimulateHit	kEventParamDirectObject	typeControlRef
	kEventParamControlPart	typeControlPartCode
	kEventParamKeyModifiers	typeUInt32
kEventControlHitTest	kEventParamDirectObject	typeControlRef
	kEventParamMouseLocation	typeQDPoint
	kEventParamControlPart	typeControlPartCode
kEventControlDraw	kEventParamDirectObject	typeControlRef
	kEventParamControlPart (Optional)	typeControlPartCode
	kEventParamGrafPort (Optional)	typeGrafPtr
	kEventParamRgnHandle (Optional)	typeQDRgnHandle
	kEventParamCGContextRef (Optional)	typeCGContextRef
kEventControlApply-Background	kEventParamDirectObject	typeControlRef
	kEventParamControlSubControl	typeControlRef
	kEventParamControlDrawDepth	typeShortInteger
	kEventParamGrafPort (Optional)	typeGrafPtr
kEventControlApply-TextColor	kEventParamDirectObject	typeControlRef
	kEventParamControlSubControl	typeControlRef
	kEventParamControlDrawDepth	typeShortInteger
	kEventParamControlDrawInColor	typeBoolean

	kEventParamPreviousPart	typeControlPartCode
	kEventParamCurrentPart	typeControlPartCode
kEventControlEnabled-StateChanged	kEventParamDirectObject	typeControlRef
kEventControl-ArbitraryMessage	kEventParamDirectObject	typeControlRef
	kEventParamControlMessage	typeShortInteger
	kEventParamControlParam	typeLongInteger
	kEventParamControlResult	typeLongInteger

Control Bounds Constants

Define control bounds change-event attributes.

```
enum {
    kControlBoundsChangeSizeChanged = (1 << 2),
    kControlBoundsChangePositionChanged = (1 << 3)
};
```

Constants

`kControlBoundsChangeSizeChanged`

The dimensions of the control (width and height) changed.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kControlBoundsChangePositionChanged`

The position of the control changed (that is, the top-left corner moved).

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

Discussion

When the system sends out a `kEventControlBoundsChanged` event, it also sends along a parameter containing attributes of the event. These attributes can be used to determine what aspect of the control changed (position, size, or both).

Control Event Parameters

Define parameters related to control events.

```
enum {
    kEventParamControlPart = 'cprt',
    kEventParamInitCollection = 'icol',
    kEventParamControlMessage = 'cmsg',
    kEventParamControlParam = 'cprm',
    kEventParamControlResult = 'crsl',
    kEventParamControlRegion = 'crgn',
    kEventParamControlAction = 'caup',
    kEventParamControlIndicatorDragConstraint = 'cidc',
    kEventParamControlIndicatorRegion = 'cirn',
    kEventParamControlIsGhosting = 'cgst',
    kEventParamControlIndicatorOffset = 'ciof',
    kEventParamControlClickActivationResult = 'ccar',
    kEventParamControlSubControl = 'csub',
    kEventParamControlOptimalBounds = 'cobn',
    kEventParamControlOptimalBaselineOffset = 'cobo',
    kEventParamControlDataTag = 'cdtg',
    kEventParamControlDataBuffer = 'cdbf',
    kEventParamControlDataBufferSize = 'cdbs',
    kEventParamControlDrawDepth = 'cddp',
    kEventParamControlDrawInColor = 'cdic',
    kEventParamControlFeatures = 'cftr',
    kEventParamControlPartBounds = 'cpbd',
    kEventParamControlOriginalOwningWindow = 'coow',
    kEventParamControlCurrentOwningWindow = 'ccow',
    kEventParamControlFocusEverything = 'cfev',
    kEventParamNextControl = 'cnxc',
    kEventParamStartControl = 'cstc',
    kEventParamControlSubview = 'csvw',
    kEventParamControlPreviousPart = 'copc',
    kEventParamControlCurrentPart = 'cnpc',
    kEventParamControlInvalRgn = 'civr',
    kEventParamControlValue = 'cval',
    kEventParamControlHit = 'chit',
    kEventParamControlPartAutoRepeats = 'caur',
    kEventParamControlFrameMetrics = 'cfmt',
    kEventParamControlWouldAcceptDrop = 'cldg',
    kEventParamControlPrefersShape = 'cpsh',
    typeControlActionUPP = 'caup',
    typeIndicatorDragConstraint = 'cidc',
    typeControlPartCode = 'cprt',
    typeControlFrameMetrics = 'cins'
};
```

Constants

`kEventParamControlPart`

typeControlPartCode

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventParamInitCollection`

typeCollection

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventParamControlMessage`
typeShortInteger
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamControlParam`
typeLongInteger
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamControlResult`
typeLongInteger
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamControlRegion`
typeQDRgnHandle
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamControlAction`
typeControlActionUPP
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamControlIndicatorDragConstraint`
typeIndicatorDragConstraint
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamControlIndicatorRegion`
typeQDRgnHandle
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamControlIsGhosting`
typeBoolean
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamControlIndicatorOffset`
typeQDPoint
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamControlClickActivationResult`
typeClickActivationResult
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamControlSubControl`
typeControlRef
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamControlOptimalBounds`
typeQDRectangle
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamControlOptimalBaselineOffset`
typeShortInteger
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamControlDataTag`
typeEnumeration
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamControlDataBuffer`
typePtr
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamControlDataBufferSize`
typeLongInteger
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamControlDrawDepth`
typeShortInteger
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamControlDrawInColor`
typeBoolean
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamControlFeatures`
typeUInt32
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamControlPartBounds`
typeQDRectangle
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamControlOriginalOwningWindow`
typeWindowRef
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamControlCurrentOwningWindow`
typeWindowRef
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamControlFocusEverything`
typeBoolean
Available in Mac OS X v10.2 and later.
Declared in `CarbonEvents.h`.

`kEventParamNextControl`
typeControlRef
Available in Mac OS X v10.2 and later.
Declared in `CarbonEvents.h`.

`kEventParamStartControl`
typeControlRef
Available in Mac OS X v10.2 and later.
Declared in `CarbonEvents.h`.

`kEventParamControlSubview`
typeControlRef
Available in Mac OS X v10.2 and later.
Declared in `CarbonEvents.h`.

`kEventParamControlPreviousPart`
typeControlPartCode
Available in Mac OS X v10.2 and later.
Declared in `CarbonEvents.h`.

`kEventParamControlCurrentPart`
typeControlPartCode
Available in Mac OS X v10.2 and later.
Declared in `CarbonEvents.h`.

`kEventParamControlInvalRgn`
typeQDRgnHandle
Available in Mac OS X v10.2 and later.
Declared in `CarbonEvents.h`.

`kEventParamControlValue`
typeLongInteger
Available in Mac OS X v10.2 and later.
Declared in `CarbonEvents.h`.

`kEventParamControlHit`
typeBoolean
Available in Mac OS X v10.3 and later.
Declared in `CarbonEvents.h`.

`kEventParamControlPartAutoRepeats`
typeBoolean
Available in Mac OS X v10.3 and later.
Declared in `CarbonEvents.h`.

`kEventParamControlFrameMetrics`
typeControlFrameMetrics
Available in Mac OS X v10.3 and later.
Declared in `CarbonEvents.h`.

`kEventParamControlWouldAcceptDrop`
typeBoolean
Available in Mac OS X v10.3 and later.
Declared in `CarbonEvents.h`.

`kEventParamControlPrefersShape`
typeBoolean
Available in Mac OS X v10.4 and later.
Declared in `CarbonEvents.h`.

`typeControlActionUPP`
ControlActionUPP
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`typeIndicatorDragConstraint`
IndicatorDragConstraint
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`typeControlPartCode`
ControlPartCode
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`typeControlFrameMetrics`
HIViewFrameMetrics
Available in Mac OS X v10.3 and later.
Declared in `CarbonEvents.h`.

Ink Events

Ink Event Constants

Define constants related to events from `kEventClassInk`.

```
enum {
    kEventInkPoint = 10,
    kEventInkGesture = 11,
    kEventInkText = 12
};
```

Constants

`kEventInkPoint`

A mouse event will be handled as an ink point and used for recognition. The Ink Manager has determined that the mouse event in `kEventParamEventRef` should be used for recognition. If the application handles the event and returns `noErr`, the Ink Manager does nothing further with the mouse event. If the application returns any other value (including `eventNotHandledErr`), the Ink Manager processes the point normally.

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

`kEventInkGesture`

The Ink Manager recognizes the current ink phrase as one of the known system gestures. Applications can install a handler for these events to provide targeted gestures and support for context-dependent (tentative) gestures. Applications should return `noErr` if they handled the gesture. If the gesture was context dependent and does not apply to the current situation, applications should return `eventNotHandledErr`.

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

`kEventInkText`

The Ink Manager recognizes a word. The `kEventParamInkTextRef` parameter contains the ink text reference with all the information about the word. For more information, see `Ink.h`.

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

Discussion

Table 3-6 shows the parameters associated with ink events

Table 3-5 Parameter names and types for ink event kinds

Event kind	Parameter name	Parameter type
`kEventInkPoint`	`kEventParamEventRef`	`typeEventRef`
`kEventInkGesture`	`kEventParamInkGesture`	`typeHIRect`
	`kEventParamInkGestureBounds`	`typeHIRect`
	`kEventParamInkGestureHotspot`	`typeHIPoint`
`kEventInkText`	`kEventParamInkTextRef`	`typePtr`
	`kEventParamInkKeyboardShortcut`	`typeBoolean`

Ink Event Parameters

Define constants for parameters to ink events.

```
enum {
    kEventParamInkTextRef = 'iwrd',
    kEventParamInkKeyboardShortcut = 'ikbd',
    kEventParamInkGestureKind = 'gknd',
    kEventParamInkGestureBounds = 'gbnd',
    kEventParamInkGestureHotspot = 'ghot'
};
```

Constants

`kEventParamInkTextRef`
The ink text reference containing the data for the word the Ink Manager recognized. (`typePtr`)

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

`kEventParamInkKeyboardShortcut`
A Boolean whose value indicates whether the word the Ink Manager recognized is a keyboard shortcut. That is, the Command or Control key was pressed and the top-choice alternate text is a single character. (`typeBoolean`)

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

`kEventParamInkGestureKind`
Kind of gesture. (`typeUInt32`)

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

`kEventParamInkGestureBounds`
Bounds of the gesture in global coordinates. (`typeHIRect`)

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

`kEventParamInkGestureHotspot`
Hotspot, in global coordinates, for the gesture. (`typeHIPoint`)

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

Keyboard Events

Keyboard Event Constants

Define constants related to events from `kEventClassKeyboard`.

```
enum {
    kEventRawKeyDown = 1,
    kEventRawKeyRepeat = 2,
    kEventRawKeyUp = 3,
    kEventRawKeyModifiersChanged = 4,
    kEventHotKeyPressed = 5,
    kEventHotKeyReleased = 6
};
```

Constants

`kEventRawKeyDown`
A key was pressed.
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventRawKeyRepeat`
Sent periodically as a key is held down by the user.
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventRawKeyUp`
A key was released.
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventRawKeyModifiersChanged`
The keyboard modifiers have changed.
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventHotKeyPressed`
A registered hot key was pressed.
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventHotKeyReleased`
A registered hot key was released.
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

Discussion
These events are the lowest-level keyboard events.

Table 3-6 shows the parameters associated with keyboard events.

Table 3-6 Parameter names and types for keyboard event kinds

Event kind	Parameter name	Parameter type
`kEventRawKeyDown`	`kEventParamKeyMacCharCodes`	`typeChar`
	`kEventParamKeyCode`	`typeUInt32`
	`kEventParamKeyModifiers`	`typeUInt32`

	kEventParamKeyboardType	typeUInt32
kEventRawKeyRepeat	kEventParamKeyMacCharCodes	typeChar
	kEventParamKeyCode	typeUInt32
	kEventParamKeyModifiers	typeUInt32
	kEventParamKeyboardType	typeUInt32
kEventRawKeyUp	kEventParamKeyMacCharCodes	typeChar
	kEventParamKeyCode	typeUInt32
	kEventParamKeyModifiers	typeUInt32
	kEventParamKeyboardType	typeUInt32
kEventRawKey-ModifiersChanged	kEventParamKeyModifiers	typeUInt32
kEventHotKeyPressed	kEventParamDirectObject	typeEventHotKeyID
kEventHotKeyReleased	kEventParamDirectObject	typeEventHotKeyID

Key Modifier Event Masks

Define values used to determine whether additional modifier keys are down for a keyboard or mouse event.

```
enum {
    kEventKeyModifierNumLockMask = 1L << kEventKeyModifierNumLockBit,
    kEventKeyModifierFnMask = 1L << kEventKeyModifierFnBit
};
```

Constants

`kEventKeyModifierNumLockMask`

A bit mask containing `kEventKeyModifierNumLockBit`. (Mac OS X only)

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventKeyModifierFnMask`

A bit mask containing `kEventKeyModifierFnBit`. (Mac OS X only)

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

Key Modifier Event Bits

Define key modifier change event bits.

```
enum {
    kEventKeyModifierNumLockBit = 16,
    kEventKeyModifierFnBit = 17
};
```

Constants

`kEventKeyModifierNumLockBit`

This keyboard event was generated either on the numeric keypad or in the numeric section of an iBook or PowerBook keyboard with the Num Lock key pressed. This state bit does not provide an indication of the Num Lock key on non-portable keyboards. This bit is set on Mac OS X only.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventKeyModifierFnBit`

The Fn key was pressed when this keyboard event was generated. This bit is set on Mac OS X only.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

Discussion

Note that bits 8 through 15 (`cmdKeyBit` to `rightControlKeyBit`) are compatible with the Classic Event Manager modifiers.

Keyboard Event Parameters and Types

Define constants for parameters to raw keyboard events.

```
enum {
    kEventParamKeyCode = 'kcod',
    kEventParamKeyMacCharCodes = 'kchr',
    kEventParamKeyModifiers = 'kmod',
    kEventParamKeyUnicodes = 'kuni',
    kEventParamKeyboardType = 'kbdt',
    typeEventHotKeyID = 'hkid'
};
```

Constants

`kEventParamKeyCode`

typeUInt32

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventParamKeyMacCharCodes`

typeChar

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventParamKeyModifiers`

typeUInt32

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventParamKeyUnicodes`
typeUnicodeText
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`typeEventHotKeyID`
EventHotKeyID
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

Symbolic Hot Key Definitions

Define CFDictionaryRef keys returned by `CopySymbolicHotKeys`.

```
#define kHISymbolicHotKeyCode CFSTR("kHISymbolicHotKeyCode")
#define kHISymbolicHotKeyModifiers CFSTR("kHISymbolicHotKeyModifiers")
#define kHISymbolicHotKeyEnabled CFSTR("kHISymbolicHotKeyEnabled")
```

Constants

`kHISymbolicHotKeyCode`
The virtual key code of the hot key, represented as a CFNumber.
Available in Mac OS X v10.3 and later.
Declared in `CarbonEvents.h`.

`kHISymbolicHotKeyModifiers`
The hot key's keyboard modifiers, represented as a CFNumber.
Available in Mac OS X v10.3 and later.
Declared in `CarbonEvents.h`.

`kHISymbolicHotKeyEnabled`
The enable state of the hot key, represented as a CFBoolean.
Available in Mac OS X v10.3 and later.
Declared in `CarbonEvents.h`.

Hot Key Constants

Define hot key states used by `PushSymbolicHotKeyMode`.

```
enum {
    kHIHotKeyModeAllEnabled = 0,
    kHIHotKeyModeAllDisabled = (1 << 0),
    kHIHotKeyModeAllDisabledExceptUniversalAccess = (1 <<  1)
};
```

Constants

`kHIHotKeyModeAllEnabled`
All hot keys are enabled.
Available in Mac OS X v10.4 and later.
Declared in `CarbonEvents.h`.

`kHIHotKeyModeAllDisabled`
All hot keys are disabled.

Available in Mac OS X v10.4 and later.

Declared in `CarbonEvents.h`.

`kHIHotKeyModeAllDisabledExceptUniversalAccess`
All hot keys are disabled except for the Universal Access hot keys (that is, zooming, white-on-black, and enhanced contrast).

Available in Mac OS X v10.4 and later.

Declared in `CarbonEvents.h`.

Menu Events

Menu Event Constants

Define constants related to events from `kEventClassMenu`.

```
enum {
    kEventMenuBeginTracking = 1,
    kEventMenuEndTracking = 2,
    kEventMenuChangeTrackingMode = 3,
    kEventMenuOpening = 4,
    kEventMenuClosed = 5,
    kEventMenuTargetItem = 6,
    kEventMenuMatchKey = 7,
    kEventMenuEnableItems = 8,
    kEventMenuPopulate = 9,
    kEventMenuMeasureItemWidth = 100,
    kEventMenuMeasureItemHeight = 101,
    kEventMenuDrawItem = 102,
    kEventMenuDrawItemContent = 103,
    kEventMenuDispose = 1001,
    kEventMenuCalculateSize = 1004,
    kEventMenuCreateFrameView = 1005,     kEventMenuGetFrameBounds = 1006,
kEventMenuBecomeScrollable = 1007,     kEventMenuCeaseToBeScrollable = 1008,
    kEventMenuBarShown = 2000,     kEventMenuBarHidden = 2001
};
```

Constants

`kEventMenuBeginTracking`
The user has begun tracking the menubar or a pop-up menu. The direct object parameter is a valid menu reference if tracking a pop-up menu, or `NULL` if tracking the menubar. The `kEventParamCurrentMenuTrackingMode` parameter indicates whether the user is tracking the menus using the mouse or the keyboard. The handler may return `userCanceledErr` to stop menu tracking.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventMenuEndTracking`

The user has finished tracking the menubar or a pop-up menu. In Mac OS X v10.3 and later, when a menu tracking session ends, the Menu Manager sends `kEventMenuEndTracking` to every menu that was opened during the session, in addition to the root menu. This is done to allow menus with dynamic content to remove that content at the end of menu tracking; for example, a menu containing many IconRefs might want to load the IconRefs dynamically in response to the `kEventMenuMenuPopulate` event and remove them in response to the `kEventMenuEndTracking` event to avoid the memory overhead of keeping the IconRef data in memory while the menu is not being displayed.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventMenuChangeTrackingMode`

The user has switched from selecting a menu with the mouse to selecting with the keyboard, or from selecting with the keyboard to selecting with the mouse.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventMenuOpening`

A menu is opening. This event is sent each time that the menu is opened (that is, more than once during a given tracking session if the user opens the menu multiple times). It is sent before the menu is actually drawn, so you can update the menu contents (including making changes that will alter the menu size) and the new contents will be drawn correctly. The `kEventParamMenuFirstOpen` parameter indicates whether this is the first time this menu has been opened during this menu tracking session. The handler may return `userCanceledErr` to prevent this menu from opening. Note that for most applications, you should handle the `kEventMenuPopulate` event instead.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventMenuClosed`

A menu has been closed. Sent after the menu is hidden.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventMenuTargetItem`

The mouse is moving over a particular menu item. This event is sent for both enabled and disabled items.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventMenuMatchKey`

A menu is about to be examined for items that match a command key event. A handler for this event may perform its own command key matching and override the Menu Manager's default matching algorithms. Returning `noErr` from your handler indicates that you have found a match. The handler for this event should not examine submenus of this menu for a match; a separate event will be sent for each submenu.

When called from `IsMenuKeyEvent`, the `kEventParamEventRef` parameter contains the event reference that was passed to `IsMenuKeyEvent`, for your handler to examine; when called from `MenuKey` or `MenuEvent`, the `EventRef` parameter contains an event created from the information passed to `MenuKey` or `MenuEvent`. Note that in the `MenuKey` case, no virtual key code (`kEventParamKeyCode`) or key modifiers (`kEventParamKeyModifiers`) will be available.

The `kEventParamMenuEventOptions` parameter contains a copy of the options that were passed to `IsMenuKeyEvent`, or `0` if called from `MenuKey` or `MenuEvent`. The only option that your handler will need to obey is `kMenuEventIncludeDisabledItems`.

If your handler finds a match, it should set the `kEventParamMenuItemIndex` parameter to contain the item index of the matching item, and return `noErr`. If it does not find a match, it should return `menuItemNotFoundErr`. Any other return value will cause the Menu Manager to use its default command key matching algorithm for this menu.

This event is sent after `kEventMenuEnableItems`.

In CarbonLib and Mac OS X through version 10.3, the Menu Manager sends a `kEventMenuEnableItems` event to the menu before sending `kEventMenuMatchKey`. In Mac OS X 10.4 and later, the Menu Manager no longer sends `kEventMenuEnableItems` (or the resulting `kEventCommandUpdateStatus` events) to the menu; a handler for `kEventMenuMatchKey` is expected to determine on its own whether a matching menu item is enabled.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventMenuEnableItems`

A request that the items in the menu be properly enabled or disabled according to the current state of the application. This event is sent from inside `MenuKey`, `MenuEvent`, and `IsMenuKeyEvent` before those functions examine the menu for an item that matches a keyboard event. It is also sent during menu tracking before a menu is first made visible; it is sent right after `kEventMenuOpening`, once per menu per menu tracking session.

If you install an event handler for `kEventProcessCommand`, you should also install a handler for `kEventMenuEnableItems`. This is necessary because the Carbon event system will attempt to match command keys against the available menus before returning the keyboard event to your application via `WaitNextEvent`. If you have menu command event handlers installed for your menu items, your handlers will be called without you ever receiving the keyboard event or calling `MenuKey`/`MenuEvent`/`IsMenuKeyEvent` yourself. Therefore, you have no opportunity to enable your menu items properly other than from a `kEventMenuEnableItems` handler.

It is not necessary to handle this event if you do not install `kEventProcessCommand` handlers for your menu items; in that case, the command key event will be returned from `WaitNextEvent` or `ReceiveNextEvent` as normal, and you can set up your menus before calling `MenuKey`/`MenuEvent`/`IsMenuKeyEvent`.

The `kEventParamEnableMenuForKeyEvent` parameter indicates whether this menu should be enabled for key event matching (`true`) or because the menu itself is about to become visible (`false`). If true, only the item enable state, command key, command key modifiers, and (optionally) the command key glyph need to be correct. If false, the entire menu item contents must be correct. This may be useful if you have custom menu content that is expensive to prepare.

Note that the standard application handler for `kEventMenuEnableItems` automatically sends `kEventCommandUpdateStatus` to your menu commands. As this can cause a performance hit if you have many menu items, you can choose to bypass these updates by installing a no-op handler for `kEventMenuEnableItems` that simply returns `noErr`.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventMenuPopulate`

Sent when an application should dynamically create a menu. You should use this event instead of `kEventMenuOpening` as the Menu Manager sends it before it searches a menu for a matching command key sequence; therefore you can use this event to dynamically add menu items that have command-key equivalents, making them selectable even if the menu itself is never displayed. The `kEventMenuPopulate` event is sent just once during a menu tracking session, even if the menu is opened and closed multiple times; the `kEventWindowOpening` event is sent each time the menu opens.

To determine whether this event was triggered by a command-key sequence, you should examine the `kEventParamMenuContext` parameter for the `kMenuContextKeyMatching` flag. If the event corresponds to the actual display of a menu, the `kEventContextMenuBarTracking` or `kEventContextPopUpTracking` flags are set.

Note that in Mac OS X v10.2 and later, the Menu Manager sends this event before it searches a menu for a matching command ID. To determine if this event was triggered by a command ID, check for the `kMenuContextCommandIDSearch` flag in the `kEventParamMenuContext` parameter. If that flag is set, the command ID that triggered this event is contained in the `kEventParamMenuCommand` parameter.)

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

`kEventMenuMeasureItemWidth`

Sent by the standard window definition if a menu item has the `kMenuItemAttrCustomDraw` attribute set. You should install your handler directly on the menu. Your handler should return a customized width for the menu item in the `kEventParamMenuItemWidth` parameter.

The default behavior (if you are using the standard menu definition) is to return the standard width for the item.

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

`kEventMenuMeasureItemHeight`

Sent by the standard window definition if a menu item has the `kMenuItemAttrCustomDraw` attribute set. You should install your handler directly on the menu. Your handler should return a customized height for the menu item in the `kEventParamMenuItemHeight` parameter.

The default behavior (if you are using the standard menu definition) is to return the standard height for the item.

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

`kEventMenuDrawItem`

Sent by the standard window definition if a menu item has the `kMenuItemAttrCustomDraw` attribute set. You should install your handler directly on the menu. Use your handler to override the drawing of the menu item and background.

The default behavior (if you are using the standard menu definition) is to call the Appearance Manager function `DrawThemeMenuItem` to draw the menu item's background and content.

If you have the standard event handler installed, the event also contains additional parameters indicating the bounds of the various portions of the menu item content, as well as the baseline of the menu item text. Using these parameters, you can call `CallNextEventHandler` to let the system handlers draw the standard menu content and then your handler can draw custom content on top.

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

`kEventMenuDrawItemContent`

Sent by the standard window definition if a menu item has the `kMenuItemAttrCustomDraw` attribute set. You should install your handler directly on the menu. You use your handler to override the drawing of one or more parts of the menu item's content (that is the mark character, icon, text, and command key information).

When you receive this event, the background and highlighting (if applicable) has already been drawn using the standard system appearance.

The default behavior (if you are using the standard menu definition) is to draw the standard menu item content.

If you have the standard event handler installed, the event also contains additional parameters indicating the bounds of the various portions of the menu item content, as well as the baseline of the menu item text. Using these parameters, you can call `CallNextEventHandler` to let the system handlers draw the standard menu content and then your handler can draw custom content on top.

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

`kEventMenuDispose`

Sent when a menu is being disposed.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventMenuCalculateSize`

Sent by `CalcMenuSize` to request that the menu calculate its size. The Menu Manager provides a default handler for all menus that calls the menu's MDEF or menu content view to determine the menu size. Applications typically do not need to handle this event. A custom menu definition or menu content view should use `kMenuSizeMsg` or `kEventControlGetOptimalBounds` to calculate its size. Note that if the menu uses an MDEF, the MDEF sets the menu's width and height in response to `kMenuSizeMsg`. The default handler for this event saves the old width and height before calling the MDEF and restores them afterward. `CalcMenuSize` sets the final menu width and height based on the dimensions returned from this event; applications may override this event to customize the width or height of a menu by modifying the `kEventParamDimensions` parameter. This event is sent only to the menu and is not propagated past the menu.

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

`kEventMenuCreateFrameView`

Requests that a menu content view create the HIView that will be used to draw the menu window frame. The HIMenuView class provides a default handler for this event that creates an instance of the standard menu window frame view. This event is sent only to the menu content view and is not propagated past the view.

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

`kEventMenuGetFrameBounds`

Requests that a menu content view calculate the bounding rect, in global coordinates, of the menu window frame that should contain the menu. This event is sent by the Menu Manager before displaying pull-down, popup, and hierarchical menus. It provides an opportunity for the menu content view to determine the position of the menu frame based on the position of the menu title, parent menu item, or popup menu location. The HIMenuView class provides a default handler for this event that calculates an appropriate location based on the bounds of the menu, the available screen space, and the frame metrics of the menu window content view. This event is sent only to the menu content view and is not propagated past the view.

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

`kEventMenuBecomeScrollable`

Requests that a menu content view prepare to be scrollable, which it does by installing the appropriate event handlers, timers, and the like. This event is sent by the Menu Manager when a menu becomes the most recently opened menu in the menu hierarchy. It is an indication that this menu content view is now a candidate for scrolling. The Menu Manager provides a default handler for this event that installs event handlers to provide automatic scrolling behavior for HIView-based menus. If a menu content view does not wish to use the Menu Manager's default scrolling support, it can override this event and return `noErr` to prevent the event from being propagated to the Menu Manager's default handler. This event is sent only to the menu content view and is not propagated past the view.

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

`kEventMenuCeaseToBeScrollable`
: Requests that a menu content view cease to be scrollable. This event is sent by the Menu Manager when a menu ceases to be the most recently opened menu. This occurs when the menu is closed, or when a submenu of the most recently opened menu is opened. It is an indication that this menu content view is no longer a candidate for scrolling. The Menu Manager provides a default handler for this event that removes event handlers installed in response to `kEventMenuBecomeScrollable`. This event is sent only to the menu content view and is not propagated past the view.

  Available in Mac OS X v10.3 and later.

  Declared in `CarbonEvents.h`.

`kEventMenuBarShown`
: Sent to all handlers registered for this event when the front process shows its menubar. This event is sent only to the application target.

  Available in Mac OS X v10.3 and later.

  Declared in `CarbonEvents.h`.

`kEventMenuBarHidden`
: Sent to all handlers registered for this event when the front process hides its menubar. This event is sent only to the application target.

  Available in Mac OS X v10.3 and later.

  Declared in `CarbonEvents.h`.

Discussion
Some menu events are sent or handled by the standard menu definition, which is a collection of handlers that define the default menu behavior. If you have specified a custom menu definition, you will not get the behavior provided by the standard definition.

Table 3-7 shows the parameters associated with menu events.

Table 3-7 Parameter names and types for menu event kinds

Event kind	Parameter name	Parameter type
`kEventMenuBeginTracking`	`kEventParamDirectObject`	`typeMenuRef`
	`kEventParamCurrentMenuTrackingMode`	`typeMenuTrackingMode`
	`kEventParamMenuContext` (Mac OS X v10.1 and later and CarbonLib 1.5 and later.)	`typeUInt32`
`kEventMenuEndTracking`	`kEventParamDirectObject`	`typeMenuRef`
	`kEventParamMenuContext` (Mac OS X v10.1 and later and CarbonLib 1.5 and later.)	`typeUInt32`
	`kEventParamMenuDismissed` (Mac OS X v10.3 and later.)	`typeUInt32`
`kEventMenuChangeTracking Mode`	`kEventParamDirectObject`	`typeMenuRef`
	`kEventParamCurrentMenuTrackingMode`	`typeMenuTrackingMode`

	kEventParamNewMenuTrackingMode	typeMenuTrackingMode
	kEventParamMenuContext	typeUInt32
kEventMenuOpening	kEventParamDirectObject	typeMenuRef
	kEventParamMenuFirstOpen	typeBoolean
	kEventParamMenuContext (Mac OS X v 10.0 and later and CarbonLib 1.5 and later.)	typeUInt32
kEventMenuClosed	kEventParamDirectObject	typeMenuRef
	kEventParamMenuContext (Mac OS X v10.1 and later and CarbonLib 1.5 an later.)	typeUInt32
kEventMenuTargetItem	kEventParamDirectObject	typeMenuRef
	kEventParamMenuItemIndex	typeMenuItemIndex
	kEventParamMenuCommand	typeMenuCommand
	kEventParamMenuContext (Mac OS X v10.1 and later and CarbonLib 1.5 and later.)	typeUInt32
kEventMenuMatchKey	kEventParamDirectObject	typeMenuRef
	kEventParamEventRef	typeEventRef
	kEventParamMenuEventOptions	typeMenuEventOptions
	kEventParamMenuContext (Mac OS X v10.1 and later, and CarbonLib 1.5 and later.)	typeUInt32
	kEventParamMenuItemIndex	typeMenuItemIndex
kEventMenuEnable-Items	kEventParamDirectObject	typeMenuRef
	kEventParamEnableMenuForKeyEvent	typeBoolean
	kEventParamMenuContext (Mac OS X v10.0 and later, and CarbonLib 1.1 and later.)	typeUInt32
kEventMenuPopulate	kEventParamDirectObject	typeMenuRef
	kEventParamMenuContext	typeUInt32
	kEventParamMenuCommand (Mac OS X v10.2 and later, and CarbonLib 1.6 and later.)	typeMenuCommand
kEventMenuMeasure-ItemWidth	kEventParamDirectObject	typeMenuRef
	kEventParamMenuItemIndex	typeMenuItemIndex

	kEventParamMenuItemWidth	typeShortInteger
kEventMenuMeasure-ItemHeight	kEventParamDirectObject	typeMenuRef
	kEventParamMenuItemIndex	typeMenuItemIndex
	kEventParamMenuItemHeight	typeShortInteger
kEventMenuDrawItem	kEventParamDirectObject	typeMenuRef
	kEventParamCurrentBounds	typeQDRectangle
	kEventParamMenuItemIndex	typeMenuItemIndex
	kEventParamMenuItemBounds	typeQDRectangle
	kEventParamMenuVirtualTop	typeLongInteger
	kEventParamMenuVirtualBottom	typeLongInteger
	kEventParamMenuDrawState	typeThemeMenuState
	kEventParamMenuItemType	typeThemeMenuItemType
	kEventParamCGContextRef	typeCGContextRef
	kEventParamMenuMarkBounds	typeQDRectangle
	kEventParamMenuIconBounds	typeQDRectangle
	kEventParamMenuTextBounds	typeQDRectangle
	kEventParamMenuTextBaseline	typeShortInteger
	kEventParamMenuKeyCommandKeyBounds	typeQDRectangle
kEventMenuDraw-ItemContent	kEventParamDirectObject	typeMenuRef
	kEventParamMenuItemIndex	typeMenuItemIndex
	kEventParamMenuItemBounds	typeQDRectangle
	kEventParamDeviceDepth	typeShortInteger
	kEventParamDeviceColor	typeBoolean
	kEventParamCGContextRef	typeCGContextRef
	kEventParamMenuMarkBounds	typeQDRectangle
	kEventParamMenuIconBounds	typeQDRectangle
	kEventParamMenuTextBounds	typeQDRectangle

	kEventParamMenuTextBaseline	typeShortInteger
	kEventParamMenuKeyCommandKeyBounds	typeQDRectangle
kEventMenuDispose	kEventParamDirectObject	typeMenuRef
kEventMenuCalculate-Size	kEventParamDirectObject	typeMenuRef
	kEventParamControlRef	typeControlRef
	kEventParamGDevice	typeGDHandle
	kEventParamAvailableBounds	typeQDRectangle
	kEventParamDimensions	typeHISize
kEventMenuCreate-FrameView	kEventParamEventRef	typeEventRef

	kEventParamMenuItemBounds	typeHIRect
	kEventParamGDevice	typeGDHandle
	kEventParamAvailableBounds	typeHIRect
	kEventParamParentMenu	typeMenuRef
	kEventParamParentMenuItem	typeMenuItemIndex
	kEventParamMenuPopupItem	typeMenuItemIndex
	kEventParamBounds	typeHIRect
	kEventParamOrigin	typeHIPoint
kEventMenuBecome-Scrollable	*None*	
kEventMenuCease-ToBeScrollable	*None*	
kEventMenuBarShown	*None*	

kEventMenuBarHidden	*None*	

Menu Context Constants

Define constants that describe the usage or context of a menu event.

```
enum {
    kMenuContextMenuBar = 1 << 0,
    kMenuContextPullDown = 1 << 8,
    kMenuContextPopUp = 1 << 9,
    kMenuContextSubmenu = 1 << 10,
    kMenuContextMenuBarTracking = 1 << 16,
    kMenuContextPopUpTracking = 1 << 17,
    kMenuContextKeyMatching = 1 << 18,
    kMenuContextMenuEnabling = 1 << 19,
    kMenuContextCommandIDSearch = 1 << 20
};
```

Constants

`kMenuContextMenuBar`
The menu associated with this event is in the menu bar or is a submenu of a menu in the menubar.

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

`kMenuContextPulldown`
The menu associated with this event is a pulldown menu located in the menu bar.

`kMenuContextPopUp`
The menu associated with this event is a popup menu displayed by the Menu Manager function `PopUpMenuSelect`.

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

`kMenuContextSubmenu`
The menu associated with this event is a submenu of a pulldown or popup menu.

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

`kMenuContextMenuBarTracking`
This event is being sent while a menu is being tracked in the menu bar.

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

`kMenuContextPopUpTracking`
This event is being sent while a popup menu is being tracked.

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

`kMenuContextKeyMatching`
This event is being sent while trying to match a command-key equivalent to a menu item.

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

`kMenuContextMenuEnabling`
Sent at idle time to update the enabled state of the menus.

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

`kMenuContextCommandIDSearch`
Sent while trying to match a command ID using the Menu Manager function `CountMenuItemsWithCommandID` or `GetIndMenuItemWithCommandID`.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

Discussion
The bits corresponding to these constants are set in the `kEventParamMenuContext` parameter of the menu event.

Menu Event Parameters

Define constants for parameters to menu events.

```
enum {
    kEventParamCurrentMenuTrackingMode = 'cmtm',
    kEventParamNewMenuTrackingMode = 'nmtm',
    kEventParamMenuFirstOpen = '1sto',
    kEventParamMenuItemIndex = 'item',
    kEventParamMenuCommand = 'mcmd',
    kEventParamEnableMenuForKeyEvent = 'fork',
    kEventParamMenuEventOptions = 'meop',
    kEventParamMenuContext = 'mctx',
    kEventParamMenuItemBounds = 'mitb',
    kEventParamMenuMarkBounds = 'mmkb',
    kEventParamMenuIconBounds = 'micb',
    kEventParamMenuTextBounds = 'mtxb',
    kEventParamMenuTextBaseline = 'mtbl',
    kEventParamMenuCommandKeyBounds = 'mcmb',
    kEventParamMenuVirtualTop = 'mvrt',
    kEventParamMenuVirtualBottom = 'mvrb',
    kEventParamMenuDrawState = 'mdrs',
    kEventParamMenuItemType = 'mitp',
    kEventParamMenuItemWidth = 'mitw',
    kEventParamMenuItemHeight = 'mith',
    typeMenuItemIndex = 'midx',
    typeMenuCommand = 'mcmd',
    typeMenuTrackingMode = 'mtmd',
    typeMenuEventOptions = 'meop',
    typeThemeMenuState = 'tmns',
    typeThemeMenuItemType = 'tmit'
};
```

Constants
`kEventParamCurrentMenuTrackingMode`
typeMenuTrackingMode

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventParamNewMenuTrackingMode`
typeMenuTrackingMode
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamMenuFirstOpen`
typeBoolean
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamMenuItemIndex`
typeMenuItemIndex
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamMenuCommand`
typeMenuCommand
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamEnableMenuForKeyEvent`
typeBoolean
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamMenuEventOptions`
typeMenuEventOptions
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`typeMenuItemIndex`
MenuItemIndex
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`typeMenuCommand`
MenuCommand
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`typeMenuTrackingMode`
MenuTrackingMode
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`typeMenuEventOptions`
MenuEventOptions
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

Services Menu Command Keys

Define CFDictionaryRef keys returned by `CopyServicesMenuCommandKeys`.

```
#define kHIServicesMenuProviderName CFSTR("kHIServicesMenuProviderName")
#define kHIServicesMenuItemName CFSTR("kHIServicesMenuItemName")
#define kHIServicesMenuCharCode CFSTR("kHIServicesMenuCharCode")
#define kHIServicesMenuKeyModifiers CFSTR("kHIServicesMenuKeyModifiers")
```

Constants

`kHIServicesMenuProviderName`
The name of the service provider.
Available in Mac OS X v10.4 and later.
Declared in `CarbonEvents.h`.

`kHIServicesMenuItemName`
The name of the menu item.
Available in Mac OS X v10.4 and later.
Declared in `CarbonEvents.h`.

`kHIServicesMenuCharCode`
The character code of the menu item shortcut.
Available in Mac OS X v10.4 and later.
Declared in `CarbonEvents.h`.

`kHIServicesMenuKeyModifiers`
The keyboard modifiers of the menu item shortcut in Menu Manager modifiers format.
Available in Mac OS X v10.4 and later.
Declared in `CarbonEvents.h`.

Mouse Events

Mouse Events

Define constants related to events from `kEventClassMouse`.

```
enum {
    kEventMouseDown = 1,
    kEventMouseUp = 2,
    kEventMouseMoved = 5,
    kEventMouseDragged = 6,
    kEventMouseEntered = 8,
    kEventMouseExited = 9,
    kEventMouseWheelMoved = 10
};
```

Constants

`kEventMouseDown`
A mouse button was pressed. Note that if you install a handler for this event on a window, you must allow the event to propagate (either by calling `CallNextEventHandler` or returning `eventNotHandledErr`) so that the window can be activated.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventMouseUp`
A mouse button was released.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventMouseMoved`
The mouse moved.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventMouseDragged`
The mouse moved, and a button was down.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventMouseEntered`
The mouse entered a tracking region. Used with mouse tracking regions. See `CreateMouseTrackingRegion` (page 253) for more information.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`kEventMouseExited`
The mouse left a tracking region. Used with mouse tracking regions. See `CreateMouseTrackingRegion` (page 253) for more information.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`kEventMouseWheelMoved`
The mouse wheel moved.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

Discussion

Table 3-8 shows the parameters related to mouse events.

Table 3-8 Parameter names and types for mouse event kinds

Event kind	Parameter name	Parameter type
kEventMouseDown	kEventParamMouseLocation	typeQDPoint
	kEventParamKeyModifiers	typeUInt32
	kEventParamMouseButton	typeMouseButton
	kEventParamClickCount	typeUInt32
	kEventParamWindowRef	typeWindowRef
	kEventParamWindowMouseLocation	typeHIPoint
	kEventParamWindowPartCode	typeWindowPartCode
	kEventParamMouseChord	typeUInt32
	kEventParamTabletEventType	typeUInt32
	kEventParamTabletPointRec	typeTabletPointRec
	kEventParamTabletProximityRec	typeTabletProximityRec
kEventMouseUp	kEventParamMouseLocation	typeQDPoint
	kEventParamKeyModifiers	typeUInt32
	kEventParamMouseButton	typeMouseButton
	kEventParamWindowRef	typeWindowRef
	kEventParamWindowMouseLocation	typeHIPoint
	kEventParamWindowPartCode	typeWindowPartCode
	kEventParamClickCount	typeUInt32
	kEventParamMouseChord	typeUInt32
	kEventParamTabletEventType	typeUInt32
	kEventParamTabletPointRec	typeTabletPointRec
	kEventParamTabletProximityRec	typeTabletProximityRec
kEventMouseMoved	kEventParamMouseLocation	typeQDPoint
	kEventParamKeyModifiers	typeUInt32
	kEventParamMouseDelta	typeHIPoint
	kEventParamWindowRef	typeWindowRef

	kEventParamWindowMouseLocation	typeHIPoint
	kEventParamWindowPartCode	typeWindowPartCode
	kEventParamTabletEventType	typeUInt32
	kEventParamTabletPointRec	typeTabletPointRec
	kEventParamTabletProximityRec	typeTabletProximityRec
kEventMouseDragged	kEventParamMouseLocation	typeQDPoint
	kEventParamKeyModifiers	typeUInt32
	kEventParamMouseButton	typeMouseButton
	kEventParamMouseChord	typeUInt32
	kEventParamMouseDelta	typeHIPoint
	kEventParamWindowRef	typeWindowRef
	kEventParamWindowMouseLocation	typeHIPoint
	kEventParamWindowPartCode	typeWindowPartCode
	kEventParamTabletEventType	typeUInt32
	kEventParamTabletPointRec	typeTabletPointRec
	kEventParamTabletProximityRec	typeTabletProximityRec
kEventMouseEntered	kEventParamMouseTrackingRef	typeMouseTrackingRef
	kEventParamMouseLocation	typeQDPoint
	kEventParamKeyModifiers	typeUInt32
	kEventParamWindowRef	typeWindowRef
	kEventParamWindowMouseLocation	typeHIPoint
kEventMouseExited	kEventParamMouseTrackingRef	typeMouseTrackingRef
	kEventParamMouseLocation	typeQDPoint
	kEventParamKeyModifiers	typeUInt32
	kEventParamWindowRef	typeWindowRef
	kEventParamWindowMouseLocation	typeHIPoint
kEventMouse-WheelMoved	kEventParamMouseLocation	typeHIPoint
	kEventParamKeyModifiers	typeUInt32

	kEventParamWindowRef	typeWindowRef
	kEventParamWindowMouseLocation	typeHIPoint
	kEventParamWindowPartCode	typeWindowPartCode
	kEventParamMouseWheelAxis	typeMouseWheelAxis
	kEventParamMouseWheelDelta	typeSInt32

Mouse Button Constants

Define mouse button constants.

```
typedef UInt16 EventMouseButton;
enum {
    kEventMouseButtonPrimary = 1,
    kEventMouseButtonSecondary = 2,
    kEventMouseButtonTertiary = 3
};
```

Constants

`kEventMouseButtonPrimary`

The primary mouse button (default for one-button mice, typically the left button for multi-button mice).

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventMouseButtonSecondary`

The “right-click” mouse button.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventMouseButtonTertiary`

The tertiary mouse button.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

Mouse Wheel Constants

Define mouse scroll-wheel-axis constants.

```
typedef UInt16 EventMouseWheelAxis;
enum {
    kEventMouseWheelAxisX = 0,
    kEventMouseWheelAxisY = 1
};
```

Constants

`kEventMouseWheelAxisX`
The x-axis (left-right movement).

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventMouseWheelAxisY`
The y-axis (up-down movement).

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

Mouse Tracking Region Options

Define constants used by the `CreateMouseTrackingRegion` function.

```
typedef UInt32 MouseTrackingOptions;
enum {
    kMouseTrackingOptionsLocalClip = 0,
    kMouseTrackingOptionsGlobalClip = 1,
    kMouseTrackingOptionsStandard = kMouseTrackingOptionsLocalClip
};
```

Constants

`kMouseTrackingOptionsLocalClip`
The region passed to `CreateMouseTrackingRegion` (page 253) is defined in local coordinates, and that the region is clipped to the owning window's content region.

Available in Mac OS X v10.2 and later.

Not available to 64-bit applications.

Declared in `CarbonEvents.h`.

`kMouseTrackingOptionsGlobalClip`
The region passed to `CreateMouseTrackingRegion` (page 253) is defined in global coordinates and that the region is clipped to the owning window's structure region.

Available in Mac OS X v10.2 and later.

Not available to 64-bit applications.

Declared in `CarbonEvents.h`.

`kMouseTrackingOptionsStandard`
Same as `kMouseTrackingOptionsLocalClip`.

Available in Mac OS X v10.2 and later.

Not available to 64-bit applications.

Declared in `CarbonEvents.h`.

Alternate Mouse Tracking Result Constants

Define constants for alternate mouse tracking results.

```
enum {
    kMouseTrackingMousePressed = kMouseTrackingMouseDown,
    kMouseTrackingMouseReleased = kMouseTrackingMouseUp
};
```

Constants

`kMouseTrackingMousePressed`

The user pressed any mouse button.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kMouseTrackingMouseReleased`

The user released the mouse button.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

Mouse Event Parameters

Define constants for parameters to mouse events.

```
enum {
    kEventParamMouseLocation = 'mloc',
    kEventParamWindowMouseLocation = 'wmou',
    kEventParamMouseButton = 'mbtn',
    kEventParamClickCount = 'ccnt',
    kEventParamMouseWheelAxis = 'mwax',
    kEventParamMouseWheelDelta = 'mwdl',
    kEventParamMouseDelta = 'mdta',
    kEventParamMouseChord = 'chor',
    kEventParamTabletEventType = 'tblt',
    kEventParamMouseTrackingRef = 'mtrf',
    typeMouseButton = 'mbtn',
    typeMouseWheelAxis = 'mwax',
    typeMouseTrackingRef = 'mtrf'
};
```

Constants

`kEventParamMouseLocation`

typeQDPoint

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventParamMouseButton`

typeMouseButton

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventParamClickCount`
typeUInt32
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamMouseWheelAxis`
typeMouseWheelAxis
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamMouseWheelDelta`
typeSInt32
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamMouseDelta`
typeQDPoint
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamMouseChord`
typeUInt32
Available in Mac OS X v10.1 and later.
Declared in `CarbonEvents.h`.

`typeMouseButton`
EventMouseButton
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`typeMouseWheelAxis`
EventMouseWheelAxis
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

Mouse Tracking Option Constant

Define options for the `TrackMouseLocationWithOptions` function.

```
enum {
    kTrackMouseLocationOptionDontConsumeMouseUp = (1 << 0)
};
```

Constants

`kTrackMouseLocationOptionDontConsumeMouseUp`
Leave mouse-up events in the event queue (the default is to pull them.)
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

Discussion

This constant can be passed to `TrackMouseLocationWithOptions` (page 304) in the `inOptions` parameter.

Mouse Tracking Constants

Define constants for mouse tracking.

```
typedef UInt16 MouseTrackingResult;
enum {
    kMouseTrackingMouseDown = 1,
    kMouseTrackingMouseUp = 2,
    kMouseTrackingMouseExited = 3,
    kMouseTrackingMouseEntered = 4,
    kMouseTrackingMouseDragged = 5,
    kMouseTrackingKeyModifiersChanged = 6,
    kMouseTrackingUserCancelled = 7,
    kMouseTrackingTimedOut = 8,
    kMouseTrackingMouseMoved = 9
};
```

Constants

`kMouseTrackingMouseDown`
The user pressed any mouse button.

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

`kMouseTrackingMouseUp`
The user released the mouse button.

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

`kMouseTrackingMouseExited`
The mouse exited the specified region.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kMouseTrackingMouseEntered`
The mouse entered the specified region.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kMouseTrackingMouseDragged`
The mouse moved while the mouse button was down.

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

`kMouseTrackingKeyModifiersChanged`
One or more keyboard modifiers (option, control, and so on) for the mouse changed.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kMouseTrackingMouseMoved`
Prior to Mac OS X v10.2, this constant was equivalent to `kMouseTrackingMouseDragged`. In Mac OS X v10.2 and later, `kMouseTrackingMouseMoved` indicates that the mouse moved while the mouse button was up.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

Discussion
These constants are returned by `TrackMouseLocation` (page 303) and `TrackMouseRegion` (page 305), which are designed as replacements to calls such as `StillDown` and `WaitMouseUp`. The advantage over those routines is that `TrackMouseLocation` and `TrackMouseRegion` block if the user is not moving the mouse, whereas mouse tracking loops based on `StillDown` and `WaitMouseUp` spin, chewing up valuable CPU time that could be better spent elsewhere. It is highly recommended that any tracking loops in your application stop using `StillDown` and `WaitMouseUp` and start using `TrackMouseLocation` or `TrackMouseRegion`. See the notes on those functions for more information.

Mouse Tracking Selectors

Define a constant for "sticky" mode used by the `HIMouseTrackingGetParameters` function.

```
enum {
    kMouseParamsSticky = 'stic'
};
```

Constants
`kMouseParamsSticky`
Requests the time and distance for determining "sticky" mouse tracking. When the mouse is clicked on a menu title, the toolbox enters a sticky mouse-tracking mode that varies according to the time and distance between the mouse-down event and the mouse-up event. In this mode, the menu is tracked even though the mouse has already been released.

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

Services Manager Constants

Services Manager Events

Define constants related to Services Manager events.

```
enum {
    kEventServiceCopy = 1,
    kEventServicePaste = 2,
    kEventServiceGetTypes = 3,
    kEventServicePerform = 4
};
```

Constants
`kEventServiceCopy`
The user wants to invoke a service that requires your application to provide data. Your application must update the scrap reference in the `kEventParamScrapRef` parameter to indicate the appropriate data from the current selection or user focus. See the Discussion section for additional information about this parameter for Mac OS X v10.3 and later.

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

`kEventServicePaste`
The user has invoked a service that requires your application to receive data. Your application must update the current user focus with the data provided by the `kEventParamScrapRef` parameter. See the Discussion section for additional information about this parameter for Mac OS X v10.3 and later.

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

`kEventServiceGetTypes`
Sent when the Services Manager needs to know what types of data it can cut-and-paste into the scrap. The Services Manager uses this information to update the Services menu, indicating which services are available for the current selection. This event passes two `CFMutableArray` references to you in the `kEventParamServiceCopyTypes` and `kEventParamServicePasteTypes` parameters. You should fill out these arrays with Core Foundation strings indicating which types your application can copy and paste. Note that you can use the `CreateTypeStringWithOSType` (page 255) to create a `CFStringRef` from an `OSType`.

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

`kEventServicePerform`
Sent when your application must perform a service. The `kEventParamScrapRef` parameter holds the scrap information, and the `kEventParamServiceMessageName` parameter contains a Core Foundation string indicating what service was requested. Only applications that can provide services receive this event. See the Discussion section for additional information about this parameter for Mac OS X v10.3 and later.

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

Discussion
In Mac OS X 10.3 and later, the `kEventServiceCopy`, `kEventServicePaste`, and `kEventServicePerform` events include a PasteboardRef and a ScrapRef. A handler for this event should provide its data using either Pasteboard or Scrap Manager APIs, and the corresponding pasteboard or scrap reference, depending on which is more convenient or appropriate. Data only needs to be placed on one of the pasteboard or scrap; it does not need to be placed on both. Data written to the pasteboard is also be available on the scrap, and vice versa.

Table 3-9 Parameter names and types for Service class events

Event kind	Parameter name	Parameter type
`kEventServiceCopy`	`kEventParamPasteboardRef` (Mac OS X v10.3 and later.)	`typePasteboardRef`
	`kEventParamScrapRef` (Mac OS X v10.1 and later.)	`typeScrapRef`
`kEventServicePaste`	`kEventParamPasteboardRef` (Mac OS X v10.3 and later.)	`typePasteboardRef`
	`kEventParamScrapRef` (Mac OS X v10.1 and later.)	`typeScrapRef`
`kEventService-GetTypes`	`kEventParamServiceCopyTypes`	`typeCFMutableArrayRef`

	kEventParamServicePasteTypes	typeCFMutableArrayRef
kEventServicePerform	kEventParamPasteboardRef (Mac OS X v10.3 and later.)	typePasteboardRef
	kEventParamScrapRef (Mac OS X v10.1 and later.)	typeScrapRef
	kEventParamServiceMessageName	typeCFStringRef
	kEventParamServiceUserData	typeCFStringRef

Services Manager Event Parameters

Define constants for parameters to Service Manager events.

```
enum {
    kEventParamScrapRef = 'scrp',
    kEventParamServiceCopyTypes = 'svsd',
    kEventParamServicePasteTypes = 'svpt',
    kEventParamServiceMessageName = 'svmg',
    kEventParamServiceUserData = 'svud',
    typeScrapRef = 'scrp',
    typeCFMutableArrayRef = 'cfma'
};
```

Constants

`kEventParamScrapRef`

When provided as a parameter to the `kEventServicePaste` event, the current selection should be replaced by data from this scrap. When provided as a parameter to `kEventServicePerform`, the scrap that should be used to send and receive data from the requester. When provided as a parameter to the `kEventServiceCopy` event, data from the current selection should be placed into this scrap.

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

`kEventParamServiceCopyTypes`

When provided as a parameter to the `kEventServiceGetTypes` event, add CFString references to this array to report the types that can be pasted from the current selection. These strings will be released automatically after the event is handled.

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

`kEventParamServicePasteTypes`

When provided as a parameter to the `kEventServiceGetTypes` event, add CFString references to this array to report the types that can be copied from the current selection. These strings will be released automatically after the event is handled.

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

`kEventParamServiceMessageName`
When provided as a parameter to the `kEventServicePerform` event, contains the name of the advertised service that was invoked.

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

`kEventParamServiceUserData`
When provided as a parameter to the `kEventServicePerform` event, contains extra data provided by the requestor.

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

Tablet Event Constants

Tablet Events

Define constants for events related to drawing tablets.

```
enum {
    kEventTabletPoint = 1,
    kEventTabletProximity = 2,
    kEventTabletPointer = 1
};
```

Constants

`kEventTabletPoint`
Indicates that the pen has moved on a tablet. (Mac OS X only)

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

`kEventTabletProximity`
Indicates that the pen has entered the proximity region of the tablet. (Mac OS X only)

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventTabletPointer`
Same as `kEventTabletPoint`. This deprecated constant is here for compatibility only.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

Tablet Event Parameters

Define constants for parameters to table events.

```
enum {
    kEventParamTabletPointRec = 'tbrc',
    kEventParamTabletProximityRec = 'tbpx',
    typeTabletPointRec = 'tbrc',
    typeTabletProximityRec = 'tbpx',
    kEventParamTabletPointerRec = 'tbrc',
    typeTabletPointerRec = 'tbrc'
};
```

Constants

`kEventParamTabletPointRec`
typeTabletPointRec
Available in Mac OS X v10.1 and later.
Declared in `CarbonEvents.h`.

`kEventParamTabletProximityRec`
typeTabletProximityRec
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`typeTabletPointRec`
kEventParamTabletPointRec
Available in Mac OS X v10.1 and later.
Declared in `CarbonEvents.h`.

`typeTabletProximityRec`
kEventParamTabletProximityRec
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamTabletPointerRec`
typeTabletPointerRec
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`typeTabletPointerRec`
kEventParamTabletPointerRec
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

Text Input Events

Text Input Event Constants

Define constants related to events from `kEventClassTextInput`.

```
enum {
    kEventTextInputUpdateActiveInputArea = 1,
    kEventTextInputUnicodeForKeyEvent = 2,
    kEventTextInputOffsetToPos = 3,
    kEventTextInputPosToOffset = 4,
    kEventTextInputShowHideBottomWindow = 5,
    kEventTextInputGetSelectedText = 6,
    kEventTextInputUnicodeText = 7,
    kEventTextInputFilterText = 14
};
```

Constants

`kEventTextInputUpdateActiveInputArea`

Tells the application text engine to initiate or terminate or manage the content of inline input session.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventTextInputUnicodeForKeyEvent`

Provides Unicode text resulting from a key event (in which TSM originates the event) or from a `kEventTextInputUnicodeText` event produced by an input method, such as the Character Palette class input method, or a Handwriting input method. A client need not be fully TSM-aware to process or receive this event, which has become the standard way of getting Unicode text from key events. You can also get Mac encoding characters from the raw keyboard event contained in this event. If no `UnicodeForKeyEvent` handler is installed, and no `kUnicodeNotFromInputMethod` AppleEvent handler is installed (or the application has not created a Unicode TSMDocument), the Mac encoding charCodes (if these can be converted from the Unicodes) are provided to `WaitNextEvent`. This event is generated automatically by TSM when a `kEventRawKeyDown` event is sent to the application event target. The typical keyboard event flow begins with a `kEventRawKeyDown` event posted to the event queue. This event is dequeued during `WaitNextEvent` or `RunApplicationEventLoop`, and sent to the event dispatcher target. If the key down event reaches the application target, it is handled by TSM, which generates a `kEventTextInputUnicodeForKeyEvent` event and sends it to the event dispatcher target. The event dispatcher resends the event to the user focus target, which sends it to the focused window.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventTextInputOffsetToPos`

Convert from inline session text offset to global QD Point. This event is typically produced by an input method so that it can best position a palette “near” the text being operated on by the user.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventTextInputPosToOffset`

Convert from global QD point to inline session text offset. This event is typically produced by an input method to perform proper cursor management as the cursor moves over various subranges, or clauses of text (or the boundaries between these) in the inline input session.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventTextInputShowHideBottomWindow`
Show/Hide the bottom line input window. This event is produced by Input Methods to control the Text Services Manager bottom-line input window, and is not normally handled by an application.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventTextInputGetSelectedText`
Get the selected text (or the character before or after the insertion point, based on the value of the `leadingEdge` parameter) from the application's text engine.)

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventTextInputUnicodeText`
Produced only by input methods or other text services and is delivered to the Text Services Manager by `SendTextInputEvent`. The Text Services Manager does not dispatch this event to the user focus, so application handlers should not install handlers for this event. Instead, the Text Services Manager chains this event into any active keyboard input method in order to prevent interference with existing inline input sessions. The keyboard input method can either insert the text into the inline session or confirm its session and return the `UnicodeText` event to the Text Services Manager unhandled, in which case the Text Services Manager converts the event into a `UnicodeForKey` event (converting the Unicodes to Mac character codes and synthesizing information where needed) and finally dispatch the resulting event to the user focus as usual.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`kEventTextInputFilterText`
Sent before any final-form text is sent to the user focus. Final form text includes text produced by a keyboard layout, Ink input method, Character palette or any other Text Services Manager text service, and any text being "confirmed" (or committed) from an inline input session. In the case of text confirmed from an inline input session, the Text Services Manager takes the resulting text buffer filtered by the event handler and adjusts all parameters in the `UpdateActiveInputArea` event produced by the input method. The text filtering action is thus transparent to both the application's `UpdateActiveInputArea` handler and the input method confirming the text.

Available in Mac OS X v10.4 and later.

Declared in `CarbonEvents.h`.

Discussion
The following text input events re-implement the Apple events defined in the *Text Services Manager Reference*, and provide the benefits of Carbon event targeting, dispatching and propagation to applications that have formerly handled the Text Services Manager suite of Apple events. You can install text input handlers on controls, windows, or the application event target (which is equivalent to Apple-event-based handling). In all cases, if a given text input handler is not installed, the Text Services Manager converts the event into an AppleEvent and re-dispatches it via `AESend` to the current process, making adoption as gradual as is desired.

Table 3-10 shows the parameters related to text input events.

Table 3-10 Required parameter names and types for text input event kinds

Event kind	Parameter name	Parameter type
`kEventTextInput-UpdateActiveInput-Area`	`kEventParamTextInputSendComponent-Instance`	`typeComponentInstance`

	kEventParamTextInputSendRefCon	typeLongInteger
	kEventParamTextInputSendSLRec	typeIntlWritingCode
	kEventParamTextInputSendFixLen	typeLongInteger
	kEventParamTextInputSendText	typeUnicodeText for a Unicode document; typeChar otherwise
kEventTextInput-UnicodeForKeyEvent	kEventParamTextInputSendComponent-Instance	typeComponentInstance
	kEventParamTextInputSendRefCon	typeLongInteger
	kEventParamTextInputSendSLRec	typeIntlWritingCode
	kEventParamTextInputSendText	typeUnicodeText
	kEventParamTextInputSendKeyboard Event	typeEventRef
kEventTextInput-OffsetToPos	kEventParamTextInputSendComponent Instance	typeComponentInstance
	kEventParamTextInputSendRefCon	typeLongInteger
	kEventParamTextInputSendTextOffset	typeLongInteger
	kEventParamTextInputReplyPoint	typeQDPoint
	kEventParamTextInputSendSLRec (Optional)	typeIntlWritingCode
	kEventParamTextInputSendLeadingEdge (Optional)	typeBoolean
	kEventParamTextInputSendReplySLRec (Optional)	typeIntlWritingCode
	kEventParamTextInputSendReplyFont (Optional)	typeLongInteger
	kEventParamTextInputSendReplyFMFont (Optional)	typeUInt32
	kEventParamTextInput-SendReplyPointSize (Optional)	typeFixed
	kEventParamTextInput-SendReplyLineHeight (Optional)	typeShortInteger
	kEventParamTextInput-SendReplyLineAscent (Optional)	typeShortInteger

	kEventParamTextInputSendReplyTextAngle (Optional)	typeFixed
kEventTextInput-PosToOffset	kEventParamTextInputSendComponentInstance	typeComponentInstance
	kEventParamTextInputSendRefCon	typeLongInteger
	kEventParamTextInputSendCurrentPoint	typeQDPoint
	kEventParamTextInputReplyRegionClass	typeLongInteger
	kEventParamTextInputReplyTextOffset	typeLongInteger
	kEventParamTextInputSendDraggingMode (Optional)	typeBoolean
	kEventParamTextInputReplyLeadingEdge (Optional)	typeBoolean
	kEventParamTextInputSendReplySLRec (Optional)	typeIntlWritingCode
kEventTextInputShow-HideBottomWindow	kEventParamTextInputSendComponent-Instance	typeComponentInstance
	kEventParamTextInputSendRefCon	typeLongInteger
	kEventParamTextInputSendShowHide (Optional)	typeBoolean
	kEventParamTextInputReplyShowHide (Optional)	typeBoolean
kEventTextInputGet-SelectedText	kEventParamTextInputSendComponent-Instance	typeComponentInstance
	kEventParamTextInputSendRefCon	typeLongInteger
	kEventParamTextInputSendLeadingEdge (Optional)	typeBoolean
	kEventParamTextInputSendTextService-Encoding (Optional)	TypeUInt32
	kEventParamTextInput-SendTextServiceMacEncoding (Optional)	TypeUInt32
	kEventParamTextInputReplyText (Optional)	typeUnicodeText or typeChar depending on the TSMDocument type.
	kEventParamTextInputSendReplySLRec (Optional)	typeIntlWritingCode

	kEventParamTextInputGlyphInfoArray (Optional)	TypeGlyphInfoArray
kEventTextInput-UnicodeText	kEventParamTextInputSendComponent-Instance	typeComponentInstance
	kEventParamTextInputSendSLRec	typeIntlWritingCode
	kEventParamTextInputSendText	typeUnicodeText
	kEventParamTextInputSendTextService-Encoding (Optional)	TypeUInt32
	kEventParamTextInputSendText ServiceMacEncoding (Optional)	TypeUInt32
	kEventParamTextInputGlyphInfo Array (Optional)	TypeGlyphInfoArray
kEventTextInput-FilterText	kEventParamTextInputSendRefCon	typeLongInteger
	kEventParamTextInputSendText	typeUnicodeText
	kEventParamTextInputReplyText	typeUnicodeText

Deprecated Text Input Constants

Define deprecated text input events.

```
enum {
    kEventUpdateActiveInputArea = kEventTextInputUpdateActiveInputArea,
    kEventUnicodeForKeyEvent = kEventTextInputUnicodeForKeyEvent,
    kEventOffsetToPos = kEventTextInputOffsetToPos,
    kEventPosToOffset = kEventTextInputPosToOffset,
    kEventShowHideBottomWindow = kEventTextInputShowHideBottomWindow,
    kEventGetSelectedText = kEventTextInputGetSelectedText
};
```

Constants

`kEventUpdateActiveInputArea`

Equivalent to `kEventTextInputUpdateActiveInputArea`.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventUnicodeForKeyEvent`

Equivalent to `kEventTextInputUnicodeForKeyEvent`.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventOffsetToPos`
Equivalent to `kEventTextInputOffsetToPos`.
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventPosToOffset`
Equivalent to `kEventTextInputPosToOffset`.
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventShowHideBottomWindow`
Equivalent to `kEventTextInputShowHideBottomWindow`.
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventGetSelectedText`
Equivalent to `kEventTextInputGetSelectedText`.
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

Discussion
These constants are superseded by constants described in "Text Input Event Constants" (page 403) and are included for backwards compatibility.

Text Input Event Parameters

Define constants for parameters to text input events.

```
enum {
    kEventParamTextInputSendRefCon = 'tsrc',
    kEventParamTextInputSendComponentInstance = 'tsci',
    kEventParamTextInputSendSLRec = 'tssl',
    kEventParamTextInputReplySLRec = 'trsl',
    kEventParamTextInputSendText = 'tstx',
    kEventParamTextInputReplyText = 'trtx',
    kEventParamTextInputSendUpdateRng = 'tsup',
    kEventParamTextInputSendHiliteRng = 'tshi',
    kEventParamTextInputSendClauseRng = 'tscl',
    kEventParamTextInputSendPinRng = 'tspn',
    kEventParamTextInputSendFixLen = 'tsfx',
    kEventParamTextInputSendLeadingEdge = 'tsle',
    kEventParamTextInputReplyLeadingEdge = 'trle',
    kEventParamTextInputSendTextOffset = 'tsto',
    kEventParamTextInputReplyTextOffset = 'trto',
    kEventParamTextInputReplyRegionClass = 'trrg',
    kEventParamTextInputSendCurrentPoint = 'tscp',
    kEventParamTextInputSendDraggingMode = 'tsdm',
    kEventParamTextInputReplyPoint = 'trpt',
    kEventParamTextInputReplyFont = 'trft',
    kEventParamTextInputReplyFMFont = 'trfm',
    kEventParamTextInputReplyPointSize = 'trpz',
    kEventParamTextInputReplyLineHeight = 'trlh',
    kEventParamTextInputReplyLineAscent = 'trla',
    kEventParamTextInputReplyTextAngle = 'trta',
    kEventParamTextInputSendShowHide = 'tssh',
    kEventParamTextInputReplyShowHide = 'trsh',
    kEventParamTextInputSendKeyboardEvent = 'tske',
    kEventParamTextInputSendTextServiceEncoding = 'tsse',
    kEventParamTextInputSendTextServiceMacEncoding = 'tssm',
    kEventParamTextInputGlyphInfoArray = 'glph',
    kEventParamTextInputSendGlyphInfoArray =  kEventParamTextInputGlyphInfoArray,
    kEventParamTextInputReplyGlyphInfoArray = 'rgph',
    kEventParamTextInputSendReplaceRange = 'tsrp'
};
```

Constants

`kEventParamTextInputSendRefCon`

typeLongInteger

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventParamTextInputSendComponentInstance`

typeComponentInstance

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventParamTextInputSendSLRec`

typeIntlWritingCode

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventParamTextInputReplySLRec`
typeIntlWritingCode
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamTextInputSendText`
typeUnicodeText (if TSMDocument is Unicode), otherwise typeChar
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamTextInputReplyText`
typeUnicodeText (if TSMDocument is Unicode), otherwise typeChar
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamTextInputSendUpdateRng`
typeTextRangeArray
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamTextInputSendHiliteRng`
typeTextRangeArray
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamTextInputSendClauseRng`
typeOffsetArray
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamTextInputSendPinRng`
typeTextRange
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamTextInputSendFixLen`
typeLongInteger
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamTextInputSendLeadingEdge`
typeBoolean
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamTextInputReplyLeadingEdge`
typeBoolean
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamTextInputSendTextOffset`
typeLongInteger
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamTextInputReplyTextOffset`
typeLongInteger
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamTextInputReplyRegionClass`
typeLongInteger
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamTextInputSendCurrentPoint`
typeQDPoint
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamTextInputSendDraggingMode`
typeBoolean
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamTextInputReplyPoint`
typeQDPoint
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamTextInputReplyFont`
typeLongInteger
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamTextInputReplyFMFont`
typeUInt32
Available in Mac OS X v10.1 and later.
Declared in `CarbonEvents.h`.

`kEventParamTextInputReplyPointSize`
typeFixed
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamTextInputReplyLineHeight`
typeShortInteger
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamTextInputReplyLineAscent`
typeShortInteger
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamTextInputReplyTextAngle`
typeFixed
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamTextInputSendShowHide`
typeBoolean
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamTextInputReplyShowHide`
typeBoolean
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamTextInputSendKeyboardEvent`
typeEventRef
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamTextInputSendTextServiceEncoding`
typeUInt32
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamTextInputSendTextServiceMacEncoding`
typeUInt32
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamTextInputReplyGlyphInfoArray`
typeGlyphInfoArray
Available in Mac OS X v10.3 and later.
Declared in `CarbonEvents.h`.

`kEventParamTextInputSendReplaceRange`
typeCFRange
Available in Mac OS X v10.3 and later.
Declared in `CarbonEvents.h`.

Text Service Manager Document Events

Text Service Manager Document Event Parameters

Define constants for Text Service Manager Document event parameters and types.

```
enum {
    kEventParamTSMDocAccessSendRefCon = kEventParamTSMSendRefCon,
    kEventParamTSMDocAccessSendComponentInstance =
kEventParamTSMSendComponentInstance,
    kEventParamTSMDocAccessCharacterCount = 'tdct',
    kEventParamTSMDocAccessReplyCharacterRange = 'tdrr',
    kEventParamTSMDocAccessReplyCharactersPtr = 'tdrp',
    kEventParamTSMDocAccessSendCharacterIndex = 'tdsi',
    kEventParamTSMDocAccessSendCharacterRange = 'tdsr',
    kEventParamTSMDocAccessSendCharactersPtr = 'tdsp',
    kEventParamTSMDocAccessRequestedCharacterAttributes = 'tdca',
    kEventParamTSMDocAccessReplyATSFont = 'tdaf',
    kEventParamTSMDocAccessReplyFontSize = 'tdrs',
    kEventParamTSMDocAccessEffectiveRange = 'tder',
    kEventParamTSMDocAccessReplyATSUGlyphSelector = 'tdrg',
    kEventParamTSMDocAccessLockCount = 'tdlc',
    kEventParamTSMDocAccessLineBounds = 'tdlb',
    typeATSFontRef = 'atsf',
    typeGlyphSelector = 'glfs'
};
```

Constants

`kEventParamTSMDocAccessSendRefCon`

typeLongInteger

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

`kEventParamTSMDocAccessSendComponentInstance`

typeComponentInstance

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

`kEventParamTSMDocAccessCharacterCount`

typeCFIndex

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

`kEventParamTSMDocAccessReplyCharacterRange`

typeCFRange

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

`kEventParamTSMDocAccessReplyCharactersPtr`

typePtr

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

`kEventParamTSMDocAccessSendCharacterIndex`

typeCFIndex

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

`kEventParamTSMDocAccessSendCharactersPtr`
typePtr
Available in Mac OS X v10.3 and later.
Declared in `CarbonEvents.h`.

`kEventParamTSMDocAccessRequestedCharacterAttributes`
typeUInt32
Available in Mac OS X v10.3 and later.
Declared in `CarbonEvents.h`.

`kEventParamTSMDocAccessReplyATSFont`
typeATSFontRef
Available in Mac OS X v10.3 and later.
Declared in `CarbonEvents.h`.

`kEventParamTSMDocAccessReplyFontSize`
typeFloat
Available in Mac OS X v10.3 and later.
Declared in `CarbonEvents.h`.

`kEventParamTSMDocAccessEffectiveRange`
typeRange
Available in Mac OS X v10.3 and later.
Declared in `CarbonEvents.h`.

`kEventParamTSMDocAccessReplyATSUGlyphSelector`
typeGlyphSelector
Available in Mac OS X v10.3 and later.
Declared in `CarbonEvents.h`.

`kEventParamTSMDocAccessLockCount`
typeCFIndex
Available in Mac OS X v10.3 and later.
Declared in `CarbonEvents.h`.

`kEventParamTSMDocAccessLineBounds`
typeCFMutableArrayRef
Available in Mac OS X v10.4 and later.
Declared in `CarbonEvents.h`.

`typeATSFontRef`
ATSFontRef
Available in Mac OS X v10.3 and later.
Declared in `CarbonEvents.h`.

`typeGlyphSelector`
ATSUGlyphSelector
Available in Mac OS X v10.3 and later.
Declared in `CarbonEvents.h`.

Timer Constants

Idle Timer Event Constants

Define constants used for timer events.

```
enum {
    kEventLoopIdleTimerStarted = 1,
    kEventLoopIdleTimerIdling = 2,
    kEventLoopIdleTimerStopped = 3
};
```

Constants

`kEventLoopIdleTimerStarted`

The idle period has just begun (and this is the first time your callback is being called for this idle period).

Available in Mac OS X v10.2 and later.

Declared in `CarbonEventsCore.h`.

`kEventLoopIdleTimerIdling`

The idle period is continuing.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEventsCore.h`.

`kEventLoopIdleTimerStopped`

The idle period has just stopped (a user event occurred). Your callback should do any necessary cleanup of the idle process now that a user event has occurred.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEventsCore.h`.

Discussion

These constants are passed to your idle timer callback function. For more information, see the `InstallEventLoopIdleTimer` (page 275) function.

Toolbar Events

Toolbar Event Parameters

Define constants for parameters to toolbar events.

```
enum {
    kEventParamToolbar = 'tbar',
    kEventParamToolbarItem = 'tbit',
    kEventParamToolbarItemIdentifier = 'tbii',
    kEventParamToolbarItemConfigData = 'tbid',
    typeHIToolbarRef = 'tbar',
    typeHIToolbarItemRef = 'tbit'
};
```

Constants

`kEventParamToolbar`
typeHIToolbarRef
Available in Mac OS X v10.2 and later.
Declared in `HIToolbar.h`.

`kEventParamToolbarItem`
typeHIToolbarItemRef
Available in Mac OS X v10.2 and later.
Declared in `HIToolbar.h`.

`kEventParamToolbarItemIdentifier`
typeHIToolbarRef
Available in Mac OS X v10.2 and later.
Declared in `HIToolbar.h`.

`kEventParamToolbarItemConfigData`
typeCFStringRef
Available in Mac OS X v10.2 and later.
Declared in `HIToolbar.h`.

Discussion

For details about toolbar events and event parameters, see *HIToolbar Reference*in the User Experience section of the Carbon documentation.

Volume Events

Volume Event Constants

Define constants related to events from `kEventClassVolume`.

```
enum {
    kEventVolumeMounted = 1,
    kEventVolumeUnmounted = 2
};
```

Constants

`kEventVolumeMounted`
New volume (hard drive or removable media) mounted.
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventVolumeUnmounted`
Volume has been ejected or unmounted.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

Volume Reference Constant

Define the type of a volume reference.

```
enum {
    typeFSVolumeRefNum = 'voln'
};
```

Constants

`typeFSVolumeRefNum`
An `FSVolumeRefNum` identifying the volume that was mounted or unmounted.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

Window Events

Window Action Event Constants

Define constants related to events from `kEventClassWindow`.

```
enum {
    kEventWindowCollapse = 66,
    kEventWindowCollapseAll = 68,
    kEventWindowExpand = 69,
    kEventWindowExpandAll = 71,
    kEventWindowClose = 72,
    kEventWindowCloseAll = 74,
    kEventWindowZoom = 75,
    kEventWindowZoomAll = 77,
    kEventWindowContextualMenuSelect = 78,
    kEventWindowPathSelect = 79,
    kEventWindowGetIdealSize = 80,
    kEventWindowGetMinimumSize = 81,
    kEventWindowGetMaximumSize = 82,
    kEventWindowConstrain = 83,
    kEventWindowHandleContentClick = 85,
    kEventWindowTransitionStarted = 88,
    kEventWindowTransitionCompleted = 89,
    kEventWindowGetDockTileMenu = 90,
    kEventWindowGetDockTileMenu = 90,
    kEventWindowProxyBeginDrag = 128,
    kEventWindowProxyEndDrag = 129,
    kEventWindowToolbarSwitchMode = 150
};
```

Constants

`kEventWindowCollapse`

If the window is not collapsed, this event is sent by the standard window handler after it has received `kEventWindowClickCollapseRgn` and received `true` from a call to `TrackBox`. The default behavior is to call `CollapseWindow` and then send `kEventWindowCollapsed` if no error is received from `CollapseWindow`.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowCollapseAll`

Sent by the standard window handler (when the option key is down) after it has received `kEventWindowClickCollapseRgn` and then received true from a call to `TrackBox`. The default response is to send each window of the same class as the clicked window a `kEventWindowCollapse` event.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowExpand`

If the window is collapsed, this event is sent by the standard window handler after it has received `kEventWindowClickCollapseRgn` and received true from a call to `TrackBox`. The default response is to call `CollapseWindow`, then send `kEventWindowExpanded`. Note that you will not receive this event before a window is expanded from the dock, since minimized windows in the dock don't uses collapse boxes to unminimize.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowExpandAll`
Sent by the standard window handler (when the option key is down) after it has received `kEventWindowClickCollapseRgn` and then received true from a call to `TrackBox`. The default response is to send each window of the same class as the clicked window a `kEventWindowExpand` event.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowClose`
Sent by the standard window handler after it has received `kEventWindowClickCloseRgn` and successfully called `TrackBox`. Your application might intercept this event to check if the document is dirty, and display a Save/Don't Save/Cancel alert.

The default response is to call the Window Manager function `DisposeWindow`.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowCloseAll`
Sent by the standard window handler (when the option key is down) after it has received `kEventWindowClickCloseRgn` and received true from a call to `TrackGoAway`. The standard window handler's response is to send each window with the same class as the clicked window a `kEventWindowClose` event.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowZoom`
Sent by the standard window handler upon receiving `kEventWindowClickZoomRgn` and then receiving true from a call to `TrackBox`. The default behavior is to zoom the window using `ZoomWindowIdeal` then, if successful, send a `kEventWindowZoomed` event.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowZoomAll`
Sent by the standard window handler (when the option key is down) after it has received `kEventObjectClickZoomRgn` and received true from a call to `TrackBox`. The standard window handler's response is to send each window with the same class as the clicked window a `kEventObjectZoom` event and then to reposition all zoomed windows using the `kWindowCascadeOnParentWindowScreen` positioning method. For more details, see the *Window Manager Reference* for more details.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowContextualMenuSelect`
Sent when either the right mouse button is pressed, or the control key is held down and the left mouse button is pressed, or the left mouse button is held down for more than 1/4th of a second (and nothing else is handling the generated mouse tracking events). The standard window handler ignores this event. Note that this event supports `kEventParamMouseLocation` and other parameters associated with the `kEventMouseDown` event.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowPathSelect`

Sent when the Window Manager function `IsWindowPathSelectClick` would return true. The standard window handler sends this event while handling `kEventWindowClickDragRgn` if the click occurs in the proxy icon. Set the menu reference parameter (`kEventParamMenuRef`) in the event if you wish to customize the menu passed to the Window Manager function `WindowPathSelect`.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowGetIdealSize`

Sent by the standard window handler to determine the standard state for zooming. The standard window handler ignores this event.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowGetMinimumSize`

Sent by the standard window handler to determine the minimum size of the window (used during window resizing).

In Mac OS X v10.2 and later, the default behavior is to call the Window Manager function `GetWindowResizeLimits` and return the size obtained in the `kEventParamDimensions` parameter. There is no default behavior before Mac OS X v10.2.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowGetMaximumSize`

Sent by the standard window handler to determine the maximum size of the window (used during window resizing). In Mac OS X v10.2 and later, this event is also sent by the Window Manager functions `ResizeWindow` and `GrowWindow` if the `sizeContraints` parameter was set to `NULL`.

In Mac OS X v10.2 and later, the default behavior is to call the Window Manager function `GetWindowResizeLimits` and return the size obtained in the `kEventParamDimensions` parameter. There is no default behavior before Mac OS X v10.2.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowConstrain`

Sent by the standard window handler to warn of a change in the available window positioning bounds on the window (for example, due to a change in screen resolution or Dock size).

In Mac OS v10.0 the default behavior is to call the Window Manager function `ConstrainWindowToScreen` on the window with the `kWindowConstrainMoveRegardlessOfFit` attribute set and a window region code of `kWindowDragRgn`. The window is constrained to the bounds returned by the Window Manager function `GetAvailableWindowPositioningBounds` for that display device.

In Mac OS X v10.1 and later the default behavior is to call `ConstrainWindowToScreen` on the window with the `kWindowConstrainMoveRegardlessOfFit` and `kWindowConstrainAllowPartial` attributes set, and a window region code of `kWindowDragRgn`. Instead of accepting the normal device bounds, you can also modify the `kEventParamAvailableBounds` for this event, and the default handler constrains the window to those bounds.

In Mac OS X v10.2 and later, you can set the following optional parameters:

- `kEventParamAttributes`: You can set the constraint attributes to pass to `ConstrainWindowToScreen` by specifying them in this parameter.
- `kEventParamWindowRegionCode`: If you set this parameter (which must be of type `WindowRegionCode`), the standard window handler passes this value to `ConstrainWindowToScreen` instead of `kWindowDragRgn`.

In addition, the following optional parameters may exist in Mac OS X v10.2 and later:

- `kEventParamRgnHandle`: Contains the gray region before a configuration change in the available graphics devices (screens). This parameter exists only if the constrain event occurred because the user changed the screen configuration. You can call the Window Manager function `GetGrayRgn` to obtain the current gray region.
- `kEventParamCurrentDockRect`: Holds the current bounds of the dock. This parameter and `kEventParamPreviousDockRect` exist only if the constrain event resulted from a change in the Dock size or position.
- `kEventParamPreviousDockRect`: Holds the previous bounds of the dock.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowHandleContentClick`

Sent by the standard window handler in response to `kEventWindowClickContentRgn` when a mouse click is in the content region but is not a contextual menu invocation or a click on a control. Note that this event supports `kEventParamMouseLocation` and other parameters associated with the `kEventMouseDown` event.

The standard handler ignores this event.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CarbonEvents.h`.

`kEventWindowTransitionStarted`

Sent to all handlers registered for it. It is sent by the `TransitionWindow`, `TransitionWindowAndParent`, and `TransitionWindowWithOptions` APIs just before the first frame of the transition animation.

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

`kEventWindowTransitionCompleted`
Sent to all handlers registered for it. It is sent by the `TransitionWindow`, `TransitionWindowAndParent`, and `TransitionWindowWithOptions` APIs just after the last frame of the transition animation.

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

`kEventWindowGetDockTileMenu`
Sent when a dock tile wants to display a menu. The sender of this event releases the menu after the Dock has displayed it, so if you want to keep the menu, you must call `RetainMenu` on it before returning from the event handler.

If you do not handle this event, the default behavior is to call the Window Manager function `GetWindowDockTileMenu` and return the menu obtained in the `kEventParamMenuRef` parameter. If no menu is specified, the default handler returns `eventNotHandledErr`.

Note that in most cases it is simpler to call the `SetWindowDockTileMenu` function directly rather than register for this event.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`kEventWindowProxyBeginDrag`
Sent before a proxy icon drag; you can attach data to the `DragRef` in the event. The standard handler ignores this event.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowProxyEndDrag`
Sent after the proxy icon drag is complete, whether successful or not. The standard handler ignores this event.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowToolbarSwitchMode`
The toolbar button (that is, the oblong button used to show and hide the toolbar) was successfully clicked. The standard window handler sends this event when receiving a `true` return value from `TrackBox` during the handling of the `kEventWindowClickToobarButtonRgn` event. Note, however, that you do not have to have the standard window handler installed to receive this event; any window that has a toolbar receives this event when its toolbar button is successfully clicked. Note that if you handle this event, your application is responsible for keeping track of the toolbar's mode (visible or hidden).

The default response is to toggle the toolbar (that is, show it if it is hidden, and vice-versa) when the toolbar button is clicked. If the option key is held down during the click, all toolbars in the windows of the current process are toggled. If the command key is down during the click, the toolbar mode is cycled between icons and text, icons alone, and text alone. If both the command and option keys are held during the click, the system displays the toolbar configuration sheet.

Available in Mac OS X v10.1 and later.

Declared in `CarbonEvents.h`.

Discussion
These events indicate that certain changes have been made to a window. These events have greater semantic meaning than the low-level window click events and are usually preferred for overriding.

Table 3-11 shows the parameters related to window action events.

Table 3-11 Parameter names and types for window action event kinds

Event kind	Parameter name	Parameter type
kEventWindowCollapse	kEventParamDirectObject	typeWindowRef
kEventWindowCollapsed	kEventParamDirectObject	typeWindowRef
kEventWindowCollapseAll	kEventParamDirectObject	typeWindowRef
kEventWindowExpand	kEventParamDirectObject	typeWindowRef
kEventWindowExpanded	kEventParamDirectObject	typeWindowRef
kEventWindowExpandAll	kEventParamDirectObject	typeWindowRef
kEventWindowClose	kEventParamDirectObject	typeWindowRef
kEventWindowClosed	kEventParamDirectObject	typeWindowRef
kEventWindowCloseAll	kEventParamDirectObject	typeWindowRef
kEventWindowZoom	kEventParamDirectObject	typeWindowRef
kEventWindowZoomed	kEventParamDirectObject	typeWindowRef
kEventWindowZoomAll	kEventParamDirectObject	typeWindowRef
kEventWindow-ContextualMenuSelect	kEventParamDirectObject	typeWindowRef
	Other parameters from kEventMouseDown	
kEventWindowPathSelect	kEventParamDirectObject	typeWindowRef
	kEventParamMenuRef	typeMenuRef
kEventWindowGetIdealSize	kEventParamDirectObject	typeWindowRef
	kEventParamDimensions	typeQDPoint
kEventWindowGetMinimumSize	kEventParamDirectObject	typeWindowRef
	kEventParamDimensions	typeQDPoint
kEventWindowGetMaximumSize	kEventParamDirectObject	typeWindowRef
	kEventParamDimensions	typeQDPoint
kEventWindowConstrain	kEventParamDirectObject	typeWindowRef
	kEventParamAvailableBounds	typeQDRectangle
	kEventParamAttributes	typeUInt32
	kEventParamWindowRegionCode	typeQDRgnHandle

	kEventParamPreviousDockRect	typeHIRect
	kEventParamCurrentDockRect	typeHIRect

	Other parameters from kEventMouseDown	
kEventWindowProxyBeginDrag	kEventParamDirectObject	typeWindowRef
kEventWindowProxyEndDrag	kEventParamDirectObject	typeWindowRef
kEventWindowToolbarSwitchMode	kEventParamDirectObject	typeWindowRef

Window Activation Event Constants

Define constants related to events from kEventClassWindow that specify whether a window is activated or deactivated.

```
enum {
    kEventWindowActivated = 5,
    kEventWindowDeactivated = 6,
    kEventWindowHandleActivate = 91,
    kEventWindowHandleDeactivate = 92
    kEventWindowGetClickActivation = 7,
    kEventWindowGetClickModality = 8
};
```

Constants

kEventWindowActivated

The window is active now. Sent to any window that is activated, regardless of whether the window has the standard window handler installed.

In Mac OS X v10.3 and later, the standard window handler responds to this event by sending a kEventWindowHandleActivate event to the window. On earlier releases of Mac OS X and CarbonLib, the standard window handler calls ActivateControl on the window's root control.

Note that this event is sent directly to the window target. If no handler takes the event (that is, they all return eventNotHandledErr), then the Window Manager posts this event to the event queue. Doing so allows the Carbon Event Manager to convert the event into an old-style event record (EventRecord), to be returned from WaitNextEvent.

Available in Mac OS X v10.0 and later.

Declared in CarbonEvents.h.

`kEventWindowDeactivated`

The window is inactive now. Sent to any window that is deactivated, regardless of whether the window has the standard window handler installed.

In Mac OS X v10.3 and later, the standard window handler responds to this event by sending a `kEventWindowHandleDeactivate` event to the window. On earlier releases of Mac OS X and CarbonLib, the standard window handler calls `DeactivateControl` on the window's root control.

Note that this event is sent directly to the window target. If no handler takes the event (that is, they all return `eventNotHandledErr`), then the Window Manager posts this event to the event queue. Doing so allows the Carbon Event Manager to convert the event into an old-style event record (`EventRecord`), to be returned from `WaitNextEvent`.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowHandleActivate`

The window has received a `kEventWindowActivated` event, and its contents should become active. This event is generated by the standard window handler in response to a `kEventWindowActivated` event. You can handle this event by activating the window's content appropriately. The standard window handler responds to this event by calling `ActivateControl` on the window's root control.

Available in Mac OS X v10.4 and later.

Declared in `CarbonEvents.h`.

`kEventWindowHandleDeactivate`

The window has received a `kEventWindowDeactivated` event, and its contents should become inactive. This event is generated by the standard window handler in response to a `kEventWindowDeactivated` event. You can handle this event by deactivating the window's content appropriately. The standard window handler responds to this event by calling `DeactivateControl` on the window's root control.

Available in Mac OS X v10.4 and later.

Declared in `CarbonEvents.h`.

`kEventWindowGetClickActivation`

Sent when a click occurs in a background window that has the standard window handler installed.

The default behavior is to bring the window forward and absorb the click (that is, the mouse click is not passed on to the window). In addition, the appropriate click activation part code is returned in the `kEventParamClickActivationResult` parameter. You can use this event to override this behavior and implement click-through.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowGetClickModality`

Sent to a window by the event dispatcher target before dispatching a mouse-down or mouse-up event to the clicked window. A handler for this event may examine application state to determine whether this click should be allowed. This event may also be sent in circumstances other than a mouse event:

- In `SelectWindow`
- When handling the cmd-~ key sequence
- When restoring a collapsed window from the Dock
- When handling the `kHICommandSelectWindow` command
- When activating a clicked window during application activation,

In each case, the result of this event is used to determine whether z-ordering, activation, and highlighting of the window should be allowed.

This event contains an optional EventRef parameter that is the original mouse event. If the parameter is not present, the handler should generally assume that the click was a single click.

A default handler for this event is installed on the application target. The default handler determines whether this is a modal click by examining the modality of the visible, uncollapsed windows in front of the clicked window, the location of the click, and the keyboard modifiers. A custom handler may, of course, entirely ignore window z-order or modality, and determine modality in any way it deems necessary.

Available in Mac OS X v10.4 and later.

Declared in `CarbonEvents.h`.

Discussion
Events related to activating and deactivating a window.

Table 3-12 shows the parameters related to window activation events.

Table 3-12 Parameter names and types for window activation event kinds

Event kind	Parameter name	Parameter type
`kEventWindow-Activated`	`kEventParamDirectObject`	`typeWindowRef`
`kEventWindow-Deactivated`	`kEventParamDirectObject`	`typeWindowRef`
`kEventWindowHandle-Activate`	`kEventParamDirectObject`	`typeWindowRef`
`kEventWindowHandle-Deactivate`	`kEventParamDirectObject`	`typeWindowRef`
`kEventWindowGetClick-Activation`	`kEventParamDirectObject`	`typeWindowRef`
	`kEventParamMouseLocation`	`typeQDPoint`
	`kEventParamKeyModifiers`	`typeUInt32`
	`kEventParamWindowDefPart`	`typeWindowDefPartCode`

	kEventParamControlRef	typeControlRef
	kEventParamClickActivation	typeClickActivation-Result
kEventWindowGet-ClickModality	kEventParamDirectObject	typeWindowRef
	kEventParamWindowPartCode	typeWindowPartCode
	kEventParamKeyModifiers	typeUInt32
	kEventParamEventRef (Optional)	typeEventRef
	kEventParamModalClickResult	typeModalClickResult
	kEventParamModalWindow (Required only if kEventParamModalClickResult is kHIModalClickIsModal.)	typeWindowRef
	kEventParamWindowModality (Required only if kEventParamModalClickResult is kHIModalClickIsModal.)	typeWindowModality

Window Click Event Constants

Define constants related to events from `kEventClassWindow` occurring in the standard window controls or regions (close, resize, drag, and so on).

```
enum {
    kEventWindowClickDragRgn = 32,
    kEventWindowClickResizeRgn = 33,
    kEventWindowClickCollapseRgn = 34,
    kEventWindowClickCloseRgn = 35,
    kEventWindowClickZoomRgn = 36,
    kEventWindowClickContentRgn = 37,
    kEventWindowClickProxyIconRgn = 38,
    kEventWindowClickToolbarButtonRgn = 41,
    kEventWindowClickStructureRgn = 42
};
```

Constants

`kEventWindowClickDragRgn`

Sent when the mouse is down in the drag region. The standard window handler calls `DragWindow`.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CarbonEvents.h`.

`kEventWindowClickResizeRgn`
Sent when the mouse is down in the resize area. The standard window handler calls `ResizeWindow`.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CarbonEvents.h`.

`kEventWindowClickCollapseRgn`
Sent when the mouse is down in the collapse widget. The default behavior is to call `CollapseWindow`, and then generate `kEventWindowExpand` or `kEventWindowCollapse` (whichever is the opposite of the window's original collapse state).

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CarbonEvents.h`.

`kEventWindowClickCloseRgn`
Sent when the mouse is down in the close widget. The standard window handler calls `TrackGoAway`, and then generates `kEventWindowClose`.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CarbonEvents.h`.

`kEventWindowClickZoomRgn`
Sent when the mouse is down in the zoom widget. The standard window handler calls `TrackBox`, and then generates `kEventWindowZoom`.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CarbonEvents.h`.

`kEventWindowClickContentRgn`
Sent when the mouse is down in the content region. The standard window handler checks for contextual menu clicks and clicks on controls, and sends `kEventWindowContextualMenuSelect`, `kEventControlClick`, and `kEventWindowHandleContentClick` events as appropriate.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CarbonEvents.h`.

`kEventWindowClickProxyIconRgn`
Sent when the mouse is down in the proxy icon. The standard window handler handles proxy icon dragging, and generates proxy icon events.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CarbonEvents.h`.

`kEventWindowClickToolbarButtonRgn`
Sent when the mouse is down in the toolbar button. The default behavior is to call `TrackBox` and then generate a `kEventWindowToolbarSwitchMode` event.

Available in Mac OS X v10.1 and later.

Not available to 64-bit applications.

Declared in `CarbonEvents.h`.

Discussion
Low-level events which generate higher-level "action" events described in "Window Action Event Constants" (page 418). These events are generated only for windows with the standard window handler installed. Most clients should allow the standard window handler to implement these events.

Window State Event Constants

Define constants related to events from `kEventClassWindow` that notify of a change in the window's state.

```
enum {
    kEventWindowShowing = 22,
    kEventWindowHiding = 23,
    kEventWindowShown = 24,
    kEventWindowHidden = 25,
    kEventWindowCollapsing = 86,
    kEventWindowCollapsed = 67,
    kEventWindowExpanding = 87,
    kEventWindowExpanded = 70,
    kEventWindowZoomed = 76,
    kEventWindowBoundsChanging = 26,
    kEventWindowBoundsChanged = 27,
    kEventWindowResizeStarted = 28,
    kEventWindowResizeCompleted = 29,
    kEventWindowDragStarted = 30,
    kEventWindowDragCompleted = 31,
    kEventWindowClosed = 73
};
```

Constants

`kEventWindowShowing`

A window is being shown. This is sent inside `ShowHide`. This event is propagated to all handlers that registered for the event in the event target's handler chain, regardless of return value.

The standard window handler ignores this event.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowHiding`

A window is being hidden. This is sent inside `ShowHide`. This event is propagated to all handlers that registered for the event in the event target's handler chain, regardless of return value.

The standard window handler ignores this event.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowShown`

The window has been shown. This event is propagated to all handlers that registered for the event in the event target's handler chain, regardless of return value.

The standard window handler ignores this event.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowHidden`
The window has been hidden. This event is propagated to all handlers that registered for the event in the event target's handler chain, regardless of return value.

The standard window handler ignores this event.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowCollapsing`
The window is collapsing. This event is propagated to all handlers that registered for the event in the event target's handler chain, regardless of return value.

The standard window handler ignores this event.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`kEventWindowCollapsed`
The object has successfully collapsed. This event is propagated to all handlers that registered for the event in the event target's handler chain, regardless of return value.

The standard window handler ignores this event.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowExpanding`
The window is expanding. This event is propagated to all handlers that registered for the event in the event target's handler chain, regardless of return value.

The standard window handler ignores this event.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`kEventWindowExpanded`
The window has successfully expanded. This event is propagated to all handlers that registered for the event in the event target's handler chain, regardless of return value.

The standard window handler ignores this event.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowZoomed`
The window has been successfully zoomed. This event is propagated to all handlers that registered for the event in the event target's handler chain, regardless of return value.

In CarbonLib 1.1 through 1.4 and Mac OS X prior to v10.2, this event is sent only by the standard window handler after handling `kEventWindowZoom`. In CarbonLib 1.5 and later and Mac OS X v10.2 and later, this event is sent by the Window Manager functions `ZoomWindow` and `ZoomWindowIdeal`.

The standard window handler ignores this event.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowBoundsChanging`

Sent during `DragWindow` or `ResizeWindow`, before the window is actually moved or resized. You can alter the current bounds in the event (the `kEventParamCurrentBounds` parameter) to change the eventual size and location of the window. Do not call the Window Manager functions `SizeWindow` or `SetWindowBounds` from inside a handler for this event.

In Mac OS X v10.1 and later, this event is sent before all changes to a window's bounds, whether initiated by a user or by a Window Manager call. If the event was sent in response to a user action, the `kWindowBoundsChangeUserDrag` or `kWindowBoundsChangeUserResize` attribute will be set in the `kEventParamAttributes` parameter.

The standard window handler ignores this event.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowBoundsChanged`

The window has been moved or resized (or both). Do not call the Window Manager functions `SizeWindow` or `SetWindowBounds` from inside a handler for this event. If you want to enforce certain window bounds, you should do so from a `kEventWindowBoundsChanging` event handler.

This event is propagated to all handlers that registered for the event in the event target's handler chain, regardless of return value.

In Mac OS X v10.2 and later, the standard window handler can take this event under the following conditions:

- the window uses live resizing (the `kWindowLiveResizeAttribute` attribute is set.
- the user is the one resizing the window
- an update event for the window exists in the event queue

If these conditions are met, the standard window handler removes the update event from the event queue and sends it to the event dispatcher target. Doing so simplifies redrawing window content during live resizing.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowResizeStarted`

The user has just started to resize a window. This event is propagated to all handlers that registered for the event in the event target's handler chain, regardless of return value.

The standard window handler ignores this event.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowResizeCompleted`

The user has just finished resizing a window. This event is propagated to all handlers that registered for the event in the event target's handler chain, regardless of return value.

The standard window handler ignores this event.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowDragStarted`

The user has just started to drag a window. This event is propagated to all handlers that registered for the event in the event target's handler chain, regardless of return value.

The standard window handler ignores this event.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowDragCompleted`

The user has completed a window drag. This event is propagated to all handlers that registered for the event in the event target's handler chain, regardless of return value.

The standard window handler ignores this event.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowClosed`

Dispatched by `DisposeWindow` before the window is disposed. This event is propagated to all handlers that registered for the event in the event target's handler chain, regardless of return value.

In CarbonLib 1.5 and earlier and Mac OS X prior to v10.2, if a visible window is destroyed, `kEventWindowClosed` is sent before the `kEventWindowHidden` event. In CarbonLib 1.6 and Mac OS X v10.2 and later, the `kEventWindowClosed` event is sent after `kEventWindowHidden`.

The standard window handler ignores this event.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

Discussion

Table 3-13 shows the parameters related to window state change events.

Table 3-13 Parameter names and types for window state change event kinds

Event kind	Parameter name	Parameter type
`kEventWindowBoundsChanging`	`kEventParamDirectObject`	`typeWindowRef`
	`kEventParamAttributes`	`typeUInt32`
	`kEventParamOriginalBounds`	`typeQDRectangle`
	`kEventParamPreviousBounds`	`typeQDRectangle`
	`kEventParamCurrentBounds`	`typeQDRectangle`
`kEventWindowBoundsChanged`	`kEventParamDirectObject`	`typeWindowRef`
	`kEventParamAttributes`	`typeUInt32`
	`kEventParamOriginalBounds`	`typeQDRectangle`
	`kEventParamPreviousBounds`	`typeQDRectangle`
	`kEventParamCurrentBounds`	`typeQDRectangle`
`kEventWindowShown`	`kEventParamDirectObject`	`typeWindowRef`

kEventWindowShowing	kEventParamDirectObject	typeWindowRef
kEventWindowHidden	kEventParamDirectObject	typeWindowRef
kEventWindowHiding	kEventParamDirectObject	typeWindowRef
kEventWindowResizeStarted	kEventParamDirectObject	typeWindowRef
kEventWindowResizeCompleted	kEventParamDirectObject	typeWindowRef
kEventWindowDragStarted	kEventParamDirectObject	typeWindowRef
kEventWindowDragCompleted	kEventParamDirectObject	typeWindowRef

Window Refresh Event Constants

Define constants related to window refresh events from `kEventClassWindow`.

```
enum {
    kEventWindowUpdate = 1,
    kEventWindowDrawContent = 2
};
```

Constants

`kEventWindowUpdate`

Low-level update event. Sent to any window that needs updating regardless of whether the window has the standard window handler installed. You must call the Window Manager function `BeginUpdate`, and the QuickDraw function `SetPort` before drawing your window content, then call `EndUpdate` when you are finished.

The standard window handler for this event calls `BeginUpdate` and `SetPort`, sends a `kEventWindowDrawContent` event to the window, and then calls `EndUpdate`.

Note that this event is sent directly to the window target. If no handler takes the event (that is, they all return `eventNotHandledErr`), then the Window Manager posts this event to the event queue. Doing so allows the Carbon Event Manager to convert the event into an old-style event record (`EventRecord`), to be returned from `WaitNextEvent`.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CarbonEvents.h`.

`kEventWindowDrawContent`

Higher-level update event sent only if you have the standard window handler installed. Functions exactly as `kEventWindowUpdate`, except that the Carbon Event Manager calls `Begin/EndUpdate` and `SetPort` for you. All you need to do is draw the window content.

The standard window handler calls `DrawControls` for this window.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `CarbonEvents.h`.

Discussion

Events related to drawing a window's content.

Table 3-14 shows the parameters related to window refresh events.

Table 3-14 Parameter names and types for window refresh event kinds

Event kind	Parameter name	Parameter type
`kEventWindowUpdate`	`kEventParamDirectObject`	`typeWindowRef`
`kEventWindowDrawContent`	`kEventParamDirectObject`	`typeWindowRef`

Window Cursor Change Event Constant

Define a constant related to events from `kEventClassWindow` that specify that the cursor must change.

```
enum {
    kEventWindowCursorChange = 40
};
```

Constants

`kEventWindowCursorChange`

Sent when the mouse is moving over the content region. This event is used to manage ownership of the cursor. You should only change the cursor if you receive this event; otherwise, someone else needed to adjust the cursor and handled the event (for example, a TSM Input Method when the mouse is over an inline input region).

The standard handler ignores this event.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

Discussion

Table 3-15 shows the parameters related to window cursor change events.

Table 3-15 Parameter names and types for window cursor change event kinds

Event kind	Parameter name	Parameter type
`kEventWindowCursorChange`	`kEventParamDirectObject`	`typeWindowRef`
	`kEventParamMouseLocation`	`typeQDPoint`
	`kEventParamKeyModifiers`	`typeUInt32`

Window Focus Event Constants

Define constants related to events from `kEventClassWindow` that describe changes in the user focus.

```
enum {
    kEventWindowFocusAcquired = 200,
    kEventWindowFocusRelinquish = 201,
    kEventWindowFocusContent = 202,
    kEventWindowFocusToolbar = 203,
    kEventWindowFocusDrawer = 204
};
```

Constants

`kEventWindowFocusAcquired`

The user (or some other action) has caused the focus to shift to your window. In response to this, you should focus any control that might need to be focused.

The standard window handler calls the Control Manager function `SetKeyboardFocus` to highlight the first control in the window.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowFocusRelinquish`

The user has shifted the focus to another window. You should take the necessary steps to unhighlight the focus and so on.

The default behavior is to clear the current keyboard focus.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowFocusContent`

Focus should be shifted to the main content area of your window. You should set the focus to the content view of your window; if that area already has focus, then do nothing.

If the content area of the window already has focus, the standard handler does nothing. Otherwise, it calls the HIView function `HIViewAdvanceFocus` to move the focus to the first control in the content area.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`kEventWindowFocusToolbar`

Focus should be shifted to the window's toolbar. You should set the focus to the first item in the toolbar; if the toolbar already has focus, then do nothing.

If the toolbar already has focus, the default behavior is to do nothing. Otherwise, it calls the HIView function `HIViewAdvanceFocus` to move the focus to the first control in the toolbar.

If the window does not have a toolbar, this event is not handled.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`kEventWindowFocusDrawer`

Focus should be shifted to the drawer of a window. You should set the focus to the first item in the drawer. If the drawer already has focus, you should move the focus to the next or previous drawer, if any, depending on whether the modifiers parameter contains the shift key modifier. If the focus is not already contained within the drawer, the basic window handler responds to this event by calling `SetUserFocusWindow` and sending a `kEventWindowFocusContent` event to the appropriate drawer.

Available in Mac OS X v10.4 and later.

Declared in `CarbonEvents.h`.

Discussion
These events are related to focus changes between windows. They are generated by `SetUserFocusWindow` (page 1934). Because that function is called by default only by the standard window handler, these events are normally sent only to windows with the standard window handler installed.

Table 3-16 shows the parameters related to window focus events.

Table 3-16 Parameter names and types for window focus event kinds

Event kind	Parameter name	Parameter type
`kEventWindowFocusAcquire`	`kEventParamDirectObject`	`typeWindowRef`
`kEventWindowFocusRelinquish`	`kEventParamDirectObject`	`typeWindowRef`
`kEventWindowFocusContent`	`kEventParamDirectObject`	`typeWindowRef`
`kEventWindowFocusToolbar`	`kEventParamDirectObject`	`typeWindowRef`
`kEventWindowFocusDrawer`	`kEventParamDirectObject`	`typeWindowRef`
	`kEventParamKeyModifiers`	`typeUInt32`

Window Sheet Event Constants

Define constants for events from `kEventClassWindow` that describe window sheet changes.

```
enum {
    kEventWindowSheetOpening = 210,
    kEventWindowSheetOpened = 211,
    kEventWindowSheetClosing = 212,
    kEventWindowSheetClosed = 213
};
```

Constants

`kEventWindowSheetOpening`
A sheet is opening. This event is sent to the sheet, its parent window, and the application target before the sheet begins to open. An event handler for this event may return `userCanceledErr` if the sheet should not be opened. Any other return value is ignored, and the sheet is allowed to open.

Available in Mac OS X v10.4 and later.

Declared in `CarbonEvents.h`.

`kEventWindowSheetOpened`
A sheet has opened. This event is sent to the sheet, its parent window, and the application target after the sheet is fully open.

Available in Mac OS X v10.4 and later.

Declared in `CarbonEvents.h`.

`kEventWindowSheetClosing`
A sheet is closing. This event is sent to the sheet, its parent window, and the application target before the sheet begins to close. An event handler for this event may return `userCanceledErr` if the sheet should not close. Any other return value is ignored, and the sheet is allowed to close.

Available in Mac OS X v10.4 and later.

Declared in `CarbonEvents.h`.

`kEventWindowSheetClosed`
A sheet has closed. This event is sent to the sheet, its parent window, and the application target after the sheet is fully closed.

Available in Mac OS X v10.4 and later.

Declared in `CarbonEvents.h`.

Discussion
These events are related to sheet changes. Table 3-17 shows the parameters related to window sheet events.

Table 3-17 Parameter names and types for window sheet event kinds

Event kind	Parameter name	Parameter type
`kEventWindowSheetOpening`	`kEventParamDirectObject`	`typeWindowRef`
`kEventWindowSheetOpened`	`kEventParamDirectObject`	`typeWindowRef`
`kEventWindowSheetClosing`	`kEventParamDirectObject`	`typeWindowRef`
`kEventWindowSheetClosed`	`kEventParamDirectObject`	`typeWindowRef`

Window Drawer Event Constants

Define constants related to events from `kEventClassWindow` describing window drawer changes.

```
enum {
    kEventWindowDrawerOpening = 220,
    kEventWindowDrawerOpened = 221,
    kEventWindowDrawerClosing = 222,
    kEventWindowDrawerClosed = 223
};
```

Constants
`kEventWindowDrawerOpening`
Sent to the drawer and its parent window when the drawer is opening. If you don't want the drawer to open, your handler should return `userCanceledErr`.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`kEventWindowDrawerOpened`
Sent to the drawer and its parent window when the drawer has fully opened.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`kEventWindowDrawerClosing`
Sent to the drawer and its parent window when the drawer is closing. If you don't want the drawer to close, your handler should return `userCanceledErr`.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

`kEventWindowDrawerClosed`
Sent to the drawer and its parent when the drawer has fully closed.

Available in Mac OS X v10.2 and later.

Declared in `CarbonEvents.h`.

Discussion
Table 3-18 shows parameters related to window drawer events.

Table 3-18 Parameter names and types for window drawer event kinds

Event kind	Parameter name	Parameter type
`kEventWindowDrawerOpening`	`kEventParamDirectObject`	`typeWindowRef`
`kEventWindowDrawerOpened`	`kEventParamDirectObject`	`typeWindowRef`
`kEventWindowDrawerClosing`	`kEventParamDirectObject`	`typeWindowRef`
`kEventWindowDrawerClosed`	`kEventParamDirectObject`	`typeWindowRef`

Window Definition Message Constants

Define constants for events that correspond to classic WDEF messages.

```
enum {
    kEventWindowDrawFrame = 1000,
    kEventWindowDrawPart = 1001,
    kEventWindowGetRegion = 1002,
    kEventWindowHitTest = 1003,
    kEventWindowInit = 1004,
    kEventWindowDispose = 1005,
    kEventWindowDragHilite = 1006,
    kEventWindowModified = 1007,
    kEventWindowSetupProxyDragImage = 1008,
    kEventWindowStateChanged = 1009,
    kEventWindowMeasureTitle = 1010,
    kEventWindowDrawGrowBox = 1011,
    kEventWindowGetGrowImageRegion = 1012,
    kEventWindowPaint = 1013
};
```

Constants

`kEventWindowDrawFrame`

Sent by the Window Manager when it's time to draw a window's structure. This is the replacement to the old `wDraw` defProc message (though it is a special case of the 0 part code indicating to draw the entire window frame).

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowDrawPart`

Sent by the Window Manager when it's time to draw a specific part of a window's structure, such as the close box. This is typically sent during window tracking.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowGetRegion`

Sent by the Window Manager when it needs to get a specific region from a window, or when the `GetWindowRegion` function is called. The region you should modify is sent in the `kEventParamRgnHandle` parameter.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowHitTest`

Sent when the Window Manager needs to determine what part of a window would be "hit" with a given mouse location in global coordinates. If you handle this event, you should set the `kEventParamWindowDefPart` parameter to reflect the part code hit.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowInit`

Sent by the Window Manager when the window is being created. This is a hook to allow you to do any initialization you might need to do. Note that if the window definition changes, you may receive this event more than once. See the `kEventWindowDispose` event for more information.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowDispose`
Sent by the Window Manager when the window is being disposed. You should dispose of any private data structures associated with the window. Note, however, that receiving this event does not necessarily mean that the window is being destroyed. Sometimes the Window Manager may need to change the window definition (such as when `ChangeWindowAttributes` is used to change the appearance of the window). In such cases, the window receives a `kEventWindowDispose` event followed by a `kEventWindowInit` event to disconnect the old window definition and connect the new one.

If you want to know when your window is actually being destroyed, you should register for the `kEventWindowClosed` event.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowDragHilite`
Sent by the Window Manager when it is time to draw/erase any drag highlight in the window structure. This is typically sent from within the `HiliteWindowFrameForDrag` function.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowModified`
Sent by the Window Manager when it is time to redraw window structure to account for a change in the document modified state. This is typically sent from within the `SetWindowModified` function.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowSetupProxyDragImage`
Sent by the Window Manager when it is time to generate a drag image for the window proxy. This is typically sent from within the `BeginWindowProxyDrag` function.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowStateChanged`
Sent by the Window Manager when a particular window state changes. See the state-change flags in `MacWindows.h`.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowMeasureTitle`
Sent when the Window Manager needs to know how much space the window's title area takes up.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowDrawGrowBox`
This is a compatibility event used before Mac OS 8 and not useful now. When the `DrawGrowIcon` function is called, this event is sent to the window to tell it to draw the grow box. This is really needed only for windows that do not have the grow box integrated into the window frame. Scroll bar delimiter lines are also drawn.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowGetGrowImageRegion`

This is a special way for a window to override the standard resize outline for windows that do not do live resizing. As the user resizes the window, this event is sent with the current size the user has chosen expressed as a rectangle. You should calculate your window outline and modify the `kEventParamRgnHandle` parameter to reflect your desired outline.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowPaint`

Sent when it is time to draw the entire window (such as when the window is first displayed). This is a convenience event that gives you a chance to draw all the window elements at once.

If you do not handle this event, the Window Manager sends the `kEventWindowDrawFrame` event to your window and erases the content region to its background color.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

Discussion

These events, which correspond to WDEF messages, are sent to all windows, regardless of whether they have the standard window handler installed.

Table 3-19 shows the parameters related to window definition events.

Table 3-19 Parameter names and types for window definition event kinds

Event kind	Parameter name	Parameter type
`kEventWindowDrawFrame`	`kEventParamDirectObject`	`typeWindowRef`
`kEventWindowDrawPart`	`kEventParamDirectObject`	`typeWindowRef`
	`kEventParamWindowDefPart`	`typeWindowDefPartCode`
`kEventWindowGetRegion`	`kEventParamDirectObject`	`typeWindowRef`
	`kEventParamWindowRegionCode`	`typeWindowRegionCode`
	`kEventParamRgnHandle`	`typeQDRgnHandle`
`kEventWindowHitTest`	`kEventParamDirectObject`	`typeWindowRef`
	`kEventParamMouseLocation`	`typeQDPoint`
	`kEventParamWindowDefPart`	`typeWindowDefPartCode`
`kEventWindowInit`	`kEventParamDirectObject`	`typeWindowRef`
	`kEventParamWindowFeatures`	`typeUInt32`
`kEventWindowDispose`	`kEventParamDirectObject`	`typeWindowRef`
`kEventWindowDragHilite`	`kEventParamDirectObject`	`typeWindowRef`
	`kEventParamWindowDragHiliteFlag`	`typeBoolean`
`kEventWindowModified`	`kEventParamDirectObject`	`typeWindowRef`

	kEventParamWindowModifiedFlag	typeBoolean
kEventWindowSetup-ProxyDrag Image	kEventParamDirectObject	typeWindowRef
	kEventParamWindowProxyImageRgn	typeQDRgnHandle
	kEventParamWindowProxyOutlineRgn	typeQDRgnHandle
	kEventParamWindowProxyGWorlPtr	typeGWorldPtr
kEventWindowState-Changed	kEventParamDirectObject	typeWindowRef
	kEventParamWindowStateChangedFlags	typeUInt32
kEventWindowMeasure-Title	kEventParamDirectObject	typeWindowRef
	kEventParamWindowTitleFullWidth	typeSInt16
	kEventParamWindowTitleTextWidth	typeSInt16
kEventWindow-DrawGrowBox	kEventParamDirectObject	typeWindowRef
kEventWindowGetGrow-Image Region	kEventParamDirectObject	typeWindowRef
	kEventParamWindowGrowRect	typeQDRectangle
	kEventParamRgnHandle	typeQDRectangle
kEventWindowPaint	kEventParamDirectObject	typeWindowRef

Alternate Window Definition Event Constants

Define alternate names for window definition events.

```
enum {
    kEventWindowDefDrawFrame = kEventWindowDrawFrame,
    kEventWindowDefDrawPart = kEventWindowDrawPart,
    kEventWindowDefGetRegion = kEventWindowGetRegion,
    kEventWindowDefHitTest = kEventWindowHitTest,
    kEventWindowDefInit = kEventWindowInit,
    kEventWindowDefDispose = kEventWindowDispose,
    kEventWindowDefDragHilite = kEventWindowDragHilite,
    kEventWindowDefModified = kEventWindowModified,
    kEventWindowDefSetupProxyDragImage = kEventWindowSetupProxyDragImage,
    kEventWindowDefStateChanged = kEventWindowStateChanged,
    kEventWindowDefMeasureTitle = kEventWindowMeasureTitle,
    kEventWindowDefDrawGrowBox = kEventWindowDrawGrowBox,
    kEventWindowDefGetGrowImageRegion = kEventWindowGetGrowImageRegion
};
```

Constants

`kEventWindowDefDrawFrame`
Equivalent to `kEventWindowDrawFrame`.
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventWindowDefDrawPart`
Equivalent to `kEventWindowDrawPart`.
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventWindowDefGetRegion`
Equivalent to `kEventWindowGetRegion`.
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventWindowDefHitTest`
Equivalent to `kEventWindowHitTest`.
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventWindowDefInit`
Equivalent to `kEventWindowInit`.
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventWindowDefDispose`
Equivalent to `kEventWindowDispose`.
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventWindowDefDragHilite`
Equivalent to `kEventWindowDragHilite`.
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventWindowDefModified`
Equivalent to `kEventWindowModified`.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowDefSetupProxyDragImage`
Equivalent to `kEventWindowSetupProxyDragImage`.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowDefStateChanged`
Equivalent to `kEventWindowStateChanged`.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowDefMeasureTitle`
Equivalent to `kEventWindowMeasureTitle`.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowDefDrawGrowBox`
Equivalent to `kEventWindowDrawGrowBox`.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventWindowDefGetGrowImageRegion`
Equivalent to `kEventWindowGetGrowImageRegion`.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

Discussion
For clarity, you can use these event names in place of the standard window events when using them in your custom window definitions. For descriptions of these events, see "Window Definition Message Constants" (page 439).

Window Bounds Attributes

Define constants that describe how a window's bounds are changing.

```
enum {
    kWindowBoundsChangeUserDrag = (1 << 0),
    kWindowBoundsChangeUserResize = (1 << 1),
    kWindowBoundsChangeSizeChanged = (1 << 2),
    kWindowBoundsChangeOriginChanged = (1 << 3),
    kWindowBoundsChangeZoom = (1 << 4)
};
```

Constants
`kWindowBoundsChangeUserDrag`
The bounds are changing because the user is dragging the window around.

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kWindowBoundsChangeUserResize`
: The bounds are changing because the user is resizing the window.

  Available in Mac OS X v10.0 and later.

  Declared in `CarbonEvents.h`.

`kWindowBoundsChangeSizeChanged`
: The dimensions of the window (width and height) are changing.

  Available in Mac OS X v10.0 and later.

  Declared in `CarbonEvents.h`.

`kWindowBoundsChangeOriginChanged`
: The origin of the window is changing.

  Available in Mac OS X v10.0 and later.

  Declared in `CarbonEvents.h`.

`kWindowBoundsChangeZoom`
: The bounds are changing as a result of the user clicking the zoom button.

  Available in Mac OS X v10.2 and later.

  Declared in `CarbonEvents.h`.

Discussion
When the toolbox sends out a `kEventWindowBoundsChanging` or `kEventWindowBoundsChanged` event, it also sends along a parameter containing attributes of the event (`kEventParamAttributes`). You can use these attributes to determine what aspect of the window changed (origin, size, or both), and whether or not some user action is driving the change (drag, resize, or zoom).

Window Event Parameters and Types

Define constants for parameters and attributes related to window events.

```
enum {
    kEventParamWindowFeatures = 'wftr',
    kEventParamWindowDefPart = 'wdpc',
    kEventParamWindowPartCode = wpar',
    kEventParamCurrentBounds = 'crct',
    kEventParamOriginalBounds = 'orct',
    kEventParamPreviousBounds = 'prct',
    kEventParamClickActivation = 'clac',
    kEventParamWindowRegionCode = 'wshp',
    kEventParamWindowDragHiliteFlag = 'wdhf',
    kEventParamWindowModifiedFlag = 'wmff',
    kEventParamWindowProxyGWorldPtr = 'wpgw',
    kEventParamWindowProxyImageRgn = 'wpir',
    kEventParamWindowProxyOutlineRgn = 'wpor',
    kEventParamWindowStateChangedFlags = 'wscf',
    kEventParamWindowTitleFullWidth = 'wtfw',
    kEventParamWindowTitleTextWidth = 'wttw',
    kEventParamWindowGrowRect = 'grct',
    kEventParamPreviousDockRect = 'pdrc',
    kEventParamPreviousDockDevice = 'pdgd',
    kEventParamCurrentDockRect = 'cdrc',
    kEventParamCurrentDockDevice = 'cdgd',
    kEventParamWindowTransitionAction = 'wtac',
    kEventParamWindowTransitionEffect = 'wtef',
    typeWindowRegionCode = 'wshp',
    typeWindowDefPartCode = 'wdpt',
    typeClickActivationResult = 'clac',
    typeWindowTransitionAction = 'wtac',
    typeWindowTransitionEffect = 'wtef'
};
```

Constants

`kEventParamWindowFeatures`

typeUInt32

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventParamWindowDefPart`

typeWindowDefPartCode

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventParamWindowPartCode`

typeWindowPartCode

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

`kEventParamCurrentBounds`

typeQDRectangle

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`kEventParamOriginalBounds`
typeQDRectangle
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamPreviousBounds`
typeQDRectangle
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamClickActivation`
typeClickActivationResult
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamWindowRegionCode`
typeWindowRegionCode
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamWindowDragHiliteFlag`
typeBoolean
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamWindowModifiedFlag`
typeBoolean
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamWindowProxyGWorldPtr`
typeGWorldPtr
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamWindowProxyImageRgn`
typeQDRgnHandle
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamWindowProxyOutlineRgn`
typeQDRgnHandle
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamWindowStateChangedFlags`
typeUInt32
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamWindowTitleFullWidth`
typeSInt16
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamWindowTitleTextWidth`
typeSInt16
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamWindowGrowRect`
typeQDRectangle
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`kEventParamPreviousDockRect`
typeHIRect
Available in Mac OS X v10.2 and later.
Declared in `CarbonEvents.h`.

`kEventParamPreviousDockDevice`
typeGDHandle
Available in Mac OS X v10.3 and later.
Declared in `CarbonEvents.h`.

`kEventParamCurrentDockRect`
typeHIRect
Available in Mac OS X v10.2 and later.
Declared in `CarbonEvents.h`.

`kEventParamCurrentDockDevice`
typeGDHandle
Available in Mac OS X v10.3 and later.
Declared in `CarbonEvents.h`.

`kEventParamWindowTransitionAction`
typeWindowTransitionAction
Available in Mac OS X v10.3 and later.
Declared in `CarbonEvents.h`.

`kEventParamWindowTransitionEffect`
typeWindowTransitionEffect
Available in Mac OS X v10.3 and later.
Declared in `CarbonEvents.h`.

`typeWindowRegionCode`
WindowRegionCode
Available in Mac OS X v10.0 and later.
Declared in `CarbonEvents.h`.

`typeWindowDefPartCode`
WindowDefPartCode

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`typeWindowPartCode`
WindowPartCode

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

`typeClickActivationResult`
ClickActivationResult

Available in Mac OS X v10.0 and later.

Declared in `CarbonEvents.h`.

`typeWindowTransitionAction`
WindowTransitionAction

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

`typeWindowTransitionEffect`
WindowTransitionEffect

Available in Mac OS X v10.3 and later.

Declared in `CarbonEvents.h`.

Modal Window Event Parameters and Types

Define constants related to events from `kEventClassWindow` used to determine whether a mouse-down or mouse-up event is blocked by a modal window.

```
enum {
    typeModalClickResult = 'wmcr',
    typeWindowModality = 'wmod',
    kEventParamModalClickResult = typeModalClickResult,
    kEventParamModalWindow = 'mwin',
    kEventParamWindowModality = typeWindowModality
};
```

Constants

`typeModalClickResult`
HIModalClickResult

Available in Mac OS X v10.4 and later.

Declared in `CarbonEvents.h`.

`typeWindowModality`
WindowModality

Available in Mac OS X v10.4 and later.

Declared in `CarbonEvents.h`.

`kEventParamModalClickResult`
On exit, a value indicating how the click should be handled. For details, see "Modal Window Click Constants" (page 451).

Available in Mac OS X v10.4 and later.

Declared in `CarbonEvents.h`.

`kEventParamModalWindow`
On exit, the modal window that caused the click to be blocked, if any. The sender of this event uses this information to determine which window should be activated if the application is inactive. This parameter is only required if the `kEventParamModalClickResult` parameter contains `kHIModalClickIsModal`. If an event handler wants to report that a click has been blocked by modality, but cannot determine which window blocked the click, it is acceptable to either not add this parameter to the event, or to set the parameter to a `NULL` window reference.

Available in Mac OS X v10.4 and later.

Declared in `CarbonEvents.h`.

`kEventParamWindowModality`
On exit, the modality of the modal window that is in front of the clicked window, if any. This parameter is required only if the `kEventParamModalClickResult` parameter contains `kHIModalClickIsModal`.

Available in Mac OS X v10.4 and later.

Declared in `CarbonEvents.h`.

Modal Window Click Constants

Define constants that describe responses to the `kEventWindowGetModalityClick` event.

```
typedef UInt32 HIModalClickResult;
enum {
    kHIModalClickIsModal = 1 << 0,
    kHIModalClickAllowEvent = 1 << 1,
    kHIModalClickAnnounce = 1 << 2,
    kHIModalClickRaiseWindow = 1 << 3,
};
```

Constants

`kHIModalClickIsModal`
A modal window prevents the mouse event from being passed to the clicked window. If this bit is set, the `kEventParamModalWindow` and `kEventParamWindowModality` parameters should be set before the event handler returns. If this bit is clear, normal event handling occurs: the clicked window is typically z-ordered to the top of its window group, activated, becomes the user focus window, and receives the mouse event for further processing.

Available in Mac OS X v10.4 and later.

Declared in `CarbonEvents.h`.

`kHIModalClickAllowEvent`
If `kHIModalClickIsModal` is set, the `kHIModalClickAllowEvent` flag indicates whether the click event should be allowed to pass to the clicked window. If `kHIModalClickIsModal` is not set, the setting of `kHIModalClickAllowEvent` is ignored.

Available in Mac OS X v10.4 and later.

Declared in `CarbonEvents.h`.

`kHIModalClickAnnounce`
If `kHIModalClickIsModal` is set and `kHIModalClickAllowEvent` is not set, `kHIModalClickAnnounce` indicates whether the caller should announce that the click has been blocked by a modal window using the appropriate UI (typically, by calling `SysBeep`). If `kHIModalClickIsModal` is not set, or if `kHIModalClickAllowEvent` is set, the setting of `kHIModalClickAnnounce` is ignored.

Available in Mac OS X v10.4 and later.

Declared in `CarbonEvents.h`.

`kHIModalClickRaiseWindow`
If `kHIModalClickIsModal` and `kHIModalClickAllowEvent` are set, `kHIModalClickRaiseWindow` indicates whether the clicked window should be z-ordered to the top of its window group. The window is not, however, activated, nor does it become the user focus window. If `kHIModalClickIsModal` or `kHIModalClickAllowEvent` is not set, `kHIModalClickRaiseWindow` is ignored.

Available in Mac OS X v10.4 and later.

Declared in `CarbonEvents.h`.

Result Codes

The most common result codes returned by the Carbon Event Manager are listed below.

Result Code	Value	Description
`noErr`	0	No error. Available in Mac OS X v10.0 and later.
`eventAlreadyPostedErr`	-9860	Returned from `PostEventToQueue` (page 286) if the event in question is already in the queue you are posting it to (or any other queue). Available in Mac OS X v10.0 and later.
`eventTargetBusyErr`	-9861	The event target you are trying to modify is busy (for example, dispatching an event). Available in Mac OS X v10.1 and later.
`eventClassInvalidErr`	-9862	This is obsolete and will be removed. Available in Mac OS X v10.0 and later.
`eventClassIncorrectErr`	-9864	This is obsolete and will be removed. Available in Mac OS X v10.0 and later.
`eventHandlerAlreadyInstalledErr`	-9866	Returned from `InstallEventHandler` (page 274) if the handler callback you pass is already installed for a given event type you are trying to register. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
eventInternalErr	-9868	A generic error. Available in Mac OS X v10.0 and later.
eventKindIncorrectErr	-9869	This is obsolete and will be removed. Available in Mac OS X v10.0 and later.
eventParameterNotFoundErr	-9870	The piece of data you are requesting from an event is not present. Available in Mac OS X v10.0 and later.
eventNotHandledErr	-9874	This is what you should return from an event handler when your handler has received an event it doesn't currently want to (or isn't able to) handle. If you handle an event, you should return noErr from your event handler. Available in Mac OS X v10.0 and later.
eventLoopTimedOutErr	-9875	The event loop has timed out. This can be returned from calls to ReceiveNextEvent (page 289) or RunCurrentEventLoop (page 298). Available in Mac OS X v10.0 and later.
eventLoopQuitErr	-9876	The event loop was quit, probably by a call to QuitEventLoop (page 289). This can be returned from ReceiveNextEvent (page 289) or RunCurrentEventLoop (page 298). Available in Mac OS X v10.0 and later.
eventNotInQueueErr	-9877	Returned from RemoveEventFromQueue (page 294) when trying to remove an event that's not in any queue. Available in Mac OS X v10.0 and later.
eventHotKeyExistsErr	-9878	The hot key combination you chose already exists Available in Mac OS X v10.0 and later.
eventHotKeyInvalidErr	-9879	This error code is not currently used. Available in Mac OS X v10.0 and later.

Carbon Help Manager Reference

Framework: Carbon/Carbon.h

Declared in MacHelp.h

Overview

The Carbon Help Manager is an API that provides an interface for displaying short onscreen hints in help tags. You can attach identifying text to individual windows, menus, or controls. Help tags replace Balloon Help, introduced with System 7.

This document is relevant for developers creating a user interface for their Carbon application. To use this document, you should be familiar with the basics of programming with the fundamental objects of the Mac OS user interface (windows, menus, controls, and so forth)

Functions by Task

Obtaining a Reference to the Help Menu

`HMGetHelpMenu` (page 461)
Returns a reference to the Help menu.

Attaching Help Tag Content Directly to an Object

`HMSetControlHelpContent` (page 468)
Associates a help tag with a control.

`HMSetWindowHelpContent` (page 471)
Associates a help tag with a window.

`HMSetMenuItemHelpContent` (page 469)
Associates a help tag with a menu item.

`HMGetControlHelpContent` (page 460)
Returns the help tag associated with a control.

`HMGetWindowHelpContent` (page 464)
Returns the help tag associated with a window.

`HMGetMenuItemHelpContent` (page 462)
Returns the help tag associated with a menu item.

Installing and Retrieving Help Tag Callbacks

`HMInstallControlContentCallback` (page 465)
Installs a help tag callback for a control.

`HMInstallWindowContentCallback` (page 468)
Installs a help tag callback for a window.

`HMInstallMenuItemContentCallback` (page 466)
Installs a help tag callback for a menu's items.

`HMInstallMenuTitleContentCallback` (page 467)
Installs a help tag callback for a menu title.

`HMGetControlContentCallback` (page 460)
Retrieves the help tag callback associated with a control.

`HMGetWindowContentCallback` (page 464)
Retrieves the help tag callback associated with a window.

`HMGetMenuItemContentCallback` (page 462)
Retrieves the help tag callback associated with a menu's items.

`HMGetMenuTitleContentCallback` (page 463)
Retrieves the help tag callback associated with a menu's title.

Displaying and Hiding Help Tags

`HMDisplayTag` (page 459)
Displays a help tag at an application-defined location.

`HMHideTag` (page 465)
Hides the most recently displayed help tag.

Enabling and Disabling Help Tags

`HMAreHelpTagsDisplayed` (page 459)
Determines whether help tags are currently enabled.

`HMSetHelpTagsDisplayed` (page 469)
Enables or disables help tags.

Getting and Setting Help Tag Delay Time

`HMSetTagDelay` (page 470)
Sets the help tag delay time.

`HMGetTagDelay` (page 463)
Returns the current help tag delay time.

Working With Universal Procedure Pointers to Help Tag Callback Functions

`NewHMControlContentUPP` (page 475)
Creates a new universal procedure pointer (UPP) to a help tag callback for a control.

`NewHMWindowContentUPP` (page 477)
Creates a new universal procedure pointer (UPP) to a help tag callback for a window.

`NewHMMenuItemContentUPP` (page 476)
Creates a new universal procedure pointer (UPP) to a help tag callback for a menu item.

`NewHMMenuTitleContentUPP` (page 477)
Creates a new universal procedure pointer (UPP) to a help tag callback for a menu title.

`DisposeHMControlContentUPP` (page 457)
Disposes of a universal procedure pointer (UPP) to a help tag callback for a control.

`DisposeHMWindowContentUPP` (page 459)
Disposes of a universal procedure pointer (UPP) to a help tag callback for a window.

`DisposeHMMenuItemContentUPP` (page 458)
Disposes of a universal procedure pointer (UPP) to a help tag callback for a menu item.

`DisposeHMMenuTitleContentUPP` (page 458)
Disposes of a universal procedure pointer (UPP) to a help tag callback for a menu title.

`InvokeHMControlContentUPP` (page 471)
Calls your help tag callback for a control.

`InvokeHMWindowContentUPP` (page 474)
Calls your help tag callback for a window.

`InvokeHMMenuItemContentUPP` (page 472)
Calls your help tag callback for a menu item.

`InvokeHMMenuTitleContentUPP` (page 473)
Calls your help tag callback for a menu title.

Functions

DisposeHMControlContentUPP

Disposes of a universal procedure pointer (UPP) to a help tag callback for a control.

```
void DisposeHMControlContentUPP (
   HMControlContentUPP userUPP
);
```

Parameters

userUPP
The UPP to dispose of.

Discussion

To create a UPP to a help tag callback for a control, use `NewHMControlContentUPP` (page 475). For a description of the help tag callback for a control, see `HMControlContentProcPtr` (page 478).

Availability
Available in CarbonLib 1.0.2 and later.
Available in Mac OS X 10.0 and later.

Declared In
MacHelp.h

DisposeHMMenuItemContentUPP

Disposes of a universal procedure pointer (UPP) to a help tag callback for a menu item.

```
void DisposeHMMenuItemContentUPP (
   HMMenuItemContentUPP userUPP
);
```

Parameters

userUPP
The UPP to dispose of.

Discussion
To create a UPP to a help tag callback for a menu item, use NewHMMenuItemContentUPP (page 476). For a description of the help tag callback for a menu item, see HMMenuItemContentProcPtr (page 479).

Availability
Available in CarbonLib 1.0.2 and later.
Available in Mac OS X 10.0 and later.

Declared In
MacHelp.h

DisposeHMMenuTitleContentUPP

Disposes of a universal procedure pointer (UPP) to a help tag callback for a menu title.

```
void DisposeHMMenuTitleContentUPP (
   HMMenuTitleContentUPP userUPP
);
```

Parameters

userUPP
The UPP to dispose of.

Discussion
To create a UPP to a help tag callback for a menu title, use NewHMMenuTitleContentUPP (page 477). For a description of the help tag callback for a menu title, see HMMenuTitleContentProcPtr (page 480).

Availability
Available in CarbonLib 1.0.2 and later.
Available in Mac OS X 10.0 and later.

Declared In
MacHelp.h

DisposeHMWindowContentUPP

Disposes of a universal procedure pointer (UPP) to a help tag callback for a window.

```
void DisposeHMWindowContentUPP (
   HMWindowContentUPP userUPP
);
```

Parameters

userUPP

The UPP to dispose of.

Discussion

To create a UPP to a help tag callback for a window, use `NewHMWindowContentUPP` (page 477). For a description of the help tag callback for a window, see `HMWindowContentProcPtr` (page 482).

Availability

Available in CarbonLib 1.0.2 and later.

Available in Mac OS X 10.0 and later.

Declared In

`MacHelp.h`

HMAreHelpTagsDisplayed

Determines whether help tags are currently enabled.

```
Boolean HMAreHelpTagsDisplayed (
   void
);
```

Return Value

`true` if help tags are currently enabled; otherwise, `false`.

Availability

Available in CarbonLib 1.0.2 and later.

Available in Mac OS X 10.0 and later.

Not available to 64-bit applications.

Declared In

`MacHelp.h`

HMDisplayTag

Displays a help tag at an application-defined location.

```
OSStatus HMDisplayTag (
   const HMHelpContentRec *inContent
);
```

Parameters

inContent

A pointer to a help tag structure that describes the help tag you want to display.

Return Value
A result code. See "Result Codes" (page 494).

Discussion
Use the `HMDisplayTag` function to display a help tag at a location not associated with a control, window, or menu.

Availability
Available in CarbonLib 1.5 and later.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`MacHelp.h`

HMGetControlContentCallback

Retrieves the help tag callback associated with a control.

```
OSStatus HMGetControlContentCallback (
   ControlRef inControl,
   HMControlContentUPP *outContentUPP
);
```

Parameters

inControl
A reference to the control for which to retrieve the help tag callback.

outContentUPP
On return, a universal procedure pointer to the help tag callback.

Return Value
A result code. See "Result Codes" (page 494).

Discussion
To install a help tag callback for a control, use the `HMInstallControlContentCallback` (page 465) function.

Availability
Available in CarbonLib 1.0.2 and later.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`MacHelp.h`

HMGetControlHelpContent

Returns the help tag associated with a control.

```
OSStatus HMGetControlHelpContent (
   ControlRef inControl,
   HMHelpContentRec *outContent
);
```

Parameters

inControl

A reference to the control for which to retrieve the help tag.

outContent

A pointer to a help tag structure. On return, this structure describes the help tag for the control.

Return Value
A result code. See "Result Codes" (page 494).

Discussion
To attach a help tag to a control, use the `HMSetControlHelpContent` (page 468) function.

Availability
Available in CarbonLib 1.0.2 and later.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`MacHelp.h`

HMGetHelpMenu

Returns a reference to the Help menu.

```
OSStatus HMGetHelpMenu (
   MenuRef *outHelpMenu,
   MenuItemIndex *outFirstCustomItemIndex
);
```

Parameters

outHelpMenu

On return, a pointer to a menu reference to the Help menu.

outFirstCustomItemIndex

On return, a pointer to the menu item index that will be used by the first application-supplied item added to the menu. This parameter may be `NULL`.

Return Value
A result code. See "Result Codes" (page 494).

Discussion
The `HMGetHelpMenu` function returns a reference to the Help menu, to which you can add your own custom menu items.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
MacHelp.h

HMGetMenuItemContentCallback

Retrieves the help tag callback associated with a menu's items.

```
OSStatus HMGetMenuItemContentCallback (
   MenuRef inMenu,
   HMMenuItemContentUPP *outContentUPP
);
```

Parameters

inMenu
A reference to the menu for which to retrieve the menu item help tag callback.

outContentUPP
On return, a universal procedure pointer to the help tag callback.

Return Value
A result code. See "Result Codes" (page 494).

Discussion
To install a menu item help tag callback, use the `HMInstallMenuItemContentCallback` (page 466) function.

Availability
Available in CarbonLib 1.0.2 and later.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
MacHelp.h

HMGetMenuItemHelpContent

Returns the help tag associated with a menu item.

```
OSStatus HMGetMenuItemHelpContent (
   MenuRef inMenu,
   MenuItemIndex inItem,
   HMHelpContentRec *outContent
);
```

Parameters

inMenu
A reference to the menu containing the menu item for which to retrieve the help tag.

inItem
The index of the menu item.

outContent
A pointer to a help tag structure. On return, this structure describes the help tag for the menu item.

Return Value
A result code. See "Result Codes" (page 494).

Discussion
To attach a help tag to a menu item, use the `HMSetMenuItemHelpContent` (page 469) function.

Availability
Available in CarbonLib 1.0.2 and later.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`MacHelp.h`

HMGetMenuTitleContentCallback

Retrieves the help tag callback associated with a menu's title.

```
OSStatus HMGetMenuTitleContentCallback (
   MenuRef inMenu,
   HMMenuTitleContentUPP *outContentUPP
);
```

Parameters

inMenu
A reference to the menu for which to retrieve the help tag callback.

outContentUPP
On return, a universal procedure pointer to the help tag callback.

Return Value
A result code. See "Result Codes" (page 494).

Discussion
To install a menu title help tag callback, use the `HMInstallMenuTitleContentCallback` (page 467) function.

Availability
Available in CarbonLib 1.0.2 and later.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`MacHelp.h`

HMGetTagDelay

Returns the current help tag delay time.

```
OSStatus HMGetTagDelay (
   Duration *outDelay
);
```

Parameters

outDelay
On return, a pointer to the help tag delay time. A positive value represents the delay time in milliseconds; a negative value represents the delay time in microseconds.

Return Value
A result code. See "Result Codes" (page 494).

Discussion
The help tag delay time returned by the `HMGetTagDelay` function is the amount of time that the mouse must remain motionless over a control, window, menu title, or menu item before the associated help tag is displayed.

Availability
Available in CarbonLib 1.0.2 and later.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`MacHelp.h`

HMGetWindowContentCallback

Retrieves the help tag callback associated with a window.

```
OSStatus HMGetWindowContentCallback (
   WindowRef inWindow,
   HMWindowContentUPP *outContentUPP
);
```

Parameters

`inWindow`
A reference to the window for which to retrieve the help tag callback.

`outContentUPP`
On return, a universal procedure pointer to the help tag callback.

Return Value
A result code. See "Result Codes" (page 494).

Discussion
To install a help tag callback for a window, use the `HMInstallWindowContentCallback` (page 468) function.

Availability
Available in CarbonLib 1.0.2 and later.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`MacHelp.h`

HMGetWindowHelpContent

Returns the help tag associated with a window.

```
OSStatus HMGetWindowHelpContent (
   WindowRef inWindow,
   HMHelpContentRec *outContent
);
```

Parameters

inWindow

A reference to the window for which to retrieve the help tag.

outContent

A pointer to a help tag structure. On return, this structure describes the help tag for the window.

Return Value
A result code. See "Result Codes" (page 494).

Discussion
To attach a help tag to a window, use the `HMSetWindowHelpContent` (page 471) function.

Availability
Available in CarbonLib 1.0.2 and later.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`MacHelp.h`

HMHideTag

Hides the most recently displayed help tag.

```
OSStatus HMHideTag (
   void
);
```

Return Value
A result code. See "Result Codes" (page 494).

Discussion
The Carbon Help Manager automatically removes help tags from the screen when user input occurs. To hide a tag before the Carbon Help Manager removes it, use the `HMHideTag` function. `HMHideTag` removes the most recently displayed help tag from the screen. If no help tag is currently visible, `HMHideTag` does nothing.

Availability
Available in CarbonLib 1.5 and later.
Available in Mac OS X 10.1 and later.
Not available to 64-bit applications.

Declared In
`MacHelp.h`

HMInstallControlContentCallback

Installs a help tag callback for a control.

```
OSStatus HMInstallControlContentCallback (
   ControlRef inControl,
   HMControlContentUPP inContentUPP
);
```

Parameters

inControl

A reference to the control for which to install the help tag callback.

inContentUPP

A universal procedure pointer to the help tag callback.

Return Value

A result code. See "Result Codes" (page 494).

Discussion

`HMInstallControlContentCallback` associates your help tag callback with the control specified in the `inControl` parameter. Thereafter, whenever the user hovers the mouse over this control, the Carbon Help Manager calls your callback to determine the content to display in the help tag for the control. For a description of the help tag callback for a control, see `HMControlContentProcPtr` (page 478).

Availability

Available in CarbonLib 1.0.2 and later.

Available in Mac OS X 10.0 and later.

Not available to 64-bit applications.

Declared In

`MacHelp.h`

HMInstallMenuItemContentCallback

Installs a help tag callback for a menu's items.

```
OSStatus HMInstallMenuItemContentCallback (
   MenuRef inMenu,
   HMMenuItemContentUPP inContentUPP
);
```

Parameters

inMenu

A reference to the menu for which to install the help tag callback.

inContentUPP

A universal procedure pointer to the help tag callback.

Return Value

A result code. See "Result Codes" (page 494).

Discussion

`HMInstallMenuItemContentCallback` associates your help tag callback with the menu specified in the `inMenu` parameter. Thereafter, whenever the user hovers the mouse over a menu item in this menu, the Carbon Help Manager calls your callback to determine the content to display in the help tag for the menu item. For a description of the help tag callback for a menu item, see `HMMenuItemContentProcPtr` (page 479).

Special Considerations

Although the `HMInstallMenuItemContentCallback` function is available in CarbonLib, CarbonLib currently does not support menu item help tags. Any help tag content you supply for a menu item using a help tag callback in CarbonLib is not displayed.

Availability

Available in CarbonLib 1.0.2 and later.

Available in Mac OS X 10.0 and later.

Not available to 64-bit applications.

Declared In

`MacHelp.h`

HMInstallMenuTitleContentCallback

Installs a help tag callback for a menu title.

```
OSStatus HMInstallMenuTitleContentCallback (
   MenuRef inMenu,
   HMMenuTitleContentUPP inContentUPP
);
```

Parameters

inMenu

A reference to the menu for which to install the help tag callback.

inContentUPP

A universal procedure pointer to the help tag callback.

Return Value

A result code. See "Result Codes" (page 494).

Discussion

`HMInstallMenuTitleContentCallback` associates your help tag callback with the menu specified in the `inMenu` parameter. Thereafter, whenever the user hovers the mouse over the title of this menu in the menu bar, the Carbon Help Manager calls your callback to determine the content to display in the help tag for the menu title. For a description of the help tag callback for a menu title, see `HMMenuTitleContentProcPtr` (page 480).

Special Considerations

Although the `HMInstallMenuTitleContentCallback` function is available in CarbonLib, CarbonLib does not support menu title help tags. Any help tag content you supply for a menu title using a help tag callback in CarbonLib is not displayed.

Availability

Available in CarbonLib 1.0.2 and later.

Available in Mac OS X 10.0 and later.

Not available to 64-bit applications.

Declared In

`MacHelp.h`

HMInstallWindowContentCallback

Installs a help tag callback for a window.

```
OSStatus HMInstallWindowContentCallback (
   WindowRef inWindow,
   HMWindowContentUPP inContentUPP
);
```

Parameters

inWindow

A reference to the window for which to install the help tag callback.

inContentUPP

A universal procedure pointer to the help tag content callback.

Return Value

A result code. See "Result Codes" (page 494).

Discussion

`HMInstallWindowContentCallback` associates your help tag callback with the window specified in the `inWindow` parameter. Thereafter, whenever the user hovers the mouse over this window, the Carbon Help Manager calls this callback to determine the content to display in the help tag for the window. For a description of the help tag callback for a window, see `HMWindowContentProcPtr` (page 482).

Availability

Available in CarbonLib 1.0.2 and later.

Available in Mac OS X 10.0 and later.

Not available to 64-bit applications.

Declared In

`MacHelp.h`

HMSetControlHelpContent

Associates a help tag with a control.

```
OSStatus HMSetControlHelpContent (
   ControlRef inControl,
   const HMHelpContentRec *inContent
);
```

Parameters

inControl

A reference to the control with which you want to associate the help tag.

inContent

A pointer to a help tag structure that describes the help tag for the control.

Return Value

A result code. See "Result Codes" (page 494).

Discussion

Once you attach a help tag to a control using the `HMSetControlHelpContent` function, this help tag is displayed by the Carbon Help Manager whenever the user hovers the mouse over the control while help tags are enabled.

Use `HMSetControlHelpContent` to supply the content for a help tag when you create a control. To supply the content for a help tag only when the tag is about to be displayed to the user, install a help tag callback for the control with the function `HMInstallControlContentCallback` (page 465).

Availability
Available in CarbonLib 1.0.2 and later.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`MacHelp.h`

HMSetHelpTagsDisplayed

Enables or disables help tags.

```
OSStatus HMSetHelpTagsDisplayed (
   Boolean inDisplayTags
);
```

Parameters

inDisplayTags
Pass `true` to enable help tags; `false` to disable help tags.

Return Value
A result code. See "Result Codes" (page 494).

Discussion
Help tags are enabled by default when an application is launched; your application does not need to call `HMSetHelpTagsDisplayed` to turn on help tag display. Disabling help tags with `HMSetHelpTagsDisplayed` only turns off help tags in your application; help tag display in other applications is unaffected.

Availability
Available in CarbonLib 1.0.2 and later.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`MacHelp.h`

HMSetMenuItemHelpContent

Associates a help tag with a menu item.

```
OSStatus HMSetMenuItemHelpContent (
   MenuRef inMenu,
   MenuItemIndex inItem,
   const HMHelpContentRec *inContent
);
```

Parameters

inMenu
A reference to the menu containing the menu item with which to associate the help tag.

inItem
The index of the menu item.

inContent
A pointer to a help tag structure that describes the help tag for the menu item.

Return Value
A result code. See "Result Codes" (page 494).

Discussion
Once you attach a help tag to a menu item using the `HMSetMenuItemHelpContent` function, this help tag is displayed by the Carbon Help Manager whenever the user hovers the mouse over the menu item while help tags are enabled.

Use `HMSetMenuItemHelpContent` to supply the content for a help tag when you create a menu. To supply the content for a help tag only when the tag is about to be displayed to the user, install a help tag callback for the menu's items with the function `HMInstallMenuItemContentCallback` (page 466).

Special Considerations

CarbonLib does not support menu item help tags. Any help tag content you supply with the `HMSetMenuItemHelpContent` function in CarbonLib is not displayed.

In versions of Mac OS X version 10.1 and earlier, the Carbon Help Manager does not correctly interpret an empty rectangle in the `absHotRect` field of the help tag structure passed to `HMSetMenuItemHelpContent` when setting the help content for a menu title. Because there is no Menu Manager function for determining the bounds of a menu title, Apple recommends that you install a help tag callback to supply help content for a menu title. See `HMMenuTitleContentProcPtr` (page 480) for a description of the help tag callback for a menu title.

Availability
Available in CarbonLib 1.0.2 and later.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`MacHelp.h`

HMSetTagDelay

Sets the help tag delay time.

```
OSStatus HMSetTagDelay (
   Duration inDelay
);
```

Parameters

inDelay
The help tag delay time. A positive value represents the delay time in milliseconds; a negative value represents the delay time in microseconds.

Return Value
A result code. See "Result Codes" (page 494).

Discussion
The help tag delay time is the amount of time that the mouse must remain motionless over a control, window, menu title, or menu item before the associated help tag is displayed.

Availability
Available in CarbonLib 1.0.2 and later.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`MacHelp.h`

HMSetWindowHelpContent

Associates a help tag with a window.

```
OSStatus HMSetWindowHelpContent (
   WindowRef inWindow,
   const HMHelpContentRec *inContent
);
```

Parameters

inWindow
A reference to the window with which to associate the help tag.

inContent
A pointer to a help tag structure that describes the help tag for the window.

Return Value
A result code. See "Result Codes" (page 494).

Discussion
Once you attach a help tag to a window using the `HMSetWindowHelpContent` function, this help tag is displayed by the Carbon Help Manager whenever the user hovers the mouse over the window while help tags are enabled.

Use `HMSetWindowHelpContent` to supply the content for a help tag when you create a window. To supply the content for a help tag only when the tag is about to be displayed to the user, install a help tag callback for the window with the function `HMInstallWindowContentCallback` (page 468).

Availability
Available in CarbonLib 1.0.2 and later.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`MacHelp.h`

InvokeHMControlContentUPP

Calls your help tag callback for a control.

```
OSStatus InvokeHMControlContentUPP (
   ControlRef inControl,
   Point inGlobalMouse,
   HMContentRequest inRequest,
   HMContentProvidedType *outContentProvided,
   HMHelpContentRec *ioHelpContent,
   HMControlContentUPP userUPP
);
```

Parameters

inControl

A reference to the control for which the callback should supply help tag content.

inGlobalMouse

The current mouse position, in global coordinates.

inRequest

A value that specifies the type of the help tag content request. See "Content Request Types" (page 487) for a description of the possible requests.

outContentProvided

On output, a pointer to a value that indicates whether the help tag callback was able to fulfill the request specified in the `inRequest` parameter. See "Content Provided Types" (page 492) for a description of the values returned here.

ioHelpContent

A pointer to a help tag structure that describes the help tag for the control. On input, you must supply a value in the `version` field. On output, if the value of the `outContentProvided` parameter is `kHMContentProvided`, the help tag structure describes the help tag for the control.

userUPP

A universal procedure pointer to the help tag callback to invoke.

Return Value

A result code. See "Result Codes" (page 494).

Discussion

Use this function to invoke your help tag callback for a control, rather than calling your callback directly, to ensure code compatibility across different compiler targets. Typically, you do not need to invoke a help tag callback yourself. If you associate your callback with a control, using the `HMInstallControlContentCallback` (page 465) function, the operating system calls your callback when it is needed. For more information on the help tag callback for a control, see `HMControlContentProcPtr` (page 478).

Availability

Available in CarbonLib 1.0.2 and later.

Available in Mac OS X 10.0 and later.

Declared In

`MacHelp.h`

InvokeHMMenuItemContentUPP

Calls your help tag callback for a menu item.

```
OSStatus InvokeHMMenuItemContentUPP (
   const MenuTrackingData *inTrackingData,
   HMContentRequest inRequest,
   HMContentProvidedType *outContentProvided,
   HMHelpContentRec *ioHelpContent,
   HMMenuItemContentUPP userUPP
);
```

Parameters

inTrackingData

A pointer to the tracking information for the menu for which the callback should provide a menu-item help tag. The specific menu item for which the callback should provide a help tag is at the index number given in the `itemUnderMouse` field of the tracking data structure.

inRequest

A value that specifies the type of the help tag content request. See "Content Request Types" (page 487) for a description of the possible requests.

outContentProvided

On output, a pointer to a value that indicates whether the help tag callback was able to fulfill the request specified in the `inRequest` parameter. See "Content Provided Types" (page 492) for a description of the values returned here.

ioHelpContent

A pointer to a help tag structure that describes the help tag for the menu item. On input, you must supply a value in the `version` field. On output, if the value of the `outContentProvided` parameter is `kHMContentProvided`, the help tag structure describes the menu-item help tag.

userUPP

A universal procedure pointer to the help tag callback to invoke.

Return Value

A result code. See "Result Codes" (page 494).

Discussion

Use this function to invoke your help tag callback for a menu item, rather than calling your callback directly, to ensure code compatibility across different compiler targets. Typically, you do not need to invoke a help tag callback yourself. If you associate your callback with a menu's items, using the `HMInstallMenuItemContentCallback` (page 466) function, the operating system calls your callback when it is needed. For more information on the help tag callback for a menu item, see `HMMenuItemContentProcPtr` (page 479).

Availability

Available in CarbonLib 1.0.2 and later.

Available in Mac OS X 10.0 and later.

Declared In

`MacHelp.h`

InvokeHMMenuTitleContentUPP

Calls your help tag callback for a menu title.

```
OSStatus InvokeHMMenuTitleContentUPP (
   MenuRef inMenu,
   HMContentRequest inRequest,
   HMContentProvidedType *outContentProvided,
   HMHelpContentRec *ioHelpContent,
   HMMenuTitleContentUPP userUPP
);
```

Parameters

inMenu

A reference to the menu for which to provide a help tag.

inRequest

A value that specifies the type of the help tag content request. See "Content Request Types" (page 487) for a description of the possible requests.

outContentProvided

On output, a pointer to a value that indicates whether the help tag callback was able to fulfill the request specified in the `inRequest` parameter. See "Content Provided Types" (page 492) for a description of the values returned here

ioHelpContent

A pointer to a help tag structure that describes the help tag for the menu title. On input, you must supply a value in the `version` field. On output, if the value of the `outContentProvided` parameter is `kHMContentProvided`, the help tag structure describes the menu-title help tag.

userUPP

A universal procedure pointer to the help tag callback to invoke.

Return Value

A result code. See "Result Codes" (page 494).

Discussion

Use this function to invoke your help tag callback for a menu title, rather than calling your callback directly, to ensure code compatibility across different compiler targets. Typically, you do not need to invoke a help tag callback yourself. If you associate your callback with a menu, using the `HMInstallMenuTitleContentCallback` (page 467) function, the operating system calls your callback when it is needed. For more information on the help tag callback for a menu title, see `HMMenuTitleContentProcPtr` (page 480).

Availability

Available in CarbonLib 1.0.2 and later.

Available in Mac OS X 10.0 and later.

Declared In

`MacHelp.h`

InvokeHMWindowContentUPP

Calls your help tag callback for a window.

```
OSStatus InvokeHMWindowContentUPP (
   WindowRef inWindow,
   Point inGlobalMouse,
   HMContentRequest inRequest,
   HMContentProvidedType *outContentProvided,
   HMHelpContentRec *ioHelpContent,
   HMWindowContentUPP userUPP
);
```

Parameters

inWindow

A reference to the window for which the callback should provide a help tag.

inGlobalMouse

The current mouse position, in global coordinates.

inRequest

A value that specifies the type of the help tag content request. See "Content Request Types" (page 487) for a description of the possible requests.

outContentProvided

On output, a pointer to a value that indicates whether the help tag callback was able to fulfill the request specified in the `inRequest` parameter. See "Content Provided Types" (page 492) for a description of the values returned here.

ioHelpContent

A pointer to a help tag structure that describes the help tag for the window. On input, you must supply a value in the `version` field. On output, if the value of the `outContentProvided` parameter is `kHMContentProvided`, the help tag structure describes the help tag for the window.

userUPP

A universal procedure pointer to the help tag callback to invoke.

Return Value

A result code. See "Result Codes" (page 494).

Discussion

Use this function to invoke your help tag callback for a window, rather than calling your callback directly, to ensure code compatibility across different compiler targets. Typically, you do not need to invoke a help tag callback yourself. If you associate your callback with a window, using the `HMInstallWindowContentCallback` (page 468) function, the operating system calls your callback when it is needed. For more information on the help tag callback for a window, see `HMWindowContentProcPtr` (page 482).

Availability

Available in CarbonLib 1.0.2 and later.

Available in Mac OS X 10.0 and later.

Declared In

`MacHelp.h`

NewHMControlContentUPP

Creates a new universal procedure pointer (UPP) to a help tag callback for a control.

```
HMControlContentUPP NewHMControlContentUPP (
   HMControlContentProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your help tag callback. See `HMControlContentProcPtr` data type fir a description.

Return Value

On return, a UPP to the help tag callback. See `HMControlContentUPP` data type for a description.

Discussion

Pass the UPP returned by `NewHMControlContentUPP` to the `HMInstallControlContentCallback` (page 465) function to install your help tag callback with a control. When you are finished with the help tag callback—for example, when you dispose of the control—you should dispose of the UPP with the `DisposeHMControlContentUPP` (page 457) function.

Availability

Available in CarbonLib 1.0.2 and later.

Available in Mac OS X 10.0 and later.

Declared In

`MacHelp.h`

NewHMMenuItemContentUPP

Creates a new universal procedure pointer (UPP) to a help tag callback for a menu item.

```
HMMenuItemContentUPP NewHMMenuItemContentUPP (
   HMMenuItemContentProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your help tag callback.

Return Value

On return, a UPP to the help tag callback. See the `HMMenuItemContentUPP` data type for a description.

Discussion

Pass the UPP returned by `NewHMMenuItemContentUPP` to the `HMInstallMenuItemContentCallback` (page 466) function to install your help tag callback with a menu's items. When you are finished with the help tag callback—for example, when you dispose of the menu—you should dispose of the UPP with the `DisposeHMMenuItemContentUPP` (page 458) function.

Availability

Available in CarbonLib 1.0.2 and later.

Available in Mac OS X 10.0 and later.

Declared In

`MacHelp.h`

NewHMMenuTitleContentUPP

Creates a new universal procedure pointer (UPP) to a help tag callback for a menu title.

```
HMMenuTitleContentUPP NewHMMenuTitleContentUPP (
   HMMenuTitleContentProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your help tag callback.

Return Value

On return, a UPP to the help tag callback. See the `HMMenuTitleContentUPP` data type for a description

Discussion

Pass the UPP returned by `NewHMMenuTitleContentUPP` to the `HMInstallMenuTitleContentCallback` (page 467) function to install your help tag callback with a menu's title. When you are finished with the help tag callback—for example, when you dispose of the menu—you should dispose of the UPP with the `DisposeHMMenuTitleContentUPP` (page 458) function.

Availability

Available in CarbonLib 1.0.2 and later.

Available in Mac OS X 10.0 and later.

Declared In

`MacHelp.h`

NewHMWindowContentUPP

Creates a new universal procedure pointer (UPP) to a help tag callback for a window.

```
HMWindowContentUPP NewHMWindowContentUPP (
   HMWindowContentProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your help tag callback.

Return Value

On return, a UPP to the help tag callback function. See the `HMWindowContentUPP` data type for a description.

Discussion

Pass the UPP returned by `NewHMWindowContentUPP` to the `HMInstallWindowContentCallback` (page 468) function to install your help tag callback with a window. When you are finished with the help tag callback—for example, when you dispose of the window—you should dispose of the UPP with the `DisposeHMWindowContentUPP` (page 459) function.

Availability

Available in CarbonLib 1.0.2 and later.

Available in Mac OS X 10.0 and later.

Declared In

`MacHelp.h`

Callbacks

HMControlContentProcPtr

Defines a pointer to the help tag callback for a control. Your help tag callback provides help tag content for a control.

```
typedef OSStatus(* HMControlContentProcPtr)
(
    ControlRef inControl,
    Point inGlobalMouse,
    HMContentRequest inRequest,
    HMContentProvidedType *outContentProvided,
    HMHelpContentPtr ioHelpContent
);
```

If you name your function `MyHMControlContentCallback`, you would declare it like this:

```
OSStatus MyHMControlContentCallback (
    ControlRef inControl,
    Point inGlobalMouse,
    HMContentRequest inRequest,
    HMContentProvidedType *outContentProvided,
    HMHelpContentPtr ioHelpContent
);
```

Parameters

inControl
A reference to the control for which your callback should supply help tag content.

inGlobalMouse
The current mouse position, in global coordinates.

inRequest
A value that specifies the type of the help tag content request. See "Content Request Types" (page 487) for a description of the possible requests.

outContentProvided
On output, a pointer to a value that indicates whether your help tag callback was able to fulfill the request specified in the `inRequest` parameter. Your callback should return one of the constants described in "Content Provided Types" (page 492).

ioHelpContent
A pointer to a help tag structure that describes the help tag for the control. On input, the Carbon Help Manager supplies a value in the `version` field. If the value of the `inRequest` parameter is `kHMSupplyContent`, your callback must fill in the remaining fields of the structure or specify that it was unable to fulfill the help tag content request.

Return Value

A result code. See "Result Codes" (page 494).

Discussion
When the user hovers the mouse over a control for which you've registered a help tag callback, the Carbon Help Manager calls your callback with a `kHMSupplyContent` request in the `inRequest` parameter. To supply a help tag, your callback should fill in the fields of the help tag structure pointed to in the `ioHelpContent` parameter.

When the help tag for the control is no longer needed, the Carbon Help Manager calls your callback with a `kHMDisposeContent` request. When you receive this request, you should free any memory allocated for the help tag content and perform any other cleanup necessary before the Carbon Help Manager removes the help tag from the screen.

If your help tag callback handles the content request, your callback should return the constant `kHMContentProvided` in the `outContentProvided` parameter. Otherwise, your callback should indicate that it was unable to handle the help tag content request by returning the constant `kHMContentNotProvided` in the `outContentProvided` parameter.

To register a help tag callback with a control, pass a universal procedure pointer (UPP) to your callback function to the `HMInstallControlContentCallback` (page 465) function. You can create a UPP to your callback function with the `NewHMControlContentUPP` (page 475) function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MacHelp.h`

HMMenuItemContentProcPtr

Defines a pointer to the help tag callback for a menu item. Your help tag callback provides help tag content for a menu item.

```
typedef OSStatus(* HMMenuItemContentProcPtr)
(
    const MenuTrackingData *inTrackingData,
    HMContentRequest inRequest,
    HMContentProvidedType *outContentProvided,
    HMHelpContentPtr ioHelpContent
);
```

If you name your function `MyHMMenuItemContentCallback`, you would declare it like this:

```
OSStatus MyHMMenuItemContentCallback (
    const MenuTrackingData *inTrackingData,
    HMContentRequest inRequest,
    HMContentProvidedType *outContentProvided,
    HMHelpContentPtr ioHelpContent
);
```

Parameters

`inTrackingData`

A pointer to the tracking information for the menu for which your callback should provide a menu-item help tag. The specific menu item for which your callback should provide a help tag is at the index number given in the `itemUnderMouse` field of the tracking data structure.

inRequest

A value that specifies the type of the help tag content request. See "Content Request Types" (page 487) for a description of the possible requests.

outContentProvided

On output, a pointer to a value that indicates whether your help tag callback was able to fulfill the request specified in the `inRequest` parameter. Your callback should return one of the constants described in "Content Provided Types" (page 492).

ioHelpContent

A pointer to a help tag structure that describes the help tag for the menu item. On input, the Carbon Help Manager supplies a value in the `version` field. If the value of the `inRequest` parameter is `kHMSupplyContent`, your callback must fill in the remaining fields of the structure or specify that it was unable to fulfill the help tag content request.

Return Value
A result code. See "Result Codes" (page 494).

Discussion
When the user hovers the mouse over a menu item in a menu for which you've registered a help tag callback, the Carbon Help Manager calls your callback with a `kHMSupplyContent` request in the `inRequest` parameter. To supply a help tag, your callback should fill in the remaining fields of the help tag structure pointed to in the `ioHelpContent` parameter.

When the help tag for the menu item is no longer needed, the Carbon Help Manager calls your callback with a `kHMDisposeContent` request. When you receive this request, you should free any memory allocated for the help tag content and perform any other cleanup necessary before the Carbon Help Manager removes the help tag from the screen.

If your help tag callback handles the request for help tag content, your callback should return the constant `kHMContentProvided` in the `outContentProvided` parameter. Otherwise, your callback should indicate that it was unable to handle the help tag content request by returning the constant `kHMContentNotProvided` in the `outContentProvided` parameter.

To register a menu-item help tag callback with a menu, pass a universal procedure pointer (UPP) to your callback function to the `HMInstallMenuItemContentCallback` (page 466) function. You can create a UPP to your callback function with the `NewHMMenuItemContentUPP` (page 476) function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MacHelp.h`

HMMenuTitleContentProcPtr

Defines a pointer to the help tag callback for a menu title. Your help tag callback provides help tag content for a menu's title.

```
typedef OSStatus(* HMMenuTitleContentProcPtr)
(
    MenuRef inMenu,
    HMContentRequest inRequest,
    HMContentProvidedType *outContentProvided,
    HMHelpContentPtr ioHelpContent
);
```

If you name your function `MyHMMenuTitleContentCallback`, you would declare it like this:

```
OSStatus MyHMMenuTitleContentCallback (
    MenuRef inMenu,
    HMContentRequest inRequest,
    HMContentProvidedType *outContentProvided,
    HMHelpContentPtr ioHelpContent
);
```

Parameters

inMenu

A reference to the menu for which to provide help tag content.

inRequest

A value that specifies the type of the help tag content request. See "Content Request Types" (page 487) for a description of the possible requests.

outContentProvided

On output, a pointer to a value that indicates whether your help tag callback was able to fulfill the request specified in the `inRequest` parameter. Your callback should return one of the constants described in "Content Provided Types" (page 492).

ioHelpContent

A pointer to a help tag structure that describes the help tag for the menu title. On input, the Carbon Help Manager supplies a value in the `version` field. If the value of the `inRequest` parameter is `kHMSupplyContent`, your callback must fill in the remaining fields of the structure or specify that it was unable to fulfill the help tag content request.

Return Value

A result code. See "Result Codes" (page 494).

Discussion

When the user hovers the mouse over the title of a menu for which you've registered a help tag callback, the Carbon Help Manager calls your callback with a `kHMSupplyContent` request in the `inRequest` parameter. To supply a help tag, your callback should fill in the remaining fields of the help tag structure pointed to in the `ioHelpContent` parameter.

When the help tag for the menu title is no longer needed, the Carbon Help Manager calls your callback with a `kHMDisposeContent` request. When you receive this request, you should free any memory allocated for the help tag content and perform any other cleanup necessary before the Carbon Help Manager removes the help tag from the screen.

If your help tag callback handles the request for help tag content, your callback should return the constant `kHMContentProvided` in the `outContentProvided` parameter. Otherwise, your callback should indicate that it was unable to handle the help tag content request by returning the constant `kHMContentNotProvided` in the `outContentProvided` parameter.

To register a menu title help tag callback with a menu, pass a universal procedure pointer (UPP) to your callback function to the `HMInstallMenuTitleContentCallback` (page 467) function. You can create a UPP to your callback function with the `NewHMMenuTitleContentUPP` (page 477) function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MacHelp.h`

HMWindowContentProcPtr

Defines a pointer to the help tag callback for a window. Your help tag callback provides help tag content for a window.

```
typedef OSStatus(* HMWindowContentProcPtr)
(
    WindowRef inWindow,
    Point inGlobalMouse,
    HMContentRequest inRequest,
    HMContentProvidedType *outContentProvided,
    HMHelpContentPtr ioHelpContent
);
```

If you name your function `MyHMWindowContentCallback`, you would declare it like this:

```
OSStatus MyHMWindowContentCallback (
    WindowRef inWindow,
    Point inGlobalMouse,
    HMContentRequest inRequest,
    HMContentProvidedType *outContentProvided,
    HMHelpContentPtr ioHelpContent
);
```

Parameters

inWindow
A reference to the window for which your callback should provide help tag content.

inGlobalMouse
The current mouse position, in global coordinates.

inRequest
A value that specifies the type of the help tag content request. See "Content Request Types" (page 487) for a description of the possible requests.

outContentProvided
On output, a pointer to a value that indicates whether your help tag callback was able to fulfill the request specified in the `inRequest` parameter. Your callback should return one of the constants described in "Content Provided Types" (page 492).

ioHelpContent
A pointer to a help tag structure that describes the help tag for the window. On input, the Carbon Help Manager supplies a value in the `version` field. If the value of the `inRequest` parameter is `kHMSupplyContent`, your callback must fill in the remaining fields of the structure or specify that it was unable to fulfill the help tag content request.

Return Value
A result code. See "Result Codes" (page 494).

Discussion
When the user hovers the mouse over a window for which you've registered a help tag callback, the Carbon Help Manager calls your callback with a `kHMSupplyContent` request in the `inRequest` parameter. To supply a help tag, your callback should fill in the fields of the help tag structure pointed to in the `ioHelpContent` parameter.

When the help tag for the window is no longer needed, the Carbon Help Manager calls your callback with a `kHMDisposeContent` request. When you receive this request, you should free any memory allocated for the help tag content and perform any other cleanup necessary before the Carbon Help Manager removes the help tag from the screen.

If your help tag callback handles the request for help tag content, your callback should return the constant `kHMContentProvided` in the `outContentProvided` parameter. Otherwise, your callback should indicate that it was unable to handle the help tag content request by returning the constant `kHMContentNotProvided` in the `outContentProvided` parameter.

To register a help tag callback with a window, pass a universal procedure pointer (UPP) to your callback function to the `HMInstallWindowContentCallback` (page 468) function. You can create a UPP to your callback function with the `NewHMWindowContentUPP` (page 477) function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MacHelp.h`

Data Types

HMHelpContentRec

Describes a help tag.

```
struct HMHelpContentRec {
    SInt32 version;
    Rect absHotRect;
    HMTagDisplaySide tagSide;
    HMHelpContent content[2];
};
typedef struct HMHelpContentRec HMHelpContentRec;
```

Fields
`version`
The structure version.

`absHotRect`

The hot rectangle for the help tag, expressed in global coordinates. The hot rectangle defines the area on the screen over which the user must hover the mouse to trigger the Carbon Help Manager to display the help tag.

You may pass an empty rectangle—a rectangle with coordinates (0,0,0,0)—in this field. The Carbon Help Manager automatically substitutes the current location of the control, window, or menu item for the empty rectangle when the help tag is displayed.

`tagSide`

A value that specifies which side of the hot rectangle the help tag is displayed. For a description of the constants used here, see "Help Tag Display Locations" (page 489).

`content`

An array of two help tag content structures describing the help message for the tag. The first structure describes the content displayed by default in the help tag (the minimum content). The second structure describes additional content that is displayed in the help tag if the user holds down the Command key while the help tag is displayed (the maximum, or expanded, content).

Special Considerations

On Mac OS X version 10.1.x and earlier, you cannot supply an empty hot rectangle from a help tag callback. You can, however, supply an empty hot rectangle to the `HMSetControlHelpContent`, `HMSetWindowHelpContent`, and `HMSetMenuItemHelpContent` functions.

When you supply an empty hot rectangle for a control help tag, the Carbon Help Manager uses the function `LocalToGlobal` to convert the control's bounds from window-local coordinates into global coordinates. `LocalToGlobal` only returns true global coordinates if the port origin is (0,0). If your application sets the port origin to a non-zero value, it should do so only temporarily; your application should never leave the port origin set to a non-zero value across calls to the event system that may attempt to display a help tag. Setting the port origin to a non-zero value typically prevents help tags from being displayed.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MacHelp.h`

HMHelpContentPtr

A pointer to a help tag structure.

```
typedef HMHelpContentRec* HMHelpContentPtr;
```

Discussion
See `HMHelpContentRec` (page 483) for more information.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MacHelp.h`

HMHelpContent

Contains a help tag message.

```
struct HMHelpContent {
    HMContentType contentType;
    union {
        CFStringRef tagCFString;
        Str255 tagString;
        HMStringResType tagStringRes;
        TEHandle tagTEHandle;
        SInt16 tagTextRes;
          SInt16 tagStrRes;
    } u;
};
```

Fields

`contentType`

A value that indicates the format of the help content contained in the structure. The help tag content formats that are allowed are described by the constants "Help Tag Content Types" (page 488).

`tagCFString`

If the value of the `contentType` field is `kHMCFStringContent`, a CFString specifying the help tag message. If the value of the `contentType` field is `kHMCFStringLocalizedContent`, a CFString containing the name of the localized help tag message in the `Localizable.strings` file.

`tagString`

If the value of the `contentType` field is `kHMPascalStrContent`, a Pascal string specifying the help tag message.

`tagStringRes`

If the value of the `contentType` field is `kHMStringResContent`, a 'STR#' resource ID and an index number specifying the help tag message.

`tagTEHandle`

If the value of the `contentType` field is `kHMTEHandleContent`, a TextEdit handle specifying the help tag message. This type of help tag content is only supported in CarbonLib and in Mac OS X version 10.2 and later.

`tagTextRes`

If the value of the `contentType` field is `kHMTextResContent`, the resource ID of a 'TEXT' resource and a 'styl' resource describing the help tag message. This type of help tag content is only supported in CarbonLib and in Mac OS X version 10.2 and later.

`tagStrRes`

If the value of the `contentType` field is `kHMStrResContent`, a 'STR ' resource ID, specifying the help tag message.

Discussion

The `HMHelpContent` structure is used in the `content` field of the `HMHelpContentRec` (page 483) structure to hold the help content associated with a help tag. The `HMHelpContent` structure describes a single help message.

HMControlContentUPP

Defines a universal procedure pointer to the help tag callback for a control.

```
typedef struct OpaqueHMControlContentProcPtr* HMControlContentUPP;
```

Discussion

For more information, see the description of the `HMControlContentProcPtr` (page 478) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MacHelp.h`

HMWindowContentUPP

Defines a universal procedure pointer to the help tag callback for a window.

```
typedef struct OpaqueHMWindowContentProcPtr* HMWindowContentUPP;
```

Discussion
For more information, see the description of the `HMWindowContentProcPtr` (page 482) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MacHelp.h`

HMMenuItemContentUPP

Defines a universal procedure pointer to the help tag callback for a menu item.

```
typedef struct OpaqueHMMenuItemContentProcPtr* HMMenuItemContentUPP;
```

Discussion
For more information, see the description of the `HMMenuItemContentProcPtr` (page 479) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MacHelp.h`

HMMenuTitleContentUPP

Defines a universal procedure pointer to the help tag callback for a menu title.

```
typedef struct OpaqueHMMenuTitleContentProcPtr* HMMenuTitleContentUPP;
```

Discussion
For more information, see the description of the `HMMenuTitleContentProcPtr` (page 480) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`MacHelp.h`

Constants

Help Manager Version

Represents the current version of the `HMHelpContentRec` structure.

```
enum {
    kMacHelpVersion = 3
};
```

Constants

`kMacHelpVersion`

The current structure version.

Available in Mac OS X v10.0 and later.

Declared in `MacHelp.h`.

Discussion

When the Carbon Help Manager calls your help tag callback, it supplies the `kMacHelpVersion` constant in the `version` field of the `HMHelpContentRec` (page 483) structure it passes to your callback.

Content Request Types

Identify the type of request made to a help tag callback.

```
typedef SInt16 HMContentRequest;
enum {
    kHMSupplyContent =                0,
    kHMDisposeContent =                1
};
```

Constants

`kHMSupplyContent`

The help tag callback should supply help content.

Available in Mac OS X v10.0 and later.

Declared in `MacHelp.h`.

`kHMDisposeContent`

The help tag callback should dispose of help content.

Available in Mac OS X v10.0 and later.

Declared in `MacHelp.h`.

Discussion

These constants are passed to your help tag callback in the `inRequest` parameter to indicate the nature of the help tag content request. In particular, the Carbon Help Manager passes `kHMSupplyContent` when the user pauses with the mouse above a user interface object for which a help tag callback is registered. When the user moves the mouse away from the object, the Carbon Help Manager passes `kHMDisposeContent` to your callback.

Help Tag Content Types

Identify the type of content contained in a help tag.

```
typedef UInt32 HMContentType;
enum {
    kHMNoContent = 'none',
    kHMCFStringContent = 'cfst',
    kHMCFStringLocalizedContent = ‘cfsl’,
    kHMPascalStrContent = 'pstr',
    kHMStringResContent = 'str#',
    kHMTEHandleContent = 'txth',
    kHMTextResContent = 'text',
    kHMStrResContent = 'str '
};
```

Constants

`kHMNoContent`

The help tag contains no content.

Available in Mac OS X v10.0 and later.

Declared in `MacHelp.h`.

`kHMCFStringContent`

The help tag content is a CFString object.

Available in Mac OS X v10.0 and later.

Declared in `MacHelp.h`.

`kHMCFStringLocalizedContent`

The help tag content is a localized string contained in the `Localizeable.strings` file. The `content` field of the help tag structure contains a CFString key which the Carbon Help Manager uses to retrieve the help tag string from the `Localizable.strings` file in the appropriate language folder.

Available in Mac OS X v10.2 and later.

Declared in `MacHelp.h`.

`kHMPascalStrContent`

The help tag content is a Pascal string.

Available in Mac OS X v10.0 and later.

Declared in `MacHelp.h`.

`kHMStringResContent`

The help tag content is a text string, stored in the list of strings in a resource of type '`STR#`'.

Available in Mac OS X v10.0 and later.

Declared in `MacHelp.h`.

`kHMTEHandleContent`

The help tag content is contained in a TextEdit record, referred to by a TextEdit handle. This type of help tag content is only supported in CarbonLib and in Mac OS X version 10.2 and later.

Available in Mac OS X v10.0 and later.

Declared in `MacHelp.h`.

`kHMTextResContent`
The help tag content is styled text, described by the combination of a text resource ('`TEXT`') and a style resource ('`styl`'). This type of help tag content is only supported in CarbonLib and in Mac OS X version 10.2 and later.

Available in Mac OS X v10.0 and later.

Declared in `MacHelp.h`.

`kHMStrResContent`
The help tag content is a text string stored in a resource of type '`STR `'.

Available in Mac OS X v10.0 and later.

Declared in `MacHelp.h`.

Discussion
These constants are used in the `contentType` field of the `HMHelpContent` (page 484) structure to identify the format of the help content contained in that structure.

Help Tag Display Locations

Specify which side of the hot rectangle to display the help tag.

```
typedef SInt16 HMTagDisplaySide;
enum {
    kHMDefaultSide = 0,
    kHMOutsideTopScriptAligned = 1,
    kHMOutsideLeftCenterAligned = 2,
    kHMOutsideBottomScriptAligned = 3,
    kHMOutsideRightCenterAligned = 4,
    kHMOutsideTopLeftAligned = 5,
    kHMOutsideTopRightAligned = 6,
    kHMOutsideLeftTopAligned = 7,
    kHMOutsideLeftBottomAligned = 8,
    kHMOutsideBottomLeftAligned = 9,
    kHMOutsideBottomRightAligned = 10,
    kHMOutsideRightTopAligned = 11,
    kHMOutsideRightBottomAligned = 12,
    kHMOutsideTopCenterAligned = 13,
    kHMOutsideBottomCenterAligned = 14,
    kHMInsideRightCenterAligned = 15,
    kHMInsideLeftCenterAligned = 16,
    kHMInsideBottomCenterAligned = 17,
    kHMInsideTopCenterAligned = 18,
    kHMInsideTopLeftCorner = 19,
    kHMInsideTopRightCorner = 20,
    kHMInsideBottomLeftCorner = 21,
    kHMInsideBottomRightCorner = 22,
    kHMAbsoluteCenterAligned = 23
};
```

Constants
`kHMDefaultSide`
Display the help tag at the default system location. The system default is below the hot rectangle, horizontally centered.

Available in Mac OS X v10.0 and later.

Declared in `MacHelp.h`.

`kHMOutsideTopScriptAligned`
Display the help tag above the hot rectangle, aligned with the right or left side, depending upon the direction of the system script.

Available in Mac OS X v10.0 and later.

Declared in `MacHelp.h`.

`kHMOutsideLeftCenterAligned`
Display the help tag to the left of the hot rectangle, centered vertically.

Available in Mac OS X v10.0 and later.

Declared in `MacHelp.h`.

`kHMOutsideBottomScriptAligned`
Display the help tag below the hot rectangle, aligned with the right or left side, depending upon the direction of the system script.

Available in Mac OS X v10.0 and later.

Declared in `MacHelp.h`.

`kHMOutsideRightCenterAligned`
Display the help tag to the right of the hot rectangle, centered vertically.

Available in Mac OS X v10.0 and later.

Declared in `MacHelp.h`.

`kHMOutsideTopLeftAligned`
Display the help tag above the hot rectangle, with their left edges aligned.

Available in Mac OS X v10.0 and later.

Declared in `MacHelp.h`.

`kHMOutsideTopRightAligned`
Display the help tag above the hot rectangle, with their right edges aligned.

Available in Mac OS X v10.0 and later.

Declared in `MacHelp.h`.

`kHMOutsideLeftTopAligned`
Display the help tag to the left of the hot rectangle, with their top edges aligned.

Available in Mac OS X v10.0 and later.

Declared in `MacHelp.h`.

`kHMOutsideLeftBottomAligned`
Display the help tag to the left of the hot rectangle, with their bottom edges aligned.

Available in Mac OS X v10.0 and later.

Declared in `MacHelp.h`.

`kHMOutsideBottomLeftAligned`
Display the help tag below the hot rectangle, with their left edges aligned.

Available in Mac OS X v10.0 and later.

Declared in `MacHelp.h`.

`kHMOutsideBottomRightAligned`
Display the help tag below the hot rectangle, with their right edges aligned.

Available in Mac OS X v10.0 and later.

Declared in `MacHelp.h`.

`kHMOutsideRightTopAligned`
Display the help tag to the right of the hot rectangle, with their top edges aligned.

Available in Mac OS X v10.0 and later.

Declared in `MacHelp.h`.

`kHMOutsideRightBottomAligned`
Display the help tag to the right of the hot rectangle, with their bottom edges aligned.

Available in Mac OS X v10.0 and later.

Declared in `MacHelp.h`.

`kHMOutsideTopCenterAligned`
Display the help tag above the hot rectangle, centered horizontally.

Available in Mac OS X v10.0 and later.

Declared in `MacHelp.h`.

`kHMOutsideBottomCenterAligned`
Display the help tag below the hot rectangle, centered horizontally.

Available in Mac OS X v10.0 and later.

Declared in `MacHelp.h`.

`kHMInsideRightCenterAligned`
Display the help tag inside the hot rectangle, with their right edges aligned and centered vertically.

Available in Mac OS X v10.0 and later.

Declared in `MacHelp.h`.

`kHMInsideLeftCenterAligned`
Display the help tag inside the hot rectangle, with their left edges aligned and centered vertically.

Available in Mac OS X v10.0 and later.

Declared in `MacHelp.h`.

`kHMInsideBottomCenterAligned`
Display the help tag inside the hot rectangle, with their bottom edges aligned and centered horizontally.

Available in Mac OS X v10.0 and later.

Declared in `MacHelp.h`.

`kHMInsideTopCenterAligned`
Display the help tag inside the hot rectangle, with their top edges aligned and centered horizontally.

Available in Mac OS X v10.0 and later.

Declared in `MacHelp.h`.

`kHMInsideTopLeftCorner`
Display the help tag inside the hot rectangle, with their top and left edges aligned.

Available in Mac OS X v10.0 and later.

Declared in `MacHelp.h`.

`kHMInsideTopRightCorner`
Display the help tag inside the hot rectangle, with their top and right edges aligned.

Available in Mac OS X v10.0 and later.

Declared in `MacHelp.h`.

`kHMInsideBottomLeftCorner`
Display the help tag inside the hot rectangle, with their bottom and left edges aligned.

Available in Mac OS X v10.0 and later.

Declared in `MacHelp.h`.

`kHMInsideBottomRightCorner`
Display the help tag inside the hot rectangle, with their bottom and right edges aligned.

Available in Mac OS X v10.0 and later.

Declared in `MacHelp.h`.

`kHMAbsoluteCenterAligned`
Display the help tag centered vertically and horizontally within the hot rectangle.

Available in Mac OS X v10.0 and later.

Declared in `MacHelp.h`.

Discussion
The locations described by these constants are relative to the help tag's hot rectangle, which defines, in global coordinates, the area on the screen with which the help tag is associated. These constants are used in the `tagSide` field of the `HMHelpContentRec` (page 483) structure.

Content Provided Types

Indicate whether or not help tag content has been supplied.

```
typedef SInt16 HMContentProvidedType;
enum {
    kHMContentProvided = 0,
    kHMContentNotProvided = 1,
    kHMContentNotProvidedDontPropagate = 2
};
```

Constants
`kHMContentProvided`
Help tag content has been provided.

Available in Mac OS X v10.0 and later.

Declared in `MacHelp.h`.

`kHMContentNotProvided`
Help tag content was not provided. When your callback returns this constant, the Carbon Help Manager calls up to the next help tag callback in the hierarchy. If that callback also fails to provide help content, the Carbon Help Manager continues to propagate the request for help tag content until the request is fulfilled, the top of the hierarchy is reached, or a help tag callback tells the Carbon Help Manager to stop propagating the request.

Available in Mac OS X v10.0 and later.

Declared in `MacHelp.h`.

`kHMContentNotProvidedDontPropagate`
Help tag content was not provided. When your callback returns this constant, the Carbon Help Manager assumes that there is no help content for the control, window, menu title, or menu item and does not propagate the request.

Available in Mac OS X v10.0 and later.

Declared in `MacHelp.h`.

Discussion
Your help tag callback function should return one of these constants in its `outContentProvided` parameter.

Help Tag Content Indexes

Identify an index into the array of help tag content structures in a help tag.

```
enum {
    kHMMinimumContentIndex = 0,
    kHMMaximumContentIndex = 1
};
```

Constants

`kHMMinimumContentIndex`
The index of the help tag's minimum (or default) content.
Available in Mac OS X v10.0 and later.
Declared in `MacHelp.h`.

`kHMMaximumContentIndex`
The index of the help tag's maximum (or expanded) content.
Available in Mac OS X v10.0 and later.
Declared in `MacHelp.h`.

Discussion
These constants are used to access the minimum or maximum content of a help tag, in the `content` field of the `HMHelpContentRec` (page 483) structure.

Obsolete Help Tag Display Locations

Indicate the side of the hot rectangle on which the help tag should be displayed.

```
enum {
    kHMTopSide = 1,
    kHMLeftSide = 2,
    kHMBottomSide = 3,
    kHMRightSide = 4,
    kHMTopLeftCorner = 5,
    kHMTopRightCorner = 6,
    kHMLeftTopCorner = 7,
    kHMLeftBottomCorner = 8,
    kHMBottomLeftCorner = 9,
    kHMBottomRightCorner = 10,
    kHMRightTopCorner = 11,
    kHMRightBottomCorner = 12
};
```

Discussion
These constants have been replaced by the constants described in "Help Tag Display Locations"; you should use those constants instead.

Result Codes

The most common result codes returned by the Carbon Help Manager are listed in the table below.

Result Code	Value	Description
`errHMIllegalContentForMinimumState`	-10980	Minimum content for a help tag is unrecognized. Available in Mac OS X v10.0 and later.
`errHMIllegalContentForMaximumState`	-10981	Maximum content for a help tag is unrecognized. Available in Mac OS X v10.0 and later.

Color Picker Manager Reference

Framework: Carbon/Carbon.h

Declared in ColorPicker.h

Overview

Using Color Picker Manager functions, your application can use the standard user interface for soliciting color choices from users. Your application can use these functions to display, respond to events within, and close a color picker dialog box. The Color Picker Manager provides standard color pickers (which allow users to select colors from ranges of colors) and a standard dialog box allowing users to interact with the color picker. Your application can also create its own color pickers and dialog boxes to work with the Color Picker Manager.

Carbon supports the Color Picker Manager functions that most applications rely on, `GetColor`, `PickColor`, and `NPickColor`. In addition, Carbon will support all the functions described as supported in "Technote 1100: Color Picker 2.1."

That same Technote specifies certain functions from earlier versions of the Color Picker Manager that are no longer supported by the Mac OS; Carbon will not support these functions. In addition, many of the functions that start with the word "Picker", such as `PickerInit`, `PickerGetProfile`, and `PickerItemHit`, are no longer supported. These routines provided low-level access to the Color Picker Manager that was rarely used.

Functions by Task

Converting Between SmallFract and Fixed Values

`Fix2SmallFract` (page 498)
Converts a fixed integer to a `SmallFract` value.

`SmallFract2Fix` (page 506)
Converts a `SmallFract` value to a fixed integer.

Converting Colors Among Color Models

`CMY2RGB` (page 497)
Converts a CMY color to its equivalent RGB color.

`HSL2RGB` (page 500)
Converts an HSL color to an RGB color.

`HSV2RGB` (page 500)
Converts an HSV color to an RGB color.

`RGB2CMY` (page 505)
Converts an RGB color to a CMY color.

`RGB2HSL` (page 505)
Converts an RGB color to an HSL color.

`RGB2HSV` (page 505)
Converts an RGB color to an HSV color.

Using the Standard Color Picker Dialog Box

`NPickColor` (page 503)
Displays the Color Picker dialog.

`GetColor` (page 499)
Requests the user to choose a color. This function is obsolete; use the `PickColor` function instead.

`PickColor` (page 504)
Requests the user to choose a color from the standard color picker dialog box.

Working With Universal Procedure Pointers

`NewUserEventUPP` (page 503)
Creates a universal procedure pointer (UPP) to an event filter callback.

`DisposeUserEventUPP` (page 498)
Disposes of a a universal procedure pointer (UPP) to an event filter callback.

`InvokeUserEventUPP` (page 501)
Invokes an event filter callback.

`NewNColorChangedUPP` (page 502)
Creates a universal procedure pointer (UPP) to a color-changed callback.

`InvokeNColorChangedUPP` (page 501)
Invokes a color-changed callback.

`DisposeNColorChangedUPP` (page 497)
Disposes of a a universal procedure pointer (UPP) to a color-changed callback.

`NewColorChangedUPP` (page 502)
Creates a universal procedure pointer (UPP) to a color-changed callback.

`InvokeColorChangedUPP` (page 501)
Invokes a color-changed callback.

`DisposeColorChangedUPP` (page 497)
Disposes of a a universal procedure pointer (UPP) to a color-changed callback.

Functions

CMY2RGB

Converts a CMY color to its equivalent RGB color.

```
void CMY2RGB (
   const CMYColor *cColor,
   RGBColor *rColor
);
```

Parameters

cColor

A pointer to a `CMYColor` structure to be converted.

rColor

A pointer to an `RGBColor` structure for the converted color.

Availability

Available in CarbonLib 1.0 and later when running Mac OS 8.1 or later.

Available in Mac OS X 10.0 and later.

Not available to 64-bit applications.

Declared In

`ColorPicker.h`

DisposeColorChangedUPP

Disposes of a a universal procedure pointer (UPP) to a color-changed callback.

```
void DisposeColorChangedUPP (
   ColorChangedUPP userUPP
);
```

Parameters

userUPP

Availability

Available in CarbonLib 1.0 and later.

Available in Mac OS X 10.0 and later.

Not available to 64-bit applications.

Declared In

`ColorPicker.h`

DisposeNColorChangedUPP

Disposes of a a universal procedure pointer (UPP) to a color-changed callback.

```
void DisposeNColorChangedUPP (
   NColorChangedUPP userUPP
);
```

Parameters

userUPP

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.

Declared In
`ColorPicker.h`

DisposeUserEventUPP

Disposes of a a universal procedure pointer (UPP) to an event filter callback.

```
void DisposeUserEventUPP (
   UserEventUPP userUPP
);
```

Parameters

userUPP

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`ColorPicker.h`

Fix2SmallFract

Converts a fixed integer to a `SmallFract` value.

```
SmallFract Fix2SmallFract (
   Fixed f
);
```

Parameters

f

The value of type `Fixed` to be converted to a `SmallFract` value.

Return Value
A `SmallFract` converted from the fixed integer value specified in the `f` parameter. See the description of the `SmallFract` data type.

Discussion
A `SmallFract` value can represent a value between 0 and 65,535. Introduced by the original Color Picker Package, `SmallFract` values are used in `CMYColor`, `HSLColor`, and `HSVColor` structures. They can be assigned directly to and from integers.

Availability
Available in CarbonLib 1.0 and later when running Mac OS 8.1 or later.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`ColorPicker.h`

GetColor

Requests the user to choose a color. This function is obsolete; use the `PickColor` function instead.

```
Boolean GetColor (
   Point where,
   ConstStr255Param prompt,
   const RGBColor *inColor,
   RGBColor *outColor
);
```

Parameters

`where`

A point defining the location of the upper-left corner of the dialog box. If you set this parameter to (0,0), the dialog box is centered horizontally on the main screen, with one-third of the empty space above the box and two-thirds below, regardless of the screen size. If you set this parameter to (–1,–1), the `GetColor` function displays the dialog box on the screen supporting the greatest pixel depth.

`prompt`

Text for prompting the user to choose a color. This string is displayed in the upper-left corner of the dialog box.

`inColor`

A pointer to an `RGBColor` structure for a color at entry to the picker. This is the original color, which the user may want for comparison.

`outColor`

A pointer to an `RGBColor` structure describing the new color. This is set to the last color that the user picked before clicking OK. On entry, the `outColor` parameter is treated as undefined, so the output color sample initially matches the input. Although the color being picked may vary widely, the input color sample remains fixed, and clicking the input sample resets the output color sample to match it.

Return Value
`True` if the user clicks the OK button; `false` if the user clicks the Cancel button. In either case, the dialog box is removed.

Discussion
The `GetColor` function does not support ColorSync 1.0 color matching; however, the `PickColor` function does. This function was designed for use for version 1.0 of the Color Picker Package and is still supported for backward compatibility.

Availability
Available in CarbonLib 1.0 and later when running Mac OS 8.1 or later.
Available in Mac OS X 10.0 and later.

Declared In
`ColorPicker.h`

HSL2RGB

Converts an HSL color to an RGB color.

```
void HSL2RGB (
   const HSLColor *hColor,
   RGBColor *rColor
);
```

Parameters

hColor

A pointer to the `HSLColor` structure to be converted.

rColor

A pointer to an `RGBColor` structure for the converted color.

Availability
Available in CarbonLib 1.0 and later when running Mac OS 8.1 or later.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`ColorPicker.h`

HSV2RGB

Converts an HSV color to an RGB color.

```
void HSV2RGB (
   const HSVColor *hColor,
   RGBColor *rColor
);
```

Parameters

hColor

A pointer to the `HSVColor` structure to be converted.

rColor

A pointer to an `RGBColor` structure for the converted color.

Availability
Available in CarbonLib 1.0 and later when running Mac OS 8.1 or later.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`ColorPicker.h`

InvokeColorChangedUPP

Invokes a color-changed callback.

```
void InvokeColorChangedUPP (
   SInt32 userData,
   PMColor *newColor,
   ColorChangedUPP userUPP
);
```

Parameters

newColor

userUPP

Discussion

You should not need to use the function `InvokeColorChangedUPP`, as the Color Picker Manager calls your color-changed callback function for you.

Availability

Available in CarbonLib 1.0 and later.

Available in Mac OS X 10.0 and later.

Not available to 64-bit applications.

Declared In

`ColorPicker.h`

InvokeNColorChangedUPP

Invokes a color-changed callback.

```
void InvokeNColorChangedUPP (
   SRefCon userData,
   NPMColor *newColor,
   NColorChangedUPP userUPP
);
```

Parameters

newColor

userUPP

Discussion

You should not need to use the function `InvokeNColorChangedUPP`, as the Color Picker Manager calls your color-changed callback function for you.

Availability

Available in CarbonLib 1.0 and later.

Available in Mac OS X 10.0 and later.

Declared In

`ColorPicker.h`

InvokeUserEventUPP

Invokes an event filter callback.

```
Boolean InvokeUserEventUPP (
   EventRecord *event,
   UserEventUPP userUPP
);
```

Parameters

event

userUPP

Discussion

You should not need to use the function `InvokeUserEventUPP`, as the Color Picker Manager calls your event filter callback function for you.

Availability

Available in CarbonLib 1.0 and later.

Available in Mac OS X 10.0 and later.

Not available to 64-bit applications.

Declared In

`ColorPicker.h`

NewColorChangedUPP

Creates a universal procedure pointer (UPP) to a color-changed callback.

```
ColorChangedUPP NewColorChangedUPP (
   ColorChangedProcPtr userRoutine
);
```

Parameters

userRoutine

Return Value

See the description of the `ColorChangedUPP` data type.

Availability

Available in CarbonLib 1.0 and later.

Available in Mac OS X 10.0 and later.

Not available to 64-bit applications.

Declared In

`ColorPicker.h`

NewNColorChangedUPP

Creates a universal procedure pointer (UPP) to a color-changed callback.

```
NColorChangedUPP NewNColorChangedUPP (
   NColorChangedProcPtr userRoutine
);
```

Parameters

userRoutine

Return Value
See the description of the `NColorChangedUPP` data type.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.

Declared In
`ColorPicker.h`

NewUserEventUPP

Creates a universal procedure pointer (UPP) to an event filter callback.

```
UserEventUPP NewUserEventUPP (
   UserEventProcPtr userRoutine
);
```

Parameters

userRoutine

Return Value
See the description of the `UserEventUPP` data type.

Availability
Available in CarbonLib 1.0 and later.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`ColorPicker.h`

NPickColor

Displays the Color Picker dialog.

```
OSErr NPickColor (
   NColorPickerInfo *theColorInfo
);
```

Parameters

theColorInfo

A pointer to a color picker parameter (`NColorPickerInfo`) data structure. On input, you specify information such as the location of the dialog. Make sure that you set `theColor.profile` field in this strucure to the color space that you want the color returned in. On output, the data structure specifies information such as whether the user changed the color.

Return Value
A result code. See "Color Picker Result Codes" (page 522).

Discussion
The `NPickColor` function displays the standard dialog for color pickers. Use the color picker parameter data structure to specify information to and obtain information from the Color Picker Manager.

Availability
Available in CarbonLib 1.0 and later when ColorPicker 2.1 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

This call is identical to the unsupported function `PickColor` , but it replaces the older ColorSync 1.0 data types with new ColorSync 2.x profile references. When filling out the parameter block for a call to the function `NPickColor`, you must replace all profile handles with profile references. The optional color-changed proc you has also changed; a new data structure `NCMColor` replaces the `CMColor` data type and uses profile references.

Related Sample Code
CarbonSketch

Declared In
`ColorPicker.h`

PickColor

Requests the user to choose a color from the standard color picker dialog box.

```
OSErr PickColor (
   ColorPickerInfo *theColorInfo
);
```

Parameters

`theColorInfo`

A pointer to the `ColorPickerInfo (Old)` (page 510) structure, to specify information to and obtain information from the Color Picker Manager.

Return Value
A result code. See "Color Picker Result Codes" (page 522).

Discussion
The `PickColor` function displays the standard modal dialog box for color pickers. When the user clicks the OK button, `PickColor` removes the dialog box and returns `true` in the `newColorChosen` field and the user's selected color in the `theColor` field of `theColorInfo`. When the user clicks the Cancel button, `PickColor` removes the dialog box and returns `false` in the `newColorChosen` field.

Availability
Available in CarbonLib 1.0 and later when ColorPicker 2.0 or later is present.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`ColorPicker.h`

RGB2CMY

Converts an RGB color to a CMY color.

```
void RGB2CMY (
   const RGBColor *rColor,
   CMYColor *cColor
);
```

Parameters

rColor

A pointer to an `RGBColor` structure to be converted.

cColor

A pointer to a `CMYColor` structure for the converted color.

Availability

Available in CarbonLib 1.0 and later when running Mac OS 8.1 or later.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In

`ColorPicker.h`

RGB2HSL

Converts an RGB color to an HSL color.

```
void RGB2HSL (
   const RGBColor *rColor,
   HSLColor *hColor
);
```

Parameters

rColor

A pointer to the `RGBColor` structure to be converted.

hColor

A pointer to an `HSLColor` structure for the converted color.

Availability

Available in CarbonLib 1.0 and later when running Mac OS 8.1 or later.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In

`ColorPicker.h`

RGB2HSV

Converts an RGB color to an HSV color.

```
void RGB2HSV (
   const RGBColor *rColor,
   HSVColor *hColor
);
```

Parameters

rColor

A pointer to the `RGBColor` structure to be converted.

hColor

A pointer to an `HSVColor` structure for the converted color.

Availability
Available in CarbonLib 1.0 and later when running Mac OS 8.1 or later.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`ColorPicker.h`

SmallFract2Fix

Converts a `SmallFract` value to a fixed integer.

```
Fixed SmallFract2Fix (
   SmallFract s
);
```

Parameters

s

The value of type `SmallFract` to be converted into a fixed integer.

Return Value
A fixed integer converted from the `SmallFract` value specified in the `s` parameter.

Availability
Available in CarbonLib 1.0 and later when running Mac OS 8.1 or later.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`ColorPicker.h`

Callbacks by Task

Changing Colors in a Document

`NColorChangedProcPtr` (page 508)

Defines a pointer to your color-changed callback function, which applies a new color to a user's document.

`ColorChangedProcPtr` (page 507)
Defines a pointer to your color-changed callback function, which applies a new color to a user document.

Handling Application-Directed Events in a Color Picker

`UserEventProcPtr` (page 508)
Defines a pointer to your event filter callback function, which determines whether your application or the Color Picker Manager handles this user event.

Callbacks

ColorChangedProcPtr

Defines a pointer to your color-changed callback function, which applies a new color to a user document.

```
typedef void (*ColorChangedProcPtr) (
    SInt32 userData,
    PMColor *newColor
);
```

If you name your function `MyColorChangedProc`, you would declare it like this:

```
void MyColorChangedProc (
    SInt32 userData,
    PMColor *newColor
);
```

Parameters

userData
Data that your application supplies in the `colorProcData` field of `ColorPickerInfo (Old)` (page 510). Your application can use this value for any purpose it needs.

newColor
A pointer to a `PMColor` (page 516) structure that contains the new color selected by the user. Your color-changed function should update the user's document to use this color.

Discussion

Your application should supply the `colorProc` field of the color picker parameter with a pointer to your color change callback function.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`ColorPicker.h`

NColorChangedProcPtr

Defines a pointer to your color-changed callback function, which applies a new color to a user's document.

```
typedef void (*NColorChangedProcPtr)
(
    SInt32 userData,
    NPMColor *newColor
);
```

If you name your function `MyNColorChangedProc`, you would declare it like this:

```
void MyNColorChangedProc (
    SInt32 userData,
    NPMColor *newColor
);
```

Parameters

newColor

Availability

Available in Mac OS X v10.0 and later.

Declared In

`ColorPicker.h`

UserEventProcPtr

Defines a pointer to your event filter callback function, which determines whether your application or the Color Picker Manager handles this user event.

```
typedef Boolean (*UserEventProcPtr) (
    EventRecord *event
);
```

If you name your function `MyUserEventProc`, you would declare it like this:

```
Boolean MyUserEventProc (
    EventRecord *event
);
```

Parameters

event

A pointer to an event record.

Return Value

`True` if your application handles the event, `false` otherwise. The Color Picker Manager will process the event further only if `false` is returned.

Discussion

Your application should supply the `eventProc` field of the color picker parameter block with a pointer to your filter function. Your filter function should examine the event record passed in the first parameter to determine whether your application needs to handle the event contained in the record.

Applications can generally allow the Color Picker Manager to handle all events that might occur while displaying the standard dialog box. Update events are exceptions to this, however.

The `PickColor` function calls the Dialog Manager function `DialogSelect`. `DialogSelect` does not allow background windows to receive update events; therefore, at a minimum, your event filter function should handle update events. If your application needs to filter or preprocess other events before `DialogSelect` handles them, your application should do so in its event filter function.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ColorPicker.h`

Data Types

CMYColor

Contains cyan, magenta, and yellow values for a color.

```
struct CMYColor {
    SmallFract cyan;
    SmallFract magenta;
    SmallFract yellow;
};
typedef struct CMYColor CMYColor;
```

Fields

`cyan`
The `SmallFract` (page 517) value for the cyan component.

`magenta`
The `SmallFract` value for the magenta component.

`yellow`
The `SmallFract` value for the yellow component.

Discussion
The `CMYColor` structure contains cyan, magenta, and yellow colors. Your application can use a `CMYColor` structure to specify a color in a `PMColor` (page 516) structure. For example, your application supplies a `PMColor` structure in a `ColorPickerInfo (Old)` (page 510) block that it passes to the `PickColor` (page 504) function. Note that CMY and RGB colors are complementary.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ColorPicker.h`

ColorChangedUPP

Defines a universal procedure pointer to a color-changed callback.

```
typedef ColorChangedProcPtr ColorChangedUPP;
```

Discussion
For more information, see the description of the `ColorChangedProcPtr` (page 507) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ColorPicker.h`

ColorPickerInfo (Old)

Contains information needed to display a standard color picker dialog box.

```
struct ColorPickerInfo {
    PMColor theColor;
    CMProfileHandle dstProfile;
    UInt32 flags;
    DialogPlacementSpec placeWhere;
    Point dialogOrigin;
    OSType pickerType;
    UserEventUPP eventProc;
    ColorChangedUPP colorProc;
    UInt32 colorProcData;
    Str255 prompt;
    PickerMenuItemInfo mInfo;
    Boolean newColorChosen;
    SInt8 filler;
};
typedef struct ColorPickerInfo ColorPickerInfo;
```

Fields

`theColor`
A `PMColor` (page 516) structure. The color that your application supplies in this field is passed to the color picker for editing. This becomes the original color for the color picker. After the user clicks either the OK or Cancel button to close the dialog box, this field contains the new color, that is, the color last chosen by the user. Although the new colors selected by the user may vary widely, the original color remains fixed for comparison.

`dstProfile`
A handle to a ColorSync 1.0 profile for the final output device. To use the default system profile, set this field to `NULL`.

`flags`
Bits representing the color picker flags, which are described in detail in "Color Picker Flags" (page 518). Your application can set any of the following flags: `CanModifyPalette`, `CanAnimatePalette`, `AppIsColorSyncAware`. The color picker may set any of the following flags and override your application settings: `InSystemDialog`, `InApplicationDialog`, `InPickerDialog`, `DetachedFromChoices`.

`placeWhere`
: A specification for where to position the dialog box. Your application uses one of the following constants (described in "Dialog Placement Constants" (page 520)) to specify the position for the color picker dialog box: `kAtSpecifiedOrigin`, `kDeepestColorScreen`, `kCenterOnMainScreen`.

`dialogOrigin`
: The point, in global coordinates, at which to locate the upper-left corner of the dialog box. This origin point is used only if your application supplies the `kAtSpecifiedOrigin` specifier in the `placeWhere` field.

`pickerType`
: The component subtype of the initial color picker. If your application sets this field to 0, the default color picker is used (that is, the last color picker chosen by the user). When `PickColor` returns, this field contains the component subtype of the color picker that was chosen when the user closed the color picker dialog box.

`eventProc`
: A pointer to an application-defined event filter function for handling user events meant for your application. If your filter function returns `true`, the Color Picker Manager will not process the event any further. If your filter function returns `false`, the Color Picker Manager handles the event as if it were meant for the color picker. The event filter function you can supply here is described in `UserEventProcPtr` (page 508).

`colorProc`
: A pointer to an application-defined function to handle color changes. This function, described in `ColorChangedProcPtr` (page 507), should support the updating of colors in a document as the user selects them.

`colorProcData`
: A long integer that the Color Picker Manager passes to the application-defined function supplied in the `colorProc` field. Your application-defined function can use this value for any purpose it needs.

`prompt`
: A text string prompting the user to choose a color for a particular use (for example, "Choose a highlight color:").

`mInfo`
: A `PickerMenuItemInfo` (page 515) structure. This structure allows your application to specify your Edit menu for use when a color picker dialog box is displayed.

`newColorChosen`
: `True` if the user chose a color and clicked the OK button, and `false` if the user clicked Cancel.

`filler`

Discussion
When your application calls the `PickColor` (page 504) function to display a standard color picker dialog box, your application uses a color picker parameter block to specify information to and obtain information from the Color Picker Manager. The color picker parameter block is defined by the `ColorPickerInfo` data type.

This version of the Color Picker Manager uses ColorSync 1.0 profiles only. The ColorSync 1.0 profile is a handle-based profile. The profile format is defined by Apple Computer. You cannot use version 2.0 profiles, which are identified by profile references, with this version of the Color Picker Manager. ColorSync 1.0 profiles typically reside in the ColorSyncTM Profiles folder (within the Preferences folder of the System Folder). They may also be embedded with the images to which they pertain in graphics files.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
ColorPicker.h

HSLColor

Contains hue, saturation and lightness information for a color.

```
struct HSLColor {
    SmallFract hue;
    SmallFract saturation;
    SmallFract lightness;
};
typedef struct HSLColor HSLColor;
```

Fields

`hue`
The `SmallFract` (page 517) value for the hue.

`saturation`
The `SmallFract` value for the saturation, where 1 is full color.

`lightness`
The `SmallFract` value for lightness, where 1 is full white.

Discussion
The `HSLColor` structure contains a color's hue, saturation, and lightness values. Your application can use an `HSLColor` structure to specify a color in a `PMColor` (page 516) structure. For example, your application supplies a `PMColor` structure in a `ColorPickerInfo (Old)` (page 510) block that it passes to the `PickColor` (page 504) function. Note that the standard HLS order is altered to HSL.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
ColorPicker.h

HSVColor

Contains hue, saturation and value information for a color.

```
struct HSVColor {
    SmallFract hue;
    SmallFract saturation;
    SmallFract value;
};
typedef struct HSVColor HSVColor;
```

Fields

`hue`
The `SmallFract` (page 517) value for the hue.

`saturation`
The `SmallFract` value for the saturation, where 1 is full color.

`value`
The `SmallFract` value for the color's value, where 1 is maximum intensity.

Discussion
The `HSVColor` structure contains the hue, saturation, and value of a color. Your application can use an `HSVColor` structure to specify a color in a `PMColor` (page 516) structure. For example, your application supplies a `PMColor` structure in a `ColorPickerInfo (Old)` (page 510) block that it passes to the `PickColor` (page 504) function.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ColorPicker.h`

NColorChangedUPP

Defines a universal procedure pointer to your color-changed callback.

```
typedef NColorChangedProcPtr NColorChangedUPP;
```

Discussion
For more information, see the description of the `NColorChangedProcPtr` (page 508) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ColorPicker.h`

NColorPickerInfo

Contains information needed to display a standard color picker dialog.

```
struct NColorPickerInfo {
    NPMColor theColor;
    CMProfileRef dstProfile;
    UInt32 flags;
    DialogPlacementSpec placeWhere;
    Point dialogOrigin;
    OSType pickerType;
    UserEventUPP eventProc;
    NColorChangedUPP colorProc;
    UInt32 colorProcData;
    Str255 prompt;
    PickerMenuItemInfo mInfo;
    Boolean newColorChosen;
    UInt8 reserved;
};
typedef struct NColorPickerInfo NColorPickerInfo;
```

Fields

`theColor`
: An `NPMColor` structure that contains a color profile and a color.

`dstProfile`
: The destination profile.

`flags`
: The options to apply when displaying the color picker dialog. For information on the flags that you can supply, see "Color Picker Flags" (page 518).

`dialogOrigin`
: A constant that specifies where on the screen to place the color picker dialog. The constant `kAtSpecifiedOrigin` specifies to place the top-left corner of the color picker dialog at the point specified in the `dialogOrigin` field of the color picker parameter block. The constant `kDeepestColorScreen` specifies to center the color picker dialog on the screen with the greatest color depth. The constant `kCenterOnMainScreen` specifies to center the color picker dialog on the main screen.

`pickerType`
: The type of color picker.

`eventProc`
: A a universal procedure pointer to an event-filter callback.

`colorProc`
: A universal procedure pointer to a color-changed callback.

`colorProcData`
: Data needed for your color-changed callback.

`prompt`
: A string to use as a prompt.

`mInfo`
: A structure that contains information needed for your application to specify an Edit menu for use when a color picker dialog box is displayed.

`newColorChosen`
: A Boolean value that specifies whether or not a new color was chosen.

`reserved`
: Reserved for future use.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ColorPicker.h`

NPMColor

Contains a color profile and a color.

```
struct NPMColor {
    CMProfileRef profile;
    CMColor color;
};
typedef struct NPMColor NPMColor;
```

Fields

`profile`
A color-matching profile.

`color`
A color, as specified in a color-matching structure.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ColorPicker.h`

NPMColorPtr

A pointer to an `NPMColor` data structure.

```
typedef NPMColor * NPMColorPtr;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ColorPicker.h`

PickerMenuItemInfo

Contains information needed for your application to specify an Edit menu for use when a color picker dialog box is displayed.

```
struct PickerMenuItemInfo {
    short editMenuID;
    short cutItem;
    short copyItem;
    short pasteItem;
    short clearItem;
    short undoItem;
};
typedef struct PickerMenuItemInfo PickerMenuItemInfo;
```

Fields

`editMenuID`
The resource ID of the Edit menu for the color picker.

`cutItem`
The item number of the Cut command.

`copyItem`
The item number of the Copy command.

`pasteItem`
The item number of the Paste command.

`clearItem`
The item number of the Clear command.

`undoItem`
The item number of the Undo command.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ColorPicker.h`

PMColor

Contains a color profile and a color.

```
 {
    CMProfileHandle profile;
    CMColor color;
};
typedef struct PMColor PMColor;
```

Fields

`profile`
A handle to a color-matching profile (`CMProfile` structure). If your application sets this field to `NULL`, then the Color Picker Manager uses the default system profile.

`color`
A color, as specified in a color-matching structure. (`CMColor` is a union data type defined in the ColorSync programming interface.

Discussion
For defining colors, version 2.0 of the Color Picker Manager uses a picker color structure. For example, when your application creates a `ColorPickerInfo` parameter block to pass to `PickColor` (page 504) , your application supplies a picker color structure. The color that your application supplies in this field is passed to the color picker for editing. After the user clicks either the OK or Cancel button to close the dialog box, this field contains the color last chosen by the user.

The picker color structure includes a ColorSync 1.0 profile, a structure that matches colors among hardware devices such as displays, printers, and scanners. This color-matching profile (a data structure of type `CMProfile`) defines the color space of the color (which includes the type of color—RGB, CMYK, HSL, and so on). Using the `dstProfile` field of `ColorPickerInfo (Old)` (page 510) or the PickerSetProfile function, your application can specify a destination color-matching profile, which describes the color space of the device for which the color is being chosen. Given information about the destination profile, color pickers that are ColorSync aware can help the user choose a color that's within the destination device's gamut.

This version of the Color Picker Manager uses ColorSync 1.0 profiles only. The ColorSync 1.0 profile is a handle-based profile. The profile format is defined by Apple Computer. You cannot use version 2.0 profiles, which are identified by profile references, with this version of the Color Picker Manager. ColorSync 1.0 profiles typically reside in the ColorSyncTM Profiles folder (within the Preferences folder of the System Folder). They may also be embedded with the images to which they pertain in graphics files.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ColorPicker.h`

PMColorPtr

A pointer to a `PMColor` data structure.

```
typedef PMColor * PMColorPtr;
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ColorPicker.h`

SmallFract

Defines a data type for an unsigned short value.

```
typedef  unsigned short SmallFract;
```

Discussion
The `SmallFract` type is derived from the low-order word of a fixed integer. The Color Picker Manager uses `SmallFract` values to save memory and to be compatible with the Color QuickDraw `RGBColor` structure. You can use the `Fix2SmallFract` (page 498) function to convert a fixed integer to a `SmallFract` value. You can use the `SmallFract2Fix` (page 506) function to convert a `SmallFract` value to a fixed integer.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ColorPicker.h`

UserEventUPP

Defines a universal procedure pointer to an event-filter callback.

```
typedef UserEventProcPtr UserEventUPP;
```

Discussion
For more information, see the description of the `UserEventProcPtr` (page 508) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`ColorPicker.h`

Constants

Color Picker Flags

Specify a variety of options to apply when displaying the color picker dialog.

```
enum {
    kColorPickerDialogIsMoveable = 1,
    kColorPickerDialogIsModal = 2,
    kColorPickerCanModifyPalette = 4,
    kColorPickerCanAnimatePalette = 8,
    kColorPickerAppIsColorSyncAware = 16,
    kColorPickerInSystemDialog = 32,
    kColorPickerInApplicationDialog = 64,
    kColorPickerInPickerDialog = 128,
    kColorPickerDetachedFromChoices = 256,
    kColorPickerCallColorProcLive = 512
};
```

Constants
`kColorPickerDialogIsMoveable`
If your application sets the bit represented by this constant when creating a custom dialog box, then the color picker dialog box is moveable by the user.

Available in Mac OS X v10.0 and later.

Declared in `ColorPicker.h`.

`kColorPickerDialogIsModal`

If your application sets the bit represented by this constant when creating a custom dialog box, then the color picker dialog box is a modal dialog box.

Available in Mac OS X v10.0 and later.

Declared in `ColorPicker.h`.

`kColorPickerCanModifyPalette`

Your application should set the bit represented by this constant if your application can install a palette of its own that may modify (but not animate) the current color table. If you do not want the colors in the document to change as the user makes choices in the color picker dialog box, do not set this flag.

Available in Mac OS X v10.0 and later.

Declared in `ColorPicker.h`.

`kColorPickerCanAnimatePalette`

If your application sets the bit represented by this constant, then the color picker may modify or animate the palette.

Available in Mac OS X v10.0 and later.

Declared in `ColorPicker.h`.

`kColorPickerAppIsColorSyncAware`

Your application should set the bit represented by this constant if your application uses ColorSync color matching. If your application sets this bit, a color may be returned to your application in a different color space than the one initially passed to the `PickColor` function. For example, your application could pass an RGB color with no color-matching profile in the field `theColor` in `ColorPickerInfo`, and the Color Picker Manager could return a CMYK color with its associated profile. If your application does not set this flag, the Color Picker Manager automatically converts any color it receives back from the color picker to an RGB color.

This version of the Color Picker Manager uses ColorSync 1.0 profiles only. The ColorSync 1.0 profile is a handle-based profile. The profile format is defined by Apple Computer. You cannot use version 2.0 profiles, which are identified by profile references, with this version of the Color Picker Manager. ColorSync 1.0 profiles typically reside in the ColorSyncTM Profiles folder (within the Preferences folder of the System Folder). They may also be embedded with the images to which they pertain in graphics files.

Available in Mac OS X v10.0 and later.

Declared in `ColorPicker.h`.

`kColorPickerInSystemDialog`

The color picker sets this flag to indicate that the color picker is in a system-owned dialog box.

Available in Mac OS X v10.0 and later.

Declared in `ColorPicker.h`.

`kColorPickerInApplicationDialog`

The color picker sets this flag to indicate that the color picker is in an application-owned dialog box.

Available in Mac OS X v10.0 and later.

Declared in `ColorPicker.h`.

`kColorPickerInPickerDialog`

The color picker sets this flag to indicate that the color picker is in its own dialog box.

Available in Mac OS X v10.0 and later.

Declared in `ColorPicker.h`.

`kColorPickerDetachedFromChoices`
The color picker sets this flag to indicate that the color picker has been detached from the choices list.

Available in Mac OS X v10.0 and later.

Declared in `ColorPicker.h`.

`kColorPickerCallColorProcLive`
Available in Mac OS X v10.0 and later.

Declared in `ColorPicker.h`.

Discussion
In the `flags` field of the `ColorPickerInfo (Old)` (page 510) parameter block your application specifies characteristics for the color picker dialog box.

The color picker may set any of the `InSystemDialog`, `InApplicationDialog`, `InPickerDialog`, or `DetachedFromChoices` flags and override your application settings.

Special Considerations

Dialog Placement Constants

Specify where on the screen to place the color picker dialog.

```
typedef SInt16 DialogPlacementSpec;
enum {
    kAtSpecifiedOrigin = 0,
    kDeepestColorScreen = 1,
    kCenterOnMainScreen = 2
};
```

Constants
`kAtSpecifiedOrigin`
Specify to place the top-left corner of the color picker dialog at the point specified in the `dialogOrigin` field of the color picker parameter block.

Available in Mac OS X v10.0 and later.

Declared in `ColorPicker.h`.

`kDeepestColorScreen`
Specify to center the color picker dialog on the screen with the greatest color depth.

Available in Mac OS X v10.0 and later.

Declared in `ColorPicker.h`.

`kCenterOnMainScreen`
Specify to center the color picker dialog on the main screen.

Available in Mac OS X v10.0 and later.

Declared in `ColorPicker.h`.

Discussion
In the `placeWhere` field of the `ColorPickerInfo (Old)` (page 510) , your application specifies where to place the color picker dialog box. Your application uses the `DialogPlacementSpec` enumeration to specify the position of the color picker dialog box.

Maximum Small Fraction

Defines the maximum value for the `SmallFract` data type.

```
enum {
    kMaximumSmallFract = 0x0000FFFF
};
```

Width and Height Constants

Specify the width and height of the color picker dialog.

```
enum {
    kDefaultColorPickerWidth = 383,
    kDefaultColorPickerHeight = 238
};
```

Constants

`kDefaultColorPickerWidth`
Specifies the width of the color picker dialog.
Available in Mac OS X v10.0 and later.
Declared in `ColorPicker.h`.

`kDefaultColorPickerHeight`
Specifies the height of the color picker dialog.
Available in Mac OS X v10.0 and later.
Declared in `ColorPicker.h`.

Old Maximum Small Fraction

Defines the maximum value for the `SmallFract` data type.

```
enum {
    MaxSmallFract = 0x0000FFFF
};
```

Constants

`MaxSmallFract`
The maximum value of the `SmallFract` data type, as a long integer.
Available in Mac OS X v10.0 and later.
Declared in `ColorPicker.h`.

Old Color Picker Flags

Specify a variety of options to apply when displaying the color picker dialog.

```
enum {
    DialogIsMoveable = 1,
    DialogIsModal = 2,
    CanModifyPalette = 4,
    CanAnimatePalette = 8,
    AppIsColorSyncAware = 16,
    InSystemDialog = 32,
    InApplicationDialog = 64,
    InPickerDialog = 128,
    DetachedFromChoices = 256,
    CallColorProcLive = 512
};
```

Result Codes

The most common result codes returned by Color Picker are listed below.

Result Code	Value	Description
`firstPickerError`	-4000	Available in Mac OS X v10.0 and later.
`invalidPickerType`	-4000	Available in Mac OS X v10.0 and later.
`requiredFlagsDontMatch`	-4001	Available in Mac OS X v10.0 and later.
`pickerResourceError`	-4002	Available in Mac OS X v10.0 and later.
`cantLoadPicker`	-4003	Available in Mac OS X v10.0 and later.
`cantCreatePickerWindow`	-4004	Available in Mac OS X v10.0 and later.
`cantLoadPackage`	-4005	Available in Mac OS X v10.0 and later.
`pickerCantLive`	-4006	Available in Mac OS X v10.0 and later.
`colorSyncNotInstalled`	-4007	Available in Mac OS X v10.0 and later.
`badProfileError`	-4008	Available in Mac OS X v10.0 and later.
`noHelpForItem`	-4009	Available in Mac OS X v10.0 and later.

Control Manager Reference

Framework: Carbon/Carbon.h

Declared in Controls.h
ControlDefinitions.h

Overview

Your application uses the Control Manager to create and manage controls. Controls are onscreen objects that the user can manipulate with the mouse. By manipulating controls, the user can take an immediate action or change settings to modify a future action. For example, a scroll bar control allows a user to immediately change the portion of the document that your application displays, whereas a pop-up menu control for connection speed might allow the user to change the rate by which your application handles subsequent data transmissions.

Virtually all applications need to implement controls, at least in the form of scroll bars for document windows. Other standard Mac OS controls include buttons, checkboxes, radio buttons, and pop-up menus. You can use the Control Manager to create and manage these controls, too.

In Mac OS X v10.2 and later, Control Manager controls may be implemented as HIViews. View-based controls offer additional flexibility and extensibility for developers. For more information, see the document *HIView Programming Guide*.

Important: Documentation for the data browser control is available separately in *Data Browser Programming Guide*.

Carbon supports most Control Manager functions, with the following changes:

- The C-style, lowercase versions of Control Manager function names are no longer supported. If your application uses any Control Manager lowercase function names, you must replace them with their uppercase equivalents.
- Custom control definition procedures (also known as CDEFs), must be compiled as PowerPC-native code, and can not be stored as resources. See the Carbon Porting Guide for more information.
- Your application must use the functions defined by the Control Manager to create and dispose of Control Manager data structures. For example, instead of directly creating and disposing of control records, applications must call the Control Manager functions `GetNewControl` and `DisposeControl`.
- With the availability of the Appearance Manager, you should not access the `PopupPrivateData` structure, but rather pass the `kControlPopupButtonMenuHandleTag` tag to `GetControlData` to obtain its contents.
- Your application must use Control Manager accessor functions to access Control Manager data structures.

- You are encouraged to adopt the standard Mac OS control definition procedures in your application. Applications that use the standard control definition procedures inherit the Mac OS human interface appearance. Applications that use custom control definition procedures will work correctly, but because custom definition procedures invoke their own drawing routines, Mac OS X can't draw these applications with the current appearance.

Functions by Task

Creating and Removing Controls

`CreateBevelButtonControl` (page 539)
Creates a bevel button control.

`CreateChasingArrowsControl` (page 540)
Creates a chasing arrows control.

`CreateCheckBoxControl` (page 541)
Creates a checkbox control.

`CreateCheckGroupBoxControl` (page 542)
Creates a group box control that has a check box as its title.

`CreateClockControl` (page 542)
Creates a clock control.

`CreateDisclosureButtonControl` (page 544)
Creates a new instance of the Disclosure Button Control.

`CreateDisclosureTriangleControl` (page 545)
Creates a disclosure triangle control.

`CreateEditUnicodeTextControl` (page 547)
Creates a new edit text control.

`CreateGroupBoxControl` (page 548)
Creates a group box control.

`CreateIconControl` (page 549)
Creates an icon control.

`CreateImageWellControl` (page 549)
Creates an image well control.

`CreateListBoxControl` (page 550)
Creates a list box control.

`CreateLittleArrowsControl` (page 552)
Creates a little arrows control.

`CreatePictureControl` (page 553)
Creates a picture control.

`CreatePlacardControl` (page 554)
Creates a placard control.

`CreatePopupArrowControl` (page 554)
Creates a pop-up arrow control.

`CreatePopupButtonControl` (page 555)
Creates a pop-up button control.

`CreatePopupGroupBoxControl` (page 556)
Creates a group box control that has a pop-up button as its title.

`CreateProgressBarControl` (page 558)
Creates a progress bar control.

`CreatePushButtonControl` (page 558)
Creates a push button control.

`CreatePushButtonWithIconControl` (page 559)
Creates a push button control containing an icon or other graphical content.

`CreateRadioButtonControl` (page 560)
Creates a radio button control.

`CreateRadioGroupControl` (page 561)
Creates a radio group control.

`CreateRelevanceBarControl` (page 561)
Creates a relevance bar control.

`CreateRoundButtonControl` (page 564)
Creates a new instance of the round button control.

`CreateScrollBarControl` (page 564)
Creates a scroll bar control.

`CreateSeparatorControl` (page 567)
Creates a separator control.

`CreateSliderControl` (page 567)
Creates a slider control.

`CreateStaticTextControl` (page 569)
Creates a new static text control.

`CreateTabsControl` (page 569)
Creates a tabs control.

`CreateUserPaneControl` (page 571)
Creates a user pane control.

`CreateWindowHeaderControl` (page 571)
Creates a window header control.

`DisposeControl` (page 573)
Decrements a control's reference count and destroys it if the reference count becomes 0.

`GetNewControl` (page 610)
Creates a control from a control resource.

`KillControls` (page 632)
Removes all of the controls from a window that you wish to keep.

`RegisterControlDefinition` (page 640)
Registers an old-style control definition.

`CreateCustomControl` (page 543) Deprecated in Mac OS X v10.5
Creates a custom control. (Deprecated. Register your custom subclass of the HIView class and create an instance of your class using `HIObjectCreate`.)

Embedding Controls

`AutoEmbedControl` (page 536)
Automatically embeds a control in the smallest appropriate embedder control.

`CountSubControls` (page 538)
Obtains the number of embedded controls within a control.

`CreateRootControl` (page 562)
Creates the root control for a specified window.

`DumpControlHierarchy` (page 582)
Writes a textual representation of the control hierarchy for a specified window into a file.

`EmbedControl` (page 583)
Embeds one control inside another.

`GetControlOwner` (page 600)
Returns the window to which a control is bound.

`GetIndexedSubControl` (page 608)
Obtains a handle to a specified embedded control.

`GetRootControl` (page 611)
Obtains a handle to a window's root control.

`GetSuperControl` (page 611)
Obtains a handle to an embedder control.

Displaying Controls

`DisableControl` (page 573)
Disables a control.

`Draw1Control` (page 580)
Draws a control and any embedded controls that are currently visible in the specified window.

`DrawControlInCurrentPort` (page 581)
Draws a control in the current graphics port.

`DrawControls` (page 581)
Draws all controls currently visible in the specified window.

`GetControlViewSize` (page 607)
Obtains the size of the content to which a control's size is proportioned.

`IsControlVisible` (page 631)
Determines whether a control is visible.

`SetControlViewSize` (page 662)
Informs the Control Manager of the size of the content to which a control's size is proportioned.

`SetUpControlBackground` (page 667)
Applies the proper background color for the given control to the current port.

`SetUpControlTextColor` (page 668)
Applies the proper text color for the given control to the current port.¬¬

`UpdateControls` (page 672)
Draws controls in the specified update region of a window.

HideControl (page 618)
Makes a control, and any latent embedded controls, invisible.

ShowControl (page 669)
Makes an invisible control, and any latent embedded controls, visible.

SetControlVisibility (page 663)
Sets the visibility of a control, and any embedded controls, and specifies whether it should be drawn.

Handling Events in Controls

FindControl (page 585)
Obtains the location of a mouse-down event in a control.

FindControlUnderMouse (page 586)
Obtains the location of a mouse-down event in a control.

GetControlAction (page 591)
Returns a pointer to the action function associated with a control structure.

GetControlClickActivation (page 593)
Gets the control's preferred behavior for responding to particular click.

GetControlCommandID (page 594)
Gets the command ID for a control.

HandleControlClick (page 613)
Responds to cursor movements in a control while the mouse button is down and returns the location of the next mouse-up event.

HandleControlContextualMenuClick (page 614)
Allows a control to display a contextual menu.

HandleControlDragReceive (page 615)
Tells a control to accept the data from a drag.

HandleControlDragTracking (page 615)
Tells a control to respond visually to a drag.

HandleControlSetCursor (page 617)
Requests that a control set the cursor based on the mouse location.

IsAutomaticControlDragTrackingEnabledForWindow (page 629)
Indicates whether automatic drag tracking is enabled for the specified window.

IsControlDragTrackingEnabled (page 630)
Indicates whether a control's drag track and receive support is enabled.

SetAutomaticControlDragTrackingEnabledForWindow (page 643)
Enables or disables automatic drag tracking for a window.

SetControlAction (page 649)
Sets the action function for a control.

SetControlCommandID (page 651)
Sets the command ID for a control.

SetControlDragTrackingEnabled (page 653)
Sets the drag tracking state for a control.

TestControl (page 670)
Obtains the control part in which a mouse-down event occurred.

`HandleControlKey` (page 616) Deprecated in Mac OS X v10.5
Sends a keyboard event to a control with keyboard focus. (Deprecated. For HIView-based controls, send the view a `kEventTextInputUnicodeForKeyEvent` event.)

Manipulating Controls

`ActivateControl` (page 535)
Activates a control and any latent embedded controls.

`DeactivateControl` (page 572)
Deactivates a control and any latent embedded controls.

`EnableControl` (page 584)
Enables a control.

`GetControlRegion` (page 605)
Obtains the region corresponding to a given control part.

`IsControlActive` (page 629)
Returns whether a control is active.

`IsControlEnabled` (page 631)
Indicates whether a control is enabled.

`IsControlHilited` (page 631)
Indicates whether or not the control is highlighted.

`MoveControl` (page 633)
Moves a control within its window.

`SizeControl` (page 670)
Changes the size of a control's rectangle.

Handling Keyboard Focus

`AdvanceKeyboardFocus` (page 535)
Advances the keyboard focus to the next focusable control in a window.

`ClearKeyboardFocus` (page 537)
Removes the keyboard focus for the currently focused control in a window.

`GetKeyboardFocus` (page 609)
Obtains a handle to the control with the current keyboard focus for a specified window.

`ReverseKeyboardFocus` (page 642)
Returns keyboard focus to the prior focusable control in a window.

`SetKeyboardFocus` (page 665)
Sets the current keyboard focus to a specified control part for a window.

Accessing Control Settings and Data

`ChangeControlPropertyAttributes` (page 537)
Changes a property attribute.

`CopyControlTitleAsCFString` (page 538)
Makes a copy of the control's title as a Core Foundation string.

`GetBestControlRect` (page 587)
Obtains a control's optimal size and text placement.

`GetControl32BitMaximum` (page 589)
Obtains the maximum setting of a control.

`GetControl32BitMinimum` (page 590)
Obtains the minimum setting of a control.

`GetControl32BitValue` (page 590)
Obtains the current setting of a control.

`GetControlBounds` (page 592)
Gets the bounds of a control.

`GetControlByID` (page 592)
Finds a control in a window by its unique ID.

`GetControlData` (page 594)
Obtains control-specific data.

`GetControlDataSize` (page 596)
Obtains the size of a control's tagged data.

`GetControlHilite` (page 597)
Gets the highlight status of a control.

`GetControlID` (page 598)
Gets the control ID for a control.

`GetControlKind` (page 598)
Returns the kind of the given control.

`GetControlProperty` (page 602)
Obtains a piece of data that has been previously associated with a control.

`GetControlPropertySize` (page 603)
Obtains the size of a piece of data that has previously been associated with a control.

`GetControlReference` (page 604)
Obtains a control's current reference value.

`GetImageWellContentInfo` (page 608)
Gets information about the content of an image well.

`GetControlPropertyAttributes` (page 603)
Gets the property attributes for a control.

`GetTabContentRect` (page 612)
Gets the content rectangle for a tab.

`IsValidControlHandle` (page 632)
Reports whether a given handle is a control handle.

`RemoveControlProperty` (page 641)
Removes a piece of data that has been previously associated with a control.

`SetControl32BitMaximum` (page 647)
Changes the maximum setting of a control and, if appropriate, redraws it accordingly.

`SetControl32BitMinimum` (page 648)
Changes the minimum setting of a control and, if appropriate, redraws it accordingly.

SetControl32BitValue (page 648)
Changes the current setting of a control and redraws it accordingly.

SetControlData (page 652)
Sets control-specific data.

SetControlBounds (page 650)
Sets the bounds of a control.

SetControlID (page 655)
Sets a control's ID.

SetControlTitleWithCFString (page 661)
Sets the title for a control to the specified Core Foundation string.

SetDisclosureTriangleLastValue (page 664)
Sets the last value of a disclosure triangle.

SetImageWellContentInfo (page 664)
Sets the content information for an image well.

SetImageWellTransform (page 665)
Sets an image well transform.

SetTabEnabled (page 666)
Enables and disables a tab control.

SetControlFontStyle (page 654)
Sets the font style for a control.

SetControlProperty (page 658)
Associates data with a control.

SetControlReference (page 659)
Changes a control's current reference value.

Manipulating Menus in Controls

The functions described in this section can only be called for pop-up button and pop-up group box controls, which can support pop-up menus that activate when the user presses the control with the mouse.

GetControlPopupMenuHandle (page 601)
Gets the menu handle for a pop-up control.

GetControlPopupMenuID (page 601)
Gets the menu ID of a pop-up menu.

SetControlPopupMenuHandle (page 657)
Sets the menu handle for a pop-up control.

SetControlPopupMenuID (page 657)
Sets the menu ID for a pop-up control

Manipulating Bevel Buttons

Bevel button controls have additional features that you can or should manipulate to display them properly. This section describes the functions you can use to manipulate these features.

`GetBevelButtonContentInfo` (page 588)
Gets the content information for a bevel button.

`GetBevelButtonMenuHandle` (page 588)
Gets the menu handle for a bevel button.

`GetBevelButtonMenuValue` (page 589)
Gets the value of a bevel button menu.

`SetBevelButtonContentInfo` (page 644)
Sets the content information for a bevel button.

`SetBevelButtonGraphicAlignment` (page 644)
Sets the alignment for a bevel button.

`SetBevelButtonMenuValue` (page 645)
Sets the value of a bevel button menu.

`SetBevelButtonTextAlignment` (page 645)
Sets the alignment of the text for a bevel button.

`SetBevelButtonTextPlacement` (page 646)
Sets the placement for bevel button text.

`SetBevelButtonTransform` (page 647)
Sets the transform for a bevel button.

Managing Control UPPs

`DisposeControlActionUPP` (page 574)
Disposes of a control action UPP.

`DisposeControlCNTLToCollectionUPP` (page 574)
Disposes of a CNLT to collection UPP.

`DisposeControlEditTextValidationUPP` (page 576)
Disposes of an edit text validation UPP.

`DisposeControlKeyFilterUPP` (page 576)
Disposes of a key filter UPP.

`DisposeControlUserPaneActivateUPP` (page 576)
Disposes of a user pane activate UPP.

`DisposeControlUserPaneBackgroundUPP` (page 577)
Disposes of a user pane background UPP.

`DisposeControlUserPaneDrawUPP` (page 577)
Disposes of a user pane draw UPP.

`DisposeControlUserPaneFocusUPP` (page 577)
Disposes of a user pane focus UPP.

`DisposeControlUserPaneHitTestUPP` (page 578)
Disposes of a user pane hit test UPP.

`DisposeControlUserPaneIdleUPP` (page 578)
Disposes of a user pane idle UPP.

`DisposeControlUserPaneKeyDownUPP` (page 578)
Disposes of a user pane key down UPP.

DisposeControlUserPaneTrackingUPP (page 579)
Disposes of a user pane tracking UPP.

DisposeEditUnicodePostUpdateUPP (page 579)
Disposes of an edit unicode post update UPP.

InvokeControlActionUPP (page 620)
Invokes a control action UPP.

InvokeControlCNTLToCollectionUPP (page 621)
Invokes a control-to-collection UPP.

InvokeControlEditTextValidationUPP (page 623)
Invokes a control edit text validation UPP.

InvokeControlKeyFilterUPP (page 624)
Invokes a control key filter UPP.

InvokeControlUserPaneActivateUPP (page 624)
Invokes a control user pane activate UPP.

InvokeControlUserPaneBackgroundUPP (page 625)
Invokes a user pane background UPP.

InvokeControlUserPaneDrawUPP (page 625)
Invokes a user pane draw UPP.

InvokeControlUserPaneFocusUPP (page 626)
Invokes a user pane focus UPP.

InvokeControlUserPaneHitTestUPP (page 626)
Invokes a user pane hit test UPP.

InvokeControlUserPaneIdleUPP (page 627)
Invokes a user pane idle UPP.

InvokeControlUserPaneKeyDownUPP (page 627)
Invokes a user pane key down UPP.

InvokeControlUserPaneTrackingUPP (page 628)
Invokes a user pane tracking UPP.

InvokeEditUnicodePostUpdateUPP (page 628)
Invokes a Unicode post update UPP.

NewControlActionUPP (page 636)
Creates a UPP for a control action callback function.

NewControlCNTLToCollectionUPP (page 636)
Creates a UPP for a control-to-collection callback function.

NewControlEditTextValidationUPP (page 637)
Creates a UPP for a control edit text validation callback function.

NewControlKeyFilterUPP (page 637)

NewControlUserPaneActivateUPP (page 638)

NewControlUserPaneBackgroundUPP (page 638)

NewControlUserPaneDrawUPP (page 638)

NewControlUserPaneFocusUPP (page 638)

NewControlUserPaneHitTestUPP (page 639)

NewControlUserPaneIdleUPP (page 639)

NewControlUserPaneKeyDownUPP (page 639)

NewControlUserPaneTrackingUPP (page 640)

NewEditUnicodePostUpdateUPP (page 640)

DisposeControlDefUPP (page 575) Deprecated in Mac OS X v10.5
: Disposes of a control definition UPP. (Deprecated. Use a custom HIView to draw a custom control.)

InvokeControlDefUPP (page 622) Deprecated in Mac OS X v10.5
: Invokes a control definition UPP. (Deprecated. Use a custom HIView to draw a custom control.)

NewControlDefUPP (page 637) Deprecated in Mac OS X v10.5
: Creates a UPP for a control definition callback function. (Deprecated. Use a custom HIView to draw a custom control.)

Obsolete Functions

These functions are outdated and are not recommended.

CreateScrollingTextBoxControl (page 566)
: Creates a scrolling text box control.

DisposeControlColorUPP (page 575)

GetControlFeatures (page 597)
: Obtains the features a control supports.

GetControlMaximum (page 599)
: Obtains a control's maximum setting. (Deprecated. Use GetControl32BitMaximum (page 589) instead.)

GetControlMinimum (page 600)
: Obtains a control's minimum setting. (Deprecated. Use GetControl32BitMinimum (page 590) instead.)

GetControlValue (page 606)
: Obtains a control's current setting. (Deprecated. Use GetControl32BitValue (page 590) instead.)

GetControlVariant (page 607)
: Returns the variation code specified in the control definition function for a particular control. (Deprecated. Use custom HIViews instead of custom CDEFs. See *HIView Programming Guide*.)

InvokeControlColorUPP (page 622)

NewControlColorUPP (page 636)

`SetControlColorProc` (page 650)
Associates a `ControlColorUPP` with a given Control, thereby allowing you to bypass the embedding hierarchy-based color setup of `SetUpControlBackground`/`SetUpControlTextColor` and replace it with your own.

`GetControlDataHandle` (page 595)
Obtains a handle to control-specific data. (Deprecated. Use custom HIViews instead of custom CDEFs. See *HIView Programming Guide*.)

`SetControlDataHandle` (page 653)
(Deprecated. Use custom HIViews instead of custom CDEFs. See *HIView Programming Guide*.)

`SetControlMaximum` (page 655)
Changes the maximum setting of a control and redraws its indicator or scroll box accordingly. (Deprecated. Use `SetControl32BitMaximum` (page 647) instead.)

`SetControlMinimum` (page 656)
Changes the minimum setting of a control and redraws its indicator or scroll box accordingly. (Deprecated. Use `SetControl32BitMinimum` (page 648) instead.)

`SetControlSupervisor` (page 659)
Routes mouse-down events to the embedder control.

`SetControlValue` (page 661)
Changes the current setting of a control and redraws it accordingly. (Deprecated. Use `SetControl32BitValue` (page 648) instead.)

`TrackControl` (page 671)
Responds to cursor movements in a control while the mouse button is down. (Deprecated. Use `HandleControlClick` (page 613) instead.)

`DragControl` (page 579)
Draws and moves an outline of a control or its indicator while the user drags it. (Deprecated. Use Drag Manager functions if you want drag-and-drop support for controls. See *Drag Manager Reference*.)

`HiliteControl` (page 619)
Changes the highlighting of a control.

`SendControlMessage` (page 642)
Sends a message to a control definition function. (Deprecated. For custom controls, use a custom HIView instead of a control definition function. See *HIView Programming Guide*.)

`GetControlTitle` (page 605) Deprecated in Mac OS X v10.5
Obtains the title of a control. (Deprecated. Use `HIViewCopyText` (page 2448) or `CopyControlTitleAsCFString` (page 538) instead.)

`NewControl` (page 634) Deprecated in Mac OS X v10.5
Creates a control based on parameter data. (Deprecated. Use the specific control creation function instead (for example, `CreateCheckBoxControl` (page 541)).)

`SetControlTitle` (page 660) Deprecated in Mac OS X v10.5
Changes the title of a control and redraws the control accordingly. (Deprecated. Use `HIViewSetText` (page 2488) or `SetControlTitleWithCFString` (page 661) instead.)

`CreateEditTextControl` (page 546) Deprecated in Mac OS X v10.4
Creates a new edit text control. (Deprecated. Use `CreateEditUnicodeTextControl` (page 547) instead.)

`IdleControls` (page 620) Deprecated in Mac OS X v10.4
Performs idle event processing. (Deprecated. You should remove all calls to `IdleControls` because it uses unnecessary processor time. System-supplied controls do not respond to `IdleControls` in Mac OS X.)

Functions

ActivateControl

Activates a control and any latent embedded controls.

```
OSErr ActivateControl (
   ControlRef inControl
);
```

Parameters

inControl

A handle to the control to activate. If you pass a window's root control, `ActivateControl` activates all controls in that window. For a description of this data type, see ControlRef (page 709).

Return Value

A result code. See "Control Manager Result Codes" (page 824).

Discussion

The `ActivateControl` function should be called instead of `HiliteControl` to activate a specified control and its latent embedded controls.

An embedded control is considered latent when it is deactivated or hidden due to its embedder control being deactivated or hidden. If you activate a latent embedded control whose embedder is deactivated, the embedded control becomes latent until the embedder is activated. However, if you deactivate a latent embedded control, it will not be activated when its embedder is activated.

If a control definition function supports activate events, it will receive a `kControlMsgActivate` message before redrawing itself in its active state.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Related Sample Code

BSDLLCTest

Declared In

`Controls.h`

AdvanceKeyboardFocus

Advances the keyboard focus to the next focusable control in a window.

```
OSErr AdvanceKeyboardFocus (
   WindowRef inWindow
);
```

Parameters

inWindow

A pointer to the window for which to advance keyboard focus.

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Discussion
The `AdvanceKeyboardFocus` function skips over deactivated and hidden controls until it finds the next focusable control in the window. If it does not find a focusable item, it simply returns.

When `AdvanceKeyboardFocus` is called, the Control Manager calls your control definition function and passes `kControlMsgFocus` in its `message` parameter and `kControlFocusNextPart` in its `param` parameter. In response to this message, your control definition function should change keyboard focus to its next part, the entire control, or remove keyboard focus from the control, depending upon the circumstances. See `ControlDefProcPtr` (page 677) for a discussion of possible responses to this message.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Controls.h`

AutoEmbedControl

Automatically embeds a control in the smallest appropriate embedder control.

```
OSErr AutoEmbedControl (
   ControlRef inControl,
   WindowRef inWindow
);
```

Parameters

inControl
A handle to the control to be embedded.

inWindow
A pointer to the window in which to embed the control.

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Discussion
The Dialog Manager uses `AutoEmbedControl` (page 536) to position dialog items in an embedding hierarchy based on both visual containment and the item list resource order. As items are added to a dialog box during creation, controls that already exist in the window will be containers for new controls if they both visually contain the control and have set the `kControlSupportsEmbedding` feature bit. For this reason, you should place the largest embedder controls at the beginning of the item list resource. As an example, the Dialog Manager would embed radio buttons in a tab control if they visually "fit" inside the tab control, as long as the tab control was already created in a `'DITL'` resource and established as an embedder control. For more information on embedding hierarchies in dialog and alert boxes, see the function `EmbedControl` (page 583).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Controls.h`

ChangeControlPropertyAttributes

Changes a property attribute.

```
OSStatus ChangeControlPropertyAttributes (
   ControlRef control,
   OSType propertyCreator,
   OSType propertyTag,
   OptionBits attributesToSet,
   OptionBits attributesToClear
);
```

Parameters

control

The control whose property's attributes you want to change. For a description of this data type, see ControlRef (page 709).

propertyCreator

An OSType signature, usually the signature of your application. Do not use all lower case signatures, as these are reserved for use by Apple.

propertyTag

An OSType signature, defined by your application, defining the property whose attributes you want to change.

attributesToSet

A bit field indicating the attributes you want to set for this property.

attributesToClear

A bit field indicating the attributes you want to clear for this property.

Return Value

A result code. See "Control Manager Result Codes" (page 824).

Discussion

If you have associated control properties with a control (by calling `SetControlProperty` (page 658), you can also assign arbitrary attribute bits to the property. You can use these attributes to indicate information about the property data.

Currently, `kControlPropertyPersistent` is the only control property attribute that is defined.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Controls.h`

ClearKeyboardFocus

Removes the keyboard focus for the currently focused control in a window.

```
OSErr ClearKeyboardFocus (
   WindowRef inWindow
);
```

Parameters

inWindow

A pointer to the window in which to clear keyboard focus.

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Discussion
When the `ClearKeyboardFocus` function is called, the Control Manager calls your control definition function and passes `kControlMsgFocus` in its `message` parameter and `kControlFocusNoPart` in its `param` parameter. See `ControlDefProcPtr` (page 677) for a discussion of possible responses to this message.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Controls.h`

CopyControlTitleAsCFString

Makes a copy of the control's title as a Core Foundation string.

```
OSStatus CopyControlTitleAsCFString (
   ControlRef inControl,
   CFStringRef *outString
);
```

Parameters

inControl

The control whose title is to be copied. For a description of this data type, see ControlRef (page 709).

outString

A copy of the control's title.

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Controls.h`

CountSubControls

Obtains the number of embedded controls within a control.

```
OSErr CountSubControls (
   ControlRef inControl,
   UInt16 *outNumChildren
);
```

Parameters

inControl

The control whose embedded controls are to be counted. For a description of this data type, see ControlRef (page 709).

outNumChildren

On input, a pointer to an unsigned 16-bit integer value. On return, the value is set to the number of embedded subcontrols.

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Discussion
The `CountSubControls` function is useful for iterating over the control hierarchy. You can use the count produced to determine how many subcontrols there are and then call `GetIndexedSubControl` (page 608) to get each.

Availability
Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Related Sample Code
HID Calibrator

Declared In
`Controls.h`

CreateBevelButtonControl

Creates a bevel button control.

```
OSStatus CreateBevelButtonControl (
   WindowRef window,
   const Rect *boundsRect,
   CFStringRef title,
   ControlBevelThickness thickness,
   ControlBevelButtonBehavior behavior,
   ControlButtonContentInfoPtr info,
   MenuID menuID,
   ControlBevelButtonMenuBehavior menuBehavior,
   ControlBevelButtonMenuPlacement menuPlacement,
   ControlRef *outControl
);
```

Parameters

window

The window that is to contain the control. This parameter may be `NULL` in Mac OS X v10.3 and later.

boundsRect

The bounds of the desired control in the window's local coordinates.

title
The title of the control.

thickness
The thickness of the button. For possible values, see "Control Bevel Thickness Constants" (page 753).

behavior
The behavior the button is to have. For possible values, see "Bevel Button Behavior Constants" (page 721).

info
A value of type `ControlButtonContentInfoPtr` for the content information.

menuID
The menu ID. This parameter may be 0 if you don't have a menu. Icon suite, picture, color icon, and `IconRef` are supported on Mac OS X v10.0 through Mac OS X v10.4. Values of type `CGImageRef` are supported in Mac OS X v10.4.

menuBehavior
The behavior of the menu. For possible values, see "Bevel Button Menu Constant" (page 727).

menuPlacement
The placement of the menu. For possible values, see "Control Bevel Button Menu Placement Constants" (page 753).

outControl
On return, `outControl` points to the new control. For a description of this data type, see ControlRef (page 709).

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`HIButtonViews.h`

CreateChasingArrowsControl

Creates a chasing arrows control.

```
OSStatus CreateChasingArrowsControl (
   WindowRef window,
   const Rect *boundsRect,
   ControlRef *outControl
);
```

Parameters

window
The window that is to contain the control. This parameter may be `NULL` in Mac OS X v10.3 and later.

boundsRect
The bounds of the desired control in the window's local coordinates.

outControl
On return, `outControl` points to the new control. For a description of this data type, see ControlRef (page 709).

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Discussion
This control automatically animates via an event loop timer.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`HIProgressViews.h`

CreateCheckBoxControl

Creates a checkbox control.

```
OSStatus CreateCheckBoxControl (
   WindowRef window,
   const Rect *boundsRect,
   CFStringRef title,
   SInt32 initialValue,
   Boolean autoToggle,
   ControlRef *outControl
);
```

Parameters

window
The window that is to contain the checkbox control. This parameter may be `NULL` in Mac OS X v10.3 and later.

boundsRect
The bounds of the desired checkbox in the window's local coordinates.

title
The title of the checkbox.

initialValue
The initial setting of the checkbox. Set to a non-zero value to indicate the checked state.

autoToggle
If set to `true`, clicking the checkbox will automatically toggle its state (checked or unchecked).

outControl
On return, `outControl` points to the new checkbox. For a description of this data type, see ControlRef (page 709).

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`HIButtonViews.h`

CreateCheckGroupBoxControl

Creates a group box control that has a check box as its title.

```
OSStatus CreateCheckGroupBoxControl (
   WindowRef window,
   const Rect *boundsRect,
   CFStringRef title,
   SInt32 initialValue,
   Boolean primary,
   Boolean autoToggle,
   ControlRef *outControl
);
```

Parameters

window

The window in which the control is to be placed. This parameter may be `NULL` in Mac OS X v10.3 and later.

boundsRect

The bounds of the control in the window's local coordinates.

title

The title of the control. The title is used as the title of the check box.

initialValue

The initial value of the check box.

primary

A Boolean whose value is `true` to create a primary group box or `false` to create a secondary group box.

autoToggle

A Boolean whose value is true to create an auto-toggling check box. Auto-toggling check box titles are only supported on Mac OS X; this parameter must be `false` when used with CarbonLib.

outControl

On return, the new control. For a description of this data type, see ControlRef (page 709).

Return Value

A result code. See "Control Manager Result Codes" (page 824).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`HIContainerViews.h`

CreateClockControl

Creates a clock control.

```
OSStatus CreateClockControl (
   WindowRef window,
   const Rect *boundsRect,
   ControlClockType clockType,
   ControlClockFlags clockFlags,
   ControlRef *outControl
);
```

Parameters

window

The window that is to contain the control. This parameter may be `NULL` in Mac OS X v10.3 and later.

boundsRect

The bounds of the desired control in the window's local coordinates.

clockType

The clock type. For possible values, see "Control Clock Type Constants" (page 753).

clockFlags

Clock options. For possible values, see "Clock Value Flag Constants" (page 734).

outControl

On return, `outControl` points to the new control. For a description of this data type, see ControlRef (page 709).

Return Value

A result code. See "Control Manager Result Codes" (page 824).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`HIClockView.h`

CreateCustomControl

Creates a custom control. (Deprecated in Mac OS X v10.5. Register your custom subclass of the HIView class and create an instance of your class using `HIObjectCreate`.)

```
OSStatus CreateCustomControl (
   WindowRef owningWindow,
   const Rect *contBounds,
   const ControlDefSpec *def,
   Collection initData,
   ControlRef *outControl
);
```

Parameters

owningWindow

The window that is to contain the control. This parameter may be `NULL` in Mac OS X v10.3 and later.

contBounds

The bounds of the new control in the window's local coordinates.

def

A pointer to the control definition function you want to associate with the new control.

initData
The initial state of the control. For additional information, see "Control Collection Tag Constants" (page 768).

outControl
On return, `outControl` points to the new control.

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Controls.h`

CreateDisclosureButtonControl

Creates a new instance of the Disclosure Button Control.

```
OSStatus CreateDisclosureButtonControl (
   WindowRef inWindow,
   const Rect *inBoundsRect,
   SInt32 inValue,
   Boolean inAutoToggles,
   ControlRef *outControl
);
```

Parameters

inWindow
The `WindowRef` in which to create the control. This parameter may be `NULL` in Mac OS X v10.3 and later.

inBoundsRect
The bounding rectangle for the control in the window's local coordinates. The height of the control is fixed and the control will be centered vertically within the rectangle you specify.

inValue
The initial value; either `kControlDisclosureButtonClosed` or `kControlDisclosureButtonDisclosed`.

inAutoToggles
A Boolean value indicating whether its value should change automatically after tracking the mouse.

outControl
On successful exit, this will contain the new control. For a description of this data type, see ControlRef (page 709).

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Discussion
`CreateDisclosureButtonControl` is preferred over `NewControl` (page 634) because it allows you to specify the exact set of parameters required to create the control without overloading parameter semantics. The initial minimum of the Disclosure Button will be `kControlDisclosureButtonClosed`, and the maximum will be `kControlDisclosureButtonDisclosed`.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDisclosureViews.h`

CreateDisclosureTriangleControl

Creates a disclosure triangle control.

```
OSStatus CreateDisclosureTriangleControl (
   WindowRef inWindow,
   const Rect *inBoundsRect,
   ControlDisclosureTriangleOrientation inOrientation,
   CFStringRef inTitle,
   SInt32 inInitialValue,
   Boolean inDrawTitle,
   Boolean inAutoToggles,
   ControlRef *outControl
);
```

Parameters

window
The window that is to contain the control. This parameter may be `NULL` in Mac OS X v10.3 and later.

inBoundsRect
The desired position, in the window's local coordinates, for the disclosure triangle.

inOrientation
The direction the disclosure triangle should point when it is "closed." Passing `kControlDisclosureTrianglePointDefault` is only legal as of Mac OS X and CarbonLib 1.5. For other possible values, see "Control Disclosure Triangle Orientation Constants" (page 753).

inTitle
The title for the disclosure triangle. The title is displayed only if the value of the `inDrawTitle` parameter is `true`. Displaying the title only works on Mac OS X.

inInitialValue
The initial state of the disclosure triangle. A value of `0` causes the disclosure triangle to be drawn initially in the "closed" state, and a value of `1` causes the triangle to be drawn initially in the "open" state.

inDrawTitle
A Boolean whose value is true if the disclosure triangle should draw its title next to the widget. Displaying the title only works on Mac OS X.

inAutoToggles
A Boolean whose value is `true` to enable auto toggling; otherwise, `false`. When auto toggling is enabled, the disclosure triangle automatically changes from "open" to "closed" and from "closed" to "open" when it is clicked.

outControl

On return, `outControl` points to the new control. For a description of this data type, see ControlRef (page 709).

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Discussion
A disclosure triangle is a small control that gives the user a way to toggle the visibility of information or other user interface. When information is in a hidden state, a disclosure triangle is considered "closed" and should point to the right (or sometimes to the left). When the user clicks it, a disclosure triangle rotates downwards into the "open" state. The application should respond by revealing the appropriate information or interface.

On Mac OS X, a root control is created for the window if one does not already exist. If a root control exists for the window, the disclosure triangle control is embedded in it.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`HIDisclosureViews.h`

CreateEditTextControl

Creates a new edit text control. (Deprecated in Mac OS X v10.4. Use `CreateEditUnicodeTextControl` (page 547) instead.)

```
OSStatus CreateEditTextControl (
   WindowRef window,
   const Rect *boundsRect,
   CFStringRef text,
   Boolean isPassword,
   Boolean useInlineInput,
   const ControlFontStyleRec *style,
   ControlRef *outControl
);
```

Parameters

window

The window in which the control is to be placed. May be `NULL` in Mac OS X v10.3 and later.

boundsRect

The bounds of the control in the window's local coordinates.

text

The text of the control. May be `NULL`.

isPassword

A Boolean indicating whether the field is to be used as a password field. Passing `false` indicates that the field is to display entered text normally. Passing `true` means that the field is to be used as a password field; any text typed into the field is displayed as bullets.

useInlineInput

A Boolean indicating whether the control is to accept inline input. Pass `true` to accept inline input; otherwise pass `false`.

style
The control's font style, size, color, and so on. May be `NULL`.

outControl
On return, the new control.

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`ControlDefinitions.h`

CreateEditUnicodeTextControl

Creates a new edit text control.

```
OSStatus CreateEditUnicodeTextControl (
   WindowRef window,
   const Rect *boundsRect,
   CFStringRef text,
   Boolean isPassword,
   const ControlFontStyleRec *style,
   ControlRef *outControl
);
```

Parameters

window
The window in which the control is to be placed. This parameter may be `NULL` in Mac OS X v10.3 and later.

boundsRect
The bounds of the control in the window's local coordinates.

text
The text of the control. May be `NULL`.

isPassword
A Boolean indicating whether the field is to be used as a password field. Passing `false` indicates that text entered in the field is to be displayed normally. Passing `true` means that the field is to be used as a password field; any text typed into the field is displayed as bullets.

style
The control's font style, size, color, and so on. May be `NULL`.

outControl
On return, the new control. For a description of this data type, see ControlRef (page 709).

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Discussion
This function is the preferred way of creating edit text controls. Use it instead of the `CreateEditTextControl` (page 546) function. The resulting control handles Unicode text and draws its text using anti-aliasing. Controls created by `CreateEditTextControl` do not handle Unicode text and are not drawn with anti-aliasing.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`HITextViews.h`

CreateGroupBoxControl

Creates a group box control.

```
OSStatus CreateGroupBoxControl (
   WindowRef window,
   const Rect *boundsRect,
   CFStringRef title,
   Boolean primary,
   ControlRef *outControl
);
```

Parameters

window
The window that is to contain the control. This parameter may be `NULL` in Mac OS X v10.3 and later.

boundsRect
The bounds of the desired control in the window's local coordinates.

title
The title of the control. This parameter can be `NULL` if you don't want the control to have a title.

primary
A Boolean whose value is `true` to create a primary group box or `false` to create a secondary group box. Secondary group boxes are intended to be contained within primary group boxes and have a slightly different appearance.

outControl
On return, `outControl` points to the new control. For a description of this data type, see ControlRef (page 709).

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`HIContainerViews.h`

CreateIconControl

Creates an icon control.

```
OSStatus CreateIconControl (
   WindowRef inWindow,
   const Rect *inBoundsRect,
   const ControlButtonContentInfo *inIconContent,
   Boolean inDontTrack,
   ControlRef *outControl
);
```

Parameters

inWindow

The window in which the control is to be placed. This parameter may be `NULL` in Mac OS X v10.3 and later.

inBoundsRect

The bounds of the control in the window's local coordinates.

inIconContent

The descriptor for the icon you want the control to display. Mac OS X and CarbonLib 1.5 (and beyond) support all of the icon content types. Prior to CarbonLib 1.5, the only content types that are properly respected are `kControlContentIconSuiteRes`, `kControlContentCIconRes`, and `kControlContentICONRes`.

inDontTrack

A Boolean whose value is `true` to indicate that the control should not be highlighted when it is clicked; `false` means that the control should be highlighted and the mouse tracked when the control is clicked.

outControl

On return, the new control. For a description of this data type, see ControlRef (page 709).

Return Value

A result code. See "Control Manager Result Codes" (page 824).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`HIImageViews.h`

CreateImageWellControl

Creates an image well control.

```
OSStatus CreateImageWellControl (
   WindowRef window,
   const Rect *boundsRect,
   const ControlButtonContentInfo *info,
   ControlRef *outControl
);
```

Parameters

window

The window that is to contain the control. This parameter may be `NULL` in Mac OS X v10.3 and later.

boundsRect

The bounds of the control in the window's local coordinates.

info

The image that is to be displayed in the image well. The image can be an icon suite, picture, color icon, or an `IconRef` in Mac OS X v10.0 and later. It can be also be a `CGImageRef` in Mac OS X v10.4 and later.

outControl

On return, `outControl` points to the new control. For a description of this data type, see ControlRef (page 709).

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Discussion
An image well control is a control that displays an image inside a frame (or "well"). The user can drag other images onto the well.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`HIImageViews.h`

CreateListBoxControl

Creates a list box control.

```
OSStatus CreateListBoxControl (
   WindowRef window,
   const Rect *boundsRect,
   Boolean autoSize,
   SInt16 numRows,
   SInt16 numColumns,
   Boolean horizScroll,
   Boolean vertScroll,
   SInt16 cellHeight,
   SInt16 cellWidth,
   Boolean hasGrowSpace,
   const ListDefSpec *listDef,
   ControlRef *outControl
);
```

Parameters

window

The window that is to contain the control. This parameter may be `NULL` in Mac OS X v10.3 and later.

boundsRect

The bounds of the control in the window's local coordinates.

autoSize

A Boolean whose value is `true` to enable auto-sizing; otherwise, `false`. When auto-sizing is enabled, the control automatically resizes itself as necessary to ensure that the height of the control is an exact multiple of the cell height.

numRows

The number of rows the control is to have.

numColumns

The number of columns the control is to have.

horizScroll

A Boolean whose value is `true` if the control is to have a horizontal scroll bar; otherwise, `false`.

vertScroll

A Boolean whose value is `true` if the control is to have a vertical scroll bar; otherwise, `false`.

cellHeight

The height of cells in the control.

cellWidth

The width of cells in the control.

hasGrowSpace

A Boolean whose value is `true` to indicate that the control is drawn so that there is room for a size box; otherwise, `false`.

listDef

A pointer to the list definition function you want to associate with the new control. This parameter may be `NULL` if you want to use the standard list definition function, which only displays text.

outControl

On return, `outControl` points to the new control. For a description of this data type, see ControlRef (page 709).

Return Value

A result code. See "Control Manager Result Codes" (page 824).

Discussion
The list is created with default values, and uses the standard LDEF (0) if you don't specify a custom list definition function in the `listDef` parameter. You can set the LDEF to use by using `kControlListBoxLDEFTag`. You can change the list by getting the list handle. To get the list handle, call `GetControlData` (page 594) and pass the `kControlListBoxListHandletag` constant.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ControlDefinitions.h`

CreateLittleArrowsControl

Creates a little arrows control.

```
OSStatus CreateLittleArrowsControl (
   WindowRef window,
   const Rect *boundsRect,
   SInt32 value,
   SInt32 minimum,
   SInt32 maximum,
   SInt32 increment,
   ControlRef *outControl
);
```

Parameters

window
The window that is to contain the control. This parameter may be `NULL` in Mac OS X v10.3 and later.

boundsRect
The bounds of the control in the window's local coordinates.

value
The initial value of the control.

minimum
The minimum value the control can have.

maximum
The maximum value the control can have.

increment
The amount to increment each time an arrow is clicked.

outControl
On return, `outControl` points to the new control. For a description of this data type, see ControlRef (page 709).

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Discussion
This control implements the little up and down arrows seen in the Date & Time system preferences panel. To change the value of this control, you need to create a control action proc. The following sample code creates the control and sets the action proc:

```
CreateLittleArrowsControl(&rect, minimum, maximum, increment,  value);
SetControlAction(Arrows, LittleArrowActionProc);
```

Here is sample code for the action proc:

```
void LittleArrowActionProc(ControlRef cref, ControlPartCode part)  {
    SInt32 val = GetControl32BitValue(cref);
    SInt32 s = 0;
   GetControlData(cref, 0, kControlLittleArrowsIncrementValueTag, sizeof(SInt32),
 &s, nil;
    switch (part) {
        case kControlUpButtonPart:
            SetControl32BitValue(cref, val+s);
            break;
        case kControlDownButtonPart:
            SetControl32BitValue(cref, val-s);
            break;
        };
    };
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`HILittleArrows.h`

CreatePictureControl

Creates a picture control.

```
OSStatus CreatePictureControl (
   WindowRef window,
   const Rect *boundsRect,
   const ControlButtonContentInfo *content,
   Boolean dontTrack,
   ControlRef *outControl
);
```

Parameters

window
The window in which the control is to be placed. This parameter may be `NULL` in Mac OS X v10.3 and later.

boundsRect
The bounds of the control in the window's local coordinates.

content
The descriptor for the picture you want the control to display. Only picture content is supported. You can change the picture by calling `SetControlData` (page 652) and passing the `kControlPictureHandleTag` constant.

dontTrack
A Boolean whose value is `true` to indicate that the control should not be highlighted when it is clicked; `false` means that the control should be highlighted and the mouse tracked when the control is clicked.

outControl
On return, the new control.

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`ControlDefinitions.h`

CreatePlacardControl

Creates a placard control.

```
OSStatus CreatePlacardControl (
   WindowRef window,
   const Rect *boundsRect,
   ControlRef *outControl
);
```

Parameters

window
The window that is to contain the control. This parameter may be `NULL` in Mac OS X v10.3 and later.

boundsRect
The bounding box of the control in the window's local coordinates.

outControl
On return, the new control. For a description of this data type, see ControlRef (page 709).

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`HIContainerViews.h`

CreatePopupArrowControl

Creates a pop-up arrow control.

```
OSStatus CreatePopupArrowControl (
   WindowRef window,
   const Rect *boundsRect,
   ControlPopupArrowOrientation orientation,
   ControlPopupArrowSize size,
   ControlRef *outControl
);
```

Parameters

window

The window that is to contain the control. This parameter may be `NULL` in Mac OS X v10.3 and later.

boundsRect

The bounds of the control in the window's local coordinates.

orientation

The orientation of the control.

size

The size of the control.

outControl

On return, the new control. For a description of this data type, see ControlRef (page 709).

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`HIPopupButton.h`

CreatePopupButtonControl

Creates a pop-up button control.

```
OSStatus CreatePopupButtonControl (
   WindowRef window,
   const Rect *boundsRect,
   CFStringRef title,
   MenuID menuID,
   Boolean variableWidth,
   SInt16 titleWidth,
   SInt16 titleJustification,
   Style titleStyle,
   ControlRef *outControl
);
```

Parameters

window

The window in which the control is to be placed. This parameter may be `NULL` in Mac OS X v10.3 and later.

boundsRect

The bounds of the control in the window's local coordinates.

title
The title of the control.

menuID
The ID of a menu that should be used by the control. A menu with this ID should be inserted into the menubar with `InsertMenu(menu, kInsertHierarchicalMenu)`. You can also pass `-12345` to have the control delay its acquisition of a menu; in this case, you can build the menu and later provide it to the control with `SetControlData` and `kControlPopupButtonMenuRefTag` or `kControlPopupButtonOwnedMenuRefTag`.

variableWidth
A Boolean whose value indicates whether the width of the control is allowed to vary according to the width of the selected menu item text (`true`), or should remain fixed to the original control bounds width (`false`).

titleWidth
The width of the title.

titleJustification
The justification of the title. Use a TextEdit justification constant (`teFlushDefault`, `teCenter`, `teFlushRight`, or `teFlushLeft`).

titleStyle
A QuickDraw style bitfield indicating the font style of the title.

outControl
On return, the new control. For a description of this data type, see ControlRef (page 709).

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`HIPopupButton.h`

CreatePopupGroupBoxControl

Creates a group box control that has a pop-up button as its title.

```
OSStatus CreatePopupGroupBoxControl (
   WindowRef window,
   const Rect *boundsRect,
   CFStringRef title,
   Boolean primary,
   MenuID menuID,
   Boolean variableWidth,
   SInt16 titleWidth,
   SInt16 titleJustification,
   Style titleStyle,
   ControlRef *outControl
);
```

Parameters

window

The window that is to contain the control. This parameter may be `NULL` in Mac OS X v10.3 and later.

boundsRect

The bounds of the control in the window's local coordinates.

title

The title of the control. The title is used as the title of the pop-up button.

primary

A Boolean whose value is `true` to create a primary group box or `false` to create a secondary group box.

menuID

The menu ID of the menu that is to be displayed by the pop-up button. A menu with this ID should be inserted into the menubar with `InsertMenu(menu, kInsertHierarchicalMenu)`. You can also pass `-12345` to have the control delay its acquisition of a menu; in this case, you can build the menu and later provide it to the control with `SetControlData` and `kControlPopupButtonMenuRefTag` or `kControlPopupButtonOwnedMenuRefTag`.

variableWidth

A Boolean whose value is `true` if the pop-up button is to have a variable-width title or `false` if the pop-up button is to have a fixed-width title. Fixed-width titles are only supported by Mac OS X; this parameter must be `true` when used with CarbonLib.

titleWidth

The width in pixels of the pop-up button title.

titleJustification

The justification of the pop-up button title. Use a TextEdit justification constant (`teFlushDefault`, `teCenter`, `teFlushRight`, or `teFlushLeft`).

titleStyle

The QuickDraw text style of the pop-up button title.

outControl

On return, `outControl` points to the new control. For a description of this data type, see ControlRef (page 709).

Return Value

A result code. See "Control Manager Result Codes" (page 824).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In
HIContainerViews.h

CreateProgressBarControl

Creates a progress bar control.

```
OSStatus CreateProgressBarControl (
   WindowRef window,
   const Rect *boundsRect,
   SInt32 value,
   SInt32 minimum,
   SInt32 maximum,
   Boolean indeterminate,
   ControlRef *outControl
);
```

Parameters

window
The window that is to contain the control. This parameter may be `NULL` in Mac OS X v10.3 and later.

boundsRect
The bounds of the control in the window's local coordinates.

value
The initial value of the control.

minimum
The minimum value of the control.

maximum
The maximum value of the control.

indeterminate
A Boolean whose value is `true` if you want the control to display a rotating barber pole effect to indicate that something is happening (an indeterminate progress bar) or `false` if you want to display a determinate progress bar that uses the values of the `minimum` and `maximum` parameters to show progress from minimum to maximum.

outControl
On return, `outControl` points to the new control. For a description of this data type, see ControlRef (page 709).

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
HIProgressViews.h

CreatePushButtonControl

Creates a push button control.

```
OSStatus CreatePushButtonControl (
   WindowRef window,
   const Rect *boundsRect,
   CFStringRef title,
   ControlRef *outControl
);
```

Parameters

window

The window in which the control is to be placed. This parameter may be `NULL` in Mac OS X v10.3 and later.

boundsRect

The bounds of the control in the window's local coordinates.

title

The control title. May be `NULL`.

outControl

On return, the new control. For a description of this data type, see ControlRef (page 709).

Return Value

A result code. See "Control Manager Result Codes" (page 824).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`HIButtonViews.h`

CreatePushButtonWithIconControl

Creates a push button control containing an icon or other graphical content.

```
OSStatus CreatePushButtonWithIconControl (
   WindowRef window,
   const Rect *boundsRect,
   CFStringRef title,
   ControlButtonContentInfo *icon,
   ControlPushButtonIconAlignment iconAlignment,
   ControlRef *outControl
);
```

Parameters

window

The window in which the control is to be placed. This parameter may be `NULL` in Mac OS X v10.3 and later.

boundsRect

The bounds of the control, in local coordinates of the window.

title

The control title. May be `NULL`.

icon

The control graphic content. The value of this parameter can be `kControlContentCIconRes` in Mac OS X v10.0 and later. It can also be `kControlContentCGImageRef` in Mac OS X v10.4 and later.

iconAlignment
The alignment of the control graphic content.For possible values, see "Control Push Button Icon Alignment Constants" (page 753).

outControl
On return, the new control. For a description of this data type, see ControlRef (page 709).

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`HIButtonViews.h`

CreateRadioButtonControl

Creates a radio button control.

```
OSStatus CreateRadioButtonControl (
   WindowRef window,
   const Rect *boundsRect,
   CFStringRef title,
   SInt32 initialValue,
   Boolean autoToggle,
   ControlRef *outControl
);
```

Parameters

window
The window in which the control is to be placed. This parameter may be `NULL` in Mac OS X v10.3 and later.

boundsRect
The bounds of the control in the window's local coordinates.

title
The control title. May be `NULL`.

initialValue
The initial value of the control. Should be `0` (off), `1` (on), or `2` (mixed). The control is automatically given a minimum value of 0 and a maximum value of 2.

autoToggle
A Boolean whose value indicates whether this control should have auto-toggle behavior. If `true`, the control automatically toggles between on and off states when clicked. This parameter should be `false` if the control is embedded into a radio group control; in that case, the radio group handles setting the correct control value in response to a click.

outControl
On return, the new control.

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
HIButtonViews.h

CreateRadioGroupControl

Creates a radio group control.

```
OSStatus CreateRadioGroupControl (
   WindowRef window,
   const Rect *boundsRect,
   ControlRef *outControl
);
```

Parameters

window
The window that is to contain the control. This parameter may be NULL in Mac OS X v10.3 and later.

boundsRect
The bounds of the control in the window's local coordinates.

outControl
On return, outControl points to the new control. For a description of this data type, see ControlRef (page 709).

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Discussion
This control implements a radio group. It is an embedding control and can therefore only be used when a control hierarchy is established for its owning window. You should only embed radio buttons within it. As radio buttons are embedded into it, the group sets up its value, min, and max to represent the number of embedded items. The current value of the control is the index of the sub-control that is the current "on" radio button. To get the current radio button control handle, you can use the Control Manager call GetIndexedSubControl (page 608), passing in the value of the radio group.

Note that when creating radio buttons for use in a radio group control, you should not use the auto-toggle version of the radio button. The radio group control handles toggling the radio button values itself; auto-toggle radio buttons do not work properly in a radio group control on Mac OS 9.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
HIButtonViews.h

CreateRelevanceBarControl

Creates a relevance bar control.

```
OSStatus CreateRelevanceBarControl (
   WindowRef window,
   const Rect *boundsRect,
   SInt32 value,
   SInt32 minimum,
   SInt32 maximum,
   ControlRef *outControl
);
```

Parameters

window

The window that is to contain the control. This parameter may be `NULL` in Mac OS X v10.3 and later.

boundsRect

The bounds of the control in the window's local coordinates.

value

The initial value of the control.

minimum

The minimum value of the control.

maximum

The maximum value of the control.

outControl

On return, `outControl` points to the new control. For a description of this data type, see ControlRef (page 709).

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`HIRelevanceBar.h`

CreateRootControl

Creates the root control for a specified window.

```
OSErr CreateRootControl (
   WindowRef inWindow,
   ControlRef *outControl
);
```

Parameters

inWindow

A pointer to the window in which you wish to create a root control.

outControl

On input, a pointer to a `ControlHandle` value. On return, the `ControlHandle` value is set to a handle to the root control.

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Discussion
Establishing an embedding hierarchy can be accomplished in two steps: creating a root control and embedding controls within it.

To embed controls in a window, you must create a root control for that window. The root control is the container for all other window controls. You create the root control in one of two ways—by calling the `CreateRootControl` function or by setting the appropriate dialog flag. The root control can be retrieved by calling the function `GetRootControl` (page 611).

The `CreateRootControl` function creates the root control for a window if no other controls are present. If there are any controls in the window prior to calling `CreateRootControl`, an error is returned and the root control is not created. Note that the minimum, maximum, and initial settings for a root control are reserved and should not be changed.

The root control is implemented as a user pane control. You can attach any application-defined user pane functions to the root control to perform actions such as hit testing, drawing, handling keyboard focus, erasing to the correct background, and processing idle and keyboard events.

Once you have created a root control, newly created controls will automatically be embedded in the root control when you call `NewControl` (page 634) or `GetNewControl` (page 610). You can specify that a specific control be embedded into another by calling `EmbedControl` (page 583).

By acting on an embedder control, you can move, disable, or hide groups of items. For example, you can use a blank user pane control as the embedder control for all items in a particular "page" of a tab control. After creating as many user panes as you have tabs, you can hide one and show the next when a tab is clicked. All the controls embedded in the user pane will be hidden and shown automatically when the user pane is hidden and shown.

In addition to calling `CreateRootControl`, you can establish an embedding hierarchy in a dialog box by either setting the feature bit `kDialogFlagsUseControlHierarchy` in the extended dialog resource or passing it in the `inFlags` parameter of the Dialog Manager function `NewFeaturesDialog`. An embedding hierarchy can be created in an alert box by setting the `kAlertFlagsUseControlHierarchy` bit in the extended alert resource. It is important to note that a preexisting alert or dialog item will become a control if it is in an alert or dialog box that now uses an embedding hierarchy.

The embedding hierarchy enforces drawing order by drawing the embedding control before its embedded controls. Using an embedding hierarchy also enforces orderly hit-testing, since it performs an "inside-out" hit test to determine the most deeply nested control that is hit by the mouse. An embedding hierarchy is also necessary for controls to make use of keyboard focus, the default focusing order for which is a linear progression that uses the order the controls were added to the window. For more details on keyboard focus, see "Handling Keyboard Focus".

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

QTCarbonShell

Declared In
`Controls.h`

CreateRoundButtonControl

Creates a new instance of the round button control.

```
OSStatus CreateRoundButtonControl (
   WindowRef inWindow,
   const Rect *inBoundsRect,
   ControlRoundButtonSize inSize,
   ControlButtonContentInfo *inContent,
   ControlRef *outControl
);
```

Parameters

inWindow

The `WindowRef` in which to create the control.

inBoundsRect

The bounds of the control in the window's local coordinates. The height and width of the control are fixed (specified by the `ControlRoundButtonSize` parameter) and the control will be centered within the rectangle you specify.

inSize

The button size; either `kControlRoundButtonNormalSize` or `kControlRoundButtonLargeSize`.

inContent

Any optional content displayed in the button. In Mac OS X v10.0 and later, `kControlContentIconRef` is supported.

outControl

On return, the new control. For a description of this data type, see ControlRef (page 709).

Return Value

A result code. See "Control Manager Result Codes" (page 824).

Discussion

`CreateRoundButtonControl` is preferred over `NewControl` (page 634) because it allows you to specify the exact set of parameters required to create the control without overloading parameter semantics.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`HIButtonViews.h`

CreateScrollBarControl

Creates a scroll bar control.

```
OSStatus CreateScrollBarControl (
   WindowRef window,
   const Rect *boundsRect,
   SInt32 value,
   SInt32 minimum,
   SInt32 maximum,
   SInt32 viewSize,
   Boolean liveTracking,
   ControlActionUPP liveTrackingProc,
   ControlRef *outControl
);
```

Parameters

window

The window in which the control is to be placed. This parameter may be `NULL` in Mac OS X v10.3 and later.

boundsRect

The bounds of the control in the window's local coordinates.

value

The initial value of the control.

minimum

The minimum value of the control.

maximum

The maximum value of the control.

viewSize

The size of the visible area of the scroll bar content. If this parameter is a non-zero value, this function creates a proportional scroll bar thumb; a value of `0` causes a non-proportional scroll bar thumb to be created.

liveTracking

A Boolean indicating whether or not live tracking is enabled for this scroll bar. If set to `true` and a valid `liveTrackingProc` is also passed in, the callback is called repeatedly as the thumb is moved during tracking. If set to `false`, a semi-transparent thumb called a "ghost thumb" draws and no live tracking occurs.

liveTrackingProc

If the value of the `liveTracking` parameter is `true`, a `ControlActionUPP` callback is to be called as the control live tracks. This callback is called repeatedly as the scroll thumb is moved during tracking.

outControl

On return, the new control. For a description of this data type, see ControlRef (page 709).

Return Value

A result code. See "Control Manager Result Codes" (page 824).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`HIScrollView.h`

CreateScrollingTextBoxControl

Creates a scrolling text box control.

```
OSStatus CreateScrollingTextBoxControl (
   WindowRef window,
   const Rect *boundsRect,
   SInt16 contentResID,
   Boolean autoScroll,
   UInt32 delayBeforeAutoScroll,
   UInt32 delayBetweenAutoScroll,
   UInt16 autoScrollAmount,
   ControlRef *outControl
);
```

Parameters

window
The window that is to contain the control. This parameter may be `NULL` in Mac OS X v10.3 and later.

boundsRect
The bounds of the control in the window's local coordinates.

contentResID
The resource ID of '`TEXT`' and (optionally) '`style`' resources whose contents are to be displayed.

autoScroll
A Boolean whose value is `true` to enable automatic scrolling; otherwise, `false`.

delayBeforeAutoScroll
The number of ticks to wait before scrolling automatically. This parameter is ignored and can be set to `0` if the value of the `autoScroll` parameter is `false`.

delayBetweenAutoScroll
The number of ticks to wait between automatic scrolls. This parameter is ignored and can be set to `0` if the value of the `autoScroll` parameter is `false`.

autoScrollAmount
The number of pixels to scroll. This parameter is ignored and can be set to `0` if the value of the `autoScroll` parameter is `false`.

outControl
On return, `outControl` points to the newly-created control.

Return Value

A result code. See "Control Manager Result Codes" (page 824).

Discussion

This control implements a scrolling box of text that cannot be edited. This is useful for credits in about boxes.

The standard version of this control has a scroll bar, but the autoscrolling variant does not. The autoscrolling variant needs two pieces of information to work: delay (in ticks) before the scrolling starts, and time (in ticks) between scrolls. This control scrolls one pixel at a time if created by `NewControl` (page 634), unless changed by calling `SetControlData` (page 652).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`ControlDefinitions.h`

CreateSeparatorControl

Creates a separator control.

```
OSStatus CreateSeparatorControl (
   WindowRef window,
   const Rect *boundsRect,
   ControlRef *outControl
);
```

Parameters

window

The window that is to contain the control. This parameter may be `NULL` in Mac OS X v10.3 and later.

boundsRect

The bounds of the control in the window's local coordinates.

outControl

On return, `outControl` points to the new control. For a description of this data type, see ControlRef (page 709).

Return Value

A result code. See "Control Manager Result Codes" (page 824).

Discussion

The horizontal or vertical orientation of a separator line is determined automatically based on the relative height and width of its control bounds.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`HISeparator.h`

CreateSliderControl

Creates a slider control.

```
OSStatus CreateSliderControl (
   WindowRef window,
   const Rect *boundsRect,
   SInt32 value,
   SInt32 minimum,
   SInt32 maximum,
   ControlSliderOrientation orientation,
   UInt16 numTickMarks,
   Boolean liveTracking,
   ControlActionUPP liveTrackingProc,
   ControlRef *outControl
);
```

Parameters

window

The window that is to contain the control. This parameter may be `NULL` in Mac OS X v10.3 and later.

boundsRect
The bounds of the control in the window's local coordinates.

value
The initial value of the control.

minimum
The minimum value of the control.

maximum
The maximum value of the control.

orientation
The orientation of the control. For possible values, see "Control Slider Orientation Constants" (page 754).

numTickMarks
The number of tick marks the slider control is to have.

liveTracking
A Boolean whose value is `true` to enable live tracking for the control; otherwise, `false`.

liveTrackingProc
If the value of the `liveTracking` parameter is `true`, a `ControlActionUPP` callback is to be called as the control live tracks. This callback is called repeatedly as the slider is moved during tracking.

outControl
On return, `outControl` points to the new control. For a description of this data type, see ControlRef (page 709).

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Discussion
Mac OS X has a "Scroll to here" option in the General pane of System Preferences that allows users to click in the page up or page down regions of a slider and have the indicator jump directly to the clicked position, which alters the value of the slider and moves any associated content appropriately. As long as the mouse button is held down, the click is treated as though the user clicked the indicator.

If you want the sliders in your application to work with the "Scroll to here" option, you must do the following:

1. Create live-tracking sliders, not sliders that show a "ghost" thumb when you click on it. You can request live-tracking sliders by passing `true` in the `liveTracking` parameter to `CreateSliderControl`. If you create sliders with `NewControl` (page 634), use the `kControlSliderLiveFeedback` variant.

2. Write an appropriate ControlActionProc and associate it with your slider by calling `SetControlAction` (page 649). This allows your application to update its content appropriately when the live-tracking slider is clicked.

3. When calling`HandleControlClick` (page 613) or `TrackControl` (page 671) TrackControl, pass -1 in the action proc parameter. This is a request for the Control Manager to use the action proc you associated with your control in step 2. If you rely on the standard window event handler to do your control tracking, this step is handled for you automatically.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
HISlider.h

CreateStaticTextControl

Creates a new static text control.

```
OSStatus CreateStaticTextControl (
   WindowRef window,
   const Rect *boundsRect,
   CFStringRef text,
   const ControlFontStyleRec *style,
   ControlRef *outControl
);
```

Parameters

window
The window in which the control is to be placed. This parameter may be NULL in Mac OS X v10.3 and later.

boundsRect
The bounds of the control in the window's local coordinates.

text
The text of the control. May be NULL.

style
The control's font style, size, color, and so on. May be NULL.

outControl
On return, the new control. For a description of this data type, see ControlRef (page 709).

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
HITextViews.h

CreateTabsControl

Creates a tabs control.

```
OSStatus CreateTabsControl (
   WindowRef window,
   const Rect *boundsRect,
   ControlTabSize size,
   ControlTabDirection direction,
   UInt16 numTabs,
   const ControlTabEntry *tabArray,
   ControlRef *outControl
);
```

Parameters

window

The window in which the control is to be placed. This parameter may be `NULL` in Mac OS X v10.3 and later.

boundsRect

The bounds of the control in the window's local coordinates.

size

The control tab size. See "`Control Tab Size Constants`" (page 754) for possible values.

direction

The control tab direction. See "`Control Tab Direction Constants`" (page 754) for possible values.

numTabs

The initial number of tabs.

tabArray

Information about each tab. There must be the same number of entries as specified by the `numTabs` parameter.

outControl

On return, the new control. For a description of this data type, see ControlRef (page 709).

Return Value

A result code. See "Control Manager Result Codes" (page 824).

Discussion

If you want to customize the accessibility information provided for individual tabs of a tabs control, such as by handling various `kEventClassAccessibility` Carbon Events and by calling `HIObjectSetAuxiliaryAccessibilityAttribute`, you need to know how to build or interpret AXUIElement reference that represent individual tabs. The AXUIElement representing an individual tab must be constructed using the tab control's `ControlRef` and the `UInt64` identifier of the one-based index of the tab to which the element refers. A `UInt64` identifier of 0 represents the tabs control as a whole. You cannot interpret or create tab control elements whose identifiers are greater than the count of tabs in the tabs control.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`HITabbedView.h`

CreateUserPaneControl

Creates a user pane control.

```
OSStatus CreateUserPaneControl (
   WindowRef window,
   const Rect *boundsRect,
   UInt32 features,
   ControlRef *outControl
);
```

Parameters

window

The window in which the control is to be placed. This parameter may be `NULL` in Mac OS X v10.3 and later.

boundsRect

The bounds of the control in the window's local coordinates.

features

The user pane features with which the user pane is to be created. For possible constants, see "Control Features Constants" (page 741).

outControl

On return, the new control. For a description of this data type, see ControlRef (page 709).

Return Value

A result code. See "Control Manager Result Codes" (page 824).

Discussion

User panes have two primary purposes: to allow easy implementation of a custom control by the developer, and to provide a generic container for embedding other controls.

In Carbon, with the advent of Carbon-event-based controls, you may find it easier to write a new control from scratch than to customize a user pane control. The set of callbacks provided by the user pane will not be extended to support new Control Manager features; instead, you should just write a real control.User panes do not, by default, support embedding. If you try to embed a control into a user pane, you will get the `errControlIsNotEmbedder`. You can make a user pane support embedding by passing the `kControlSupportsEmbedding` flag in the `features` parameter when you create the control.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`HIContainerViews.h`

CreateWindowHeaderControl

Creates a window header control.

```
OSStatus CreateWindowHeaderControl (
   WindowRef window,
   const Rect *boundsRect,
   Boolean isListHeader,
   ControlRef *outControl
);
```

Parameters

window

The window in which the control is to be placed. This parameter may be `NULL` in Mac OS X v10.3 and later.

boundsRect

The bounds of the control in the window's local coordinates.

isListHeader

A Boolean whose value is `true` if the control should have an appropriate appearance to be the header of a list; otherwise, `false`.

outControl

On return, the new control. For a description of this data type, see ControlRef (page 709).

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`HIContainerViews.h`

DeactivateControl

Deactivates a control and any latent embedded controls.

```
OSErr DeactivateControl (
   ControlRef inControl
);
```

Parameters

inControl

A handle to the control to deactivate. If you pass a window's root control, `DeactivateControl` deactivates all controls in that window.

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Discussion
The `DeactivateControl` function should be called instead of `HiliteControl` to deactivate a specified control and its latent embedded controls.

An embedded control is considered latent when it is deactivated or hidden due to its embedder control being deactivated or hidden. If you activate a latent embedded control whose embedder is deactivated, the embedded control becomes latent until the embedder is activated. However, if you deactivate a latent embedded control, it will not be activated when its embedder is activated.

If a control definition function supports activate events, it will receive a `kControlMsgActivate` message before redrawing itself in its inactive state.

DisposeControl

Decrements a control's reference count and destroys it if the reference count becomes 0.

```
void DisposeControl (
   ControlRef theControl
);
```

Parameters

theControl
The control you want to dispose of. For a description of this data type, see ControlRef (page 709).

Discussion
The `DisposeControl` function reduces the control's reference count and, if the reference count becomes 0, releases the memory occupied by the control structure and any data structures associated with the control. Before destroying the control, DisposeControl removes the control (and any embedded controls it may possess) from the screen and deletes the control from the window's control list.

To destroy all of the controls from a window you want to keep, use the function `KillControls` (page 632). If an embedding hierarchy is present, passing the root control to the `DisposeControl` function is the effectively the same as calling `KillControls` (page 632). In that situation, `DisposeControl` disposes of the controls embedded within a control before disposing of the container control.

You should use `DisposeControl` when you want to retain the window but remove one of its controls. The Window Manager functions `CloseWindow` and `DisposeWindow` automatically remove all controls associated with the window and release the memory the controls occupy.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

```

Parameters

userUPP
The UPP that is to be disposed of.

Availability
Available in Mac OS X v10.0 and later.

Declared In
HITextViews.h

DragControl

Draws and moves an outline of a control or its indicator while the user drags it. (**Deprecated.** Use Drag Manager functions if you want drag-and-drop support for controls. See *Drag Manager Reference*.)

Not recommended

```
void DragControl (
   ControlRef theControl,
   Point startPoint,
   const Rect *limitRect,
   const Rect *slopRect,
   DragConstraint axis
);
```

Parameters

theControl

A handle to the control to drag. For a description of this data type, see ControlRef (page 709).

startPoint

The location of the cursor at the time the mouse button was first pressed, in global coordinates. Your application retrieves this point from the `where` field of the event structure.

limitRect

A pointer to a rectangle—whose coordinates should normally coincide with or be contained in the window's content region—delimiting the area in which the user can drag the control's outline.

slopRect

A pointer to a rectangle that allows some extra space for the user to move the mouse while still constraining the control within the rectangle specified in the `limitRect` parameter.

axis

The axis along which the user may drag the control's outline. Specify the `axis` using one of the following values: `noConstraint` (no constraint), `hAxisOnly` (drag along horizontal axis only), `vAxisOnly` (drag along vertical axis only).

Discussion

The `DragControl` function moves a dotted outline of a control, such as a scroll box, around the screen, following the movements of the cursor until the user releases the mouse button. When the user releases the mouse button, `DragControl` moves the control to the new location.

The function `TrackControl` (page 671) automatically calls the `DragControl` function as appropriate; when you use `TrackControl`, you don't need to call `DragControl`.

Before tracking the cursor, `DragControl` calls the control definition function. If you define your own control definition function, you can specify custom dragging behavior.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Controls.h`

Draw1Control

Draws a control and any embedded controls that are currently visible in the specified window.

```
void Draw1Control (
   ControlRef theControl
);
```

Parameters

theControl

A handle to the control to draw. For a description of this data type, see ControlRef (page 709).

Discussion

Although you should generally use the functionUpdateControls (page 672) to update controls, you can use the DrawOneControl function to update a single control. If an embedding hierarchy exists and the control passed in has embedded controls, DrawOneControl draws the control and embedded controls. If the root control for a window is passed in, the result is the same as if DrawControls was called.

If you are using compositing mode, you generally do not need to call Draw1Control. If you call Draw1Control in compositing mode, keep in mind that it draws the specified control as well as all other controls that intersect the control.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

Controls.h

DrawControlInCurrentPort

Draws a control in the current graphics port.

```
void DrawControlInCurrentPort (
   ControlRef inControl
);
```

Parameters

inControl

A handle to the control to draw. For a description of this data type, see ControlRef (page 709).

Discussion

Typically, controls are automatically drawn in their owner's graphics port with the functions DrawControls (page 581), Draw1Control (page 580), and UpdateControls (page 672). DrawControlInCurrentPort permits easy offscreen control drawing and printing. All standard system controls support this function.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

Controls.h

DrawControls

Draws all controls currently visible in the specified window.

```
void DrawControls (
   WindowRef theWindow
);
```

Parameters

theWindow

A pointer to a window whose controls you want to display.

Discussion

Because the `UpdateControls` function redraws only those controls that need updating, your application should generally use it instead of `DrawControls` when you receive an update event for a window that contains controls. You should typically call either `DrawControls` or `UpdateControls` after calling the Window Manager function `BeginUpdate` and before calling `EndUpdate`.

While the Dialog Manager automatically draws and updates controls in alert boxes and dialog boxes, Window Manager functions such as `SelectWindow`, `ShowWindow`, and `BringToFront` do not automatically update the window's controls.

When the Appearance Manager is not available, the `DrawControls` function draws all controls currently visible in the specified window in reverse order of creation; thus, in case of overlapping controls, the control created first appears frontmost in the window. If you only wish to draw controls in need of update, call `UpdateControls` (page 672) instead.

Note that `DrawControls` generally should not be called if you are using compositing mode.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Controls.h`

DumpControlHierarchy

Writes a textual representation of the control hierarchy for a specified window into a file.

```
OSErr DumpControlHierarchy (
   WindowRef inWindow,
   const FSSpec *inDumpFile
);
```

Parameters

inWindow

A pointer to the window whose control hierarchy you wish to examine.

inDumpFile

A pointer to a file specification in which to place a text description of the window's control hierarchy.

Return Value

A result code. See "Control Manager Result Codes" (page 824).

Discussion
The `DumpControlHierarchy` function places a text listing of the current control hierarchy for the window specified into the specified file, overwriting any existing file. If the specified window does not contain a control hierarchy, `DumpControlHierarchy` notes this in the text file. This function is useful for debugging embedding-related problems.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`HIToolboxDebugging.h`

EmbedControl

Embeds one control inside another.

```
OSErr EmbedControl (
   ControlRef inControl,
   ControlRef inContainer
);
```

Parameters

inControl
The control that is to be embedded. For a description of this data type, see ControlRef (page 709).

inContainer
The control in which the control specified by `inControl` is to be is to embedded. For a description of this data type, see ControlRef (page 709).

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Discussion
Establishing an embedding hierarchy can be accomplished in two steps: creating a root control and embedding controls within it.

To embed controls in a window, you must create a root control for that window. The root control is the container for all other window controls. You create the root control in one of two ways—by calling the `CreateRootControl` (page 562) function or by setting the appropriate dialog flag. The root control can be retrieved by calling `GetRootControl` (page 611).

The root control is implemented as a user pane control. You can attach any application-defined user pane functions to the root control to perform actions such as hit testing, drawing, handling keyboard focus, erasing to the correct background, and processing idle and keyboard events.

Once you have created a root control, newly created controls will automatically be embedded in the root control when you call `NewControl` (page 634) or `GetNewControl` (page 610). You can specify that a specific control be embedded into another by calling `EmbedControl`.

Note that an embedding hierarchy must be established before your application calls the `EmbedControl` function. If the specified control does not support embedding or there is no root control in the owning window, an error is returned. Prior to Mac OS X, if the control you wish to embed is in a different window from the embedder control, an error is returned. On Mac OS X, however, you can use `EmbedControl` to

move a control from one window to another. On Mac OS X v.10.0 and v.10.1, you can move all controls except for the edit text and unicode edit text controls. Support for the edit text controls is available in Mac OS X v.10.2 and later.

By acting on an embedder control, you can move, disable, or hide groups of items. For example, you can use a blank user pane control as the embedder control for all items in a particular "page" of a tab control. After creating as many user panes as you have tabs, you can hide one and show the next when a tab is clicked. All the controls embedded in the user pane will be hidden and shown automatically when the user pane is hidden and shown.

In addition to calling `CreateRootControl`, you can establish an embedding hierarchy in a dialog box by either setting the feature bit `kDialogFlagsUseControlHierarchy` in the extended dialog resource or passing it in the `inFlags` parameter of the Dialog Manager function `NewFeaturesDialog`. An embedding hierarchy can be created in an alert box by setting the `kAlertFlagsUseControlHierarchy` bit in the extended alert resource. It is important to note that a preexisting alert or dialog item will become a control if it is in an alert or dialog box that now uses an embedding hierarchy.

The embedding hierarchy enforces drawing order by drawing the embedding control before its embedded controls. Using an embedding hierarchy also enforces orderly hit-testing, since it performs an "inside-out" hit test to determine the most deeply nested control that is hit by the mouse. An embedding hierarchy is also necessary for controls to make use of keyboard focus, the default focusing order for which is a linear progression that uses the order the controls were added to the window. For more details on keyboard focus, see "Handling Keyboard Focus".

`Controls.h`

FindControl

Obtains the location of a mouse-down event in a control.

```
ControlPartCode FindControl (
   Point testPoint,
   WindowRef theWindow,
   ControlRef *theControl
);
```

Parameters

`testPoint`

A point, specified in coordinates local to the window, where the mouse-down event occurred. Before calling `FindControl`, use the `GlobalToLocal` function to convert the point stored in the `where` field of the event structure (which describes the location of the mouse-down event) to coordinates local to the window.

`theWindow`

A pointer to the window in which the mouse-down event occurred. Pass the window pointer returned by the `FindWindow` function.

`theControl`

A pointer to a control handle. On output, `FindControl` returns a handle to the control in which the mouse-down event occurred or `NULL` if the point was not over a control. For a description of this data type, see ControlRef (page 709).

Return Value
The control part code of the control in which the mouse-down event occurred; see "Control Meta Part Code Constants" (page 790), "Control Part Code Constants " (page 748), and" Control State Part Code Constants" (page 751). For a description of this data type, see ControlPartCode (page 708).

Discussion
The `FindControl` function is not recommended when the Appearance Manager is available. When the Appearance Manager is available, you should call `FindControlUnderMouse` (page 586) to determine the location of a mouse-down event in a control. `FindControlUnderMouse` will return a handle to the control even if no part was hit and can determine whether a mouse-down event has occurred even if the control is deactivated, while `FindControl` does not.

If the Appearance Manager is not available, then, when a mouse-down event occurs, your application can call `FindControl` after using the Window Manager function `FindWindow` to ascertain that a mouse-down event has occurred in the content region of a window containing controls.

When the user presses the mouse button while the cursor is in a visible, active control, `FindControl` returns as its function result a part code identifying the control's part the function also returns a handle to the control in the parameter `theControl`.

If the mouse-down event occurs in an invisible or inactive control, or if it occurs outside a control, `FindControl` sets the value referenced through `theControl` to `NULL` and returns 0 as its function result.

The `FindControl` function also returns `NULL` in the value referenced through the parameter `theControl` and 0 as its function result if the window is invisible or if it doesn't contain the given point. (However, `FindWindow` won't return a window pointer to an invisible window or to one that doesn't contain the point where the mouse-down event occurred. As long as you call `FindWindow` before `FindControl`, this situation won't arise.)

After using `FindControl` to determine that a mouse-down event has occurred in a control, you typically call the function `TrackControl` (page 671) to follow and respond to the cursor movements in that control, and then to determine in which part of the control the mouse-up event occurs.

The pop-up control definition function does not define part codes for pop-up menus. Instead, your application should store the handles for your pop-up menus when you create them. Your application should then test the handles you store against the handles returned by `FindControl` before responding to users' choices in pop-up menus.

The Dialog Manager automatically calls `FindControl` and `TrackControl` for mouse-down events inside controls of alert boxes and dialog boxes.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Controls.h`

FindControlUnderMouse

Obtains the location of a mouse-down event in a control.

```
ControlRef FindControlUnderMouse (
   Point inWhere,
   WindowRef inWindow,
   ControlPartCode *outPart
);
```

Parameters

inWhere
A point, specified in coordinates local to the window, where the mouse-down event occurred. Before calling `FindControlUnderMouse`, use the QuickDraw `GlobalToLocal` function to convert the point stored in the `where` field of the event structure (which describes the location of the mouse-down event) to coordinates local to the window.

inWindow
A pointer to the window in which the mouse-down event occurred.

outPart
On input, a pointer to a signed 16-bit integer value. On return, the value is set to the part code of the control part that was selected; see "Control Part Code Constants " (page 748), "Control Part Code Constants " (page 748), and " Control State Part Code Constants" (page 751).

Return Value
A handle to the control that was selected. If the mouse-down event did not occur over a control part, `FindControlUnderMouse` returns `NULL`. For a description of this data type, see ControlRef (page 709).

Discussion
You should call the `FindControlUnderMouse` function instead of `FindControl` (page 585) to determine whether a mouse-down event occurred in a control, particularly if an embedding hierarchy is present. `FindControlUnderMouse` will return a handle to the control even if no part was hit and can determine whether a mouse-down event has occurred even if the control is deactivated, while `FindControl` does not.

When a mouse-down event occurs, your application should call `FindControlUnderMouse` after using the Window Manager function `FindWindow` to ascertain that a mouse-down event has occurred in the content region of a window containing controls.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

`Controls.h`

GetBestControlRect

Obtains a control's optimal size and text placement.

```
OSErr GetBestControlRect (
   ControlRef inControl,
   Rect *outRect,
   SInt16 *outBaseLineOffset
);
```

Parameters

inControl
A handle to the control to be examined.

outRect
On input, a pointer to an empty rectangle (0, 0, 0, 0). On return, the rectangle is set to the optimal size for the control. If the control doesn't support getting an optimal size rectangle, the control's bounding rectangle is passed back.

outBaseLineOffset
On input, a pointer to a signed 16-bit integer value. On return, the value is set to the offset from the bottom of control to the base of the text (usually a negative value). If the control doesn't support optimal sizing or has no text, 0 is passed back.

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Discussion
You can call the `GetBestControlRect` function to automatically position and size controls in accordance with human interface guidelines. This function is particularly helpful in determining the correct placement of control text whose length is not known until run-time. For example, the `StandardAlert` function uses `GetBestControlRect` to automatically size and position buttons in a newly created alert box.

`Controls.h`

GetBevelButtonContentInfo

Gets the content information for a bevel button.

```
OSErr GetBevelButtonContentInfo (
   ControlRef inButton,
   ControlButtonContentInfoPtr outContent
);
```

Parameters

inButton
The control reference for the button to query.

outContent
A value of type `ControlButtonContentInfoPtr` for the bevel button's content information.

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`HIButtonViews.h`

GetBevelButtonMenuHandle

Gets the menu handle for a bevel button.

```
OSErr GetBevelButtonMenuHandle (
   ControlRef inButton,
   MenuHandle *outHandle
);
```

Parameters

inButton
The control reference for the button to query.

outHandle
A pointer to the menu handle.

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
HIButtonViews.h

GetBevelButtonMenuValue

Gets the value of a bevel button menu.

```
OSErr GetBevelButtonMenuValue (
   ControlRef inButton,
   MenuItemIndex *outValue
);
```

Parameters

inButton
The control reference for the button to query.

outValue
A pointer to the value of the bevel button menu.

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
HIButtonViews.h

GetControl32BitMaximum

Obtains the maximum setting of a control.

```
SInt32 GetControl32BitMaximum (
   ControlRef theControl
);
```

Parameters

theControl
A handle to the control whose maximum setting you wish to obtain. For a description of this data type, see ControlRef (page 709).

Return Value
The maximum setting of the control.

Discussion
Your application may use the `GetControl32BitMaximum` function to obtain a 32-bit value previously set with the function `SetControl32BitMaximum` (page 647).

If your application uses a 32-bit control maximum value, it should not attempt to obtain this value by calling the pre–Mac OS 8.5 function `GetControlMaximum` because the 16-bit value that is returned does not accurately reflect the current 32-bit control value.

Availability
Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In
`Controls.h`

GetControl32BitMinimum

Obtains the minimum setting of a control.

```
SInt32 GetControl32BitMinimum (
   ControlRef theControl
);
```

Parameters

theControl
A handle to the control whose minimum setting you wish to obtain. For a description of this data type, see ControlRef (page 709).

Return Value
The minimum setting of the control.

Discussion
Your application may use the `GetControl32BitMinimum` function to obtain a 32-bit value previously set with the function `SetControl32BitMinimum` (page 648).

If your application uses a 32-bit control minimum value, it should not attempt to obtain this value by calling the pre–Mac OS 8.5 function `GetControlMinimum` because the 16-bit value that is returned does not accurately reflect the current 32-bit control value.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
HID Calibrator
HID Explorer

Declared In
`Controls.h`

GetControl32BitValue

Obtains the current setting of a control.

```
SInt32 GetControl32BitValue (
   ControlRef theControl
);
```

Parameters

theControl

A handle to the control whose current setting you wish to obtain.

Return Value

The current setting of the control.

Discussion

Your application may use the `GetControl32BitValue` function to obtain a 32-bit value previously set with the function `SetControl32BitValue` (page 648).

If your application uses a 32-bit control value, it should not attempt to obtain this value by calling the pre–Mac OS 8.5 function `GetControlValue` because the 16-bit value that is returned does not accurately reflect the current 32-bit control value.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Related Sample Code

HID Calibrator

HID Explorer

Declared In

`Controls.h`

GetControlAction

Returns a pointer to the action function associated with a control structure.

```
ControlActionUPP GetControlAction (
   ControlRef theControl
);
```

Parameters

theControl

A handle to a control.

Return Value

The action function associated with the control. The action function is called by the `HandleControlClick` and `TrackControl` functions if you set the `InAction` parameter to `(ControlActionUPP)-1`. See `ControlActionProcPtr` (page 675) for an example of an action function.

Discussion

The action function returned by the `GetControlAction` function defines an action to take in response to a mouse button being held down while the cursor is in the control. An action function is usually specified in the `InAction` parameter of the functions `HandleControlClick` (page 613) and `TrackControl` (page 671). You can use the function `SetControlAction` (page 649) to change the action function.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In
`Controls.h`

GetControlBounds

Gets the bounds of a control.

```
Rect * GetControlBounds (
   ControlRef control,
   Rect *bounds
);
```

Parameters

control

The control to query. For a description of this data type, see ControlRef (page 709).

bounds

On input, a pointer to a QuickDraw rectangle. On output, the rectangle contains the bounds of the control in local coordinates.

Return Value
A pointer to the rectangle passed in the `bounds` parameter.

Discussion
When called in a composited window, this function returns the view's frame, which is equivalent to calling `HIViewGetFrame`.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
CarbonSketch
HID Explorer

Declared In
`Controls.h`

GetControlByID

Finds a control in a window by its unique ID.

```
OSStatus GetControlByID (
   WindowRef inWindow,
   const ControlID *inID,
   ControlRef *outControl
);
```

Parameters

inWindow

The window to query.

inID

The control ID.

outControl

A pointer to a value of type `ControlRef` that, on output, is filled in with the control reference for the control specified by inID. For a description of this data type, see ControlRef (page 709).

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Discussion
As of Mac OS X v10.3, this function is superseded by the `HIViewFindByID` function, which is preferred over the `GetControlByID` function. The first parameter to the `HIViewFindByID` function is a view and not a window, so you can start the search at any point in the hierarchy.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code

Declared In
`Controls.h`

GetControlClickActivation

Gets the control's preferred behavior for responding to particular click.

```
OSStatus GetControlClickActivation (
   ControlRef inControl,
   Point inWhere,
   EventModifiers inModifiers,
   ClickActivationResult *outResult
);
```

Parameters

inControl

inWhere

The location at which the control was clicked.

inModifiers

Information from the `modifiers` field of the event structure specifying the state of the modifier keys and the mouse button at the time the event was posted. .

outResult

A pointer to a value of type `ClickActivationResult` containing the result. For possible values, see "Click Activation Constants" (page 780).

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Discussion
Some complex controls, such as Data Browser, require proper sequencing of window activation and click processing. In some cases, the control might want the window to be left inactive yet still handle the click, or vice- versa. This function lets a control client ask the control how it wants to behave for a particular click.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Controls.h`

GetControlCommandID

Gets the command ID for a control.

```
OSStatus GetControlCommandID (
   ControlRef inControl,
   UInt32 *outCommandID
);
```

Parameters

inControl

outCommandID

A pointer to the command ID.

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Controls.h`

GetControlData

Obtains control-specific data.

```
OSErr GetControlData (
   ControlRef inControl,
   ControlPartCode inPart,
   ResType inTagName,
   Size inBufferSize,
   void *inBuffer,
   Size *outActualSize
);
```

Parameters

inControl

A handle to the control to be examined.

inPart

"Control Meta Part Code Constants" (page 790)The part code of the control part from which data is to be obtained; see , "Control Part Code Constants " (page 748), and " Control State Part Code Constants" (page 751). Passing `kControlEntireControl` indicates that either the control has no parts or the data is not tied to any specific part of the control. For a description of this data type, see ControlPartCode (page 708).

inTagName

A constant representing the control-specific data you wish to obtain see the data tag constants in the "Control Manager Constants" (page 719) section.

inBufferSize

The size (in bytes) of the data pointed to by the `inBuffer` parameter. For variable-length control data, pass the value returned in the `outMaxSize` parameter of `GetControlDataSize` (page 596) in the `inBufferSize` parameter. The number of bytes must match the actual data size.

inBuffer

On input, a pointer to a buffer allocated by your application. On return, the buffer contains a copy of the control-specific data. If you pass `NULL` on input, it is equivalent to calling `GetControlDataSize` (page 596). The actual size of the control-specific data will be returned in the `outActualSize` parameter. For variable-length data, the number of bytes must match the actual data size.

outActualSize

On input, a pointer to a `Size` value. On return, the value is set to the actual size of the data. You can pass `NULL` if you don't care about this value.

Return Value
A result code. See "Control Manager Result Codes" (page 824). The result code `errDataNotSupported` indicates that the `inTagName` parameter is not valid.

Discussion
The `GetControlData` function will only copy the amount of data specified in the `inBufferSize` parameter, but will tell you the actual size of the buffer so you will know if the data was truncated.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
BSDLLCTest
CarbonCocoa_PictureCursor
HID Explorer
QTCarbonShell

Declared In
`Controls.h`

GetControlDataHandle

Obtains a handle to control-specific data. (**Deprecated.** Use custom HIViews instead of custom CDEFs. See *HIView Programming Guide*.)

```
Handle GetControlDataHandle (
   ControlRef control
);
```

Return Value
A handle to control-specific data.

Discussion
The control data handle is for control-specific data used by a control's implementation. The control data handle is set by calling `SetControlDataHandle` (page 653).

In general, you should not attempt to interpret the contents of this handle if you did not implement the control yourself. For controls that are provided by the operating system, the format of the data handle may change from one release of the operating system to the next.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Controls.h`

GetControlDataSize

Obtains the size of a control's tagged data.

```
OSErr GetControlDataSize (
   ControlRef inControl,
   ControlPartCode inPart,
   ResType inTagName,
   Size *outMaxSize
);
```

Parameters

inControl
A handle to the control to be examined.For a description of this data type, see ControlRef (page 709).

inPart
The part code of the control part with which the data is associated; see"Control Meta Part Code Constants" (page 790), "Control Part Code Constants " (page 748), and " Control State Part Code Constants" (page 751). Passing `kControlEntireControl` indicates that either the control has no parts or the data is not tied to any specific part of the control.

inTagName
A constant representing the control-specific data whose size is to be obtained see the data tag constants in the "Control Manager Constants" (page 719) section.

outMaxSize
On input, a pointer to a `Size` value. On return, the value is set to the size (in bytes) of the control's tagged data. This value should be passed to `SetControlData` (page 652) and `GetControlData` (page 594) to allocate a sufficiently large buffer for variable-length data.

Return Value
A result code. See "Control Manager Result Codes" (page 824). The result code `errDataNotSupported` indicates that the `inTagName` parameter is not valid.

Discussion
Pass the value returned in the `outMaxSize` parameter of `GetControlDataSize` in the `inBufferSize` parameter of `SetControlData` (page 652) and `GetControlData` (page 594) to allocate an adequate buffer for variable-length data.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Controls.h`

GetControlFeatures

Obtains the features a control supports.

Not recommended

```
OSErr GetControlFeatures (
   ControlRef inControl,
   UInt32 *outFeatures
);
```

Parameters

inControl
A handle to the control to be examined. For a description of this data type, see ControlRef (page 709).

outFeatures
On input, a pointer to an unsigned 32-bit integer value. On return, the value contains a bit field specifying the features the control supports. For a list of the features a control may support, see `ControlDefProcPtr` (page 677).

Return Value
A result code. See "Control Manager Result Codes" (page 824). The result code `errMsgNotSupported` indicates that the control does not support Appearance-compliant features.

Discussion
The `GetControlFeatures` function obtains the Appearance-compliant features a control definition function supports, in response to a `kControlMsgGetFeatures` message.

Carbon Porting Notes

Some feature bits may not be relevant when using Carbon event-based messages.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Controls.h`

GetControlHilite

Gets the highlight status of a control.

```
UInt16 GetControlHilite (
   ControlRef control
);
```

Parameters

control

The control to query. For a description of this data type, see ControlRef (page 709).

Return Value

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
Controls.h

GetControlID

Gets the control ID for a control.

```
OSStatus GetControlID (
   ControlRef inControl,
   ControlID *outID
);
```

Parameters

inControl

The control to query. For a description of this data type, see ControlRef (page 709).

outID

A pointer to a value of type `ControlID` that, on return, contains the control ID of the control specified by `inControl`.

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
CarbonSketch

Declared In
Controls.h

GetControlKind

Returns the kind of the given control.

```
OSStatus GetControlKind (
   ControlRef inControl,
   ControlKind *outControlKind
);
```

Parameters

inControl

The control to query. For a description of this data type, see ControlRef (page 709).

outControlKind

On successful exit, this will contain the control signature and kind. See `ControlDefinitions.h` for the kinds of each system control. For a description of this data type, see ControlKind (page 707).

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Discussion
`GetControlKind` allows you to query the kind of any control.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
HID Calibrator

Declared In
`Controls.h`

GetControlMaximum

Obtains a control's maximum setting. (**Deprecated.** Use `GetControl32BitMaximum` (page 589) instead.)

Not recommended

```
SInt16 GetControlMaximum (
   ControlRef theControl
);
```

Parameters

theControl

A handle to the control whose maximum value you wish to determine. For a description of this data type, see ControlRef (page 709).

Return Value
The specified control's maximum setting.

Discussion
When you create a control, you specify an initial maximum setting either in the control resource or in the `max` parameter of the function `NewControl` (page 634). You can change the maximum setting by using the function `SetControlMaximum` (page 655).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
CarbonSketch

Declared In
`Controls.h`

GetControlMinimum

Obtains a control's minimum setting. (**Deprecated.** Use `GetControl32BitMinimum` (page 590) instead.)

Not recommended

```
SInt16 GetControlMinimum (
   ControlRef theControl
);
```

Parameters

theControl
A handle to the control whose minimum value you wish to determine.

Return Value
The specified control's minimum setting.

Discussion
When you create a control, you specify an initial minimum setting either in the control resource or in the `min` parameter of the function `NewControl` (page 634). You can change the minimum setting by using the function `SetControlMinimum` (page 656).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
CarbonSketch

Declared In
`Controls.h`

GetControlOwner

Returns the window to which a control is bound.

```
WindowRef GetControlOwner (
   ControlRef control
);
```

Parameters

control
The control to query. For a description of this data type, see ControlRef (page 709).

Return Value
The window reference to which the control is bound, or `NULL` if the control is not bound to a window.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
CarbonSketch

Declared In
`Controls.h`

GetControlPopupMenuHandle

Gets the menu handle for a pop-up control.

```
MenuRef GetControlPopupMenuHandle (
   ControlRef control
);
```

Parameters

control
The pop-up control to query.

Return Value
See the Menu Manager documentation for a description of the `MenuRef` data type.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
BSDLLCTest

Declared In
`Controls.h`

GetControlPopupMenuID

Gets the menu ID of a pop-up menu.

```
short GetControlPopupMenuID (
   ControlRef control
);
```

Parameters

control
The pop-up control to query.

Return Value
The menu ID.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
Controls.h

GetControlProperty

Obtains a piece of data that has been previously associated with a control.

```
OSStatus GetControlProperty (
   ControlRef control,
   OSType propertyCreator,
   OSType propertyTag,
   ByteCount bufferSize,
   ByteCount *actualSize,
   void *propertyBuffer
);
```

Parameters

control
A handle to the control whose associated data you wish to obtain.

propertyCreator
Your program's signature, as registered through Apple Developer Technical Support. If your program is of a type that would not normally have a signature (for example, a plug-in), you should still register and use a signature in this case, even though your program's file may not have the same creator code as the signature that you register. The 'macs' property signature is reserved for the system and should not be used.

propertyTag
The application-defined code identifying the data.

bufferSize
A value specifying the size of the data to be obtained. If the size of the data is unknown, use the function GetControlPropertySize (page 603) to get the data's size. If the size specified in the bufferSize parameter does not match the actual size of the property, GetControlProperty only retrieves data up to the size specified or up to the actual size of the property, whichever is smaller, and an error is returned.

actualSize
On input, a pointer to an unsigned 32-bit integer. On return, this value is set to the actual size of the associated data. You may pass NULL for the actualSize parameter if you are not interested in this information.

propertyBuffer
On input, a pointer to a buffer. On return, this buffer contains a copy of the data that is associated with the specified control.

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Discussion
You may use the function GetControlProperty to obtain a copy of data previously set by your application with the function SetControlProperty (page 658).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
CarbonCocoa_PictureCursor
HID Calibrator
HID Explorer

Declared In
`Controls.h`

GetControlPropertyAttributes

Gets the property attributes for a control.

```
OSStatus GetControlPropertyAttributes (
   ControlRef control,
   OSType propertyCreator,
   OSType propertyTag,
   OptionBits *attributes
);
```

Parameters

control
The control to query. For a description of this data type, see ControlRef (page 709).

propertyCreator
The OSType signature, usually the signature of your application, for the property creator of the attributes that are to be obtained.

propertyTag
The OSType signature for the property tag for the attributes that are to be obtained.

attributes
A pointer to a value of type `UInt32` that, on return, contains the attributes of the control specified by `control`.

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Controls.h`

GetControlPropertySize

Obtains the size of a piece of data that has previously been associated with a control.

```
OSStatus GetControlPropertySize (
   ControlRef control,
   OSType propertyCreator,
   OSType propertyTag,
   ByteCount *size
);
```

Parameters

control

A handle to the control whose associated data you wish to examine. For a description of this data type, see ControlRef (page 709).

propertyCreator

Your program's signature, as registered through Apple Developer Technical Support. If your program is of a type that would not normally have a signature (for example, a plug-in), you should still register and use a signature in this case, even though your program's file may not have the same creator code as the signature that you register. The `'macs'` property signature is reserved for the system and should not be used.

propertyTag

The application-defined code identifying the data.

size

On input, a pointer to an unsigned 32-bit integer. On return, this value is set to the actual size of the data.

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Discussion
If you want to retrieve a piece of associated data with the function `GetControlProperty` (page 602), you will typically need to use the `GetControlPropertySize` function beforehand to determine the size of the associated data.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Controls.h`

GetControlReference

Obtains a control's current reference value.

```
SRefCon GetControlReference (
   ControlRef theControl
);
```

Parameters

theControl

A handle to the control whose current reference value you wish to determine.

Return Value
The current reference value for the specified control.

Discussion
When you create a control, you specify an initial reference value, either in the control resource or in the `refCon` parameter of the function `NewControl` (page 634). The reference value is stored in the `contrlRfCon` field of the control structure. You can use this field for any purpose, and you can use the function `SetControlReference` (page 659) to change this value.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Controls.h`

GetControlRegion

Obtains the region corresponding to a given control part.

```
OSStatus GetControlRegion (
   ControlRef inControl,
   ControlPartCode inPart,
   RgnHandle outRegion
);
```

Parameters

inControl
A handle to the control whose part region you want to obtain.

inPart
A constant identifying the control part for which a region is to be obtained. You may specify the `kControlStructureMetaPart` and `kControlContentMetaPart` control part codes, as well as the standard control part codes. See "Control Meta Part Code Constants" (page 790), "Control Part Code Constants " (page 748), and " Control State Part Code Constants" (page 751) for descriptions of possible values.

outRegion
On input, a value of type `RgnHandle`. On return, `GetControlRegion` sets the region to contain the actual dimensions and position of the control part, in local coordinates.

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Controls.h`

GetControlTitle

Obtains the title of a control. (Deprecated in Mac OS X v10.5. Use `HIViewCopyText` (page 2448) or `CopyControlTitleAsCFString` (page 538) instead.)

```
void GetControlTitle (
   ControlRef theControl,
   Str255 title
);
```

Parameters

theControl

A handle to the control whose title you want to determine.

title

On input, a pascal string. On output, the title of the control.

Discussion

The `GetControlTitle` function produces the title of the specified control, which is stored in the `contrlTitle` field of the control structure.

When you create a control, you specify an initial title either in the control resource or in the `title` parameter of the function `NewControl` (page 634). You can change the title by using `SetControlTitle` (page 660).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Controls.h`

GetControlValue

Obtains a control's current setting. (**Deprecated.** Use `GetControl32BitValue` (page 590) instead.)

Not recommended

```
SInt16 GetControlValue (
   ControlRef theControl
);
```

Parameters

theControl

On input, a handle to a control.

Return Value

The current setting of the control.

Discussion

When you create a control, you specify an initial setting either in the control resource or in the `value` parameter of the function `NewControl` (page 634). You can change the setting by calling `SetControlValue` (page 661).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Related Sample Code

BSDLLCTest

CarbonSketch
ictbSample

Declared In
`Controls.h`

GetControlVariant

Returns the variation code specified in the control definition function for a particular control. (**Deprecated.** Use custom HIViews instead of custom CDEFs. See *HIView Programming Guide*.)

Not recommended

```
ControlVariant GetControlVariant (
   ControlRef theControl
);
```

Parameters

`theControl`
A handle to the control whose variation code you wish to determine.

Return Value
The variation code for the specified control see the control definition IDs in the "Control Manager Constants" (page 719) section for descriptions of control variation codes. For a description of this data type, see ControlVariant (page 712).

Discussion
A control definition function can use a variation code to describe variations of the same basic control. For example, all pop-up arrows share the same basic control definition function, which is stored in a resource of type `'CDEF'` and has a resource ID of 12. The standard pop-up arrow is large and points to the right; it has a control definition ID of 192. A variation of this is a large, left-pointing arrow, which has a control definition ID of 193. Still another variation, in which the arrow points up, has a control definition ID of 194.

Carbon Porting Notes

Use only if you are using message-based custom controls (CDEFs).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Controls.h`

GetControlViewSize

Obtains the size of the content to which a control's size is proportioned.

```
SInt32 GetControlViewSize (
   ControlRef theControl
);
```

Parameters

theControl

A value of type `ControlHandle`. Pass a handle to the control whose view size you wish to obtain.

Return Value

A value equal to the current size of the content being displayed, expressed in terms of the same units of measurement as are used for the minimum, maximum, and current settings of the control.

Discussion

Your application should call the `GetControlViewSize` function to obtain the current view size of a control. This value is used by the scrollbar control to support proportional scroll boxes.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Controls.h`

GetImageWellContentInfo

Gets information about the content of an image well.

```
OSErr GetImageWellContentInfo (
   ControlRef inButton,
   ControlButtonContentInfoPtr outContent
);
```

Parameters

inButton

The control reference to query.

outContent

On return, the value type `ControlButtonContentInfoPtr` for the control specified by `inButton`.

Return Value

A result code. See "Control Manager Result Codes" (page 824).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`HIImageViews.h`

GetIndexedSubControl

Obtains a handle to a specified embedded control.

```
OSErr GetIndexedSubControl (
   ControlRef inControl,
   UInt16 inIndex,
   ControlRef *outSubControl
);
```

Parameters

inControl

The control from which an embedded control handle is to be obtained. For a description of this data type, see ControlRef (page 709).

inIndex

A one-based index—an integer between 1 and the value returned in the `outNumChildren` parameter of `CountSubControls` (page 538)—specifying the control you wish to access.

outSubControl

On input, a pointer to a `ControlHandle` value. On return, the `ControlHandle` value is set to a handle to the embedded control.

Return Value

A result code. See "Control Manager Result Codes" (page 824). If the index passed in is invalid, the `paramErr` result code is returned.

Discussion

The `GetIndexedSubControl` function is useful for iterating over the control hierarchy. Also, the value of a radio group control is the index of its currently selected embedded radio button control. So, passing the current value of a radio group control into `GetIndexedSubControl` will give you a handle to the currently selected radio button control.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

`Controls.h`

GetKeyboardFocus

Obtains a handle to the control with the current keyboard focus for a specified window.

```
OSErr GetKeyboardFocus (
   WindowRef inWindow,
   ControlRef *outControl
);
```

Parameters

inWindow

A pointer to the window for which to obtain keyboard focus.

outControl

On input, a pointer to a `ControlHandle` value. On return, the `ControlHandle` value is set to a handle to the control that currently has keyboard focus. Produces `NULL` if no control has focus.

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Discussion
The `GetKeyboardFocus` function returns the handle of the control with current keyboard focus within a specified window.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Controls.h`

GetNewControl

Creates a control from a control resource.

```
ControlRef GetNewControl (
   SInt16 resourceID,
   WindowRef owningWindow
);
```

Parameters

resourceID
The resource ID of the control you wish to create.

owningWindow
A pointer to the window in which to place the control.

Return Value
A handle to the control created from the specified control resource. If `GetNewControl` can't read the control resource from the resource file, it returns `NULL`. For a description of this data type, see ControlRef (page 709).

Discussion
The `GetNewControl` function creates a control structure from the information in the specified control resource, adds the control structure to the control list for the specified window, and returns as its function result a handle to the control. You use this handle when referring to the control in most other Control Manager functions. After making a copy of the control resource, `GetNewControl` releases the memory occupied by the original control resource before returning.

The control resource specifies the rectangle for the control, its initial setting, its visibility state, its maximum and minimum settings, its control definition ID, a reference value, and its title (if any). After you use `GetNewControl` to create the control, you can change the control characteristics with other Control Manager functions.

If the control resource specifies that the control should be visible, the Control Manager draws the control. If the control resource specifies that the control should initially be invisible, you can use the function `ShowControl` (page 669) to make the control visible.

When an embedding hierarchy is established within a window, `GetNewControl` automatically embeds the newly created control in the root control of the owning window.

Availability
Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In
`Controls.h`

GetRootControl

Obtains a handle to a window's root control.

```
OSErr GetRootControl (
   WindowRef inWindow,
   ControlRef *outControl
);
```

Parameters

inWindow

A pointer to the window to be examined.

outControl

Pass a pointer to a `ControlHandle` value. On return, the `ControlHandle` value is set to a handle to the root control.

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Discussion
You can call `GetRootControl` to determine whether or not a root control (and therefore an embedding hierarchy) exists within a specified window. Once you have the root control's handle, you can pass it to functions such as `DisposeControl` (page 573), `ActivateControl` (page 535),and `DeactivateControl` (page 572) to apply specified actions to the entire embedding hierarchy.

Note that the minimum, maximum, and initial settings for a root control are reserved and should not be changed.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
QTCarbonShell

Declared In
`Controls.h`

GetSuperControl

Obtains a handle to an embedder control.

```
OSErr GetSuperControl (
   ControlRef inControl,
   ControlRef *outParent
);
```

Parameters

inControl

A handle to an embedded control. For a description of this data type, see ControlRef (page 709).

outParent

A pointer to a `ControlHandle` value. On return, the `ControlHandle` value is set to a handle to the embedder control. For a description of this data type, see ControlRef (page 709).

Return Value

A result code. See "Control Manager Result Codes" (page 824).

Discussion

The `GetSuperControl` function gets a handle to the parent control of the control passed in.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Related Sample Code

QTCarbonShell

Declared In

`Controls.h`

GetTabContentRect

Gets the content rectangle for a tab.

```
OSErr GetTabContentRect (
   ControlRef inTabControl,
   Rect *outContentRect
);
```

Parameters

inTabControl

The tab control reference to query.

outContentRect

On return, the value of this parameter is a pointer to the content rectangle for the tab specified by `inTabControl`.

Return Value

A result code. See "Control Manager Result Codes" (page 824).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`HITabbedView.h`

HandleControlClick

Responds to cursor movements in a control while the mouse button is down and returns the location of the next mouse-up event.

```
ControlPartCode HandleControlClick (
   ControlRef inControl,
   Point inWhere,
   EventModifiers inModifiers,
   ControlActionUPP inAction
);
```

Parameters

inControl

A handle to the control in which the mouse-down event occurred. Pass the control handle returned by `FindControl` or `FindControlUnderMouse`.

inWhere

A point, specified in local coordinates, where the mouse-down event occurred. Supply the same point you passed to `FindControl` or `FindControlUnderMouse`.

inModifiers

Information from the `modifiers` field of the event structure specifying the state of the modifier keys and the mouse button at the time the event was posted.

inAction

A universal procedure pointer to an action function defining what action your application takes while the user holds down the mouse button. See `ControlActionProcPtr` (page 675) for a description of such an action function. The value of the `inAction` parameter can be a valid `procPtr`, `NULL`, or -1. A value of -1 indicates that the control should either perform auto tracking, or if it is incapable of doing so, do nothing (like `NULL`). For custom controls, what you pass in this parameter depends on how you define the control. If the part index is greater than 128, the pointer must be of type `DragGrayRegionUPP` unless the control supports live feedback, in which case it should be a `ControlActionUPP`.

Return Value

Returns a value of type `ControlPartCode` identifying the control's part see "Control Meta Part Code Constants" (page 790), "Control Part Code Constants " (page 748), and" Control State Part Code Constants" (page 751). For a description of this data type, see ControlPartCode (page 708).

Discussion

Call the `HandleControlClick` function after a call to `FindControl` (page 585) or `FindControlUnderMouse` (page 586). The `HandleControlClick` function should be called instead of `TrackControl` (page 671) to follow the user's cursor movements in a control and provide visual feedback until the user releases the mouse button. Unlike `TrackControl`, `HandleControlClick` allows modifier keys to be passed in so that the control may use these if the control (such as a list box or editable text field) is set up to handle its own tracking.

The visual feedback given by `HandleControlClick` depends on the control part in which the mouse-down event occurs. When highlighting is appropriate, for example, `HandleControlClick` highlights the control part (and removes the highlighting when the user releases the mouse button). When the user holds down the mouse button while the cursor is in an indicator (such as the scroll box of a scroll bar) and moves the mouse, `HandleControlClick` responds by dragging a dotted outline or a ghost image of the indicator. If the user releases the mouse button when the cursor is in an indicator such as the scroll box, `HandleControlClick` calls the control definition function to reposition the indicator.

While the user holds down the mouse button with the cursor in one of the standard controls, `HandleControlClick` performs the following actions, depending on the value you pass in the parameter `inAction`.

- If you pass `NULL` in the `inAction` parameter, `HandleControlClick` uses no action function and therefore performs no additional actions beyond highlighting the control or dragging the indicator. This is appropriate for push buttons, checkboxes, radio buttons, and the scroll box of a scroll bar.
- If you pass a pointer to an action function in the `inAction` parameter, it must define some action that your application repeats as long as the user holds down the mouse button. This is appropriate for the scroll arrows and gray areas of a scroll bar.
- If you pass `(ControlActionUPP)-1L` in the `inAction` parameter, `HandleControlClick` calls the control action function associated with the control. This is appropriate when you are tracking the cursor in a pop-up menu. You can call `GetControlAction` (page 591) to get a pointer to the control action function that is associated with the control, and you can call `SetControlAction` (page 649) to set the control action function that is associated with the control.

For `'CDEF'` resources that implement custom dragging, you usually call `HandleControlClick`, which returns 0 regardless of the user's changes of the control setting. To avoid this, you should use another method to determine whether the user has changed the control setting, for instance, comparing the control's value before and after your call to `HandleControlClick`.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
CarbonSketch

Declared In
`Controls.h`

HandleControlContextualMenuClick

Allows a control to display a contextual menu.

```
OSStatus HandleControlContextualMenuClick (
   ControlRef inControl,
   Point inWhere,
   Boolean *menuDisplayed
);
```

Parameters

inControl

inWhere

The location that was clicked.

menuDisplayed

Pointer to a Boolean whose value is true if the control displayed a contextual menu; otherwise, `false`.

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Controls.h`

HandleControlDragReceive

Tells a control to accept the data from a drag.

```
OSStatus HandleControlDragReceive (
   ControlRef inControl,
   DragReference inDrag
);
```

Parameters

inControl

inDrag

The drag reference that was dropped on the control.

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Discussion
Call this function when the user drops a drag on a control in your window to give the control an opportunity to take any interesting data from the drag. Before calling this function, you must call `SetControlDragTrackingEnabled` (page 653) to enable drag and drop support for the control.Note that this function should not be called in a composited window. Instead, the `SetAutomaticControlDragTrackingEnabledForWindow` API should be used to enable automatic control drag tracking.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Controls.h`

HandleControlDragTracking

Tells a control to respond visually to a drag.

```
OSStatus HandleControlDragTracking (
   ControlRef inControl,
   DragTrackingMessage inMessage,
   DragReference inDrag,
   Boolean *outLikesDrag
);
```

Parameters

inControl

inMessage

A drag message indicating the state of the drag above the control. The meaning of the value you pass in must be relative to the control, not the whole window. For when the drag first enters the control, you should pass `kDragTrackingEnterControl`. While the drag stays within the control, pass `kDragTrackingInControl`. When the drag leaves the control, pass `kDragTrackingLeaveControl`.

inDrag

The drag reference that is over the control.

outLikesDrag

On output, a pointer to a Boolean whose value is `true` if the control can accept the data in the drag reference or `false` if the control cannot accept the data. If the value is `false`,there is no need to call `HandleControlDragReceive` (page 615) when the user drops the dragged object onto the control because the control cannot accept the data.

Return Value

A result code. See "Control Manager Result Codes" (page 824).

Discussion

Call this function when a drag is above a control in your window and you want to give that control a chance to draw appropriately in response to the drag. Before calling this function, you must call `SetControlDragTrackingEnabled` (page 653) to enable drag and drop support for the control.Note that this function should not be called in a composited window. Instead, the `SetAutomaticControlDragTrackingEnabledForWindow` API should be used to enable automatic control drag tracking.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Controls.h`

HandleControlKey

Sends a keyboard event to a control with keyboard focus. (Deprecated in Mac OS X v10.5. For HIView-based controls, send the view a `kEventTextInputUnicodeForKeyEvent` event.)

```
ControlPartCode HandleControlKey (
   ControlRef inControl,
   SInt16 inKeyCode,
   SInt16 inCharCode,
   EventModifiers inModifiers
);
```

Parameters

inControl

A handle to the control that currently has keyboard focus.

inKeyCode

The virtual key code, derived from the event structure. This value represents the key pressed or released by the user. It is always the same for a specific physical key on a particular keyboard regardless of which modifier keys were also pressed.

inCharCode

A character, derived from the event structure. The value that is generated depends on the virtual key code, the state of the modifier keys, and the current `'KCHR'` resource.

inModifiers

Information from the `modifiers` field of the event structure specifying the state of the modifier keys and the mouse button at the time the event was posted.

Return Value

The part code that was hit during the keyboard event; see "Control Meta Part Code Constants" (page 790), "Control Part Code Constants " (page 748), and" Control State Part Code Constants" (page 751). For a description of this data type, see ControlPartCode (page 708).

Discussion

If you have determined that a keyboard event has occurred in a given window, before calling the `HandleControlKey` function, call `GetKeyboardFocus` (page 609) to get the handle to the control that currently has keyboard focus. The `HandleControlKey` function passes the values specified in its `inKeyCode`, `inCharCode`, and `inModifiers` parameters to control definition functions that set the `kControlSupportsFocus` feature bit.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Controls.h`

HandleControlSetCursor

Requests that a control set the cursor based on the mouse location.

```
OSStatus HandleControlSetCursor (
   ControlRef control,
   Point localPoint,
   EventModifiers modifiers,
   Boolean *cursorWasSet
);
```

Parameters

inControl

.

localPoint

The location of the mouse.

modifiers

Information from the `modifiers` field of the event structure specifying the state of the modifier keys and the mouse button at the time the event was posted.

cursorWasSet

Out output, a pointer to a Boolean whose value is `true` if the cursor was set; otherwise, `false`.

Return Value

A result code. See "Control Manager Result Codes" (page 824).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Controls.h`

HideControl

Makes a control, and any latent embedded controls, invisible.

```
void HideControl (
   ControlRef theControl
);
```

Parameters

theControl

A handle to the control to hide.

Discussion

The `HideControl` function makes the specified control invisible. This can be useful, for example, before adjusting a control's size and location. It also adds the control's rectangle to the window's update region, so that anything else that was previously obscured by the control will reappear on the screen. If the control is already invisible, `HideControl` has no effect.

When hiding groups of controls, the state of an embedded control that is hidden or deactivated is preserved so that when the embedder control is shown or activated, the embedded control appears in the same state as the embedder. If the specified control has embedded controls, `HideControl` makes the embedded controls invisible as well.

An embedded control is considered latent when it is deactivated or hidden due to its embedder control being deactivated or hidden. If you call `HideControl` on a latent embedded control, it would not be displayed the next time `ShowControl` (page 669) was called on its embedder control.

To make the control visible again, call `ShowControl` (page 669).

You can also call `SetControlVisibility` (page 663) to hide or show a control without causing it to redraw.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Controls.h`

HiliteControl

Changes the highlighting of a control.

Not recommended

```
void HiliteControl (
   ControlRef theControl,
   ControlPartCode hiliteState
);
```

Parameters

theControl

A handle to the control. For a description of this data type, see ControlRef (page 709).

hiliteState

A value from 0 to 255 that specifies the highlighting state of the control. The value of 0 signifies an active control with no highlighting. A value from 1 through 253 signifies a part code designating the part of the (active) control to highlight. Values 254 and 255 signify that the control is to be made disabled or inactive, respectively, and drawn accordingly. For a description of part code constants, see "Control Part Code Constants " (page 748), "Control Part Code Constants " (page 748), and " Control State Part Code Constants" (page 751).

Discussion
If the Appearance Manager is available, you should call the functions `ActivateControl` (page 535) and `DeactivateControl` (page 572) instead of `HiliteControl` to activate or deactivate a control. This is important if the control is in an embedding hierarchy, since calling these functions will ensure that any latent embedded controls will be activated and deactivated correctly.

If the Appearance Manager is not available, then when you need to make a control inactive (such as when its window is not frontmost) or in any other way change the highlighting of a control, you can use the `HiliteControl` function.

The `HiliteControl` function calls the control definition function to redraw the control with the highlighting specified in the `hiliteState` parameter. The `HiliteControl` function uses the value in this parameter to change the value of the `contrlHilite` field of the control structure.

Except for scroll bars, which you should hide using `HideControl` (page 618), you should use `HiliteControl` to make all controls inactive when their windows are not frontmost. The function `TrackControl` (page 671) automatically uses the `HiliteControl` function as appropriate; when you use `TrackControl`, you don't need to call `HiliteControl`.

Carbon Porting Notes

If you are activating or deactivating a control, you should use `ActivateControl` or `DeactivateControl` instead. Otherwise okay to use.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Controls.h`

IdleControls

Performs idle event processing. (Deprecated in Mac OS X v10.4. You should remove all calls to `IdleControls` because it uses unnecessary processor time. System-supplied controls do not respond to `IdleControls` in Mac OS X.)

Not recommended

```
void IdleControls (
   WindowRef inWindow
);
```

Parameters

inWindow

A pointer to a window containing controls that support idle events.

Discussion

Your application should call the `IdleControls` function to give idle time to any controls that want the `kControlMsgIdle` message. `IdleControls` calls the control with an idle event so the control can do idle-time processing. You should call `IdleControls` at least once in your event loop. See `ControlDefProcPtr` (page 677) for more details on how a control definition function should handle idle processing.

Special Considerations

Idle events are not recommended. If you have a custom control that needs time to perform tasks (such as animation), use Carbon Event timers instead. See *Carbon Event Manager Programming Guide* for more details.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.4.

Not available to 64-bit applications.

Declared In

`Controls.h`

InvokeControlActionUPP

Invokes a control action UPP.

```
void InvokeControlActionUPP (
   ControlRef theControl,
   ControlPartCode partCode,
   ControlActionUPP userUPP
);
```

Parameters

theControl

The control for which the control action UPP is to be invoked. For a description of this data type, see ControlRef (page 709).

partCode

The part code for which the control action UPP is to be invoked. For possible values, see "Control Meta Part Code Constants" (page 790), "Control Part Code Constants " (page 748), and " Control State Part Code Constants" (page 751).

userUPP

The UPP that is to be invoked.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Controls.h`

InvokeControlCNTLToCollectionUPP

Invokes a control-to-collection UPP.

```
OSStatus InvokeControlCNTLToCollectionUPP (
   const Rect *bounds,
   SInt16 value,
   Boolean visible,
   SInt16 max,
   SInt16 min,
   SInt16 procID,
   SRefCon refCon,
   ConstStr255Param title,
   Collection collection,
   ControlCNTLToCollectionUPP userUPP
);
```

Parameters

bounds

The bounds of the control.

value

The value of the control.

visible

A Boolean whose value is `true` if the control is visible; otherwise, `false`.

max

The maximum value of the control.

min

The minimum value of the control.

procID
The proc ID.

refCon
The refcon.

title
The title of the control.

collection
The collection.

userUPP
The UPP that is to be invoked.

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Controls.h`

InvokeControlColorUPP

Not recommended

```
OSStatus InvokeControlColorUPP (
   ControlRef inControl,
   SInt16 inMessage,
   SInt16 inDrawDepth,
   Boolean inDrawInColor,
   ControlColorUPP userUPP
);
```

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Carbon Porting Notes

Instead of specifying a callback to redraw your background, you should make the background a control and then embed your other controls within it.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Controls.h`

InvokeControlDefUPP

Invokes a control definition UPP. (Deprecated in Mac OS X v10.5. Use a custom HIView to draw a custom control.)

```
SInt32 InvokeControlDefUPP (
   SInt16 varCode,
   ControlRef theControl,
   ControlDefProcMessage message,
   SInt32 param,
   ControlDefUPP userUPP
);
```

Parameters

varCode

The variation code.

theControl

The control. For a description of this data type, see ControlRef (page 709).

message

The message.

param

The maximum value of the control.

userUPP

The UPP that is to be invoked.

Return Value

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

```
void InvokeControlUserPaneBackgroundUPP (
   ControlRef control,
   ControlBackgroundPtr info,
   ControlUserPaneBackgroundUPP userUPP
);
```

Parameters

control
The control.

info
A pointer to information such as the depth and type of the drawing device. For a description of the `ControlBackgroundPtr` data type, see ControlBackgroundRec (page 698).

userUPP
The UPP that is to be activated.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`HIContainerViews.h`

InvokeControlUserPaneDrawUPP

Invokes a user pane draw UPP.

```
void InvokeControlUserPaneDrawUPP (
   ControlRef control,
   ControlPartCode part,
   ControlUserPaneDrawUPP userUPP
);
```

Parameters

control
The control.

userUPP
The part.

userUPP
The UPP that is to be activated.

Availability
Available in Mac OS X v10.0 and later.

Declared In
HIContainerViews.h

InvokeControlUserPaneFocusUPP

Invokes a user pane focus UPP.

```
ControlPartCode InvokeControlUserPaneFocusUPP (
   ControlRef control,
   ControlFocusPart action,
   ControlUserPaneFocusUPP userUPP
);
```

Parameters

control
The control.

action
The action.

userUPP
The UPP that is to be activated.

Return Value
For a description of this data type, see ControlPartCode (page 708).

Availability
Available in Mac OS X v10.0 and later.

Declared In
HIContainerViews.h

InvokeControlUserPaneHitTestUPP

Invokes a user pane hit test UPP.

```
ControlPartCode InvokeControlUserPaneHitTestUPP (
   ControlRef control,
   Point where,
   ControlUserPaneHitTestUPP userUPP
);
```

Parameters

control
The control.

where
The location.

userUPP
The UPP that is to be activated.

Return Value
See ControlPartCode (page 708) for a description of the `ControlPartCode` data type.

Availability
Available in Mac OS X v10.0 and later.

Declared In
HIContainerViews.h

InvokeControlUserPaneIdleUPP

Invokes a user pane idle UPP.

```
void InvokeControlUserPaneIdleUPP (
   ControlRef control,
   ControlUserPaneIdleUPP userUPP
);
```

Parameters

control
The control.

userUPP
The UPP that is to be activated.

Availability
Available in Mac OS X v10.0 and later.

Declared In
HIContainerViews.h

InvokeControlUserPaneKeyDownUPP

Invokes a user pane key down UPP.

```
ControlPartCode InvokeControlUserPaneKeyDownUPP (
   ControlRef control,
   SInt16 keyCode,
   SInt16 charCode,
   SInt16 modifiers,
   ControlUserPaneKeyDownUPP userUPP
);
```

Parameters

control
The control.

keyCode
The key code.

charCode
The character code.

modifiers
The modifiers.

userUPP
The UPP that is to be activated.

Return Value
For a description of this data type, see ControlPartCode (page 708).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`HIContainerViews.h`

InvokeControlUserPaneTrackingUPP

Invokes a user pane tracking UPP.

```
ControlPartCode InvokeControlUserPaneTrackingUPP (
   ControlRef control,
   Point startPt,
   ControlActionUPP actionProc,
   ControlUserPaneTrackingUPP userUPP
);
```

Parameters

control
The control.

startPt
The starting point.

actionProc
The action proc.

userUPP
The UPP that is to be activated.

Return Value
For a description of this data type, see ControlPartCode (page 708).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`HIContainerViews.h`

InvokeEditUnicodePostUpdateUPP

Invokes a Unicode post update UPP.

```
Boolean InvokeEditUnicodePostUpdateUPP (
   UniCharArrayHandle uniText,
   UniCharCount uniTextLength,
   UniCharArrayOffset iStartOffset,
   UniCharArrayOffset iEndOffset,
   void *refcon,
   EditUnicodePostUpdateUPP userUPP
);
```

Parameters

uniText
The UPP that is to be activated.

uniTextLength
The length of text in `Unitext` parameter.

iStartOffset
The starting offset.

iEndOffset
The ending offset.

refcon
The refcon.

userUPP
The UPP that is to be activated.

Return Value

Availability
Available in Mac OS X v10.0 and later.

Declared In
`HITextViews.h`

IsAutomaticControlDragTrackingEnabledForWindow

Indicates whether automatic drag tracking is enabled for the specified window.

```
OSStatus IsAutomaticControlDragTrackingEnabledForWindow (
   WindowRef inWindow,
   Boolean *outTracks
);
```

Parameters

inWindow

outTracks
On output, a pointer to a Boolean whose value is `true` if the Control Manager's automatic drag tracking is enabled for the window; otherwise, `false`.

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Discussion
For more information on automatic drag tracking, see `SetAutomaticControlDragTrackingEnabledForWindow` (page 643).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Controls.h`

IsControlActive

Returns whether a control is active.

```
Boolean IsControlActive (
   ControlRef inControl
);
```

Parameters

inControl

A handle to the control to be examined.

Return Value

A Boolean whose value is `true` if the control is active; otherwise, `false`.

Discussion

If you wish to determine whether a control is active, you should call `IsControlActive` instead of testing the `contrlHilite` field of the control structure.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Controls.h`

IsControlDragTrackingEnabled

Indicates whether a control's drag track and receive support is enabled.

```
OSStatus IsControlDragTrackingEnabled (
   ControlRef inControl,
   Boolean *outTracks
);
```

Parameters

inControl

.

outTracks

On output, a pointer to a Boolean whose value is `true` if automatic drag tracking and receive support is enabled for the control; otherwise, `false`.

Return Value

A result code. See "Control Manager Result Codes" (page 824).

Discussion

Call this function to determine whether drag and drop support is enabled for a control. Some controls don't support drag and drop; these controls don't track or receive drags even if the `outTracks` parameter indicates a value of `true`.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Controls.h`

IsControlEnabled

Indicates whether a control is enabled.

```
Boolean IsControlEnabled (
   ControlRef inControl
);
```

Parameters

inControl
The control that is to be queried.

Return Value

A Boolean whose value is `true` if the control is enabled; otherwise, `false`.

Availability

Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In

`Controls.h`

IsControlHilited

Indicates whether or not the control is highlighted.

```
Boolean IsControlHilited (
   ControlRef control
);
```

Parameters

control
The control that is to be queried.

Return Value

A Boolean whose value is `true` if the control is highlighted; otherwise, `false`.

Availability

Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In

`Controls.h`

IsControlVisible

Determines whether a control is visible.

```
Boolean IsControlVisible (
   ControlRef inControl
);
```

Parameters

inControl
A handle to the control to be examined.

Return Value
If `true`, the control is visible. If `false`, the control is hidden.

Discussion
If you want to determine whether a control is visible, call `IsControlVisible`. Note that this function indicates the actual user visibility; if the control is marked visible, but its owning window or view is hidden, `isControlVisible` returns `false`. (In compositing mode, if a window is hidden, its root view is also marked as hidden. Similarly, any subviews of a hidden view are considered hidden.) A control's latent visibility (its visibility ignoring the visibility of its parents) can be determined by calling the HIView function `HIViewIsLatentlyVisible`.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Controls.h`

IsValidControlHandle

Reports whether a given handle is a control handle.

```
Boolean IsValidControlHandle (
   ControlRef theControl
);
```

Parameters
`theControl`
A value of type `ControlHandle`. Pass the handle to be examined.

Return Value
`true` if the specified handle is a valid control handle; otherwise, `false`.

Discussion
The `IsValidControlHandle` function confirms whether a given handle is a valid control handle, but it does not check the validity of the data contained in the control itself.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Controls.h`

KillControls

Removes all of the controls from a window that you wish to keep.

```
void KillControls (
   WindowRef theWindow
);
```

Parameters

theWindow

A pointer to the window whose controls you wish to remove.

Discussion

The `KillControls` function disposes of all controls associated with the specified window. To remove just one control, use `DisposeControl` (page 573). If an embedding hierarchy is present, `KillControls` disposes of the controls embedded within a control before disposing of the container control.

You should use `KillControls` when you wish to retain the window but dispose of its controls. The Window Manager functions `CloseWindow` and `DisposeWindow` automatically remove all controls associated with the window and release the memory the controls occupy.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Controls.h`

MoveControl

Moves a control within its window.

```
void MoveControl (
   ControlRef theControl,
   SInt16 h,
   SInt16 v
);
```

Parameters

theControl

A handle to the control you wish to move.

h

The horizontal coordinate (local to the control's window) of the new location of the upper-left corner of the control's rectangle.

v

The vertical coordinate (local to the control's window) of the new location of the upper-left corner of the control's rectangle.

Discussion

The `MoveControl` function moves the control to the new location specified by the `h` and `v` parameters, using them to change the rectangle specified in the `contrlRect` field of the control structure. When the control is visible, `MoveControl` first hides it and then redraws it at its new location.

For example, if the user resizes a document window that contains a scroll bar, your application can use `MoveControl` to move the scroll bar to its new location.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Related Sample Code
QTCarbonShell

Declared In
`Controls.h`

NewControl

Creates a control based on parameter data. (Deprecated in Mac OS X v10.5. Use the specific control creation function instead (for example, `CreateCheckBoxControl` (page 541)).)

```
ControlRef NewControl (
   WindowRef owningWindow,
   const Rect *boundsRect,
   ConstStr255Param controlTitle,
   Boolean initiallyVisible,
   SInt16 initialValue,
   SInt16 minimumValue,
   SInt16 maximumValue,
   SInt16 procID,
   SRefCon controlReference
);
```

Parameters

owningWindow

A pointer to the window in which you want to place the control. All coordinates pertaining to the control are interpreted in this window's local coordinate system.

boundsRect

A pointer to a rectangle, specified in the given window's local coordinates, that encloses the control and thus determines its size and location. When specifying this rectangle, you should follow the guidelines presented in "Dialog Box Layout", in Mac OS 8 Human Interface Guidelines, for control placement and alignment.

controlTitle

The title string, used for push buttons, checkboxes, radio buttons, and pop-up menus. When specifying a multiple-line title, separate the lines with the ASCII character code 0x0D (carriage return). For controls that don't use titles, pass an empty string.

initiallyVisible

A Boolean value specifying the visible/invisible state for the control. If you pass `true` in this parameter, `NewControl` draws the control immediately, without using your window's standard updating mechanism. If you pass `false`, you must later use `ShowControl` (page 669) to display the control.

initialValue

The initial setting for the control. For sliders and scrollbars, pass the appropriate integer value. For checkboxes and radio buttons, pass the constant indicating the current setting (as defined in "Checkbox Value Constants" (page 732) and "Radio Button Value Constants" (page 806). For plain buttons that do not retain a setting, pass 0.

minimumValue

The minimum setting for the control. For sliders and scrollbars, pass the appropriate minimum integer value. For checkboxes and radio buttons, pass 0 (or the equivalent constant from "Checkbox Value Constants" (page 732) or "Radio Button Value Constants" (page 806)). For plain buttons that do not retain a setting, pass 0.

maximumValue

The maximum setting for the control. For sliders and scrollbars, pass the appropriate maximum integer value. For scroll bars, if the maximum value is equal to the minimum value, the control definition function automatically disables the scroll bar. For checkboxes and radio buttons, pass 1 (or the equivalent constant defined in "Checkbox Value Constants" (page 732) or "Radio Button Value Constants" (page 806)). For plain buttons that do not retain a setting, pass 0.

procID

The control definition ID. If the control definition function isn't in memory, it is read in. On Mac OS X, if you do not pass a valid procID (that is, if it does not correspond to a CDEF resource), NewControl will not create a control and will simply return NULL. On Mac OS 9 and earlier, passing an invalid procID will cause NewControl to create a pushbutton control.

controlReference

The control's reference value, which is set and used only by your application.

Return Value

A handle to the control described in its parameters. If `NewControl` runs out of memory or fails, it returns `NULL`. For a description of this data type, see ControlRef (page 709).

Discussion

The `NewControl` function creates a control structure from the information you specify in its parameters, adds the control structure to the control list for the specified window, and returns as its function result a handle to the control. You use this handle when referring to the control in most other Control Manager functions. Generally, you should use the function `GetNewControl` (page 610) instead of `NewControl`, because `GetNewControl` is a resource-based control-creation function that allows you to localize your application without recompiling.

When an embedding hierarchy is established within a window, `NewControl` automatically embeds the newly created control in the root control of the owning window.

Carbon Porting Notes

Carbon does not support custom control definitions stored in `'CDEF'` resources. If you want to specify a custom control definition for `NewControl`, you must compile your definition function directly in your application and then register the function by calling `RegisterControlDefinition` (page 640). When `NewControl` gets a `procID` value that doesn't recognize, it checks a special mapping table to find the pointer that is registered for the resource ID embedded in the `procID` parameter. It then calls that function to implement your control.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Controls.h`

NewControlActionUPP

Creates a UPP for a control action callback function.

```
ControlActionUPP NewControlActionUPP (
   ControlActionProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your control action callback function. See `ControlActionProcPtr` (page 675) for information about defining this function.

Return Value

A UPP to your control action callback function.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Controls.h`

NewControlCNTLToCollectionUPP

Creates a UPP for a control-to-collection callback function.

```
ControlCNTLToCollectionUPP NewControlCNTLToCollectionUPP (
   ControlCNTLToCollectionProcPtr userRoutine
);
```

Return Value

A UPP to your control-to-collection callback function.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Controls.h`

NewControlColorUPP

Not recommended

```
ControlColorUPP NewControlColorUPP (
   ControlColorProcPtr userRoutine
);
```

Carbon Porting Notes

Instead of specifying a callback to redraw your background, you should make the background a control and then embed your other controls within it.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In
Controls.h

NewControlDefUPP

Creates a UPP for a control definition callback function. (Deprecated in Mac OS X v10.5. Use a custom HIView to draw a custom control.)

```
ControlDefUPP NewControlDefUPP (
   ControlDefProcPtr userRoutine
);
```

Return Value
A UPP to your control definition callback function.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
Controls.h

NewControlEditTextValidationUPP

Creates a UPP for a control edit text validation callback function.

```

);
```

Return Value

Availability
Available in Mac OS X v10.0 and later.

Declared In
`HITextViews.h`

RegisterControlDefinition

Registers an old-style control definition.

```
OSStatus RegisterControlDefinition (
   SInt16 inCDEFResID,
   const ControlDefSpec *inControlDef,
   ControlCNTLToCollectionUPP inConversionProc
);
```

Parameters

CDEFResID

The virtual resource ID you want to assign to the control definition.

def

A pointer to the control definition function you want to register. Pass `NULL` if you want to unregister a given CDEF proc ID.

conversionProc

A UPP to a callback function to place initialization data (such as the bounds, min and max values, and so on) into a collection.

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Discussion
Mac OS X does not allow you to store custom control definitions in resources. However, some older functions such as `GetNewControl` (page 610) expect a resource ID when creating controls. To work around this, you can use `RegisterControlDefinition` to register "virtual" resource IDs for your control definition functions.

Since custom control definitions receive initialization data as a collection in the `param` parameter, you must provide a callback to properly package this information. See "Control Collection Tag Constants" (page 768) for a list of tags you can apply to the collection. If you do not supply a conversion callback, the Control Manager sends an empty collection to your control definition.

To unregister a control definition, pass `NULL` in the `inDefSpec` parameter for a given CDEF proc ID.

In Mac OS X v10.2 and later, you should consider reimplementing your custom control code using custom HIViews. See I*ntroducing HIView* for more information.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Controls.h`

RemoveControlProperty

Removes a piece of data that has been previously associated with a control.

```
OSStatus RemoveControlProperty (
   ControlRef control,
   OSType propertyCreator,
   OSType propertyTag
);
```

Parameters

control
A handle to the control whose associated data you wish to remove.

propertyCreator
Your program's signature, as registered through Apple Developer Technical Support. If your program is of a type that would not normally have a signature (for example, a plug-in), you should still register and use a signature in this case, even though your program's file may not have the same creator code as the signature that you register. The `'macs'` property signature is reserved for the system and should not be used.

propertyTag
The application-defined code identifying the associated data.

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Discussion
Your application may dissociate data it has previously set with the `SetControlProperty` (page 658) function by calling the `RemoveControlProperty` function.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Controls.h`

ReverseKeyboardFocus

Returns keyboard focus to the prior focusable control in a window.

```
OSErr ReverseKeyboardFocus (
   WindowRef inWindow
);
```

Parameters

inWindow

A pointer to the window for which to reverse keyboard focus.

Return Value

A result code. See "Control Manager Result Codes" (page 824).

Discussion

The `ReverseKeyboardFocus` function reverses the progression of keyboard focus, skipping over deactivated and hidden controls until it finds the previous control to receive keyboard focus in the window.

When `ReverseKeyboardFocus` is called, the Control Manager calls your control definition function and passes `kControlMsgFocus` in its `message` parameter and `kControlFocusPrevPart` in its `param` parameter. In response to this message, your control definition function should change keyboard focus to its previous part, the entire control, or remove keyboard focus from the control, depending upon the circumstances. See `ControlDefProcPtr` (page 677) for a discussion of possible responses to this message.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Controls.h`

SendControlMessage

Sends a message to a control definition function. (**Deprecated.** For custom controls, use a custom HIView instead of a control definition function. See *HIView Programming Guide*.)

Not recommended

```
SInt32 SendControlMessage (
   ControlRef inControl,
   SInt16 inMessage,
   void *inParam
);
```

Parameters

inControl

A handle to the control that is to receive a low-level message. For a description of this data type, see ControlRef (page 709).

inMessage

A bit field representing the message(s) you wish to send; see `ControlDefProcPtr` (page 677).

inParam

The message-dependent data passed in the `param` parameter of the control definition function.

Return Value
Varying data, depending upon the message sent in the `inMessage` parameter.

Discussion
Your application does not normally need to call the `SendControlMessage` function. If you have a special need to call a control definition function directly, call `SendControlMessage` to access and manipulate the control's attributes.

Before calling `SendControlMessage`, you should determine whether the control supports the specific message you wish to send by calling `GetControlFeatures` (page 597) and examining the feature bit field returned. If there are no feature bits returned that correspond to the message you wish to send (for messages 0 through 12), you can assume that all system controls support that message.

Carbon Porting Notes

Don't send messages to standard system control definitions.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Controls.h`

SetAutomaticControlDragTrackingEnabledForWindow

Enables or disables automatic drag tracking for a window.

```
OSStatus SetAutomaticControlDragTrackingEnabledForWindow (
   WindowRef inWindow,
   Boolean inTracks
);
```

Parameters

inWindow

inTracks

A Boolean whose value is `true` to enable the Control Manager's automatic drag tracking support or `false` to disable automatic drag tracking support.

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Discussion
By default, your application is responsible for installing drag tracking and receive handlers on a given window. The Control Manager, however, has support for automatically tracking and receiving drags over controls that you can enable by calling this function with the `inTracks` parameter set to `true`.

The Control Manager automatic drag tracking detects the control the drag is over and calls `HandleControlDragTracking` (page 615) and `HandleControlDragReceive` (page 615) appropriately. By default, the Control Manager's automatic drag tracking is disabled.

Earlier versions of system software enabled automatic drag tracking by default, but as of Mac OS X v10.1.3, Mac OS 9.2, and CarbonLib 1.4, you must call this function to enable automatic drag tracking.

Availability
Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Related Sample Code
CarbonCocoa_PictureCursor

Declared In

SetBevelButtonContentInfo

Sets the content information for a bevel button.

```
OSErr SetBevelButtonContentInfo (
   ControlRef inButton,
   ControlButtonContentInfoPtr inContent
);
```

Parameters

inButton
The control reference for the bevel button whose content information is to be set.

inContent
A value of type `ControlButtonContentInfoPtr` for the content information that is to be set.

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`HIButtonViews.h`

SetBevelButtonGraphicAlignment

Sets the alignment for a bevel button.

```
OSErr SetBevelButtonGraphicAlignment (
   ControlRef inButton,
   ControlButtonGraphicAlignment inAlign,
   SInt16 inHOffset,
   SInt16 inVOffset
);
```

Parameters

inButton
The control reference for the bevel button that is to be aligned.

inAlign
The alignment that is to be set. For possible values, see "Bevel Button Graphic Alignment Constants" (page 726).

inHOffset
The horizontal offset, in pixels, that is to be applied to the alignment specified by the `inAlign` parameter.

inVOffset
The vertical offset, in pixels, that is to be applied to the alignment specified by the `inAlign` parameter.

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`HIButtonViews.h`

SetBevelButtonMenuValue

Sets the value of a bevel button menu.

```
OSErr SetBevelButtonMenuValue (
   ControlRef inButton,
   MenuItemIndex inValue
);
```

Parameters

inButton
The control reference for the bevel button whose menu value is to be set.

inValue
The value that is to be set.

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`HIButtonViews.h`

SetBevelButtonTextAlignment

Sets the alignment of the text for a bevel button.

```
OSErr SetBevelButtonTextAlignment (
   ControlRef inButton,
   ControlButtonTextAlignment inAlign,
   SInt16 inHOffset
);
```

Parameters

inButton

The control reference for the bevel button whose text is to be aligned.

inAlign

The alignment that is to be set. For possible values, see"Bevel Button Text Alignment Constants " (page 729).

inHOffset

The horizontal offset, in pixels, that is to be applied to the alignment specified by the `inAlign` parameter.

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`HIButtonViews.h`

SetBevelButtonTextPlacement

Sets the placement for bevel button text.

```
OSErr SetBevelButtonTextPlacement (
   ControlRef inButton,
   ControlButtonTextPlacement inWhere
);
```

Parameters

inButton

The control reference for the bevel button whose text is to be placed.

inWhere

The placement that is to be set. For possible values, see "Bevel Button Text Placement Constants " (page 730).

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`HIButtonViews.h`

SetBevelButtonTransform

Sets the transform for a bevel button.

```
OSErr SetBevelButtonTransform (
   ControlRef inButton,
   IconTransformType transform
);
```

Parameters

inButton

The control reference for the bevel button whose text is to be placed.

transform

The transform that is to be set. For possible values, see the `IconTransformType` enumeration described in the *Icon Services and Utilities Reference*.

Return Value

A result code. See "Control Manager Result Codes" (page 824).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`HIButtonViews.h`

SetControl32BitMaximum

Changes the maximum setting of a control and, if appropriate, redraws it accordingly.

```
void SetControl32BitMaximum (
   ControlRef theControl,
   SInt32 newMaximum
);
```

Parameters

theControl

A handle to the control whose maximum setting you wish to change. For a description of this data type, see ControlRef (page 709).

newMaximum

The new maximum setting of the control. In general, to avoid unpredictable behavior, do not set the maximum control value lower than the current minimum value.

Discussion

Your application may use the `SetControl32BitMaximum` function to set a 32-bit value as the maximum setting for a control.

If your application uses a 32-bit control maximum value, it should not attempt to obtain this value by calling the pre–Mac OS 8.5 function `GetControlMaximum` because the 16-bit value that is returned does not accurately reflect the current 32-bit control value. Instead, use the function `GetControl32BitMaximum` (page 589).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Related Sample Code
HID Calibrator
HID Explorer

Declared In
`Controls.h`

SetControl32BitMinimum

Changes the minimum setting of a control and, if appropriate, redraws it accordingly.

```
void SetControl32BitMinimum (
   ControlRef theControl,
   SInt32 newMinimum
);
```

Parameters

theControl
A handle to the control whose minimum setting you wish to change. For a description of this data type, see ControlRef (page 709).

newMinimum
A value specifying the new minimum setting of the control. In general, to avoid unpredictable behavior, do not set the minimum control value higher than the current maximum value.

Discussion
Your application may use the `SetControl32BitMinimum` function to set a 32-bit value as the minimum setting for a control.

If your application uses a 32-bit control minimum value, it should not attempt to obtain this value by calling the pre–Mac OS 8.5 function `GetControlMinimum` because the 16-bit value that is returned does not accurately reflect the current 32-bit control value. Instead, use the function `GetControl32BitMinimum` (page 590).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

SetControl32BitValue

Changes the current setting of a control and redraws it accordingly.

```
void SetControl32BitValue (
   ControlRef theControl,
   SInt32 newValue
);
```

Parameters

theControl

A handle to the control whose current setting you wish to change. For a description of this data type, see ControlRef (page 709).

newValue

A value specifying the new setting of the control. If the specified value is less than the minimum setting for the control, `SetControl32BitValue` sets the current setting of the control to its minimum setting. If the specified value is greater than the maximum setting, `SetControl32BitValue` sets the control to its maximum.

Discussion

Your application may use the `SetControl32BitValue` function to set a 32-bit value as the current setting for a control.

If your application uses a 32-bit control value, it should not attempt to obtain this value by calling the pre–Mac OS 8.5 function `GetControlValue` because the 16-bit value that is returned does not accurately reflect the current 32-bit control value. Instead, use the function `GetControl32BitValue` (page 590).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Controls.h`

SetControlAction

Sets the action function for a control.

```
void SetControlAction (
   ControlRef theControl,
   ControlActionUPP actionProc
);
```

Parameters

theControl

A handle to the control whose action function is to be changed.

actionProc

A universal procedure pointer to an action function defining what action your application takes while the user holds down the mouse button. See `ControlActionProcPtr` (page 675) for a description of an action function.

Discussion
The `SetControlAction` function associates the action function specified by `actionProc` with the control specified by `theControl`. If the cursor is in the specified control, the `HandleControlClick` (page 613) and `TrackControl` (page 671) functions call the specified action function when the user holds down the mouse button. You must provide the action function, and it must define some action to perform repeatedly as long as the user holds down the mouse button. `HandleControlUnderClick` and `TrackControl` always highlight and drag the control as appropriate.

`SetControlAction` should be used to set the application-defined action function for providing live feedback for standard system scroll bar controls.

Note that the action function associated with a control is used by `TrackControl` only if you set the action function to `TrackControl` to `Pointer(-1)`. Also, an action function can be specified in the `actionProc` parameter to `TrackControl`, so you don't have to call `SetControlAction` to change it.

SetControlColorProc

Associates a `ControlColorUPP` with a given Control, thereby allowing you to bypass the embedding hierarchy-based color setup of `SetUpControlBackground`/`SetUpControlTextColor` and replace it with your own.

Not recommended

```
OSStatus SetControlColorProc (
   ControlRef inControl,
   ControlColorUPP inProc
);
```

Parameters

inControl

The ControlRef with whom the color proc should be associated. For a description of this data type, see ControlRef (page 709).

inProc

The color proc to associate with the `ControlRef`. If you pass `NULL`, the `ControlRef` will be dissociated from any previously installed color proc. For a description of the `ControlColorUPP` data type,

Return Value

A result code. See "Control Manager Result Codes" (page 824). An OSStatus code indicating success or failure. The most likely error is a controlHandleInvalidErr resulting from a bad ControlRef.

Discussion

Before an embedded Control can erase, it calls `SetUpControlBackground` (page 667) to have its background color set up by any parent controls. Similarly, any Control that draws text calls `SetUpControlTextColor` (page 668) to have the appropriate text color set up. This allows certain controls (such as tabs and placards) to offer special backgrounds and text colors for any child controls. By default, the set up functions only move up the Control Manager embedding hierarchy looking for a parent which has a special background.

This is fine in a plain vanilla embedding case, but many application frameworks find it troublesome; if there are interesting views between two controls in the embedding hierarchy, the framework needs to be in charge of the background and text colors, otherwise drawing defects will occur.

You can only associate a single color proc with a given `ControlRef`.

Carbon Porting Notes

Instead of specifying a callback to redraw your background, you should make the background a control and then embed your other controls within it.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

`Controls.h`

SetControlCommandID

Sets the command ID for a control.

```
OSStatus SetControlCommandID (
   ControlRef inControl,
   UInt32 inCommandID
);
```

Parameters

inControl

The control to set.

inCommandID

The command ID that is to be set.

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Controls.h`

SetControlData

Sets control-specific data.

```
OSErr SetControlData (
   ControlRef inControl,
   ControlPartCode inPart,
   ResType inTagName,
   Size inSize,
   const void *inData
);
```

Parameters

inControl

A handle to the control for which data is to be set.

inPart

The part code of the control part for which data is to be set; see "Control Meta Part Code Constants" (page 790), "Control Part Code Constants " (page 748), and " Control State Part Code Constants" (page 751). Passing `kControlEntireControl` indicates that either the control has no parts or the data is not tied to any specific part of the control.

inTagName

A constant representing the control-specific data you wish to set see the data tag constants in the "Control Manager Constants" (page 719) section.

inSize

The size (in bytes) of the data pointed to by the `inData` parameter. For variable-length control data, pass the value returned in the `outMaxSize` parameter of `GetControlDataSize` (page 596) in the `inSize` parameter. The number of bytes must match the actual data size.

inData

A pointer to a buffer allocated by your application. This buffer contains the data that you are sending to the control. After calling `SetControlData`, your application is responsible for disposing of this buffer, if necessary, as information is copied by control.

Return Value
A result code. See "Control Manager Result Codes" (page 824). The result code `errDataNotSupported` indicates that the `inTagName` parameter is not valid.

Discussion
The `SetControlData` function sets control-specific data represented by the value in the `inTagName` parameter to the data pointed to by the `inData` parameter. `SetControlData` could be used, for example, to switch a progress indicator from a determinate to indeterminate state. For a list of the control attributes that can be set, see the data tag constants in the "Control Manager Constants" (page 719) section.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

SetControlDataHandle

(**Deprecated.** Use custom HIViews instead of custom CDEFs. See *HIView Programming Guide*.)

Not recommended

```
void SetControlDataHandle (
   ControlRef control,
   Handle dataHandle
);
```

Carbon Porting Notes

Only useful for message-based custom controls (CDEFs).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Controls.h`

SetControlDragTrackingEnabled

Sets the drag tracking state for a control.

```
OSStatus SetControlDragTrackingEnabled (
   ControlRef inControl,
   Boolean inTracks
);
```

Parameters

inControl

The control for which the drag tracking state is to be set.

inTracks

A Boolean whose value is `true` if you want the control to track and receive drags or `false` if want to disable support for drag and drop.

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Discussion
Call this function to enable a control's support for drag and drop. If you don't enable drag and drop support, the control won't track drags.

Some controls don't support drag and drop; these controls won't track or receive drags even if you call this function with the `inTracks` parameter set to `true`.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
CarbonCocoa_PictureCursor

Declared In
`Controls.h`

SetControlFontStyle

Sets the font style for a control.

```
OSErr SetControlFontStyle (
   ControlRef inControl,
   const ControlFontStyleRec *inStyle
);
```

Parameters

inControl

A handle to the control whose font style is to be set. For a description of this data type, see ControlRef (page 709).

inStyle

A pointer to a `ControlFontStyleRec` (page 704) structure. If the `flags` field is cleared, the control uses the system font unless the control variant `kControlUsesOwningWindowsFontVariant` has been specified (control uses window font).

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Discussion
The `SetControlFontStyle` function sets the font style for a given control. To specify the font for controls in a dialog box, it is generally easier to use the dialog font table resource. `SetControlFontStyle` allows you to override a control's default font (system or window font, depending upon whether the control variant `kControlUsesOwningWindowsFontVariant` has been specified). Once you have set a control's font with this function, you can cause the control to revert to its default font by passing a control font style structure with a cleared `flags` field in the `inStyle` parameter.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

`Controls.h`

SetControlMaximum

Changes the maximum setting of a control and redraws its indicator or scroll box accordingly. (**Deprecated.** Use `SetControl32BitMaximum` (page 647) instead.)

Not recommended

```
void SetControlMaximum (
   ControlRef theControl,
   SInt16 newMaximum
);
```

Parameters

theControl

A handle to the control whose maximum setting you wish to change.

newMaximum

The new maximum setting.

Discussion

The `SetControlMaximum` function changes the maximum value of a control to the value specified by the `newMaximum` parameter and redraws its indicator or scroll box to reflect its new range.

When you set the maximum setting of a scroll bar equal to its minimum setting, the control definition function makes the scroll bar inactive. When you make the maximum setting exceed the minimum, the control definition function makes the scroll bar active again.

When you create a control, you specify an initial maximum setting either in the control resource or in the `max` parameter of the function `NewControl` (page 634). To determine a control's current maximum setting, use the function `GetControlMaximum` (page 599).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Related Sample Code

BSDLLCTest

CarbonSketch

HID Explorer

SetControlMinimum

Changes the minimum setting of a control and redraws its indicator or scroll box accordingly. (**Deprecated.** Use `SetControl32BitMinimum` (page 648) instead.)

Not recommended

```
void SetControlMinimum (
   ControlRef theControl,
   SInt16 newMinimum
);
```

Parameters

theControl

A handle to the control whose minimum setting you wish to change. For a description of this data type, see ControlRef (page 709).

newMinimum

The new minimum setting.

Discussion
The `SetControlMinimum` function changes the control's minimum value to the value specified by the `newMinimum` parameter and redraws its indicator or scroll box to reflect its new range.

When you create a control, you specify an initial minimum setting either in the control resource or in the `min` parameter of the `NewControl` (page 634) function. To obtain a control's current minimum setting, use the function `GetControlMinimum` (page 600).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Not available to 64-bit applications.

Declared In
`Controls.h`

SetControlPopupMenuID

Sets the menu ID for a pop-up control

```
void SetControlPopupMenuID (
   ControlRef control,
   short menuID
);
```

Parameters

control
The pop-up control.

menuID
The menu ID to set.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Controls.h`

SetControlProperty

Associates data with a control.

```
OSStatus SetControlProperty (
   ControlRef control,
   OSType propertyCreator,
   OSType propertyTag,
   ByteCount propertySize,
   const void *propertyData
);
```

Parameters

control
A handle to the control with which you wish to associate data. For a description of this data type, see ControlRef (page 709).

propertyCreator
Your program's signature, as registered through Apple Developer Technical Support. If your program is of a type that would not normally have a signature (for example, a plug-in), you should still register and use a signature in this case, even though your program's file may not have the same creator code as the signature that you register. The `'macs'` property signature is reserved for the system and should not be used.

propertyTag
A value identifying the data. You define the tag your application uses to identify the data.

propertySize
A value specifying the size of the data.

propertyData
On input, a pointer to data of any type. Pass a pointer to a buffer containing the data to be associated; this buffer should be at least as large as the value specified in the `propertySize` parameter.

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Discussion
Your application may use the `SetControlProperty` function to associate any type of data with a control.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

SetControlReference

Changes a control's current reference value.

```
void SetControlReference (
   ControlRef theControl,
   SRefCon data
);
```

Parameters

theControl

A handle to the control whose reference value you want to change. For a description of this data type, see ControlRef (page 709).

data

The new reference value for the control.

Discussion
The SetControlReference function sets the control's reference value to the value you specify in the data parameter.

When you create a control, you specify an initial reference value, either in the control resource or in the refCon parameter of the function NewControl (page 634). Call GetControlReference (page 604) to obtain the current value. You can use this value for any purpose.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
Controls.h

SetControlSupervisor

Routes mouse-down events to the embedder control.

Not recommended

```
OSErr SetControlSupervisor (
   ControlRef inControl,
   ControlRef inBoss
);
```

Parameters

inControl

A handle to an embedded control. For a description of this data type, see ControlRef (page 709).

inBoss

A handle to the embedder control to which mouse-down events are to be routed. For a description of this data type, see ControlRef (page 709).

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Discussion
The `SetControlSupervisor` function allows an embedder control to respond to mouse-down events occurring in its embedded controls.

An example of a standard control that uses this function is the radio group control. Mouse-down events in the embedded controls of a radio group are intercepted by the group control. (The embedded controls in this case must support radio behavior if a mouse-down event occurs in an embedded control within a radio group control that does not support radio behavior, the control tracks normally and the group is not involved.) The group handles all interactions and switches the embedded control's value on and off. If the value of the radio group changes, `TrackControl` (page 671) or `HandleControlClick` (page 613) will return the `kControlRadioGroupPart` part code. If the user tracks off the radio button or clicks the current radio button, `kControlNoPart` is returned.

Carbon Porting Notes

If you are using the Carbon Event Manager, send the event to the next higher control in the containment hierarchy instead.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Controls.h`

SetControlTitle

Changes the title of a control and redraws the control accordingly. (Deprecated in Mac OS X v10.5. Use `HIViewSetText` (page 2488) or `SetControlTitleWithCFString` (page 661) instead.)

Not recommended

```
void SetControlTitle (
   ControlRef theControl,
   ConstStr255Param title
);
```

Parameters

theControl

A handle to a control, the title of which you want to change.

title

The new title for the control.

Discussion
The `SetControlTitle` function changes the `contrlTitle` field of the control structure to the given string and redraws the control, using the system font for the control title.

The Control Manager allows multiple lines of text in the titles of buttons, checkboxes, and radio buttons. When specifying a multiple-line title, separate the lines with the ASCII character code 0x0D (carriage return). If the control is a button, each line is horizontally centered, and the font leading is inserted between lines. (The height of each line is equal to the distance from the ascent line to the descent line plus the leading of the font used. Be sure to make the total height of the rectangle greater than the number of lines times this height.) If the control is a checkbox or a radio button, the text is justified as appropriate for the user's current script system, and the checkbox or button is vertically centered within its rectangle.

When you create a control, you specify an initial title either in the control resource or in the `title` parameter of the function `NewControl` (page 634). To determine a control's current title, use the function `GetControlTitle` (page 605).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

CarbonCocoa_PictureCursor
HID Explorer

Declared In
`Controls.h`

SetControlValue

Changes the current setting of a control and redraws it accordingly. (**Deprecated.** Use `SetControl32BitValue` (page 648) instead.)

Not recommended

```
void SetControlValue (
   ControlRef theControl,
   SInt16 newValue
);
```

Parameters

theControl

A handle to the control whose current setting you wish to change. For a description of this data type, see ControlRef (page 709).

newValue

The new setting for the control.

Discussion

For controls whose values the user can set, you can use the `SetControlValue` function to change the value to the specified value and redraw the control to reflect the new setting. For checkboxes and radio buttons, the value 1 fills the control with the appropriate mark, and 0 removes the mark. For Mac OS 8 checkboxes and radio buttons, 2 represents a mixed state; see "Checkbox Value Constants" (page 732) and "Radio Button Value Constants" (page 806). For scroll bars, `SetControlValue` redraws the scroll box where appropriate.

If the specified value is less than the minimum setting for the control, `SetControlValue` sets the control to its minimum setting; if the value is greater than the maximum setting, `SetControlValue` sets the control to its maximum.

When you create a control, you specify an initial setting either in the control resource or in the `value` parameter of the function `NewControl` (page 634). To determine a control's current setting before changing it in response to a user's click in that control, use the function `GetControlValue` (page 606).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

HID Explorer

ictbSample

Declared In

`Controls.h`

SetControlViewSize

Informs the Control Manager of the size of the content to which a control's size is proportioned.

```
void SetControlViewSize (
   ControlRef theControl,
   SInt32 newViewSize
);
```

Parameters

theControl

A handle to the control whose view size is to be set. For a description of this data type, see ControlRef (page 709).

newViewSize

A value specifying the size of the content being displayed. This value should be expressed in terms of the same units of measurement as are used for the minimum, maximum, and current settings of the control.

Discussion

Your application should call the `SetControlViewSize` function to support proportional scroll boxes. If the user selects the systemwide Appearance preference for proportional scroll boxes and your application doesn't call `SetControlViewSize`, it will still have the traditional square scroll boxes.

To support a proportional scroll box, simply pass the size of the view area—in terms of whatever units the scroll bar uses—to `SetControlViewSize`. The system automatically handles resizing the scroll box, once your application supplies this information.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Controls.h`

SetControlVisibility

Sets the visibility of a control, and any embedded controls, and specifies whether it should be drawn.

```
OSErr SetControlVisibility (
   ControlRef inControl,
   Boolean inIsVisible,
   Boolean inDoDraw
);
```

Parameters

inControl

A handle to the control whose visibility is to be set.

inIsVisible

A Boolean value indicating whether the control is visible or invisible. If you set this value to `true`, the control will be visible. If `false`, the control will be invisible. If you wish to show a control (and latent embedded subcontrols) but do not want to cause screen drawing, pass `true` for this parameter and false in the `inDoDraw` parameter.

inDoDraw

A Boolean value indicating whether the control should be drawn or erased. If `true`, the control's display on the screen should be updated (drawn or erased) based on the value passed in the `inIsVisible` parameter. If `false`, the display will not be updated.

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Discussion
You should call the `SetControlVisibility` function instead of setting the `contrlVis` field of the control structure to set the visibility of a control and specify whether it will be drawn. If the control has embedded controls, `SetControlVisibility` allows you to set their visibility and specify whether or not they will be drawn. If you wish to show a control but do not want it to be drawn onscreen, pass `true` in the `inIsVisible` parameter and false in the `inDoDraw` parameter.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In

SetImageWellContentInfo

Sets the content information for an image well.

```
OSErr SetImageWellContentInfo (
   ControlRef inButton,
   ControlButtonContentInfoPtr inContent
);
```

Parameters

inButton

The control reference for the image well whose content information is to be set.

inContent

The content to set.

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`HIImageViews.h`

SetImageWellTransform

Sets an image well transform.

```
OSErr SetImageWellTransform (
   ControlRef inButton,
   IconTransformType inTransform
);
```

Parameters

inButton

The control reference for the image well.

inTransform

The transform to set. For possible values, see the `IconTransformType` enumeration described in the *Icon Services and Utilities Reference*.

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Discussion
An transform is a visual appearance modification that is to be made when drawing the control's content.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`HIImageViews.h`

SetKeyboardFocus

Sets the current keyboard focus to a specified control part for a window.

```
OSErr SetKeyboardFocus (
   WindowRef inWindow,
   ControlRef inControl,
   ControlFocusPart inPart
);
```

Parameters

inWindow

A pointer to the window containing the control that is to receive keyboard focus.

inControl

A handle to the control that is to receive keyboard focus.

inPart

A part code specifying the part of a control to receive keyboard focus. To clear a control's keyboard focus, pass `kControlFocusNoPart`. For a description of this data type, see ControlFocusPart (page 703)

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Discussion
A control with keyboard focus receives keyboard events. The Dialog Manager tests to see which control has keyboard focus when a keyboard event is processed and sends the event to that control. If no control has keyboard focus, the keyboard event is discarded. A control retains keyboard focus if it is hidden or deactivated.

Keyboard focus is only available if an embedding hierarchy has been established in the focusable control's window. The default focusing order is based on the order in which controls are added to the window. For more details on embedding hierarchies, see `EmbedControl` (page 583).

The `SetKeyboardFocus` function sets the keyboard focus to a specified control part. The control to receive keyboard focus can be deactivated or invisible. This permits you to set the focus for an item in a dialog box before the dialog box is displayed.

Availability
Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

`HITabbedView.h`

SetUpControlBackground

Applies the proper background color for the given control to the current port.

```
OSErr SetUpControlBackground (
   ControlRef inControl,
   SInt16 inDepth,
   Boolean inIsColorDevice
);
```

Parameters

inControl

The `ControlRef` that wants to erase. For a description of this data type, see ControlRef (page 709).

inDepth

A short integer indicating the color depth of the device onto which drawing will take place.On Mac OS X, this parameter is ignored; you should always pass `32`.

inIsColorDevice

A Boolean indicating whether the draw device is a color device. On Mac OS X, this parameter is ignored; you should always pass `true`.

Return Value
A result code. See "Control Manager Result Codes" (page 824). An OSStatus code indicating success or failure. The most likely error is a `controlHandleInvalidErr`, resulting from a bad `ControlRef`. Any non-noErr result indicates that the color set up failed, and that the caller should probably give up its attempt to draw.

Discussion
An embedding-savvy control which erases before drawing must ensure that its background color properly matches the body color of any parent controls on top of which it draws. This routine asks the Control Manager to determine and apply the proper background color to the current port.

If a ControlColorProc callback has been provided for the given control, the callback will be called to set up the background color. If no proc exists, or if the proc returns a value other than `noErr`, the Control Manager ascends the parent chain for the given control looking for a control which has a special background (see the `kControlHasSpecialBackground` feature bit). The first such parent is asked to set up the background color (see the `kControlMsgSetUpBackground` message). If no such parent exists, the Control Manager applies any ThemeBrush which has been associated with the owning window (see `SetThemeWindowBackground`).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Controls.h`

SetUpControlTextColor

Applies the proper text color for the given control to the current port.¬¬

```
OSErr SetUpControlTextColor (
   ControlRef inControl,
   SInt16 inDepth,
   Boolean inIsColorDevice
);
```

Parameters

`inControl`
The `ControlRef` that wants to draw text.

`inDepth`
A short integer indicating the color depth of the device onto which drawing will take place. On Mac OS X, this parameter is ignored; you should always pass `32`.

`inIsColorDevice`
A Boolean indicating whether the draw device is a color device. On Mac OS X, this parameter is ignored; you should always pass `true`.

Return Value
A result code. See "Control Manager Result Codes" (page 824). An OSStatus code indicating success or failure. The most likely error is a `controlHandleInvalidErr`, resulting from a bad `ControlRef`. Any non-noErr result indicates that the color set up failed, and that the caller should probably give up its attempt to draw.

Discussion
An embedding-savvy control which draws text must ensure that its text color properly contrasts the background on which it draws. This routine asks the Control Manager to determine and apply the proper text color to the current port.

If a ControlColorProc has been provided for the given control, the proc will be called to set up the text color. If no proc exists, or if the proc returns a value other than noErr, the Control Manager ascends the parent chain for the given control looking for a control which has a special background (see the `kControlHasSpecialBackground` feature bit). The first such parent is asked to set up the text color (see the `kControlMsgApplyTextColor` message). If no such parent exists, the Control Manager chooses a text color which contrasts any ThemeBrush which has been associated with the owning window (see `SetThemeWindowBackground`).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Controls.h`

ShowControl

Makes an invisible control, and any latent embedded controls, visible.

```
void ShowControl (
   ControlRef theControl
);
```

Parameters

theControl
A handle to the control to make visible. For a description of this data type, see ControlRef (page 709).

Discussion
If the specified control is invisible, the `ShowControl` function makes it visible and immediately draws the control within its window without using your window's standard updating mechanism. Note that the `ShowControl` function draws the control in its window, but the control can still be completely or partially obscured by overlapping windows or other objects. If the control is already visible, `ShowControl` has no effect.

When showing groups of controls, the state of an embedded control that is hidden or deactivated is preserved, so that when the embedder control is shown or activated, the embedded control appears in the same state as the embedder. If the specified control has embedded controls, `ShowControl` makes the embedded controls visible as well.

An embedded control is considered latent when it is deactivated or hidden due to its embedder control being deactivated or hidden. If you call `ShowControl` on a latent embedded control whose embedder is disabled, the embedded control will remain invisible until its embedder control is enabled.

You can make a control invisible in several ways:

- Specifying its invisibility in the control resource.
- Passing a value of `false` in the `visible` parameter of `NewControl` (page 634).
- Calling `HideControl` (page 618).
- Calling `SetControlVisibility` (page 663).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Controls.h`

SizeControl

Changes the size of a control's rectangle.

```
void SizeControl (
   ControlRef theControl,
   SInt16 w,
   SInt16 h
);
```

Parameters

theControl

A handle to the control you wish to resize.

w

The new width, in pixels, of the resized control.

h

The new height, in pixels, of the resized control.

Discussion

The `SizeControl` function changes the rectangle specified in the `contrlRect` field of the control structure. The lower-right corner of the rectangle is adjusted so that it has the width and height specified by the `w` and `h` parameters the position of the upper-left corner is not changed. If the control is currently visible, it's first hidden and then redrawn in its new size. The `SizeControl` function will change the window's update region.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

`Controls.h`

TestControl

Obtains the control part in which a mouse-down event occurred.

```
ControlPartCode TestControl (
   ControlRef theControl,
   Point testPoint
);
```

Parameters

theControl

A handle to the control in which the mouse-down event occurred.

testPoint

The point, in a window's local coordinates, where the mouse-down event occurred.

Return Value

The part code of the control part, or `0` if the point is outside the control; see "Control Meta Part Code Constants" (page 790), "Control Part Code Constants " (page 748), and" Control State Part Code Constants" (page 751). If the control is invisible or inactive, `TestControl` returns 0. For a description of this data type, see ControlPartCode (page 708).

Discussion
The `TestControl` function is called by the `FindControl` (page 585) and `TrackControl` (page 671) functions; your application does not normally call it.

When the control specified by the parameter `theControl` is visible and active, `TestControl` tests which part of the control contains the point specified by the parameter `testPoint`.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Controls.h`

TrackControl

Responds to cursor movements in a control while the mouse button is down. (**Deprecated.** Use `HandleControlClick` (page 613) instead.)

Not recommended

```
ControlPartCode TrackControl (
   ControlRef theControl,
   Point startPoint,
   ControlActionUPP actionProc
);
```

Parameters

theControl
A handle to the control in which a mouse-down event occurred. For a description of this data type, see ControlRef (page 709).

startPoint
A point, specified in coordinates local to the window, where the mouse-down event occurred.

actionProc
A pointer to an action function defining the action your application takes while the user holds down the mouse button. The value of the `actionProc` parameter can be a valid `procPtr`, `NULL`, or `-1`. A value of `-1` indicates that the control should either perform auto tracking, or if it is incapable of doing so, do nothing (like `NULL`). See `ControlActionProcPtr` (page 675) for information about an action function to specify in this parameter.

Return Value
If the user releases the mouse button while the cursor is inside a control part, `TrackControl` returns a value of type `ControlPartCode`identifying the control part in which the mouse-up event occurs; see "Control Meta Part Code Constants" (page 790), "Control Part Code Constants " (page 748), and" Control State Part Code Constants" (page 751). `TrackControl` returns 0 if the user releases the mouse button while the cursor is outside the control part. If the user releases the mouse button when the cursor is in an indicator such as a scroll box, `TrackControl` calls the control's control definition function to reposition the indicator. For a description of this data type, see ControlPartCode (page 708).

Discussion
When the Appearance Manager is available, you should typically call `HandleControlClick` (page 613) instead of `TrackControl` to follow the user's cursor movements in a control and provide visual feedback until the user releases the mouse button. Unlike the `TrackControl` function, `HandleControlClick` also accepts modifier key information so that the control may take into account the current modifier key state if the control is set up to handle its own tracking.

If the Appearance Manager is not available, you can use the `TrackControl` function to follow the user's cursor movements in a control and provide visual feedback until the user releases the mouse button. The visual feedback given by `TrackControl` depends on the control part in which the mouse-down event occurs. When highlighting is appropriate, for example, `TrackControl` highlights the control part (and removes the highlighting when the user releases the mouse button). When the user holds down the mouse button while the cursor is in an indicator (such as the scroll box of a scroll bar) and moves the mouse, `TrackControl` responds by dragging a dotted outline of the indicator.

While the user holds down the mouse button with the cursor in one of the standard controls, `TrackControl` performs the following actions, depending on the value you pass in the parameter `actionProc`. (For other controls, what you pass in this parameter depends on how you define the control.)

- If you pass `NULL` in the `actionProc` parameter, `TrackControl` uses no action function and therefore performs no additional actions beyond highlighting the control or dragging the indicator. This is appropriate for buttons, checkboxes, radio buttons, and the scroll box of a scroll bar.
- If you pass a pointer to an action function in the `actionProc` parameter, you must provide the function, and it must define some action that your application repeats as long as the user holds down the mouse button. This is appropriate for the scroll arrows and gray areas of a scroll bar.
- If you pass `Pointer(-1)` in the `actionProc` parameter, `TrackControl` looks in the `contrlAction` field of the control structure for a pointer to the control's action function. This is appropriate when you are tracking the cursor in a pop-up menu. (You can use the `GetControlAction` function to determine the value of this field, and you can use the `SetControlAction` function to change this value.) If the `contrlAction` field of the control structure contains a function pointer, `TrackControl` uses the action function it points to; if the field of the control structure also contains the value `Pointer(-1)`, `TrackControl` calls the control's control definition function to perform the necessary action you may wish to do this if you define your own control definition function for a custom control. If the field of the control structure contains the value `NULL`, `TrackControl` performs no action.

Note that when you need to handle events in alert and dialog boxes, Dialog Manager functions automatically call `FindControl` and `TrackControl`.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Controls.h`

UpdateControls

Draws controls in the specified update region of a window.

```
void UpdateControls (
   WindowRef inWindow,
   RgnHandle inUpdateRegion
);
```

Parameters

theWindow

On input, a pointer to the window containing the controls to update.

updateRegion

On input, a handle to the update region of the specified window.

Discussion

The `UpdateControls` function, which should not be called in a compositing window, draws only those controls in the specified window that need updating. This function is faster than the `DrawControls` (page 581) function, which draws all of the controls in a window. By contrast, `UpdateControls` draws only those controls in the update region.

Your application should call `UpdateControls` upon receiving an update event for a window that contains controls. While the Dialog Manager handles update events for controls in alert boxes and dialog boxes, Window Manager functions such as `SelectWindow`, `ShowWindow`, and `BringToFront` do not automatically call `UpdateControls` to display the window's controls.

In response to an update event, you normally call `UpdateControls` after using the Window Manager function `BeginUpdate` and before using the Window Manager function `EndUpdate`. You should set the `updateRegion` parameter to the visible region of the window's port, as specified in the port's `visRgn` field. Note that if your application draws parts of a control outside of its rectangle, `UpdateControls` might not redraw it.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Callbacks by Task

Defining Your Own Action Function

`ControlActionProcPtr` (page 675)

Defines actions to be performed repeatedly in response to a mouse-down event in a control part.

Defining Your Own Control Definition Function

`ControlDefProcPtr` (page 677)

If you wish to define new, nonstandard controls for your application, you must write a control definition function and either register it with the system using `RegisterControlDefinition` (page 640) or create it directly using `CreateCustomControl` (page 543).

Defining Your Own Key Filter Function

`ControlKeyFilterProcPtr` (page 686)
The key filter function allows for the interception and possible changing of keystrokes destined for a control.

Defining Your Own Text Validation Function

`ControlEditTextValidationProcPtr` (page 685)
Ensures that the content of an editable text control is valid.

Defining Your Own User Pane Functions

`ControlUserPaneActivateProcPtr` (page 687)
Handles activate and deactivate event processing.

`ControlUserPaneBackgroundProcPtr` (page 688)
Sets the background color or pattern for user panes that support embedding.

`ControlUserPaneDrawProcPtr` (page 690)
Draws the content of your user pane control in the rectangle of user pane control.

`ControlUserPaneFocusProcPtr` (page 691)
Handles keyboard focus.

`ControlUserPaneHitTestProcPtr` (page 692)
Returns the part code of the control that the point was in when the mouse-down event occurred.

`ControlUserPaneIdleProcPtr` (page 692)
Performs idle processing.

`ControlUserPaneKeyDownProcPtr` (page 693)
Handles keyboard event processing.

`ControlUserPaneTrackingProcPtr` (page 695)
Tracks a control while the user holds down the mouse button.

Miscellaneous

`ControlCNTLToCollectionProcPtr` (page 676)

`ControlColorProcPtr` (page 677)

`EditUnicodePostUpdateProcPtr` (page 696)

Callbacks

ControlActionProcPtr

Defines actions to be performed repeatedly in response to a mouse-down event in a control part.

```
typedef void (*ControlActionProcPtr) (
    ControlRef theControl,
    ControlPartCode partCode
);
```

If you name your function `MyControlActionProc`, you would declare it like this:

```
void MyControlActionProc (
    ControlRef theControl,
    ControlPartCode partCode
);
```

Parameters

theControl

The control in which the mouse-down event occurred. For a description of this data type, see ControlRef (page 709).

partCode

The control part in which the mouse-down event occurred; see "Control Meta Part Code Constants" (page 790), "Control Part Code Constants " (page 748), and " Control State Part Code Constants" (page 751). When the cursor is still in the control part where the mouse-down event first occurred, this parameter contains that control's part code. When the user drags the cursor outside the original control part, this parameter contains 0.

Discussion

The Control Manager defines the data type `ControlActionUPP` to identify the universal procedure pointer for this application-defined callback function. To provide a pointer to your callback, you can use the function `NewControlActionUPP` (page 636). You can do so with code similar to the following:

```
ControlActionUPP myActionUPP;
myActionUPP = NewControlActionUPP (MyControlActionCallback);
```

When a mouse-down event occurs in a control, `HandleControlClick` (page 613) and `TrackControl` (page 671) respond as is appropriate, typically by highlighting the control or dragging the indicator as long as the user holds down the mouse button. You can define other actions to be performed repeatedly during this interval. To do so, define your own action function and point to it in the `actionProc` parameter of the `TrackControl` function or the `inAction` parameter of `HandleControlClick`. This is the only way to specify actions in response to all mouse-down events in a control or indicator.

When your action function is called for a control part, the action function is passed a handle to the control and the control's part code. The action function should then respond as is appropriate. `MyActionProc` is an example of such an action function. The only exception to this is for indicators that don't support live feedback.

If the mouse-down event occurs in an indicator of a control that does not support live feedback, your action function should take no parameters, because the user may move the cursor outside the indicator while dragging it.

As an alternative to passing a pointer to your action function in a parameter to `TrackControl`, you can use the function `SetControlAction` (page 649) to store a pointer to the action function in the `contrlAction` field in the control structure. When you pass `Pointer(-1)` instead of a function pointer to `TrackControl`, `TrackControl` uses the action function pointed to in the control structure.

Availability
Available in Mac OS X v10.0 and later.

ControlCNTLToCollectionProcPtr

```
typedef OSStatus (*ControlCNTLToCollectionProcPtr) (
    const Rect * bounds,
    SInt16 value,
    Boolean visible,
    SInt16 max,
    SInt16 min,
    SInt16 procID,
    SInt32 refCon,
    ConstStr255Param title,
    Collection collection
);
```

If you name your function `MyControlCNTLToCollectionProc`, you would declare it like this:

```
OSStatus ControlCNTLToCollectionProcPtr (
    const Rect * bounds,
    SInt16 value,
    Boolean visible,
    SInt16 max,
    SInt16 min,
    SInt16 procID,
    SInt32 refCon,
    ConstStr255Param title,
    Collection collection
);
```

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

`Controls.h`

ControlColorProcPtr

```
typedef OSStatus (*ControlColorProcPtr) (
    ControlRef inControl,
    SInt16 inMessage,
    SInt16 inDrawDepth,
    Boolean inDrawInColor
);
```

If you name your function `MyControlColorProc`, you would declare it like this:

```
OSStatus ControlColorProcPtr (
    ControlRef inControl,
    SInt16 inMessage,
    SInt16 inDrawDepth,
    Boolean inDrawInColor
);
```

Return Value
A result code. See "Control Manager Result Codes" (page 824).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Controls.h`

ControlDefProcPtr

If you wish to define new, nonstandard controls for your application, you must write a control definition function and either register it with the system using `RegisterControlDefinition` (page 640) or create it directly using `CreateCustomControl` (page 543).

```
typedef SInt32 (*ControlDefProcPtr) (
    SInt16 varCode,
    ControlRef theControl,
    ControlDefProcMessage message,
    SInt32 param
);
```

If you name your function `MyControlDefProc`, you would declare it like this:

```
SInt32 MyControlDefProc (
    SInt16 varCode,
    ControlRef theControl,
    ControlDefProcMessage message,
    SInt32 param
);
```

Parameters
varCode
The control's variation code.

theControl
A handle to the control that the operation will affect.

message
A code for the task to be performed. See "Control Definition Message Constants" (page 735) for a description of the constants which you can use here. The subsections that follow explain each of these tasks in detail. For a description of this data type, see ControlDefProcMessage (page 702).

param
Data associated with the task specified by the `message` parameter. If the task requires no data, this parameter is ignored.

Return Value
The function results that your control definition function returns depend on the value that the Control Manager passes in the `message` parameter.

Discussion
Note that Carbon does not allow you to store custom control definitions in a `'CDEF'` resource file as you could in preCarbon systems.

The Control Manager defines the data type `ControlDefUPP` to identify the universal procedure pointer for this application-defined callback function. To provide a pointer to your callback, you can use the function `NewControlDefUPP` (page 637). You can do so with code similar to the following:

```
ControlDefUPP myControlDefUPP;
myControlDefUPP = NewControlDefUPP (MyControlDefCallback);
```

A control definition function determines how a control generally looks and behaves. Various Control Manager functions call a control definition function whenever they need to perform a control-dependent action, such as drawing the control on the screen. In addition to standard control definition functions, defined by the system, you can make your own custom control definition functions.

When various Control Manager functions need to perform a type-dependent action on the control, they call the control definition function and pass it the variation code for its type as a parameter. You can define your own variation codes; this allows you to use one custom definition to handle several variations of the same general control.

To define your own type of control, you write a control definition function, compile it as a resource of type `'CDEF'`, and store it in your resource file. Whenever you create a control, you specify a control definition ID, which the Control Manager uses to determine the control definition function. The control definition ID is an integer that contains the resource ID of the control definition function in its upper 12 bits and a variation code in its lower 4 bits. Thus, for a given resource ID and variation code

control definition ID = (16 x resource ID) + variation code

For example, buttons, checkboxes, and radio buttons all use the standard control definition function with resource ID 0. Because they have variation codes of 0, 1, and 2, respectively, their respective control definition IDs are 0, 1, and 2. See the control definition IDs in the "Control Manager Constants" section for more details.

The Control Manager calls the Resource Manager to access a control definition function with the given resource ID. The Resource Manager reads a control definition function into memory and returns a handle to it. The Control Manager stores this handle in the `contrlDefProc` field of the control structure.

The Control Manager calls your control definition function under various circumstances; the Control Manager uses the `message` parameter to inform your control definition function what action it must perform. The data that the Control Manager passes in the `param` parameter, the action that your control definition function

must undertake, and the function results that your control definition function returns all depend on the value that the Control Manager passes in the `message` parameter. The rest of this section describes how to respond to the various values that the Control Manager passes in the `message` parameter.

Drawing the Control or Its Part

When the Control Manager passes the value `drawCntl` in the `message` parameter, your control definition function should respond by drawing the indicator or the entire control.

The Control Manager passes one of the drawing constants described in `ReverseKeyboardFocus` (page 642) in the low word of the `param` parameter to specify whether the user is drawing an indicator or the whole control. The high-order word of the `param` parameter may contain undefined data; therefore, evaluate only the low-order word of this parameter.

With the exception of part code 128, which is reserved for future use and should not be used, any other value indicates a part code for the control.

If the specified control is visible, your control definition function should draw the control (or the part specified in the `param` parameter) within the control's rectangle. If the control is invisible (that is, if its `contrlVis` field is set to 0), your control definition function does nothing.

When drawing the control or its part, take into account the current values of its `contrlHilite` and `contrlValue` fields in the control structure.

If the part code for your control's indicator is passed in `param`, assume that the indicator hasn't moved the Control Manager, for example, may be calling your control definition function so that you may simply highlight the indicator. However, when your application calls `ClearKeyboardFocus` (page 537), `SetKeyboardFocus` (page 665), and "Control Meta Part Code Constants" (page 790), they in turn may call your control definition function with the `drawCntl` message to redraw the indicator. Since these functions have no way of determining what part code you chose for your indicator, they all pass 129 in `param`, meaning that you should move your indicator. Your control definition function must detect this part code as a special case and remove the indicator from its former location before drawing it. If your control has more than one indicator, you should interpret 129 to mean all indicators.

When sent the message `drawCntl`, your control definition function should return 0 as its function result.

Testing Where the Mouse-Down Event Occurs

When the Control Manager passes the value for the `testCntl` constant in the `message` parameter, your control definition function should respond by determining whether a specified point is in a visible control.

The Control Manager passes a point (in local coordinates) in the `param` parameter. The point's vertical coordinate is contained in the high-order word of the long integer, and horizontal coordinate is contained in the low-order word.

Your control definition function should return the part code of the part that contains the specified point; it should return 0 if the point is outside the control or if the control is inactive.

Calculating the Control and Indicator Regions on 24-Bit Systems

When the Control Manager passes the value for the `calcCRgns` constant in the `message` parameter, your control definition function should calculate the region passed in the `param` parameter for the specified control or its indicator.

The Control Manager passes a QuickDraw region handle in the `param` parameter. If the high-order bit of `param` is set, the region requested is that of the control's indicator otherwise, the region requested is that of the entire control. Your control definition function should clear the high bit of the region handle before calculating the region.

When passed this message, your control definition function should always return 0, and it should express the region in the local coordinate system of the control's window.

Note that the `calcCRgns` message will never be sent to any system running on 32-bit mode and is therefore obsolete in Mac OS 7.6 and later. On Mac OS 7.6 and later, the `calcCntlRgn` and `calcThumbRgn` messages are sent instead.

Calculating the Control and Indicator Regions on 32-Bit Systems

When the Control Manager passes the values for the `calcCntlRgn` or `calcThumbRgn` constants in the `message` parameter, your control definition function should calculate the region for the specified control or its indicator using the QuickDraw region handle passed in the `param` parameter.

If the Control Manager passes the value for the `calcThumbRgn` constant in the `message` parameter, calculate the region occupied by the indicator. If the Control Manager passes the value for the `calcCntlRgn` constant in the `message` parameter, calculate the region for the entire control.

When passed this message, your control definition function should always return 0, and it should express the region in the local coordinate system of the control's window.

Performing Additional Control Initialization

After initializing fields of a control structure as appropriate when creating a new control, the Control Manager passes `initCntl` in the `message` parameter to give your control definition function the opportunity to perform any type-specific initialization you may require. For example, the standard control definition function for scroll bars allocates space for a region to hold the scroll box and stores the region handle in the `contrlData` field of the new control structure.

When passed the value for the `initCntl` constant in the `message` parameter, your control definition function should ignore the `param` parameter and return 0 as a function result.

Performing Additional Control Disposal Actions

The function `DisposeControl` (page 573) passes `dispCntl` in the `message` parameter to give your control definition function the opportunity to carry out any additional actions when disposing of a control. For example, the standard definition function for scroll bars releases the memory occupied by the scroll box region, whose handle is kept in the `contrlData` field of the control structure.

When passed the value for the `dispCntl` constant in the `message` parameter, your control definition function should ignore the `param` parameter and return 0 as a function result.

Dragging the Control or Its Indicator

When a mouse-up event occurs in the indicator of a control, the " Control State Part Code Constants" (page 751) or `ControlKeyDownRec` (page 706) functions call your control definition function and pass `posCntl` in the `message` parameter. In this case, the Control Manager passes a point (in coordinates local to the control's window) in the `param` parameter that specifies the vertical and horizontal offset, in pixels, by which your control definition function should move the indicator from its current position. Typically, this is the offset

between the points where the cursor was when the user pressed and released the mouse button while dragging the indicator. The point's vertical offset is contained in the high-order word of the `param` parameter, and its horizontal offset is contained in the low-order word.

Your definition function should calculate the control's new setting based on the given offset and then, to reflect the new setting, redraw the control and update the `contrlValue` field in the control structure. Your control definition function should ignore the `param` parameter and return 0 as a function result.

Calculating Parameters for Dragging the Indicator

When the Control Manager passes the value for `thumbCntl` in the `message` parameter, your control definition function should respond by calculating values analogous to the `limitRect`, `slopRect`, and `axis` parameters of `DragControl` that constrain how the indicator is dragged. On entry, the fields *`limitRect.top`* and *`limitRect.left`* contain the point where the mouse-down event first occurred.

The Control Manager passes a pointer to a structure of type `IndicatorDragConstraint` in the param parameter. Your definition function should store the appropriate values into the fields of the structure pointed to by the param parameter; they're analogous to the similarly named parameters of the Window Manager function `DragGrayRgn`.

Performing Custom Dragging

When the Control Manager passes the value for the `dragCntl` constant in the message parameter, the `param` parameter typically contains a custom dragging constant with one of the values described in "Drag Control Constants" to specify whether the user is dragging an indicator or the whole control.

When the Appearance Manager is present, the message `kControlMsgHandleTracking` should be sent instead of `dragCntl` to handle any custom tracking; see "Performing Custom Tracking" below.

If you want to use the Control Manager's default method of dragging, which is to call `DragControl` to drag the control or the Window Manager function DragGrayRgn to drag its indicator, return 0 as the function result for your control definition function.

If your control definition function returns a non-zero value, your control definition function (not the Control Manager) must drag the specified control (or its indicator) to follow the cursor until the user releases the mouse button. If the user drags the entire control, your definition function should use the function `MoveControl` to reposition the control to its new location after the user releases the mouse button. If the user drags the indicator, your definition function must calculate the control's new setting (based on the pixel offset between the points where the cursor was when the user pressed and released the mouse button while dragging the indicator) and then, to reflect the new setting, redraw the control and update the `contrlValue` field in the control structure. Note that, in this case, the functions `HandleControlClick` and `TrackControl` return 0 whether or not the user changes the indicator's position. Thus, you must determine whether the user has changed the control's setting by another method, for instance, by comparing the control's value before and after the call to `HandleControlClick`.

Executing an Action Function

The only way to specify actions in response to all mouse-down events in a control or its indicator is to define your own control definition function that specifies an action function. When you create the control, your control definition function must first respond to the `initCntl` message by storing (ControlDefUPP)-1L in the `contrlAction` field of the control structure. (The Control Manager sends the `initCntl` message to your control definition function after initializing the fields of a new control structure.) Then, when your application passes (ControlActionUPP)-1L in the actionProc n passes (ControlActionUPP)-1L in the actionProc parameter of `HandleControlClick` or `TrackControl`, `HandleControlClick` calls your control definition

function with the `autoTrack` message. The Control Manager passes the part code of the part where the mouse-down event occurs in the param parameter. Your control definition function should then use this information to respond as an action function would.

Note that for the `autoTrack` message, the high-order word of the param parameter may contain undefined data; therefore, evaluate only the low-order word of this parameter.

If the mouse-down event occurs in an indicator of a control that supports live feedback, your action function should take two parameters (a handle to the control and the part code of the control where the mouse-down event first occurred). This action function is the same one you would use to define actions to be performed in control part codes in respotrolActionProcPtr"> ControlActionProcPtr.

If the mouse-down event occurs in an indicator of a control that does not support live feedback, your action function should take no parameters, because the user may move the cursor outside the indicator while dragging it.

Specifying Whether Appearance-Compliant Messages Are Supported

If your control definition function supports Appearance-compliant messages, it should return `kControlSupportsNewMessages` as a function result when the Control Manager passes `kControlMsgTestNewMsgSupport` in the message parameter.

Specifying Which Appearance-Compliant Messages Are Supported

If your control definition function supports Appearance-compliant messages, it should return a bit field of the features it supports in response to the `kControlMsgGetFeatures` message. Your control definition function should ignore the param parameter.

Drawing a Ghost Image of the Indicator

If your control definition function supports indicator ghosting, it should return `kControlSupportsGhosting` as one of the feature bits in response to a `kControlMsgGetFeatures` message. If this bit is set and the control indicator is being tracked, the Control Manager calls your control definition function and passes `kControlMsgDrawGhost` in the message parameter. A handle to the region where the ghost should be drawn will be passed in the `param` parameter.

Your control definition function should respond by redrawing the control with the ghosted indicator at the specified location and should return 0 as its function result.

Note that the ghost indicator should always be drawn before the actual indicator so that it appears underneath the actual indicator.

Calculating the Optimal Control Rectangle

If your control definition function supports calculating the optimal dimensions of the control rectangle, it should return `kControlSupportsCalcBestRect` as one of the feature bits in response to the `kControlMsgGetFeatures` message. If this bit is set and `GetBestControlRect` is called, the Control Manager will call your control definition function and pass `kControlMsgCalcBestRect` in the message parameter. The Control Manager passes a pointer to a control size calculation structure, `ControlCalcSizeRec`, in the `param` parameter.

Your control definition function should respond by calculating the width and height of the optimal control rectangle and adjusting the rectangle by setting the `height` and `width` fields of the control size calculation structure to the appropriate values. If your control definition function displays text, it should pass in the offset from the bottom of control to the base of the text in the `baseLine` field of the structure. Your control

definition function should return the offset value stored in the structure's in the `baseLine` field of the structure. Your control definition function should return the offset value stored in the structure's `baseLine` field.

Performing Custom Tracking

If your control definition function supports custom tracking, it should return `kControlHandlesTracking` as one of the feature bits in response to a `kControlMsgGetFeatures` message. If this bit is set and a mouse-down event occurs in your control, `TrackControl` or `HandleControlClick` calls your control definition function and passes `kControlMsgHandlesTracking` in the message parameter. The Control Manager passes a pointer to a control tracking structure, `ControlTrackingRec`, in the `param` parameter. Your control definition function should respond appropriately and return the part code that was hit, or kControlNoPart if the mouse-down event occurred outside the control; see "Control Meta Part Code Constants" (page 790) "Control Part Code Constants " (page 748) and " Control State Part Code Constants" (page 751).

Handling Keyboard Focus

If your control definition function can change its keyboard focus, it should set `kControlSupportsFocus` and `kControlGetsFocusOnClick` as feature bits in response to a `kControlMsgGetFeatures` message. If these bits are set and the `AdvanceKeyboardFocus`, `ReverseKeyboardFocus`, `ClearKeyboardFocus`, or `SetKeyboardFocus` function is called, the Control Manager calls your control definition function and passes `kControlMsgFocus` in the message parameter.

The Control Manager passes one of the control focus part code constants described in "Control Meta Part Code Constants" (page 790).

If the Control Manager passes in a part code, your control definition function should focus on the specified part code. Your function can interpret this in any way it wishes.

Your control definition function should return the control focus part code or actual control part that was focused on. Return `kControlFocusNoPart` if your control does not accept focus or has just relinquished it. Return a non-zero part code to indicate that your control received keyboard focus. Your control definition function is responsible for maintaining which part is focused.

Handling Keyboard Events

If your control definition function can handle keyboard events, it should return `kControlSupportsFocus` —every control that supports keyboard focus must also be able to handle keyboard events—as one of the feature bits in response to a `kControlMsgGetFeatures` message. If this bit is set, the Control Manager will pass `kControlMsgKeyDown` in the message parameter. The Control Manager passes a pointer to a control key down structure, `ControlKeyDownRec`, in the `param` parameter. Your control definition function should respond by processing the keyboard event as appropriate and return 0 as the function result.

Performing Idle Processing

If your control definition function can perform idle processing, it should return `kControlWantsIdle` as one of the feature bits in response to a `kControlMsgGetFeatures` message. If this bit is set and `IdleControls` is called for the window your control is in, the Control Manager will pass `kControlMsgIdle` in the message parameter. Your control definition function should ignore the `param` parameter and respond appropriately. For example, indeterminate progress indicators and asynchronous arrows use idle time to perform their animation.

Your control definition function should return 0 as the function result.

Getting and Setting Control-Specific Data

If your control definition function supports getting and setting control-specific data, it should return `kControlSupportsDataAccess` as one of its features bits in response to the `kControlMsgGetFeatures` message. If this bit is set, the Control Manager will call your control definition function and pass `kControlMsgSetData` in the message parameter when `ControlDataAccessRec`, in the param parameter. Your definition function should respond by filling out the structure and returning an operating system status message as the function result.

Handling Activate and Deactivate Events

If your control definition function wants to be informed whenever it is being activated or deactivated, it should return `kControlWantsActivate` as one of the feature bits in response to the `kControlMsgGetFeatures` message. If this bit is set and your control definition function is being activated or deactivated, the Control Manager calls it and passes `kControlMsgActivate` in the message parameter. The Control Manager passes a 0 or 1 in the param parameter. A value of 0 indicates that the control is being deactivated; 1 indicates that it is being activated.

Your control definition function should respond by performing any special processing before the user pane becomes activated or deactivated, such as deactivating its `TEHandle` or `ListHandle` if it is about to be deactivated.

Your control definition function should return 0 as the function result.

Setting a Control's Background Color or Pattern

If your control definition function supports embedding and draws its own background, it should return `kControlHasSpecialBackground` as one of the feature bits in response to the `kControlMsgGetFeatures` message. If this bit is set and an embedding hierarchy of controls is being drawn in your control, the Control Manager passes `kControlMsgSetUpBackground` in the message parameter of your control definition function. The Control Manager passes a pointer to a filled-in control background structure, `ControlBackgroundRec`, in the `param` parameter. Your control definition function should respond by setting its background color or pattern to whatever is appropriate given the bit depth and device type passed in. Your control definition function should return 0 as the function result.

Supporting Live Feedback

If your control definition function supports live feedback while tracking the indicator, it should return `kControlSupportsLiveFeedback` as one of the feature bits in response to the `kControlMsgGetFeatures` message. If this bit is set, the Control Manager will call your control definition function when it tracks the indicator and pass `kControlMsgCalcValueFromPos` in the message parameter. The Control Manager passes a handle to the indicator region being dragged in the param parameter.

Your control definition function should respond by calculating its value and drawing the control based on the new indicator region passed in. Your control definition function should not recalculate its indicator position. After the user is done dragging the indicator, your control definition function will be called with a `posCntl` message at which time you can recalculate the position of the indicator. Not recalculating the indicator position each time your control definition function is called creates a smooth dragging experience for the user.

Your control definition function should return 0 as the function result.

Being Informed When Subcontrols Are Added or Removed

If your control definition function wishes to be informed when subcontrols are added or removed, it should return `kControlSupportsEmbedding` as one of the feature bits in response to the `kControlMsgGetFeatures` message. If this bit is set, the Control Manager passes `ControlMsgSubControlAdded` in the message parameter immediately after a subcontrol is added, or it passes `kControlMsgSubControlRemoved` just before a subcontrol is removed.

Being Informed When Subcontrols Are Added or Removed

If your control definition function wishes to be informed when subcontrols are added or removed, it should return `kControlSupportsEmbedding` as one of the feature bits in response to the `kControlMsgGetFeatures` message. If this bit is set, the Control Manager passes `ControlMsgSubControlAdded` in the message parameter immediately after a subcontrol is added, or it passes `kControlMsgSubControlRemoved` just before a subcontrol is removed from your embedder control. A handle to the control being added or removed from the embedding hierarchy is passed in the param parameter. Your control definition function should respond appropriately and return 0 as the function result.

Typically, a control definition function only supports this message if it wants to do extra processing in response to changes in its embedded controls. Radio groups use these messages to perform necessary processing for handling embedded controls. For example, if a currently selected radio button is deleted, the group can adjust itself accordingly.

Carbon Porting Notes

Moving forward, you should consider using Carbon Event-based custom controls rather than those based on CDEF messages. See *Handling Carbon Windows and Controls* for more information about creating Carbon event-based controls.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Controls.h`

ControlEditTextValidationProcPtr

Ensures that the content of an editable text control is valid.

```
typedef void (*ControlEditTextValidationProcPtr) (
    ControlRef control
);
```

If you name your function `MyControlEditTextValidationProc`, you would declare it like this:

```
void MyControlEditTextValidationProc (
    ControlRef control
);
```

Parameters

control

A handle to the control containing the editable text to be validated. For a description of this data type, see ControlRef (page 709).

Discussion
Your application typically uses a `MyControlEditTextValidationCallback` function in conjunction with a key filter function to ensure that editable text is valid in cases such as a cut, paste, or clear, where a key filter cannot be called. Use the `kControlEditTextValidationProcTag` control data tag constant, described in "Editable Text Control Data Tag Constants" (page 756), with the functions `SetControlData` and `GetControlData` to set or retrieve a `MyControlEditTextValidationCallback` function.

Note that if you are using the inline input editable text control variant, the Control Manager will not call your `MyControlEditTextValidationCallback` function during inline input. Instead, you may install your own Text Services Manager `TSMTEPostUpdateUPP` callback function to validate text during inline input, or your application can validate the input itself, immediately prior to using the text.

The Control Manager defines the data type `ControlEditTextValidationUPP` to identify the universal procedure pointer for this application-defined callback function. To provide a pointer to your callback, you can use the function `NewControlEditTextValidationUPP` (page 637). You can do so with code similar to the following:

```
ControlEditTextValidationUPP myControlEditTextValidationUPP;
myControlEditTextValidationUPP = NewControlEditTextValidationUPP
(MyControlEditTextValidationCallback);
```

You can then pass `myControlEditTextValidationUPP` in the `inData` parameter of `SetControlData`. When you no longer need the universal procedure pointer, you should remove it using the `DisposeRoutineDescriptor` function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`HITextViews.h`

ControlKeyFilterProcPtr

The key filter function allows for the interception and possible changing of keystrokes destined for a control.

```
typedef ControlKeyFilterResult (*ControlKeyFilterProcPtr) (
    ControlRef theControl,
    SInt16 * keyCode,
    SInt16 * charCode,
    EventModifiers * modifiers
);
```

If you name your function `MyControlKeyFilterProc`, you would declare it like this:

```
ControlKeyFilterResult MyControlKeyFilterProc (
    ControlRef theControl,
    SInt16 * keyCode,
    SInt16 * charCode,
    EventModifiers * modifiers
);
```

Parameters

`theControl`
A handle to the control in which the key-down event occurred.

keyCode

The virtual key code derived from the event structure. This value represents the key pressed or released by the user. It is always the same for a specific physical key on a particular keyboard regardless of which modifier keys were also pressed.

charCode

A particular character derived from the event structure. This value depends on the virtual key code, the state of the modifier keys, and the current `'KCHR'` resource. Because this filter provides WorldScript-encoded text in its parameters, it provides no meaningful information for key events generated when a Unicode keyboard layout or input method is active; these layouts and input methods generate Unicode text that often cannot be translated into any WorldScript encoding.

modifiers

The constant in the `modifiers` field of the event structure specifying the state of the modifier keys and the mouse button at the time the event was posted.

Return Value
Returns a value indicating whether or not it allowed or blocked keystrokes; see "Key Filter Result Codes" (page 782). For a description of this data type, see ControlKeyFilterResult (page 707).

Discussion
Controls that support text input (such as editable text and list box controls) can attach a key filter function to filter key strokes and modify them on return.

Important: On Mac OS X, you should avoid using this filter, or at most, use the filter as an indication that the text is changing but do not depend on the charCode parameter to the filter. Use a `kEventTextInputUnicodeForKeyEvent` Carbon event handler as a replacement for the ControlKeyFilter callback; on Mac OS X v10.4 and later, you can also use a `kEventTextShouldChangeInRange` or `kEventTextDidChange` event handler.

The Control Manager defines the data type `ControlKeyFilterUPP` to identify the universal procedure pointer for this application-defined callback function. To provide a pointer to your callback, you can use the function `NewControlKeyFilterUPP` (page 637). You can do so with code similar to the following:

```
ControlKeyFilterUPP myControlKeyFilterUPP;
myControlKeyFilterUPP = NewControlKeyFilterUPP (MyControlKeyFilterCallback);
```

Your key filter function can intercept and change keystrokes destined for a control. Your key filter function can change the keystroke, leave it alone, or block your control definition function from receiving it. For example, an editable text control can use a key filter function to allow only numeric values to be input in its field.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Controls.h`

ControlUserPaneActivateProcPtr

Handles activate and deactivate event processing.

```
typedef void (*ControlUserPaneActivateProcPtr) (
    ControlRef control,
    Boolean activating
);
```

If you name your function `MyControlUserPaneActivateProc`, you would declare it like this:

```
void MyControlUserPaneActivateProc (
    ControlRef control,
    Boolean activating
);
```

Parameters

control

A handle to the control in which the activate event occurred.

activating

If `true`, the control is being activated. If `false`, the control is being deactivated.

Discussion

The Control Manager defines the data type `UserPaneActivateUPP` to identify the universal procedure pointer for this application-defined callback function. To provide a pointer to your callback, you can use the function `NewControlUserPaneActivateUPP` (page 638). You can do so with code similar to the following:

```
ControlUserPaneActivateUPP myControlUserPaneActivateUPP;
myControlUserPaneActivateUPP = NewControlUserPaneActivateUPP
(MyControlUserPaneActivateCallback);
```

Your `MyControlUserPaneActivateCallback` function should perform any special processing before the user pane becomes activated or deactivated. For example, it should deactivate its `TEHandle` or `ListHandle` if the user pane is about to be deactivated.

This function is called only if you've set the `kControlWantsActivate` feature bit on creation of the user pane control.

Once you have provided a user pane application-defined function, you can call the function `SetControlData` (page 652) in order to associate your function with a control. User pane application-defined functions are identified to `SetControlData` by tag constants for a description of the tag constants, see the "Control Manager Constants" section. For example, once you have created the function `MyControlUserPaneActivateCallback`, pass `kControlUserPaneActivateProcTag` in the `tagName` parameter of `SetControlData` (page 652).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`HIContainerViews.h`

ControlUserPaneBackgroundProcPtr

Sets the background color or pattern for user panes that support embedding.

```
typedef void (*ControlUserPaneBackgroundProcPtr) (
    ControlRef control,
    ControlBackgroundPtr info
);
```

If you name your function `MyControlUserPaneBackgroundProc`, you would declare it like this:

```
void MyControlUserPaneBackgroundProc (
    ControlRef control,
    ControlBackgroundPtr info
);
```

Parameters

control

A handle to the control for which the background color or pattern is to be set.

info

A pointer to information such as the depth and type of the drawing device. For a description of the `ControlBackgroundPtr` data type, see ControlBackgroundRec (page 698).

Discussion

The Control Manager defines the data type `ControlUserPaneBackgroundUPP` to identify the universal procedure pointer for this application-defined callback function. To provide a pointer to your callback, you can use the function `NewControlUserPaneBackgroundUPP` (page 638). You can do so with code similar to the following:

```
ControlUserPaneBackgroundUPP myControlUserPaneBackgroundUPP;
myControlUserPaneBackgroundUPP = NewControlUserPaneBackgroundUPP
(MyControlUserPaneBackgroundCallback);
```

Your `MyControlUserPaneBackgroundCallback` function should set the user pane background color or pattern to whatever is appropriate given the bit depth and device type passed in. Your `MyControlUserPaneBackgroundCallback` function is called to set up the background color. This ensures that when an embedded control calls `EraseRgn` or `EraseRect`, the background is erased to the correct color or pattern.

This function is called only if there is a control embedded in the user pane and if you've set the `kControlHasSpecialBackground` and `kControlSupportsEmbedding` feature bits on creation of the user pane control.

Once you have provided a user pane application-defined function, you can call the function `SetControlData` (page 652) in order to associate your function with a control. User pane application-defined functions are identified to `SetControlData` by tag constants for a description of the tag constants, see the "Control Manager Constants" section. For example, once you have created the function `MyControlUserPaneBackgroundCallback`, pass `kControlUserPaneBackgroundProcTag` in the `tagName` parameter of `SetControlData` (page 652).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`HIContainerViews.h`

ControlUserPaneDrawProcPtr

Draws the content of your user pane control in the rectangle of user pane control.

```
typedef void (*ControlUserPaneDrawProcPtr) (
    ControlRef control,
    SInt16 part
);
```

If you name your function `MyControlUserPaneDrawProc`, you would declare it like this:

```
void MyControlUserPaneDrawProc (
    ControlRef control,
    SInt16 part
);
```

Parameters

control

A handle to the user pane control in which you wish drawing to occur. For a description of this data type, see ControlRef (page 709).

part

The part code of the control you should draw. If 0, draw the entire control.

Discussion

The Control Manager defines the data type `ControlUserPaneDrawUPP` to identify the universal procedure pointer for this application-defined callback function. To provide a pointer to your callback, you can use the function `NewControlUserPaneDrawUPP` (page 638). You can do so with code similar to the following:

```
ControlUserPaneDrawUPP myControlUserPaneDrawUPP;
myControlUserPaneDrawUPP = NewControlUserPaneDrawUPP
(MyControlUserPaneDrawCallback);
```

Application-defined user pane functions provide you with the ability to create a custom theme-compliant control without writing your own control definition function. A user pane is a general purpose stub control; it can be used as the root control for a window, as well as providing a way to hook in application-defined functions such as those described below. When the Appearance Manager is available, user panes should be used in dialog boxes instead of user items.

Once you have provided a user pane application-defined function, you can call the function `SetControlData` (page 652) in order to associate your function with a control. User pane application-defined functions are identified to `SetControlData` by tag constants for a description of the tag constants, see the “Control Manager Constants” section.

For example, to set a user pane draw function, pass the constant `kControlUserPaneDrawProcTag` in the `tagName` parameter of `SetControlData` (page 652).The Control Manager then draws the control using a universal procedure pointer to your user pane draw function.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`HIContainerViews.h`

ControlUserPaneFocusProcPtr

Handles keyboard focus.

```
typedef ControlPartCode (*ControlUserPaneFocusProcPtr) (
    ControlRef control,
    ControlFocusPart action
);
```

If you name your function `MyControlUserPaneFocusProc`, you would declare it like this:

```
ControlPartCode MyControlUserPaneFocusProc (
    ControlRef control,
    ControlFocusPart action
);
```

Parameters

control

A handle to the control that is to adjust its focus.

action

The part code of the user pane to receive keyboard focus; see `ControlDefProcPtr` (page 677).

Return Value

The part of the user pane actually focused. The constant `kControlFocusNoPart` is returned if the user pane has lost the focus or cannot be focused. For a description of this data type, see ControlPartCode (page 708).

Discussion

The Control Manager defines the data type `ControlUserPaneFocusUPP` to identify the universal procedure pointer for this application-defined callback function. To provide a pointer to your callback, you can use the function `NewControlUserPaneFocusUPP` (page 638). You can do so with code similar to the following:

```
ControlUserPaneFocusUPP myControlUserPaneFocusUPP;
myControlUserPaneFocusUPP = NewControlUserPaneFocusUPP
(MyControlUserPaneFocusCallback);
```

Your `MyControlUserPaneFocusCallback` function is called in response to a change in keyboard focus. It should respond by changing keyboard focus based on the part code passed in the `action` parameter. This function is called only if you've set the `kControlSupportsFocus` feature bit on creation of the user pane control.

Once you have provided a user pane application-defined function, you can call the function `SetControlData` (page 652) in order to associate your function with a control. User pane application-defined functions are identified to `SetControlData` by tag constants for a description of the tag constants, see the "Control Manager Constants" section. For example, once you have created the function `MyControlUserPaneFocusCallback`, pass `kControlUserPaneFocusProcTag` in the `tagName` parameter of `SetControlData` (page 652).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`HIContainerViews.h`

ControlUserPaneHitTestProcPtr

Returns the part code of the control that the point was in when the mouse-down event occurred.

```
typedef ControlPartCode (*ControlUserPaneHitTestProcPtr) (
    ControlRef control,
    Point where
);
```

If you name your function `MyControlUserPaneHitTestProc`, you would declare it like this:

```
ControlPartCode MyControlUserPaneHitTestProc (
    ControlRef control,
    Point where
);
```

Parameters

control

A handle to the control in which the mouse-down event occurred. For a description of this data type, see ControlRef (page 709).

where

The point, in a window's local coordinates, where the mouse-down event occurred.

Return Value

The part code of the control where the mouse-down event occurred. If the point was not over a control, your function should return `kControlNoPart`. For a description of this data type, see ControlPartCode (page 708).

Discussion

The Control Manager defines the data type `ControlUserPaneHitTestUPP` to identify the universal procedure pointer for this application-defined callback function. To provide a pointer to your callback, you can use the function `NewControlUserPaneHitTestUPP` (page 639). You can do so with code similar to the following:

```
ControlUserPaneHitTestUPP myControlUserPaneHitTestUPP;
myControlUserPaneHitTestUPP = NewControlUserPaneHitTestUPP
(MyControlUserPaneHitTestCallback);
```

Once you have provided a user pane application-defined function, you can call the function `SetControlData` (page 652) in order to associate your function with a control. User pane application-defined functions are identified to `SetControlData` by tag constants for a description of the tag constants, see the "Control Manager Constants" section. For example, once you have created the function `MyControlUserPaneHitTestCallback`, pass `kControlUserPaneHitTestProcTag` in the `tagName` parameter of `SetControlData`.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`HIContainerViews.h`

ControlUserPaneIdleProcPtr

Performs idle processing.

```
typedef void (*ControlUserPaneIdleProcPtr) (
    ControlRef control
);
```

If you name your function `MyControlUserPaneIdleProc`, you would declare it like this:

```
void MyControlUserPaneIdleProc (
    ControlRef control
);
```

Parameters

control

A handle to the control for which you wish to perform idle processing. For a description of this data type, see ControlRef (page 709).

Discussion

The Control Manager defines the data type `ControlUserPaneIdleUPP` to identify the universal procedure pointer for this application-defined callback function. To provide a pointer to your callback, you can use the function `NewControlUserPaneIdleUPP` (page 639). You can do so with code similar to the following:

```
ControlUserPaneIdleUPP myControlUserPaneIdleUPP;
myControlUserPaneIdleUPP = NewControlUserPaneIdleUPP
(MyControlUserPaneIdleCallback);
```

This function is called only if you've set the `kControlWantsIdle` feature bit on creation of the user pane control.

Once you have provided a user pane application-defined function, you can call the function `SetControlData` (page 652) in order to associate your function with a control. User pane application-defined functions are identified to `SetControlData` by tag constants for a description of the tag constants, see the "Control Manager Constants" section. For example, once you have created the function `MyControlUserPaneIdleCallback`, pass `kControlUserPaneIdleProcTag` in the `tagName` parameter of `SetControlData` (page 652).

Availability

This function is available with Appearance Manager 1.0 and later.

Declared In

`HIContainerViews.h`

ControlUserPaneKeyDownProcPtr

Handles keyboard event processing.

```
typedef ControlPartCode (*ControlUserPaneKeyDownProcPtr) (
    ControlRef control,
    SInt16 keyCode,
    SInt16 charCode,
    SInt16 modifiers
);
```

If you name your function `MyControlUserPaneKeyDownProc`, you would declare it like this:

```
ControlPartCode MyControlUserPaneKeyDownProc (
    ControlRef control,
```

```
    SInt16 keyCode,
    SInt16 charCode,
    SInt16 modifiers
);
```

Parameters

control

A handle to the control in which the keyboard event occurred. For a description of this data type, see ControlRef (page 709).

keyCode

The virtual key code derived from event structure. This value represents the key pressed or released by the user. It is always the same for a specific physical key on a particular keyboard regardless of which modifier keys were also pressed.

charCode

A particular character derived from the event structure. This value depends on the virtual key code, the state of the modifier keys, and the current `'KCHR'` resource.

modifiers

The constant in the `modifiers` field of the event structure specifying the state of the modifier keys and the mouse button at the time the event was posted.

Return Value

The part code of the control where the keyboard event occurred. If the keyboard event did not occur in a control, your function should return `kControlNoPart`. For a description of this data type, see ControlPartCode (page 708).

Discussion

The Control Manager defines the data type `UserPaneKeyDownUPP` to identify the universal procedure pointer for this application-defined callback function. To provide a pointer to your callback, you can use the function `NewControlUserPaneKeyDownUPP` (page 639). You can do so with code similar to the following:

```
ControlUserPaneKeyDownUPP myControlUserPaneKeyDownUPP;
myControlUserPaneKeyDownUPP = NewControlUserPaneKeyDownUPP
(MyControlUserPaneKeyDownCallback);
```

Your `MyControlUserPaneKeyDownCallback` function should handle the key pressed or released by the user and return the part code of the control where the keyboard event occurred. This function is called only if you've set the `kControlSupportsFocus` feature bit on creation of the user pane control.

Once you have provided a user pane application-defined function, you can call the function `SetControlData` (page 652) in order to associate your function with a control. User pane application-defined functions are identified to `SetControlData` by tag constants for a description of the tag constants, see the "Control Manager Constants" section. For example, once you have created the function `MyControlUserPaneKeyDownCallback`, pass `kControlUserPaneKeyDownProcTag` in the `tagName` parameter of `SetControlData` (page 652).

Availability

Available in Mac OS X v10.0 and later.

Declared In

`HIContainerViews.h`

ControlUserPaneTrackingProcPtr

Tracks a control while the user holds down the mouse button.

```
typedef ControlPartCode (*ControlUserPaneTrackingProcPtr) (
    ControlRef control,
    Point startPt,
    ControlActionUPP actionProc
);
```

If you name your function `MyControlUserPaneTrackingProc`, you would declare it like this:

```
ControlPartCode MyControlUserPaneTrackingProc (
    ControlRef control,
    Point startPt,
    ControlActionUPP actionProc
);
```

Parameters

control

A handle to the control in which the mouse-down event occurred. For a description of this data type, see ControlRef (page 709).

startPt

The location of the cursor at the time the mouse button was first pressed, in local coordinates. Your application retrieves this point from the `where` field of the event structure.

actionProc

A pointer to an action function defining what action your application takes while the user holds down the mouse button. The value of the `actionProc` parameter can be a valid `procPtr`, `NULL`, or -1. A value of -1 indicates that the control should either perform auto tracking, or if it is incapable of doing so, do nothing (like `NULL`). For a description of this data type, see ControlActionProcPtr (page 675).

Return Value

The part code of the control part that was tracked. If tracking was unsuccessful, `kControlNoPartCode` is returned. For a description of this data type, see ControlPartCode (page 708).

Discussion

The Control Manager defines the data type `ControlUserPaneTrackingUPP` to identify the universal procedure pointer for this application-defined callback function. To provide a pointer to your callback, you can use the function `NewControlUserPaneTrackingUPP` (page 640). You can do so with code similar to the following:

```
ControlUserPaneTrackingUPP myControlUserPaneTrackingUPP;
myControlUserPaneTrackingUPP = NewControlUserPaneTrackingUPP
(MyControlUserPaneTrackingCallback);
```

Your `MyControlUserPaneTrackingCallback` function should track the control by repeatedly calling the action function specified in the `actionProc` parameter until the mouse button is released. When the mouse button is released, your function should return the part code of the control part that was tracked. This function is called only if you've set the `kControlHandlesTracking` feature bit on creation of the user pane control.

Once you have provided a user pane application-defined function, you can call the function `SetControlData` (page 652) in order to associate your function with a control. User pane application-defined functions are identified to `SetControlData` by tag constants for a description of the tag constants, see the

"Control Manager Constants" section. For example, once you have created the function `MyControlUserPaneTrackingCallback`, pass `kControlUserPaneTrackingProcTag` in the `tagName` parameter of `SetControlData` (page 652).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`HIContainerViews.h`

EditUnicodePostUpdateProcPtr

```
typedef Boolean (*EditUnicodePostUpdateProcPtr) (
    UniCharArrayHandle uniText,
    UniCharCount uniTextLength,
    UniCharArrayOffset iStartOffset,
    UniCharArrayOffset iEndOffset,
    void * refcon
);
```

If you name your function `MyEditUnicodePostUpdateProc`, you would declare it like this:

```
Boolean EditUnicodePostUpdateProcPtr (
    UniCharArrayHandle uniText,
    UniCharCount uniTextLength,
    UniCharArrayOffset iStartOffset,
    UniCharArrayOffset iEndOffset,
    void * refcon
);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`HITextViews.h`

Data Types

AuxCtlHandle

```
typedef AuxCtlPtr* AuxCtlHandle;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Controls.h`

AuxCtlPtr

```
typedef AuxCtlRec* AuxCtlPtr;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Controls.h`

AuxCtlRec

```
struct AuxCtlRec {
    Handle acNext;
    ControlRef acOwner;
    CCTabHandle acCTable;
    SInt16 acFlags;
    SInt32 acReserved;
    SInt32 acRefCon;
};
typedef AuxCtlRec AuxCtlRec;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Controls.h`

ClickActivationResult

```
typedef UInt32 ClickActivationResult;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Controls.h`

ControlApplyTextColorRec

```
struct ControlApplyTextColorRec {
    SInt16 depth;
    Boolean colorDevice;
    Boolean active;
};
typedef struct ControlApplyTextColorRec ControlApplyTextColorRec;
typedef ControlApplyTextColorRec * ControlApplyTextColorPtr;
```

Fields
`depth`
The Control Manager sets this field to specify the bit depth (in pixels) of the current graphics port.

`colorDevice`
The Control Manager passes a value of `true` if you are drawing on a color device; otherwise, `false`.

`active`
The Control Manager passes a value of `true` to specify a color suitable for active text; otherwise, `false`.

Discussion
If you implement a custom control definition function, when the Control Manager passes the message `kControlMsgApplyTextColor` in your control definition function's `message` parameter, it also passes a pointer to a structure of type `ControlApplyTextColorRec` in the `param` parameter. The Control Manager sets the `ControlApplyTextColorRec` structure to contain data describing the current drawing environment, and your control definition function is responsible for using that data to apply the proper text color to the current graphics port.

See "Control Definition Message Constants" (page 735) for more details on the `kControlMsgApplyTextColor` message.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Controls.h`

ControlBackgroundRec

```
struct ControlBackgroundRec {
  SInt16 depth;
   Boolean colorDevice;
};
typedef struct ControlBackgroundRec ControlBackgroundRec;
typedef ControlBackgroundRec * ControlBackgroundPtr;
```

Fields
`depth`
A signed 16-bit integer indicating the bit depth (in pixels) of the current graphics port.

`colorDevice`
A Boolean value. If `true`, you are drawing on a color device. If `false`, you are drawing on a monochrome device.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Controls.h`

ControlBevelButtonBehavior

```
typedef UInt16 ControlBevelButtonBehavior;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In

Declared In
HIButtonViews.h

ControlButtonContentInfo

```
struct ControlButtonContentInfo {
    ControlContentType contentType
    union {
        SInt16 resID;
        CIconHandle cIconHandle;
        Handle iconSuite;
        IconRef iconRef;
        PicHandle picture;
        Handle ICONHandle;
        CGImageRef imageRef;
    } u;
};
typedef struct ControlButtonContentInfo ControlButtonContentInfo;
typedef ControlButtonContentInfo ControlImageContentInfo;
```

Fields

`contentType`

Specifies the bevel button or image well content type and whether the content is text-only, resource-based, or handle-based; see "Control Content Type Constants" (page 770) for possible values. The value specified in the `contentType` field determines which of the other fields in the structure are used. For a description of this data type, see ControlContentType (page 701).

`u`

If the content type specified in the `contentType` field is `kControlContentIconSuiteRes`, `kControlContentCIconRes`, or `kControlContentPictRes`, this field contains the resource ID of a picture, color icon, or icon suite resource. If the `contentType` field is `kControlContentCGImageRef`, this field contains a `CGImageRef`.

Discussion
You can use the `ControlButtonContentInfo` structure to specify the content for a bevel button or image well. Values of type `ControlButtonContentInfo` are set via `SetControlData` (page 652) and obtained from `GetControlData` (page 594), in conjunction with the `kControlBevelButtonContentTag` and `kControlImageWellContentTag` constants; see "Bevel Button Control Data Tag Constants" (page 723) and "Image Well Control Data Tag Constants" (page 765).

Version Notes
The `ControlButtonContentInfo` type is available with Appearance Manager 1.0 and later.

Availability
Available in Mac OS X v10.0 and later.

`Controls.h`

ControlCalcSizeRec

```
struct ControlCalcSizeRec {
    SInt16 height;
    SInt16 width;
    SInt16 baseLine;
};
typedef struct ControlCalcSizeRec ControlCalcSizeRec;
typedef ControlCalcSizeRec * ControlCalcSizePtr;
```

Fields

`height`
The optimal height (in pixels) of the control's bounding rectangle.

`width`
The optimal width (in pixels) of the control's bounding rectangle.

`baseLine`
The offset from the bottom of the control to the base of the text. This value is generally negative.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Controls.h`

ControlCapabilities

```
typedef UInt32 ControlCapabilities;
```

ControlClickActivationRec

```
struct ControlClickActivationRec {
    Point localPoint;
    EventModifiers modifiers;
    ClickActivationResult result;
};
typedef struct ControlClickActivationRec ControlClickActivationRec;
typedef ControlClickActivationRec * ControlClickActivationPtr;
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In

ControlContextualMenuClickRec

```
struct ControlContextualMenuClickRec {
    Point localPoint;
    Boolean menuDisplayed;
};
typedef struct ControlContextualMenuClickRec ControlContextualMenuClickRec;
typedef ControlContextualMenuClickRec * ControlContextualMenuClickPtr;
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Controls.h`

ControlDataAccessRec

```
struct ControlDataAccessRec {
    ResType tag;
    ResType part;
    Size size;
    Ptr dataPtr;
};
typedef struct ControlDataAccessRec ControlDataAccessRec;
typedef ControlDataAccessRec * ControlDataAccessPtr;
```

Fields

`tag`

A constant representing a piece of data that is passed in (in response to a `kControlMsgSetData` message) or returned (in response to a `kControlMsgGetData` message); see "Scrolling Text Box Control Data Tag Constants" (page 809) for a description of these constants. The control definition function should return `errDataNotSupported` if the value in the `tag` parameter is unknown or invalid.

`part`

The part of the control that this data should be applied to. If the information is not tied to a specific part of the control or the control has no parts, pass 0.

`size`

On entry, the size of the buffer pointed to by the `dataPtr`field. In response to a `kControlMsgGetData` message, this field should be adjusted to reflect the actual size of the data that the control is maintaining. If the size of the buffer being passed in is smaller than the actual size of the data, the control definition function should return `errDataSizeMismatch`.

`dataPtr`

A pointer to a buffer to read or write the information requested. In response to a `kControlMsgGetData` message, this field could be `NULL`, indicating that you wish to return the size of the data in the `size` field.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Controls.h`

ControlDefProcMessage

Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Controls.h`

ControlDefType

```
typedef UInt32 ControlDefType;
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Controls.h`

ControlEditTextSelectionRec

```
struct ControlEditTextSelectionRec {
    SInt16 selStart;
    SInt16 selEnd;
};
typedef struct ControlEditTextSelectionRec ControlEditTextSelectionRec;
typedef ControlEditTextSelectionRec * ControlEditTextSelectionPtr;
```

Fields

`selStart`

The start of the editable text selection.

`selEnd`

The end of the editable text selection.

Discussion

You can use the `ControlEditTextSelectionRec` type to specify a selection range in an editable text control. You pass a pointer to the editable text selection structure to `GetControlData` (page 594) and `SetControlData` (page 652) to access and set the current selection range in an editable text control.

Version Notes

The `ControlEditTextSelectionRec` type is available with Appearance Manager 1.0 and later.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`HITextViews.h`

ControlFocusPart

```
typedef SInt16 ControlFocusPart;
```

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Controls.h`

ControlFontStyleRec

```
struct ControlFontStyleRec {
    SInt16 flags;
    SInt16 font;
    SInt16 size;
    SInt16 style;
    SInt16 mode;
    SInt16 just;
    RGBColor foreColor;
    RGBColor backColor;
};
typedef struct ControlFontStyleRec ControlFontStyleRec;
typedef ControlFontStyleRec * ControlFontStylePtr;
```

Fields

`flags`

A value specifying which fields of the structure should be applied to the control; see "Mac OS 8.5 Control Font Style Flag Constant" (page 787) and "Control Font Style Flag Constants" (page 745). If none of the flags in the `flags` field of the structure are set, the control uses the system font unless the control variant `kControlUsesOwningWindowsFontVariant` has been specified, in which case the control uses the window font.

`font`

If the `kControlUseFontMask` bit is set, then this field contains a value specifying the ID of the font family to use. If this bit is not set, then the system default font is used. A meta font constant can be specified instead; see "Meta Font Constants" (page 791).

`size`

If the `kControlUseSizeMask` bit is set, then this field contains a value specifying the point size of the text. If the `kControlAddSizeMask` bit is set, this value will represent the size to add to the current point size of the text. A meta font constant can be specified instead; see "Meta Font Constants" (page 791).

`style`

If the `kControlUseFaceMask` bit is set, then this field contains a value specifying which styles to apply to the text. If all bits are clear, the plain font style is used. The bit numbers and the styles they represent are bold (0), italic (1), underline (2), outline (3), shadow (4), condensed (5), and extended (6).

`mode`

If the `kControlUseModeMask` bit is set, then this field contains a value specifying how characters are drawn in the bit image. See *Inside Macintosh: Imaging With QuickDraw* for a discussion of transfer modes.

`just`

If the `kControlUseJustMask` bit is set, then this field contains a value specifying text justification. Possible values are `teFlushDefault` (0), `teCenter` (1), `teFlushRight` (-1), and `teFlushLeft` (-2).

`foreColor`

If the `kControlUseForeColorMask` bit is set, then this field contains an RGB color value to use when drawing the text.

`backColor`

If the `kControlUseBackColorMask` bit is set, then this field contains an RGB color value to use when drawing the background behind the text. In certain text modes, background color is ignored.

Discussion
You can use the `ControlFontStyleRec` type to specify a control's font. You pass a pointer to the control font style structure in the `inStyle` parameter of `SetControlFontStyle` (page 654) to specify a control's font. If none of the flags in the `flags` field of the structure are set, the control uses the system font unless the control variant `kControlUsesOwningWindowsFontVariant` has been specified, in which case the control uses the window font. The `ControlFontStyleRec` type is available with Appearance Manager 1.0 and later.

Note that if you wish to specify the font for controls in a dialog box, you should use a dialog font table resource, which is automatically read in by the Dialog Manager.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Controls.h`

ControlGetRegionRec

```
struct ControlGetRegionRec {
    RgnHandle region;
    ControlPartCode part;
};
typedef struct ControlGetRegionRec ControlGetRegionRec;
typedef ControlGetRegionRec * ControlGetRegionPtr;
```

Fields
`region`
A value allocated by the Control Manager. Your control definition function should set this field to the region that contains the control part specified in the `part` field.

`part`
The Control Manager passes a constant identifying the control part for which a region is to be obtained. For descriptions of possible values, see "Control Part Code Constants " (page 748), "Control Part Code Constants " (page 748), and " Control State Part Code Constants" (page 751). For a description of this data type, see ControlPartCode (page 708).

Discussion
If you implement a custom control definition function, when the Control Manager passes the message `kControlMsgGetRegion` in your control definition function's `message` parameter, it also passes a pointer to a structure of type `ControlGetRegionRec` in the `param` parameter. Your control definition function is responsible for setting the `region` field of the `ControlGetRegionRec` structure to the region that contains the control part which the Control Manager specifies in the `part` field.

See "Control Definition Message Constants" (page 735) for more details on the `kControlMsgGetRegion` message.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Controls.h`

    EventModifiers modifiers;
    SInt16 keyCode;
    SInt16 charCode;
};
typedef struct ControlKeyDownRec ControlKeyDownRec;
typedef ControlKeyDownRec * ControlKeyDownPtr;
```

Fields
`modifiers`
The constant in the `modifiers` field of the event structure specifying the state of the modifier keys and the mouse button at the time the event was posted.

`keyCode`
: The virtual key code derived from the event structure. This value represents the key pressed or released by the user. It is always the same for a specific physical key on a particular keyboard regardless of which modifier keys were also pressed.

`charCode`
: A particular character derived from the event structure. This value depends on the virtual key code, the state of the modifier keys, and the current `'KCHR'` resource.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

    UInt8 contrlHilite;
    SInt16 contrlValue;
    SInt16 contrlMin;
    SInt16 contrlMax;
    Handle contrlDefProc;
    Handle contrlData;
    ControlActionUPP contrlAction;
    SInt32 contrlRfCon;
    Str255 contrlTitle;
};
typedef ControlRecord ControlRecord;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Controls.h`

ControlRef

Defines an opaque type that represents a control.

```
typedef struct OpaqueControlRef * ControlRef;
```

Discussion
A control is a user interface object that gives feedback or otherwise facilitates user interaction. The `ControlRef` type is an opaque type used to describe a control's properties. You can obtain and change the values in a control by calling specific control accessor functions.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`HIObject.h`

ControlSetCursorRec

```
struct ControlSetCursorRec {
    Point localPoint;
    EventModifiers modifiers;
    Boolean cursorWasSet;
};
typedef struct ControlSetCursorRec ControlSetCursorRec;
typedef ControlSetCursorRec * ControlSetCursorPtr;
```

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In

Controls.h

ControlTabEntry

```
struct ControlTabEntry {
    ControlButtonContentInfo * icon;
    CFStringRef name;
    Boolean enabled;
};
typedef struct ControlTabEntry ControlTabEntry;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
HITabbedView.h

ControlTabInfoRec

```
struct ControlTabInfoRec {
    SInt16 version;
    SInt16 iconSuiteID;
    Str255 name;
};
typedef struct ControlTabInfoRec ControlTabInfoRec;
```

Fields

`version`
The version of the tab information structure. The only currently available version value is 0.

`iconSuiteID`
The ID of an icon suite to use for the tab label. If the specified ID is not found, no icon is displayed for the tab label. Pass 0 for no icon.

`name`
The title to be used for the tab label.

Discussion
You can use the `ControlTabInfoRec` type to specify the icon and title for a tab control. If you are not creating a tab control with a `'tab#'` resource, you can call `SetControlMaximum` to set the number of tabs in a tab control. Then use the functions `SetControlData` (page 652) and `GetControlData` (page 594) with the `ControlTabInfoRec` structure to access information for an individual tab in a tab control.

Version Notes
The `ControlTabInfoRec` type is available with Appearance Manager 1.0.1 and later.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`HITabbedView.h`

ControlTabInfoRecV1

```
struct ControlTabInfoRecV1 {
    SInt16 version;
    SInt16 iconSuiteID;
    CFStringRef name;
};
typedef struct ControlTabInfoRecV1 ControlTabInfoRecV1;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`HITabbedView.h`

ControlTemplate

```
struct ControlTemplate {
    Rect controlRect;
    SInt16 controlValue;
    Boolean controlVisible;
    UInt8 fill;
    SInt16 controlMaximum;
    SInt16 controlMinimum;
    SInt16 controlDefProcID;
    SInt32 controlReference;
    Str255 controlTitle;
};
typedef struct ControlTemplate ControlTemplate;
typedef ControlTemplate * ControlTemplatePtr;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Controls.h`

ControlTrackingRec

```
struct ControlTrackingRec {
    Point startPt;
    EventModifiers modifiers;
    ControlActionUPP action;
};
typedef struct ControlTrackingRec ControlTrackingRec;
typedef ControlTrackingRec * ControlTrackingPtr;
```

Fields

`startPt`

The location of the cursor at the time the mouse button was first pressed, in local coordinates. Your application retrieves this point from the `where` field of the event structure.

`modifiers`

The constant in the `modifiers` field of the event structure specifying the state of the modifier keys and the mouse button at the time the event was posted.

`action`

A pointer to an action function defining what action your application takes while the user holds down the mouse button. The value of the `actionProc` parameter can be a valid `procPtr`, `NULL`, or -1. A value of -1 indicates that the control should either perform auto tracking, or if it is incapable of doing so, do nothing (like `NULL`). See `ControlActionProcPtr` (page 675) for more information about the action function.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Controls.h`

ControlVariant

```
typedef SInt16 ControlVariant;
```

Availability

Available in Mac OS X v10.0 and later.

Declared In

DataBrowserCallbacks

```
struct DataBrowserCallbacks {
    UInt32 version
    union {
        struct {
            DataBrowserItemDataUPP itemDataCallback;
            DataBrowserItemCompareUPP itemCompareCallback;
            DataBrowserItemNotificationUPP itemNotificationCallback;
            DataBrowserAddDragItemUPP addDragItemCallback;
            DataBrowserAcceptDragUPP acceptDragCallback;
            DataBrowserReceiveDragUPP receiveDragCallback;
            DataBrowserPostProcessDragUPP postProcessDragCallback;
            DataBrowserItemHelpContentUPP itemHelpContentCallback;
            DataBrowserGetContextualMenuUPP getContextualMenuCallback;
            DataBrowserSelectContextualMenuUPP selectContextualMenuCallback;
        } v1;
    } u;
};
typedef struct DataBrowserCallbacks DataBrowserCallbacks;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
HIDataBrowser.h

DataBrowserCustomCallbacks

```
struct DataBrowserCustomCallbacks {
    UInt32 version
    union {
        struct {
            DataBrowserDrawItemUPP drawItemCallback;
            DataBrowserEditItemUPP editTextCallback;
            DataBrowserHitTestUPP hitTestCallback;
            DataBrowserTrackingUPP trackingCallback;
            DataBrowserItemDragRgnUPP dragRegionCallback;
            DataBrowserItemAcceptDragUPP acceptDragCallback;
            DataBrowserItemReceiveDragUPP receiveDragCallback;
        } v1;
    } u;
};
typedef struct DataBrowserCustomCallbacks DataBrowserCustomCallbacks;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
HIDataBrowser.h

DataBrowserDragFlags

```
typedef  DataBrowserDragFlags;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
HIDataBrowser.h

DataBrowserListViewColumnDesc

```
struct DataBrowserListViewColumnDesc {
    DataBrowserTableViewColumnDesc propertyDesc;
    DataBrowserListViewHeaderDesc headerBtnDesc;
};
typedef struct DataBrowserListViewColumnDesc DataBrowserListViewColumnDesc;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
HIDataBrowser.h

DataBrowserListViewHeaderDesc

```
struct DataBrowserListViewHeaderDesc {
    UInt32 version;
    UInt16 minimumWidth;
    UInt16 maximumWidth;
    SInt16 titleOffset;
    CFStringRef titleString;
    DataBrowserSortOrder initialOrder;
    ControlFontStyleRec btnFontStyle;
    ControlButtonContentInfo btnContentInfo;
};
typedef struct DataBrowserListViewHeaderDesc DataBrowserListViewHeaderDesc;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
HIDataBrowser.h

DataBrowserPropertyDesc

```
struct DataBrowserPropertyDesc {
    DataBrowserPropertyID propertyID;
    DataBrowserPropertyType propertyType;
    DataBrowserPropertyFlags propertyFlags;
};
typedef struct DataBrowserPropertyDesc DataBrowserPropertyDesc;
typedef DataBrowserPropertyDesc DataBrowserTableViewColumnDesc;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`HIDataBrowser.h`

DataBrowserPropertyFlags

```
typedef  DataBrowserPropertyFlags;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`HIDataBrowser.h`

DataBrowserPropertyPart

```
typedef OSType DataBrowserPropertyPart;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`HIDataBrowser.h`

DataBrowserPropertyType

```
typedef OSType DataBrowserPropertyType;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`HIDataBrowser.h`

DataBrowserTableViewColumnDesc

```
typedef DataBrowserPropertyDesc DataBrowserTableViewColumnDesc;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
HIDataBrowser.h

DataBrowserTableViewColumnIndex

```
typedef UInt32 DataBrowserTableViewColumnIndex;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
HIDataBrowser.h

DataBrowserTableViewRowIndex

```
typedef UInt32 DataBrowserTableViewRowIndex;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
HIDataBrowser.h

DataBrowserTableViewColumnID

```
typedef DataBrowserPropertyID DataBrowserTableViewColumnID;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
HIDataBrowser.h

DataBrowserViewStyle

```
typedef OSType DataBrowserViewStyle;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
HIDataBrowser.h

DBItemProcDataType

```
typedef void* DBItemProcDataType;
```

Availability
Available in Mac OS X v10.0 through Mac OS X v10.0.

Declared In
`ControlDefinitions.h`

DBRevealItemDataType

```
typedef DataBrowserRevealOptions DBRevealItemDataType;
```

Availability
Available in Mac OS X v10.0 through Mac OS X v10.0.

Declared In
`ControlDefinitions.h`

DBSetSelectionDataType

```
typedef const DataBrowserItemID* DBSetSelectionDataType;
```

Availability
Available in Mac OS X v10.0 through Mac OS X v10.0.

Declared In
`ControlDefinitions.h`

IndicatorDragConstraint

```
struct IndicatorDragConstraint {
    Rect limitRect;
    Rect slopRect;
    DragConstraint axis;
};
typedef struct IndicatorDragConstraint IndicatorDragConstraint;
typedef IndicatorDragConstraint * IndicatorDragConstraintPtr;
```

Fields

`limitRect`
A pointer to a rectangle—whose coordinates should normally coincide with or be contained in the window's content region—delimiting the area in which the user can drag the control's outline.

`slopRect`
A pointer to a rectangle that allows some extra space for the user to move the mouse while still constraining the control within the rectangle specified in the `limitRect` parameter.

`axis`
The axis along which the user may drag the control's outline see "Part Identifier Constants" (page 792).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Controls.h`

IndicatorDragConstraintHandle

```
typedef IndicatorDragConstraintPtr* IndicatorDragConstraintHandle;
```

PopupPrivateData

```
struct PopupPrivateData {
    MenuRef mHandle;
    SInt16 mID;
};
typedef PopupPrivateData PopupPrivateData;
```

Discussion
Use of this structure is not recommended. When the Appearance Manager is available, you should pass the value `kControlPopupButtonMenuHandleTag` in the `tagName` parameter of the `GetControlData` (page 594) function to get the menu handle of a button, and the menu handle and the menu ID of the menu associated with a pop-up menu.

Availability
Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared In
`ControlDefinitions.h`

PopupPrivateDataHandle

```
typedef PopupPrivateDataPtr* PopupPrivateDataHandle;
```

Availability
Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared In
`ControlDefinitions.h`

PopupPrivateDataPtr

```
typedef PopupPrivateData* PopupPrivateDataPtr;
```

Availability
Available in Mac OS X v10.0 through Mac OS X v10.4.

Declared In
`ControlDefinitions.h`

kHIUserPaneClassID

Defines the HIObject class ID for the HIUserPane class.

```
#define kHIUserPaneClassID CFSTR("com.apple.HIUserPane");
```

Availability
Available in Mac OS X v10.4 and later.

Constants

Appearance–compliant Push Button, Radio Button, and Checkbox Control Definition IDs

```
enum {
    kControlPushButtonProc = 368,
    kControlCheckBoxProc = 369,
    kControlRadioButtonProc = 370,
    kControlPushButLeftIconProc = 374,
    kControlPushButRightIconProc = 375
};
```

Constants

`kControlPushButtonProc`
Resource ID: 23

Appearance-compliant push button.This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

`kControlCheckBoxProc`
Resource ID: 23

Appearance-compliant checkbox. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

`kControlRadioButtonProc`
Resource ID: 23

Appearance-compliant radio button. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

`kControlPushButLeftIconProc`
Resource ID: 23

Appearance-compliant push button with a color icon to the left of the control title. (This direction is reversed when the system justification is right to left). The `contrlMax` field of the control structure for this control contains the resource ID of the `'cicn'` resource drawn in the pushbutton. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

`kControlPushButRightIconProc`
Resource ID: 23

Appearance-compliant push button with a color icon to right of control title. (This direction is reversed when the system justification is right to left). The `contrlMax` field of the control structure for this control contains the resource ID of the `'cicn'` resource drawn in the pushbutton. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

Discussion
When creating a control, your application supplies a control definition ID to one of the Control Manager control-creation functions or to the control resource; see `'CNTL'`. The control definition ID indicates the type of control to create. A control definition ID is an integer that contains the resource ID of a control definition function in its upper 12 bits and a variation code in its lower 4 bits. A control definition ID is derived as follows:

control definition ID = 16 * (`'CDEF'` resource ID) + variation code

A control definition function determines how a control generally looks and behaves. Control definition functions are stored as resources of type `'CDEF'`. Various Control Manager functions call a control definition function whenever they need to perform some control-dependent action, such as drawing the control on the screen. For more information on how to create a control definition function, see "Defining Your Own Control Definition Function".

A control definition function, in turn, can use a variation code to describe variations of the same basic control. For example, all pop-up arrows share the same basic control definition function, which is stored in a resource of type `'CDEF'` and has a resource ID of 12. The standard pop-up arrow is large and points to the right; it has a control definition ID of 192. A variation of this is a large, left-pointing arrow, which has a control definition ID of 193. Still another variation, in which the arrow points up, has a control definition ID of 194.

Your application can use the constants listed here in place of control definition IDs.

If your application contains code that uses the older, pre-Appearance control definition IDs or their constants, your application can use the Appearance Manager to map the old IDs to those for the new, updated controls introduced by the Appearance Manager. In particular, the control definition IDs for pre-Appearance checkboxes, buttons, scroll bars, radio buttons, and pop-up menus will be automatically mapped to Appearance-compliant equivalents.

Asynchronous Arrows Control Definition ID

```
enum {
    kControlChasingArrowsProc = 112
};
```

Constants

`kControlChasingArrowsProc`

Resource ID: 7

Asynchronous arrows. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIProgressViews.h`.

Discussion

When creating a control, your application supplies a control definition ID to one of the Control Manager control-creation functions or to the control resource; see `'CNTL'`. The control definition ID indicates the type of control to create. A control definition ID is an integer that contains the resource ID of a control definition function in its upper 12 bits and a variation code in its lower 4 bits. A control definition ID is derived as follows:

control definition ID = 16 * (`'CDEF'` resource ID) + variation code

A control definition function determines how a control generally looks and behaves. Control definition functions are stored as resources of type `'CDEF'`. Various Control Manager functions call a control definition function whenever they need to perform some control-dependent action, such as drawing the control on the screen. For more information on how to create a control definition function, see `ControlDefProcPtr` (page 677).

A control definition function, in turn, can use a variation code to describe variations of the same basic control. For example, all pop-up arrows share the same basic control definition function, which is stored in a resource of type `'CDEF'` and has a resource ID of 12. The standard pop-up arrow is large and points to the right; it has a control definition ID of 192. A variation of this is a large, left-pointing arrow, which has a control definition ID of 193. Still another variation, in which the arrow points up, has a control definition ID of 194.

Your application can use the constant listed here in place of a control definition ID.

Bevel Button Behavior Constants

```
enum {
    kControlBehaviorPushbutton = 0,
    kControlBehaviorToggles = 0x0100,
    kControlBehaviorSticky = 0x0200,
    kControlBehaviorSingleValueMenu = 0,
    kControlBehaviorMultiValueMenu = 0x4000,
    kControlBehaviorOffsetContents = 0x8000
};
```

Constants

`kControlBehaviorPushbutton`

Push button (momentary) behavior. The bevel button pops up after being clicked.

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

`kControlBehaviorToggles`
Toggle behavior. The bevel button toggles state automatically when clicked.

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

`kControlBehaviorSticky`
Sticky behavior. Once clicked, the bevel button stays down until your application sets the control's value to 0. This behavior is useful in tool palettes and radio groups.

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

`kControlBehaviorMultiValueMenu`
If this bit is set, the menus are multi-valued. The bevel button does not maintain the menu value as it normally would (requiring that only one item is selected at a time). This allows the user to toggle entries in a menu and have multiple items checked. In this mode, the menu value accessed with the `kControlMenuLastValueTag` will return the value of the last menu item selected.

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

`kControlBehaviorOffsetContents`
Bevel button contents are offset (one pixel down and to the right) when button is pressed.

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

Discussion
You can pass the bevel button behavior constants in the high byte of the `minimumValue` parameter of `NewControl` (page 634) to create a bevel button with a specific behavior.

You can pass the bevel button menu constant, `kControlBehaviorMultiValueMenu`, in the high byte of the `minimumValue` parameter of `NewControl` (page 634) to create a bevel button with a menu of a certain behavior. Bevel buttons with menus have two values: the value of the button and the value of the menu. You can specify the direction of the pop-up menu arrow (down or right) by using the `kControlBevelButtonMenuOnRight` bevel button variant.

The bevel button behavior constants and the bevel button menu constant are available with Appearance Manager 1.0 and later.

Bevel Button Control Data Tag Constants

```
enum {
    kControlBevelButtonContentTag = 'cont',
    kControlBevelButtonTransformTag = 'tran',
    kControlBevelButtonTextAlignTag = 'tali',
    kControlBevelButtonTextOffsetTag = 'toff',
    kControlBevelButtonGraphicAlignTag = 'gali',
    kControlBevelButtonGraphicOffsetTag = 'goff',
    kControlBevelButtonTextPlaceTag = 'tplc',
    kControlBevelButtonMenuValueTag = 'mval',
    kControlBevelButtonMenuHandleTag = 'mhnd',
    kControlBevelButtonMenuRefTag = 'mhnd',
    kControlBevelButtonCenterPopupGlyphTag = 'pglc',
    kControlBevelButtonIsMultiValueMenuTag = 'mult'
};
```

Constants

`kControlBevelButtonContentTag`

Gets or sets a bevel button's content type for drawing see "Bevel Button Menu Constant" (page 727).

Data type returned or set: `ControlButtonContentInfo`structure

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

`kControlBevelButtonTransformTag`

Gets or sets a transform that is added to the standard transform of a bevel button

Data type returned or set: `IconTransformType`

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

`kControlBevelButtonTextAlignTag`

Gets or sets the alignment of text in a bevel button; see "Bevel Button Menu Constant" (page 727).

Data type returned or set: `ControlButtonTextAlignment`

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

`kControlBevelButtonTextOffsetTag`

Gets or sets the number of pixels that text is offset in a bevel button from the button's left or right edge this is used with left, right, or system justification, but it is ignored when the text is center aligned.

Data type returned or set: `SInt16`

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

`kControlBevelButtonGraphicAlignTag`

Gets or sets the alignment of graphics in a bevel button in relation to any text the button may contain; see "Bevel Button Menu Constant" (page 727).

Data type returned or set: `ControlButtonGraphicAlignment`

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

`kControlBevelButtonGraphicOffsetTag`
Gets or sets the horizontal and vertical amounts that a graphic element contained in a bevel button is offset from the button's edges this value is ignored when the graphic is specified to be center aligned on the button. Note that offset values should not be used for bevel buttons with content of type `kControlContentIconRef`, because `IconRef` based icons may change with a theme switch; see "Bevel Button Menu Constant" (page 727).

Data type returned or set: `point`

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

`kControlBevelButtonTextPlaceTag`
Gets or sets the placement of a bevel button's text see "Bevel Button Menu Constant" (page 727).

Data type returned or set: `ControlButtonTextPlacement`

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

`kControlBevelButtonMenuValueTag`
Gets the menu value for a bevel button with an attached menu; see "Bevel Button Menu Constant" (page 727).

Data type returned: `SInt16`

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

`kControlBevelButtonMenuHandleTag`
Gets or sets the menu handle for a bevel button with an attached menu. To set a non-resource-based menu for a bevel button, you must pass in a non-zero value in the `initialValue` parameter of the `NewControl` function, then call the `SetControlData` function with the `kControlBevelButtonMenuHandleTag` constant and the return value from a call to the `NewMenu` function.

Data type returned: `MenuHandle`

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

`kControlBevelButtonCenterPopupGlyphTag`
Gets or sets the position of the pop-up arrow in a bevel button when a pop-up menu is attached.

Data type returned or set: `Boolean`; if `true`, glyph is vertically centered on the right; if `false`, glyph is on the bottom right.

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

`kControlBevelButtonMultiValueMenuTag`
Gets or sets whether the associated menu is a multi-value menu. Available in Mac OS X v10.3 and later.

Data type returned or set: `Boolean`; if `true`, the menu can have multiple selections; otherwise, `false`.

Discussion
You can use the control data tag constants to set or obtain data that is associated with a control. The control data tag constants are passed in the `inTagName` parameters of `SetControlData` (page 652) and `GetControlData` (page 594) to specify the piece of data in a control that you wish to set or get. You can also pass these constants in the `inTagName` parameter of `GetControlDataSize` (page 596) if you wish to

determine the size of variable-length control data. These constants can also be used by custom control definition functions that return the feature bit `kControlSupportsDataAccess` in response to a `kControlMsgGetFeatures` message.

The data that your application sets or obtains can be of various types, dependent upon the control. Therefore, the descriptions of the control data tag constants list the data types for the information that you can set in the `inData` parameter to the `SetControlData` function and that you can get in the `inBuffer` parameter to the `GetControlData` function.

Version Notes
The control data tag constants are available with Appearance Manager 1.0 and later.

Bevel Button Control Definition IDs

```
enum {
    kControlBevelButtonSmallBevelProc = 32,
    kControlBevelButtonNormalBevelProc = 33,
    kControlBevelButtonLargeBevelProc = 34
};
```

Constants

`kControlBevelButtonSmallBevelProc`
Resource ID: 2

Bevel button with a small bevel.

`kControlBevelButtonSmallBevelProc` + `kControlBevelButtonMenuOnRight`

Resource ID: 2 Control Definition ID: 4

Small bevel button with a pop-up menu. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

`kControlBevelButtonNormalBevelProc`
Resource ID: 2

Bevel button with a normal bevel. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

`kControlBevelButtonLargeBevelProc`
Resource ID: 2

Bevel button with a large bevel. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

Discussion
When creating a control, your application supplies a control definition ID to one of the Control Manager control-creation functions or to the control resource; see `'CNTL'`. The control definition ID indicates the type of control to create. A control definition ID is an integer that contains the resource ID of a control definition function in its upper 12 bits and a variation code in its lower 4 bits. A control definition ID is derived as follows:

control definition ID = 16 * ('CDEF' resource ID) + variation code

A control definition function determines how a control generally looks and behaves. Control definition functions are stored as resources of type 'CDEF'. Various Control Manager functions call a control definition function whenever they need to perform some control-dependent action, such as drawing the control on the screen. For more information on how to create a control definition function, see ControlDefProcPtr (page 677).

A control definition function, in turn, can use a variation code to describe variations of the same basic control. For example, all pop-up arrows share the same basic control definition function, which is stored in a resource of type 'CDEF' and has a resource ID of 12. The standard pop-up arrow is large and points to the right; it has a control definition ID of 192. A variation of this is a large, left-pointing arrow, which has a control definition ID of 193. Still another variation, in which the arrow points up, has a control definition ID of 194.

Your application can use the constants listed here in place of control definition IDs.

Bevel Button Graphic Alignment Constants

```
typedef SInt16 ControlButtonGraphicAlignment;
enum {
    kControlBevelButtonAlignSysDirection = -1,
    kControlBevelButtonAlignCenter = 0,
    kControlBevelButtonAlignLeft = 1,
    kControlBevelButtonAlignRight = 2,
    kControlBevelButtonAlignTop = 3,
    kControlBevelButtonAlignBottom = 4,
    kControlBevelButtonAlignTopLeft = 5,
    kControlBevelButtonAlignBottomLeft = 6,
    kControlBevelButtonAlignTopRight = 7,
    kControlBevelButtonAlignBottomRight = 8
};
```

Constants

`kControlBevelButtonAlignSysDirection`
Bevel button graphic is aligned according to the system default script direction (only left or right).
Available in Mac OS X v10.0 and later.
Declared in HIButtonViews.h.

`kControlBevelButtonAlignCenter`
Bevel button graphic is aligned center.
Available in Mac OS X v10.0 and later.
Declared in HIButtonViews.h.

`kControlBevelButtonAlignLeft`
Bevel button graphic is aligned left.
Available in Mac OS X v10.0 and later.
Declared in HIButtonViews.h.

`kControlBevelButtonAlignRight`
Bevel button graphic is aligned right.
Available in Mac OS X v10.0 and later.
Declared in HIButtonViews.h.

`kControlBevelButtonAlignTop`
Bevel button graphic is aligned top.

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

`kControlBevelButtonAlignBottom`
Bevel button graphic is aligned bottom.

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

`kControlBevelButtonAlignTopLeft`
Bevel button graphic is aligned top left.

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

`kControlBevelButtonAlignBottomLeft`
Bevel button graphic is aligned bottom left.

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

`kControlBevelButtonAlignTopRight`
Bevel button graphic is aligned top right.

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

`kControlBevelButtonAlignBottomRight`
Bevel button graphic is aligned bottom right.

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

Discussion
You can use the `ControlButtonGraphicAlignment` constants to specify the alignment of icons and pictures in bevel buttons. These constants are passed in the `inData` parameter of `SetControlData` (page 652) and returned by `GetControlData` (page 594).

Version Notes
The `ControlButtonGraphicAlignment` constants are available with Appearance Manager 1.0 and later.

Bevel Button Menu Constant

```
enum {
    kControlBehaviorCommandMenu = 0x2000
};
```

Constants
`kControlBehaviorCommandMenu`
If this bit is set, the menu contains commands, not choices, and should not be marked with a checkmark. If this bit is set, it overrides the `kControlBehaviorMultiValueMenu` bit. This constant is only available with Appearance 1.0.1 and later.

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

Discussion
You can pass one or more bevel button menu constants in the high byte of the `minimumValue` parameter of `NewControl` (page 634) to create a bevel button with a menu of a certain behavior. Bevel buttons with menus have two values: the value of the button and the value of the menu. You can specify the direction of the pop-up menu arrow (down or right) by using the `kControlBevelButtonMenuOnRight` bevel button variant.

Bevel Button Menu Control Data Tag Constants

```
enum {
    kControlBevelButtonLastMenuTag = 'lmnu',
    kControlBevelButtonMenuDelayTag = 'mdly'
};
```

Constants

`kControlBevelButtonLastMenuTag`
Gets the menu ID of the last menu selected in the submenu or main menu. Available with Appearance Manager 1.0.1 and later.

Data type returned: `SInt16`

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

`kControlBevelButtonMenuDelayTag`
Gets or sets the delay (in number of ticks) before the menu is displayed. Available with Appearance Manager 1.0.1 and later.

Data type returned or set: `SInt32`

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

Discussion
You can use the control data tag constants to set or obtain data that is associated with a control. The control data tag constants are passed in the `inTagName` parameters of `SetControlData` (page 652) and `GetControlData` (page 594) to specify the piece of data in a control that you wish to set or get. You can also pass these constants in the `inTagName` parameter of `GetControlDataSize` (page 596) if you wish to determine the size of variable-length control data. These constants can also be used by custom control definition functions that return the feature bit `kControlSupportsDataAccess` in response to a `kControlMsgGetFeatures` message.

The data that your application sets or obtains can be of various types, dependent upon the control. Therefore, the descriptions of the control data tag constants list the data types for the information that you can set in the `inData` parameter to the `SetControlData` function and that you can get in the `inBuffer` parameter to the `GetControlData` function.

Bevel Button Text Alignment Constants

```
typedef SInt16 ControlButtonTextAlignment;
enum {
    kControlBevelButtonAlignTextSysDirection = teFlushDefault,
    kControlBevelButtonAlignTextCenter = teCenter,
    kControlBevelButtonAlignTextFlushRight = teFlushRight,
    kControlBevelButtonAlignTextFlushLeft = teFlushLeft
};
```

Constants

`kControlBevelButtonAlignTextSysDirection`
Bevel button text is aligned according to the current script direction (left or right).

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

`kControlBevelButtonAlignTextCenter`
Bevel button text is aligned center.

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

`kControlBevelButtonAlignTextFlushRight`
Bevel button text is aligned flush right.

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

`kControlBevelButtonAlignTextFlushLeft`
Bevel button text is aligned flush left.

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

Discussion

You can use the `ControlButtonTextAlignment` constants to specify the alignment of text in a bevel button. These constants are passed in the `inData` parameter of `SetControlData` (page 652) and returned by `GetControlData` (page 594).

Version Notes

The `ControlButtonTextAlignment` constants are available with Appearance Manager 1.0 and later.

Bevel Button Text Placement Constants

```
typedef SInt16 ControlButtonTextPlacement;
enum {
    kControlBevelButtonPlaceSysDirection = -1,
    kControlBevelButtonPlaceNormally = 0,
    kControlBevelButtonPlaceToRightOfGraphic = 1,
    kControlBevelButtonPlaceToLeftOfGraphic = 2,
    kControlBevelButtonPlaceBelowGraphic = 3,
    kControlBevelButtonPlaceAboveGraphic = 4
};
```

Constants

`kControlBevelButtonPlaceSysDirection`
Bevel button text is placed according to the system default script direction.
Available in Mac OS X v10.0 and later.
Declared in `HIButtonViews.h`.

`kControlBevelButtonPlaceNormally`
Bevel button text is centered.
Available in Mac OS X v10.0 and later.
Declared in `HIButtonViews.h`.

`kControlBevelButtonPlaceToRightOfGraphic`
Bevel button text is placed to the right of the graphic.
Available in Mac OS X v10.0 and later.
Declared in `HIButtonViews.h`.

`kControlBevelButtonPlaceToLeftOfGraphic`
Bevel button text is placed to the left of the graphic.
Available in Mac OS X v10.0 and later.
Declared in `HIButtonViews.h`.

`kControlBevelButtonPlaceBelowGraphic`
Bevel button text is placed below the graphic.
Available in Mac OS X v10.0 and later.
Declared in `HIButtonViews.h`.

`kControlBevelButtonPlaceAboveGraphic`
Bevel button text is placed above the graphic.
Available in Mac OS X v10.0 and later.
Declared in `HIButtonViews.h`.

Discussion

You can use the `ControlButtonTextPlacement` constants to specify the placement of text in a bevel button, in relation to an icon or picture. These constants are passed in the `inData` parameter of `SetControlData` (page 652) and returned by `GetControlData` (page 594). They can be used in conjunction with bevel button text and graphic alignment constants to create, for example, a button where the graphic and text are left justified with the text below the graphic.

Version Notes

The `ControlButtonTextPlacement` constants are available with Appearance Manager 1.0 and later.

Checkbox and Radio Button AutoToggle Control Definition IDs

```
enum {
    kControlCheckBoxAutoToggleProc = 371,
    kControlRadioButtonAutoToggleProc = 372
};
```

Constants

`kControlCheckBoxAutoToggleProc`
Identifies a checkbox control (`'CDEF'` resource ID 23) that automatically changes among its various states (on, off, mixed) in response to user actions. Your application must only call the function `GetControl32BitValue` (page 590) to get the checkbox's new state—there is no need to manually change the control's value after tracking successfully.

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

`kControlRadioButtonAutoToggleProc`
Identifies a radio button control (`'CDEF'` resource ID 23) that automatically changes among its various states (on, off, mixed) in response to user actions. Your application must only call the function `GetControl32BitValue` (page 590) to get the radio button's new state—there is no need to manually change the control's value after tracking successfully.

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

Discussion
The Mac OS 8.5 Control Manager defines these new control definition IDs.

When creating a control, your application supplies a control definition ID to one of the Control Manager control-creation functions or to the control resource; see `'CNTL'`. The control definition ID indicates the type of control to create. A control definition ID is an integer that contains the resource ID of a control definition function in its upper 12 bits and a variation code in its lower 4 bits. A control definition ID is derived as follows:

control definition ID = 16 * (`'CDEF'` resource ID) + variation code

A control definition function determines how a control generally looks and behaves. Control definition functions are stored as resources of type `'CDEF'`. Various Control Manager functions call a control definition function whenever they need to perform some control-dependent action, such as drawing the control on the screen. For more information on how to create a control definition function, see `ControlDefProcPtr` (page 677).

A control definition function, in turn, can use a variation code to describe variations of the same basic control. For example, all pop-up arrows share the same basic control definition function, which is stored in a resource of type `'CDEF'` and has a resource ID of 12. The standard pop-up arrow is large and points to the right; it has a control definition ID of 192. A variation of this is a large, left-pointing arrow, which has a control definition ID of 193. Still another variation, in which the arrow points up, has a control definition ID of 194.

Your application can use the constants listed here in place of control definition IDs. These constants, and their associated IDs, are not supported unless the Appearance Manager is available.

Checkbox Value Constants

```
enum {
    kControlCheckBoxUncheckedValue = 0,
    kControlCheckBoxCheckedValue = 1,
    kControlCheckBoxMixedValue = 2
};
```

Constants

`kControlCheckBoxUncheckedValue`
The checkbox is unchecked.

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

`kControlCheckBoxCheckedValue`
The checkbox is checked.

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

`kControlCheckBoxMixedValue`
Mixed value. Indicates that a setting is on for some elements in a selection and off for others. This state only applies to standard Appearance-compliant checkboxes.

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

Discussion
The checkbox value constants specify the value of a standard checkbox control and are passed in the `newValue` parameter of `SetControlValue` (page 661) and are returned by `GetControlValue` (page 606) .

Version Notes
The checkbox value constants are changed with Appearance Manager 1.0 to support mixed-value checkboxes.

Clock Control Data Tag Constants

```
enum {
    kControlClockLongDateTag = 'date',
    kControlClockFontStyleTag = kControlFontStyleTag,
    kControlClockAnimatingTag = 'anim'
};
```

Constants

`kControlClockLongDateTag`
Gets or sets the clock control's time or date.

Data type returned or set: `LongDateRec` structure. Note that depending on the variant of clock control specified, some of the fields in the `longDateRec` structure may not be valid. For example, if the control variant displays only a non-live user-adjustable date, the hour and minute fields are not valid and will contain garbage.

Available in Mac OS X v10.0 and later.

Declared in `HIClockView.h`.

Discussion
You can use the control data tag constants to set or obtain data that is associated with a control. The control data tag constants are passed in the `inTagName` parameters of `SetControlData` (page 652) and `GetControlData` (page 594) to specify the piece of data in a control that you wish to set or get. You can also pass these constants in the `inTagName` parameter of `GetControlDataSize` (page 596) if you wish to determine the size of variable-length control data. These constants can also be used by custom control definition functions that return the feature bit `kControlSupportsDataAccess` in response to a `kControlMsgGetFeatures` message.

The data that your application sets or obtains can be of various types, dependent upon the control. Therefore, the descriptions of the control data tag constants list the data types for the information that you can set in the `inData` parameter to the `SetControlData` function and that you can get in the `inBuffer` parameter to the `GetControlData` function.

Version Notes
The control data tag constants are available with Appearance Manager 1.0 and later.

Clock Control Definition IDs

```
enum {
    kControlClockTimeProc = 240,
    kControlClockTimeSecondsProc = 241,
    kControlClockDateProc = 242,
    kControlClockMonthYearProc = 243
};
```

Constants

`kControlClockTimeProc`
Resource ID: 15

Clock control displaying hour/minutes. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIClockView.h`.

`kControlClockTimeSecondsProc`
Resource ID: 15

Clock control displaying hours/minutes/seconds. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIClockView.h`.

`kControlClockDateProc`
Resource ID: 15

Clock control displaying date/month/year. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIClockView.h`.

`kControlClockMonthYearProc`

Resource ID: 15

Clock control displaying month/year. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIClockView.h`.

Discussion

When creating a control, your application supplies a control definition ID to one of the Control Manager control-creation functions or to the control resource; see `'CNTL'`. The control definition ID indicates the type of control to create. A control definition ID is an integer that contains the resource ID of a control definition function in its upper 12 bits and a variation code in its lower 4 bits. A control definition ID is derived as follows:

control definition ID = 16 * (`'CDEF'` resource ID) + variation code

A control definition function determines how a control generally looks and behaves. Control definition functions are stored as resources of type `'CDEF'`. Various Control Manager functions call a control definition function whenever they need to perform some control-dependent action, such as drawing the control on the screen. For more information on how to create a control definition function, see `ControlDefProcPtr` (page 677).

A control definition function, in turn, can use a variation code to describe variations of the same basic control. For example, all pop-up arrows share the same basic control definition function, which is stored in a resource of type `'CDEF'` and has a resource ID of 12. The standard pop-up arrow is large and points to the right; it has a control definition ID of 192. A variation of this is a large, left-pointing arrow, which has a control definition ID of 193. Still another variation, in which the arrow points up, has a control definition ID of 194.

Your application can use the constants listed here in place of control definition IDs.

Clock Value Flag Constants

```
typedef UInt32 ControlClockFlags;
enum {
    kControlClockFlagStandard = 0,
    kControlClockNoFlags = 0,
    kControlClockFlagDisplayOnly = 1,
    kControlClockIsDisplayOnly = 1,
    kControlClockFlagLive = 2,
    kControlClockIsLive = 2
};
```

Constants

`kControlClockNoFlags`

Indicates that clock is editable but does not display the current “live” time.

Available in Mac OS X v10.0 and later.

Declared in `HIClockView.h`.

`kControlClockIsDisplayOnly`

When only this bit is set, the clock is not editable. When this bit and the `kControlClockIsLive` bit is set, the clock automatically updates on idle (clock will have the current time).

Available in Mac OS X v10.0 and later.

Declared in `HIClockView.h`.

`kControlClockIsLive`

When only this bit is set, the clock automatically updates on idle and any changes to the clock affect the system clock. When this bit and the `kControlClockIsDisplayOnly` bit is set, the clock automatically updates on idle (clock will have the current time), but is not editable.

Available in Mac OS X v10.0 and later.

Declared in `HIClockView.h`.

Discussion
You can use the clock value flag constants to specify behaviors for a clock control. You can pass one or more of these mask constants into the control (`'CNTL'`) resource or in the `initialValue` parameter of `NewControl` (page 634). Note that the standard clock control is editable and supports keyboard focus. Also, the little arrows that allow manipulation of the date and time are part of the control, not a separate embedded little arrows control. The clock value flag constants are available with Appearance Manager 1.0 and later.

Control Definition Message Constants

The Control Manager passes constants of type `ControlDefProcMessage` to Indicate the action your control definition function must perform.

```
enum {
    drawCntl = 0,
    testCntl = 1,
    calcCRgns = 2,
    initCntl = 3,
    dispCntl = 4,
    posCntl = 5,
    thumbCntl = 6,
    dragCntl = 7,
    autoTrack = 8,
    calcCntlRgn = 10,
    calcThumbRgn = 11,
    drawThumbOutline = 12,
    kControlMsgDrawGhost = 13,
    kControlMsgCalcBestRect = 14,
    kControlMsgHandleTracking = 15,
    kControlMsgFocus = 16,
    kControlMsgKeyDown = 17,
    kControlMsgIdle = 18,
    kControlMsgGetFeatures = 19,
    kControlMsgSetData = 20,
    kControlMsgGetData = 21,
    kControlMsgActivate = 22,
    kControlMsgSetUpBackground = 23,
    kControlMsgCalcValueFromPos = 26,
    kControlMsgTestNewMsgSupport = 27,
    kControlMsgSubValueChanged = 25,
    kControlMsgSubControlAdded = 28,
    kControlMsgSubControlRemoved = 29,
    kControlMsgApplyTextColor = 30,
    kControlMsgGetRegion = 31,
    kControlMsgFlatten = 32,
    kControlMsgSetCursor = 33,
    kControlMsgDragEnter = 38,
    kControlMsgDragLeave = 39,
    kControlMsgDragWithin = 40,
    kControlMsgDragReceive = 41,
    kControlMsgDisplayDebugInfo = 46,
    kControlMsgContextualMenuClick = 47,
    kControlMsgGetClickActivation = 48
};
```

Constants

`drawCntl`

Draw the entire control or part of a control.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Controls.h`.

`testCntl`

Test where the mouse has been pressed.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Controls.h`.

`calcCRgns`
: Calculate the region for the control or the indicator in 24-bit systems. This message is obsolete in Mac OS 7.6 and later.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Controls.h`.

`initCntl`
: Perform additional control initialization.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Controls.h`.

`dispCntl`
: Perform additional control disposal actions.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Controls.h`.

`posCntl`
: Move and update the indicator setting.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Controls.h`.

`thumbCntl`
: Calculate the parameters for dragging the indicator.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Controls.h`.

`dragCntl`
: Perform customized dragging (of the control or its indicator).

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Controls.h`.

`autoTrack`
: Execute the specified action function.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Controls.h`.

`calcCntlRgn`
: Calculate the control region in 32-bit systems.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Controls.h`.

`calcThumbRgn`
Calculate the indicator region in 32-bit systems.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Controls.h`.

`kControlMsgDrawGhost`
Draw a ghost image of the indicator.
Available with Appearance Manager 1.0 and later.
Not available to 64-bit applications.
Declared in `Controls.h`.

`kControlMsgCalcBestRect`
Calculate the optimal control rectangle.
Available with Appearance Manager 1.0 and later.
Not available to 64-bit applications.
Declared in `Controls.h`.

`kControlMsgHandleTracking`
Perform custom tracking.
Available with Appearance Manager 1.0 and later.
Not available to 64-bit applications.
Declared in `Controls.h`.

`kControlMsgFocus`
Handle keyboard focus.
Available with Appearance Manager 1.0 and later.
Not available to 64-bit applications.
Declared in `Controls.h`.

`kControlMsgKeyDown`
Handle keyboard events.
Available with Appearance Manager 1.0 and later.
Not available to 64-bit applications.
Declared in `Controls.h`.

`kControlMsgIdle`
Perform idle processing.
Available with Appearance Manager 1.0 and later.
Not available to 64-bit applications.
Declared in `Controls.h`.

`kControlMsgGetFeatures`
Specify which Appearance-compliant messages are supported.
Available with Appearance Manager 1.0 and later.
Not available to 64-bit applications.
Declared in `Controls.h`.

`kControlMsgSetData`
Set control-specific data.

Available with Appearance Manager 1.0 and later.

Not available to 64-bit applications.

Declared in `Controls.h`.

`kControlMsgGetData`
Get control-specific data.

Available with Appearance Manager 1.0 and later.

Not available to 64-bit applications.

Declared in `Controls.h`.

`kControlMsgActivate`
Handle activate and deactivate events.

Available with Appearance Manager 1.0 and later.

Not available to 64-bit applications.

Declared in `Controls.h`.

`kControlMsgSetUpBackground`
Set the control's background color or pattern (only available if the control supports embedding).

Available with Appearance Manager 1.0 and later.

Not available to 64-bit applications.

Declared in `Controls.h`.

`kControlMsgCalcValueFromPos`
Support live feedback while dragging the indicator and calculate the control value based on the new indicator region.

Available with Appearance Manager 1.0 and later.

Not available to 64-bit applications.

Declared in `Controls.h`.

`kControlMsgTestNewMsgSupport`
Specify whether Appearance-compliant messages are supported.

Available with Appearance Manager 1.0 and later.

Not available to 64-bit applications.

Declared in `Controls.h`.

`kControlMsgSubValueChanged`
Be informed that the value of a subcontrol embedded in the control has changed; this message is useful for radio groups.

Available with Appearance 1.0.1 and later.

Not available to 64-bit applications.

Declared in `Controls.h`.

`kControlMsgSubControlAdded`
Be informed that a subcontrol has been embedded in the control.

Available with Appearance 1.0.1 and later.

Not available to 64-bit applications.

Declared in `Controls.h`.

`kControlMsgSubControlRemoved`

Be informed that a subcontrol is about to be removed from the control.

Available with Appearance 1.0.1 and later.

Not available to 64-bit applications.

Declared in `Controls.h`.

`kControlMsgApplyTextColor`

Set the foreground color to be consistent with the current drawing environment and suitable for display against the background color or pattern. To indicate that your control definition function supports this message, set the `kControlHasSpecialBackground` feature bit. When this message is sent, the Control Manager passes a pointer to a structure of type `ControlGetRegionRec` (page 705) in your control definition function's `param` parameter. The Control Manager sets the `ControlApplyTextColorRec` structure to contain data describing the current drawing environment. Your control definition function is responsible for using this data to apply a text color which is consistent with the current theme and optimally readable on the control's background. Your control definition function should return 0 as the function result.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Controls.h`.

`kControlMsgGetRegion`

Obtain the region occupied by the specified control part. To indicate that your control definition function supports this message, set the `kControlSupportsGetRegion` feature bit. When this message is sent, the Control Manager passes a pointer to a structure of type `ControlGetRegionRec` (page 705) in your control definition function's `param` parameter. Your control definition function is responsible for setting the `region` field of the `ControlGetRegionRec` structure to the region that contains the control part which the Control Manager specifies in the `part` field. Your control definition function return a result code of type `OSStatus` as the function result.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Controls.h`.

Discussion

The Control Manager may pass these constants in the `message` parameter of your control definition function to specify the actions that your function must perform. For more information, see `ControlDefProcPtr` (page 677).

Control Features Constants

```
enum {
    kControlSupportsGhosting = 1 << 0,
    kControlSupportsEmbedding = 1 << 1,
    kControlSupportsFocus = 1 << 2,
    kControlWantsIdle = 1 << 3,
    kControlWantsActivate = 1 << 4,
    kControlHandlesTracking = 1 << 5,
    kControlSupportsDataAccess = 1 << 6,
    kControlHasSpecialBackground = 1 << 7,
    kControlGetsFocusOnClick = 1 << 8,
    kControlSupportsCalcBestRect = 1 << 9,
    kControlSupportsLiveFeedback = 1 << 10,
    kControlHasRadioBehavior = 1 << 11,
    kControlSupportsDragAndDrop = 1 << 12,
    kControlAutoToggles = 1 << 14,
    kControlSupportsGetRegion = 1 << 17,
    kControlSupportsFlattening = 1 << 19,
    kControlSupportsSetCursor = 1 << 20,
    kControlSupportsContextualMenus = 1 << 21,
    kControlSupportsClickActivation = 1 << 22,
    kControlIdlesWithTimer = 1 << 23
};
```

Constants

`kControlSupportsGhosting`
If this bit (bit 0) is set, the control definition function supports the `kControlMsgDrawGhost` message.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlSupportsEmbedding`
If this bit (bit 1) is set, the control definition function supports the `kControlMsgSubControlAdded` and `kControlMsgSubControlRemoved`messages.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlSupportsFocus`
If this bit (bit 2) is set, the control definition function supports the `kControlMsgKeyDown` message. If this bit and the `kControlGetsFocusOnClick` bit are set, the control definition function supports the `kControlMsgFocus` message.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlWantsIdle`
If this bit (bit 3) is set, the control definition function supports the `kControlMsgIdle` message.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlWantsActivate`
If this bit (bit 4) is set, the control definition function supports the `kControlMsgActivate` message.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlHandlesTracking`
If this bit (bit 5) is set, the control definition function supports the `kControlMsgHandleTracking` message.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlSupportsDataAccess`
If this bit (bit 6) is set, the control definition function supports the `kControlMsgGetData` and `kControlMsgSetData` messages.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlHasSpecialBackground`
If this bit (bit 7) is set, the control definition function supports the `kControlMsgSetUpBackground` message.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlGetsFocusOnClick`
If this bit (bit 8) and the `kControlSupportsFocus` bit are set, the control definition function supports the `kControlMsgFocus` message.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlSupportsCalcBestRect`
If this bit (bit 9) is set, the control definition function supports the `kControlMsgCalcBestRect` message.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlSupportsLiveFeedback`
If this bit (bit 10) is set, the control definition function supports the `kControlMsgCalcValueFromPos` message.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlHasRadioBehavior`
If this bit (bit 11) is set, the control definition function supports radio button behavior and can be embedded in a radio group control. This constant is available with Appearance 1.0.1 and later.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlAutoToggles`
If the bit specified by this mask is set, the control definition function supports automatically changing among various states (on, off, mixed) in response to user actions.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlSupportsGetRegion`
If the bit specified by this mask is set, the control definition function supports the `kControlMsgGetRegion` message, described in "Control Definition Message Constants" (page 735).

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

Discussion
If your control definition function supports Appearance-compliant messages, it should return a bit field of the features it supports, composed of one or more of these bits.

Control Focus Part Code Constants

```
enum {
    kControlFocusNoPart = 0,
    kControlFocusNextPart = -1,
    kControlFocusPrevPart = -2
};
```

Constants
`kControlFocusNoPart`
Your control definition function should relinquish its focus and return `kControlFocusNoPart`. It might respond by deactivating its text edit handle and erasing its focus ring. If the control is at the end of its subparts, it should return `kControlFocusNoPart`. This tells the focusing mechanism to jump to the next control that supports focus.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlFocusNextPart`
Your control definition function should change keyboard focus to its next part, the entire control, or remove keyboard focus from the control, depending upon the circumstances.

For multiple part controls that already had keyboard focus, the next part of the control would receive keyboard focus when `kControlFocusNextPart` was passed in the `param` parameter. For example, a clock control with keyboard focus would change its focus to the left-most element of the control (the month field).

For single-part controls that did not have keyboard focus and are now receiving it, the entire control would receive keyboard focus when `kControlFocusNextPart` was passed in the `param` parameter.

For single-part controls that already had keyboard focus and are now losing it, the entire control would lose keyboard focus.

If you are passed `kControlFocusNextPart` and have run out of parts, return `kControlFocusNoPart` to indicate that the user tabbed past the control.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlFocusPrevPart`

Your control definition function should change keyboard focus to its previous part, the entire control, or remove keyboard focus from the control, depending upon the circumstances.

For multiple part controls that already had keyboard focus, the previous part of the control would receive keyboard focus when `kControlFocusPrevPart` was passed in the `param` parameter. For example, a clock control with keyboard focus would change its focus to the right-most element of the control (the year field).

For single-part controls that did not have keyboard focus and are now receiving it, the entire control would receive keyboard focus when `kControlFocusNextPart` was passed in the `param` parameter.

For single-part controls that already had keyboard focus and are now losing it, the entire control would lose keyboard focus.

If you are passed `kControlFocusPrevPart` and have run out of parts, return `kControlFocusNoPart` to indicate that the user tabbed past the control.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

Control Font Style and Key Filter Data Tag Constants

```
enum {
    kControlFontStyleTag = 'font',
    kControlKeyFilterTag = 'fltr',
    kControlKindTag = 'kind',
    kControlSizeTag = 'size'
};
```

Constants

`kControlFontStyleTag`

Sent with a pointer to a ControlKind record to be filled in. Only valid for GetControlData.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlKeyFilterTag`

Gets or sets the key filter function for controls that handle filtered input (includes editable text and list box).

Data type returned or set: `ControlKeyFilterUPP`

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

Discussion

You can use the control data tag constants to set or obtain data that is associated with a control. The control data tag constants are passed in the `inTagName` parameters of `SetControlData` (page 652) and `GetControlData` (page 594) to specify the piece of data in a control that you wish to set or get. You can also pass these constants in the `inTagName` parameter of `GetControlDataSize` (page 596) if you wish to determine the size of variable-length control data (e.g., text in an editable text control). These constants can also be used by custom control definition functions that return the feature bit `kControlSupportsDataAccess` in response to a `kControlMsgGetFeatures` message.

The data that your application sets or obtains can be of various types, dependent upon the control. Therefore, the descriptions of the control data tag constants list the data types for the information that you can set in the `inData` parameter to the `SetControlData` function and that you can get in the `inBuffer` parameter to the `GetControlData` function.

Version Notes
The control data tag constants are available with Appearance Manager 1.0 and later.

Control Font Style Flag Constants

```
enum {
    kControlUseFontMask = 0x0001,
    kControlUseFaceMask = 0x0002,
    kControlUseSizeMask = 0x0004,
    kControlUseForeColorMask = 0x0008,
    kControlUseBackColorMask = 0x0010,
    kControlUseModeMask = 0x0020,
    kControlUseJustMask = 0x0040,
    kControlUseAllMask = 0x00FF,
    kControlAddFontSizeMask = 0x0100
};
```

Constants

`kControlUseFontMask`
If the `kControlUseFontMask` flag is set (bit 0), the `font` field of the control font style structure is applied to the control.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlUseFaceMask`
If the `kControlUseFaceMask` flag is set (bit 1), the `style` field of the control font style structure is applied to the control. This flag is ignored if you specify a meta font value; see "Meta Font Constants" (page 791).

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlUseSizeMask`
If the `kControlUseSizeMask` flag is set (bit 2), the `size` field of the control font style structure is applied to the control. This flag is ignored if you specify a meta font value; see "Meta Font Constants" (page 791).

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlUseForeColorMask`
If the `kControlUseForeColorMask` flag is set (bit 3), the `foreColor` field of the control font style structure is applied to the control. This flag only applies to static text controls.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlUseBackColorMask`
If the `kControlUseBackColorMask` flag is set (bit 4), the `backColor` field of the control font style structure is applied to the control. This flag only applies to static text controls.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlUseModeMask`
If the `kControlUseModeMask` flag is set (bit 5), the text mode specified in the `mode` field of the control font style structure is applied to the control.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlUseJustMask`
If the `kControlUseJustMask` flag is set (bit 6), the `just` field of the control font style structure is applied to the control.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlUseAllMask`
If `kControlUseAllMask` is used, all flags in this mask will be set except `kControlUseAddFontSizeMask`.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlAddFontSizeMask`
If the `kControlUseAddFontSizeMask` flag is set (bit 8), the Dialog Manager will add a specified font size to the `size` field of the control font style structure. This flag is ignored if you specify a meta font value; see "Meta Font Constants" (page 791).

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

Discussion
You can pass one or more control font style flag constants in the `flags` field of the control font style structure to specify the field(s) of the structure that should be applied to the control; see ControlFontStyleRec (page 704). If none of the flags are set, the control uses the system font unless a control variant specifies use of a window font.

Version Notes
These control font style flag constants are available with Appearance Manager 1.0 and later.

Control Key Script Behavior Constants

```
enum {
    kControlKeyScriptBehaviorAllowAnyScript = 'any ',
    kControlKeyScriptBehaviorPrefersRoman = 'prmn',
    kControlKeyScriptBehaviorRequiresRoman = 'rrmn'
};
```

Constants

`kControlKeyScriptBehaviorAllowAnyScript`

Does not change the current keyboard and allows the user to change the keyboard at will. This is the default for non-password fields.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlKeyScriptBehaviorPrefersRoman`

Changes the current keyboard to Roman whenever the editable text field receives focus but allows the user to change the keyboard at will. This is the default for password fields.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlKeyScriptBehaviorRequiresRoman`

Changes the current keyboard to Roman whenever the editable text field receives focus and does not allow the user to change the keyboard.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

Discussion

With the Mac OS 8.5 Control Manager, you can use these constants of type `ControlKeyScriptBehavior` to specify the kind of behavior to be used in an editable text control with respect to changing and locking the keyboard menu as the field is focused. The `ControlKeyScriptBehavior` constants are set and retrieved with the `kControlEditTextKeyScriptBehaviorTag` control data tag constant; for details on `kControlEditTextKeyScriptBehaviorTag`, see "Editable Text Control Data Tag Constants" (page 756).

Control Part Code Constants

```
enum {
    kControlLabelPart = 1,
    kControlMenuPart = 2,
    kControlTrianglePart = 4,
    kControlEditTextPart = 5,
    kControlPicturePart = 6,
    kControlIconPart = 7,
    kControlClockPart = 8,
    kControlListBoxPart = 24,
    kControlListBoxDoubleClickPart = 25,
    kControlImageWellPart = 26,
    kControlRadioGroupPart = 27,
    kControlButtonPart = 10,
    kControlCheckBoxPart = 11,
    kControlRadioButtonPart = 11,
    kControlUpButtonPart = 20,
    kControlDownButtonPart = 21,
    kControlPageUpPart = 22,
    kControlPageDownPart = 23,
    kControlClockHourDayPart = 9,
    kControlClockMinuteMonthPart = 10,
    kControlClockSecondYearPart = 11,
    kControlClockAMPMPart = 12,
    kControlDataBrowserPart = 24,
    kControlDataBrowserDraggedPart = 25
};
```

Constants

`kControlLabelPart`
Identifies the label of a pop-up menu control.
Available in Mac OS X v10.0 and later.
Declared in `ControlDefinitions.h`.

`kControlMenuPart`
Identifies the menu of a pop-up menu control. For bevel buttons with a menu attached, this part code specifies a menu item of the bevel button.
Available in Mac OS X v10.0 and later.
Declared in `ControlDefinitions.h`.

`kControlTrianglePart`
Identifies a disclosure triangle control.
Available in Mac OS X v10.0 and later.
Declared in `ControlDefinitions.h`.

`kControlEditTextPart`
Identifies an editable text control.
Available with Appearance Manager 1.0 and later.
Declared in `ControlDefinitions.h`.

`kControlPicturePart`
Identifies a picture control.
Available with Appearance Manager 1.0 and later.
Declared in `ControlDefinitions.h`.

`kControlIconPart`
Identifies an icon control.
Available with Appearance Manager 1.0 and later.
Declared in `ControlDefinitions.h`.

`kControlClockPart`
Identifies a clock control.
Available with Appearance Manager 1.0 and later.
Declared in `ControlDefinitions.h`.

`kControlListBoxPart`
Identifies a list box control.
Available with Appearance Manager 1.0 and later.
Declared in `ControlDefinitions.h`.

`kControlListBoxDoubleClickPart`
Identifies a double-click in a list box control.
Available with Appearance Manager 1.0 and later.
Declared in `ControlDefinitions.h`.

`kControlImageWellPart`
Identifies an image well control.
Available with Appearance Manager 1.0 and later.
Declared in `ControlDefinitions.h`.

`kControlRadioGroupPart`
Identifies a radio group control.
Available with Appearance Manager 1.0.2 and later.
Declared in `ControlDefinitions.h`.

`kControlButtonPart`
Identifies either a push button or bevel button control. For bevel buttons with a menu attached, this part code specifies the button but not the attached menu.
Available in Mac OS X v10.0 and later.
Declared in `ControlDefinitions.h`.

`kControlCheckBoxPart`
Identifies a checkbox control.
Available in Mac OS X v10.0 and later.
Declared in `ControlDefinitions.h`.

`kControlRadioButtonPart`
Identifies a radio button control.
Available in Mac OS X v10.0 and later.
Declared in `ControlDefinitions.h`.

`kControlUpButtonPart`
Identifies the up button of a scroll bar control (the arrow at the top or the left).
Available in Mac OS X v10.0 and later.
Declared in `ControlDefinitions.h`.

`kControlDownButtonPart`
Identifies the down button of a scroll bar control (the arrow at the right or the bottom).

Available in Mac OS X v10.0 and later.

Declared in `ControlDefinitions.h`.

`kControlPageUpPart`
Identifies the page-up part of a scroll bar control.

Available in Mac OS X v10.0 and later.

Declared in `ControlDefinitions.h`.

`kControlPageDownPart`
Identifies the page-down part of a scroll bar control.

Available in Mac OS X v10.0 and later.

Declared in `ControlDefinitions.h`.

`kControlClockHourDayPart`
Identifies the part of a clock control that contains the hour or the day. The Mac OS 8.5 Control Manager defines this new control part code constant.

Available in Mac OS X v10.0 and later.

Declared in `ControlDefinitions.h`.

`kControlClockMinuteMonthPart`
Identifies the part of a clock control that contains the minute or the month. The Mac OS 8.5 Control Manager defines this new control part code constant.

Available in Mac OS X v10.0 and later.

Declared in `ControlDefinitions.h`.

`kControlClockSecondYearPart`
Identifies the part of a clock control that contains the second or the year. The Mac OS 8.5 Control Manager defines this new control part code constant.

Available in Mac OS X v10.0 and later.

Declared in `ControlDefinitions.h`.

`kControlClockAMPMPart`
Identifies the part of a clock control that contains the AM/PM information. The Mac OS 8.5 Control Manager defines this new control part code constant.

Available in Mac OS X v10.0 and later.

Declared in `ControlDefinitions.h`.

Discussion
Constants of type `ControlPartCode` identify specific parts of controls.

Part codes are meaningful only within the scope of a single control definition function. For example, the standard tab control uses part codes 1...N, where N is the number of tabs, even though those numbers do collide with part codes defined for use with other control definition functions. Therefore, when you wish to specify part codes for the tab control for use with the function `SetControlData`, for example, you should use a part code corresponding to a 1-based index of the tab whose data you wish to set. In other words, the first tab is part code 1, the second tab is part code 2, and so on.

Control State Part Code Constants

```
enum {
    kControlNoPart = 0,
    kControlIndicatorPart = 129,
    kControlDisabledPart = 254,
    kControlInactivePart = 255
};
```

Constants

`kControlNoPart`

Identifies no specific control part. This value unhighlights any highlighted part of the control when passed to the `HiliteControl` function. For events in bevel buttons with an attached menu, this part code indicates that either the mouse was released outside the bevel button and menu or that the button was disabled.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlIndicatorPart`

Identifies the scroll box of a scroll bar control.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlDisabledPart`

Used with `HiliteControl` (page 619)to disable the control.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlInactivePart`

Used with `HiliteControl` (page 619) to make the control inactive.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

Discussion

Constants of type `ControlPartCode` identify specific parts of controls.

Part codes are meaningful only within the scope of a single control definition function. For example, the standard tab control uses part codes 1...N, where N is the number of tabs, even though those numbers do collide with part codes defined for use with other control definition functions. Therefore, when you wish to specify part codes for the tab control for use with the function `SetControlData`, for example, you should use a part code corresponding to a 1-based index of the tab whose data you wish to set. In other words, the first tab is part code 1, the second tab is part code 2, and so on.

Note that if you wish to create part codes for a custom control definition function, you may assign values anywhere within the ranges 1–128 and 130–253. Note also that the function `FindControl` does not typically return the `kControlDisabledPart` or `kControlInactivePart` part codes and never returns them with standard controls.

Control Variant Constants

```
enum {
    kControlNoVariant = 0,
    kControlUsesOwningWindowsFontVariant = 1 << 3
};
```

Constants

`kControlNoVariant`

Specifies no change to the standard control resource.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlUsesOwningWindowsFontVariant`

Specifies that the control use the window font for any control text.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

Discussion

You can use the control variant constants with any of the standard control resource IDs to specify additional features of a control.

Version Notes

The control variant constants are changed with Appearance Manager 1.0 to support the additional control types available with the Appearance Manager.

Control Bevel Button Menu Placement Constants

```
typedef UInt16 ControlBevelButtonMenuPlacement;
enum {
    kControlBevelButtonMenuOnBottom = 0,
    kControlBevelButtonMenuOnRight = (1 << 2)
};
```

Control Bevel Thickness Constants

```
typedef UInt16 ControlBevelThickness;
enum {
    kControlBevelButtonSmallBevel = 0,
    kControlBevelButtonNormalBevel = 1,
    kControlBevelButtonLargeBevel = 2
};
```

Control Clock Type Constants

```
typedef UInt16 ControlClockType;
enum {
    kControlClockTypeHourMinute = 0,
    kControlClockTypeHourMinuteSecond = 1,
    kControlClockTypeMonthDayYear = 2,
    kControlClockTypeMonthYear = 3
};
```

Control Disclosure Triangle Orientation Constants

```
typedef UInt16 ControlDisclosureTriangleOrientation;
enum {
    kControlDisclosureTrianglePointDefault = 0,
    kControlDisclosureTrianglePointRight = 1,
    kControlDisclosureTrianglePointLeft = 2
};
```

Control Notify Constants

```
enum {
    controlNotifyNothing = 'nada',
    controlNotifyClick = 'clik',
    controlNotifyFocus = 'focu',
    controlNotifyKey = 'key '
};
```

Control Push Button Icon Alignment Constants

```
typedef UInt16 ControlPushButtonIconAlignment;
enum {
    kControlPushButtonIconOnLeft = 6,
```

```
    kControlPushButtonIconOnRight = 7
};
```

Control Round Button Size Constants

```
typedef SInt16 ControlRoundButtonSize;
enum {
    kControlRoundButtonNormalSize = kControlSizeNormal,
    kControlRoundButtonLargeSize = kControlSizeLarge
};
```

Control Slider Orientation Constants

```
typedef UInt16 ControlSliderOrientation;
enum {
    kControlSliderPointsDownOrRight = 0,
    kControlSliderPointsUpOrLeft = 1,
    kControlSliderDoesNotPoint = 2
};
```

Control Tab Direction Constants

```
typedef UInt16 ControlTabDirection;
enum {
    kControlTabDirectionNorth = 0,
    kControlTabDirectionSouth = 1,
    kControlTabDirectionEast = 2,
    kControlTabDirectionWest = 3
};
```

Control Tab Size Constants

```
typedef UInt16 ControlTabSize;
enum {
    kControlTabSizeLarge = kControlSizeNormal,
    kControlTabSizeSmall = kControlSizeSmall
};
```

Drag Control Constants

Specify whether the user is dragging an indicator or the whole control.

```
enum {
    kDragControlEntireControl = 0,
    kDragControlIndicator = 1
};
```

Constants

`kDragControlEntireControl`
Dragging the entire control.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Controls.h`.

`kDragControlIndicator`
Dragging the indicator.
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.
Declared in `Controls.h`.

Drawing Constants

```
enum {
    kDrawControlEntireControl = 0,
    kDrawControlIndicatorOnly = 129
};
```

Constants

`kDrawControlEntireControl`
Draw the entire control.
Available in Mac OS X v10.0 and later.
Declared in `Controls.h`.

`kDrawControlIndicatorOnly`
Draw the indicator only.
Available in Mac OS X v10.0 and later.
Declared in `Controls.h`.

Discussion
The Control Manager passes one of these drawing constants in the low word of the `param` parameter to specify whether the user is drawing an indicator or the whole control. The high-order word of the `param` parameter may contain undefined data; therefore, evaluate only the low-order word of this parameter.

Editable Text Control Data Tag Constants

```
enum {
    kControlEditTextStyleTag = kControlFontStyleTag,
    kControlEditTextTextTag = 'text',
    kControlEditTextTEHandleTag = 'than',
    kControlEditTextKeyFilterTag = kControlKeyFilterTag,
    kControlEditTextSelectionTag = 'sele',
    kControlEditTextPasswordTag = 'pass'
};
enum {
    kControlEditTextKeyScriptBehaviorTag = 'kscr',
    kControlEditTextLockedTag = 'lock',
    kControlEditTextFixedTextTag = 'ftxt',
    kControlEditTextValidationProcTag = 'vali',
    kControlEditTextInlinePreUpdateProcTag = 'prup',
    kControlEditTextInlinePostUpdateProcTag = 'poup'
};
enum {
    kControlEditTextCFStringTag = 'cfst',
    kControlEditTextPasswordCFStringTag = 'pwcf'
};
```

Constants

`kControlEditTextTextTag`

Gets or sets text in an editable text control.

Data type returned or set: character buffer

Available in Mac OS X v10.0 and later.

Declared in `HITextViews.h`.

`kControlEditTextTEHandleTag`

Gets a handle to a text edit structure.

Data type returned: `TEHandle`

Available in Mac OS X v10.0 and later.

Declared in `ControlDefinitions.h`.

`kControlEditTextSelectionTag`

Gets or sets the selection in an editable text control.

Data type returned or set: `ControlEditTextSelectionRec` structure

Available in Mac OS X v10.0 and later.

Declared in `HITextViews.h`.

`kControlEditTextKeyScriptBehaviorTag`

Gets or sets the kind of behavior to be used in an editable text control with respect to changing and locking the keyboard menu as the field is focused.

Data type retrieved or set: `ControlKeyScriptBehavior`. The default for password fields is `kControlKeyScriptBehaviorPrefersRoman`. The default for non-password fields is `kControlKeyScriptBehaviorAllowAnyScript`. See `ControlEditTextValidationProcPtr` (page 685) for descriptions of possible values.

Available in Appearance 1.1 or Mac OS 8.5 and later.

Available in Mac OS X v10.0 and later.

Declared in `HITextViews.h`.

`kControlEditTextLockedTag`

Gets or sets whether the text in an editable text control is currently editable.

Data type retrieved or set: `Boolean`; if `true`, the text is locked and cannot be edited; if `false`, the text is editable.

Available in Appearance 1.1 or Mac OS 8.5 and later.

Available in Mac OS X v10.0 and later.

Declared in `HITextViews.h`.

`kControlEditTextFixedTextTag`

Gets or sets inline input text in an editable text control, after confirming any text in the active input area with the Text Services Manager function `FixTSMDocument`.

Data type retrieved or set: character buffer

Available in Appearance 1.1 or Mac OS 8.5 and later.

Available in Mac OS X v10.0 and later.

Declared in `HITextViews.h`.

`kControlEditTextValidationProcTag`

Gets or sets a universal procedure pointer to a callback function such as that described in `ControlEditTextValidationProcPtr` (page 685), which can be used to validate editable text after an operation that changes the text, such as inline text entry, a cut, or paste.

Data type retrieved or set: `ControlEditTextValidationUPP`

Available in Appearance 1.1 or Mac OS 8.5 and later.

Available in Mac OS X v10.0 and later.

Declared in `HITextViews.h`.

`kControlEditTextInlinePreUpdateProcTag`

Gets or sets a universal procedure pointer to a Text Services Manager pre-update callback function.

Data type retrieved or set: `TSMTEPreUpdateUPP`

Available in Appearance 1.1 or Mac OS 8.5 and later.

Available in Mac OS X v10.0 and later.

Declared in `ControlDefinitions.h`.

`kControlEditTextInlinePostUpdateProcTag`

Gets or sets a universal procedure pointer to a Text Services Manager post-update callback function.

Data type retrieved or set: `TSMTEPostUpdateUPP`

Available in Appearance 1.1 or Mac OS 8.5 and later.

Available in Mac OS X v10.0 and later.

Declared in `ControlDefinitions.h`.

`kControlEditTextCFStringTag`

Retrieves the contents of the edit text field as a CFString.

Data type retrieved: `CFStringRef`. You must release the string when you no longer need it.

Available in CarbonLib 1.5 and Mac OS X v10.0 and later.

Available in Mac OS X v10.0 and later.

Declared in `HITextViews.h`.

`kControlEditTextPasswordCFStringTag`

Extract the content of the edit text field if it is a password field.

Data type retrieved: `CFStringRef`. You must release the string when you no longer need it.

Available in CarbonLib 1.5 and Mac OS X v10.0 and later.

Available in Mac OS X v10.1 and later.

Declared in `HITextViews.h`.

Discussion

You can use the control data tag constants to set or obtain data that is associated with a control. The control data tag constants are passed in the `inTagName` parameters of `SetControlData` (page 652) and `GetControlData` (page 594) to specify the piece of data in a control that you wish to set or get. You can also pass these constants in the `inTagName` parameter of `GetControlDataSize` (page 596) if you wish to determine the size of variable-length control data (e.g., text in an editable text control). These constants can also be used by custom control definition functions that return the feature bit `kControlSupportsDataAccess` in response to a `kControlMsgGetFeatures` message.

The data that your application sets or obtains can be of various types, dependent upon the control. Therefore, the descriptions of the control data tag constants list the data types for the information that you can set in the `inData` parameter to the `SetControlData` function and that you can get in the `inBuffer` parameter to the `GetControlData` function.

Version Notes

The control data tag constants are available with Appearance Manager 1.0 and later.

Editable Text Control Definition ID Constants

```
enum {
    kControlEditTextProc = 272,
    kControlEditTextPasswordProc = 274
};
```

Constants

`kControlEditTextProc`

Resource ID: 17

Editable text field for windows. This control maintains its own text handle (`TEHandle`).

This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `ControlDefinitions.h`.

`kControlEditTextPasswordProc`

Resource ID: 17

Editable text field for passwords. This control is supported by the Script Manager. Password text can be accessed via the `kEditTextPasswordTag` constant; see "Editable Text Control Data Tag Constants" (page 756).

This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `ControlDefinitions.h`.

Discussion
When creating a control, your application supplies a control definition ID to one of the Control Manager control-creation functions or to the control resource; see `'CNTL'`. The control definition ID indicates the type of control to create. A control definition ID is an integer that contains the resource ID of a control definition function in its upper 12 bits and a variation code in its lower 4 bits. A control definition ID is derived as follows:

control definition ID = 16 * (`'CDEF'` resource ID) + variation code

A control definition function determines how a control generally looks and behaves. Control definition functions are stored as resources of type `'CDEF'`. Various Control Manager functions call a control definition function whenever they need to perform some control-dependent action, such as drawing the control on the screen. For more information on how to create a control definition function, see `ControlDefProcPtr` (page 677).

A control definition function, in turn, can use a variation code to describe variations of the same basic control. For example, all pop-up arrows share the same basic control definition function, which is stored in a resource of type `'CDEF'` and has a resource ID of 12. The standard pop-up arrow is large and points to the right; it has a control definition ID of 192. A variation of this is a large, left-pointing arrow, which has a control definition ID of 193. Still another variation, in which the arrow points up, has a control definition ID of 194.

Your application can use the constants listed here in place of control definition IDs.

Data Browser Error Constants

```
enum {
    errDataBrowserNotConfigured = -4970,
    errDataBrowserItemNotFound = -4971,
    errDataBrowserItemNotAdded = -4975,
    errDataBrowserPropertyNotFound = -4972,
    errDataBrowserInvalidPropertyPart = -4973,
    errDataBrowserInvalidPropertyData = -4974,
    errDataBrowserPropertyNotSupported = -4979
};
```

Group Box Control Data Tag Constants

```
enum {
    kControlGroupBoxMenuHandleTag = 'mhan',
    kControlGroupBoxMenuRefTag = 'mhan',
    kControlGroupBoxFontStyleTag = kControlFontStyleTag,
    kControlGroupBoxFrameRectTag = 'frec'
};
```

Constants
`kControlGroupBoxMenuHandleTag`
Gets the menu handle of a group box.
Data type returned: `MenuHandle`
Available in Mac OS X v10.0 and later.
Declared in `HIContainerViews.h`.

`kControlGroupBoxFrameRectTag`

Gets the full rectangle that content is drawn in. This is slightly different from the content region because the full rectangle includes the frame drawn around the content. Available in Mac OS X v10.3 and later.

Data type returned: `Rect`

Available in Mac OS X v10.3 and later.

Declared in `HIContainerViews.h`.

Discussion

You can use the control data tag constants to set or obtain data that is associated with a control. The control data tag constants are passed in the `inTagName` parameters of `SetControlData` (page 652) and `GetControlData` (page 594) to specify the piece of data in a control that you wish to set or get. You can also pass these constants in the `inTagName` parameter of `GetControlDataSize` (page 596) if you wish to determine the size of variable-length control data. These constants can also be used by custom control definition functions that return the feature bit `kControlSupportsDataAccess` in response to a `kControlMsgGetFeatures` message.

The data that your application sets or obtains can be of various types, dependent upon the control. Therefore, the descriptions of the control data tag constants list the data types for the information that you can set in the `inData` parameter to the `SetControlData` function and that you can get in the `inBuffer` parameter to the `GetControlData` function.

Version Notes

The control data tag constants are available with Appearance Manager 1.0 and later.

Group Box Control Definition ID Constants

```
enum {
    kControlGroupBoxTextTitleProc = 160,
    kControlGroupBoxCheckBoxProc = 161,
    kControlGroupBoxPopupButtonProc = 162,
    kControlGroupBoxSecondaryTextTitleProc = 164,
    kControlGroupBoxSecondaryCheckBoxProc = 165,
    kControlGroupBoxSecondaryPopupButtonProc = 166
};
```

Constants

`kControlGroupBoxTextTitleProc`

Resource ID: 10

Primary group box with text title. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIContainerViews.h`.

`kControlGroupBoxCheckBoxProc`

Resource ID: 10

Primary group box with checkbox title. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIContainerViews.h`.

`kControlGroupBoxPopupButtonProc`
Resource ID: 10

Primary group box with pop-up button title. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIContainerViews.h`.

`kControlGroupBoxSecondaryTextTitleProc`
Resource ID: 10

Secondary group box with text title. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIContainerViews.h`.

`kControlGroupBoxSecondaryCheckBoxProc`
Resource ID: 10

Secondary group box with checkbox title. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIContainerViews.h`.

`kControlGroupBoxSecondaryPopupButtonProc`
Resource ID: 10

Secondary group box with pop-up button title. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIContainerViews.h`.

Discussion
When creating a control, your application supplies a control definition ID to one of the Control Manager control-creation functions or to the control resource; see `'CNTL'`. The control definition ID indicates the type of control to create. A control definition ID is an integer that contains the resource ID of a control definition function in its upper 12 bits and a variation code in its lower 4 bits. A control definition ID is derived as follows:

control definition ID = 16 * (`'CDEF'` resource ID) + variation code

A control definition function determines how a control generally looks and behaves. Control definition functions are stored as resources of type `'CDEF'`. Various Control Manager functions call a control definition function whenever they need to perform some control-dependent action, such as drawing the control on the screen. For more information on how to create a control definition function, see `ControlDefProcPtr` (page 677).

A control definition function, in turn, can use a variation code to describe variations of the same basic control. For example, all pop-up arrows share the same basic control definition function, which is stored in a resource of type `'CDEF'` and has a resource ID of 12. The standard pop-up arrow is large and points to the right; it has a control definition ID of 192. A variation of this is a large, left-pointing arrow, which has a control definition ID of 193. Still another variation, in which the arrow points up, has a control definition ID of 194.

Your application can use the constants listed here in place of control definition IDs.

Icon Control Data Tag Constants

```
enum {
    kControlIconTransformTag = 'trfm',
    kControlIconAlignmentTag = 'algn'
};
```

Constants

`kControlIconTransformTag`

Gets or sets a transform that is added to the standard transform of an icon see "Icon Utilities."

Data type returned or set: `IconTransformType`

Available in Mac OS X v10.0 and later.

Declared in `HIImageViews.h`.

`kControlIconAlignmentTag`

Gets or sets an icon's position (centered, left, right).

Data type returned or set: `IconAlignmentType`

Available in Mac OS X v10.0 and later.

Declared in `HIImageViews.h`.

Discussion

You can use the control data tag constants to set or obtain data that is associated with a control. The control data tag constants are passed in the `inTagName` parameters of `SetControlData` (page 652) and `GetControlData` (page 594) to specify the piece of data in a control that you wish to set or get. You can also pass these constants in the `inTagName` parameter of `GetControlDataSize` (page 596) if you wish to determine the size of variable-length control data. These constants can also be used by custom control definition functions that return the feature bit `kControlSupportsDataAccess` in response to a `kControlMsgGetFeatures` message.

The data that your application sets or obtains can be of various types, dependent upon the control. Therefore, the descriptions of the control data tag constants list the data types for the information that you can set in the `inData` parameter to the `SetControlData` function and that you can get in the `inBuffer` parameter to the `GetControlData` function.

Version Notes

The control data tag constants are available with Appearance Manager 1.0 and later.

Icon Control Definition ID Constants

```
enum {
    kControlIconProc = 320,
    kControlIconNoTrackProc = 321,
    kControlIconSuiteProc = 322,
    kControlIconSuiteNoTrackProc = 323
};
enum {
    kControlIconRefProc = 324,
    kControlIconRefNoTrackProc = 325
};
```

Constants

`kControlIconProc`
Resource ID: 20

Icon control. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIImageViews.h`.

`kControlIconNoTrackProc`
Resource ID: 20

Non-tracking icon. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIImageViews.h`.

`kControlIconSuiteProc`
Resource ID: 20

Icon suite. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIImageViews.h`.

`kControlIconSuiteNoTrackProc`
Resource ID: 20

Non-tracking icon suite. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIImageViews.h`.

`kControlIconRefProc`

Identifies the variant of the icon control (`'CDEF'` resource ID 20) that supports all standard types of icon-based content. Note that you do not supply content for this control upon its creation with a call to the `NewControl` function. Rather, after the control's creation you can set or change its content at any time by passing the `SetControlData` function the `kControlIconContentTag` control data tag constant and a `ControlButtonContentInfo` structure containing any of the allowable data types. Supported data types for this icon control variant are specified with the following `ControlContentType` values: `kControlContentIconSuiteRes`, `kControlContentCIconRes` (uses a black-and-white `'ICON'` resource if the color resource isn't available), `kControlContentIconSuiteHandle`, `kControlContentCIconHandle`, and `kControlContentIconRef`. Note, too, that if you supply the `kControlContentIconRef` value, you must first use Icon Services functions to register your resources and generate `IconRef` values. See the `ControlButtonContentInfo` (page 699) data type and "Control Content Type Constants" (page 770) for more information.

Declared in `HIImageViews.h`.

Available in Mac OS 8.5 and later.

`kControlIconRefNoTrackProc`

Identifies the non-tracking variant of the icon control (`'CDEF'` resource ID 20) that supports all standard types of icon-based content. This control immediately returns `kControlIconPart` as the part code hit without tracking. Note that you do not supply content for this control upon its creation with a call to the `NewControl` function. Rather, after the control's creation you can set or change its content at any time by passing the `SetControlData` function the `kControlIconContentTag` control data tag constant and a `ControlButtonContentInfo` structure containing any of the allowable data types. Supported data types for this icon control variant are specified with the following `ControlContentType` values: `kControlContentIconSuiteRes`, `kControlContentCIconRes` (uses a black-and-white `'ICON'` resource if the color resource isn't available), `kControlContentIconSuiteHandle`, `kControlContentCIconHandle`, and `kControlContentIconRef`. Note, too, that if you supply the `kControlContentIconRef` value, you must first use Icon Services functions to register your resources and generate `IconRef` values. See the `ControlButtonContentInfo` (page 699) data type and "Control Content Type Constants" (page 770) for more information.

Declared in `HIImageViews.h`.

Available in Mac OS 8.5 and later.

Discussion

When creating a control, your application supplies a control definition ID to one of the Control Manager control-creation functions or to the control resource; see `'CNTL'`. The control definition ID indicates the type of control to create. A control definition ID is an integer that contains the resource ID of a control definition function in its upper 12 bits and a variation code in its lower 4 bits. A control definition ID is derived as follows:

control definition ID = 16 * (`'CDEF'` resource ID) + variation code

A control definition function determines how a control generally looks and behaves. Control definition functions are stored as resources of type `'CDEF'`. Various Control Manager functions call a control definition function whenever they need to perform some control-dependent action, such as drawing the control on the screen. For more information on how to create a control definition function, see `ControlDefProcPtr` (page 677).

A control definition function, in turn, can use a variation code to describe variations of the same basic control. For example, all pop-up arrows share the same basic control definition function, which is stored in a resource of type 'CDEF' and has a resource ID of 12. The standard pop-up arrow is large and points to the right; it has a control definition ID of 192. A variation of this is a large, left-pointing arrow, which has a control definition ID of 193. Still another variation, in which the arrow points up, has a control definition ID of 194.

Your application can use the constants listed here in place of control definition IDs.

Image Well Control Data Tag Constants

```
enum {
    kControlImageWellContentTag = 'cont',
    kControlImageWellTransformTag = 'tran',
    kControlImageWellIsDragDestinationTag = 'drag'
};
```

Constants

`kControlImageWellContentTag`

Gets or sets the content for an image well; see `ControlButtonContentInfo` (page 699).

Data type returned or set: `ControlButtonContentInfo` structure

Available in Mac OS X v10.0 and later.

Declared in `HIImageViews.h`.

`kControlImageWellTransformTag`

Gets or sets a transform that is added to the standard transform of an image well.

Data type returned or set: `IconTransformType`

Available in Mac OS X v10.0 and later.

Declared in `HIImageViews.h`.

Discussion

You can use the control data tag constants to set or obtain data that is associated with a control. The control data tag constants are passed in the `inTagName` parameters of `SetControlData` (page 652) and `GetControlData` (page 594) to specify the piece of data in a control that you wish to set or get. You can also pass these constants in the `inTagName` parameter of `GetControlDataSize` (page 596) if you wish to determine the size of variable-length control data. These constants can also be used by custom control definition functions that return the feature bit `kControlSupportsDataAccess` in response to a `kControlMsgGetFeatures` message.

The data that your application sets or obtains can be of various types, dependent upon the control. Therefore, the descriptions of the control data tag constants list the data types for the information that you can set in the `inData` parameter to the `SetControlData` function and that you can get in the `inBuffer` parameter to the `GetControlData` function.

Version Notes

The control data tag constants are available with Appearance Manager 1.0 and later.

Image Well Control Definition ID

```
enum {
    kControlImageWellProc = 176
};
```

Constants

`kControlImageWellProc`

Resource ID: 11

Image well. This control behaves as a palette-type object: it can be selected by clicking, and clicking on another object should change the keyboard focus. If the keyboard focus is removed, your application should then set the value to 0 to remove the checked border.

This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIImageViews.h`.

Discussion

When creating a control, your application supplies a control definition ID to one of the Control Manager control-creation functions or to the control resource; see `'CNTL'`. The control definition ID indicates the type of control to create. A control definition ID is an integer that contains the resource ID of a control definition function in its upper 12 bits and a variation code in its lower 4 bits. A control definition ID is derived as follows:

control definition ID = 16 * (`'CDEF'` resource ID) + variation code

A control definition function determines how a control generally looks and behaves. Control definition functions are stored as resources of type `'CDEF'`. Various Control Manager functions call a control definition function whenever they need to perform some control-dependent action, such as drawing the control on the screen. For more information on how to create a control definition function, see `ControlDefProcPtr` (page 677).

A control definition function, in turn, can use a variation code to describe variations of the same basic control. For example, all pop-up arrows share the same basic control definition function, which is stored in a resource of type `'CDEF'` and has a resource ID of 12. The standard pop-up arrow is large and points to the right; it has a control definition ID of 192. A variation of this is a large, left-pointing arrow, which has a control definition ID of 193. Still another variation, in which the arrow points up, has a control definition ID of 194.

Your application can use the constant listed here in place of a control definition ID.

inLabel

```
enum {
    inLabel = kControlLabelPart,
    inMenu = kControlMenuPart,
    inTriangle = kControlTrianglePart,
    inButton = kControlButtonPart,
    inCheckBox = kControlCheckBoxPart,
    inUpButton = kControlUpButtonPart,
    inDownButton = kControlDownButtonPart,
    inPageUp = kControlPageUpPart,
    inPageDown = kControlPageDownPart
};
```

inThumb

```
enum {
    inThumb = kControlIndicatorPart,
    kNoHiliteControlPart = kControlNoPart,
    kInIndicatorControlPart = kControlIndicatorPart,
    kReservedControlPart = kControlDisabledPart,
    kControlInactiveControlPart = kControlInactivePart
};
```

kControlBevelButtonOwnedMenuRefTag

```
enum {
    kControlBevelButtonOwnedMenuRefTag = 'omrf',
    kControlBevelButtonKindTag = 'bebk'
};
```

Bevel Button Size Constants

```
enum {
    kControlBevelButtonSmallBevelVariant = 0,
    kControlBevelButtonNormalBevelVariant = (1 << 0),
    kControlBevelButtonLargeBevelVariant = (1 << 1),
    kControlBevelButtonMenuOnRightVariant = (1 << 2)
};
```

Control Can Auto Invalidate Constant

```
enum {
    kControlCanAutoInvalidate = 1
};
```

Control Chasing Arrows Animating Tag Constant

```
enum {
    kControlChasingArrowsAnimatingTag = 'anim'
```

```
};
```

Control Collection Tag Constants

Specify initial control values passed in a collection.

```
enum {
    kControlCollectionTagBounds = 'boun',
    kControlCollectionTagValue = 'valu',
    kControlCollectionTagMinimum = 'min ',
    kControlCollectionTagMaximum = 'max ',
    kControlCollectionTagViewSize = 'view',
    kControlCollectionTagVisibility = 'visi',
    kControlCollectionTagRefCon = 'refc',
    kControlCollectionTagTitle = 'titl',
    kControlCollectionTagUnicodeTitle = 'uttl',
    kControlCollectionTagIDSignature = 'idsi',
    kControlCollectionTagIDID = 'idid',
    kControlCollectionTagCommand = 'cmd ',
    kControlCollectionTagVarCode = 'varc'
};
```

Constants

`kControlCollectionTagBounds`
A value of type `Rect` that contains the bounding rectangle of the control.
Available in Mac OS X v10.0 and later.
Declared in `Controls.h`.

`kControlCollectionTagValue`
A value of type `SInt32` that contains the value of the control.
Available in Mac OS X v10.0 and later.
Declared in `Controls.h`.

`kControlCollectionTagMinimum`
A value of type `SInt32` that contains the minimum value of the control.
Available in Mac OS X v10.0 and later.
Declared in `Controls.h`.

`kControlCollectionTagMaximum`
A value of type `SInt32` that contains the maximum value of the control.
Available in Mac OS X v10.0 and later.
Declared in `Controls.h`.

`kControlCollectionTagViewSize`
A value of type `SInt32` that contains the view size of the control.
Available in Mac OS X v10.0 and later.
Declared in `Controls.h`.

`kControlCollectionTagVisibility`
A Boolean that contains the visible state of the control. This tag is only interpreted on CarbonLib versions through 1.5.x and Mac OS X v10.0.x. This tag is not interpreted on CarbonLib 1.6 and later nor on Mac OS X v10.1 and later; use of this tag is not recommended.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlCollectionTagRefCon`
A value of type `SInt32` that contains the refcon for the control.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlCollectionTagTitle`
A character array of arbitrary size that contains the title of the control.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlCollectionTagUnicodeTitle`
A character array of arbitrary size that contains the title of the control as received via `CFStringCreateExternalRepresentation`.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlCollectionTagIDSignature`
An OSType that contains the ControlID signature for the control.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlCollectionTagIDID`
A value of type `SInt32` that contains the ControlID ID for the control.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlCollectionTagCommand`
A value of type `UInt32` that contains the command.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlCollectionTagVarCode`
A value of type `SInt16` that contains the variant for the control.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

Discussion
These standard tags are used in the initial data collection that is passed in the `param` parameter to the `initCntl` message and in the `kEventParamInitCollection` parameter to the `kEventControlInitialize` event (Carbon only).

All tags at ID 0 in a control's collection are reserved for Control Manager use. Custom control definitions should use other IDs.

Most of these tags are interpreted when you call `CreateCustomControl` (page 543). The Control Manager puts the value in the right place before it calls the control definition with the initialization message.

Control Collection Tag Subcontrols Constant

```
enum {
    kControlCollectionTagSubControls = 'subc'
};
```

Control Content Type Constants

```
enum {
    kControlContentTextOnly = 0,
    kControlNoContent = 0,
    kControlContentIconSuiteRes = 1,
    kControlContentCIconRes = 2,
    kControlContentPictRes = 3,
    kControlContentICONRes = 4,
    kControlContentIconSuiteHandle = 129,
    kControlContentCIconHandle = 130,
    kControlContentPictHandle = 131,
    kControlContentIconRef = 132,
    kControlContentICON = 133
};
```

Constants

`kControlContentTextOnly`
Content type is text. This constant is passed in the `contentType` field of the `ControlButtonContentInfo` structure if the content is text only. The variation code `kControlUsesOwningWindowsFontVariant` applies when text content is used.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlContentIconSuiteRes`
Content type uses an icon suite resource ID. The resource ID of the icon suite resource you wish to display should be in the `resID` field of the `ControlButtonContentInfo` structure.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlContentCIconRes`
Content type is a color icon resource ID. The resource ID of the color icon resource you wish to display should be in the `resID` field of the `ControlButtonContentInfo` structure.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlContentPictRes`
Content type is a picture resource ID. The resource ID of the picture resource you wish to display should be in the `resID` field of the `ControlButtonContentInfo` structure.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlContentIconSuiteHandle`
Content type is an icon suite handle. The handle of the icon suite you wish to display should be in the `iconSuite` field of the `ControlButtonContentInfo` structure.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlContentCIconHandle`
Content type uses a color icon handle. The handle of the color icon you wish to display should be in the `cIconHandle` field of the `ControlButtonContentInfo` structure.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlContentPictHandle`
Content type uses a picture handle. The handle of the picture you wish to display should be in the `picture` field of the `ControlButtonContentInfo` structure.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlContentIconRef`
Content type is `IconRef`. An `IconRef` value for the icon you wish to display should be provided in the `iconRef` field of the `ControlButtonContentInfo` structure. Note that the `kControlBevelButtonGraphicOffsetTag` control data tag constant should not be used with `IconRef` based bevel button content, because `IconRef` based icons may change with a theme switch; see "Bevel Button Control Data Tag Constants" (page 723). Supported with Mac OS 8.5 and later.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

Control Data Browser Tag Constants

```
enum {
    kControlDataBrowserIncludesFrameAndFocusTag = 'brdr',
    kControlDataBrowserKeyFilterTag = kControlEditTextKeyFilterTag,
    kControlDataBrowserEditTextKeyFilterTag = kControlDataBrowserKeyFilterTag,
   kControlDataBrowserEditTextValidationProcTag =  kControlEditTextValidationProcTag
};
```

Control Def Constants

```
enum {
    kControlDefProcPtr = 0,
    kControlDefObjectClass = 1
};
```

Constants

`kControlDefProcPtr`
Indicates raw, proc-ptr based access.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Controls.h`.

`kControlDefObjectClass`
Indicates event-based definition (Mac OS X only).

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Controls.h`.

Control Def Type Constants

```
enum {
    kControlDefProcType = 'CDEF',
    kControlTemplateResourceType = 'CNTL',
    kControlColorTableResourceType = 'cctb',
    kControlDefProcResourceType = 'CDEF'
};
```

Disclosure Triangle Constants

```
enum {
    kControlDisclosureButtonClosed = 0,
    kControlDisclosureButtonDisclosed = 1
};
```

Constants

`kControlDisclosureButtonClosed`
The control will be drawn suggesting a closed state.
Available in Mac OS X v10.0 and later.
Declared in `HIDisclosureViews.h`.

`kControlDisclosureButtonDisclosed`
The control will be drawn suggesting a disclosed state.
Available in Mac OS X v10.0 and later.
Declared in `HIDisclosureViews.h`.

Unicode Control Data Tags

Specify data tags used with Unicode edit text controls.

```
enum {
  kControlEditTextSingleLineTag = 'sglc',
  kControlEditTextInsertTextBufferTag = 'intx',
  kControlEditTextInsertCFStringRefTag = 'incf',
  kControlEditUnicodeTextPostUpdateProcTag = 'upup'
};
```

Constants

`kControlEditTextSingleLineTag`
Indicates whether the control should always be single line.
Data to set or get is type `Boolean`.
Available in Mac OS X v10.2 and later.
Declared in `HITextViews.h`.

`kControlEditTextInsertTextBufferTag`
Gets or sets the control's text as WorldScript encoded text. Available in Mac OS X v10.3 and later.
Data to get or set is an array of `char` types.
Available in Mac OS X v10.3 and later.
Declared in `HITextViews.h`.

`kControlEditTextInsertCFStringRefTag`

Gets or sets the control's text as a CFString. Available in Mac OS X v10.3 and later.

Data to get or set is type `CFStringRef`. If obtaining the string, be sure to release it after you are done with it.

Available in Mac OS X v10.3 and later.

Declared in `HITextViews.h`.

`kControlEditUnicodeTextPostUpdateProcTag`

Gets or sets the post-update callback function.

Data to get or set is type `UnicodePostUpdateUPP`.

Available in Mac OS X v10.0 and later.

Declared in `HITextViews.h`.

Discussion

You use these tags in conjunction with `GetControlData` (page 594) and `SetControlData` (page 652) on Unicode edit text controls.

Control Edit Unicode Text Post Update Proc Tag Constant

```
enum {
    kControlEditUnicodeTextPostUpdateProcTag = 'upup'
};
```

Control Edit Unicode Text Proc Constants

```
enum {
    kControlEditUnicodeTextProc = 912,
    kControlEditUnicodeTextPasswordProc = 914
};
```

Control Entire Control Constant

```
enum {
    kControlEntireControl = 0
};
```

Control Kind Bevel Button Constant

```
enum {
    kControlKindBevelButton = 'bevl'
};
```

Control Kind Chasing Arrows Constant

```
enum {
    kControlKindChasingArrows = 'carr'
};
```

Control Kind Clock Constant

```
enum {
    kControlKindClock = 'clck'
};
```

Control Kind Data Browser Constant

```
enum {
    kControlKindDataBrowser = 'datb'
};
```

Control Kind Disclosure Button Constant

```
enum {
```

```
    kControlKindDisclosureButton = 'disb'
};
```

Control Kind Disclosure Triangle Constant

```
enum {
    kControlKindDisclosureTriangle = 'dist'
};
```

Control Kind Edit Text Constant

```
enum {
    kControlKindEditText = 'etxt'
};
```

Control Kind Edit Unicode Text Constant

```
enum {
    kControlKindEditUnicodeText = 'eutx'
};
```

Control Kind Group Box Constants

```
enum {
    kControlKindGroupBox = 'grpb',
    kControlKindCheckGroupBox = 'cgrp',
    kControlKindPopupGroupBox = 'pgrp'
};
```

Control Kind Icon Constant

```
enum {
    kControlKindIcon = 'icon'
};
```

Control Kind Image Well Constant

```
enum {
    kControlKindImageWell = 'well'
};
```

Control Kind List Box Constant

```
enum {
    kControlKindListBox = 'lbox'
};
```

kControlKindLittleArrows

```
enum {
    kControlKindLittleArrows = 'larr'
};
```

Control Kind Picture Constant

```
enum {
    kControlKindPicture = 'pict'
};
```

Control Kind Placard Constant

```
enum {
    kControlKindPlacard = 'plac'
};
```

Control Kind Pop-up Arrow Constant

```
enum {
    kControlKindPopupArrow = 'parr'
};
```

Control Kind Pop-up Button Constant

```
enum {
    kControlKindPopupButton = 'popb'
};
```

Control Kind Progress Bar Constants

```
enum {
    kControlKindProgressBar = 'prgb',
    kControlKindRelevanceBar = 'relb'
};
```

Control Kind Push and Radio Button Constants

```
enum {
    kControlKindPushButton = 'push',
    kControlKindPushIconButton = 'picn',
    kControlKindRadioButton = 'rdio',
    kControlKindCheckBox = 'cbox'
};
```

Control Kind Radio Group Constant

```
enum {
    kControlKindRadioGroup = 'rgrp'
};
```

Control Kind Round Button Constant

```
enum {
    kControlKindRoundButton = 'rndb'
};
```

Control Kind Scroll Bar Constant

```
enum {
    kControlKindScrollBar = 'sbar'
};
```

Control Kind Scrolling Text Box Constant

```
enum {
    kControlKindScrollingTextBox = 'stbx'
};
```

Control Kind Separator Constant

```
enum {
    kControlKindSeparator = 'sepa'
};
```

Control Kind Signature Apple Constant

```
enum {
    kControlKindSignatureApple = 'appl'
};
```

Constants

`kControlKindSignatureApple`
Signature of all system controls.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

Control Kind Slider Constant

```
enum {
    kControlKindSlider = 'sldr'
};
```

Control Kind Static Text Constant

```
enum {
    kControlKindStaticText = 'stxt'
};
```

Control Kind Tabs Constant

```
enum {
    kControlKindTabs = 'tabs'
};
```

Control Kind User Pane Constant

```
enum {
    kControlKindUserPane = 'upan'
};
```

Control Kind Window Header Constant

```
enum {
    kControlKindWindowHeader = 'whed'
};
```

Control Picture Handle Tag Constant

```
enum {
    kControlPictureHandleTag = 'pich'
};
```

Control Pop-up Arrow Orientation Constants

```
enum {
    kControlPopupArrowOrientationEast = 0,
    kControlPopupArrowOrientationWest = 1,
    kControlPopupArrowOrientationNorth = 2,
    kControlPopupArrowOrientationSouth = 3
};
```

Control Pop-up Arrow Size Constants

```
enum {
    kControlPopupArrowSizeNormal = 0,
    kControlPopupArrowSizeSmall = 1
};
```

Control Pop-up Button Check Current Tag Constant

```
enum {
    kControlPopupButtonCheckCurrentTag = 'chck'
};
```

Control Property Persistent Constant

```
enum {
    kControlPropertyPersistent = 0x00000001
};
```

Control Round Button Content and Size Tag Constants

```
enum {
    kControlRoundButtonContentTag = 'cont',
    kControlRoundButtonSizeTag = kControlSizeTag
};
```

Control Scrollbar Shows Arrows Tag Constant

```
enum {
    kControlScrollBarShowsArrowsTag = 'arro'
};
```

Control Size Constants

```
enum {
    kControlSizeNormal = 0,
    kControlSizeSmall = 1,
    kControlSizeLarge = 2,
    kControlSizeAuto = 0xFFFF
};
```

Control Supports New Messages Constant

```
enum {
    kControlSupportsNewMessages = ' ok '
};
```

Constants

`kControlSupportsNewMessages`
The control definition function supports new messages introduced with Mac OS 8 and the Appearance Manager.

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared in `Controls.h`.

Discussion
If your control definition function supports Appearance-compliant messages, it should return `kControlSupportsNewMessages` as a function result when the Control Manager passes `kControlMsgTestNewMsgSupport` in the `message` parameter.

Control Tab Image Content Tag Constant

```
enum {
    kControlTabImageContentTag = 'cont'
};
```

Control Tab Info Version Constants

```
enum {
    kControlTabInfoVersionZero = 0,
    kControlTabInfoVersionOne = 1
};
```

Control Tab Type Constants

```
enum {
    kControlTabListResType = 'tab#',
    kControlListDescResType = 'ldes'
};
```

Control Use Theme Font ID Mask Constant

```
enum {
    kControlUseThemeFontIDMask = 0x0080
};
```

Click Activation Constants

Specify constants that indicate the way a control prefers to respond to a click.

```
enum {
    kDoNotActivateAndIgnoreClick = 0,
    kDoNotActivateAndHandleClick = 1,
    kActivateAndIgnoreClick = 2,
    kActivateAndHandleClick = 3
};
typedef UInt32 ClickActivationResult;
```

Constants

`kDoNotActivateAndIgnoreClick`
Indicates that the click should be ignored and that the window should not be activated. This constant is defined for completeness and is rarely used.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kDoNotActivateAndHandleClick`
Indicates that the control should handle the click while the window is still in the background.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kActivateAndIgnoreClick`
Indicates that control doesn't want to respond directly to the click, but window should still be brought forward.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kActivateAndHandleClick`
Indicates that the control wants to respond to the click, but only after the window has been activated.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

Discussion

These constants are used by `GetControlClickActivation` (page 593).

Selection Constants

```
enum {
    kDragSelect = 1,
    kSelectOnlyOne = 2,
    kResetSelection = 4,
    kCmdTogglesSelection = 8,
    kNoDisjointSelection = 16,
    kAlwaysExtendSelection = 32
};
```

Drag Tracking Enter Control Constants

```
enum {
    kDragTrackingEnterControl = 2,
    kDragTrackingInControl = 3,
    kDragTrackingLeaveControl = 4
};
```

Key Filter Result Codes

```
enum {
    kControlKeyFilterBlockKey = 0,
    kControlKeyFilterPassKey = 1
};
```

Constants

`kControlKeyFilterBlockKey`

The keystroke is blocked and not received by the control.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlKeyFilterPassKey`

The keystroke is filtered and received by the control.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

Discussion

Your key filter function returns these constants to specify whether or not a keystroke is filtered or blocked.

In Control Part Constants

```
enum {
    kInLabelControlPart = kControlLabelPart,
    kInMenuControlPart = kControlMenuPart,
    kInTriangleControlPart = kControlTrianglePart,
    kInButtonControlPart = kControlButtonPart,
    kInCheckBoxControlPart = kControlCheckBoxPart,
    kInUpButtonControlPart = kControlUpButtonPart,
    kInDownButtonControlPart = kControlDownButtonPart,
    kInPageUpControlPart = kControlPageUpPart,
    kInPageDownControlPart = kControlPageDownPart
};
```

Order Constants

```
enum {
    kOrderUndefined = 0,
    kOrderIncreasing = 1,
    kOrderDecreasing = 2
};
```

List Box Control Data Tag Constants

```
enum {
    kControlListBoxListHandleTag = 'lhan',
    kControlListBoxKeyFilterTag = kControlKeyFilterTag,
    kControlListBoxFontStyleTag = kControlFontStyleTag
};
enum {
    kControlListBoxDoubleClickTag = 'dblc',
    kControlListBoxLDEFTag = 'ldef'
};
```

Constants

`kControlListBoxListHandleTag`

Gets a handle to a list box.

Data type returned: `ListHandle`

Available in Mac OS X v10.0 and later.

Declared in `ControlDefinitions.h`.

`kControlListBoxDoubleClickTag`

Checks to see whether the most recent click in a list box was a double click. Available with Appearance 1.0.1 and later.

Data type returned: `Boolean`; if `true`, the last click was a double click; if `false`, not.

Available in Mac OS X v10.0 and later.

Declared in `ControlDefinitions.h`.

`kControlListBoxLDEFTag`
Sets the `'LDEF'` resource to be used to draw a list box's contents this is useful for creating a list box without an `'ldes'` resource. Available with Appearance 1.0.1 and later.

Data type set: `SInt16`

Available in Mac OS X v10.0 and later.

Declared in `ControlDefinitions.h`.

Discussion
You can use the control data tag constants to set or obtain data that is associated with a control. The control data tag constants are passed in the `inTagName` parameters of `SetControlData` (page 652) and `GetControlData` (page 594) to specify the piece of data in a control that you wish to set or get. You can also pass these constants in the `inTagName` parameter of `GetControlDataSize` (page 596) if you wish to determine the size of variable-length control data. These constants can also be used by custom control definition functions that return the feature bit `kControlSupportsDataAccess` in response to a `kControlMsgGetFeatures` message.

The data that your application sets or obtains can be of various types, dependent upon the control. Therefore, the descriptions of the control data tag constants list the data types for the information that you can set in the `inData` parameter to the `SetControlData` function and that you can get in the `inBuffer` parameter to the `GetControlData` function.

Version Notes
The control data tag constants are available with Appearance Manager 1.0 and later.

List Box Control Definition ID Constants

```
enum {
    kControlListBoxProc = 352,
    kControlListBoxAutoSizeProc = 353
};
```

Constants
`kControlListBoxProc`
Resource ID: 21

List box. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `ControlDefinitions.h`.

`kControlListBoxAutoSizeProc`
Resource ID: 21

Autosizing list box. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `ControlDefinitions.h`.

Discussion
When creating a control, your application supplies a control definition ID to one of the Control Manager control-creation functions or to the control resource; see `'CNTL'`. The control definition ID indicates the type of control to create. A control definition ID is an integer that contains the resource ID of a control definition function in its upper 12 bits and a variation code in its lower 4 bits. A control definition ID is derived as follows:

control definition ID = 16 * ('CDEF' resource ID) + variation code

A control definition function determines how a control generally looks and behaves. Control definition functions are stored as resources of type 'CDEF'. Various Control Manager functions call a control definition function whenever they need to perform some control-dependent action, such as drawing the control on the screen. For more information on how to create a control definition function, see ControlDefProcPtr (page 677).

A control definition function, in turn, can use a variation code to describe variations of the same basic control. For example, all pop-up arrows share the same basic control definition function, which is stored in a resource of type 'CDEF' and has a resource ID of 12. The standard pop-up arrow is large and points to the right; it has a control definition ID of 192. A variation of this is a large, left-pointing arrow, which has a control definition ID of 193. Still another variation, in which the arrow points up, has a control definition ID of 194.

Your application can use the constants listed here in place of control definition IDs.

Little Arrows Control Definition ID Constant

```
enum {
    kControlLittleArrowsProc = 96
};
```

Constants

kControlLittleArrowsProc

Resource ID: 6

Little arrows. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in HILittleArrows.h.

Discussion

When creating a control, your application supplies a control definition ID to one of the Control Manager control-creation functions or to the control resource; see 'CNTL'. The control definition ID indicates the type of control to create. A control definition ID is an integer that contains the resource ID of a control definition function in its upper 12 bits and a variation code in its lower 4 bits. A control definition ID is derived as follows:

control definition ID = 16 * ('CDEF' resource ID) + variation code

A control definition function determines how a control generally looks and behaves. Control definition functions are stored as resources of type 'CDEF'. Various Control Manager functions call a control definition function whenever they need to perform some control-dependent action, such as drawing the control on the screen. For more information on how to create a control definition function, see ControlDefProcPtr (page 677).

A control definition function, in turn, can use a variation code to describe variations of the same basic control. For example, all pop-up arrows share the same basic control definition function, which is stored in a resource of type 'CDEF' and has a resource ID of 12. The standard pop-up arrow is large and points to the right; it has a control definition ID of 192. A variation of this is a large, left-pointing arrow, which has a control definition ID of 193. Still another variation, in which the arrow points up, has a control definition ID of 194.

Your application can use the constant listed here in place of a control definition ID.

Little Arrows Control Tag Constant

```
enum {
    kControlLittleArrowsIncrementValueTag = 'incr'
};
```

Constants

`kControlLittleArrowsIncrementValueTag`

Gets or sets the increment value of the control. Currently, the little arrows control does not use the increment value because the control does not change the value itself. You must use an action proc to change the value. Available in Mac OS X v10.3 and later.

Data type retrieved: `SInt32`

Available in Mac OS X v10.3 and later.

Declared in `HILittleArrows.h`.

Mac OS 8.5 Bevel Button Control Data Tag Constant

```
enum {
    kControlBevelButtonScaleIconTag = 'scal'
};
```

Constants

`kControlBevelButtonScaleIconTag`

Gets or sets whether, when the proper icon size is unavailable, an icon should be scaled for use with a given bevel button. This tag is only for use with icon suites or the `IconRef` data type.

Data type retrieved or set: `Boolean`. If `true`, indicates that if an icon of the ideal size isn't available, a larger or smaller icon should be scaled to the ideal size. If `false`, no scaling should occur; instead, a smaller icon should be drawn or a larger icon clipped. Default is `false`.

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

Discussion

The Mac OS 8.5 Control Manager defines this new control data tag constant. This constant is passed in the `inTagName` parameters of the functions `SetControlData` and `GetControlData` to specify the piece of data in a control that you wish to set or get. You can also pass this constant in the `inTagName` parameter of the function `GetControlDataSize` if you wish to determine the size of variable-length control data. This constant can also be used by custom control definition functions that return the feature bit `kControlSupportsDataAccess` in response to a `kControlMsgGetFeatures` message.

The data that your application gets or sets can be of various types. The description here shows the data type for the information that you can set in the `inData` parameter to the `SetControlData` function and that you can get in the `inBuffer` parameter to the `GetControlData` function.

Mac OS 8.5 Control Font Style Flag Constant

```
enum {
    kControlAddToMetaFontMask = 0x0200
};
```

Constants

`kControlAddToMetaFontMask`

If the bit specified by this mask is set, the control may use a meta-font while also adding other attributes to the font. If the bit specified by this mask is not set, but a meta-font is specified for the control, any additional attributes set for the font are ignored.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

Discussion

With the Mac OS 8.5 Control Manager, you can pass this new control font style flag constant in the `flags` field of the `ControlFontStyleRec` structure to specify the fields of the structure that should be applied to the control. For more on control font style flag constants, see "Control Font Style Flag Constants" (page 745) and the ControlFontStyleRec (page 704) structure.

Mac OS 8.5 Editable Text Control Definition ID Constant

```
enum {
    kControlEditTextInlineInputProc = 276
};
```

Constants

`kControlEditTextInlineInputProc`

Identifies the inline input variant of the editable text control (`'CDEF'` resource ID 17), which supports 2-byte script systems. This variant cannot be combined with the password variant of the editable text box.

Available in Mac OS X v10.0 and later.

Declared in `ControlDefinitions.h`.

Discussion

The Mac OS 8.5 Control Manager defines this new control definition ID.

When creating a control, your application supplies a control definition ID to one of the Control Manager control-creation functions or to the control resource; see `'CNTL'`. The control definition ID indicates the type of control to create. A control definition ID is an integer that contains the resource ID of a control definition function in its upper 12 bits and a variation code in its lower 4 bits. A control definition ID is derived as follows:

control definition ID = 16 * (`'CDEF'` resource ID) + variation code

A control definition function determines how a control generally looks and behaves. Control definition functions are stored as resources of type `'CDEF'`. Various Control Manager functions call a control definition function whenever they need to perform some control-dependent action, such as drawing the control on the screen. For more information on how to create a control definition function, see `ControlDefProcPtr` (page 677).

A control definition function, in turn, can use a variation code to describe variations of the same basic control. For example, all pop-up arrows share the same basic control definition function, which is stored in a resource of type `'CDEF'` and has a resource ID of 12. The standard pop-up arrow is large and points to the right; it has a control definition ID of 192. A variation of this is a large, left-pointing arrow, which has a control definition ID of 193. Still another variation, in which the arrow points up, has a control definition ID of 194.

Your application can use the constant listed here in place of a control definition ID. This of these constant, and its associated ID, is not supported unless the Appearance Manager is available.

Mac OS 8.5 Group Box Control Data Tag Constant

```
enum {
    kControlGroupBoxTitleRectTag = 'trec'
};
```

Constants

`kControlGroupBoxTitleRectTag`

Gets the rectangle that contains the title of a group box (and any associated control, such as a checkbox or other button).

Data type retrieved: `Rect`

Available in Mac OS X v10.0 and later.

Declared in `HIContainerViews.h`.

Discussion

The Mac OS 8.5 Control Manager defines this new control data tag constant. This constant is passed in the `inTagName` parameters of the functions `SetControlData` and `GetControlData` to specify the piece of data in a control that you wish to set or get. You can also pass this constant in the `inTagName` parameter of the function `GetControlDataSize` if you wish to determine the size of variable-length control data. This constant can also be used by custom control definition functions that return the feature bit `kControlSupportsDataAccess` in response to a `kControlMsgGetFeatures` message.

The data that your application gets or sets can be of various types. The description here shows the data type for the information that you can set in the `inData` parameter to the `SetControlData` function and that you can get in the `inBuffer` parameter to the `GetControlData` function.

Mac OS 8.5 Icon Control Data Tag Constants

```
enum {
    kControlIconResourceIDTag = 'ires',
    kControlIconContentTag = 'cont'
};
```

Constants

`kControlIconResourceIDTag`

Gets or sets the resource ID of the icon to use.

Data type retrieved or set: `SInt16`

Available in Mac OS X v10.0 and later.

Declared in `HIImageViews.h`.

`kControlIconContentTag`

Gets or sets the type of content to be used in an icon control.

Data type retrieved or set: `ControlButtonContentInfo` (page 699).

Available in Mac OS X v10.0 and later.

Declared in `HIImageViews.h`.

Discussion

The Mac OS 8.5 Control Manager defines these new control data tag constants. These constants are passed in the `inTagName` parameters of the functions `SetControlData` and `GetControlData` to specify the piece of data in a control that you wish to set or get. You can also pass these constants in the `inTagName` parameter of the function `GetControlDataSize` if you wish to determine the size of variable-length control data. These constants can also be used by custom control definition functions that return the feature bit `kControlSupportsDataAccess` in response to a `kControlMsgGetFeatures` message.

The data that your application gets or sets can be of various types. The descriptions here show the data types for the information that you can set in the `inData` parameter to the `SetControlData` function and that you can get in the `inBuffer` parameter to the `GetControlData` function.

Mac OS 8.5 Pop-up Button Control Data Tag Constants

```
enum {
    kControlPopupButtonExtraHeightTag = 'exht',
    kControlPopupButtonOwnedMenuRefTag = 'omrf'
};
```

Constants

`kControlPopupButtonExtraHeightTag`

Gets or sets the amount of extra vertical white space in a pop-up menu button.

Data type set or retrieved: `SInt16`; default is 0.

Available in Mac OS X v10.0 and later.

Declared in `HIPopupButton.h`.

`kControlPopUpButtonOwnedMenuRefTag`

Sets the menu to be displayed by the popup button control. This tag operates identically to `kControlPopupButtonMenuRefTag`, except that the popup button takes ownership of the specified menu. If the popup button is disposed, or a new menu is specified, the popup button control will automatically release the menu.

Data type set or retrieved: `MenuRef`

Discussion

The Mac OS 8.5 Control Manager defines this new control data tag constant. This constant is passed in the `inTagName` parameters of the functions `SetControlData` and `GetControlData` to specify the piece of data in a control that you wish to set or get. You can also pass this constant in the `inTagName` parameter of the function `GetControlDataSize` if you wish to determine the size of variable-length control data. This constant can also be used by custom control definition functions that return the feature bit `kControlSupportsDataAccess` in response to a `kControlMsgGetFeatures` message.

The data that your application gets or sets can be of various types. The description here shows the data type for the information that you can set in the `inData` parameter to the `SetControlData` function and that you can get in the `inBuffer` parameter to the `GetControlData` function.

Control Meta Part Code Constants

```
enum {
    kControlStructureMetaPart = -1,
    kControlContentMetaPart = -2,
    kControlOpaqueMetaPart = -3,
    kControlClickableMetaPart = -4
};
```

Constants

`kControlStructureMetaPart`

The entire area that the control will draw into. This area may extend beyond the bounds of the control (for example, if the control draws a focus ring outside of its bounds). You may return a superset of the drawn area if this is computationally easier to construct. This area is used to determine the area of a window that should be invalidated and redrawn when a control is invalidated. It is not necessary for a control to return a shape that precisely describes the structure area; for example, a control whose structure is an oval may simply return the oval's bounding rectangle. The default handler for the `kEventControlGetPartRegion` event returns the control's bounds when this part is requested.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlContentMetaPart`

The area of the control in which embedded controls should be positioned. This part is only defined for controls that can contain other controls (for example, the group box). This area is largely informational and is not used by the Control Manager itself. The default handler for the `kEventControlGetPartRegion` event returns `errInvalidPartCode` when this part is requested.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`kControlOpaqueMetaPart`

The area of the control that, when drawn, is filled with opaque pixels. You may also return a subset of the opaque area if this is computationally easier to construct. If a control is contained in a composited window, the Control Manager will use this area to optimize drawing of other controls that intersect this area; controls that are entirely contained within the opaque area, and that are z-ordered underneath this control, will not be drawn at all, since any drawing would be completely overwritten by this control. The default handler for the `kEventControlGetPartRegion` event returns an empty area when this part is requested.

Available in Mac OS X v10.3 and later.

Declared in `Controls.h`.

`kControlClickableMetaPart`

The area of the control that causes a mouse event to be captured by that control. If a mouse event falls inside the control bounds but outside of this area, then the Control Manager will allow the event to pass through the control to the next control behind it in z-order. This area is used to determine which parts of a window should allow async window dragging when clicked (the draggable area is computed by subtracting the clickable areas of controls in the window from the window's total area). You can also customize the clickable area of a control if you want the control to have an effectively transparent area (for example, a control that draws multiple tabs might want clicks in the space between the tabs to fall through to the next control rather than be captured by the tab-drawing control). The default handler for the `kEventControlGetPartRegion` event returns the control's bounds when this part is requested.

Available in Mac OS X v10.3 and later.

Declared in `Controls.h`.

Discussion
An application that needs the structure and content regions of a control can call `GetControlRegion` (page 605) and specify these meta-parts. A custom HIView that needs to specialize its opaque and clickable regions can provide a `kEventControlGetPartRegion` event handler that checks for these meta-parts and return an appropriate region (or HIShape).

Meta Font Constants

```
enum {
    kControlFontBigSystemFont = -1,
    kControlFontSmallSystemFont = -2,
    kControlFontSmallBoldSystemFont = -3,
    kControlFontViewSystemFont = -4
};
```

Constants

`kControlFontBigSystemFont`
Use the system font.
Available in Mac OS X v10.0 and later.
Declared in `Controls.h`.

`kControlFontSmallSystemFont`
Use the small system font.
Available in Mac OS X v10.0 and later.
Declared in `Controls.h`.

`kControlFontSmallBoldSystemFont`
Use the small emphasized system font (emphasis applied correctly for locale).
Available in Mac OS X v10.0 and later.
Declared in `Controls.h`.

Discussion
You can use the meta font constants in the `font` field of the structure `ControlFontStyleRec` (page 704) and the Font ID field of a dialog font table resource to specify the style, size, and font family of the control font. You should use these meta font constants whenever possible because the system font can change, depending upon the current theme. If none of these constants are specified, the control uses the system font unless directed to use a window font by a control variant.

Version Notes
The meta font constants are available with Appearance Manager 1.0 and later.

Constraint Constants

```
enum {
    noConstraint = kNoConstraint,
    hAxisOnly = 1,
    vAxisOnly = 2
};
```

Part Identifier Constants

```
enum {
    cFrameColor = 0,
    cBodyColor = 1,
    cTextColor = 2,
    cThumbColor = 3,
    kNumberCtlCTabEntries = 4
};
```

Constants

`cFrameColor`

Produces foreground color for scroll arrows and gray area.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`cBodyColor`

Produces color of the scroll box.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`cTextColor`

Produces text color for scroll bars. Currently unused.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

`cThumbColor`

Reserved.

Available in Mac OS X v10.0 and later.

Declared in `Controls.h`.

Discussion

The part identifier constants are not recommended with the Appearance Manager. When the Appearance Manager is available and you are using standard controls, part identifier constants are ignored and the colors are determined by the current theme. If you are creating your own control definition function, you can still use these constants in the `partIdentifier` field of a control color table structure to draw a control using colors other than the system default and to identify the part of a control that a color affects.

When the Appearance Manager is not present, you can use these constants in the `partIdentifier` field of a control color table resource `'cctb'` and the `partIdentifier` field of a control color table structure to identify the part of the control that the color affects.

Note that the colors you specify in the color table are blended to produce the colors that are actually used.

Picture Control Definition ID Constants

```
enum {
    kControlPictureProc = 304,
    kControlPictureNoTrackProc = 305
};
```

Constants

`kControlPictureProc`

Resource ID: 19

Picture control. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `ControlDefinitions.h`.

`kControlPictureNoTrackProc`

Resource ID: 19

Non-tracking picture. Immediately returns `kControlPicturePart` as the part code hit without tracking.

This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `ControlDefinitions.h`.

Discussion

When creating a control, your application supplies a control definition ID to one of the Control Manager control-creation functions or to the control resource; see `'CNTL'`. The control definition ID indicates the type of control to create. A control definition ID is an integer that contains the resource ID of a control definition function in its upper 12 bits and a variation code in its lower 4 bits. A control definition ID is derived as follows:

control definition ID = 16 * (`'CDEF'` resource ID) + variation code

A control definition function determines how a control generally looks and behaves. Control definition functions are stored as resources of type `'CDEF'`. Various Control Manager functions call a control definition function whenever they need to perform some control-dependent action, such as drawing the control on the screen. For more information on how to create a control definition function, see `ControlDefProcPtr` (page 677).

A control definition function, in turn, can use a variation code to describe variations of the same basic control. For example, all pop-up arrows share the same basic control definition function, which is stored in a resource of type `'CDEF'` and has a resource ID of 12. The standard pop-up arrow is large and points to the right; it has a control definition ID of 192. A variation of this is a large, left-pointing arrow, which has a control definition ID of 193. Still another variation, in which the arrow points up, has a control definition ID of 194.

Your application can use the constants listed here in place of control definition IDs.

Placard Control Definition ID Constant

```
enum {
    kControlPlacardProc = 224
};
```

Constants

`kControlPlacardProc`

Resource ID: 14

Placard. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIContainerViews.h`.

Discussion

When creating a control, your application supplies a control definition ID to one of the Control Manager control-creation functions or to the control resource; see `'CNTL'`. The control definition ID indicates the type of control to create. A control definition ID is an integer that contains the resource ID of a control definition function in its upper 12 bits and a variation code in its lower 4 bits. A control definition ID is derived as follows:

control definition ID = 16 * (`'CDEF'` resource ID) + variation code

A control definition function determines how a control generally looks and behaves. Control definition functions are stored as resources of type `'CDEF'`. Various Control Manager functions call a control definition function whenever they need to perform some control-dependent action, such as drawing the control on the screen. For more information on how to create a control definition function, see `ControlDefProcPtr` (page 677).

A control definition function, in turn, can use a variation code to describe variations of the same basic control. For example, all pop-up arrows share the same basic control definition function, which is stored in a resource of type `'CDEF'` and has a resource ID of 12. The standard pop-up arrow is large and points to the right; it has a control definition ID of 192. A variation of this is a large, left-pointing arrow, which has a control definition ID of 193. Still another variation, in which the arrow points up, has a control definition ID of 194.

Your application can use the constant listed here in place of a control definition ID.

Pop-up Menu Title Constants

```
enum {
    popupTitleBold = 1 << 8,
    popupTitleItalic = 1 << 9,
    popupTitleUnderline = 1 << 10,
    popupTitleOutline = 1 << 11,
    popupTitleShadow = 1 << 12,
    popupTitleCondense = 1 << 13,
    popupTitleExtend = 1 << 14,
    popupTitleNoStyle = 1 << 15
};
```

Constants

`popupTitleBold`
Draw title in bold font style.
Available in Mac OS X v10.0 and later.
Declared in `HIPopupButton.h`.

`popupTitleItalic`
Draw title in italic font style.
Available in Mac OS X v10.0 and later.
Declared in `HIPopupButton.h`.

`popupTitleUnderline`
Draw title in underline font style.
Available in Mac OS X v10.0 and later.
Declared in `HIPopupButton.h`.

`popupTitleOutline`
Draw title in outline font style.
Available in Mac OS X v10.0 and later.
Declared in `HIPopupButton.h`.

`popupTitleShadow`
Draw title in shadow font style.
Available in Mac OS X v10.0 and later.
Declared in `HIPopupButton.h`.

`popupTitleCondense`
Draw title in condensed text font style.
Available in Mac OS X v10.0 and later.
Declared in `HIPopupButton.h`.

`popupTitleExtend`
Draw title in extended text font style.
Available in Mac OS X v10.0 and later.
Declared in `HIPopupButton.h`.

`popupTitleNoStyle`
Draw title in plain text font style.
Available in Mac OS X v10.0 and later.
Declared in `HIPopupButton.h`.

Discussion
When you define a pop-up menu control in a control resource, you can use one or more of these constants in the initial setting field to specify where and how to draw the pop-up menu control title.

Pop-up Menu Title Justification Constants

```
enum {
    popupTitleLeftJust = 0x00000000,
    popupTitleCenterJust = 0x00000001,
    popupTitleRightJust = 0x000000FF
};
```

Constants

`popupTitleLeftJust`
Place title to the left of the pop-up box.
Available in Mac OS X v10.0 and later.
Declared in `HIPopupButton.h`.

`popupTitleCenterJust`
Center title over the pop-up box.
Available in Mac OS X v10.0 and later.
Declared in `HIPopupButton.h`.

`popupTitleRightJust`
Place title to the right of the pop-up box.
Available in Mac OS X v10.0 and later.
Declared in `HIPopupButton.h`.

Discussion
When you define a pop-up menu control in a control resource, you can use one or more of these constants in the initial setting field to specify where and how to draw the pop-up menu control title.

Pop-up Arrow Control Definition ID Constants

```
enum {
    kControlPopupArrowEastProc = 192,
    kControlPopupArrowWestProc = 193,
    kControlPopupArrowNorthProc = 194,
    kControlPopupArrowSouthProc = 195,
    kControlPopupArrowSmallEastProc = 196,
    kControlPopupArrowSmallWestProc = 197,
    kControlPopupArrowSmallNorthProc = 198,
    kControlPopupArrowSmallSouthProc = 199
};
```

Constants

`kControlPopupArrowEastProc`

Resource ID: 12

Large, right-facing pop-up arrow. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIPopupButton.h`.

`kControlPopupArrowWestProc`

Resource ID: 12

Large, left-facing pop-up arrow. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIPopupButton.h`.

`kControlPopupArrowNorthProc`

Resource ID: 12

Large, up-facing pop-up arrow. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIPopupButton.h`.

`kControlPopupArrowSouthProc`

Resource ID: 12

Large, down-facing pop-up arrow. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIPopupButton.h`.

`kControlPopupArrowSmallEastProc`

Resource ID: 12

Small, right-facing pop-up arrow. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIPopupButton.h`.

`kControlPopupArrowSmallWestProc`
Resource ID: 12

Small, left-facing pop-up arrow. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIPopupButton.h`.

`kControlPopupArrowSmallNorthProc`
Resource ID: 12

Small, up-facing pop-up arrow. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIPopupButton.h`.

`kControlPopupArrowSmallSouthProc`
Resource ID: 12

Small, down-facing pop-up arrow. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIPopupButton.h`.

Discussion
When creating a control, your application supplies a control definition ID to one of the Control Manager control-creation functions or to the control resource; see `'CNTL'`. The control definition ID indicates the type of control to create. A control definition ID is an integer that contains the resource ID of a control definition function in its upper 12 bits and a variation code in its lower 4 bits. A control definition ID is derived as follows:

control definition ID = 16 * (`'CDEF'` resource ID) + variation code

A control definition function determines how a control generally looks and behaves. Control definition functions are stored as resources of type `'CDEF'`. Various Control Manager functions call a control definition function whenever they need to perform some control-dependent action, such as drawing the control on the screen. For more information on how to create a control definition function, see `ControlDefProcPtr` (page 677).

A control definition function, in turn, can use a variation code to describe variations of the same basic control. For example, all pop-up arrows share the same basic control definition function, which is stored in a resource of type `'CDEF'` and has a resource ID of 12. The standard pop-up arrow is large and points to the right; it has a control definition ID of 192. A variation of this is a large, left-pointing arrow, which has a control definition ID of 193. Still another variation, in which the arrow points up, has a control definition ID of 194.

Your application can use the constants listed here in place of control definition IDs.

Pop-up Button Control Data Tag Constants

```
enum {
    kControlPopupButtonMenuHandleTag = 'mhan',
    kControlPopupButtonMenuRefTag = 'mhan',
    kControlPopupButtonMenuIDTag = 'mnid'
};
```

Constants

`kControlPopupButtonMenuHandleTag`

Gets or sets the menu handle for a popup button. Available with Appearance Manager 1.0.1 and later.

Data type returned or set: `MenuHandle`

Available in Mac OS X v10.0 and later.

Declared in `HIPopupButton.h`.

`kControlPopupButtonMenuRefTag`

Gets or sets the menu reference assigned to a popup button. If setting the menu reference, the popup button does not own the menu, so you must dispose of it yourself. To allow the popup button to take ownership of the menu, use the `kControlPopupButtonOwnedMenuRefTag` tag (defined in "Mac OS 8.5 Pop-up Button Control Data Tag Constants" (page 789)) instead.

Data type returned or set: `MenuRef`

Available in Mac OS X v10.0 and later.

Declared in `HIPopupButton.h`.

`kControlPopupButtonMenuIDTag`

Gets or sets the menu ID for a popup button. Available with Appearance Manager 1.0.1 and later.

Data type returned or set: `SInt16`

Available in Mac OS X v10.0 and later.

Declared in `HIPopupButton.h`.

Discussion

You can use the control data tag constants to set or obtain data that is associated with a control. The control data tag constants are passed in the `inTagName` parameters of `SetControlData` (page 652) and `GetControlData` (page 594) to specify the piece of data in a control that you wish to set or get. You can also pass these constants in the `inTagName` parameter of `GetControlDataSize` (page 596) if you wish to determine the size of variable-length control data. These constants can also be used by custom control definition functions that return the feature bit `kControlSupportsDataAccess` in response to a `kControlMsgGetFeatures` message.

The data that your application sets or obtains can be of various types, dependent upon the control. Therefore, the descriptions of the control data tag constants list the data types for the information that you can set in the `inData` parameter to the `SetControlData` function and that you can get in the `inBuffer` parameter to the `GetControlData` function.

Pop-up Button Control Definition ID Constants

```
enum {
    kControlPopupButtonProc = 400,
    kControlPopupFixedWidthVariant = 1 << 0,
    kControlPopupVariableWidthVariant = 1 << 1,
    kControlPopupUseAddResMenuVariant = 1 << 2,
    kControlPopupUseWFontVariant = kControlUsesOwningWindowsFontVariant
};
```

Constants

`kControlPopupButtonProc`
Resource ID: 25

Appearance-compliant standard pop-up menu. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIPopupButton.h`.

`kControlPopupFixedWidthVariant`
(+ `kControlPopupButtonProc`)

Resource ID: 25

Appearance-compliant fixed-width pop-up menu. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIPopupButton.h`.

`kControlPopupVariableWidthVariant`
(+ `kControlPopupButtonProc`)

Resource ID: 25

Appearance-compliant variable-width pop-up menu. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIPopupButton.h`.

`kControlPopupUseAddResMenuVariant`
(+ `kControlPopupButtonProc`)

Resource ID: 25

Appearance-compliant pop-up menu with a value of type `ResType` in the `contrlRfCon` field of the control structure. The Menu Manager adds resources of this type to the menu.

This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIPopupButton.h`.

`kControlPopupUseWFontVariant`
(+ `kControlPopupButtonProc`)

Resource ID: 25

Appearance-compliant pop-up menu with control title in window font. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIPopupButton.h`.

Discussion
When creating a control, your application supplies a control definition ID to one of the Control Manager control-creation functions or to the control resource; see `'CNTL'`. The control definition ID indicates the type of control to create. A control definition ID is an integer that contains the resource ID of a control definition function in its upper 12 bits and a variation code in its lower 4 bits. A control definition ID is derived as follows:

control definition ID = 16 * (`'CDEF'` resource ID) + variation code

A control definition function determines how a control generally looks and behaves. Control definition functions are stored as resources of type `'CDEF'`. Various Control Manager functions call a control definition function whenever they need to perform some control-dependent action, such as drawing the control on the screen. For more information on how to create a control definition function, see `ControlDefProcPtr` (page 677).

A control definition function, in turn, can use a variation code to describe variations of the same basic control. For example, all pop-up arrows share the same basic control definition function, which is stored in a resource of type `'CDEF'` and has a resource ID of 12. The standard pop-up arrow is large and points to the right; it has a control definition ID of 192. A variation of this is a large, left-pointing arrow, which has a control definition ID of 193. Still another variation, in which the arrow points up, has a control definition ID of 194.

Your application can use the constants listed here in place of control definition IDs.

Pop-up Width Constants

```
enum {
    popupFixedWidth = 1 << 0,
    popupVariableWidth = 1 << 1,
    popupUseAddResMenu = 1 << 2,
    popupUseWFont = 1 << 3
};
```

Pre–Appearance Control Definition ID Constants

```
enum {
    pushButProc = 0,
    checkBoxProc = 1,
    radioButProc = 2,
    scrollBarProc = 16,
    popupMenuProc = 1008
};
```

Constants

`pushButProc`

Resource ID: 0

Pre-Appearance push button.

`pushButProc` + `kControlUsesOwningWindowsFontVariant`:

Resource ID: 0

Pre-Appearance push button with its text in the window font.

Available in Mac OS X v10.0 and later.

Declared in `ControlDefinitions.h`.

`checkBoxProc`

Resource ID: 0

Pre-Appearance checkbox.

`checkBoxProc` + `kControlUsesOwningWindowsFontVariant`:

Resource ID: 0

Pre-Appearance checkbox with a control title in the window font.

Available in Mac OS X v10.0 and later.

Declared in `ControlDefinitions.h`.

`radioButProc`

Resource ID: 0

Pre-Appearance radio button.

`radioButProc` + `kControlUsesOwningWindowsFontVariant`:

Resource ID: 0

Pre-Appearance radio button with a title in the window font.

Available in Mac OS X v10.0 and later.

Declared in `ControlDefinitions.h`.

`scrollBarProc`

Resource ID: 0

Pre-Appearance scroll bar.

Available in Mac OS X v10.0 and later.

Declared in `ControlDefinitions.h`.

`popupMenuProc`

Resource ID: 63

Pre-Appearance standard pop-up menu.

`popupMenuProc + popupFixedWidth`:

Resource ID: 63; Control Definition ID: 1009

Pre-Appearance, fixed-width pop-up menu.

`popupMenuProc + popupVariableWidth`

Resource ID: 63; Control Definition ID: 1010

Pre-Appearance, variable-width pop-up menu.

`popupMenuProc + popupUseAddResMenu`

Resource ID: 63; Control Definition ID: 1012

Pre-Appearance pop-up menu with a value of type `ResType` in the `contrlRfCon` field of the control structure. The Menu Manager adds resources of this type to the menu.

`popupMenuProc + popupUseWFont`

Resource ID: 63; Control Definition ID: 1016

Pre-Appearance pop-up menu with a control title in the window font.

Available in Mac OS X v10.0 and later.

Declared in `ControlDefinitions.h`.

Discussion

When creating a control, your application supplies a control definition ID to one of the Control Manager control-creation functions or to the control resource; see `'CNTL'`. The control definition ID indicates the type of control to create. A control definition ID is an integer that contains the resource ID of a control definition function in its upper 12 bits and a variation code in its lower 4 bits. A control definition ID is derived as follows:

control definition ID = 16 * (`'CDEF'` resource ID) + variation code

A control definition function determines how a control generally looks and behaves. Control definition functions are stored as resources of type `'CDEF'`. Various Control Manager functions call a control definition function whenever they need to perform some control-dependent action, such as drawing the control on the screen. For more information on how to create a control definition function, see "Defining Your Own Control Definition Function".

A control definition function, in turn, can use a variation code to describe variations of the same basic control. For example, all pop-up arrows share the same basic control definition function, which is stored in a resource of type `'CDEF'` and has a resource ID of 12. The standard pop-up arrow is large and points to the right; it has a control definition ID of 192. A variation of this is a large, left-pointing arrow, which has a control definition ID of 193. Still another variation, in which the arrow points up, has a control definition ID of 194.

Your application can use the constants listed here in place of control definition IDs.

If your application contains code that uses the older, pre-Appearance control definition IDs or their constants, your application can use the Appearance Manager to map the old IDs to those for the new, updated controls introduced by the Appearance Manager. In particular, the control definition IDs for pre-Appearance checkboxes, buttons, scroll bars, radio buttons, and pop-up menus will be automatically mapped to Appearance-compliant equivalents.

Progress Bar Control Data Tag Constants

```
enum {
    kControlProgressBarIndeterminateTag = 'inde',
    kControlProgressBarAnimatingTag = 'anim'
};
```

Constants

`kControlProgressBarIndeterminateTag`

Gets or sets whether a progress indicator is determinate or indeterminate.

Data type returned or set: `Boolean`; if `true`, switches to an indeterminate progress indicator; if `false`, switches to an determinate progress indicator.

Available in Mac OS X v10.0 and later.

Declared in `HIProgressViews.h`.

Discussion

You can use this control data tag constant to set or obtain data that is associated with a control. This constant is passed in the `inTagName` parameters of `SetControlData` (page 652) and `GetControlData` (page 594) to specify the piece of data in a control that you wish to set or get. You can also pass this constant in the `inTagName` parameter of `GetControlDataSize` (page 596) if you wish to determine the size of variable-length control data. This constant can also be used by custom control definition functions that return the feature bit `kControlSupportsDataAccess` in response to a `kControlMsgGetFeatures` message.

The data that your application sets or obtains can be of various types, dependent upon the control. Therefore, the description of this control data tag constant lists the data type for the information that you can set in the `inData` parameter to the `SetControlData` function and that you can get in the `inBuffer` parameter to the `GetControlData` function.

Version Notes

This control data tag constant is available with Appearance Manager 1.0 and later.

Progress Bar Control Definition ID Constants

```
enum {
    kControlProgressBarProc = 80,
    kControlRelevanceBarProc = 81
};
```

Constants

`kControlProgressBarProc`

Resource ID: 5

Progress indicator. To make the control determinate or indeterminate, set the `kControlProgressBarIndeterminateTag` constant; see "Progress Bar Control Data Tag Constants" (page 804). Progress indicators are only horizontal in orientation; vertical progress indicators are not currently supported.

This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIProgressViews.h`.

Discussion

When creating a control, your application supplies a control definition ID to one of the Control Manager control-creation functions or to the control resource; see `'CNTL'`. The control definition ID indicates the type of control to create. A control definition ID is an integer that contains the resource ID of a control definition function in its upper 12 bits and a variation code in its lower 4 bits. A control definition ID is derived as follows:

control definition ID = 16 * (`'CDEF'` resource ID) + variation code

A control definition function determines how a control generally looks and behaves. Control definition functions are stored as resources of type `'CDEF'`. Various Control Manager functions call a control definition function whenever they need to perform some control-dependent action, such as drawing the control on the screen. For more information on how to create a control definition function, see `ControlDefProcPtr` (page 677).

A control definition function, in turn, can use a variation code to describe variations of the same basic control. For example, all pop-up arrows share the same basic control definition function, which is stored in a resource of type `'CDEF'` and has a resource ID of 12. The standard pop-up arrow is large and points to the right; it has a control definition ID of 192. A variation of this is a large, left-pointing arrow, which has a control definition ID of 193. Still another variation, in which the arrow points up, has a control definition ID of 194.

Your application can use the constant listed here in place of a control definition ID.

Push Button Control Data Tag Constants

```
enum {
    kControlPushButtonDefaultTag = 'dflt',
    kControlPushButtonCancelTag = 'cncl'
};
```

Constants

`kControlPushButtonDefaultTag`

Tells Appearance-compliant button whether to draw a default ring, or returns whether the Appearance Manager draws a default ring for the button.

Data type returned or set: `Boolean`

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

`kControlPushButtonCancelTag`

Gets or sets whether a given push button in a dialog or alert should be drawn with the theme-specific adornments for a Cancel button.

Data type retrieved or set: `Boolean`; default is `false`.

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

Discussion

The Mac OS 8.5 Control Manager defines this new control data tag constant. This constant is passed in the `inTagName` parameters of the functions `SetControlData` and `GetControlData` to specify the piece of data in a control that you wish to set or get. You can also pass this constant in the `inTagName` parameter of the function `GetControlDataSize` if you wish to determine the size of variable-length control data. This constant can also be used by custom control definition functions that return the feature bit `kControlSupportsDataAccess` in response to a `kControlMsgGetFeatures` message.

The data that your application gets or sets can be of various types. The description here shows the data type for the information that you can set in the `inData` parameter to the `SetControlData` function and that you can get in the `inBuffer` parameter to the `GetControlData` function.

Radio Button Value Constants

```
enum {
    kControlRadioButtonUncheckedValue = 0,
    kControlRadioButtonCheckedValue = 1,
    kControlRadioButtonMixedValue = 2
};
```

Constants

`kControlRadioButtonUncheckedValue`

The radio button is unselected.

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

`kControlRadioButtonCheckedValue`

The radio button is selected.

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

`kControlRadioButtonMixedValue`
Mixed value. Indicates that a setting is on for some elements in a selection and off for others. This state only applies to standard Appearance-compliant radio buttons.

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

Discussion
These constants specify the value of a standard radio button control and are passed in the `newValue` parameter of `SetControlValue` (page 661) and are returned by `GetControlValue` (page 606).

Version Notes
The radio button value constants are changed with Appearance Manager 1.0 to support mixed-value radio buttons.

Radio Group Control Definition ID Constant

```
enum {
    kControlRadioGroupProc = 416
};
```

Constants
`kControlRadioGroupProc`
Resource ID: 26

Radio group. Embedder control for controls that have set the feature bit `kControlHasRadioBehavior`.

This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIButtonViews.h`.

Discussion
When creating a control, your application supplies a control definition ID to one of the Control Manager control-creation functions or to the control resource; see `'CNTL'`. The control definition ID indicates the type of control to create. A control definition ID is an integer that contains the resource ID of a control definition function in its upper 12 bits and a variation code in its lower 4 bits. A control definition ID is derived as follows:

control definition ID = 16 * (`'CDEF'` resource ID) + variation code

A control definition function determines how a control generally looks and behaves. Control definition functions are stored as resources of type `'CDEF'`. Various Control Manager functions call a control definition function whenever they need to perform some control-dependent action, such as drawing the control on the screen. For more information on how to create a control definition function, see `ControlDefProcPtr` (page 677).

A control definition function, in turn, can use a variation code to describe variations of the same basic control. For example, all pop-up arrows share the same basic control definition function, which is stored in a resource of type `'CDEF'` and has a resource ID of 12. The standard pop-up arrow is large and points to the right; it has a control definition ID of 192. A variation of this is a large, left-pointing arrow, which has a control definition ID of 193. Still another variation, in which the arrow points up, has a control definition ID of 194.

Your application can use the constant listed here in place of a control definition ID.

Scroll Bar Control Definition ID Constants

```
enum {
    kControlScrollBarProc = 384,
    kControlScrollBarLiveProc = 386
};
```

Constants

`kControlScrollBarProc`

Resource ID: 24

Appearance-compliant scroll bar. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIScrollView.h`.

`kControlScrollBarLiveProc`

Resource ID: 24

Appearance-compliant scroll bar with live feedback. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIScrollView.h`.

Discussion

When creating a control, your application supplies a control definition ID to one of the Control Manager control-creation functions or to the control resource; see `'CNTL'`. The control definition ID indicates the type of control to create. A control definition ID is an integer that contains the resource ID of a control definition function in its upper 12 bits and a variation code in its lower 4 bits. A control definition ID is derived as follows:

control definition ID = 16 * (`'CDEF'` resource ID) + variation code

A control definition function determines how a control generally looks and behaves. Control definition functions are stored as resources of type `'CDEF'`. Various Control Manager functions call a control definition function whenever they need to perform some control-dependent action, such as drawing the control on the screen. For more information on how to create a control definition function, see `ControlDefProcPtr` (page 677).

A control definition function, in turn, can use a variation code to describe variations of the same basic control. For example, all pop-up arrows share the same basic control definition function, which is stored in a resource of type `'CDEF'` and has a resource ID of 12. The standard pop-up arrow is large and points to the right; it has a control definition ID of 192. A variation of this is a large, left-pointing arrow, which has a control definition ID of 193. Still another variation, in which the arrow points up, has a control definition ID of 194.

Your application can use the constants listed here in place of control definition IDs.

Scrolling Text Box Control Data Tag Constants

```
enum {
    kControlScrollTextBoxDelayBeforeAutoScrollTag = 'stdl',
    kControlScrollTextBoxDelayBetweenAutoScrollTag = 'scdl',
    kControlScrollTextBoxAutoScrollAmountTag = 'samt',
    kControlScrollTextBoxContentsTag = 'tres',
    kControlScrollTextBoxAnimatingTag = 'anim'
};
```

Constants

`kControlScrollTextBoxDelayBeforeAutoScrollTag`

Gets or sets the number of ticks to delay before the initial scrolling of an auto-scrolling text box control begins.

Data type retrieved or set: `UInt32`

Available in Mac OS X v10.0 and later.

Declared in `ControlDefinitions.h`.

`kControlScrollTextBoxDelayBetweenAutoScrollTag`

Gets or sets the number of ticks to delay between each unit of scrolling, for an auto-scrolling text box control. (The unit of scrolling for the auto-scrolling text box control is one pixel at a time, unless your application changes this value by calling the `SetControlData` function.)

Data type retrieved or set: `UInt32`

Available in Mac OS X v10.0 and later.

Declared in `ControlDefinitions.h`.

`kControlScrollTextBoxAutoScrollAmountTag`

Gets or sets the number of pixels by which an auto-scrolling text box control scrolls; default is 1.

Data type retrieved or set: `UInt16`

Available in Mac OS X v10.0 and later.

Declared in `ControlDefinitions.h`.

`kControlScrollTextBoxContentsTag`

Sets the ID of a `'TEXT'` resource—and, optionally, a `'styl'` resource—to be used as the content in a scrolling or auto-scrolling text box control.

Data type set: `SInt16`

Available in Mac OS X v10.0 and later.

Declared in `ControlDefinitions.h`.

Discussion

The Mac OS 8.5 Control Manager defines these new control data tag constants. These constants are passed in the `inTagName` parameters of the functions `SetControlData` and `GetControlData` to specify the piece of data in a control that you wish to set or get. You can also pass these constants in the `inTagName` parameter of the function `GetControlDataSize` if you wish to determine the size of variable-length control data. These constants can also be used by custom control definition functions that return the feature bit `kControlSupportsDataAccess` in response to a `kControlMsgGetFeatures` message.

The data that your application gets or sets can be of various types. The descriptions here show the data types for the information that you can set in the `inData` parameter to the `SetControlData` function and that you can get in the `inBuffer` parameter to the `GetControlData` function.

Scrolling Text Box Control Definition ID Constants

```
enum {
    kControlScrollTextBoxProc = 432,
    kControlScrollTextBoxAutoScrollProc = 433
};
```

Constants

`kControlScrollTextBoxProc`

Identifies the standard variant of the scrolling text box (`'CDEF'` resource ID 27), which contains a scroll bar. Your application can use the `kControlScrollTextBoxProc` ID to create a scrolling box of non-editable text, such as is used for an "About" box. You must pass the `NewControl` function the ID of a `'TEXT'` resource—and, optionally, a `'styl'` resource—to be used for the initial value of the control. The minimum and maximum values are reserved for the `kControlScrollTextBoxProc` variant and should be set to 0.

Available in Mac OS X v10.0 and later.

Declared in `ControlDefinitions.h`.

`kControlScrollTextBoxAutoScrollProc`

Identifies the auto-scrolling variant of the scrolling text box (`'CDEF'` resource ID 27); this variant does not contain a scroll bar. Your application can use the `kControlScrollTextBoxAutoScrollProc` ID to create a scrolling box of non-editable text, such as is used for an "About" box. You must pass the `NewControl` function the ID of a `'TEXT'` resource—and, optionally, a `'styl'` resource—to be used for the initial value of the control. For the minimum value of the control, pass a value equal to the delay, in ticks, before the control begins scrolling this delay will also be used between when scrolling completes and when it begins again. For the maximum value of the control, pass a value equal to the delay, in ticks, between each unit of scrolling. The unit of scrolling for the auto-scrolling text box control is one pixel at a time, unless your application changes this value by calling the `SetControlData` function. Note that in order to advance the content of the text box—that is, to scroll the content—you must call the `IdleControls` function on a periodic basis, such as whenever you receive a null event.

Available in Mac OS X v10.0 and later.

Declared in `ControlDefinitions.h`.

Discussion

The Mac OS 8.5 Control Manager defines these new control definition IDs.

When creating a control, your application supplies a control definition ID to one of the Control Manager control-creation functions or to the control resource; see `'CNTL'`. The control definition ID indicates the type of control to create. A control definition ID is an integer that contains the resource ID of a control definition function in its upper 12 bits and a variation code in its lower 4 bits. A control definition ID is derived as follows:

control definition ID = 16 * (`'CDEF'` resource ID) + variation code

A control definition function determines how a control generally looks and behaves. Control definition functions are stored as resources of type `'CDEF'`. Various Control Manager functions call a control definition function whenever they need to perform some control-dependent action, such as drawing the control on the screen. For more information on how to create a control definition function, see `ControlDefProcPtr` (page 677).

A control definition function, in turn, can use a variation code to describe variations of the same basic control. For example, all pop-up arrows share the same basic control definition function, which is stored in a resource of type `'CDEF'` and has a resource ID of 12. The standard pop-up arrow is large and points to the right; it has a control definition ID of 192. A variation of this is a large, left-pointing arrow, which has a control definition ID of 193. Still another variation, in which the arrow points up, has a control definition ID of 194.

Your application can use the constants listed here in place of control definition IDs. These constants, and their associated IDs, are not supported unless the Appearance Manager is available.

Separator Line Control Definition ID Constant

```
enum {
    kControlSeparatorLineProc = 144
};
```

Constants

`kControlSeparatorLineProc`

Resource ID: 9

Separator line.

Available in Mac OS X v10.0 and later.

Declared in `HISeparator.h`.

Discussion

When creating a control, your application supplies a control definition ID to one of the Control Manager control-creation functions or to the control resource; see `'CNTL'`. The control definition ID indicates the type of control to create. A control definition ID is an integer that contains the resource ID of a control definition function in its upper 12 bits and a variation code in its lower 4 bits. A control definition ID is derived as follows:

control definition ID = 16 * (`'CDEF'` resource ID) + variation code

A control definition function determines how a control generally looks and behaves. Control definition functions are stored as resources of type `'CDEF'`. Various Control Manager functions call a control definition function whenever they need to perform some control-dependent action, such as drawing the control on the screen. For more information on how to create a control definition function, see `ControlDefProcPtr` (page 677).

A control definition function, in turn, can use a variation code to describe variations of the same basic control. For example, all pop-up arrows share the same basic control definition function, which is stored in a resource of type `'CDEF'` and has a resource ID of 12. The standard pop-up arrow is large and points to the right; it has a control definition ID of 192. A variation of this is a large, left-pointing arrow, which has a control definition ID of 193. Still another variation, in which the arrow points up, has a control definition ID of 194.

Your application can use the constant listed here in place of a control definition ID.

Slider Control Definition ID Constants

```
enum {
    kControlSliderProc = 48,
    kControlSliderLiveFeedback = (1 << 0),
    kControlSliderHasTickMarks = (1 << 1),
    kControlSliderReverseDirection = (1 << 2),
    kControlSliderNonDirectional = (1 << 3)
};
```

Constants

`kControlSliderProc`

Resource ID: 3

Slider. Your application calls the function `SetControlAction` (page 649) to set the last value for the control. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HISlider.h`.

`kControlSliderLiveFeedback`

(+ `kControlSliderProc`)

Resource ID: 3

Slider with live feedback. The value of the control is updated automatically by the Control Manager before your action function is called. If no application-defined action function is supplied, the slider draws an outline of the indicator as the user moves it. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HISlider.h`.

`kControlSliderHasTickMarks`

(+ `kControlSliderProc`)

Resource ID: 3

Slider with tick marks. The control rectangle must be large enough to include the tick marks. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HISlider.h`.

`kControlSliderReverseDirection`

(+ `kControlSliderProc`)

Resource ID: 3

Slider with a directional indicator. The indicator is positioned perpendicularly to the slider; that is, if the slider is horizontal, the indicator points up, and if the slider is vertical, the indicator points left. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HISlider.h`.

`kControlSliderNonDirectional`
(+ `kControlSliderProc`)

Resource ID: 3

Slider with a rectangular, non-directional indicator. This variant overrides the `kSliderReverseDirection` and `kSliderHasTickMarks` variants. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HISlider.h`.

Discussion
When creating a control, your application supplies a control definition ID to one of the Control Manager control-creation functions or to the control resource; see `'CNTL'`. The control definition ID indicates the type of control to create. A control definition ID is an integer that contains the resource ID of a control definition function in its upper 12 bits and a variation code in its lower 4 bits. A control definition ID is derived as follows:

control definition ID = 16 * (`'CDEF'` resource ID) + variation code

A control definition function determines how a control generally looks and behaves. Control definition functions are stored as resources of type `'CDEF'`. Various Control Manager functions call a control definition function whenever they need to perform some control-dependent action, such as drawing the control on the screen. For more information on how to create a control definition function, see `ControlDefProcPtr` (page 677).

A control definition function, in turn, can use a variation code to describe variations of the same basic control. For example, all pop-up arrows share the same basic control definition function, which is stored in a resource of type `'CDEF'` and has a resource ID of 12. The standard pop-up arrow is large and points to the right; it has a control definition ID of 192. A variation of this is a large, left-pointing arrow, which has a control definition ID of 193. Still another variation, in which the arrow points up, has a control definition ID of 194.

Your application can use the constants listed here in place of control definition IDs.

Static Text Control Data Tag Constants

```
enum {
 kControlStaticTextStyleTag = kControlFontStyleTag,
 kControlStaticTextTextTag = 'text',
 kControlStaticTextTextHeightTag = 'thei',
 kControlStaticTextTruncTag = 'trun',
 kControlStaticTextCFStringTag = 'cfst',
 kControlStaticTextIsMultilineTag = 'stim'
};
```

Constants
`kControlStaticTextTextTag`

Gets or sets text in a static text control.

Data type returned or set: character buffer.

Declared in `HITextViews.h`.

Available with Appearance Manager 1.0 and later.

`kControlStaticTextTextHeightTag`

Gets the height of text in a static text control. Available with Appearance Manager 1.0 and later.

Data type returned or set:`SInt16`

Available in Mac OS X v10.0 and later.

Declared in `HITextViews.h`.

`kControlStaticTextTruncTag`

Gets or sets the control's text truncation style. Truncation will not occur unless `kControlStaticTextIsMultilineTag` is set to `false`.

Data type returned or set: `TruncCode`. The value `truncEnd` indicates that characters are truncated off the end of the string; the value `truncMiddle` indicates that characters are truncated from the middle of the string. Default is a value of -1, which indicates that no truncation occurs and the text is wrapped instead.

Available with Appearance Manager 1.1 (Mac OS 8.5) and later.

Available in Mac OS X v10.0 and later.

Declared in `HITextViews.h`.

`kControlStaticTextCFStringTag`

Gets or sets the control's current text. When setting the text, the control retains the string, so you may release the string after calling `SetControlData`. If the string you set is mutable, the control will make a copy of the string, so any changes to the string after calling `SetControlData` will not affect the control. When retrieving the text, the control retains the string before returning it to you, so you must release the string after you are done with it.

Data type returned or set: `CFStringRef`

Available in CarbonLib 1.5 and later, and Mac OS X v10.0 and later.

Available in Mac OS X v10.0 and later.

Declared in `HITextViews.h`.

`kControlStaticTextIsMultilineTag`

Gets or sets a flag specifying whether the control draws its text in multiple lines if the text is too wide for the control bounds. If `false`, the control always draws the text in a single line.

Data type returned or set: `Boolean`

Declared in `HITextViews.h`.

Available in Mac OS X v10.1 and later.

Discussion

You can use the control data tag constants to set or obtain data that is associated with a control. The control data tag constants are passed in the `inTagName` parameters of `SetControlData` (page 652) and `GetControlData` (page 594) to specify the piece of data in a control that you wish to set or get. You can also pass these constants in the `inTagName` parameter of `GetControlDataSize` (page 596) if you wish to determine the size of variable-length control data. These constants can also be used by custom control definition functions that return the feature bit `kControlSupportsDataAccess` in response to a `kControlMsgGetFeatures` message.

The data that your application sets or obtains can be of various types, dependent upon the control. Therefore, the descriptions of the control data tag constants list the data types for the information that you can set in the `inData` parameter to the `SetControlData` function and that you can get in the `inBuffer` parameter to the `GetControlData` function.

Static Text Control Definition ID Constant

```
enum {
    kControlStaticTextProc = 288
};
```

Constants

`kControlStaticTextProc`

Resource ID: 18

Static text field. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HITextViews.h`.

Discussion

When creating a control, your application supplies a control definition ID to one of the Control Manager control-creation functions or to the control resource; see `'CNTL'`. The control definition ID indicates the type of control to create. A control definition ID is an integer that contains the resource ID of a control definition function in its upper 12 bits and a variation code in its lower 4 bits. A control definition ID is derived as follows:

control definition ID = 16 * (`'CDEF'` resource ID) + variation code

A control definition function determines how a control generally looks and behaves. Control definition functions are stored as resources of type `'CDEF'`. Various Control Manager functions call a control definition function whenever they need to perform some control-dependent action, such as drawing the control on the screen. For more information on how to create a control definition function, see `ControlDefProcPtr` (page 677).

A control definition function, in turn, can use a variation code to describe variations of the same basic control. For example, all pop-up arrows share the same basic control definition function, which is stored in a resource of type `'CDEF'` and has a resource ID of 12. The standard pop-up arrow is large and points to the right; it has a control definition ID of 192. A variation of this is a large, left-pointing arrow, which has a control definition ID of 193. Still another variation, in which the arrow points up, has a control definition ID of 194.

Your application can use the constant listed here in place of a control definition ID.

Text Proc Constants

```
enum {
    staticTextProc = 256,
    editTextProc = 272,
    iconProc = 288,
    userItemProc = 304,
    pictItemProc = 320
};
```

Tab Control Data Tag Constants

```
enum {
    kControlTabContentRectTag = 'rect',
    kControlTabEnabledFlagTag = 'enab',
    kControlTabFontStyleTag = kControlFontStyleTag
};
```

Constants

`kControlTabContentRectTag`

Gets the content rectangle of a tab control.

Data type returned: `Rect`

Available in Mac OS X v10.0 and later.

Declared in `HITabbedView.h`.

`kControlTabEnabledFlagTag`

Enables or disables a single tab in a tab control.

Data type returned or set: `Boolean`; if `true`, enabled; if `false`, disabled.

Available in Mac OS X v10.0 and later.

Declared in `HITabbedView.h`.

Discussion

You can use the control data tag constants to set or obtain data that is associated with a control. The control data tag constants are passed in the `inTagName` parameters of `SetControlData` (page 652) and `GetControlData` (page 594) to specify the piece of data in a control that you wish to set or get. You can also pass these constants in the `inTagName` parameter of `GetControlDataSize` (page 596) if you wish to determine the size of variable-length control data. These constants can also be used by custom control definition functions that return the feature bit `kControlSupportsDataAccess` in response to a `kControlMsgGetFeatures` message.

The data that your application sets or obtains can be of various types, dependent upon the control. Therefore, the descriptions of the control data tag constants list the data types for the information that you can set in the `inData` parameter to the `SetControlData` function and that you can get in the `inBuffer` parameter to the `GetControlData` function.

Version Notes

The control data tag constants are available with Appearance Manager 1.0 and later.

Tab Control Definition IDs

```
enum {
    kControlTabLargeProc = 128,
    kControlTabSmallProc = 129,
    kControlTabLargeNorthProc = 128,
    kControlTabSmallNorthProc = 129,
    kControlTabLargeSouthProc = 130,
    kControlTabSmallSouthProc = 131,
    kControlTabLargeEastProc = 132,
    kControlTabSmallEastProc = 133,
    kControlTabLargeWestProc = 134,
    kControlTabSmallWestProc = 135
};
```

Constants

`kControlTabLargeProc`

Resource ID: 8

Normal tab control. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HITabbedView.h`.

`kControlTabSmallProc`

Resource ID: none

Small tab control. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HITabbedView.h`.

Discussion

When creating a control, your application supplies a control definition ID to one of the Control Manager control-creation functions or to the control resource; see `'CNTL'`. The control definition ID indicates the type of control to create. A control definition ID is an integer that contains the resource ID of a control definition function in its upper 12 bits and a variation code in its lower 4 bits. A control definition ID is derived as follows:

control definition ID = 16 * (`'CDEF'` resource ID) + variation code

A control definition function determines how a control generally looks and behaves. Control definition functions are stored as resources of type `'CDEF'`. Various Control Manager functions call a control definition function whenever they need to perform some control-dependent action, such as drawing the control on the screen. For more information on how to create a control definition function, see `ControlDefProcPtr` (page 677).

A control definition function, in turn, can use a variation code to describe variations of the same basic control. For example, all pop-up arrows share the same basic control definition function, which is stored in a resource of type `'CDEF'` and has a resource ID of 12. The standard pop-up arrow is large and points to the right; it has a control definition ID of 192. A variation of this is a large, left-pointing arrow, which has a control definition ID of 193. Still another variation, in which the arrow points up, has a control definition ID of 194.

Your application can use the constants listed here in place of control definition IDs.

Tab Control Info Tag Constant

```
enum {
    kControlTabInfoTag = 'tabi'
};
```

Constants

`kControlTabInfoTag`

Gets or sets information for a tab in a tab control; see `ControlTabInfoRec` (page 710).

Data type returned or set: `ControlTabInfoRec`.

Available in Mac OS X v10.0 and later.

Declared in `HITabbedView.h`.

Discussion

You can use this control data tag constant to set or obtain data that is associated with a control. This constant is passed in the `inTagName` parameters of `SetControlData` (page 652) and `GetControlData` (page 594) to specify the piece of data in a control that you wish to set or get. You can also pass this constant in the `inTagName` parameter of `GetControlDataSize` (page 596) if you wish to determine the size of variable-length control data. This constant can also be used by custom control definition functions that return the feature bit `kControlSupportsDataAccess` in response to a `kControlMsgGetFeatures` message.

The data that your application sets or obtains can be of various types, dependent upon the control. Therefore, the description of this control data tag constant lists the data type for the information that you can set in the `inData` parameter to the `SetControlData` function and that you can get in the `inBuffer` parameter to the `GetControlData` function.

Version Notes

This control data tag constant is available with Appearance Manager 1.0.1 and later.

Triangle Control Data Tag Constant

```
enum {
    kControlTriangleLastValueTag = 'last'
};
```

Constants

`kControlTriangleLastValueTag`

Gets or sets the last value of a disclosure triangle. Used primarily for setting up a disclosure triangle properly when using the auto-toggle variant.

Data type returned or set: `SInt16`

Available in Mac OS X v10.0 and later.

Declared in `HIDisclosureViews.h`.

Discussion

You can use this control data tag constant to set or obtain data that is associated with a control. This constant is passed in the `inTagName` parameters of `SetControlData` (page 652) and `GetControlData` (page 594) to specify the piece of data in a control that you wish to set or get. You can also pass this constant in the `inTagName` parameter of `GetControlDataSize` (page 596) if you wish to determine the size of variable-length control data. This constant can also be used by custom control definition functions that return the feature bit `kControlSupportsDataAccess` in response to a `kControlMsgGetFeatures` message.

The data that your application sets or obtains can be of various types, dependent upon the control. Therefore, the description of this control data tag constant lists the data type for the information that you can set in the `inData` parameter to the `SetControlData` function and that you can get in the `inBuffer` parameter to the `GetControlData` function.

Version Notes
This control data tag constant is available with Appearance Manager 1.0 and later.

Triangle Control Definition ID Constants

```
enum {
    kControlTriangleProc = 64,
    kControlTriangleLeftFacingProc = 65,
    kControlTriangleAutoToggleProc = 66,
    kControlTriangleLeftFacingAutoToggleProc = 67
};
```

Constants

`kControlTriangleProc`
Resource ID: 4

Disclosure triangle. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIDisclosureViews.h`.

`kControlTriangleLeftFacingProc`
Resource ID: 4

Left-facing disclosure triangle. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIDisclosureViews.h`.

`kControlTriangleAutoToggleProc`
Resource ID: 4

Auto-tracking disclosure triangle. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIDisclosureViews.h`.

`kControlTriangleLeftFacingAutoToggleProc`
Resource ID: 4

Left-facing, auto-tracking disclosure triangle. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIDisclosureViews.h`.

Discussion
When creating a control, your application supplies a control definition ID to one of the Control Manager control-creation functions or to the control resource; see `'CNTL'`. The control definition ID indicates the type of control to create. A control definition ID is an integer that contains the resource ID of a control definition function in its upper 12 bits and a variation code in its lower 4 bits. A control definition ID is derived as follows:

control definition ID = 16 * ('CDEF' resource ID) + variation code

A control definition function determines how a control generally looks and behaves. Control definition functions are stored as resources of type 'CDEF'. Various Control Manager functions call a control definition function whenever they need to perform some control-dependent action, such as drawing the control on the screen. For more information on how to create a control definition function, see ControlDefProcPtr (page 677).

A control definition function, in turn, can use a variation code to describe variations of the same basic control. For example, all pop-up arrows share the same basic control definition function, which is stored in a resource of type 'CDEF' and has a resource ID of 12. The standard pop-up arrow is large and points to the right; it has a control definition ID of 192. A variation of this is a large, left-pointing arrow, which has a control definition ID of 193. Still another variation, in which the arrow points up, has a control definition ID of 194.

Your application can use the constants listed here in place of control definition IDs.

User Item and User Pane Control Data Tag Constants

```
enum {
    kControlUserItemDrawProcTag = 'uidp',
    kControlUserPaneDrawProcTag = 'draw',
    kControlUserPaneHitTestProcTag = 'hitt',
    kControlUserPaneTrackingProcTag = 'trak',
    kControlUserPaneIdleProcTag = 'idle',
    kControlUserPaneKeyDownProcTag = 'keyd',
    kControlUserPaneActivateProcTag = 'acti',
    kControlUserPaneFocusProcTag = 'foci',
    kControlUserPaneBackgroundProcTag = 'back'
};
```

Constants

kControlUserItemDrawProcTag
: Gets or sets an application-defined item drawing function. If an embedding hierarchy is established, a user pane drawing function should be used instead of an item drawing function.

  Data type returned or set: UserItemUPP

  Available in Mac OS X v10.0 and later.

  Declared in HIContainerViews.h.

kControlUserPaneDrawProcTag
: Gets or sets a user pane drawing function; see ControlUserPaneBackgroundProcPtr (page 688). Indicates that the Control Manager needs to draw a control.

  Data type returned or set: ControlUserPaneDrawingUPP

  Available in Mac OS X v10.0 and later.

  Declared in HIContainerViews.h.

kControlUserPaneHitTestProcTag
: Gets or sets a user pane hit-testing function. Indicates that the Control Manager needs to determine if a control part was hit; see ControlUserPaneBackgroundProcPtr (page 688).

  Data type returned or set: ControlUserPaneHitTestUPP

  Available in Mac OS X v10.0 and later.

  Declared in HIContainerViews.h.

`kControlUserPaneTrackingProcTag`
: Gets or sets a user pane tracking function, which will be called when a control definition function returns the `kControlHandlesTracking` feature bit in response to a `kControlMsgGetFeatures` message. Indicates that a user pane handles its own tracking; see `ControlUserPaneBackgroundProcPtr` (page 688).

  Data type returned or set: `ControlUserPaneTrackingUPP`

  Available in Mac OS X v10.0 and later.

  Declared in `HIContainerViews.h`.

`kControlUserPaneIdleProcTag`
: Gets or sets a user pane idle function, which will be called when a control definition function returns the `kControlWantsIdle` feature bit in response to a `kControlMsgGetFeatures` message. Indicates that a user pane performs idle processing; see `ControlUserPaneBackgroundProcPtr` (page 688).

  Data type returned or set: `ControlUserPaneIdleUPP`

  Available in Mac OS X v10.0 and later.

  Declared in `HIContainerViews.h`.

`kControlUserPaneKeyDownProcTag`
: Gets or sets a user pane key down function, which will be called when a control definition function returns the `kControlSupportsFocus` feature bit in response to a `kControlMsgGetFeatures` message. Indicates that a user pane performs keyboard event processing; see `ControlUserPaneBackgroundProcPtr` (page 688).

  Data type returned or set: `ControlUserPaneKeyDownUPP`

  Available in Mac OS X v10.0 and later.

  Declared in `HIContainerViews.h`.

`kControlUserPaneActivateProcTag`
: Gets or sets a user pane activate function, which will be called when a control definition function returns the `kControlWantsActivate`feature bit in response to a `kControlMsgGetFeatures` message. Indicates that a user pane wants to be informed of activate and deactivate events; see `ControlUserPaneBackgroundProcPtr` (page 688).

  Data type returned or set: `ControlUserPaneActivateUPP`

  Available in Mac OS X v10.0 and later.

  Declared in `HIContainerViews.h`.

`kControlUserPaneFocusProcTag`
: Gets or sets a user pane keyboard focus function, which will be called when a control definition function returns the `kControlSupportsFocus` feature bit in response to a `kControlMsgGetFeatures` message. Indicates that a user pane handles keyboard focus; see `ControlUserPaneBackgroundProcPtr` (page 688).

  Data type returned or set: `ControlUserPaneFocusUPP`

  Available in Mac OS X v10.0 and later.

  Declared in `HIContainerViews.h`.

`kControlUserPaneBackgroundProcTag`

Gets or sets a user pane background function, which will be called when a control definition function returns the `kControlHasSpecialBackground`and `kControlSupportsEmbedding`feature bits in response to a `kControlMsgGetFeatures` message. Indicates that a user pane can set its background color or pattern; see `ControlUserPaneBackgroundProcPtr` (page 688).

Data type returned or set: `ControlUserPaneBackgroundUPP`

Available in Mac OS X v10.0 and later.

Declared in `HIContainerViews.h`.

Discussion
You can use the control data tag constants to set or obtain data that is associated with a control. The control data tag constants are passed in the `inTagName` parameters of `SetControlData` (page 652) and `GetControlData` (page 594) to specify the piece of data in a control that you wish to set or get. You can also pass these constants in the `inTagName` parameter of `GetControlDataSize` (page 596) if you wish to determine the size of variable-length control data. These constants can also be used by custom control definition functions that return the feature bit `kControlSupportsDataAccess` in response to a `kControlMsgGetFeatures` message.

The data that your application sets or obtains can be of various types, dependent upon the control. Therefore, the descriptions of the control data tag constants list the data types for the information that you can set in the `inData` parameter to the `SetControlData` function and that you can get in the `inBuffer` parameter to the `GetControlData` function.

Version Notes
The control data tag constants are available with Appearance Manager 1.0 and later.

User Pane Control Definition ID Constant

```
enum {
    kControlUserPaneProc = 256
};
```

Constants
`kControlUserPaneProc`

Resource ID: 16

User pane. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in `HIContainerViews.h`.

Discussion
When creating a control, your application supplies a control definition ID to one of the Control Manager control-creation functions or to the control resource; see `'CNTL'`. The control definition ID indicates the type of control to create. A control definition ID is an integer that contains the resource ID of a control definition function in its upper 12 bits and a variation code in its lower 4 bits. A control definition ID is derived as follows:

control definition ID = 16 * (`'CDEF'` resource ID) + variation code

A control definition function determines how a control generally looks and behaves. Control definition functions are stored as resources of type 'CDEF'. Various Control Manager functions call a control definition function whenever they need to perform some control-dependent action, such as drawing the control on the screen. For more information on how to create a control definition function, see ControlDefProcPtr (page 677).

A control definition function, in turn, can use a variation code to describe variations of the same basic control. For example, all pop-up arrows share the same basic control definition function, which is stored in a resource of type 'CDEF' and has a resource ID of 12. The standard pop-up arrow is large and points to the right; it has a control definition ID of 192. A variation of this is a large, left-pointing arrow, which has a control definition ID of 193. Still another variation, in which the arrow points up, has a control definition ID of 194.

Your application can use the constant listed here in place of a control definition ID.

useWFont Constants

```
enum {
    useWFont = kControlUsesOwningWindowsFontVariant
};
```

Window Control Definition IDs

```
enum {
    kControlWindowHeaderProc = 336,
    kControlWindowListViewHeaderProc = 337
};
```

Constants

kControlWindowHeaderProc

Resource ID: 21

Window header. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in HIContainerViews.h.

kControlWindowListViewHeaderProc

Resource ID: 21

Window list view header. This control definition is new with the Appearance Manager and is not supported unless the Appearance Manager is available.

Available in Mac OS X v10.0 and later.

Declared in HIContainerViews.h.

Discussion

When creating a control, your application supplies a control definition ID to one of the Control Manager control-creation functions or to the control resource; see 'CNTL'. The control definition ID indicates the type of control to create. A control definition ID is an integer that contains the resource ID of a control definition function in its upper 12 bits and a variation code in its lower 4 bits. A control definition ID is derived as follows:

control definition ID = 16 * ('CDEF' resource ID) + variation code

A control definition function determines how a control generally looks and behaves. Control definition functions are stored as resources of type 'CDEF'. Various Control Manager functions call a control definition function whenever they need to perform some control-dependent action, such as drawing the control on the screen. For more information on how to create a control definition function, see ControlDefProcPtr (page 677).

A control definition function, in turn, can use a variation code to describe variations of the same basic control. For example, all pop-up arrows share the same basic control definition function, which is stored in a resource of type 'CDEF' and has a resource ID of 12. The standard pop-up arrow is large and points to the right; it has a control definition ID of 192. A variation of this is a large, left-pointing arrow, which has a control definition ID of 193. Still another variation, in which the arrow points up, has a control definition ID of 194.

Your application can use the constants listed here in place of control definition IDs.

Window Control Data List Header Tag Constant

```
enum {
    kControlWindowHeaderIsListHeaderTag = 'islh'
};
```

Constants

kControlWindowHeaderIsListHeaderTag

Set to true if the control is to draw as a list header. Available in Mac OS X v10.3 and later.

Data type returned or set: Boolean

Available in Mac OS X v10.3 and later.

Declared in HIContainerViews.h.

Result Codes

The table below lists the result codes returned by Control Manager functions.

Result Code	Value	Description
controlPropertyInvalid	-5603	You called SetControlProperty, GetControlProperty, or a similar function with an illegal property creator OSType. Available in Mac OS X v10.0 and later.
controlPropertyNotFoundErr	-5604	The property tag and creator combination does not exist for the specified control. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
errMessageNotSupported	-30580	In general, this return value means a control, window, or menu definition does not support the message/event that underlies an API call. For example, if you call GetControlFeatures on a control whose control definition function doesn't support "new messages" (the new group of CDEF messages that came into existence with the Appearance Manager on Mac OS 8), GetControlFeatures will return this error. Available in Mac OS X v10.0 and later.
errDataNotSupported	-30581	Returned from GetControlData and SetControlData if the control doesn't support the tag name and/or part code that is passed in. It can also be returned from other functions that are essentially wrappers around GetControlData and SetControlData (such as SetControlFontStyle). Available in Mac OS X v10.0 and later.
errControlDoesntSupportFocus	-30582	The control you passed to a focusing function (such as SetKeyboardFocus) doesn't support focus. On Mac OS X, you're likely to receive errCouldntSetFocus or eventNotHandledErr i instead. Available in Mac OS X v10.0 and later.
errWindowDoesntSupportFocus	-30583	The specified window does not support focus. Available in Mac OS X v10.0 and later.
errUnknownControl	-30584	This is a variant of (and serves the same purpose as) controlHandleInvalidErr. Various Control Manager functions return this error if one of the specified controls is NULL or otherwise invalid. Available in Mac OS X v10.0 and later.
errCouldntSetFocus	-30585	The focus couldn't be set to a given control or advanced through a hierarchy of controls. This could be because the control doesn't support focusing, the control isn't currently embedded in a window, or you are attempting to advance focus in a window that contains no focusable controls. Available in Mac OS X v10.0 and later.
errNoRootControl	-30586	No root control exists. Some examples of when you might receive this error include: 1) You called GetRootControl before anyone called CreateRootControl for a given non-compositing window. 2) You called a Control Manager function (such as ClearKeyboardFocus or AutoEmbedControl) that can only do its work if there's a root control in the window, yet there's no root control. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
errRootAlreadyExists	-30587	Returned by CreateRootControl if a root control already exists for the specified control. Available in Mac OS X v10.0 and later.
errInvalidPartCode	-30588	The ControlPartCode you passed to a Control Manager function is out of range, invalid, or otherwise unsupported. For example, GetControlRegion returns errInvalidPartCode if you pass kControlNoPart. Available in Mac OS X v10.0 and later.
errControlsAlreadyExist	-30589	You called CreateRootControl after creating one or more non-root controls in a window, which is illegal; if you want an embedding hierarchy on a given window, you must call CreateRootControl before creating any other controls for a given window.This is never returned on Mac OS X, because a root control is created automatically (if it doesn't already exist) the first time any nonroot control is created in a window. Available in Mac OS X v10.0 and later.
errControlIsNotEmbedder	-30590	The control does not support embedding. Returned, for example, by GetIndexedSubControl and EmbedControl. Available in Mac OS X v10.0 and later.
errDataSizeMismatch	-30591	You called GetControlData or SetControlData with a buffer whose size does not match the size of the data you are attempting to get or set. Available in Mac OS X v10.0 and later.
errControlHiddenOrDisabled	-30592	You called TrackControl, HandleControlClick, or a similar mouse tracking function, on a control that is invisible or disabled. You cannot track controls that are invisible or disabled. Available in Mac OS X v10.0 and later.
errWindowRegionCodeInvalid	-30593	The window region code is invalid. Available in Mac OS X v10.0 and later.
errCantEmbedIntoSelf	-30594	You called EmbedControl (or a similar function) with the same control in the parent and child parameters. In other words, you cannot embed a control into itself. Available in Mac OS X v10.0 and later.
errCantEmbedRoot	-30595	You attempted to embed the root control in another control. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
errItemNotControl	-30596	You called GetDialogItemAsControl on a dialog item (such as a kHelpDialogItem) that is not represented by a control. Available in Mac OS X v10.0 and later.
controlInvalidDataVersionErr	-30597	You called GetControlData or SetControlData with a buffer that represents a versioned structure, but the version is unsupported by the control definition. This can happen with the Tabs control and the kControlTabInfoTag. Available in Mac OS X v10.0 and later.
controlHandleInvalidErr	-30599	The control reference passed in was invalid. Available in Mac OS X v10.0 and later.

Dialog Manager Reference

Framework: Carbon/Carbon.h

Declared in Dialogs.h

Overview

Your application can use the Dialog Manager to alert users to unusual situations and to solicit information from users. For example, in some situations your application might not be able to carry out a command normally, and in other situations the user must specify multiple parameters before your application can execute a command. For circumstances like these, the Macintosh user interface includes these two features:

- alerts–including alert sounds and alert boxes–which warn the user whenever an unusual or potentially undesirable situation occurs within your application
- dialog boxes, which allow the user to provide additional information or to modify settings before your application carries out a command

Virtually all applications need to implement alerts and dialog boxes. To avoid needless development effort, use the Dialog Manager to implement alerts and to create most dialog boxes. It is possible, however–and sometimes desirable–to bypass the Dialog Manager and instead use Window Manager, Control Manager, QuickDraw, and Event Manager routines to create or respond to events in complex dialog boxes.

Carbon supports the majority of the Dialog Manager. However, your application must access Dialog Manager data structures only through the supplied accessor functions. Furthermore, your application must use the functions provided for creating and disposing of Dialog Manager data structures.

Functions by Task

Creating Alert Boxes

`StandardAlert` (page 887)
Displays a standard alert box.

`Alert` (page 834)
Displays an alert box and/or plays an alert sound.

`StopAlert` (page 889)
Displays an alert box with a stop icon and/or plays an alert sound.

`NoteAlert` (page 874)
Displays an alert box with a note icon and/or plays an alert sound.

`CautionAlert` (page 839)
Displays an alert box with a caution icon and/or plays an alert sound.

`GetAlertStage` (page 850)
Determines the stage of the last occurrence of an alert.

`ResetAlertStage` (page 876)
Resets the current alert stage to the first alert stage.

Creating and Disposing of Dialog Boxes

`GetNewDialog` (page 858)
Creates a dialog box from a resource-based description.

`NewFeaturesDialog` (page 871)
Creates a dialog box from information passed in memory.

`NewDialog` (page 870)
Creates a dialog box from information passed in memory.

`NewColorDialog` (page 868)
Creates a dialog box from information passed in memory.

`CloseDialog` (page 840)
Dismisses a dialog box without disposing of the dialog structure.

`DisposeDialog` (page 847)
Dismisses a dialog box for which the Dialog Manager supplies memory and disposes of the dialog structure.

Displaying Dialog Boxes and Items

`DrawDialog` (page 849)
Draws the entire contents of a specified dialog box.

`HideDialogItem` (page 861)
Makes an item in a dialog box invisible.

`ShowDialogItem` (page 885)
Redisplays an item that has been hidden by HideDialogItem.

Filtering Dialog Box Events

`GetModalDialogEventMask` (page 857)
Obtains the events to be received by the `ModalDialog` function.

`SetModalDialogEventMask` (page 884)
Specifies the events to be received by the `ModalDialog` function.

Handling Events in Dialog Boxes

`ModalDialog` (page 865)
Handles events while your application displays a modal or movable modal dialog box.

`IsDialogEvent` (page 863)
Determines whether a modeless dialog box or a movable modal dialog box is active when an event occurs.

`DialogSelect` (page 845)
Handles most of the events inside the dialog box after you have determined that an event related to an active modeless dialog box or an active movable modal dialog box has occurred.

`UpdateDialog` (page 890)
Redraws the update region of a specified dialog box.

Handling Text in Alert and Dialog Boxes

`ParamText` (page 875)
Replaces the text strings in the static text items of your alert or dialog boxes while your application is running.

`SetDialogItemText` (page 882)
Sets the text string for static text and editable text fields.

`GetDialogItemText` (page 854)
Obtains the text string contained in an edit text or a static text item.

`SelectDialogItemText` (page 877)
Selects and highlights text contained in an edit text item.

`DialogCut` (page 844)
Handles the Cut editing command when a dialog box containing an edit text item is active.

`DialogCopy` (page 844)
Handles the Copy editing command when a dialog box containing an edit text item is active.

`DialogPaste` (page 845)
Handles the Paste editing command when a dialog box containing an edit text item is active.

`DialogDelete` (page 845)
Handles the Delete editing command when a dialog box containing an edit text item is active.

Initializing the Dialog Manager

`SetDialogFont` (page 880)
Sets the font used in static and edit text items.

Manipulating Items in Dialog Boxes and Alert Boxes

`SetDialogCancelItem` (page 878)
Sets the cancel item for a dialog box.

`GetDialogCancelItem` (page 851)
Returns the item number of the cancel item previously set with `SetDialogCancelItem`.

`SetDialogDefaultItem` (page 879)
Sets the default item for a dialog box and draws an appropriate border around the default item.

`GetDialogDefaultItem` (page 851)
Returns the item number of the default item currently set for the standard filter function.

`GetDialogItemAsControl` (page 853)
Obtains the control handle for a dialog item in an embedding hierarchy.

`GetDialogItem` (page 852)
Obtains a handle to a dialog item.

`SetDialogItem` (page 881)
Sets or changes information for a dialog item.

`GetDialogKeyboardFocusItem` (page 854)
Returns the item number of the editable text item in a dialog box that has keyboard focus.

`SetDialogTracksCursor` (page 883)
Determines whether the Dialog Manager tracks the cursor's movements and changes the cursor to an I-beam whenever it is over an edit dialog box.

`FindDialogItem` (page 849)
Determines the item number of an item at a particular location in a dialog box.

`MoveDialogItem` (page 867)
Moves a dialog item to a specified location in a window.

`SizeDialogItem` (page 886)
Sizes a dialog item.

`AutoSizeDialog` (page 838)
Automatically resizes static text fields and their dialog boxes to accommodate changed static text.

`AppendDialogItemList` (page 835)
Adds items to an existing dialog box while your program is running.

`AppendDITL` (page 836)
Adds items to an existing dialog box while your application is running.

`ShortenDITL` (page 885)
Removes items from an existing dialog box while your application is running.

`CountDITL` (page 841)
Determines the number of items in a dialog box.

Simulating User Responses in Dialog Boxes

`GetDialogTimeout` (page 856)
Obtains the original countdown duration, the time remaining, and the item selection to be simulated for a specified modal dialog box.

`SetDialogTimeout` (page 882)
Simulates an item selection in a modal dialog box after a specified amount of time elapses.

Using the Standard Filter Function

`StdFilterProc` (page 888)
Handles standard event filtering for a dialog box.

`GetStdFilterProc` (page 860)
Returns a pointer to the standard filter function.

Miscellaneous

`CloseStandardSheet` (page 841)

`CreateStandardAlert` (page 842)
Creates an alert containing standard elements and using standard formatting rules.

`CreateStandardSheet` (page 842)
Creates an alert containing standard elements and using standard formatting rules, and prepares it to be displayed as a sheet.

`DisposeModalFilterUPP` (page 848)

`DisposeModalFilterYDUPP` (page 848)

`DisposeUserItemUPP` (page 849)

`GetDialogFromWindow` (page 852)

`GetDialogPort` (page 855)

`GetDialogTextEditHandle` (page 856)

`GetDialogWindow` (page 857)

`GetParamText` (page 859)

`GetStandardAlertDefaultParams` (page 860)
Fills out an `AlertStdCFStringAlertParamRec` with default values: - not movable - no help button - default button with title "OK" - no cancel or other buttons.

`InsertDialogItem` (page 862)

`InvokeModalFilterUPP` (page 862)

`InvokeModalFilterYDUPP` (page 863)

`InvokeUserItemUPP` (page 863)

`NewModalFilterUPP` (page 873)

`NewModalFilterYDUPP` (page 873)

`NewUserItemUPP` (page 873)

`RemoveDialogItems` (page 876)

`RunStandardAlert` (page 877)
Shows and runs a standard alert using a modal dialog loop.

`SetPortDialogPort` (page 884)

Functions

Alert

Displays an alert box and/or plays an alert sound.

```
DialogItemIndex Alert (
   SInt16 alertID,
   ModalFilterUPP modalFilter
);
```

Parameters

alertID
The resource ID of an alert resource and extended alert resource. If the alert resource is missing, the Dialog Manager returns to your application without creating the requested alert. See `'alrx'` for a description of the extended alert resource.

modalFilter
A universal procedure pointer for a filter function that responds to events not handled by the `ModalDialog` (page 865) function. If you set this parameter to `null`, the Dialog Manager uses the standard event filter function.

Return Value

If no alert box is to be drawn at the current alert stage or the `'ALRT'` resource is not found, `Alert` returns –1 otherwise, it creates and displays the alert box and returns the item number of the control selected by the user see "Alert Button Constants" (page 904). See the description of the `DialogItemIndex` data type.

Discussion

The `Alert` function displays an alert box or, if appropriate for the alert stage, plays an alert sound instead of or in addition to displaying the alert box. The `Alert` function creates the alert defined in the specified alert resource and its corresponding extended alert resource. The function calls the current alert sound function and passes it the sound number specified in the alert resource for the current alert stage. If no alert box is to be drawn at this stage, `Alert` returns –1 otherwise, it uses the `NewDialog` function to create and display the alert box. The default system window colors are used unless your application provides an alert color table resource with the same resource ID as the alert resource. The `Alert` function uses the `ModalDialog` (page 865) function to get and handle most events for you.

The `Alert` function does not display a default icon in the upper-left corner of the alert box you can leave this area blank, or you can specify your own icon in the alert's item list resource, which in turn is specified in the alert resource.

The `Alert` function continues calling `ModalDialog` until the user selects an enabled control (typically a button), at which time the `Alert` function removes the alert box from the screen and returns the item number of the selected control. Your application then responds as appropriate when the user clicks this item.

Your application should never draw its own default rings. Prior to Mac OS 8, the `Alert` function would only redraw the default button ring once and never redraw it on an update event. However, when Appearance is available, default rings do redraw when you call `Alert`.

See also the functions `NoteAlert` (page 874) , `CautionAlert` (page 839) , and `StopAlert` (page 889).

Special Considerations

If you need to display an alert box while your application is running in the background or is otherwise invisible to the user, call `AEInteractWithUser`

The Dialog Manager uses the system alert sound as the error sound unless you change it by calling the `ErrorSound` function .

Version Notes

This function was changed with Appearance Manager 1.0 to support the extended alert (`'alrx'`) resource.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Dialogs.h`

AppendDialogItemList

Adds items to an existing dialog box while your program is running.

```
OSErr AppendDialogItemList (
   DialogRef dialog,
   SInt16 ditlID,
   DITLMethod method
);
```

Parameters

dialog

A pointer to the dialog box to which the items in the item list resource specified in the `ditlID` parameter are to be appended.

ditlID

The resource ID of the item list resource whose items are to be appended to the dialog box specified in the `dialog` parameter.

method

The manner in which the new items are to be displayed in the dialog box.

If you use the `overlayDITL` constant, `AppendDialogItemList` superimposes the appended items over the dialog box by interpreting the coordinates of the display rectangles for the appended items (as specified in their item list resource) as local coordinates within the dialog box.

If you use the `appendDITLRight` constant, `AppendDialogItemList` appends the items to the right of the dialog box by positioning the display rectangles of the appended items relative to the upper-right coordinate of the dialog box. The `AppendDialogItemList` function automatically expands the dialog box to accommodate the new dialog items.

If you use the `appendDITLBottom` constant, `AppendDialogItemList` appends the items to the bottom of the dialog box by positioning the display rectangles of the appended items relative to the lower-left coordinate of the dialog box. The `AppendDialogItemList` function automatically expands the dialog box to accommodate the new dialog items.

You can append a list of items relative to an existing item by passing a negative number. The absolute value of this number is interpreted as the item in the dialog box relative to which the new items are to be positioned. For example, if you pass -2, the display rectangles of the appended items are offset relative to the upper-left corner of item number 2 in the dialog box.

Return Value
A result code. See "Dialog Manager Result Codes" (page 916).

Discussion
To be Appearance-compliant, your program should use the `AppendDialogItemList` function rather than the `AppendDITL` function. Unlike `AppendDITL`, the `AppendDialogItemList` function takes a `'DITL'` resource ID instead of a handle as the parameter describing the dialog item list to be appended, and it properly appends entries from a dialog font table (`'dftb'`) resource, if there is a `'dftb'` resource with the same resource ID as the `'DITL'` resource.

The `AppendDialogItemList` function adds the items in the item list resource specified in the parameter `ditlID` to the items of a dialog box. This is especially useful if several dialog boxes share a single item list resource, because you can use `AppendDialogItemList` to add items that are appropriate for individual dialog boxes. Your application can use the Resource Manager function `GetResource` to get a handle to the item list resource whose items you wish to add.

You typically create an invisible dialog box, call the `AppendDialogItemList` function, then make the dialog box visible by using the Window Manager function `ShowWindow`.

Version Notes
This function is available with Appearance Manager 1.0 and later.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Dialogs.h`

AppendDITL

Adds items to an existing dialog box while your application is running.

```
void AppendDITL (
   DialogRef theDialog,
   Handle theHandle,
   DITLMethod method
);
```

Parameters

theDialog

A pointer to a dialog structure. This is the dialog structure to which you will add the item list resource specified in the parameter theHandle.

theHandle

A handle to the item list resource whose items you want to append to the dialog box. To avoid item number conflicts, `AppendDITL` assigns new numbers to the items you are adding. For example, if you have a dialog with item numbers 1-5, and you use `AppendDITL` to add a `'DITL'` resource containing item numbers 1-3, those become item numbers 6-8 in the dialog.

method

The manner in which you want the new items to be displayed in the existing dialog box. You can pass a negative value to offset the appended items from a particular item in the existing dialog box. You can also pass one of the values defined by the `DITLMethod` constant. See "Dialog Item List Display Constants" (page 913) for possible values.

Discussion

The `AppendDITL` function adds the items specified in the `theHandle` parameter to the items of a dialog box (handle-based). This function is especially useful if several dialog boxes share a single item list resource, because you can use `AppendDITL` to add items that are appropriate for individual dialog boxes. Your application can use the Resource Manager function `GetResource` to get a handle to the item list resource whose items you wish to add.

In the parameter `method`, you specify how to append the new items, as follows:

- If you use the `overlayDITL` constant, `AppendDITL` superimposes the appended items over the dialog box. That is, `AppendDITL` interprets the coordinates of the display rectangles for the appended items (as specified in their item list resource) as local coordinates within the dialog box.
- If you use the `appendDITLRight` constant, `AppendDITL` appends the items to the right of the dialog box by positioning the display rectangles of the appended items relative to the upper-right coordinate of the dialog box. The `AppendDITL` function automatically expands the dialog box to accommodate the new dialog items.
- If you use the `appendDITLBottom` constant, `AppendDITL` appends the items to the bottom of the dialog box by positioning the display rectangles of the appended items relative to the lower-left coordinate of the dialog box. The `AppendDITL` function automatically expands the dialog box to accommodate the new dialog items.
- You can also append a list of items relative to an existing item by passing a negative number in the parameter `method`. The absolute value of this number is interpreted as the item in the dialog box relative to which the new items are to be positioned. For example, if you pass –2, the display rectangles of the appended items are offset relative to the upper-left corner of item number 2 in the dialog box.

You typically create an invisible dialog box, call the `AppendDITL` function, then make the dialog box visible by using the Window Manager function `ShowWindow`.

Special Considerations

The `AppendDITL` function modifies the contents of the dialog box (for instance, by enlarging it). To use an unmodified version of the dialog box at a later time, your application should use the Resource Manager function `ReleaseResource` to release the memory occupied by the appended item list resource. Otherwise, if your application calls `AppendDITL` to add items to that dialog box again, the dialog box remains modified by your previous call—for example, it will still be longer at the bottom if you previously used the `appendDITLBottom` constant.

Before calling `AppendDITL`, you should make sure that it is available by using the `Gestalt` function with the `gestaltDITLExtAttr` selector. Test the bit indicated by the `gestaltDITLExtPresent` constant in the `response` parameter. If the bit is set, then `AppendDITL` is available.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Dialogs.h`

AutoSizeDialog

Automatically resizes static text fields and their dialog boxes to accommodate changed static text.

```
OSErr AutoSizeDialog (
   DialogRef inDialog
);
```

Parameters

`inDialog`

A pointer to a dialog box.

Return Value

A result code. See "Dialog Manager Result Codes" (page 916).

Discussion

The `AutoSizeDialog` function is useful in situations such as localization, where the size of a static text field (and the dialog box that contains it) may need to be altered to accommodate a change in the size of the static text.

For each static text item `AutoSizeDialog` finds in the item list resource, it adjusts the static text field and the bottom of the dialog box window to accommodate the text. Any items below a static text field are moved down. If the dialog box is visible when this function is called, it is hidden, resized, and then shown. If the dialog box has enough room to show the text as is, no resizing is done.

Note that the `AutoSizeDialog` function does not process update events for your dialog box, so your program must call the `DrawDialog` function or the `DialogSelect` function to process the update event generated from showing the window.

Version Notes

This function is available with Appearance Manager 1.0 and later.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In
Dialogs.h

CautionAlert

Displays an alert box with a caution icon and/or plays an alert sound.

```
DialogItemIndex CautionAlert (
   SInt16 alertID,
   ModalFilterUPP modalFilter
);
```

Parameters

alertID

The resource ID of an alert resource and extended alert resource. If the alert resource is missing, the Dialog Manager returns to your application without creating the requested alert. See 'alrx' for a description of the extended alert resource.

modalFilter

A universal procedure pointer for a filter function that responds to events not handled by the ModalDialog (page 865) function. If you set this parameter to null, the Dialog Manager uses the standard event filter function.

Return Value
If no alert box is to be drawn at the current alert stage, CautionAlert returns –1 otherwise, it uses NewDialog to create and display the alert box and returns the item hit; see "Alert Button Constants" (page 904). See the description of the DialogItemIndex data type.

Discussion
Displays an alert box with a caution icon in its upper-left corner or, if appropriate for the alert stage, to play an alert sound instead of or in addition to displaying the alert box.

The CautionAlert function is the same as the Alert (page 834) function except that, before drawing the items in the alert box, CautionAlert draws the caution icon in the upper-left corner. The caution icon has resource ID 2, which you can also specify with the constant kCautionIcon. By default, the Dialog Manager uses the standard caution icon from the System file. You can change this icon by providing your own 'ICON' resource with resource ID 2.

Use a caution alert to alert the user of an operation that may have undesirable results if it's allowed to continue. Give the user the choice of continuing the action (by clicking an OK button) or stopping it (by clicking a Cancel button).

Your application should never draw its own default rings or alert icons. Prior to Mac OS 8, the CautionAlert function would only redraw the alert icon and default button ring once and never redraw them on an update event. However, when Appearance is available, alert icons and default rings do redraw when you call CautionAlert.

See also the functions NoteAlert (page 874) and StopAlert (page 889).

Special Considerations

Version Notes
This function was changed with Appearance Manager 1.0 to support the extended alert ('alrx') resource.

Availability
Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In
`Dialogs.h`

CloseDialog

Dismisses a dialog box without disposing of the dialog structure.

```
void CloseDialog (
    DialogRef theDialog
);
```

Parameters

theDialog
A pointer to a dialog structure.

Return Value

Discussion
The `CloseDialog` function removes a dialog box from the screen and deletes it from the window list. The `CloseDialog` function releases the memory occupied by

- the data structures associated with the dialog box (such as its structure, content, and update regions)
- all the items in the dialog box (except for pictures and icons, which might be shared by other resources) and any data structures associated with them

Generally, you should provide memory for the dialog structure of modeless dialog boxes when you create them. (You can let the Dialog Manager provide memory for modal and movable modal dialog boxes.) You should then use `CloseDialog` to close a modeless dialog box when the user clicks the close box or chooses Close from the File menu.

Because `CloseDialog` does not dispose of the dialog resource or the item list resource, it is important to make these resources purgeable. Unlike `GetNewDialog` (page 858) , `NewColorDialog` (page 868) does not use a copy of the item list resource. Thus, if you use `NewColorDialog` to create a dialog box, you may want to use `CloseDialog` to keep the item list resource in memory even if you didn't supply a pointer to the memory.

Carbon Porting Notes

The `CloseDialog` function is not supported because developers do not allocate their own memory for dialog boxes in Carbon. Use the `DisposeDialog` function to dismiss a dialog box instead.

`Dialogs.h`

CloseStandardSheet

```
OSStatus CloseStandardSheet (
   DialogRef inSheet,
   UInt32 inResultCommand
);
```

Parameters

inSheet

inResultCommand

Return Value

A result code. See "Dialog Manager Result Codes" (page 916).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Dialogs.h`

CountDITL

Determines the number of items in a dialog box.

```
DialogItemIndex CountDITL (
   DialogRef theDialog
);
```

Parameters

theDialog

A pointer to a dialog structure.

Return Value

The number of current items in a dialog box. See the description of the `DialogItemIndex` data type.

Discussion

You typically use `CountDITL` in conjunction with `ShortenDITL` (page 885) to remove items from a dialog box.

Special Considerations

Before calling `CountDITL`, you should make sure that it is available by using the `Gestalt` function with the `gestaltDITLExtAttr` selector. Test the bit indicated by the `gestaltDITLExtPresent` constant in the `response` parameter. If the bit is set, then `CountDITL` is available.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Dialogs.h`

CreateStandardAlert

Creates an alert containing standard elements and using standard formatting rules.

```
OSStatus CreateStandardAlert (
   AlertType alertType,
   CFStringRef error,
   CFStringRef explanation,
   const AlertStdCFStringAlertParamRec *param,
   DialogRef *outAlert
);
```

Parameters

alertType
The type of alert to create. For a list of possible values, see "Alert Type Constants" (page 907).

error
The error string to display.

explanation
The explanation string to display. May be `NULL` or empty to display no explanation.

param
The parameter block describing how to create the alert. May be `NULL`.

outAlert
A pointer to a variable that, on return, refers to the new alert.

Return Value

A result code. See "Dialog Manager Result Codes" (page 916).

Discussion

This function should be used in conjunction with `RunStandardAlert` (page 877). After `CreateStandardAlert` returns, the alert is still invisible. `RunStandardAlert` shows the alert and runs a modal dialog loop to process events in the alert.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Related Sample Code

QTCarbonShell

Declared In

`Dialogs.h`

CreateStandardSheet

Creates an alert containing standard elements and using standard formatting rules, and prepares it to be displayed as a sheet.

```
OSStatus CreateStandardSheet (
   AlertType alertType,
   CFStringRef error,
   CFStringRef explanation,
   const AlertStdCFStringAlertParamRec *param,
   EventTargetRef notifyTarget,
   DialogRef *outSheet
);
```

Parameters

alertType

The type of alert to create. For a list of possible values, see "Alert Type Constants" (page 907).

error

The error string to display.

explanation

The explanation string to display. May be `NULL` or empty to display no explanation.

param

The parameter block describing how to create the alert. May be `NULL`.

notifyTarget

The event target to be notified when the user dismisses the sheet. The caller should install an event handler on this target for the `kEventProcessCommand` event. May be `NULL` if the caller does not need the command event to be sent to any target. For more information, see the Discussion below.

outSheet

A pointer to a variable that, on return, refers to the new alert.

Return Value

A result code. See "Dialog Manager Result Codes" (page 916).

Discussion

This function should be used in conjunction with `ShowSheetWindow` (page 1958). After `CreateStandardSheet` returns, the alert is still invisible. `ShowSheetWindow` will show the alert as a sheet and then return. Events in the sheet are handled asynchronously; the application should be prepared for the sheet window to be part of its window list while running its own event loop.

When a button in the sheet is pressed, the event target passed to `CreateStandardSheet` will receive a command event with one of the following commands: `kHICommandOK`, `kHICommandCancel`, or `kHICommandOther`. The system takes care of closing the sheet and releasing the alert. Therefore after using `ShowSheetWindow` (page 1958), you do not need to call `HideSheetWindow` (page 1872) or `DisposeDialog` (page 847).

Typically, the event target you pass in the *notifyTarget* parameter is the parent window of the sheet. A standard practice is to install a command event handler on the parent window just before showing the sheet window, and to remove the handler from the parent window after the sheet has been closed.

It is also possible to install a handler on the sheet window itself, in which case you would pass `NULL` in the *notifyTarget* parameter, since the command event is automatically sent to the sheet window already. If you install a handler on the sheet itself, make sure to return `eventNotHandledErr` from your handler, because `CreateStandardSheet` installs its own handler on the sheet and that handler must be allowed to run to close the sheet window and release the alert.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Related Sample Code
QTCarbonShell

Declared In
`Dialogs.h`

DialogCopy

Handles the Copy editing command when a dialog box containing an edit text item is active.

```
void DialogCopy (
   DialogRef theDialog
);
```

Parameters

`theDialog`

A pointer to a dialog structure.

Discussion
The `DialogCopy` function checks whether the dialog box has any edit text items and, if so, applies the TextEdit function `TECopy` to the selected text. Your application should test whether a dialog box is the frontmost window when handling mouse-down events in the Edit menu and then call this function when appropriate.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Dialogs.h`

DialogCut

Handles the Cut editing command when a dialog box containing an edit text item is active.

```
void DialogCut (
   DialogRef theDialog
);
```

Parameters

`theDialog`

On input, a pointer to a dialog structure.

Discussion
The `DialogCut` function checks whether the dialog box has any edit text items and, if so, applies the TextEdit function `TECut` to the selected text. Your application should test whether a dialog box is the frontmost window when handling mouse-down events in the Edit menu and then call this function when appropriate.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Dialogs.h`

DialogDelete

Handles the Delete editing command when a dialog box containing an edit text item is active.

```
void DialogDelete (
   DialogRef theDialog
);
```

Parameters

theDialog

A pointer to a dialog structure.

Discussion

The `DialogDelete` function checks whether the dialog box has any edit text items and, if so, applies the TextEdit function `TEDelete` to the selected text. Your application should test whether a dialog box is the frontmost window when handling mouse-down events in the Edit menu and then call this function when appropriate.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Dialogs.h`

DialogPaste

Handles the Paste editing command when a dialog box containing an edit text item is active.

```
void DialogPaste (
   DialogRef theDialog
);
```

Parameters

theDialog

On input, a pointer to a dialog structure.

Discussion

The `DialogPaste` function checks whether the dialog box has any edit text items and, if so, applies the TextEdit function `TEPaste` to the selected edit text item. Your application should test whether a dialog box is the frontmost window when handling mouse-down events in the Edit menu and then call this function when appropriate.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Dialogs.h`

DialogSelect

Handles most of the events inside the dialog box after you have determined that an event related to an active modeless dialog box or an active movable modal dialog box has occurred.

```
Boolean DialogSelect (
   const EventRecord *theEvent,
   DialogRef *theDialog,
   DialogItemIndex *itemHit
);
```

Parameters

theEvent

A pointer to an event structure returned by an Event Manager function such as `WaitNextEvent`.

theDialog

A pointer to a dialog structure for the dialog box where the event occurred.

itemHit

A pointer to a short integer. `DialogSelect` returns a number corresponding to the position of an item within the item list resource of the active dialog box.

Return Value

A Boolean value. If the event is an activate or update event for a dialog box, `DialogSelect` activates or updates it and returns `false`. If the event involves an enabled item, `DialogSelect` returns a function result of `true`.

Discussion

The `DialogSelect` function handles most of the events relating to a dialog box. Through its `itemHit` parameter, it returns the item number of the item selected by the user. Through the parameter `theDialog`, it returns a pointer to the dialog structure for the dialog box where the event occurred. In all other cases, the `DialogSelect` function returns `false`. When `DialogSelect` returns `true`, do whatever is appropriate as a response to the event involving that item in that particular dialog box; when it returns `false`, do nothing.

Generally, only controls should be enabled in a dialog box; therefore your application should normally respond only when `DialogSelect` returns `true` after the user clicks an enabled control, such as the OK button.

The `DialogSelect` function first obtains a pointer to the window containing the event. For update and activate events, the event structure contains the window pointer. For other types of events, `DialogSelect` calls the Window Manager function `FrontWindow`. The Dialog Manager then makes this window the current graphics port by calling the QuickDraw function `SetPort`. Then `DialogSelect` prepares to handle the event by setting up text information if there are any edit text items in the active dialog box.

When an item is a control defined in a control resource, the rectangle added to the update region is the rectangle defined in the control resource, not the display rectangle defined in the item list resource.

The `DialogSelect` function handles the event as follows:

- In response to an activate or update event for the dialog box, `DialogSelect` activates or updates its window and returns false.
- If a key-down event or an auto-key event occurs and there's an edit text item in the dialog box, `DialogSelect` uses `TextEdit` to handle text entry and editing, and `DialogSelect` returns true for a function result. Through its `itemHit` parameter, `DialogSelect` returns the item number.
- If a key-down event or an auto-key event occurs and there's no edit text item in the dialog box, `DialogSelect` returns `false`.
- If the user presses the mouse button while the cursor is in an edit text item, `DialogSelect` responds to the mouse activity as appropriate—that is, either by displaying an insertion point or by selecting text. If the edit text item is disabled, `DialogSelect` returns `false`. If the edit text item is enabled,

`DialogSelect` returns `true` and through its `itemHit` parameter returns the item number. Normally, edit text items are disabled, and you use the `GetDialogItemText` function to read the information in the items only after the OK button is clicked.

- If the user presses the mouse button while the cursor is in a control, `DialogSelect` tracks the control. If the user releases the mouse button while the cursor is in an enabled control, `DialogSelect` returns `true` for a function result and through its `itemHit` parameter returns the control's item number. Your application should respond appropriately—for example, by performing a command after the user clicks the OK button.
- If the user presses the mouse button while the cursor is in any other enabled item in the dialog box, `DialogSelect` returns `true` for a function result and through its `itemHit` parameter returns the item's number. Generally, only controls should be enabled. If your application creates a complex control—such as one that measures how far a dial is moved—your application must handle mouse events in that item before passing the event to `DialogSelect`.
- If the user presses the mouse button while the cursor is in a disabled item, or if it is in no item, or if any other event occurs, `DialogSelect` does nothing.
- If the event isn't one that `DialogSelect` specifically checks for (if it's a null event, for example), and if there's an edit text item in the dialog box, `DialogSelect` calls the TextEdit function `TEIdle` to make the insertion point blink.

Special Considerations

Because `DialogSelect` handles only mouse-down events in a dialog box and key-down events in a dialog box's edit text items, you should handle other events as appropriate before passing them to `DialogSelect`. Likewise, when `DialogSelect` calls the Control Manager function `TrackControl` , it does not allow you to specify any action function necessary for anything more complex than a button, radio button, or checkbox. If you need a more complex control (for example, one that measures how long the user holds down the mouse button or how far the user has moved an indicator), you can create your own control or a picture or an application-defined item that draws a control-like object in your dialog box. You must then test for and respond to those events yourself.

Within dialog boxes, use the functions `DialogCut` (page 844), `DialogCopy` (page 844), `DialogPaste` (page 845), and `DialogDelete` (page 845) to support Cut, Copy, Paste, and Clear commands in edit text boxes.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Dialogs.h`

DisposeDialog

Dismisses a dialog box for which the Dialog Manager supplies memory and disposes of the dialog structure.

```
void DisposeDialog (
   DialogRef theDialog
);
```

Parameters

`theDialog`

A pointer to a dialog structure.

Return Value

Discussion
The `DisposeDialog` function calls `CloseDialog` (page 840) and, in addition, releases the memory occupied by the dialog box's item list resource and the dialog structure. Call `DisposeDialog` when you're done with a dialog box if you pass `null` in the `dStorage` parameter to `GetNewDialog` (page 858) , `NewColorDialog` (page 868) , or `NewDialog` (page 870).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Available in Mac OS X v10.0 and later.

Declared In

Dialogs.h

DrawDialog

Draws the entire contents of a specified dialog box.

```
void DrawDialog (
   DialogRef theDialog
);
```

Parameters

theDialog

A pointer to a dialog structure.

Return Value

Discussion

The DrawDialog function draws all dialog items, calls the Control Manager function DrawOneControl to draw all controls, and calls the TextEdit function TEUpdate to update all static and edit text items and to draw their display rectangles. The DrawDialog function also calls the application-defined items' draw functions if the items' rectangles are within the update region.

DialogSelect (page 845) , ModalDialog (page 865) , Alert (page 834) , StopAlert (page 889) , NoteAlert (page 874) , and CautionAlert (page 839) use DrawDialog automatically. If you use GetNewDialog (page 858) to create a dialog box but don't use any of these other Dialog Manager functions when handling events in the dialog box, you can use DrawDialog to redraw the contents of the dialog box when it's visible. If the dialog box is invisible, first use the Window Manager function ShowWindow and then use DrawDialog.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

Dialogs.h

FindDialogItem

Determines the item number of an item at a particular location in a dialog box.

```
DialogItemIndexZeroBased FindDialogItem (
   DialogRef theDialog,
   Point thePt
);
```

Parameters

theDialog

A pointer to a dialog structure.

thePt

The point (in local coordinates) where the mouse-down event occurred.

Return Value

When an embedding hierarchy is established, the `FindDialogItem` function returns the deepest control selected by the user corresponding to the point specified in the `thePt` parameter. When an embedding hierarchy does not exist, `FindDialogItem` performs a linear search of the item list resource and returns a number corresponding to the hit item's position in the item list resource. For example, it returns 0 for the first item in the item list, 1 for the second, and 2 for the third. If the mouse is not over a dialog item, `FindDialogItem` returns –1. See the description of the `DialogItemIndexZeroBased` data type.

Discussion

The function `FindDialogItem` is useful for changing the cursor when the user moves the cursor over a particular item.

To get the proper item number before calling the `GetDialogItem` (page 852) function or the `SetDialogItem` (page 881) function, add 1 to the result of `FindDialogItem`, as shown here:

```
theItem = FindDialogItem(theDialog, thePoint) + 1;
```

Note that `FindDialogItem` returns the item number of disabled items as well as enabled items.

Version Notes

This function was changed with Appearance Manager 1.0 to support embedding hierarchies.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Dialogs.h`

GetAlertStage

Determines the stage of the last occurrence of an alert.

```
SInt16 GetAlertStage (
   void
);
```

Parameters

Return Value

A number from 0 to 3 as the stage of the last occurrence of an alert.

Discussion

You can use the `GetAlertStage` function to ensure that your application deactivates the active window only if an alert box is to be displayed at that stage.

Carbon Porting Notes

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Dialogs.h`

GetDialogCancelItem

Returns the item number of the cancel item previously set with `SetDialogCancelItem`.

```
SInt16 GetDialogCancelItem (
   DialogRef dialog
);
```

Parameters

dialog
On input, a pointer to the dialog structure for the dialog box whose cancel item you want to get.

Return Value
The item number of the cancel item previously set with the `SetDialogCancelItem` (page 878) function.

Discussion
If you don't explicitly call `GetDialogCanceltItem`, the standard filter function treats item 2 as the cancel item.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Dialogs.h`

GetDialogDefaultItem

Returns the item number of the default item currently set for the standard filter function.

```
SInt16 GetDialogDefaultItem (
   DialogRef dialog
);
```

Parameters

dialog
On input, a pointer to the dialog structure for the dialog box whose default item you want to get.

Return Value
The item number of the default item currently set for the standard filter function.

Discussion
If you don't explicitly call `GetDialogDefaultItem`, the standard filter function treats item 1 as the default item.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Dialogs.h`

GetDialogFromWindow

```
DialogRef GetDialogFromWindow (
   WindowRef window
);
```

Parameters

window

Return Value
See the description of the `DialogRef` data type.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Dialogs.h`

GetDialogItem

Obtains a handle to a dialog item.

```
void GetDialogItem (
   DialogRef theDialog,
   DialogItemIndex itemNo,
   DialogItemType *itemType,
   Handle *item,
   Rect *box
);
```

Parameters

theDialog
A pointer to the dialog box to examine.

itemNo
The position of the item in the dialog box's item list resource use `FindDialogItem` (page 849) to determine this value.

itemType
A pointer to a short value. On return, the value identifies the item type of the dialog item requested in the `itemNo` parameter.

item
A pointer to an item handle. On return the handle refers to the item specified in the `itemNo` parameter or, for application-defined draw functions, a pointer (coerced to a handle) to the draw function.

box

A pointer to a rectangle. On return, the rectangle specifies the display rectangle (described in coordinates local to the dialog box), for the item specified in the `itemNo` parameter.

Return Value

Discussion

The `GetDialogItem` function produces the item type, a handle to the item (or, for application-defined draw functions, the function pointer), and the display rectangle for a specified item in an item list resource. When a control hierarchy is present in the dialog box, `GetDialogItem` gets the appropriate information (for example, a text handle) from the controls. If you wish to get a control handle for a dialog item in an embedding hierarchy, see `GetDialogItemAsControl` (page 853).

You should call `GetDialogItem` before calling functions such as `SetDialogItemText` (page 882) that need a handle to a dialog item.

See also the function `SetDialogItem` (page 881).

Version Notes

This function was changed with Appearance Manager 1.0 to support retrieving item information from controls.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Related Sample Code

ictbSample

Declared In

`Dialogs.h`

GetDialogItemAsControl

Obtains the control handle for a dialog item in an embedding hierarchy.

```
OSErr GetDialogItemAsControl (
   DialogRef inDialog,
   DialogItemIndex inItemNo,
   ControlRef *outControl
);
```

Parameters

inDialog

A pointer to the dialog box to examine.

inItemNo

The position of an item in the dialog box's item list.

outControl

A pointer to a control handle that, on return, refers to the embedded control.

Return Value

A result code. See "Dialog Manager Result Codes" (page 916). The Control Manager result code `errItemNotControl` indicates that the specified dialog item is not a control.

Discussion
When an embedding hierarchy is established, `GetDialogItemAsControl` produces a handle to the embedded controls (except Help items). It should be used instead of `GetDialogItem` (page 852) when an embedding hierarchy is established.

Version Notes
This function is available with Appearance Manager 1.0 and later.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Dialogs.h`

GetDialogItemText

Obtains the text string contained in an edit text or a static text item.

```
void GetDialogItemText (
   Handle item,
   Str255 text
);
```

Parameters

item
On input, a handle to an edit text or a static text item. To get this handle, call the "Alert Button Constants" (page 904) function.

text
On output, a string containing the text of the item that is specified by the `item` parameter.

Discussion
The `GetDialogItemText` function will only return the first 255 characters in an edit text item.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Dialogs.h`

GetDialogKeyboardFocusItem

Returns the item number of the editable text item in a dialog box that has keyboard focus.

```
SInt16 GetDialogKeyboardFocusItem (
   DialogRef dialog
);
```

Parameters

dialog
On input, a pointer to the dialog structure for the dialog box whose currently focused item you want to identify.

Return Value
The number of the editable text item in a dialog box that currently has keyboard focus.

Discussion
When the Appearance Manager is available and an embedding hierarchy is established, you should call the Control Manager function `GetKeyboardFocus` instead of `GetDialogKeyboardFocusItem` to return the item number of the item in a dialog box that has keyboard focus.

The `GetDialogKeyboardFocusItem` function accesses the `edit` field in the dialog structure. `GetDialogKeyboardFocusItem` should only be called when there is no embedding hierarchy in the dialog box.

Version Notes
This function is not recommended with Appearance Manager 1.0 and later.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Dialogs.h`

GetDialogPort

```
CGrafPtr GetDialogPort (
   DialogRef dialog
);
```

Parameters
dialog

Return Value
See the QuickDraw Manager documentation for a description of the `CGrafPtr` data type.

Discussion

Special Considerations

Version Notes

Carbon Porting Notes

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

GetDialogTextEditHandle

```
TEHandle GetDialogTextEditHandle (
   DialogRef dialog
);
```

Parameters

dialog

Return Value

See the TextEdit documentation for a description of the `TEHandle` data type.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Dialogs.h`

GetDialogTimeout

Obtains the original countdown duration, the time remaining, and the item selection to be simulated for a specified modal dialog box.

```
OSStatus GetDialogTimeout (
   DialogRef inDialog,
   DialogItemIndex *outButtonToPress,
   UInt32 *outSecondsToWait,
   UInt32 *outSecondsRemaining
);
```

Parameters

inDialog

A pointer to the dialog box to be examined.

outButtonToPress

On input, a pointer to a signed 16-bit integer. On return, a value representing the number within the item list of the item that is to be selected. You may pass `NULL` for the `outButtonToPress` parameter if you do not desire this information.

outSecondsToWait

On input, a pointer to an unsigned 32-bit integer. On return, a value specifying the number of seconds that were originally set to elapse before the Dialog Manager simulates an item selection. You may pass `NULL` for the `outSecondsToWait` parameter if you do not desire this information.

outSecondsRemaining

On input, a pointer to an unsigned 32-bit integer. On return, a value specifying the number of seconds remaining before the Dialog Manager simulates an item selection. You may pass `NULL` for the `outSecondsRemaining` parameter if you do not desire this information.

Return Value

A result code. See "Dialog Manager Result Codes" (page 916).

Discussion

Also see the function `SetDialogTimeout` (page 882).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Dialogs.h`

GetDialogWindow

```
WindowRef GetDialogWindow (
   DialogRef dialog
);
```

Parameters
dialog

Return Value
See the QuickDraw Manager documentation for a description of the `WindowRef` data type.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
QTCarbonShell

Declared In
`Dialogs.h`

GetModalDialogEventMask

Obtains the events to be received by the `ModalDialog` function.

```
OSStatus GetModalDialogEventMask (
   DialogRef inDialog,
   EventMask *outMask
);
```

Parameters
inDialog
A pointer to the dialog box for which you wish to obtain the event mask.

outMask
On input, a pointer to a unsigned 16-bit integer of type `EventMask`. On return, your application may test the bits of this value to determine the event(s) that the dialog box is currently set to receive.

Return Value
A result code. See "Dialog Manager Result Codes" (page 916).

Discussion
Also see the function `SetModalDialogEventMask` (page 884).

Version Notes
This function is available with Mac OS 8.5 and later.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Dialogs.h`

GetNewDialog

Creates a dialog box from a resource-based description.

```
DialogRef GetNewDialog (
   SInt16 dialogID,
   void *dStorage,
   WindowRef behind
);
```

Parameters

dialogID

The resource ID of a dialog resource and an extended dialog resource. The resource IDs for both resources must be identical. If the dialog resource is missing, the Dialog Manager returns to your application without creating the requested dialog box. See `'DLOG'` and `'dlgx'` for a description of the dialog resource and the extended dialog resource, respectively.

dStorage

A pointer to the memory for the dialog structure. If you set this parameter to `null`, the Dialog Manager automatically allocates a nonrelocatable block in your application heap.

behind

A pointer to the window behind which the dialog box is to be placed on the desktop. Set this parameter to the window pointer `(WindowPtr)-1L` to bring the dialog box in front of all other windows.

Return Value
Returns a pointer to a dialog box. If none was created, returns `null`. See the description of the `DialogRef` data type.

Discussion
The `GetNewDialog` function creates a dialog structure from information in a dialog resource and an extended dialog resource (if it exists) and returns a pointer to the dialog structure. You can use this pointer with Window Manager or QuickDraw functions to manipulate the dialog box. If the dialog resource specifies that the dialog box should be visible, the dialog box is displayed. If the dialog resource specifies that the dialog box should initially be invisible, use the Window Manager function `ShowWindow` to display the dialog box.

The dialog resource contains a resource ID that specifies both the dialog box's item list (`'DITL'`) resource and its dialog font table (`'dftb'`) resource. After calling the Resource Manager to read these resources into memory (if they are not already in memory), `GetNewDialog` makes a copy of the `'DITL'` resource and uses that copy; thus you may have several dialog boxes with identical items.

If you supply a dialog color table (`'dctb'`) resource with the same resource ID as the dialog resource, `GetNewDialog` uses `NewColorDialog` and returns a pointer to a color graphics port. If no dialog color table resource is present, `GetNewDialog` uses `NewDialog` to return a pointer to a black-and-white graphics port, although system software draws the window frame using the system's default colors. However, if the Appearance Manager is available and the `kDialogFlagsUseThemeBackground` feature bit of the extended dialog resource is set, then the `'dctb'` resource is ignored and a color graphics port is created.

Special Considerations

The `GetNewDialog` function doesn't release the memory occupied by the resources. Therefore, your application should mark all resources used for a dialog box as purgeable or you should release the resources yourself.

If either the dialog resource or the item list resource can't be read, the function result is `null`; your application should test to ensure that `null` is not returned before performing any more operations with the dialog box or its items.

As with all other windows, dialogs are created with an update region equal to their port rectangle. However, if the dialog's `'DLOG'` resource specifies that the dialog be made visible upon creation, the Dialog Manager draws the controls immediately and calls `ValidRgn` for each of their bounding rectangles. Other items are not drawn until the first update event for the dialog box is serviced.

If you need to display an alert box while your application is running in the background or is otherwise invisible to the user, call `AEInteractWithUser`

Version Notes

This function was changed with Appearance Manager 1.0 to support the extended dialog (`'dlgx'`) resource and the dialog font table (`'dftb'`) resource.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

GetStandardAlertDefaultParams

Fills out an `AlertStdCFStringAlertParamRec` with default values: - not movable - no help button - default button with title "OK" - no cancel or other buttons.

```
OSStatus GetStandardAlertDefaultParams (
   AlertStdCFStringAlertParamPtr param,
   UInt32 version
);
```

Parameters

param

The parameter block to initialize.

version

The parameter block version; pass kStdCFStringAlertVersionOne.

Return Value

A result code. See "Dialog Manager Result Codes" (page 916).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Related Sample Code

QTCarbonShell

Declared In

`Dialogs.h`

GetStdFilterProc

Returns a pointer to the standard filter function.

```
OSErr GetStdFilterProc (
   ModalFilterUPP *theProc
);
```

Parameters

theProc

A universal procedure pointer to a filter function. On output, the Dialog Manager provides a pointer to its standard filter function.

Return Value

A result code. See "Dialog Manager Result Codes" (page 916).

Discussion

The `GetStdFilterProc` function gets a pointer to the standard filter function. You must dispatch the function yourself using the CallModalFilterProc macro; see `ModalFilterProcPtr` (page 891).

You normally don't need to use `GetStdFilterProc` unless your development environment doesn't include the code required to support `StdFilterProc` (page 888).

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In
Dialogs.h

HideDialogItem

Makes an item in a dialog box invisible.

```
void HideDialogItem (
   DialogRef theDialog,
   DialogItemIndex itemNo
);
```

Parameters

theDialog

A pointer to a dialog structure.

itemNo

A number corresponding to the position of an item in the dialog box's item list resource.

Return Value

Discussion

The HideDialogItem function hides the item specified by itemNo by giving it a display rectangle that's off the screen. Specifically, if the left coordinate of the item's display rectangle is less than 8192 (hexadecimal 0x2000), HideDialogItem adds 16,384 (hexadecimal 0x4000) to both the left and right coordinates of the rectangle. If the item is already hidden (that is, if the left coordinate is greater than 8192), HideDialogItem does nothing. To redisplay an item that's been hidden by HideDialogItem, you can use the ShowDialogItem function.

Special Considerations

If your application needs to display a number of dialog boxes that are similar except for one or two items, it's generally easier to modify the common elements using the AppendDITL (page 836) and ShortenDITL (page 885) functions than to use the HideDialogItem and ShowDialogItem (page 885) functions.

If you hid an edit text item, the next visible edit text item will be highlighted.

userUPP

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Dialogs.h`

IsDialogEvent

Determines whether a modeless dialog box or a movable modal dialog box is active when an event occurs.

```
Boolean IsDialogEvent (
   const EventRecord *theEvent
);
```

Parameters

theEvent

A pointer to an event structure returned by an Event Manager function such as `WaitNextEvent`.

Return Value

A Boolean value. If any event, including a null event, occurs when your dialog box is active, `IsDialogEvent` returns `true`; otherwise, it returns `false`.

Discussion

When `IsDialogEvent` returns `false`, pass the event to the rest of your event-handling code. When `IsDialogEvent` returns `true`, pass the event to `DialogSelect` (page 845) after testing for the events that `DialogSelect` does not handle.

A dialog structure includes a window structure. When you use the `GetNewDialog` (page 858) , `NewDialog` (page 870) , `NewFeaturesDialog` (page 871) , or `NewColorDialog` (page 868) functions to create a dialog box, the Dialog Manager sets the `windowKind` field in the window structure to `dialogKind`. To determine whether the active window is a dialog box, `IsDialogEvent` checks the `windowKind` field.

Before passing the event to `DialogSelect`, you should perform the following tests whenever `IsDialogEvent` returns `true` :

- Check whether the event is a key-down event for the Return, Enter, Esc, or Command-period keystrokes. When the user presses the Return or Enter key, your application should respond as if the user had clicked the default button; when the user presses Esc or Command-period, your application should respond as if the user had clicked the Cancel button. Use the Control Manager function `HiliteControl` to highlight the applicable button for 8 ticks.
- At this point, you may also want to check for and respond to any special events that you do not wish to pass to `DialogSelect` (page 845) or that require special processing before you pass them to `DialogSelect`. You would need to do this, for example, if the dialog box needs to respond to disk-inserted events.
- Check whether the event is an update event for a window other than the dialog box and, if it is, update your window.
- For complex items that you create, such as pictures or application-defined items that emulate complex controls, test for and respond to mouse events inside those items as appropriate. When `DialogSelect` calls the Control Manager function `TrackControl`, it does not allow you to specify the action function necessary for anything more complex than a button, radio button, or checkbox. If you need a more complex control (for example, one that measures how long the user holds down the mouse button or how far the user has moved an indicator), you can create your own control or a picture or an application-defined item that draws a control-like object in your dialog box. You must then test for and respond to those events yourself.

If your application uses `IsDialogEvent` to help handle events when you display a movable modal dialog box, perform the following additional tests before passing events to `DialogSelect` :

- Test for mouse-down events in the title bar of the movable modal dialog box and respond by dragging the dialog box accordingly.

- Test for and respond to mouse-down events in the Apple menu and, if the movable modal dialog box includes edit text items, in the Edit menu. (You should disable all other menus when you display a movable modal dialog box.)
- Play the system alert sound for every other mouse-down event outside the movable modal dialog box.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Dialogs.h`

ModalDialog

Handles events while your application displays a modal or movable modal dialog box.

```
void ModalDialog (
   ModalFilterUPP modalFilter,
   DialogItemIndex *itemHit
);
```

Parameters

`modalFilter`

A universal procedure pointer for an event filter function. For modal dialog boxes, you can specify `null` if you want to use the standard event-handling function. For movable modal dialog boxes, you should specify your own event filter function.

`itemHit`

A pointer to a short integer. After receiving an event involving an enabled item, `ModalDialog` produces a number representing the position of the selected item in the active dialog box's item list resource.

Return Value

Discussion
Call the `ModalDialog` function immediately after displaying a modal or movable modal dialog box. Your application should continue calling `ModalDialog` until the user dismisses your dialog.

For modal dialogs, the `ModalDialog` function repeatedly handles events until an event involving an enabled dialog box item—such as a click in a radio button, for example—occurs. If the event is a mouse-down event outside the content region of the dialog box, `ModalDialog` plays the system alert sound and gets the next event.

For movable modal dialogs, if the `kDialogFlagsHandleMovableModal` feature bit in the extended dialog resource is set, the `ModalDialog` function will handle all standard movable modal user interactions, such as dragging a dialog box by its title bar and allowing the user to switch into another application. However, a difference between the `ModalDialog` function's behavior with movable modal and modal dialogs is that, with movable modal dialogs, your event filter function receives all events. If you want the Dialog Manager to assist you in handling events in movable modal dialog boxes, call `GetStdFilterProc` and `StdFilterProc`.

For events inside the dialog box, `ModalDialog` passes the event to the event filter function pointed to in the `modalFilter` parameter before handling the event. When the event filter returns `false`, `ModalDialog` handles the event. If the event filter function handles the event, returning `true`, `ModalDialog` performs no more event handling.

If you set the `modalFilter` parameter to `null`, the standard event filter function is executed. The standard event filter function checks whether

- the user has pressed the Enter or Return key and, if so, returns the item number of the default button
- the user has pressed the Escape key or Command-period and, if so, returns the item number of the Cancel button
- the cursor is over an editable text box, and optionally changes the cursor to an I-beam whenever this is the case

If you set the `modalFilter` parameter to point to your own event filter function, that function can use the standard filter function to accomplish the above tasks. (To do so, you can call `GetStdFilterProc`, and dispatch the event to the standard filter function yourself, or you can call `StdFilterProc`, which obtains a `ModalFilterUPP` for the standard filter function and then dispatches the function.) Additionally, your own event filter function should also

- handle update events, so that background processes can receive processor time, and return `false`
- return `false` for all events that your event filter function doesn't handle

You can also use your event filter function to test for and respond to keyboard equivalents and more complex events—for instance, the user dragging the cursor within an application-defined item. You can use your same event filter function in most or all of your alert and modal dialog boxes.

If the event filter function does not handle the event (returning `false`), `ModalDialog` handles the event as follows:

- In response to an activate or update event for the dialog box, `ModalDialog` activates or updates its window.
- If the user presses the mouse button while the cursor is in an editable text item, `ModalDialog` responds to the mouse activity as appropriate—that is, either by displaying an insertion point or by selecting text. If a key-down event occurs and there's an editable text item, `ModalDialog` uses TextEdit to handle text entry and editing automatically. If the editable text item is enabled, `ModalDialog` produces its item number after it receives either the mouse-down or key-down event. Normally, editable text items are disabled, and you use the `GetDialogItemText` function to read the information in the items only after the user clicks the OK button.
- If the user presses the mouse button while the cursor is in a control, `ModalDialog` calls the Control Manager function `TrackControl`. If the user releases the mouse button while the cursor is in an enabled control, `ModalDialog` produces the control's item number. Your application should respond appropriately—for example, by performing a command after the user clicks the OK button.
- If the user presses the mouse button while the cursor is in any other enabled item in the dialog box, `ModalDialog` produces the item's number, and your application should respond appropriately. Generally, only controls should be enabled. If your application creates a control more complex than a button, radio button, or checkbox, your application must handle events inside that item with your event filter function.
- If the user presses the mouse button while the cursor is in a disabled item or in no item, or if any other event occurs, `ModalDialog` does nothing.

Special Considerations

The `ModalDialog` function traps all events. This prevents your event loop from receiving activate events for your windows. Thus, if one of your application's windows is active when you use `GetNewDialog` to create a modal dialog box, you must explicitly deactivate that window before displaying the modal dialog box.

When `ModalDialog` calls the Control Manager function `TrackControl`, it does not allow you to specify the action function necessary for anything more complex than a button, radio button, or checkbox. If you need a more complex control, you can create your own control, a picture, or an application-defined item that draws a control-like object in your dialog box. You must then provide an event filter function that appropriately handles events in that item.

Version Notes
This function was changed with Appearance Manager 1.0 to handle events for movable modal dialogs.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
ictbSample

Declared In
`Dialogs.h`

MoveDialogItem

Moves a dialog item to a specified location in a window.

```
OSErr MoveDialogItem (
   DialogRef inDialog,
   DialogItemIndex inItemNo,
   SInt16 inHoriz,
   SInt16 inVert
);
```

Parameters

inDialog
A pointer to the dialog box containing the item to move.

inItemNo
The position of the item in the dialog box's item list resource use `FindDialogItem` (page 849) to determine this value.

inHoriz
The new horizontal coordinate for the dialog item.

inVert
The new vertical coordinate for the dialog item.

Return Value
A result code. See "Dialog Manager Result Codes" (page 916).

Discussion
The `MoveDialogItem` function moves a dialog item to a specified location in a window. `MoveDialogItem` ensures that if the item is a control, the control rectangle and the dialog item rectangle (maintained by the Dialog Manager) are always the same.

Version Notes
This function is available with Appearance Manager 1.0 and later.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Dialogs.h`

NewColorDialog

Creates a dialog box from information passed in memory.

```
DialogRef NewColorDialog (
   void *dStorage,
   const Rect *boundsRect,
   ConstStr255Param title,
   Boolean visible,
   SInt16 procID,
   WindowRef behind,
   Boolean goAwayFlag,
   SRefCon refCon,
   Handle items
);
```

Parameters

dStorage

On input, a pointer to the memory for the dialog structure. If you set this parameter to `null`, the Dialog Manager automatically allocates a nonrelocatable block in your application heap.

boundsRect

On input, a pointer to a rectangle, given in global coordinates, that determines the size and position of the dialog box; these coordinates specify the upper-left and lower-right corners of the dialog box.

title

On input, a text string used for the title of a modeless or movable modal dialog box. You can specify an empty string (not `null`) for a title bar that contains no text.

visible

On input, a flag that specifies whether the dialog box should be drawn on the screen immediately. If you set this parameter to `false`, the dialog box is not drawn until your application uses the Window Manager function `ShowWindow` to display it.

procID

On input, the window definition ID for the type of dialog box, specified with constants defined by the Window Manager. Use the `kWindowModalDialogProc` constant to specify modal dialog boxes, the `kWindowDocumentProc` constant to specify modeless dialog boxes, and the `kWindowMovableModalDialogProc` constant to specify movable modal dialog boxes.

behind

On input, a pointer to the window behind which the dialog box is to be placed on the desktop. Set this parameter to the window pointer `(WindowPtr)-1L` to bring the dialog box in front of all other windows.

goAwayFlag

On input, a flag to specify whether a modeless dialog box can have a close box in its title bar when the dialog box is active. If you set this parameter to `true`, the modeless dialog box has a close box in its title bar when the window is active.

refCon

On input, a value that the Dialog Manager uses to set the `refCon` field of the dialog box's window structure. Your application may store any value here for any purpose. For example, your application can store a number that represents a dialog box type, or it can store a handle to a structure that maintains state information about the dialog box. You can use the Window Manager function `SetWRefCon` at any time to change this value in the dialog structure for a dialog box, and you can use the `GetWRefCon` function to determine its current value.

items

On input, a handle to an item list resource for the dialog box. You can get the handle by calling the Resource Manager function `GetResource` to read the item list resource into memory. Use the Memory Manager function `HNoPurge` to make the handle unpurgeable while you use it or use the Operating System utility function `HandToHand` to make a copy of the handle and use the copy.

Return Value

A pointer to the new dialog box. If the function doesn't create a new dialog box, returns `null`. See the description of the `DialogRef` data type.

Discussion

The `NewColorDialog` function creates a dialog box as specified by its parameters. The first eight parameters (`dStorage` through `refCon`) are passed to the Window Manager function `NewWindow`, which creates the dialog box. You can use this pointer with Window Manager or QuickDraw functions to manipulate the dialog box.

The Dialog Manager uses the default window colors for the dialog box. By using the system's default colors, you ensure that your application's interface is consistent with that of the Finder and other applications. However, if you absolutely feel compelled to break from this consistency, you can use the Window Manager function `SetWinColor` to use your own dialog color table resource that specifies colors other than the default colors. Be aware, however, that nonstandard colors in your alert and dialog boxes may initially confuse your users.

The Window Manager creates an auxiliary window structure for the color dialog box. You can access this structure with the Window Manager function `GetAuxWin`. If the dialog box's content color isn't white, it's a good idea to call `NewColorDialog` with the `visible` flag set to `false`. After the color table and color item list resource are installed, use the Window Manager function `ShowWindow` to display the dialog box if it's the frontmost window. If the dialog box is a modeless dialog box that is not in front, use the Window Manager function `ShowHide` to display it.

The `NewColorDialog` function generates an update event for the entire window contents. Thus, with the exception of controls, items aren't drawn immediately. The Dialog Manager calls the Control Manager to draw controls, and the Control Manager draws them immediately. So that the controls won't be drawn twice, the Dialog Manager calls the Window Manager function `ValidRect` for the enclosing rectangle of each control. If you find that there is too great a lag between the drawing of controls and the drawing of other items, try making the dialog box initially invisible and then calling the Window Manager function `ShowWindow` to show it.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Dialogs.h`

NewDialog

Creates a dialog box from information passed in memory.

```
DialogRef NewDialog (
   void *dStorage,
   const Rect *boundsRect,
   ConstStr255Param title,
   Boolean visible,
   SInt16 procID,
   WindowRef behind,
   Boolean goAwayFlag,
   SRefCon refCon,
   Handle items
);
```

Parameters

dStorage

On input, a pointer to the memory for the dialog structure. If you set this parameter to `null`, the Dialog Manager automatically allocates a nonrelocatable block in your application heap.

boundsRect

On input, a pointer to a rectangle, given in global coordinates, that determines the size and position of the dialog box; these coordinates specify the upper-left and lower-right corners of the dialog box.

title

On input, a text string used for the title of a modeless or movable modal dialog box. You can specify an empty string (not `null`) for a title bar that contains no text.

visible

On input, a flag that specifies whether the dialog box should be drawn on the screen immediately. If you set this parameter to `false`, the dialog box is not drawn until your application uses the Window Manager function `ShowWindow` to display it.

procID

On input, the window definition ID for the type of dialog box, specified with constants defined by the Window Manager. Use the `kWindowModalDialogProc` constant to specify modal dialog boxes, the `kWindowDocumentProc` constant to specify modeless dialog boxes, and the `kWindowMovableModalDialogProc` constant to specify movable modal dialog boxes.

behind

On input, a pointer to the window behind which the dialog box is to be placed on the desktop. Set this parameter to the window pointer `(WindowPtr)-1L` to bring the dialog box in front of all other windows.

goAwayFlag

On input, a flag to specify whether a modeless dialog box can have a close box in its title bar when the dialog box is active. If you set this parameter to `true`, the modeless dialog box has a close box in its title bar when the window is active.

refCon

On input, a value that the Dialog Manager uses to set the `refCon` field of the dialog box's window structure. Your application may store any value here for any purpose. For example, your application can store a number that represents a dialog box type, or it can store a handle to a structure that maintains state information about the dialog box. You can use the Window Manager function `SetWRefCon` at any time to change this value in the dialog structure for a dialog box, and you can use the `GetWRefCon` function to determine its current value.

items

On input, a handle to an item list resource for the dialog box. You can get the handle by calling the Resource Manager function `GetResource` to read the item list resource into memory. Use the Memory Manager function `HNoPurge` to make the handle unpurgeable while you use it or use the Operating System utility function `HandToHand` to make a copy of the handle and use the copy.

Return Value
A pointer to the new dialog box. If the function doesn't create a new dialog box, returns `null`. See the description of the `DialogRef` data type.

Discussion
The `NewDialog` function is identical to the `NewColorDialog` function, except that `NewDialog` returns a pointer to a black-and-white graphics port. See the discussion of `NewColorDialog` (page 868) for descriptions of the parameters that you also pass to `NewDialog`.

The `NewDialog` function creates a dialog box as specified by its parameters and returns a pointer to a black-and-white graphics port for the new dialog box. The first eight parameters (`wStorage` through `refCon`) are passed to the Window Manager function `NewWindow`, which creates the dialog box.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Dialogs.h`

NewFeaturesDialog

Creates a dialog box from information passed in memory.

```
DialogRef NewFeaturesDialog (
   void *inStorage,
   const Rect *inBoundsRect,
   ConstStr255Param inTitle,
   Boolean inIsVisible,
   SInt16 inProcID,
   WindowRef inBehind,
   Boolean inGoAwayFlag,
   SRefCon inRefCon,
   Handle inItemListHandle,
   UInt32 inFlags
);
```

Parameters

inStorage

A pointer to the memory for the dialog box. If you set this parameter to `null`, the Dialog Manager automatically allocates a nonrelocatable block in your application heap.

inBoundsRect

A pointer to a rectangle, given in global coordinates, that determines the size and position of the dialog box; these coordinates specify the upper-left and lower-right corners of the dialog box.

inTitle

A pointer to a text string used for the title of a modeless or movable modal dialog box. You can specify an empty string (not `null`) for a title bar that contains no text.

inIsVisible

A flag that specifies whether the dialog box should be drawn on the screen immediately. If you set this parameter to `false`, the dialog box is not drawn until your application uses the Window Manager function `ShowWindow` to display it.

inProcID

The window definition ID for the type of dialog box, specified with constants defined by the Window Manager. Use the `kWindowModalDialogProc` constant to specify modal dialog boxes, the `kWindowDocumentProc` constant to specify modeless dialog boxes, and the `kWindowMovableModalDialogProc` constant to specify movable modal dialog boxes.

inBehind

A pointer to the window behind which the dialog box is to be placed on the desktop. Set this parameter to the window pointer `(WindowPtr)-1L` to bring the dialog box in front of all other windows.

inGoAwayFlag

A Boolean value. If `true`, specifies that an active modeless dialog box has a close box in its title bar.

inRefCon

A value that the Dialog Manager uses to set the `refCon` field of the dialog box's window structure. Your application may store any value here for any purpose. For example, your application can store a number that represents a dialog box type, or it can store a handle to a structure that maintains state information about the dialog box. You can use the Window Manager function `SetWRefCon` at any time to change this value in the dialog structure for a dialog box, and you can use the `GetWRefCon` function to determine its current value.

inItemListHandle

A handle to an item list resource for the dialog box. You can get the handle by calling the Resource Manager function `GetResource` to read the item list resource into memory.

inFlags

An unsigned 32-bit mask specifying the dialog box's Appearance-compliant feature flags see "Dialog Feature Flag Constants" (page 909). To establish an embedding hierarchy in a dialog box, pass `kDialogFlagsUseControlHierarchy` in the `inFlags` parameter.

Return Value

A pointer to the newly created dialog box. If `NewFeaturesDialog` doesn't create a new dialog box, it returns `null`. See the description of the `DialogRef` data type.

Discussion

The `NewFeaturesDialog` function creates a dialog box without using `'DLOG'` or `'dlgx'` resources. Although the `inItemListHandle` parameter specifies an item list (`'DITL'`) resource for the dialog box, the corresponding dialog font table (`'dftb'`) resource is not automatically accessed. You must explicitly set the dialog box's control font style(s) individually.

Version Notes

This function is available with Appearance Manager 1.0 and later.

Carbon Porting Notes

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In
`Dialogs.h`

NoteAlert

Displays an alert box with a note icon and/or plays an alert sound.

```
DialogItemIndex NoteAlert (
   SInt16 alertID,
   ModalFilterUPP modalFilter
);
```

Parameters

alertID

The resource ID of an alert resource and extended alert resource. If the alert resource is missing, the Dialog Manager returns to your application without creating the requested alert. See `'alrx'` for a description of the extended alert resource.

modalFilter

A universal procedure pointer for a filter function that responds to events not handled by the `ModalDialog` (page 865) function. If you set this parameter to `null`, the Dialog Manager uses the standard event filter function.

Return Value
If no alert box is to be drawn at the current alert stage, `NoteAlert` returns –1 otherwise, it creates and displays the alert box and returns the item number of the control selected by the user see "Alert Button Constants" (page 904). See the description of the `DialogItemIndex` data type.

Discussion
The `NoteAlert` function displays an alert box with a note icon in its upper-left corner or, if appropriate for the alert stage, plays an alert sound instead of or in addition to displaying the alert box.

The `NoteAlert` function is the same as the `Alert` (page 834) function except that, before drawing the items in the alert box, `NoteAlert` draws the note icon in the upper-left corner. The note icon has resource ID 1, which you can also specify with the constant `noteIcon`. By default, the Dialog Manager uses the standard note icon from the System file. You can change this icon by providing your own `'ICON'` resource with resource ID 1.

Use a note alert to inform users of a minor mistake that won't have any disastrous consequences if left as is. Usually this type of alert simply offers information, and the user responds by clicking an OK button. Occasionally, a note alert may ask a simple question and provide a choice of responses.

Your application should never draw its own default rings or alert icons. Prior to Mac OS 8, the `NoteAlert` function would only redraw the alert icon and default button ring once and never redraw them on an update event. However, when Appearance is available, alert icons and default rings do redraw when you call `NoteAlert`.

See also the functions `CautionAlert` (page 839) and `StopAlert` (page 889).

Version Notes
This function was changed with Appearance Manager 1.0 to support the extended alert (`'alrx'`) resource.

Carbon Porting Notes

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Dialogs.h`

ParamText

Replaces the text strings in the static text items of your alert or dialog boxes while your application is running.

```
void ParamText (
   ConstStr255Param param0,
   ConstStr255Param param1,
   ConstStr255Param param2,
   ConstStr255Param param3
);
```

Parameters

param0
A text string to substitute for the special string `^0` in the static text items of all subsequently created alert and dialog boxes.

param1
A text string to substitute for the special string `^1` in the static text items of all subsequently created alert and dialog boxes.

param2
A text string to substitute for the special string `^2` in the static text items of all subsequently created alert and dialog boxes.

param3
A text string to substitute for the special string `^3` in the static text items of all subsequently created alert and dialog boxes.

Discussion
The `ParamText` function replaces the special strings `^0` through `^3` in the static text items of all subsequently created alert and dialog boxes with the text strings you pass as parameters. Pass empty strings (not `null`) for parameters not used.

Special Considerations

If the user launches a desk accessory (such as a driver) in your application's partition and the desk accessory calls `ParamText`, it may change the text in your application's dialog box.

You should be very careful about using `ParamText` in modeless dialog boxes. If a modeless dialog box using `ParamText` is onscreen and you display another dialog box or alert box that also uses `ParamText`, both boxes will be affected by the latest call to `ParamText`.

Note that you should try to store text strings in resource files to facilitate translation into other languages; therefore, `ParamText` is best used for supplying text strings, such as document names, that the user specifies. To avoid problems with grammar and sentence structure when you localize your application, you should use `ParamText` to supply only one text string per screen message.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Dialogs.h`

RemoveDialogItems

```
OSStatus RemoveDialogItems (
   DialogRef theDialog,
   DialogItemIndex itemNo,
   DialogItemIndex amountToRemove,
   Boolean disposeItemData
);
```

Parameters
theDialog
itemNo
amountToRemove
disposeItemData

Return Value
A result code. See "Dialog Manager Result Codes" (page 916).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Dialogs.h`

ResetAlertStage

Resets the current alert stage to the first alert stage.

```
void ResetAlertStage (
   void
);
```

Parameters

Return Value

Discussion
The `ResetAlertStage` function resets every alert to a first-stage alert.

Availability
Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In
`Dialogs.h`

RunStandardAlert

Shows and runs a standard alert using a modal dialog loop.

```
OSStatus RunStandardAlert (
   DialogRef inAlert,
   ModalFilterUPP filterProc,
   DialogItemIndex *outItemHit
);
```

Parameters

inAlert
The alert to display. On return, the alert you pass in this parameter has been released and is no longer valid. You should not call `DisposeDialog` (page 847) on this alert.

filterProc
An event filter function for handling events that do not apply to the alert. May be `NULL`.

outItemHit
On exit, contains the item index of the button that was pressed to close the alert.

Return Value
A result code. See "Dialog Manager Result Codes" (page 916).

Discussion
This function displays and runs an alert created by `CreateStandardAlert` (page 842). `RunStandardAlert` handles all user interaction with the alert.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Related Sample Code
QTCarbonShell

Declared In
`Dialogs.h`

SelectDialogItemText

Selects and highlights text contained in an edit text item.

```
void SelectDialogItemText (
   DialogRef theDialog,
   DialogItemIndex itemNo,
   SInt16 strtSel,
   SInt16 endSel
);
```

Parameters

theDialog

On input, a pointer to a dialog structure.

itemNo

On input, a number corresponding to the position of an edit text item in the dialog box's item list resource.

strtSel

On input, a number representing the position of the first character to begin selecting.

endSel

On input, a number representing one position past the last character to be selected.

Discussion

If the item in the `itemNo` parameter is an edit text item that contains text, the `SelectDialogItemText` function sets the text selection range to extend from the character position specified in the `strtSel` parameter up to but not including the character position specified in the `endSel` parameter. The selection range is highlighted unless `strtSel` equals `endSel`, in which case a blinking vertical bar is displayed to indicate an insertion point at that position. If the edit text item doesn't contain text, `SelectDialogItemText` displays the insertion point.

You can select the entire text by specifying the number 0 in the `strtSel` parameter and the number 32767 in the `endSel` parameter.

For example, if the user makes an unacceptable entry in the edit text item, your application can display an alert box reporting the problem and then use `SelectDialogItemText` to select the entire text so it can be replaced by a new entry. Without this function, the user would have to select the item before making the new entry.

Carbon Porting Notes

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Dialogs.h`

SetDialogCancelItem

Sets the cancel item for a dialog box.

```
OSErr SetDialogCancelItem (
   DialogRef theDialog,
   DialogItemIndex newItem
);
```

Parameters

theDialog

On input, a pointer to the dialog structure for the dialog box whose cancel item you want to set.

newItem

On input, the item number of the item you want to set as the cancel item; see "Alert Button Constants" (page 904).

Return Value
A result code. See "Dialog Manager Result Codes" (page 916).

Discussion
If you intend to use the standard filter function, you can first use the functions `SetDialogDefaultItem` and `SetDialogCancelItem` to set the items that the standard filter function will treat as the default and cancel items. You can use `GetDialogDefaultItem` and `GetDialogCancelItem` to determine the dialog item numbers that the standard filter function will treat as the default and cancel items.

If you call the `SetDialogCancelItem` function before you call the standard filter function, the standard filter function automatically interprets Escape and Command-period keypresses to mean that the specified cancel item has been selected.

If you don't explicitly call `SetDialogCancelItem`, the standard filter function treats item 2 as the cancel item.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Dialogs.h`

SetDialogDefaultItem

Sets the default item for a dialog box and draws an appropriate border around the default item.

```
OSErr SetDialogDefaultItem (
   DialogRef theDialog,
   DialogItemIndex newItem
);
```

Parameters

theDialog

On input, a pointer to the dialog structure for the dialog box whose default item you want to set.

newItem

On input, the item number of the item you want to set as the default item.

Return Value
A result code. See "Dialog Manager Result Codes" (page 916).

Discussion
If you call the `SetDialogDefaultItem` function before you call the standard filter function, the standard filter function automatically interprets Return and Enter keypresses to mean that the specified default item has been selected.

If you don't explicitly call `SetDialogDefaultItem`, the standard filter function treats item 1 as the default item.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Dialogs.h`

SetDialogFont

Sets the font used in static and edit text items.

```
void SetDialogFont (
   SInt16 fontNum
);
```

Parameters

`fontNum`

A font ID number. Do not rely on font number constants. Instead, use the Font Manager function `GetFNum` to find the font number to pass in this parameter.

Discussion
For subsequently created dialog and alert boxes, `SetDialogFont` sets the font of the dialog or alert box's graphics port to the specified font. If you don't call this function, the system font is used. The `SetDialogFont` function does not affect titles of controls, which are always displayed in the system font.

Special Considerations

There are a number of caveats regarding the SetDialogFont function:

1. Most importantly, your application will be much easier to localize if you always use the system font in your alert and dialog boxes and never use `SetDialogFont`.
2. The Standard File Package does not always properly calculate the position of the standard file dialog box once this function has been called; for example, the standard file dialog box may be partially obscured by a menu bar.
3. Be aware that this function affects all static text and edit text items in all of the alert and dialog boxes you subsequently display.
4. `SetDialogFont` does not change the font for control titles.
5. You can't use `SetDialogFont` to change the font size or font style.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
Dialogs.h

SetDialogItem

Sets or changes information for a dialog item.

```
void SetDialogItem (
   DialogRef theDialog,
   DialogItemIndex itemNo,
   DialogItemType itemType,
   Handle item,
   const Rect *box
);
```

Parameters

theDialog
A pointer to the dialog box containing the dialog item.

itemNo
The position of the item in the dialog box's item list resource use FindDialogItem (page 849) to determine this value.

itemType
A short value. Pass an item type constant identifying the dialog item specified in the itemNo parameter. When an embedding hierarchy is established, only the kItemDisableBit item type constant is honored.

item
Either a handle to the dialog item specified in the itemNo parameter or, for a custom dialog item, a pointer (coerced to a handle) to an application-defined item drawing function. When an embedding hierarchy is established, the item parameter is ignored unless you pass a universal procedure pointer to an application-defined item draw function.

box
A pointer to the display rectangle (in local coordinates) for the item specified in the itemNo parameter. If you set the control rectangle on an item when an embedding hierarchy is present, SetDialogItem will move and resize the item appropriately for you, on return.

Return Value

Discussion
The SetDialogItem function sets the item specified by the itemNo parameter for the specified dialog box. If an embedding hierarchy exists, however, you cannot change the type or handle of an item, although application-defined item drawing functions can still be set.

See also the function GetDialogItem (page 852).

Version Notes
This function was changed with Appearance Manager 1.0 to work with embedding hierarchies.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
Dialogs.h

SetDialogItemText

Sets the text string for static text and editable text fields.

```
void SetDialogItemText (
   Handle item,
   ConstStr255Param text
);
```

Parameters

item

A handle to an editable text field or static text field. When embedding is on, you should pass in the control handle produced by a call to the function . If embedding is not on, pass in the handle produced by the "Alert Button Constants" (page 904) function.

text

A pointer to a string containing the text to display in the field.

Discussion

The `SetDialogItemText` function sets and redraws text strings for static text and editable text fields. `SetDialogItemText` is useful for supplying a default text string—such as a document name—for an editable text field while your application is running.

Version Notes

This function was changed with Appearance Manager 1.0 to support embedding hierarchies.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Dialogs.h`

SetDialogTimeout

Simulates an item selection in a modal dialog box after a specified amount of time elapses.

```
OSStatus SetDialogTimeout (
   DialogRef inDialog,
   DialogItemIndex inButtonToPress,
   UInt32 inSecondsToWait
);
```

Parameters

inDialog

A pointer to the dialog box for which an item selection is to be simulated.

inButtonToPress

A signed 16-bit integer. Pass a value representing the number (within the item list) of the item that is to be selected.

inSecondsToWait

An unsigned 32-bit integer. Pass a value specifying the number of seconds that are to elapse before the Dialog Manager simulates an item selection. Pass 0 to clear a preexisting timeout value and cease the countdown in progress.

Return Value
A result code. See "Dialog Manager Result Codes" (page 916).

Discussion
Your application calls the `SetDialogTimeout` function each time you wish to start a countdown of the specified duration for a given modal dialog box. When the amount of time specified in the `inSecondsToWait` parameter has elapsed, the Dialog Manager simulates a click on the button specified in the `inButtonToPress` parameter. If your application calls `SetDialogTimeout` again, or if any event is received for the dialog box, the countdown is restarted.

In order to use `SetDialogTimeout` with a given modal dialog box, your application must handle events for the dialog box through the `ModalDialog` function. The Dialog Manager will not simulate an item selection for the dialog box until `ModalDialog` processes an event (including null events).

Also see the function `GetDialogTimeout` (page 856).

Version Notes
This function is available with Mac OS 8.5 and later.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Dialogs.h`

SetDialogTracksCursor

Determines whether the Dialog Manager tracks the cursor's movements and changes the cursor to an I-beam whenever it is over an edit dialog box.

```
OSErr SetDialogTracksCursor (
   DialogRef theDialog,
   Boolean tracks
);
```

Parameters

`theDialog`
On input, a pointer to the dialog structure for the dialog box containing one or more edit text items for which you want the Dialog Manager to track the cursor.

`tracks`
On input, a Boolean value. A value of `true` indicates you want the Dialog Manager to track the cursor's movements and change it to an I-beam whenever the cursor is over an edit dialog box a value of `false` indicates you don't want the Dialog Manager to track the cursor in this manner.

Return Value
A result code. See "Dialog Manager Result Codes" (page 916).

Discussion
You should call SetDialogTracksCursor before you call the standard filter function.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Dialogs.h`

SetModalDialogEventMask

Specifies the events to be received by the `ModalDialog` function.

```
OSStatus SetModalDialogEventMask (
   DialogRef inDialog,
   EventMask inMask
);
```

Parameters

inDialog
A pointer to the dialog box for which you wish to set the event mask.

inMask
The desired mask value(s) for the event(s) you wish the dialog box to receive.

Return Value
A result code. See "Dialog Manager Result Codes" (page 916).

Discussion
Your application can use the `SetModalDialogEventMask` function to specify the events received by the `ModalDialog` function for a given modal dialog box. This allows your application to specify additional events that are not by default received by `ModalDialog`, such as disk-inserted events and operating-system events. If you use `SetModalDialogEventMask` to change the `ModalDialog` function's event mask, you should pass `ModalDialog` a pointer to your own event filter function to handle any added events.

Also see the function `GetModalDialogEventMask` (page 857).

Version Notes
This function is available with Mac OS 8.5 and later.

Carbon Porting Notes

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Dialogs.h`

SetPortDialogPort

```
void SetPortDialogPort (
   DialogRef dialog
);
```

Parameters

dialog

Availability
Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In
`Dialogs.h`

ShortenDITL

Removes items from an existing dialog box while your application is running.

```
void ShortenDITL (
   DialogRef theDialog,
   DialogItemIndex numberItems
);
```

Parameters

theDialog
A pointer to a dialog structure.

numberItems
The number of items to remove (starting from the last item in the item list resource).

Discussion
The `ShortenDITL` function removes the specified number of items from the dialog box. This function is especially useful if several dialog boxes share a single item list resource, because you can use `ShortenDITL` to remove items as necessary for individual dialog boxes.

You typically create an invisible dialog box, call the `ShortenDITL` function, then make the dialog box visible by using the Window Manager function `ShowWindow`. Note that `ShortenDITL` does not automatically resize the dialog box; you can use `AutoSizeDialog` (page 838) or the Window Manager function `SizeWindow` if you need to resize the dialog box.

Special Considerations

The `ShortenDITL` function is available in System 7 and in earlier versions of the Communications Toolbox. Before calling `ShortenDITL`, you should make sure that it is available by using the `Gestalt` function with the `gestaltDITLExtAttr` selector. Test the bit indicated by the `gestaltDITLExtPresent` constant in the `response` parameter. If the bit is set, then `ShortenDITL` is available.

Carbon Porting Notes

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Dialogs.h`

ShowDialogItem

Redisplays an item that has been hidden by HideDialogItem.

```
void ShowDialogItem (
   DialogRef theDialog,
   DialogItemIndex itemNo
);
```

Parameters

theDialog

On input, a pointer to a dialog structure.

itemNo

On input, a number corresponding to the position of an item in the dialog box's item list resource.

Return Value

Discussion

The `ShowDialogItem` function redisplays the item specified in the `itemNo` parameter by restoring the display rectangle the item had prior to `HideDialogItem` (page 861). If the left coordinate of the item's display rectangle is greater than 8192, `ShowDialogItem` subtracts 16,384 from both the left and right coordinates of the rectangle. If the item is already visible (that is, if the left coordinate is less than 8192), `ShowDialogItem` does nothing.

The `ShowDialogItem` function adds the rectangle that contained the item to the update region so that it will be drawn. Note that if the item is a control you define in a control (' `CNTL` ') resource, the rectangle added to the update region is the rectangle defined in the control resource, not the display rectangle defined in the item list resource. If the item is an edit text item, `ShowDialogItem` activates it by calling the TextEdit function `TEActivate`.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Dialogs.h`

SizeDialogItem

Sizes a dialog item.

```
OSErr SizeDialogItem (
   DialogRef inDialog,
   DialogItemIndex inItemNo,
   SInt16 inWidth,
   SInt16 inHeight
);
```

Parameters

inDialog

A pointer to the dialog box containing the item to be resized.

inItemNo

The position of the item in the dialog box's item list resource use `FindDialogItem` (page 849) to determine this value.

inWidth

The new width (in pixels) of the dialog item's control rectangle.

inHeight
The new height (in pixels) of the dialog item's control rectangle.

Return Value
A result code. See "Dialog Manager Result Codes" (page 916).

Discussion
The `SizeDialogItem` function resizes a dialog item to a specified size. If the dialog item is a control, the control rectangle and the dialog item rectangle (maintained by the Dialog Manager) are always the same.

Version Notes
This function is available with Appearance Manager 1.0 and later.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Dialogs.h`

StandardAlert

Displays a standard alert box.

```
OSErr StandardAlert (
   AlertType inAlertType,
   ConstStr255Param inError,
   ConstStr255Param inExplanation,
   const AlertStdAlertParamRec *inAlertParam,
   SInt16 *outItemHit
);
```

Parameters
inAlertType
A constant indicating the type of alert box you wish to create; see "Alert Type Constants" (page 907).

inError
A pointer to a Pascal string containing the primary error text you wish to display.

inExplanation
A pointer to a Pascal string containing the secondary text you wish to display; secondary text is displayed in the small system font. Pass `null` to indicate no secondary text.

inAlertParam
A pointer to the standard alert structure; see `AlertStdAlertParamRec` (page 897). Pass `null` to specify that you do not wish to your alert box to incorporate any of the features that the standard alert structure provides.

outItemHit
A pointer to a signed 16-bit integer value. On return, the value indicates the alert button pressed; see "Alert Button Constants" (page 904).

Return Value
A result code. See "Dialog Manager Result Codes" (page 916).

Discussion
The `StandardAlert` function displays an alert box based on the values you pass it. You can pass the error text you wish displayed in the `error` and `explanation` parameters, and customize the alert button text by filling in the appropriate fields of the standard alert structure passed in the `inAlertParam` parameter.

`StandardAlert` automatically resizes the height of a dialog box to fit all static text. It ignores alert stages and therefore provides no corresponding alert sounds.

Special Considerations

This function is available with Appearance Manager 1.0 and later.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Dialogs.h`

StdFilterProc

Handles standard event filtering for a dialog box.

```
Boolean StdFilterProc (
   DialogRef theDialog,
   EventRecord *event,
   DialogItemIndex *itemHit
);
```

Parameters

`theDialog`
On input, a pointer to a dialog structure for an alert box or a modal dialog box.

`event`
On output, a pointer to an event structure returned by an Event Manager function such as `WaitNextEvent`.

`itemHit`
On output, a pointer to a short integer. `StdFilterProc` returns a number corresponding to the position of an item in the item list resource for the alert or modal dialog box.

Return Value
A Boolean value representing whether the standard filter proc handled the event. `true` means handled; otherwise `false`.

Discussion
To use the standard filter function from within your own filter function, you can call `GetStdFilterProc` (page 860) , then dispatch the event to the standard filter function yourself; or you can call `StdFilterProc`, which performs both steps for you. Calling `StdFilterProc` is equivalent to calling `GetStdFilterProc` (page 860) and then calling `ModalFilterProcPtr` (page 891).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Dialogs.h`

StopAlert

Displays an alert box with a stop icon and/or plays an alert sound.

```
DialogItemIndex StopAlert (
   SInt16 alertID,
   ModalFilterUPP modalFilter
);
```

Parameters

alertID

The resource ID of an alert resource and extended alert resource. The resource ID of both types of resources must be identical. If the alert resource is missing, the Dialog Manager returns to your application without creating the requested alert. See `'alrx'` for a description of the extended alert resource.

modalFilter

A universal procedure pointer for a filter function that responds to events not handled by the `ModalDialog` (page 865) function. If you set this parameter to `null`, the Dialog Manager uses the standard event filter function.

Return Value
If no stop alert box is to be drawn at the current alert stage, `StopAlert` returns –1 otherwise, it creates and displays the alert box and returns the item number of the control selected by the user see "Alert Button Constants" (page 904). See the description of the `DialogItemIndex` data type.

Discussion
The `StopAlert` function displays an alert box with a stop icon in its upper-left corner or, if appropriate for the alert stage, plays an alert sound instead of or in addition to displaying the alert box.

The `StopAlert` function is the same as the `Alert` (page 834) function except that, before drawing the items in the alert box, `StopAlert` draws the stop icon in the upper-left corner. The stop icon has resource ID 0, which you can also specify with the constant `stopIcon` . By default, the Dialog Manager uses the standard stop icon from the System file. You can change this icon by providing your own `'ICON'` resource with resource ID 0.

Use a stop alert to inform the user that a problem or situation is so serious that the action cannot be completed. Stop alerts typically have only a single button (OK), because all the user can do is acknowledge that the action cannot be completed.

Your application should never draw its own default rings or alert icons. Prior to Mac OS 8, the `StopAlert` function would only redraw the alert icon and default button ring once and never redraw them on an update event. However, when Appearance is available, alert icons and default rings do redraw when you call `StopAlert`.

See also the functions `NoteAlert` (page 874) and `CautionAlert` (page 839).

Version Notes
This function was changed with Appearance Manager 1.0 to support the extended alert (`'alrx'`) resource.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Dialogs.h`

UpdateDialog

Redraws the update region of a specified dialog box.

```
void UpdateDialog (
   DialogRef theDialog,
   RgnHandle updateRgn
);
```

Parameters

theDialog
A pointer to a dialog structure.

updateRgn
A handle to the window region that needs to be updated.

Discussion
The `UpdateDialog` function redraws only the region in a dialog box specified in the `updateRgn` parameter. Your application generally should not use `UpdateDialog`. The Dialog Manager generally handles update events in alert and dialog boxes. `Alert` (page 834). `StopAlert` (page 889) , `NoteAlert` (page 874) , and `CautionAlert` (page 839) handle update events on their own.

Instead of drawing the entire contents of the specified dialog box, `UpdateDialog` draws only the items in the specified update region. You can use `UpdateDialog` in response to an update event, and you should usually bracket it by calls to the Window Manager functions `BeginUpdate` and `EndUpdate`. `UpdateDialog` uses the QuickDraw function `SetPort` to make the dialog box the current graphics port.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

`Dialogs.h`

Callbacks by Task

Accessing and Modifying Low-Memory Data

`UserItemProcPtr` (page 895)

ModalFilterProcPtr (page 891)

SoundProcPtr (page 894)
Defines a pointer to your sound callback function.

Miscellaneous

ModalFilterYDProcPtr (page 893)

QTModelessCallbackProcPtr (page 894)

Callbacks

ModalFilterProcPtr

```
typedef Boolean (*ModalFilterProcPtr)
(
    DialogRef theDialog,
    EventRecord * theEvent,
    DialogItemIndex * itemHit
);
```

If you name your function `MyModalFilterProc`, you would declare it like this:

```
Boolean MyModalFilterProc (
    DialogRef theDialog,
    EventRecord * theEvent,
    DialogItemIndex * itemHit
);
```

Parameters

theDialog
A pointer to a dialog structure for an alert box or a modal dialog box.

theEvent
A pointer to an event structure returned by an Event Manager function such as `WaitNextEvent`.

itemHit
A pointer to a short integer. Your event filter function should return a number corresponding to the position of an item in the item list resource for the alert or modal dialog box.

Return Value

A Boolean value. After receiving an event that it does not handle, your function should return `false`. When your function returns `false`, `ModalDialog` handles the event, which you pass in the parameter `theEvent`. (Your function can also change the event to simulate a different event and return `false`, which passes the event to the Dialog Manager for handling.) If your function does handle the event, your function should return `true`, and through the `itemHit` parameter return the number of the item that it handled.

Discussion
To supplement the Dialog Manager's ability to handle events in the Mac OS multitasking environment, you should provide an event filter function that the Dialog Manager calls whenever it displays alert boxes and modal dialog boxes. This function can receive all events that are sent to your application.

The `ModalDialog` (page 865) function and, in turn, the `Alert` (page 834) , `NoteAlert` (page 874) , `StopAlert` (page 889) , and `CautionAlert` (page 839) functions return the item number that your event filter function returns in the `itemHit` parameter in their own itemHit parameters.

For alert and modal dialog boxes, the Dialog Manager provides a standard event filter function that checks whether

- the user has pressed the Enter or Return key and, if so, returns the item number of the default button
- the user has pressed the Escape key or Command-period and, if so, returns the item number of the Cancel button
- the cursor is over edit text in a dialog box, and optionally changes the cursor to an I-beam whenever this is the case

If the dialog box is movable modal and the `kDialogHandleMovable` bit is set, your filter function will receive all events (including apple events and update events) that your application receives.

Your own filter function should use the standard filter function to accomplish these tasks. To do so, you can call `GetStdFilterProc` (page 860) , and dispatch the event to the standard filter function yourself; or you can call `StdFilterProc` (page 888) , which obtains a `ModalFilterUPP` for the standard filter function and then dispatches the function.

Your event filter function should also perform the following tasks:

- update your windows in response to update events and return `false`. If you do not handle update events for all the windows in your application, other processes won't get time.
- return `false` for all events that your event filter function doesn't handle

You can also use the event filter function to test for and respond to keyboard equivalents and more complex events—for instance, the user dragging the cursor in an application- defined item. For example, if you provide an application-defined item that requires you to measure how long the user holds down the mouse button or how far the user drags the cursor, use the event filter function to handle events inside that item.

Movable modal dialog boxes receive all events (not just those masked by the Event message mask).

In all alert and dialog boxes, any buttons that are activated by key sequences should highlight to indicate which item has been selected. Use the Control Manager function `HiliteControl` to highlight a button for 8 ticks, long enough to be noticeable but not so long as to be annoying. The Control Manager performs this action whenever users click a button, and your application should do this whenever the user presses the keyboard equivalent of a button click.

For modal dialog boxes that contain edit text items, your application should handle menu bar access to allow use of your Edit menu and its Cut, Copy, Paste, Clear, and Undo commands. Your event filter function should then test for and handle clicks in your Edit menu and keyboard equivalents for the appropriate commands in your Edit menu. Your application should respond by using the functions `DialogCut` (page 844) , `DialogCopy` (page 844) , `DialogPaste` (page 845) , and `DialogDelete` (page 845) to support the Cut, Copy, Paste, and Clear commands.

For an alert box, you specify a universal procedure pointer to your event filter function in a parameter that you pass to the `Alert` (page 834) , `StopAlert` (page 889) , `CautionAlert` (page 839) , and `NoteAlert` (page 874) functions. For a modal dialog box, specify a pointer to your event filter function in a parameter that you pass to `UpdateDialog`.

The Dialog Manager defines the data type `ModalFilterUPP` to identify this application-defined function:

```
typedef UniversalProcPtr ModalFilterUPP;
```

You typically use the `NewModalFilterProc` macro like this:

```
ModalFilterUPP myEventFilterProc;

myEventFilterProc = NewModalFilterProc(MyEventFilter);
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Dialogs.h`

ModalFilterYDProcPtr

```
typedef Boolean (*ModalFilterYDProcPtr)
(
    DialogRef theDialog,
    EventRecord * theEvent,
    short * itemHit,
    void * yourDataPtr
);
```

If you name your function `MyModalFilterYDProc`, you would declare it like this:

```
Boolean MyModalFilterYDProc (
    DialogRef theDialog,
    EventRecord * theEvent,
    short * itemHit,
    void * yourDataPtr
);
```

Parameters

`theDialog`

`theEvent`

`itemHit`

`yourDataPtr`

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Dialogs.h`

QTModelessCallbackProcPtr

```
typedef void (*QTModelessCallbackProcPtr)
(
    EventRecord *theEvent,
    DialogRef theDialog,
    DialogItemIndex itemHit
);
```

If you name your function `MyQTModelessCallbackProc`, you would declare it like this:

```
void MyQTModelessCallbackProc (
    EventRecord *theEvent,
    DialogRef theDialog,
    DialogItemIndex itemHit
);
```

Parameters

theEvent

theDialog

itemHit

Carbon Porting Notes

This QuickTime function for manipulating dialog boxes is not supported in Carbon.

SoundProcPtr

Defines a pointer to your sound callback function.

```
typedef void (*SoundProcPtr) (
    SInt16 soundNumber
);
```

You should provide a sound callback function if you want the Dialog Manager to play sounds other than the system alert sound. If you name your function `MySoundProc`, you would declare it like this:

```
void MySoundProc (
    SInt16 soundNumber
);
```

Parameters

soundNumber

An integer from 0 to 3, representing the four possible alert stages.

Return Value

Discussion

For each of the four alert stages that can be reported in the `soundNumber` parameter, your function can emit any sound that you define. When the Dialog Manager calls your function, it passes 0 as the sound number for alert sounds specified by the silent constant in the alert resource. The Dialog Manager passes 1 for sounds specified by the `sound1` constant, 2 for sounds specified by the `sound2` constant, and 3 for sounds specified by the `sound3` constant.

The Dialog Manager defines the universal procedure pointer `SoundUPP` to identify this application-defined function:

```
typedef UniversalProcPtr SoundUPP; /
```

You typically use the `NewSoundProc` macro like this:

SoundUPP mySoundProc;

mySoundProc = NewSoundProc(MyAlertSound)

Special Considerations

When the Dialog Manager detects a click outside an alert box or a modal dialog box, it uses the Sound Manager function SysBeep to play the system alert sound. By changing settings in the Sound control panel, the user can select which sound to play as the system alert sound. For consistency with system software and other Macintosh applications, your sound function should call SysBeep whenever your sound function receives sound number 1 (which you can represent with the sound1 constant).

Version Notes
Not recommended with Appearance Manager 1.0 and later.

Carbon Porting Notes

Using custom sounds in dialog boxes is not supported in Carbon.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Dialogs.h`

UserItemProcPtr

```
typedef void (*UserItemProcPtr) (
    DialogRef theDialog,
    DialogItemIndex itemNo
);
```

If you name your function `MyUserItemProc`, you would declare it like this:

```
void MyUserItemProc (
    DialogRef theDialog,
    DialogItemIndex itemNo
);
```

Parameters

`theDialog`

On input, a pointer to the dialog structure for the dialog box containing an application-defined item. If your function can draw in more than one dialog box, this parameter tells your function which one to draw in.

itemNo

On input, a number corresponding to the position of an item in the item list resource for the specified dialog box. If your function draws more than one item, this parameter tells your function which one to draw.

Return Value

Discussion

When the Appearance Manager is available and an embedding hierarchy is established in a dialog box, you should provide the Control Manager user pane drawing function `MyUserPaneDrawCallback` instead of the user item drawing function `MyUserItemCallback` to draw an application-defined control (a dialog item becomes a control in a dialog box with an embedding hierarchy).

You can provide other user pane application-defined functions to hit test, track, perform idle processing, handle keyboard, activate, and deactivate event processing, handle keyboard focus, and set the background color or pattern in a user pane control.

When calling your draw function, the Dialog Manager sets the current port to the dialog box's graphics port. Normally, you create an invisible dialog box and then use the Window Manager function `ShowWindow` to display the dialog box.

Before you display the dialog box, use `SetDialogItem` (page 881) to install this function in the dialog structure. Before using `SetDialogItem`, you must first use `GetDialogItem` to obtain a handle to an item of type `userItem`.

If you enable the application-defined item that you draw with this function, `UpdateDialog` and `StdFilterProc` (page 888) return the item's number when the user clicks that item. If your application needs to respond to a user action more complex than this (for example, if your application needs to measure how long the user holds down the mouse or how far the user drags the cursor), your application must track the cursor itself. If you use `ModalDialog`, your event filter function must handle events inside the item; if you use `DialogSelect`, your application must handle events inside the item before handing events to `DialogSelect`.

The Dialog Manager defines the data type `UserItemUPP` to identify the universal procedure pointer for this application-defined function:

```
typedef UniversalProcPtr UserItemUPP;
```

You typically use the `NewUserItemProc` macro like this:

```
UserItemUPP myItemProc;

myItemProc = NewUserItemProc (MyItem);
```

Version Notes

This function is not recommended with Appearance Manager 1.0 and later.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Dialogs.h`

Data Types

AlertStdAlertParamRec

```
struct AlertStdAlertParamRec {
    Boolean movable;
    Boolean helpButton;
    ModalFilterUPP filterProc;
    ConstStringPtr defaultText;
    ConstStringPtr cancelText;
    ConstStringPtr otherText;
    SInt16 defaultButton;
    SInt16 cancelButton;
    UInt16 position;
};
typedef struct AlertStdAlertParamRec AlertStdAlertParamRec;
typedef AlertStdAlertParamRec * AlertStdAlertParamPtr;
```

Fields

`movable`
A Boolean value indicating whether or not the alert box is movable.

`helpButton`
A Boolean value indicating whether or not the alert includes a Help button.

`filterProc`
If the value in the `movable` field is `true` (alert is movable), then specify in this parameter a universal procedure pointer to an application-defined filter function that responds to events not handled by `ModalDialog` (page 865). If you do, all events will get routed to your application-defined event filter function for handling, even when your alert box window is in the background. If you set this parameter to `null`, the Dialog Manager uses the standard event filter function.

`defaultText`
Text for button in OK position; see "Alert Default Text Constants" (page 904). The button automatically sizes and positions itself in the alert box. To specify that the default button names should be used, pass `-1`. To indicate that no button should be displayed, pass `null`.

`cancelText`
Text for button in Cancel position; see "Alert Default Text Constants" (page 904). The button automatically sizes and positions itself in the alert box. To specify that the default button names should be used, pass `-1`. To indicate that no button should be displayed, pass `null`.

`otherText`
Text for button in leftmost position; see "Alert Default Text Constants" (page 904). The button automatically sizes and positions itself in the alert box. To specify that the default button names should be used, pass `-1`. To indicate that no button should be displayed, pass `null`.

`defaultButton`
Specifies which button acts as the default button; see "Alert Button Constants" (page 904).

`cancelButton`
Specifies which button acts as the Cancel button (can be 0); see "Alert Button Constants" (page 904).

`position`
The alert box position, as defined by a window positioning constant. In this structure, the constant `kWindowDefaultPosition` is equivalent to the constant `kWindowAlertPositionParentWindowScreen`.

Discussion
A standard alert structure of type `AlertStdAlertParamRec` can be used when you call the function `StandardAlert` (page 887) to customize the alert box. The `AlertStdAlertParamRec` type is available with Appearance Manager 1.0 and later.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Dialogs.h`

AlertStdCFStringAlertParamRec

Defines an alert or sheet.

```
struct AlertStdCFStringAlertParamRec {
    UInt32 version;
    Boolean movable;
    Boolean helpButton;
    CFStringRef defaultText;
    CFStringRef cancelText;
    CFStringRef otherText;
    SInt16 defaultButton;
    SInt16 cancelButton;
    UInt16 position;
    OptionBits flags;
};
typedef struct AlertStdCFStringAlertParamRec AlertStdCFStringAlertParamRec;
typedef AlertStdCFStringAlertParamRec * AlertStdCFStringAlertParamPtr;
```

Fields

`version`
The version of this parameter record. Set this field to `kStdCFStringAlertVersionOne`.

`movable`
A Boolean value indicating whether or not the alert is movable.

`helpButton`
A Boolean value indicating whether or not the alert contains a Help button.

`defaultText`
Text for button in the OK position. The button automatically sizes and positions itself in the alert box. To specify that the default button names should be used, pass `-1` (see "Alert Default Text Constants" (page 904) for values). To indicate that no button should be displayed, pass `null`

`cancelText`
Text for button in the Cancel position; see "Alert Default Text Constants" (page 904). The button automatically sizes and positions itself in the alert box. To specify that the default button names should be used, pass `-1` see "Alert Default Text Constants" (page 904) for values). To indicate that no button should be displayed, pass `null`.

`otherText`
Text for button in the other (leftmost) position; see "Alert Default Text Constants" (page 904). The button automatically sizes and positions itself in the alert box. To specify that the default button names should be used, pass `-1`. To indicate that no button should be displayed, pass `null`

`defaultButton`
Specifies which button acts as the default button; see "Alert Button Constants" (page 904).

`cancelButton`
Specifies which button acts as the default button; see "Alert Button Constants" (page 904).

`position`
The alert box position, as defined by a window positioning constant. In this structure, the constant `kWindowDefaultPosition` is equivalent to the constant `kWindowAlertPositionParentWindowScreen`. See the Window Manager Reference for other possible positioning constants.

`flags`
Options for this alert. See "Standard Alert and Sheet Option Flags" (page 915) for possible values.

Discussion
You pass this structure when calling `CreateStandardAlert` (page 842) or `CreateStandardSheet` (page 842).

Availability
Available in Mac OS X v10.0 and later.

    TEHandle textH;
    SInt16 editField;
    SInt16 editOpen;
    SInt16 aDefItem;
};
typedef struct DialogRecord DialogRecord;
```

Fields

Discussion

A dialog structure of type `DialogRecord` is created whenever you call the functions `Alert` (page 834) or `GetNewDialog` (page 858). These functions incorporate information from your item list resource and your alert resource or dialog resource into this structure. Your application generally should not create a dialog structure or directly access its fields.

Constants

Alert Button Constants

Define standard button types for alerts and sheets.

```
enum {
    kAlertStdAlertOKButton = 1,
    kAlertStdAlertCancelButton = 2,
    kAlertStdAlertOtherButton = 3,
    kAlertStdAlertHelpButton = 4
};
```

Constants

`kAlertStdAlertOKButton`
The OK button. The default text for this button is “OK”.
Available in Mac OS X v10.0 and later.
Declared in `Dialogs.h`.

`kAlertStdAlertCancelButton`
The Cancel button (optional). The default text for this button is “Cancel”.
Available in Mac OS X v10.0 and later.
Declared in `Dialogs.h`.

`kAlertStdAlertOtherButton`
A third button (optional). The default text for this button is “Don’t Save”.
Available in Mac OS X v10.0 and later.
Declared in `Dialogs.h`.

`kAlertStdAlertHelpButton`
The Help button (optional).
Available in Mac OS X v10.0 and later.
Declared in `Dialogs.h`.

Discussion

You can use these constants in the `defaultButton` and `cancelButton` fields in the standard alert structure to specify which buttons act as the default and Cancel buttons in the standard alert structure. These constants are also returned in the `itemHit` parameter of `StandardAlert` (page 887). Alert button constants are available with Appearance Manager 1.0 and later.

Alert Default Text Constants

Defines the default text for alerts and sheets.

```
enum {
    kAlertDefaultOKText = -1,
    kAlertDefaultCancelText = -1,
    kAlertDefaultOtherText = -1
};
```

Constants

`kAlertDefaultOKText`

The default text for the default (right) button is "OK" on an English system. The text will vary depending upon the localization of the user's system. Use this constant in the `defaultText` field of the standard alert structure.

Available in Mac OS X v10.0 and later.

Declared in `Dialogs.h`.

`kAlertDefaultCancelText`

The default text for the Cancel (middle) button is "Cancel" on an English system. The text will vary depending upon the localization of your system. Use this constant in the `cancelText` field of the standard alert structure.

Available in Mac OS X v10.0 and later.

Declared in `Dialogs.h`.

`kAlertDefaultOtherText`

The default text for the third (leftmost) button is "Don't Save" for an English system. The text will vary depending upon the localization of the user's system. Use this constant in the `otherText` field of the standard alert structure.

Available in Mac OS X v10.0 and later.

Declared in `Dialogs.h`.

Discussion

You can use these constants in the `defaultText`, `cancelText`, and `otherText` fields of the standard alert structure to specify the default text for the OK, Cancel, and Don't Save buttons. Alert default text constants are available with Appearance Manager 1.0 and later.

Alert Feature Flag Constants

```
enum {
    kAlertFlagsUseThemeBackground = (1 << 0),
    kAlertFlagsUseControlHierarchy = (1 << 1),
    kAlertFlagsAlertIsMovable = (1 << 2),
    kAlertFlagsUseThemeControls = (1 << 3)
};
```

Constants

`kAlertFlagsUseThemeBackground`

If this bit (bit 0) is set, the Dialog Manager sets the alert box's background color or pattern.

Available in Mac OS X v10.0 and later.

Declared in `Dialogs.h`.

`kAlertFlagsUseControlHierarchy`
If this bit (bit 1) is set, the Dialog Manager creates a root control in the alert box and establishes an embedding hierarchy. Any alert items become controls once the embedding hierarchy is established.

Available in Mac OS X v10.0 and later.

Declared in `Dialogs.h`.

`kAlertFlagsAlertIsMovable`
If this bit (bit 2) is set, the alert box is movable modal. The Dialog Manager handles movable modal behavior such as dragging the alert box by its title bar or switching out of the application by clicking in another one.

Available in Mac OS X v10.0 and later.

Declared in `Dialogs.h`.

`kAlertFlagsUseThemeControls`
If this bit (bit 3) is set, the Dialog Manager creates Appearance-compliant controls in your alert box. Otherwise, push buttons, checkboxes, and radio buttons will be displayed in their pre-Appearance forms when systemwide Appearance is off.

Available in Mac OS X v10.0 and later.

Declared in `Dialogs.h`.

Discussion
You can set these bits in the alert flags field of the extended alert resource to specify the alert box's Appearance-compliant features. Alert feature flag constants are available with Appearance Manager 1.0 and later.

Alert Icon Resource ID Constants

```
enum {
    kStopIcon = 0,
    kNoteIcon = 1,
    kCautionIcon = 2,
    stopIcon = kStopIcon,
    noteIcon = kNoteIcon,
    cautionIcon = kCautionIcon
};
```

Constants
`kStopIcon`
Resource ID for the standard stop icon.

Available in Mac OS X v10.0 and later.

Declared in `Dialogs.h`.

`kNoteIcon`
Resource ID for the standard note icon.

Available in Mac OS X v10.0 and later.

Declared in `Dialogs.h`.

`kCautionIcon`
Resource ID for the standard caution icon.

Available in Mac OS X v10.0 and later.

Declared in `Dialogs.h`.

`stopIcon`
Available in Mac OS X v10.0 and later.
Declared in `Dialogs.h`.

`noteIcon`
Available in Mac OS X v10.0 and later.
Declared in `Dialogs.h`.

`cautionIcon`
Available in Mac OS X v10.0 and later.
Declared in `Dialogs.h`.

Discussion
You can pass these constants in the `alertID` parameter of `StopAlert` (page 889) , `NoteAlert` (page 874), and `CautionAlert` (page 839) to specify the resource ID of the alert box icon you wish displayed.

Alert Type Constants

```
enum {
    kAlertStopAlert = 0,
    kAlertNoteAlert = 1,
    kAlertCautionAlert = 2,
    kAlertPlainAlert = 3
};
```

Constants
`kAlertStopAlert`
Stop alert box.
Available in Mac OS X v10.0 and later.
Declared in `Dialogs.h`.

`kAlertNoteAlert`
Note alert box.
Available in Mac OS X v10.0 and later.
Declared in `Dialogs.h`.

`kAlertCautionAlert`
Caution alert box.
Available in Mac OS X v10.0 and later.
Declared in `Dialogs.h`.

`kAlertPlainAlert`
Alert box with no icon.
Available in Mac OS X v10.0 and later.
Declared in `Dialogs.h`.

Discussion
You can pass constants of type `AlertType` in the `inAlertType` parameter of `StandardAlert` (page 887) to specify the type of alert box you wish to create. Alert type constants are available with Appearance Manager 1.0 and later.

ctrlItem

```
enum {
    ctrlItem = 4,
    btnCtrl = 0,
    chkCtrl = 1,
    radCtrl = 2,
    resCtrl = 3,
    statText = 8,
    editText = 16,
    iconItem = 32,
    picItem = 64,
    userItem = 0,
    itemDisable = 128
};
```

Constants

`ctrlItem`
Available in Mac OS X v10.0 and later.
Declared in `Dialogs.h`.

`btnCtrl`
Available in Mac OS X v10.0 and later.
Declared in `Dialogs.h`.

`chkCtrl`
Available in Mac OS X v10.0 and later.
Declared in `Dialogs.h`.

`radCtrl`
Available in Mac OS X v10.0 and later.
Declared in `Dialogs.h`.

`resCtrl`
Available in Mac OS X v10.0 and later.
Declared in `Dialogs.h`.

`statText`
Available in Mac OS X v10.0 and later.
Declared in `Dialogs.h`.

`editText`
Available in Mac OS X v10.0 and later.
Declared in `Dialogs.h`.

`iconItem`
Available in Mac OS X v10.0 and later.
Declared in `Dialogs.h`.

`picItem`
Available in Mac OS X v10.0 and later.
Declared in `Dialogs.h`.

`userItem`
Available in Mac OS X v10.0 and later.
Declared in `Dialogs.h`.

`itemDisable`
Available in Mac OS X v10.0 and later.

Declared in `Dialogs.h`.

Dialog Feature Flag Constants

```
enum {
    kDialogFlagsUseThemeBackground = (1 << 0),
    kDialogFlagsUseControlHierarchy = (1 << 1),
    kDialogFlagsHandleMovableModal = (1 << 2),
    kDialogFlagsUseThemeControls = (1 << 3)
};
```

Constants

`kDialogFlagsUseThemeBackground`
If this bit (bit 0) is set, the Dialog Manager sets the dialog box's background color or pattern.

Available in Mac OS X v10.0 and later.

Declared in `Dialogs.h`.

`kDialogFlagsUseControlHierarchy`
If this bit (bit 1) is set, the Dialog Manager creates a root control in the dialog box and establishes an embedding hierarchy. Any dialog items become controls once the embedding hierarchy is established.

Available in Mac OS X v10.0 and later.

Declared in `Dialogs.h`.

`kDialogFlagsHandleMovableModal`
If this bit (bit 2) is set, and the dialog box is a movable modal (specify the `kWindowMovableModalDialogProc` window definition ID), the Dialog Manager handles movable modal behavior such as dragging a dialog box by its title bar or switching out of the application by clicking in another one.

Available in Mac OS X v10.0 and later.

Declared in `Dialogs.h`.

`kDialogFlagsUseThemeControls`
If this bit (bit 3) is set, the Dialog Manager creates Appearance-compliant controls in the dialog box directly. Otherwise, push buttons, checkboxes, and radio buttons will be displayed in their pre-Appearance forms when systemwide Appearance is off.

Available in Mac OS X v10.0 and later.

Declared in `Dialogs.h`.

Discussion
You can set these bits in the dialog flags field of the extended dialog resource or pass them in the `inFlags` parameter of `NewFeaturesDialog` (page 871) to specify the dialog box's Appearance-compliant features. Dialog feature flag constants are available with Appearance Manager 1.0 and later.

Dialog Font Flag Constants

```
enum {
    kDialogFontNoFontStyle = 0,
    kDialogFontUseFontMask = 0x0001,
    kDialogFontUseFaceMask = 0x0002,
    kDialogFontUseSizeMask = 0x0004,
    kDialogFontUseForeColorMask = 0x0008,
    kDialogFontUseBackColorMask = 0x0010,
    kDialogFontUseModeMask = 0x0020,
    kDialogFontUseJustMask = 0x0040,
    kDialogFontUseAllMask = 0x00FF,
    kDialogFontAddFontSizeMask = 0x0100,
    kDialogFontUseFontNameMask = 0x0200,
    kDialogFontAddToMetaFontMask = 0x0400
};
```

Constants

`kDialogFontNoFontStyle`
If the `kDialogFontNoFontStyle` constant is used, no font style information is applied.

Available in Mac OS X v10.0 and later.

Declared in `Dialogs.h`.

`kDialogFontUseFontMask`
If the `kDialogFontUseFontMask` flag (bit 0) is set, the font ID specified in the Font ID field of the dialog font table is applied.

Available in Mac OS X v10.0 and later.

Declared in `Dialogs.h`.

`kDialogFontUseFaceMask`
If the `kDialogFontUseFaceMask` flag (bit 1) is set, the font style specified in the Style field of the dialog font table is applied.

Available in Mac OS X v10.0 and later.

Declared in `Dialogs.h`.

`kDialogFontUseSizeMask`
If the `kDialogFontUseSizeMask` flag (bit 2) is set, the font size specified in the Font Size field of the dialog font table is applied.

Available in Mac OS X v10.0 and later.

Declared in `Dialogs.h`.

`kDialogFontUseForeColorMask`
If the `kDialogFontUseForeColorMask` flag (bit 3) is set, the text color specified in the Text Color field of the dialog font table is applied. This flag only applies to static text controls.

Available in Mac OS X v10.0 and later.

Declared in `Dialogs.h`.

`kDialogFontUseBackColorMask`
If the `kDialogFontUseBackColorMask` flag (bit 4) is set, the background color specified in the Background Color field of the dialog font table is applied. This flag only applies to static text controls.

Available in Mac OS X v10.0 and later.

Declared in `Dialogs.h`.

`kDialogFontUseModeMask`
If the `kDialogFontUseModeMask` flag (bit 5) is set, the text mode specified in the Text Mode field of the dialog font table is applied.

Available in Mac OS X v10.0 and later.

Declared in `Dialogs.h`.

`kDialogFontUseJustMask`
If the `kDialogFontUseJustMask` flag (bit 6) is set, the text justification specified in the Justification field of the dialog font table is applied.

Available in Mac OS X v10.0 and later.

Declared in `Dialogs.h`.

`kDialogFontUseAllMask`
If the `kDialogFontUseAllMask` constant is used, all flags in this mask will be set except `kDialogFontAddFontSizeMask` and `kDialogFontUseFontNameMask`.

Available in Mac OS X v10.0 and later.

Declared in `Dialogs.h`.

`kDialogFontAddFontSizeMask`
If the `kDialogFontAddFontSizeMask` flag (bit 8) is set, the Dialog Manager will add a specified font size to the existing font size indicated in the Font Size field of the dialog font table resource.

Available in Mac OS X v10.0 and later.

Declared in `Dialogs.h`.

`kDialogFontUseFontNameMask`
If the `kDialogFontUseFontNameMask` flag (bit 9) is set, the Dialog Manager will use the string in the Font Name field for the font name instead of a font ID.

Available in Mac OS X v10.0 and later.

Declared in `Dialogs.h`.

`kDialogFontAddToMetaFontMask`
Available in Mac OS X v10.0 and later.

Declared in `Dialogs.h`.

Discussion
You can set the following bits in the dialog font table resource to specify fields in the dialog font table that should be used. Dialog font flag constants are available with Appearance Manager 1.0 and later.

Dialog Item Constants

```
enum {
    kControlDialogItem = 4,
    kButtonDialogItem = kControlDialogItem | 0,
    kCheckBoxDialogItem = kControlDialogItem | 1,
    kRadioButtonDialogItem = kControlDialogItem | 2,
    kResourceControlDialogItem = kControlDialogItem | 3,
    kStaticTextDialogItem = 8,
    kEditTextDialogItem = 16,
    kIconDialogItem = 32,
    kPictureDialogItem = 64,
    kUserDialogItem = 0,
    kHelpDialogItem = 1,
    kItemDisableBit = 128
};
```

Constants

`kControlDialogItem`
Available in Mac OS X v10.0 and later.
Declared in `Dialogs.h`.

`kButtonDialogItem`
Standard button control.
Available in Mac OS X v10.0 and later.
Declared in `Dialogs.h`.

`kCheckBoxDialogItem`
Standard checkbox control.
Available in Mac OS X v10.0 and later.
Declared in `Dialogs.h`.

`kRadioButtonDialogItem`
Standard radio button control.
Available in Mac OS X v10.0 and later.
Declared in `Dialogs.h`.

`kResourceControlDialogItem`
Control defined in control resource.
Available in Mac OS X v10.0 and later.
Declared in `Dialogs.h`.

`kStaticTextDialogItem`
Static text item.
Available in Mac OS X v10.0 and later.
Declared in `Dialogs.h`.

`kEditTextDialogItem`
Edit text item.
Available in Mac OS X v10.0 and later.
Declared in `Dialogs.h`.

`kIconDialogItem`
Icon.

Available in Mac OS X v10.0 and later.

Declared in `Dialogs.h`.

`kPictureDialogItem`
QuickDraw picture.

Available in Mac OS X v10.0 and later.

Declared in `Dialogs.h`.

`kUserDialogItem`
Application-defined item.

Available in Mac OS X v10.0 and later.

Declared in `Dialogs.h`.

`kHelpDialogItem`
Help balloon, as defined by the Help Manager.

Available in Mac OS X v10.0 and later.

Declared in `Dialogs.h`.

`kItemDisableBit`
Add to disable any other constant, except `kHelpDialogItem`.

Available in Mac OS X v10.0 and later.

Declared in `Dialogs.h`.

Discussion
These constants are returned in the `itemType` parameter of `GetDialogItem` (page 852) and can be passed to `SetDialogItem` (page 881) and the dialog item list resource to specify dialog item type.

Dialog Item List Display Constants

Specify methods of appending new items to a dialog.

```
typedef SInt16 DITLMethod;
enum {
    overlayDITL = 0,
    appendDITLRight = 1,
    appendDITLBottom = 2
};
```

Constants
`overlayDITL`
Superimpose the appended items over the dialog box.

Available in Mac OS X v10.0 and later.

Declared in `Dialogs.h`.

`appendDITLRight`
Position the items to the right of the dialog box and relative to its upper-right coordinate.

Available in Mac OS X v10.0 and later.

Declared in `Dialogs.h`.

`appendDITLBottom`
Position the items below the dialog box and relative to its lower-left coordinate.

Available in Mac OS X v10.0 and later.

Declared in `Dialogs.h`.

Discussion
You can pass a constant value of type `DITLMethod` to the function `AppendDITL` (page 836) to specify how you want appended dialog items displayed.

kDialogFontUseThemeFontIDMask

```
enum {
    kDialogFontUseThemeFontIDMask = 0x0080
};
```

Constants
`kDialogFontUseThemeFontIDMask`
Available in Mac OS X v10.0 and later.

Declared in `Dialogs.h`.

kHICommandOther

```
enum {
    kHICommandOther = 'othr'
};
```

Constants
`kHICommandOther`
Available in Mac OS X v10.0 and later.

Declared in `Dialogs.h`.

kOkItemIndex

```
enum {
    kOkItemIndex = 1,
    kCancelItemIndex = 2
};
```

Constants
`kOkItemIndex`
Available in Mac OS X v10.0 and later.

Declared in `Dialogs.h`.

`kCancelItemIndex`
Available in Mac OS X v10.0 and later.

Declared in `Dialogs.h`.

Standard Alert and Sheet Option Flags

Define flags used in the `AlertStdCFStringAlertParamRec` (page 898) structure.

```
enum {
    kStdAlertDoNotDisposeSheet = 1 << 0,
    kStdAlertDoNotAnimateOnDefault = 1 << 1,
    kStdAlertDoNotAnimateOnCancel = 1 << 2,
    kStdAlertDoNotAnimateOnOther = 1 << 3,
    kStdAlertDoNotCloseOnHelp     = 1 << 4
};
```

Constants

`kStdAlertDoNotDisposeSheet`

Do not dispose of the sheet window after closing it. This option allows the sheet to be used again when calling the Window Manager function `ShowSheetWindow`.

Available in Mac OS X v10.0 and later.

Declared in `Dialogs.h`.

`kStdAlertDoNotAnimateOnDefault`

Do not animate hiding the sheet window when the user presses the default button.

Available in Mac OS X v10.1 and later.

Declared in `Dialogs.h`.

`kStdAlertDoNotAnimateOnCancel`

Do not animate hiding the sheet window when the user presses the Cancel button.

Available in Mac OS X v10.1 and later.

Declared in `Dialogs.h`.

`kStdAlertDoNotAnimateOnOther`

Do not animate hiding the sheet window when the user presses the other button.

Available in Mac OS X v10.1 and later.

Declared in `Dialogs.h`.

`kStdAlertDoNotCloseOnHelp`

Specifies that the alert stay up even after the user clicks the Help button. Normally, it would close immediately. It is not necessary to set this option for sheets, as they merely send the `HICommandHelp` command to the event target provided. When you specify this option, `RunStandardAlert` (page 877) returns with the Help button item in the `outItemHit` parameter, but the alert remains up. You can then perform whatever help function you wish and then call `RunStandardAlert` again.

Declared in `Dialogs.h`.

Available in Mac OS X 10.4 or later.

Standard Alert Structure Version Constant

Indicates the version of the `AlertStdCFStringAlertParamRec` (page 898) structure.

```
enum {
    kStdCFStringAlertVersionOne = 1
};
```

Constants

`kStdCFStringAlertVersionOne`
First version. Pass this into the `version` field of the `AlertStdCFStringAlertParamRec` structure.
Available in Mac OS X v10.0 and later.
Declared in `Dialogs.h`.

kStdOkItemIndex

```
enum {
    kStdOkItemIndex = 1,
    kStdCancelItemIndex = 2,
    ok = kStdOkItemIndex,
    cancel = kStdCancelItemIndex
};
```

Constants

`kStdOkItemIndex`
Available in Mac OS X v10.0 and later.
Declared in `Dialogs.h`.

`kStdCancelItemIndex`
Available in Mac OS X v10.0 and later.
Declared in `Dialogs.h`.

`ok`
Available in Mac OS X v10.0 and later.
Declared in `Dialogs.h`.

`cancel`
Available in Mac OS X v10.0 and later.
Declared in `Dialogs.h`.

Result Codes

The result codes defined for the Dialog Manager are listed below.

Result Code	Value	Description
`dialogNoTimeoutErr`	-5640	No timeout has been set for this dialog. Available in Mac OS X v10.0 and later.

Gestalt Constants

You can check for version and feature availability information by using the Dialog Manager selectors defined in the Gestalt Manager. For more information, see *Gestalt Manager Reference*.

Drag Manager Reference

Framework: Carbon/Carbon.h

Declared in Drag.h

Overview

The Drag Manager facilitates dragging objects within the Macintosh user interface. The Drag Manager provides functions that handle the user interface for dragging an object from, within, or to one of your application's windows. The Drag Manager can be used whenever an object is dragged within your application.

Use the Drag Manager if you want your users to be able to drag items within your own application's windows or between those of your application and other applications. You can also use the Drag Manager to allow the user of your application to drag selections of your documents to the Finder to create "clippings" from your documents and to allow selections from other applications to be dragged directly into your documents.

Functions by Task

Installing and Removing Drag Handlers

`InstallReceiveHandler` (page 940) Deprecated in Mac OS X v10.5
Installs a receive handler function for one or all of your application's windows.

`InstallTrackingHandler` (page 941) Deprecated in Mac OS X v10.5
Installs a tracking handler function for one or all of your application's windows.

`RemoveReceiveHandler` (page 947) Deprecated in Mac OS X v10.5
Removes a receive handler function from one or all of your application's windows.

`RemoveTrackingHandler` (page 947) Deprecated in Mac OS X v10.5
Removes a tracking handler function from one or all of your application's windows.

Creating and Disposing of Drag References

`NewDrag` (page 944)
Creates a new drag reference for your application to use with the Drag Manager.

`DisposeDrag` (page 926)
Disposes of a drag reference and its associated data.

Adding Drag Item Flavors

`AddDragItemFlavor` (page 923) Deprecated in Mac OS X v10.5
Adds a flavor to a drag item, creating a new item if necessary.

`SetDragItemFlavorData` (page 953) Deprecated in Mac OS X v10.5
Sets the data or part of the data contained within an existing flavor.

Providing Drag Callback Functions

`SetDragInputProc` (page 952)
Sets the drag input function for the Drag Manager to use with a particular drag.

`SetDragDrawingProc` (page 948) Deprecated in Mac OS X v10.5
Sets the drag drawing function for the Drag Manager to use with a particular drag.

`SetDragSendProc` (page 955) Deprecated in Mac OS X v10.5
Sets the send data function for the Drag Manager to use with a particular drag.

Setting the Drag Image

`SetDragImageWithCGImage` (page 951)
Associates a Core Graphics image with a drag reference.

`SetDragImage` (page 950) Deprecated in Mac OS X v10.4
Associates an image with a drag reference. (Deprecated. Use `SetDragImageWithCGImage` (page 951) instead.)

Altering the Behavior of a Drag

`ChangeDragBehaviors` (page 924)
Changes the behavior of a drag.

Performing a Drag

`TrackDrag` (page 958)
Drags an item or collection of items from your application.

Getting Drag Item Information

`GetDragItemBounds` (page 932)
Gets the bounding rectangle of a drag item.

`SetDragItemBounds` (page 952)
Sets the bounding rectangle of a drag item.

`CountDragItemFlavors` (page 925) Deprecated in Mac OS X v10.5
Gets the number of flavors that are contained within a drag item.

`CountDragItems` (page 925) Deprecated in Mac OS X v10.5
Gets the number of drag items that are contained in a drag reference.

`GetDragItemReferenceNumber` (page 933) Deprecated in Mac OS X v10.5
Gets the reference number of a specific item in a drag reference.

`GetFlavorData` (page 936) Deprecated in Mac OS X v10.5
Gets all or part of the data for a specific flavor in a drag item.

`GetFlavorDataSize` (page 937) Deprecated in Mac OS X v10.5
Gets the size of the data for a specific flavor in a drag item.

`GetFlavorFlags` (page 937) Deprecated in Mac OS X v10.5
Gets the flags for a specific flavor in a drag item.

`GetFlavorType` (page 938) Deprecated in Mac OS X v10.5
Gets the type of a specific flavor in a drag item.

Getting and Setting the Drop Location

`GetDropLocation` (page 935) Deprecated in Mac OS X v10.5
Gets the Apple Event descriptor of the drop location.

`GetStandardDropLocation` (page 939) Deprecated in Mac OS X v10.5
Gets the standard drop location set by the receiver of a drag.

`SetDropLocation` (page 956) Deprecated in Mac OS X v10.5
Sets the Apple Event descriptor for the drop location of a drag.

`SetStandardDropLocation` (page 956) Deprecated in Mac OS X v10.5
Used by the receiver of a drag to set the standard drop location for a drag.

Getting Drag Status Information

`GetDragAttributes` (page 930)
Gets the current set of drag attribute flags.

`GetDragMouse` (page 934)
Gets the current mouse and pinned mouse locations.

`SetDragMouse` (page 954)
Sets the current pinned mouse location.

`GetDragOrigin` (page 934)
Gets the `mouseDown` parameter location that started the given drag.

`GetDragModifiers` (page 933)
Gets the current set of keyboard modifiers.

Accessing Drag Actions

`GetDragAllowableActions` (page 929)
Returns the actions that the drag receiver may take on the data within a drag.

`SetDragAllowableActions` (page 948)
Sets the actions that the drag receiver may take on the data within a drag.

`GetDragDropAction` (page 931)
Returns the action performed by the receiver of the drag.

`SetDragDropAction` (page 949)
Sets the action performed by the receiver of the drag.

Highlighting a Drag

`DragPostScroll` (page 928) Deprecated in Mac OS X v10.5
Restores the drag highlight after scrolling part of your window.

`DragPreScroll` (page 929) Deprecated in Mac OS X v10.5
Prepares your window or pane for scrolling.

`GetDragHiliteColor` (page 931) Deprecated in Mac OS X v10.5
Returns the drag highlight color for a window.

`HideDragHilite` (page 939) Deprecated in Mac OS X v10.5
Removes highlighting created with the `ShowDragHilite` function.

`ShowDragHilite` (page 957) Deprecated in Mac OS X v10.5
Highlights an area of your window during a drag.

`UpdateDragHilite` (page 959) Deprecated in Mac OS X v10.5
Updates the portion of the drag highlight that was drawn over by your application.

Drag Manager Utilities

`WaitMouseMoved` (page 960)
Returns `true` if a mouse movement is the beginning of a drag.

`ZoomRects` (page 960) Deprecated in Mac OS X v10.5
Animates a rectangle into a second rectangle.

`ZoomRegion` (page 961) Deprecated in Mac OS X v10.5
Animates a region's outline from one screen location to another.

Creating, Calling, and Deleting Universal Procedure Pointers

`NewDragInputUPP` (page 945)
Creates a new universal procedure pointer (UPP) to a drag input callback.

`DisposeDragInputUPP` (page 927)
Disposes of the universal procedure pointer (UPP) to a drag input callback.

`InvokeDragInputUPP` (page 942)
Calls your drag input callback.

`DisposeDragDrawingUPP` (page 926) Deprecated in Mac OS X v10.5
Disposes of the universal procedure pointer (UPP) to a drag drawing callback.

`DisposeDragReceiveHandlerUPP` (page 927) Deprecated in Mac OS X v10.5
Disposes of the universal procedure pointer (UPP) to a drag receive handler.

`DisposeDragSendDataUPP` (page 927) Deprecated in Mac OS X v10.5
Disposes of the universal procedure pointer (UPP) to a drag send data callback.

DisposeDragTrackingHandlerUPP (page 928) Deprecated in Mac OS X v10.5
: Disposes of the universal procedure pointer (UPP) to a drag tracking handler.

InvokeDragDrawingUPP (page 942) Deprecated in Mac OS X v10.5
: Calls your drag drawing callback.

InvokeDragReceiveHandlerUPP (page 943) Deprecated in Mac OS X v10.5
: Calls your drag receive handler.

InvokeDragSendDataUPP (page 943) Deprecated in Mac OS X v10.5
: Calls your drag send data callback.

InvokeDragTrackingHandlerUPP (page 944) Deprecated in Mac OS X v10.5
: Calls your drag tracking handler.

NewDragDrawingUPP (page 944) Deprecated in Mac OS X v10.5
: Creates a new universal procedure pointer (UPP) to a drag drawing callback.

NewDragReceiveHandlerUPP (page 945) Deprecated in Mac OS X v10.5
: Creates a new universal procedure pointer (UPP) to a drag receive handler.

NewDragSendDataUPP (page 946) Deprecated in Mac OS X v10.5
: Creates a new universal procedure pointer (UPP) to a drag send data callback.

NewDragTrackingHandlerUPP (page 946) Deprecated in Mac OS X v10.5
: Creates a new universal procedure pointer (UPP) to a drag tracking handler.

Functions

AddDragItemFlavor

Adds a flavor to a drag item, creating a new item if necessary. (Deprecated in Mac OS X v10.5.)

```
OSErr AddDragItemFlavor (
   DragRef theDrag,
   DragItemRef theItemRef,
   FlavorType theType,
   const void *dataPtr,
   Size dataSize,
   FlavorFlags theFlags
);
```

Parameters

theDrag
: A drag reference.

theItemRef
: The drag item to add the flavor to. You create a new drag item by providing a unique item reference number here. You add a flavor to an existing item by using the same item reference number as in a previous call. You may use any item reference number when adding a flavor to an item. Item reference numbers do not need to be specified in order, nor must they be sequential. In many cases it is easiest to use index numbers as item reference numbers (1, 2, 3...). Item reference numbers are only used as unique "key" numbers for each item. Depending on your application, it might be easier to use your own internal memory addresses as item reference numbers (as long as each item being dragged has a unique item reference number).

theType

The data type of the flavor to add. This may be any four-character scrap type. You may use your application's signature for a unique type for internal use. You must add all of the drag item flavors to a drag item before calling the `TrackDrag` function. Once the `TrackDrag` function is called, receiving applications may not operate properly if new drag items or drag item flavors are added.

dataPtr

A pointer to the flavor data to add. Pass `NULL` to defer the creation of a particular data type until a receiver has specifically requested it. If you pass `NULL`, a promise is added to the drag; when the flavor is requested, the Drag Manager calls the drag's send data function to get the data from your application.

Note that this method of setting promises differs from the method of setting Scrap Manager promises. See the Scrap Manager function `PutScrapFlavor` for more information.

dataSize

The size, in bytes, of the flavor data to add. If you pass `NULL` in the `dataPtr` parameter, the value in this parameter is ignored.

theFlags

The set of attributes to set for this flavor.

Return Value
A result code. See "Drag Manager Result Codes" (page 986).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Drag.h`

ChangeDragBehaviors

Changes the behavior of a drag.

```
OSErr ChangeDragBehaviors (
   DragRef theDrag,
   DragBehaviors inBehaviorsToSet,
   DragBehaviors inBehaviorsToClear
);
```

Parameters

theDrag

A drag reference.

inBehaviorsToSet

A value indicating the new behavior of the drag. See "Drag Behaviors" (page 974) for a description of the values you can use in this parameter.

inBehaviorsToClear

A value indicating which existing behavior, if any, should be cleared. See "Drag Behaviors" (page 974) for a description of the values you can use in this parameter.

Return Value
A result code. See "Drag Manager Result Codes" (page 986).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Drag.h`

CountDragItemFlavors

Gets the number of flavors that are contained within a drag item. (Deprecated in Mac OS X v10.5.)

```
OSErr CountDragItemFlavors (
   DragRef theDrag,
   DragItemRef theItemRef,
   UInt16 *numFlavors
);
```

Parameters

theDrag
The drag reference.

theItemRef
An item reference number.

numFlavors
On return, a pointer to the number of flavors in the specified drag item. When the `CountDragItemFlavors` function is called by an application other than the sender, the flavors that are marked with the `flavorSenderOnly` flag are not included in the count.

Return Value
A result code. See "Drag Manager Result Codes" (page 986).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Drag.h`

CountDragItems

Gets the number of drag items that are contained in a drag reference. (Deprecated in Mac OS X v10.5.)

```
OSErr CountDragItems (
   DragRef theDrag,
   UInt16 *numItems
);
```

Parameters

theDrag
The drag reference.

numItems
On return, a pointer to the number of drag items in the specified drag reference.

Return Value
A result code. See "Drag Manager Result Codes" (page 986).

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Drag.h`

DisposeDrag

Disposes of a drag reference and its associated data.

```
OSErr DisposeDrag (
   DragRef theDrag
);
```

Parameters

theDrag
The drag reference of the drag object to dispose of. If the drag reference contains any drag item flavors, the memory associated with the drag item flavors is disposed of as well.

Return Value
A result code. See "Drag Manager Result Codes" (page 986).

Discussion
You should call the `DisposeDrag` function after a drag has been performed using the `TrackDrag` function or if a drag reference was created but is no longer needed.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Drag.h`

DisposeDragDrawingUPP

Disposes of the universal procedure pointer (UPP) to a drag drawing callback. (Deprecated in Mac OS X v10.5.)

```
void DisposeDragDrawingUPP (
   DragDrawingUPP userUPP
);
```

Parameters

userUPP
The UPP to dispose of.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In
`Drag.h`

DisposeDragInputUPP

Disposes of the universal procedure pointer (UPP) to a drag input callback.

```
void DisposeDragInputUPP (
   DragInputUPP userUPP
);
```

Parameters

userUPP
The UPP to dispose of.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Drag.h`

DisposeDragReceiveHandlerUPP

Disposes of the universal procedure pointer (UPP) to a drag receive handler. (Deprecated in Mac OS X v10.5.)

```
void DisposeDragReceiveHandlerUPP (
   DragReceiveHandlerUPP userUPP
);
```

Parameters

userUPP
The UPP to dispose of.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In
`Drag.h`

DisposeDragSendDataUPP

Disposes of the universal procedure pointer (UPP) to a drag send data callback. (Deprecated in Mac OS X v10.5.)

```
void DisposeDragSendDataUPP (
   DragSendDataUPP userUPP
);
```

Parameters

userUPP
The UPP to dispose of.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In
`Drag.h`

DisposeDragTrackingHandlerUPP

Disposes of the universal procedure pointer (UPP) to a drag tracking handler. (Deprecated in Mac OS X v10.5.)

```
void DisposeDragTrackingHandlerUPP (
   DragTrackingHandlerUPP userUPP
);
```

Parameters

userUPP
The UPP to dispose of.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In
`Drag.h`

DragPostScroll

Restores the drag highlight after scrolling part of your window. (Deprecated in Mac OS X v10.5.)

```
OSErr DragPostScroll (
   DragRef theDrag
);
```

Parameters

theDrag
The drag reference.

Return Value
A result code. See "Drag Manager Result Codes" (page 986).

Discussion
The `DragPostScroll` function restores the drag highlight after scrolling part of your window. This function must be called following each call to the `DragPreScroll` function and any subsequent scrolling.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Drag.h`

DragPreScroll

Prepares your window or pane for scrolling. (Deprecated in Mac OS X v10.5.)

```
OSErr DragPreScroll (
   DragRef theDrag,
   SInt16 dH,
   SInt16 dV
);
```

Parameters

theDrag

The drag reference.

dH

The horizontal distance you intend to scroll.

dV

The vertical distance you intend to scroll.

Return Value

A result code. See "Drag Manager Result Codes" (page 986).

Discussion

Removes any drag highlighting that would be scrolled away from the `hiliteFrame` specified to the `ShowDragHilite` function when scrolling part of your window while drag highlighting is showing. Use this function if you plan to scroll part of your window using the `ScrollRect` or `CopyBits` functions.

Scrolling part of your window may inadvertently move part of the drag highlighting with it. The `DragPreScroll` function is optimized to remove from the screen only the parts of the highlighting that will be scrolled away from the `hiliteFrame` region. After calling the `DragPreScroll` function with the `dH` and `dV` that you are going to scroll, you can then scroll your window followed by a call to the `DragPostScroll` function which redraws any necessary highlighting after the scroll.

If you use an offscreen port to draw your window into while scrolling, it is recommended that you simply use the `HideDragHilite` and `ShowDragHilite` functions to preserve drag highlighting in your offscreen port. The `DragScroll` functions are optimized for onscreen scrolling.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Drag.h`

GetDragAllowableActions

Returns the actions that the drag receiver may take on the data within a drag.

```
OSStatus GetDragAllowableActions (
   DragRef theDrag,
   DragActions *outActions
);
```

Parameters

theDrag

The drag reference.

outActions

A pointer to a field that specifies, on return, the allowable drag actions. See "Drag Actions" (page 979) for a description of the values that may be returned here.

Return Value

A result code. See "Drag Manager Result Codes" (page 986).

Discussion

The drag actions returned by the `GetDragAllowableActions` function are not actually requirements; they are highly recommended suggestions for operations that the drag receiver may perform. The drag sender sets the recommended actions for a drag using the `SetDragAllowableActions` (page 948) function. The drag actions returned by `GetDragAllowableActions` are always local to the caller's process.

Availability

Available in Mac OS X v10.1 and later.

Not available to 64-bit applications.

Declared In

`Drag.h`

GetDragAttributes

Gets the current set of drag attribute flags.

```
OSErr GetDragAttributes (
   DragRef theDrag,
   DragAttributes *flags
);
```

Parameters

theDrag

A drag reference.

flags

On return, a pointer to the drag attribute flags for the specified drag reference. See "Drag Attributes" (page 973) for a description of the values that may be returned here.

Return Value

A result code. See "Drag Manager Result Codes" (page 986).

Discussion

If the `GetDragAttributes` function is called during a drag, the current set of drag attributes is returned. If the `GetDragAttributes` function is called after a drag, the set of drag attributes that were set at drop time is returned.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In
Drag.h

GetDragDropAction

Returns the action performed by the receiver of the drag.

```
OSStatus GetDragDropAction (
   DragRef theDrag,
   DragActions *outAction
);
```

Parameters

theDrag

The drag reference from which to retrieve the drop action.

outAction

A pointer to a field that, on return, specifies the action performed by the drag receiver. More than one action may be performed. See "Drag Actions" (page 979) for a description of the values that may be returned here.

Return Value
A result code. See "Drag Manager Result Codes" (page 986).

Availability
Available in Mac OS X v10.1 and later.
Not available to 64-bit applications.

Declared In
Drag.h

GetDragHiliteColor

Returns the drag highlight color for a window. (Deprecated in Mac OS X v10.5.)

```
OSErr GetDragHiliteColor (
   WindowRef window,
   RGBColor *color
);
```

Parameters

window

The window for which to return the drag highlight color.

color

On return, a pointer to the highlight color.

Return Value
A result code. See "Drag Manager Result Codes" (page 986).

Discussion
Use the `GetDragHiliteColor` function to determine the color the Drag Manager will use for a particular window. `GetDragHiliteColor` can safely be called when the `gestaltDragMgrHasImageSupport` bit is set in the `Gestalt` response to the selector `gestaltDragMgrAttr`. For more information on the `gestaltDragMgrAttr` selector, see *Inside Mac OS X: Gestalt Manager Reference*.

The Drag Manager chooses an appropriate color for highlighting, based on the color used for drag highlighting in the current Appearance Manager theme.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Drag.h`

GetDragItemBounds

Gets the bounding rectangle of a drag item.

```
OSErr GetDragItemBounds (
   DragRef theDrag,
   DragItemRef theItemRef,
   Rect *itemBounds
);
```

Parameters
`theDrag`
A drag reference.
`theItemRef`
The reference number of the drag item whose bounds you wish to obtain.
`itemBounds`
On return, a pointer to the bounding rectangle (relative to the current pinned mouse position) of the specified item in global coordinates.

Return Value
A result code. See "Drag Manager Result Codes" (page 986).

Discussion
You can use the `GetDragItemBounds` function in your tracking or receive handlers to determine the current or dropped location of each item in the drag.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Drag.h`

GetDragItemReferenceNumber

Gets the reference number of a specific item in a drag reference. (Deprecated in Mac OS X v10.5.)

```
OSErr GetDragItemReferenceNumber (
   DragRef theDrag,
   UInt16 index,
   DragItemRef *theItemRef
);
```

Parameters

theDrag

The drag reference.

index

The index of an item in a drag for which to get the reference.

theItemRef

On return, a pointer to the reference number of the item with the specified index.

Return Value

A result code. See "Drag Manager Result Codes" (page 986). If `index` is 0 or larger than the number of items in the drag, `GetDragItemReferenceNumber` returns the `badDragItemErr` result code.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Drag.h`

GetDragModifiers

Gets the current set of keyboard modifiers.

```
OSErr GetDragModifiers (
   DragRef theDrag,
   SInt16 *modifiers,
   SInt16 *mouseDownModifiers,
   SInt16 *mouseUpModifiers
);
```

Parameters

theDrag

A drag reference.

modifiers

A pointer to a variable that, on return, contains the current keyboard modifiers. You may pass `NULL` if you wish to disregard this value. The value will be 0 if the drag has not been started.

mouseDownModifiers

A pointer to a variable that, on return, contains the keyboard modifiers at the `mouseDown` parameter time. You may pass `NULL` if you wish to disregard this value. The value will be 0 if the drag has not been started.

mouseUpModifiers

A pointer to a variable that, on return, contains the keyboard modifiers at the `mouseUp` parameter time. You may pass `NULL` if you wish to disregard this value. The value will be 0 if the drag has not been completed.

Return Value
A result code. See "Drag Manager Result Codes" (page 986).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Drag.h`

GetDragMouse

Gets the current mouse and pinned mouse locations.

```
OSErr GetDragMouse (
   DragRef theDrag,
   Point *mouse,
   Point *globalPinnedMouse
);
```

Parameters

theDrag

A drag reference.

mouse

A pointer to a variable containing, on return, the current mouse location in global screen coordinates. You may pass `NULL` if you wish to ignore this value. The value will be (0, 0) if the drag is not yet used. After a drag completes, the drop location is returned.

globalPinnedMouse

A pointer to a variable containing, on return, the current pinned mouse location in global screen coordinates. You may pass `NULL` if you wish to ignore this value. The value will be (0, 0) if the drag is not yet used. After a drag completes, the drop location is returned.The pinned mouse location is the mouse location that is used to draw the drag region on the screen. The pinned mouse location is different from the mouse location when the cursor is being constrained in either dimension by a tracking handler.

Return Value
A result code. See "Drag Manager Result Codes" (page 986).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Drag.h`

GetDragOrigin

Gets the `mouseDown` parameter location that started the given drag.

```
OSErr GetDragOrigin (
   DragRef theDrag,
   Point *globalInitialMouse
);
```

Parameters

theDrag

A drag reference.

globalInitialMouse

A pointer to a variable that contains, on return, the `mouseDown` parameter location that started the drag, in global coordinates. The `mouseDown` location is returned whether or not the drag has completed.

Return Value
A result code. See "Drag Manager Result Codes" (page 986).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Drag.h`

GetDropLocation

Gets the Apple Event descriptor of the drop location. (Deprecated in Mac OS X v10.5.)

```
OSErr GetDropLocation (
   DragRef theDrag,
   AEDesc *dropLocation
);
```

Parameters

theDrag

A drag reference.

dropLocation

On return, a pointer to the Apple Event descriptor of the drop location. The drop location is only valid after the receiver has set the drop location by calling the `SetDropLocation` function. If the destination is in the Finder, the drop location will be an alias to the location in the file system that received the drag. If the receiver of the drag has not set a drop location by calling the `SetDropLocation` function, `typeNull` will be returned.

Return Value
A result code. See "Drag Manager Result Codes" (page 986).

Discussion
The `GetDropLocation` function may be called both during a drag as well as after a drag has completed.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Drag.h`

GetFlavorData

Gets all or part of the data for a specific flavor in a drag item. (Deprecated in Mac OS X v10.5.)

```
OSErr GetFlavorData (
   DragRef theDrag,
   DragItemRef theItemRef,
   FlavorType theType,
   void *dataPtr,
   Size *dataSize,
   UInt32 dataOffset
);
```

Parameters

theDrag

A drag reference.

theItemRef

The reference number of the drag item containing the flavor data.

theType

The flavor type of the flavor to get the data from.

dataPtr

A pointer to a data buffer. On return, the buffer contains the requested flavor data. Your application is responsible for allocating the memory for the flavor data and for setting the *dataSize* parameter to the number of bytes that you have allocated for the data.

dataSize

On input, a pointer to the size of the data (in bytes) that you have allocated memory for and wish to receive from the flavor. On return, a pointer to the actual number of bytes copied into the buffer specified by the `dataPtr` parameter.

If you specify a `dataSize` that is smaller than the amount of data in the flavor, the data is copied into your buffer and the `dataSize` parameter is unchanged. If you specify a `dataSize` that is larger than the amount of data in the flavor, only the amount of data in the flavor is copied into your buffer and the `dataSize` parameter contains, on return, the actual number of bytes copied. You have reached the end of the flavor's data when the `dataSize` parameter points to a number of bytes lower than you provided.

If you wish to receive the flavor data in smaller pieces than the entire size of the data, you can set the `dataSize` parameter to be as large as your buffer and call the `GetFlavorData` function multiple times while incrementing the `dataOffset` parameter by the size of your buffer. If the `dataOffset` parameter is larger than the amount of data contained within the flavor, 0 (zero) will be returned in the number pointed to by the `dataSize` parameter indicating that no data was copied into your buffer.

dataOffset

A pointer to the offset (in bytes) within the flavor structure at which to begin copying data.

Return Value
A result code. See "Drag Manager Result Codes" (page 986).

Discussion
You can first determine the size of a flavor's data by calling the `GetFlavorDataSize` function.

Note that calling the `GetFlavorData` function on a flavor that requires translation will force that translation to occur in order to return the data.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Drag.h`

GetFlavorDataSize

Gets the size of the data for a specific flavor in a drag item. (Deprecated in Mac OS X v10.5.)

```
OSErr GetFlavorDataSize (
   DragRef theDrag,
   DragItemRef theItemRef,
   FlavorType theType,
   Size *dataSize
);
```

Parameters

theDrag
A drag reference.

theItemRef
The reference number of the drag item containing the flavor.

theType
The flavor type for which to get the size of the data.

dataSize
On return, a pointer to the size of the data for the specified drag item flavor.

Return Value
A result code. See "Drag Manager Result Codes" (page 986).

Discussion
Note that calling the `GetFlavorDataSize` function on a flavor that requires translation will force that translation to be performed in order to determine the data size. Since translation may require a significant amount of time and memory during processing, call the `GetFlavorDataSize` function only when necessary.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Drag.h`

GetFlavorFlags

Gets the flags for a specific flavor in a drag item. (Deprecated in Mac OS X v10.5.)

```
OSErr GetFlavorFlags (
   DragRef theDrag,
   DragItemRef theItemRef,
   FlavorType theType,
   FlavorFlags *theFlags
);
```

Parameters

theDrag

A drag reference.

theItemRef

The reference number of the drag item containing the flavor.

theType

The flavor type for which to get the attributes.

theFlags

On return, a pointer to the attributes of the specified flavor. If a flavor is marked with the `flavorSenderOnly` flag, it is not returned to any application other than the sender.

Return Value

A result code. See "Drag Manager Result Codes" (page 986).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Drag.h`

GetFlavorType

Gets the type of a specific flavor in a drag item. (Deprecated in Mac OS X v10.5.)

```
OSErr GetFlavorType (
   DragRef theDrag,
   DragItemRef theItemRef,
   UInt16 index,
   FlavorType *theType
);
```

Parameters

theDrag

A drag reference.

theItemRef

The reference number of the drag item containing the flavor.

index

The index of the desired flavor.

theType

On return, a pointer to the type of the specified flavor. If a flavor is marked with the `flavorSenderOnly` flag, it is not returned to any application other than the sender.

Return Value
A result code. See "Drag Manager Result Codes" (page 986). If `index` is 0 or larger than the number of flavors in the item, `GetFlavorType` returns the `badDragFlavorErr` result code.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Drag.h`

GetStandardDropLocation

Gets the standard drop location set by the receiver of a drag. (Deprecated in Mac OS X v10.5.)

```
OSStatus GetStandardDropLocation (
   DragRef theDrag,
   StandardDropLocation *outDropLocation
);
```

Parameters

`theDrag`
The drag reference.

`outDropLocation`
A pointer to a value that, on return, represents the location where the drag was dropped. You can use the `GetStandardDropLcoation` function to easily determine whether a drag landed in the trash; if the drop location is the trash, the value of this parameter is `kDragStandardDropLocationTrash`. Otherwise, the value returned here is `kDragStandardDropLocationUnknown`. See "Standard Drop Locations" (page 982) for more information on these values.

Return Value
A result code. See "Drag Manager Result Codes" (page 986).

Availability
Available in Mac OS X v10.2 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Drag.h`

HideDragHilite

Removes highlighting created with the `ShowDragHilite` function. (Deprecated in Mac OS X v10.5.)

```
OSErr HideDragHilite (
   DragRef theDrag
);
```

Parameters

theDrag

The drag reference that is currently showing a drag highlight.

Return Value

A result code. See "Drag Manager Result Codes" (page 986).

Discussion

The `HideDragHilite` function assumes that the highlighting should be erased from the current port. Your application should make sure that the correct port is set before calling the `HideDragHilite` function. Also, highlighting erased by the `HideDragHilite` function is clipped to the current port. Make sure that the port's clip region is appropriately sized to remove the highlighting.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Drag.h`

InstallReceiveHandler

Installs a receive handler function for one or all of your application's windows. (Deprecated in Mac OS X v10.5.)

```
OSErr InstallReceiveHandler (
   DragReceiveHandlerUPP receiveHandler,
   WindowRef theWindow,
   void *handlerRefCon
);
```

Parameters

receiveHandler

A pointer to a receive handler function. Installing a receive handler function allows your application to accept a drag by getting drag item flavor data from the Drag Manager when the user releases the mouse button while dragging over one of your application's windows.

theWindow

A reference to the window for which to install the receive handler. When a drop occurs over this window, the Drag Manager calls your receive handler function to allow your application to accept the drag. If you pass `NULL`, the receive handler function is installed in the default handler space for your application. Receive handler functions installed in this way are called when a drop occurs over any window that belongs to your application. You may install more than one receive handler function on a single window.

handlerRefCon

A pointer to a reference constant that will be forwarded to your receive handler function when it is called by the Drag Manager. Use this constant to pass any data you wish to forward to your drag receive handler.

Return Value
A result code. See "Drag Manager Result Codes" (page 986).

Discussion
The Drag Manager sequentially calls all of the receive handler functions installed on a window when a drop occurs in that window.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Drag.h`

InstallTrackingHandler

Installs a tracking handler function for one or all of your application's windows. (Deprecated in Mac OS X v10.5.)

```
OSErr InstallTrackingHandler (
   DragTrackingHandlerUPP trackingHandler,
   WindowRef theWindow,
   void *handlerRefCon
);
```

Parameters

trackingHandler
A pointer to a tracking handler function. Installing a tracking handler function allows your application to track the user's movements through your application's windows during a drag.

theWindow
A reference to the window for which to track and handle dragging. When the cursor moves into this window during a drag, the Drag Manager sends tracking messages to the tracking handler function. If you pass `NULL`, the tracking handler function is installed in the default handler space for your application. Tracking handler functions installed in this way are called when the user moves the mouse over any window that belongs to your application. You may install more than one drag tracking handler on a single window.

handlerRefCon
A pointer to a reference constant that will be forwarded to your tracking handler function when it is called by the Drag Manager. Use this constant to pass any data you wish to forward to your tracking handler function.

Return Value
A result code. See "Drag Manager Result Codes" (page 986).

Discussion
The Drag Manager sequentially calls all of the tracking handler functions installed for a window when the user moves the cursor over that window during a drag.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Drag.h`

InvokeDragDrawingUPP

Calls your drag drawing callback. (Deprecated in Mac OS X v10.5.)

```
OSErr InvokeDragDrawingUPP (
   DragRegionMessage message,
   RgnHandle showRegion,
   Point showOrigin,
   RgnHandle hideRegion,
   Point hideOrigin,
   void *dragDrawingRefCon,
   DragRef theDrag,
   DragDrawingUPP userUPP
);
```

Return Value
A result code. See "Drag Manager Result Codes" (page 986).

Discussion
You should not need to use the function `InvokeDragDrawingUPP`, as the system calls your drag drawing callback for you.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In
`Drag.h`

InvokeDragInputUPP

Calls your drag input callback.

```
OSErr InvokeDragInputUPP (
   Point *mouse,
   SInt16 *modifiers,
   void *dragInputRefCon,
   DragRef theDrag,
   DragInputUPP userUPP
);
```

Return Value
A result code. See "Drag Manager Result Codes" (page 986).

Discussion
You should not need to use the function `InvokeDragInputUPP`, as the system calls your drag input callback for you.

Availability
Available in Mac OS X v10.0 and later.

Declared In
Drag.h

InvokeDragReceiveHandlerUPP

Calls your drag receive handler. (Deprecated in Mac OS X v10.5.)

```
OSErr InvokeDragReceiveHandlerUPP (
   WindowRef theWindow,
   void *handlerRefCon,
   DragRef theDrag,
   DragReceiveHandlerUPP userUPP
);
```

Return Value
A result code. See "Drag Manager Result Codes" (page 986).

Discussion
You should not need to use the function `InvokeDragReceiveHandlerUPP`, as the system calls your drag receive handler for you.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In
Drag.h

InvokeDragSendDataUPP

Calls your drag send data callback. (Deprecated in Mac OS X v10.5.)

```
OSErr InvokeDragSendDataUPP (
   FlavorType theType,
   void *dragSendRefCon,
   DragItemRef theItemRef,
   DragRef theDrag,
   DragSendDataUPP userUPP
);
```

Return Value
A result code. See "Drag Manager Result Codes" (page 986).

Discussion
You should not need to use the function `InvokeDragSendDataUPP`, as the system calls your drag send data callback for you.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In
Drag.h

InvokeDragTrackingHandlerUPP

Calls your drag tracking handler. (Deprecated in Mac OS X v10.5.)

```
OSErr InvokeDragTrackingHandlerUPP (
   DragTrackingMessage message,
   WindowRef theWindow,
   void *handlerRefCon,
   DragRef theDrag,
   DragTrackingHandlerUPP userUPP
);
```

Return Value
A result code. See "Drag Manager Result Codes" (page 986).

Discussion
You should not need to use the function `InvokeDragTrackingHandlerUPP`, as the system calls your drag tracking handler for you.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In
`Drag.h`

NewDrag

Creates a new drag reference for your application to use with the Drag Manager.

```
OSErr NewDrag (
   DragRef *theDrag
);
```

Parameters

theDrag

On return, a pointer to the newly created drag reference. This drag reference is required when adding drag item flavors and calling the `TrackDrag` function. Your installed drag handler functions receive this drag reference so they can call other Drag Manager functions.

Return Value
A result code. See "Drag Manager Result Codes" (page 986).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Drag.h`

NewDragDrawingUPP

Creates a new universal procedure pointer (UPP) to a drag drawing callback. (Deprecated in Mac OS X v10.5.)

```
DragDrawingUPP NewDragDrawingUPP (
   DragDrawingProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your drag drawing callback.

Return Value

On return, a UPP to the drag drawing callback. See the description of the `DragDrawingUPP` data type.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Declared In

`Drag.h`

NewDragInputUPP

Creates a new universal procedure pointer (UPP) to a drag input callback.

```
DragInputUPP NewDragInputUPP (
   DragInputProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your drag input callback.

Return Value

On return, a UPP to the drag input callback. See the description of the `DragInputUPP` data type.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Drag.h`

NewDragReceiveHandlerUPP

Creates a new universal procedure pointer (UPP) to a drag receive handler. (Deprecated in Mac OS X v10.5.)

```
DragReceiveHandlerUPP NewDragReceiveHandlerUPP (
   DragReceiveHandlerProcPtr userRoutine
);
```

Parameters

userRoutine

A pointer to your drag receive handler.

Return Value

On return, a UPP to the drag receive handler. See the description of the `DragReceiveHandlerUPP` data type.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In
`Drag.h`

NewDragSendDataUPP

Creates a new universal procedure pointer (UPP) to a drag send data callback. (Deprecated in Mac OS X v10.5.)

```
DragSendDataUPP NewDragSendDataUPP (
   DragSendDataProcPtr userRoutine
);
```

Parameters

userRoutine
A pointer to your drag send data callback.

Return Value
On return, a UPP to the drag send data callback. See the description of the `DragSendDataUPP` data type.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In
`Drag.h`

NewDragTrackingHandlerUPP

Creates a new universal procedure pointer (UPP) to a drag tracking handler. (Deprecated in Mac OS X v10.5.)

```
DragTrackingHandlerUPP NewDragTrackingHandlerUPP (
   DragTrackingHandlerProcPtr userRoutine
);
```

Parameters

userRoutine
A pointer to your drag tracking handler.

Return Value
On return, a UPP to the drag tracking handler. See the description of the `DragTrackingHandlerUPP` data type.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In
`Drag.h`

RemoveReceiveHandler

Removes a receive handler function from one or all of your application's windows. (Deprecated in Mac OS X v10.5.)

```
OSErr RemoveReceiveHandler (
   DragReceiveHandlerUPP receiveHandler,
   WindowRef theWindow
);
```

Parameters

receiveHandler

A pointer to a receive handler function.

theWindow

A reference to the window from which to remove the receive handler function. Pass `NULL` to remove the specified receive handler function from the default handler space for your application.

Return Value

A result code. See "Drag Manager Result Codes" (page 986).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Drag.h`

RemoveTrackingHandler

Removes a tracking handler function from one or all of your application's windows. (Deprecated in Mac OS X v10.5.)

```
OSErr RemoveTrackingHandler (
   DragTrackingHandlerUPP trackingHandler,
   WindowRef theWindow
);
```

Parameters

trackingHandler

A pointer to the tracking handler function to be removed.

theWindow

A reference to the window from which to remove the drag tracking handler function. Pass `NULL` to remove the specified tracking handler function from the default handler space for your application.

Return Value

A result code. See "Drag Manager Result Codes" (page 986).

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In
`Drag.h`

SetDragAllowableActions

Sets the actions that the drag receiver may take on the data within a drag.

```
OSStatus SetDragAllowableActions (
   DragRef theDrag,
   DragActions inActions,
   Boolean isLocal
);
```

Parameters

theDrag
The drag reference.

inActions
A field specifying the allowable actions for the drag. See "Drag Actions" (page 979) for a description of the values you may use here.

isLocal
A Boolean value allowing the drag sender to specify whether the actions passed in the `inActions` parameter are allowable for a local receiver or for a remote receiver. Pass `true` in this parameter if the drag actions are for local receivers.

Return Value
A result code. See "Drag Manager Result Codes" (page 986).

Discussion
The actions set by the drag sender using the `SetDragAllowableActions` function are not requirements; they are highly recommended suggestions for operations the drag receiver may perform. The caller may select whether these drag actions apply to a remote or local process with the `inLocal` parameter.

Availability
Available in Mac OS X v10.1 and later.
Not available to 64-bit applications.

Declared In
`Drag.h`

SetDragDrawingProc

Sets the drag drawing function for the Drag Manager to use with a particular drag. (Deprecated in Mac OS X v10.5.)

Not recommended

```
OSErr SetDragDrawingProc (
   DragRef theDrag,
   DragDrawingUPP drawingProc,
   void *dragDrawingRefCon
);
```

Parameters

theDrag

The drag reference for which the drag drawing function will be set.

drawingProc

The drag drawing function to be called by the Drag Manager to draw, move, and hide the "dotted outline" drag feedback on the screen during a drag.Your drag drawing function can implement any type of drag feedback, such as dragging a bitmap of the object being dragged. Details for how to write a drag drawing function are covered in the "Drag Manager Callbacks" (page 963) section.

dragDrawingRefCon

A pointer to a reference constant that will be forwarded to your drag drawing function when it is called by the Drag Manager. Use this constant to pass any data you wish to forward to your drag drawing function.

Return Value

A result code. See "Drag Manager Result Codes" (page 986).

Carbon Porting Notes

Drag drawing functions are not supported in Mac OS X, although they continue to work in CarbonLib when running Mac OS 8 and Mac OS 9.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Drag.h`

SetDragDropAction

Sets the action performed by the receiver of the drag.

```
OSStatus SetDragDropAction (
   DragRef theDrag,
   DragActions inAction
);
```

Parameters

theDrag

The drag reference for which to set the drop action.

inAction

The drop action performed. More than one action may be performed. See "Drag Actions" (page 979) for a description of the values you may use here.

Return Value

A result code. See "Drag Manager Result Codes" (page 986).

Availability
Available in Mac OS X v10.1 and later.
Not available to 64-bit applications.

Declared In
`Drag.h`

SetDragImage

Associates an image with a drag reference. (Deprecated in Mac OS X v10.4. Use `SetDragImageWithCGImage` (page 951) instead.)

```
OSErr SetDragImage (
   DragRef inDrag,
   PixMapHandle inImagePixMap,
   RgnHandle inImageRgn,
   Point inImageOffsetPt,
   DragImageFlags inImageFlags
);
```

Parameters

theDrag

The drag reference.

imagePixMap

A handle to a `PixMap` describing the image. The Drag Manager temporarily locks the `PixMapHandle` during the drag. The Drag Manager does not copy the information in this parameter; you must ensure that the data to which this parameter refers continues to exist until `TrackDrag` completes.

imageRgn

A mask describing the portion of the `PixMap` contained in the `imagePixMap` parameter which contains the drag image. Pass `NULL` for `imageRgn` if the entire `PixMap`, including white space, should be dragged.

The Drag Manager does not copy the `imageRgn` parameter data. Until `TrackDrag` completes or `SetDragImage` is called again to update the image, you must ensure that the data to which this parameter refers continues to exist.

Don't confuse the region passed to the function `TrackDrag` and that passed to the `SetDragImage` function. The former is what's drawn to the screen during dragging, while the latter is used only for drawing the correct portion of the drag image.

imageOffsetPt

The offset required to move the `PixMap` specified in the `imagePixMap` parameter to the global coordinates where the image initially appears. If this parameter is (0,0), the `PixMap` should already be in global coordinates.

theImageFlags

Flags controlling the appearance of the drag image. See "Drag Image Flags" (page 982) for a description of the values you can use in this parameter.

Return Value
A result code. See "Drag Manager Result Codes" (page 986).

Discussion
The sending application should call `SetDragImage` prior to calling `TrackDrag`. Prior to calling `SetDragImage`, the application should draw a solid, opaque image into the `PixMap` specified in the `imagePixMap` parameter. The Drag Manager will provide translucency effects. Your application can obtain a `PixMap` by calling the QuickDraw function `GetGWorldPixMap` and supplying a `GWorld` into which your application has drawn the image.

To allow the Drag Manager to analyze the `PixMap`'s colors in order to determine if it can be rendered on the available screens, Apple recommends using an 8-bit `GWorld` for the `PixMap`.

Special Considerations

`SetDragImage` installs a custom drawing procedure to do the translucent drawing. Applications calling `SetDragImage` should not also call `SetDragDrawingProc` for the same drag.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.4.
Not available to 64-bit applications.

Declared In
`Drag.h`

SetDragImageWithCGImage

Associates a Core Graphics image with a drag reference.

```
OSStatus SetDragImageWithCGImage (
   DragRef inDrag,
   CGImageRef inCGImage,
   const HIPoint *inImageOffsetPt,
   DragImageFlags inImageFlags
);
```

Parameters

inDrag
The drag reference for which to display the image.

inCGImage
A reference to the image to display during the drag. The Drag Manager retains this image for the duration of the drag, so you may release the image immediately after calling `SetDragImageWithCGImage`.

inImageOffsetPt
A pointer to the offset from the mouse location to the upper left corner of the image, normally expressed in negative values. For example, an offset of (-30, -30) centers a 60 by 60 pixel image on the mouse. Note that this differs from the usage of the offset passed to the `SetDragImage` function.

inImageFlags
Flags controlling the appearance of the drag image. See "Drag Image Flags" (page 982) for a description of the values you can use in this parameter.

Return Value
A result code. See "Drag Manager Result Codes" (page 986).

Discussion
This function is called by the sender of a drag to set the image displayed to provide user feedback during the drag. You can call the `SetDragImageWithCGImage` function at any point during the drag to update the image.

Availability
Available in Mac OS X v10.2 and later.
Not available to 64-bit applications.

Declared In
`Drag.h`

SetDragInputProc

Sets the drag input function for the Drag Manager to use with a particular drag.

```
OSErr SetDragInputProc (
   DragRef theDrag,
   DragInputUPP inputProc,
   void *dragInputRefCon
);
```

Parameters

theDrag
The drag reference for which the drag input function will be set.

inputProc
The drag input function to be called by the Drag Manager whenever the Drag Manager requires the location of the mouse, the state of the mouse button, and the status of the modifier keys on the keyboard. The Drag Manager typically calls this function once per cycle through the Drag Manager's main drag tracking loop.Your drag input function may either modify the current state of the mouse and keyboard to slightly alter dragging behavior or entirely replace the input data to drive the drag completely by itself. Details for how to write a drag input function are covered in the "Drag Manager Callbacks" (page 963) section.

dragInputRefCon
A pointer to a reference constant that will be forwarded to your drag input function when it is called by the Drag Manager. Use this constant to pass any data you wish to forward to your drag input function.

Return Value
A result code. See "Drag Manager Result Codes" (page 986).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Drag.h`

SetDragItemBounds

Sets the bounding rectangle of a drag item.

```
OSErr SetDragItemBounds (
   DragRef theDrag,
   DragItemRef theItemRef,
   const Rect *itemBounds
);
```

Parameters

theDrag

A drag reference.

theItemRef

The reference number of the drag item whose bounds you wish to set.

itemBounds

A pointer to the bounding rectangle to set for the specified drag item. This rectangle is specified in global coordinates relative to the mouse down position.

Return Value

A result code. See "Drag Manager Result Codes" (page 986).

Discussion

Your application would normally call the `SetDragItemBounds` function on each drag item before starting a drag with the `TrackDrag` function.

If you do not set the bounds of an item, the rectangle returned by the `GetDragItemBounds` function is an empty rectangle centered under the pinned mouse location.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Drag.h`

SetDragItemFlavorData

Sets the data or part of the data contained within an existing flavor. (Deprecated in Mac OS X v10.5.)

```
OSErr SetDragItemFlavorData (
   DragRef theDrag,
   DragItemRef theItemRef,
   FlavorType theType,
   const void *dataPtr,
   Size dataSize,
   UInt32 dataOffset
);
```

Parameters

theDrag

The drag reference whose flavor data will be set.

theItemRef

The drag item reference of the item that contains the flavor you wish to set all or part of the data for. The data pointed to by the *dataPtr* parameter with the size specified in the *dataSize* parameter is placed into the flavor structure at the offset specified by the *dataOffset* parameter.

theType
The data type of the existing flavor for which all or part of the data will be set.

dataPtr
A pointer to the flavor data.

dataSize
The size, in bytes, of the flavor data.

dataOffset
The offset, in bytes, into the flavor structure at which to place the data specified by the *dataPtr* and the *dataSize* parameters.

Return Value
A result code. See "Drag Manager Result Codes" (page 986).

Discussion
This function is commonly used in situations where a flavor's data is not added to the flavor when the flavor is created using the `AddDragItemFlavor` function. When the sender's drag send data function is called, the `SetDragItemFlavorData` function can be used to provide the requested data to the Drag Manager. This method is useful when the data needs to be translated by the sender and it would be expensive to compute the data before it is required.

Unlike the functions that add flavors, this function may be called both before and during a drag.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Drag.h`

SetDragMouse

Sets the current pinned mouse location.

```
OSErr SetDragMouse (
   DragRef theDrag,
   Point globalPinnedMouse
);
```

Parameters

theDrag
A drag reference.

globalPinnedMouse
The coordinates to which to set the pinned mouse location, in global screen coordinates. The pinned mouse location is used to draw the drag region on the screen.

Return Value
A result code. See "Drag Manager Result Codes" (page 986).

Discussion
To constrain the mouse within one of your application's windows, call the `SetDragMouse` function from within your tracking handler when you receive the `kDragTrackingInWindow` messages. The Drag Manager updates the position of the drag region on the screen after each time your tracking handlers are called.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Drag.h`

SetDragSendProc

Sets the send data function for the Drag Manager to use with a particular drag. (Deprecated in Mac OS X v10.5.)

```
OSErr SetDragSendProc (
   DragRef theDrag,
   DragSendDataUPP sendProc,
   void *dragSendRefCon
);
```

Parameters

theDrag
The drag reference to set the send data function for.

sendProc
The send data function that will be called by the Drag Manager when the receiver of a drop requests the flavor data of a flavor that has not been cached by the Drag Manager.

dragSendRefCon
A pointer to a reference constant that will be forwarded to your send data function when it is called by the Drag Manager. Use this constant to pass any data you wish to forward to your send data function.

Return Value
A result code. See "Drag Manager Result Codes" (page 986).

Discussion
The Drag Manager caches drag item flavor data when the flavor is added to a drag by calling the `AddDragItemFlavor` function. If `NULL` is passed to the `AddDragItemFlavor` function as the data pointer, the flavor data is not cached and the Drag Manager will call your send data function when the drag item flavor data is requested.

You do not need to provide a send data function if your application never passes `NULL` to the `AddDragItemFlavor` function when adding a drag item flavor to a drag.

Details for how to write a send data function are covered in the "Drag Manager Callbacks" (page 963) section.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Drag.h`

SetDropLocation

Sets the Apple Event descriptor for the drop location of a drag. (Deprecated in Mac OS X v10.5.)

```
OSErr SetDropLocation (
   DragRef theDrag,
   const AEDesc *dropLocation
);
```

Parameters

theDrag

A drag reference.

dropLocation

A pointer to the Apple Event descriptor of the drop location to set.

Return Value

A result code. See "Drag Manager Result Codes" (page 986).

Discussion

This function is typically called by a receive handler before attempting to get any flavor data using the `GetFlavorDataSize` or `GetFlavorData` functions. When a sender application's drag send data function is called to provide flavor data to a receiver, the `GetDropLocation` function can be called to determine the drop location while providing data.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Drag.h`

SetStandardDropLocation

Used by the receiver of a drag to set the standard drop location for a drag. (Deprecated in Mac OS X v10.5.)

```
OSStatus SetStandardDropLocation (
   DragRef theDrag,
   StandardDropLocation dropLocation
);
```

Parameters

theDrag

The drag reference.

dropLocation

A value representing the location where the drag was dropped. See "Standard Drop Locations" (page 982) for a description of the values you may use here.

Return Value

A result code. See "Drag Manager Result Codes" (page 986).

Availability

Available in Mac OS X v10.2 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In
`Drag.h`

ShowDragHilite

Highlights an area of your window during a drag. (Deprecated in Mac OS X v10.5.)

```
OSErr ShowDragHilite (
   DragRef theDrag,
   RgnHandle hiliteFrame,
   Boolean inside
);
```

Parameters

theDrag

The drag reference of the drag currently in progress.

hiliteFrame

A QuickDraw region of the frame of the window, pane, or shape you wish to highlight, in the window's local coordinate system.

inside

Pass `true` to draw the highlighting inside the frame shape. Otherwise it will be drawn outside the frame shape. Note that in either case, the highlight will not include the boundary edge of the frame. This allows you to highlight inside a window frame or a pane, or to highlight outside of a container or object in your window.

Return Value
A result code. See "Drag Manager Result Codes" (page 986).

Discussion
The `ShowDragHilite` function creates a standard drag and drop highlight in your window. Your tracking handler function should call this if a drop is allowed at the current mouse position.

You can only have one highlight showing at a time, and if you call this function when a highlight is currently visible, the first one is removed before the newly requested highlight is shown.

The `ShowDragHilite` function uses a two pixel thick line when drawing the highlight.

The `ShowDragHilite` function assumes that the highlighting should be drawn in the current port. Your application should make sure that the correct port is set before calling the `ShowDragHilite` function. Also, highlighting drawn by the `ShowDragHilite` function is clipped to the current port. Make sure that the port's clip region is appropriately sized to draw the highlighting.

The Drag Manager maintains the currently highlighted portion of your window if you use the `HideDragHilite` and `UpdateDragHilite` functions. If you intend to scroll the window that contains the highlighting, you can use the `DragPreScroll` and `DragPostScroll` functions to properly update the drag highlighting.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Drag.h`

TrackDrag

Drags an item or collection of items from your application.

```
OSErr TrackDrag (
   DragRef theDrag,
   const EventRecord *theEvent,
   RgnHandle theRegion
);
```

Parameters

theDrag
A drag reference for performing the drag operation.

theEvent
A pointer to the `mouseDown` event record that your application received that resulted in starting a drag.

theRegion
A region that represents the item or items being dragged. Note that under normal circumstances, the drag region should only include the pixels that represent the outline of the items being dragged. The Drag Manager draws the region on the screen by calling the `PaintRgn` function (not the `FrameRgn` function).

Return Value
A result code. See "Drag Manager Result Codes" (page 986). Under some circumstances, `TrackDrag` may fail with a `procNotFound` error. See "Special Considerations" below for a description of the events that may cause this problem.

Discussion
The Drag Manager follows the cursor on the screen with the "dotted outline" drag feedback and sends tracking messages to applications that have registered drag tracking handlers. The drag item flavor information cached for the drag is available to each application that becomes active during a drag.

When the user releases the mouse button, the Drag Manager calls any drag receive handlers that have been registered on the destination window. An application's drag receive handler(s) are responsible for accepting the drag and transferring the dragged data into their application.

The `TrackDrag` function returns `noErr` in situations where the user selected a destination for the drag and the destination received data from the Drag Manager. If the user drops over a non-aware application or the receiver does not accept any data from the Drag Manager, the Drag Manager automatically provides a "zoom back" animation and returns the `userCanceledErr` flag.

Special Considerations

During the call to the `TrackDrag` function, your application's context is temporarily switched out when the Drag Manager calls a different application's tracking and receive handlers. Do not depend on your application's context to be active for the entire duration of a drag.

The following actions may cause `TrackDrag` to fail with a `procNotFound` error:

- Using a high-level debugger with the Drag Manager. Although there is no workaround for this problem, your code should work fine when run without the debugger.

- Passing `TrackDrag` an event record in which the `where` field is expressed in local coordinates. In such cases, the `where` field often points outside of the window in which the drag originated. This problem can cause a crash as well as a `procNotFound` error.
- Using the Drag Manager with Text Services Manager windows when the `gestaltDragMgrFloatingWind` bit isn't defined.

For more information, see the Q&A at:

http://developer.apple.com/dev/techsupport/develop/issue29/macqa.html.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Drag.h`

UpdateDragHilite

Updates the portion of the drag highlight that was drawn over by your application. (Deprecated in Mac OS X v10.5.)

```
OSErr UpdateDragHilite (
   DragRef theDrag,
   RgnHandle updateRgn
);
```

Parameters

`theDrag`
The drag reference.

`updateRgn`
The region that needs to be updated, typically the port's `updateRgn`.

Return Value
A result code. See "Drag Manager Result Codes" (page 986).

Discussion
Use this function if your application draws into the highlighted portion of your window during a drag. For example, dragging over a folder icon in the Finder causes the Finder to redraw the folder icon in its darkened (selected) color. The Finder calls the `UpdateDragHilite` function to redraw any portion of the drag highlight that may have intersected with the folder icon.

You must guarantee, however, that any current highlighting within the `updateRgn` has been completely erased or is clipped out. If this function is asked to highlight over an area which is still highlighted, it will be redrawn incorrectly.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Drag.h`

WaitMouseMoved

Returns `true` if a mouse movement is the beginning of a drag.

```
Boolean WaitMouseMoved (
   Point initialGlobalMouse
);
```

Parameters

`initialMouse`

The point where a `mouseDown` event occurred in global screen coordinates.

Return Value

`True` if the mouse moves away from the `initialMouse` location before the mouse button is released, otherwise `false`.

Discussion

You can use this function to determine whether you should begin to drag the object when your application receives a `mouseDown` event on a draggable object.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Drag.h`

ZoomRects

Animates a rectangle into a second rectangle. (Deprecated in Mac OS X v10.5.)

```
OSErr ZoomRects (
   const Rect *fromRect,
   const Rect *toRect,
   SInt16 zoomSteps,
   ZoomAcceleration acceleration
);
```

Parameters

`fromRect`

A pointer to the starting rectangle to animate from, in global coordinates.

`toRect`

A pointer to the ending rectangle to animate to, in global coordinates.

`zoomSteps`

Specifies the number of animation steps to be shown between the source and destination rectangles. The minimum number of steps is 4. If less than 4 steps are specified, 4 will be used. The maximum number of steps is 25. If more than 25 steps are specified, 25 will be used.

acceleration

Specifies how the intermediate animation steps will be calculated. Using the `kZoomNoAcceleration` constant makes the distance between steps from the source to the destination equal. Using the `kZoomAccelerate` constant makes each step from the source to the destination increasingly larger, making the animation appear to speed up as it approaches the destination. Using the `kZoomDecelerate` constant makes each step from the source to the destination smaller, making the animation appear to slow down as it approaches the destination.

Return Value
A result code. See "Drag Manager Result Codes" (page 986).

Discussion
The `ZoomRects` function animates a movement between two rectangles on the screen. It does this by drawing gray dithered rectangles incrementally toward the destination rectangle.

The `ZoomRects` function draws on the entire screen, outside of the current port. It does not change any pixels on the screen except during the animation. It also preserves the current port and the port's settings.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Drag.h`

ZoomRegion

Animates a region's outline from one screen location to another. (Deprecated in Mac OS X v10.5.)

```
OSErr ZoomRegion (
   RgnHandle region,
   Point zoomDistance,
   SInt16 zoomSteps,
   ZoomAcceleration acceleration
);
```

Parameters

region

The region to animate.

zoomDistance

The horizontal and vertical distance from the starting point that the region will animate to.

zoomSteps

Specifies the number of animation steps to be shown between the source and destination rectangles. The minimum number of steps is 4. If less than 4 steps are specified, 4 will be used. The maximum number of steps is 25. If more than 25 steps are specified, 25 will be used.

acceleration

Specifies how the intermediate animation steps will be calculated. Using the `kZoomNoAcceleration` constant makes the distance between steps from the source to the destination equal. Using the `kZoomAccelerate` constant makes each step from the source to the destination increasingly larger, making the animation appear to speed up as it approaches the destination. Using the `kZoomDecelerate` constant makes each step from the source to the destination smaller, making the animation appear to slow down as it approaches the destination.

Return Value
A result code. See "Drag Manager Result Codes" (page 986).

Discussion
The `ZoomRegion` function animates a region from one location to another on the screen. It does this by drawing gray dithered regions incrementally toward the destination region.

The `ZoomRegion` function draws on the entire screen, outside of the current port. It does not change any pixels on the screen except during its animation. It also preserves the current port and the port's settings.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Callbacks by Task

Tracking and Receiving Drags

`DragTrackingHandlerProcPtr` (page 968)
Defines a pointer to a drag tracking handler.

`DragReceiveHandlerProcPtr` (page 966)
Defines a pointer to a drag receive handler.

Overriding Drag Manager Behavior

`DragSendDataProcPtr` (page 967)
Defines a pointer to a drag send data function, called by the Drag Manager to supply flavor data to the drag receiver.

`DragInputProcPtr` (page 964)
Defines a pointer to a drag input function that modifies keyboard and mouse input to the Drag Manager.

`DragDrawingProcPtr` (page 963)
Defines a pointer to a drag drawing function that draws the drag region.

Callbacks

DragDrawingProcPtr

Defines a pointer to a drag drawing function that draws the drag region.

Not recommended

```
typedef OSErr (*DragDrawingProcPtr) (
                DragRegionMessage message,
                RgnHandle showRegion,
                Point showOrigin,
                RgnHandle hideRegion,
                Point hideOrigin,
                void * dragDrawingRefCon,
                DragRef theDrag);
```

If you name your function `MyDragDrawingFunction`, you would declare it like this:

```
OSErr MyDragDrawingFunction (
                DragRegionMessage message,
                RgnHandle showRegion,
                Point showOrigin,
                RgnHandle hideRegion,
                Point hideOrigin,
                void * dragDrawingRefCon,
                DragRef theDrag);
```

Parameters

message

A drag region drawing message from the Drag Manager. Use this message to determine what action your drag drawing callback function should take. These messages are described further in "Drag Drawing Messages" (page 975).

showRegion

A region containing the drag region as it should be drawn or is currently visible on the screen, in global screen coordinates. The `showRegion` parameter has slightly different meanings depending on the message passed to your drag drawing callback.

showOrigin

The point corresponding to the original `mouseDown` location in the drag region within the given `showRegion`, in global screen coordinates.

hideRegion

A region containing the drag region as it should be erased from the screen, in global screen coordinates. The `hideRegion` parameter has slightly different meanings depending on the message passed to your drag drawing callback.

hideOrigin

The point corresponding to the original `mouseDown` location in the drag region within the given `hideRegion`, in global screen coordinates.

dragDrawingRefCon

A pointer to the reference constant that was provided when the `SetDragDrawingProc` function was called to install this function.

theDrag
The drag reference of the drag.

Return Value
A result code. See "Drag Manager Result Codes" (page 986).

Discussion
If your application set a custom drawing function for a drag using the `SetDragDrawingProc` function, the Drag Manager calls this drawing function to perform all drag region drawing operations.

The Drag Manager tracks the drag region as it appears on the screen and as it should follow the mouse. All drag region operations are performed on the region specified to the `TrackDrag` function. Drag region drawing is managed by sending your drag drawing callback function messages to show and hide pieces of the drag region.

The Drag Manager has its own drag region port that is used to do all drag region drawing during a drag. This port is set to the current port before calling your drag drawing function. The drag region port is for your drag drawing function's exclusive use during a drag. You may modify its fields and depend on its contents between calls to your drag drawing callback function.

Special Considerations

For Classic applications, your application's context is not available when your drag drawing callback function is called by the Drag Manager. If you need access to your application's global variables, you will need to setup and restore your application's A5 world yourself.

You cannot call the `WaitNextEvent` function or any other Event Manager functions in your drag drawing callback function. This restriction includes calling any functions that may call the Event Manager, such as the `ModalDialog` or `Alert` functions.

Carbon Porting Notes

Drag drawing functions are not supported in Mac OS X, although they continue to work in CarbonLib when running Mac OS 8 and Mac OS 9.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Drag.h`

DragInputProcPtr

Defines a pointer to a drag input function that modifies keyboard and mouse input to the Drag Manager.

```
typedef OSErr (*DragInputProcPtr) (

                Point * mouse,
                SInt16 * modifiers,
                void * dragInputRefCon,
                DragRef theDrag);
```

If you name your function `MyDragInputFunction`, you would declare it like this:

```
OSErr MyDragInputFunction (
                Point * mouse,
                SInt16 * modifiers,
```

```
                void * dragInputRefCon,
                DragRef theDrag);
```

Parameters

mouse

On entry, a pointer to the location. On return, your drag input function should provide the desired current mouse location. The mouse location is specified in global coordinates.

modifiers

On entry, a pointer to a value indicating the current state of the keyboard modifiers and mouse button. On return, your drag input function should provide a pointer to the desired state of the keyboard modifiers and mouse button. The modifiers are specified using the same format and constants as the Event Manager's `EventRecord.modifiers` field.

dragInputRefCon

A pointer to the reference constant that was provided when the `SetDragInputProc` function was called to install this function.

theDrag

The drag reference of the drag.

Return Value

A result code. See "Drag Manager Result Codes" (page 986).

Discussion

Each time the Drag Manager samples the mouse and keyboard, it calls your drag input callback (if one has been set by calling the `SetDragInputProc` function) to provide a way for your application to modify or completely change the mouse and keyboard input to the Drag Manager.

When your drag input callback function is called, the mouse and modifiers parameters contain the actual values from the physical input devices. Your drag input callback function may modify these values in any way. For example, your drag input callback function may simply inhibit the control key modifier bit from being set or it may completely replace the mouse coordinates with those generated some other way to drive the drag itself.

Note that the Drag Manager uses the `buttonState` flag in the `modifiers` parameter to determine when the mouse button has been released to finish a drag.

Special Considerations

For Classic applications, your application's context is not available when your drag input callback function is called by the Drag Manager. If you need access to your application's global variables, you will need to setup and restore your application's A5 world yourself.

You cannot call the `WaitNextEvent` function or any other Event Manager functions from your drag input callback function. This restriction includes calling any functions that may call the Event Manager, such as the `ModalDialog` or `Alert` functions.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Drag.h`

DragReceiveHandlerProcPtr

Defines a pointer to a drag receive handler.

```
typedef OSErr (*DragReceiveHandlerProcPtr)
(
                WindowRef theWindow,
                void * handlerRefCon,
                DragRef theDrag);
```

If you name your function `MyDragReceiveHandler`, you would declare it like this:

```
OSErr MyDragReceiveHandler (
                WindowRef theWindow,
                void * handlerRefCon,
                DragRef theDrag);
```

Parameters

theWindow

A reference to the window that the drop occurred in.

handlerRefCon

A pointer to the reference constant that was provided to the `InstallReceiveHandler` function when this handler was installed.

theDrag

The drag reference of the drag.

Return Value

A result code. See "Drag Manager Result Codes" (page 986).

Discussion

When the user releases a drag in a window, the Drag Manager calls any drag receive handler functions that have been installed on that window. You can get the information about the data that is being dragged, to determine if your window will accept the drop, by using the drag information functions provided by the Drag Manager. After your drag receive handler decides that it can accept the drop, use the `GetFlavorData` function to get the data from the sender of the drag.

When the Drag Manager calls your drag receive handler, the port is set to the window that the drop occurred in. If you want to provide an optional Apple Event descriptor of the drop location for the sender, use the `SetDropLocation` function to set the drop location descriptor before calling the sender with the `GetFlavorData` or `GetFlavorDataSize` functions.

If you return any result code other than `noErr` from your drag receive handler, the Drag Manager will "zoomback" the drag region to the source location and return the `userCanceledErr` result code from the `TrackDrag` function. If the drag is dropped into a location that cannot accept the drag (such as the window title bar or window scroll bars) or no acceptable data types were available, your drag receive handler should return the `dragNotAcceptedErr` result code, which will cause the Drag Manager to provide the "zoomback" animation described above.

Special Considerations

For Classic applications, the Drag Manager guarantees that your application's A5 world and low-memory environment is properly set up for your application's use. Therefore, you can allocate memory, and use your application's global variables. You can also rely on low-memory globals being valid.

Although it is possible to call `WaitNextEvent` or other functions that run the event loop from within your drag receive handler, it is not recommended as it can cause the drag to timeout and may result in a crash or in corrupt data.

Note that the Process Manager's process switching mechanism is disabled during calls to your handler. If your application is not frontmost when calling these functions, your application will not be able to switch forward. This could result in a situation where a modal dialog appears behind the front process but will not be able to come forward in order to interact with the user.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Drag.h`

DragSendDataProcPtr

Defines a pointer to a drag send data function, called by the Drag Manager to supply flavor data to the drag receiver.

```
typedef OSErr (*DragSendDataProcPtr)
(
                FlavorType theType,
                void * dragSendRefCon,
                DragItemRef theItemRef,
                DragRef theDrag);
```

If you name your function `MyDragSendDataFunction`, you would declare it like this:

```
OSErr MyDragSendDataFunction (
                FlavorType theType,
                void * dragSendRefCon,
                DragItemRef theItemRef,
                DragRef theDrag);
```

Parameters

`theType`
The flavor type being requested by a drop receiver.

`dragSendRefCon`
A pointer to the reference constant that was provided when the `SetDragSendProc` function was called to install this function.

`theItemRef`
The item reference of the item from which the flavor data is being requested.

`theDrag`
The drag reference of the drag.

Return Value
A result code. See "Drag Manager Result Codes" (page 986).

Discussion
The Drag Manager calls your drag send data function when drag item flavor data is requested by a drop receiver if the drag item flavor data is not already cached by the Drag Manager. Use the function `SetDragItemFlavorData` (page 953) to provide the requested data to the Drag Manager.

The Drag Manager caches all drag item flavor data that was specified in the data pointer when the flavor was added using the `AddDragItemFlavor` function. If the data pointer was `NULL` when the flavor was added, the Drag Manager calls the drag send data function to get the data when a receiver requests the data using the `GetFlavorData` or `GetFlavorDataSize` functions.

A second scenario where the drag send data function is called is when a drop receiver requests a flavor that is translated by the Translation Manager and the source data (which would be a different type than actually requested by the receiver) is not already cached by the Drag Manager.

You can use the `GetDropLocation` function to get the Apple event descriptor of the drop location from within your drag send data function. It is optional for the receiver to provide a drop location descriptor. If the receiver does not provide the drop location descriptor, the `typeNull` value will be returned by the `GetDropLocation` function.You do not need to provide a drag send data function if you never pass `NULL` as the data pointer when calling the `AddDragItemFlavor` function.

Special Considerations

For Classic applications, the Drag Manager guarantees that your application's A5 world and low-memory environment is properly set up for your application's use. Therefore, you can allocate memory, and use your application's global variables. You can also rely on low-memory globals being valid.

Although it is possible to call `WaitNextEvent` or other functions that run the event loop from within your drag send data callback, it is not recommended as it can cause the drag to timeout and may result in a crash or in corrupt data.

Note that the Process Manager's process switching mechanism is disabled during calls to your handler. If your application is not frontmost when calling these functions, your application will not be able to switch forward. This could result in a situation where a modal dialog appears behind the front process but will not be able to come forward in order to interact with the user.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Drag.h`

DragTrackingHandlerProcPtr

Defines a pointer to a drag tracking handler.

```
typedef OSErr (*DragTrackingHandlerProcPtr)
(
                DragTrackingMessage message,
                WindowRef theWindow,
                void * handlerRefCon,
                DragRef theDrag);
```

If you name your function `MyDragTrackingHandler`, you would declare it like this:

```
OSErr MyDragTrackingHandler (
        DragTrackingMessage message,
        WindowRef theWindow,
        void * handlerRefCon,
        DragRef theDrag);
```

Parameters

message

A tracking message from the Drag Manager indicating the action your tracking handler should take. These messages are described further in "Drag Tracking Messages" (page 976).

theWindow

A reference to the window that the mouse is currently over.

handlerRefCon

A pointer to the reference constant that was provided to the `InstallTrackingHandler` function when this handler was installed.

theDrag

The drag reference of the drag.

Return Value
A result code. See "Drag Manager Result Codes" (page 986).

Discussion
When the user drags an item or collection of items through a window, the Drag Manager calls any tracking handlers that have been installed on that window. Your tracking handler can determine the contents of the drag by calling the drag item information functions, such as `CountDragItems` (page 925), `CountDragItemFlavors` (page 925), `GetFlavorType` (page 938) and `GetFlavorFlags` (page 937), and highlighting or modifying the objects in your window accordingly.

When the Drag Manager calls your tracking handler, the port will always be set to the window that the mouse is over.

Special Considerations

For Classic applications, the Drag Manager guarantees that your application's A5 world and low-memory environment is properly set up for your application's use. Therefore, you can allocate memory, and use your application's global variables. You can also rely on low-memory globals being valid.

Although it is possible to call `WaitNextEvent` or other functions that run the event loop from within your drag tracking handler, it is not recommended as it can cause the drag to timeout and may result in a crash or in corrupt data.

Note that the Process Manager's process switching mechanism is disabled during calls to your handler. If your application is not frontmost when calling these functions, your application will not be able to switch forward. This could result in a situation where a modal dialog appears behind the front process but will not be able to come forward in order to interact with the user.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Drag.h`

Data Types

DragRef

Defines a reference to a drag object.

```
typedef struct OpaqueDragRef * DragRef;
```

Discussion
Before calling any other Drag Manager function, you must first create a new drag reference by calling the `NewDrag` function. The drag reference that is returned by the `NewDrag` function is used in all subsequent calls to the Drag Manager. Use the `DisposeDrag` function to dispose of a drag reference after you are finished using it.

The meaning of the bits in a drag reference is internal to the Drag Manager. You should not attempt to interpret the value of the drag reference.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Drag.h`

DragItemRef

Defines a reference to a drag item.

```
typedef UInt32 DragItemRef;
```

Discussion
The drag item reference is a reference number used to refer to a single item in a drag. Drag item reference numbers are created by the sender application when adding drag item flavor information to a drag. Drag item reference numbers are created by and should only be interpreted by the sender application.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Drag.h`

FlavorType

Defines a flavor type.

```
typedef OSType FlavorType;
```

Discussion
The flavor type is a four character type that describes the format of drag item flavor data. The flavor type has the same function as a scrap type; it designates the format of the associated data. Any scrap type or resource type may be used.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Drag.h`

HFSFlavor

Defines a flavor for dragging file system objects.

```
struct HFSFlavor {
    OSType fileType;
    OSType fileCreator;
    UInt16 fdFlags;
    FSSpec fileSpec;
};
typedef struct HFSFlavor HFSFlavor;
```

Fields

`fileType`
The file type of the object.

`fileCreator`
The file creator of the object.

`fdFlags`
The Finder flags of the object.

`fileSpec`
The `FSSpec` structure for the object.

Discussion

The Drag Manager defines a special flavor for dragging file system objects. The HFS drag item flavor is used when dragging document and folder icons in the Finder. The HFS drag item flavor data structure is defined by the `HFSFlavor` data type.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Drag.h`

PromiseHFSFlavor

Defines a data flavor for promising file system objects.

```
struct PromiseHFSFlavor {
    OSType fileType;
    OSType fileCreator;
    UInt16 fdFlags;
    FlavorType promisedFlavor;
};
typedef struct PromiseHFSFlavor PromiseHFSFlavor;
```

Fields

`fileType`
The file type of the object.

`fileCreator`
The file creator of the object.

`fdFlags`
The Finder flags of the object.

`promisedFlavor`

The flavor type of a separate promise flavor to contain the `FSSpec` structure for the new file. Apple recommends that you use the `kDragPromisedFlavor` type in this field.

Discussion
The promise HFS flavor type is used when you wish to create a new file when dragging to the Finder. The flavor consists of an array of `PromiseHFSFlavor` structures, with the first entry being the preferred file type you would like to create and subsequent array entries being file types in descending preference. This structure allows you to create the file in your `DragSendDataProcPtr` (page 967) callback and provide the `FSSpec` for the new file at that time.

After providing an `FSSpec`, the Finder will move the new file to the drop location. If you wish to create the file before the drag and provide the `FSSpec` data up front, create the new file in the Temporary Items folder so it does not prematurely appear in an open Finder window.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Drag.h`

DragDrawingUPP

Defines a universal procedure pointer (UPP) to a drag drawing callback.

```
typedef DragDrawingProcPtr DragDrawingUPP;
```

Discussion
For more information, see the description of the `DragDrawingProcPtr` (page 963) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Drag.h`

DragInputUPP

Defines a universal procedure pointer (UPP) to a drag input callback.

```
typedef DragInputProcPtr DragInputUPP;
```

Discussion
For more information, see the description of the `DragInputProcPtr` (page 964) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Drag.h`

DragReceiveHandlerUPP

Defines a universal procedure pointer (UPP) to a drag receive handler.

```
typedef DragReceiveHandlerProcPtr DragReceiveHandlerUPP;
```

Discussion
For more information, see the description of the `DragReceiveHandlerProcPtr` (page 966) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Drag.h`

DragSendDataUPP

Defines a universal procedure pointer (UPP) to a drag send data callback.

```
typedef DragSendDataProcPtr DragSendDataUPP;
```

Discussion
For more information, see the description of the `DragSendDataProcPtr` (page 967) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Drag.h`

DragTrackingHandlerUPP

Defines a universal procedure pointer (UPP) to a drag tracking handler.

```
typedef DragTrackingHandlerProcPtr DragTrackingHandlerUPP;
```

Discussion
For more information, see the description of the `DragTrackingHandlerProcPtr` (page 968) callback function.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Drag.h`

Constants

Drag Attributes

Provide additional information about a drag that is in progress.

```
typedef UInt32 DragAttributes;
enum {
    kDragHasLeftSenderWindow = (1L << 0),
    kDragInsideSenderApplication = (1L << 1),
    kDragInsideSenderWindow = (1L << 2) };
```

Constants

`kDragHasLeftSenderWindow`
Set if the drag has left the source window since the beginning of the drag. This flag is useful for providing window highlighting after the user has moved the mouse outside of the source window.
Available in Mac OS X v10.0 and later.
Declared in `Drag.h`.

`kDragInsideSenderApplication`
Set if the drag is currently in any window that belongs to the application that started the drag.
Available in Mac OS X v10.0 and later.
Declared in `Drag.h`.

`kDragInsideSenderWindow`
Set if the drag is currently in the same window that the drag started from.
Available in Mac OS X v10.0 and later.
Declared in `Drag.h`.

Discussion
The attribute flags defined by the `DragAttributes` type provide information about the window and application that the drag is currently occurring in. During a drag, the current drag attributes can be obtained by calling the function `GetDragAttributes` (page 930).

Drag Behaviors

Specify the current zoomback behavior of a drag.

```
typedef UInt32 DragBehaviors;
enum {
    kDragBehaviorNone = 0,
    kDragBehaviorZoomBackAnimation = (1L << 0) };
```

Constants

`kDragBehaviorNone`
The Drag Manager performs no animation for a failed drag.
Available in Mac OS X v10.0 and later.
Declared in `Drag.h`.

`kDragBehaviorZoomBackAnimation`
The Drag Manager performs zoomback animation for a failed drag. This behavior is normally enabled.
Available in Mac OS X v10.0 and later.
Declared in `Drag.h`.

Discussion
To change the behavior associated with a drag reference, use the `ChangeDragBehaviors` (page 924) function.

Drag Drawing Messages

Define messages that may be sent to your drag drawing callback.

```
typedef SInt16 DragRegionMessage;
enum {
    kDragRegionBegin = 1,
    kDragRegionDraw = 2,
    kDragRegionHide = 3,
    kDragRegionIdle = 4,
    kDragRegionEnd = 5
};
```

Constants

`kDragRegionBegin`

Your drag drawing callback function receives this message when a drag is being started and it is time to initialize your drawing function. You should not draw anything to the screen when you receive this message.The `showRegion` and `showOrigin` parameters to your drag drawing callback function contain the drag region and the `mouseDown` location, respectively, that were specified to the `TrackDrag` function. The `mouseDown` location is the origin of the drag region.The `hideRegion` parameter is `NULL` when your drag drawing callback function receives this message.

Available in Mac OS X v10.0 and later.

Declared in `Drag.h`.

`kDragRegionDraw`

Your drag drawing callback receives this message when you should move your drag region from the area of the screen defined by the `hideRegion` parameter to the area of the screen defined by the `showRegion` parameter.The `showRegion` parameter contains the drag region that was passed to the `TrackDrag` function, offset to the current pinned mouse location. This region represents the area of the screen that must be drawn into.The `hideRegion` parameter contains the drag region as it is currently visible on the screen from the last call with a `dragRegionDraw` message. This region represents the area of the screen that must be restored. Any part of the drag region that was previously obscured by a call with the `dragRegionHide` message is not included in this `hideRegion` parameter.

Available in Mac OS X v10.0 and later.

Declared in `Drag.h`.

`kDragRegionHide`

Your drag drawing callback receives this message when you should remove part of the drag region from the screen. You receive this message when the drag has ended or when part of the region must be obscured for drawing operations to occur underneath the drag region.The `showRegion` parameter is `NULL` when your drag drawing callback function receives this message.The `hideRegion` parameter contains the part of the currently visible drag region that must be removed from the screen.

Available in Mac OS X v10.0 and later.

Declared in `Drag.h`.

`kDragRegionIdle`

Your drag drawing callback receives this message when the drag region has not moved on the screen and no drawing is necessary. You can use this message if animation of the drag region is necessary.The `showRegion` parameter contains the drag region as it is currently visible on the screen.The `hideRegion` parameter is `NULL` when your drag drawing callback receives this message.

Available in Mac OS X v10.0 and later.

Declared in `Drag.h`.

`kDragRegionEnd`

Your drag drawing callback receives this message when the drag has completed and it is time to deallocate any allocations made from within your drag drawing callback. Your drag drawing callback will have already received a `dragRegionHide` message to hide the entire drag region before receiving this message. After you receive this message, your drag drawing callback will not be called again for the duration of the drag.Both the `showRegion` and `hideRegion` parameters are `NULL` when your drag drawing callback function receives this message.

Available in Mac OS X v10.0 and later.

Declared in `Drag.h`.

Discussion
See `DragDrawingProcPtr` (page 963) for more information on drag drawing callback functions.

Drag Tracking Messages

Define messages that may be sent to your drag tracking handler.

```
typedef SInt16 DragTrackingMessage;
enum {
    kDragTrackingEnterHandler = 1,
    kDragTrackingEnterWindow = 2,
    kDragTrackingInWindow = 3,
    kDragTrackingLeaveWindow = 4,
    kDragTrackingLeaveHandler = 5
};
```

Constants
`kDragTrackingEnterHandler`

Your tracking handler receives this message when the focus of a drag enters a window that is handled by your tracking handler. If the user moves the drag directly to another window that is handled by the same tracking handler, a second `kDragTrackingEnterHandler` message is not received. Your tracking handler only receives this message when the drag enters the domain of your function after leaving another.

Available in Mac OS X v10.0 and later.

Declared in `Drag.h`.

`kDragTrackingEnterWindow`

Your tracking handler receives this message when a drag enters any window that is handled by your tracking handler. This message is sent to your tracking handler for each window that the drag may enter. Your tracking handler will always receive this message within a pair of `kDragTrackingEnterHandler` and `kDragTrackingLeaveHandler` messages.

Available in Mac OS X v10.0 and later.

Declared in `Drag.h`.

`kDragTrackingInWindow`

Your tracking handler receives this message as the user is dragging within a window handled by your tracking handler. You can use this message to track the dragging process through your window. Your tracking handler will always receive this message within a pair of `kDragTrackingEnterWindow` and `kDragTrackingLeaveWindow` messages.Your tracking handler would typically draw the majority of your window highlighting and track objects in your window when you receive this message from the Drag Manager.

Available in Mac OS X v10.0 and later.

Declared in `Drag.h`.

`kDragTrackingLeaveWindow`

Your tracking handler receives this message when a drag leaves any window that is handled by your tracking handler. You are guaranteed to receive this message after receiving a corresponding `kDragTrackingEnterWindow` message. Your tracking handler will always receive this message within a pair of `kDragTrackingEnterHandler` and `kDragTrackingLeaveHandler` messages.

Available in Mac OS X v10.0 and later.

Declared in `Drag.h`.

`kDragTrackingLeaveHandler`

Your tracking handler receives this message when the focus of a drag enters a window that is not handled by your tracking handler. Your tracking handler is guaranteed to receive this message after receiving a corresponding `kDragTrackingEnterHandler` message.

Available in Mac OS X v10.0 and later.

Declared in `Drag.h`.

Discussion

See `DragTrackingHandlerProcPtr` (page 968) for more information on drag tracking handlers.

Flavor Flags

Provide additional information about drag item flavors.

```
typedef UInt32 FlavorFlags;
enum {
    flavorSenderOnly = (1 << 0),
    flavorSenderTranslated = (1 << 1),
    flavorNotSaved = (1 << 2),
    flavorSystemTranslated = (1 << 8),
    flavorDataPromised = (1 << 9) };
```

Constants

`flavorSenderOnly`

Set by the sender if the flavor should only be available to the sender of a drag. If this flag is set when adding the flavor to a drag, no Drag Manager clients other than the sender can receive this flavor.

Available in Mac OS X v10.0 and later.

Declared in `Drag.h`.

`flavorSenderTranslated`
: Set by the sender if the flavor data is translated by the sender. This flag is useful to a receiver if the receiver needs to determine if the sender is performing its own translation to generate this data type. Typically, receivers that store dragged data without interpreting each data type do not store translated types. Flavor types marked with this flag are not stored by the Finder in clipping files.

  Available in Mac OS X v10.0 and later.

  Declared in `Drag.h`.

`flavorNotSaved`
: Set by the sender if the flavor data should not be stored by the receiver. This flag is useful for marking flavor data that will become stale after the drag has completed. Receivers that store dragged data should not store flavors that are marked with this flag. Flavor types marked with this flag are not stored by the Finder in clipping files.

  Available in Mac OS X v10.0 and later.

  Declared in `Drag.h`.

`flavorSystemTranslated`
: Set if the flavor data is provided by the Translation Manager. If this flavor is requested, the Drag Manager will obtain any required data types from the sender and then it will use the Translation Manager to provide the data that the receiver requested. Typically, receivers that store dragged data without interpreting each data type do not store translated types. Flavor types marked with this flag are not stored by the Finder in clipping files.

  Available in Mac OS X v10.0 and later.

  Declared in `Drag.h`.

`flavorDataPromised`
: Set by the sender if the flavor data is promised at a later time.

  Available in Mac OS X v10.1 and later.

  Declared in `Drag.h`.

Discussion
These constants are used when calling the `AddDragItemFlavor` (page 923) function and can be obtained by calling the `GetFlavorFlags` (page 937) function.

flavorTypeDirectory

Represents a special flavor type for AOCE directory specifications.

```
enum {
    flavorTypeDirectory = 'diry'
};
```

Constants
`flavorTypeDirectory`
: The flavor type for a AOCE directory specification. Refer to the AOCE documentation for a definition of the `DSSpec` data structure.

  Available in Mac OS X v10.0 through Mac OS X v10.4.

  Declared in `Drag.h`.

Drag Actions

Specify the actions that should be or have been performed on the data in a drag.

```
enum {
    kDragActionNothing = 0,
    kDragActionCopy = 1L,
    kDragActionAlias = (1L << 1),
    kDragActionGeneric = (1L << 2),
    kDragActionPrivate = (1L << 3),
    kDragActionMove = (1L << 4),
    kDragActionDelete = (1L << 5),
    kDragActionAll = 0xFFFFFFFF };
typedef UInt32 DragActions;
```

Constants

`kDragActionNothing`
Nothing should be or has been done with the data in the drag. When set as an allowable action for remote drags, the drag is not sent to applications other than the drag sender.

Available in Mac OS X v10.1 and later.

Declared in `Drag.h`.

`kDragActionCopy`
The data contained in the drag can be or has been copied.

Available in Mac OS X v10.1 and later.

Declared in `Drag.h`.

`kDragActionAlias`
The data contained in the drag can be or has been shared.

Available in Mac OS X v10.1 and later.

Declared in `Drag.h`.

`kDragActionGeneric`
When set by the drag sender, suggests that the drag receiver can determine the drag action. When returned by the drag receiver, indicates that the receiver did not define a drag action.

Available in Mac OS X v10.1 and later.

Declared in `Drag.h`.

`kDragActionPrivate`
Suggests that the drag action should be negotiated privately between the drag source and destination.

Available in Mac OS X v10.1 and later.

Declared in `Drag.h`.

`kDragActionMove`
The data contained in the drag can be or has been moved.

Available in Mac OS X v10.1 and later.

Declared in `Drag.h`.

`kDragActionDelete`
The data contained in the drag can be or has been deleted.

Available in Mac OS X v10.1 and later.

Declared in `Drag.h`.

`kDragActionAll`
Indicates that all of the above drag actions are allowed.

Available in Mac OS X v10.1 and later.

Declared in `Drag.h`.

Discussion
The drag sender can use these constants to indicate what actions are allowable on the data contained within a drag. The drag receiver can use these constants to indicate what, if any, action was performed on the drag.

Some of the drag actions defined here enforce a mode of operation, while others are suggestions. The `DragActions` constants are used in conjunction with the `GetDragAllowableActions` (page 929), `SetDragAllowableActions` (page 948), `GetDragDropAction` (page 931), and `SetDragDropAction` (page 949) functions. Using drag actions increases compatibility with the Cocoa drag operation model.

HFS Flavor Types

Identify flavor types for file system objects.

```
enum {
    kDragFlavorTypeHFS = 'hfs ',
    kDragFlavorTypePromiseHFS = 'phfs',
    flavorTypeHFS = kDragFlavorTypeHFS,
    flavorTypePromiseHFS = kDragFlavorTypePromiseHFS
};
```

Constants
`kDragFlavorTypeHFS`
The flavor type for an HFS file system object. The Finder uses HFS flavors when dragging existing file system objects. The HFS flavor data is defined by the data type `HFSFlavor` (page 971).

Available in Mac OS X v10.0 and later.

Declared in `Drag.h`.

`kDragFlavorTypePromiseHFS`
The flavor type for promising an HFS file system object to the receiver of the drag. This flavor type can be used when a file could be created if the destination of the drag can accept file system objects. The data type `PromiseHFSFlavor` (page 971) is used to access the information in this flavor type.

Available in Mac OS X v10.0 and later.

Declared in `Drag.h`.

`flavorTypeHFS`
Use `kDragFlavorTypeHFS` instead.

Available in Mac OS X v10.0 and later.

Declared in `Drag.h`.

`flavorTypePromiseHFS`
Use `kDragFlavorTypePromiseHFS` instead.

Available in Mac OS X v10.0 and later.

Declared in `Drag.h`.

Promised Flavor Types

Identify flavor types for the `PromiseHFSFlavor` structure.

```
enum {
    kDragPromisedFlavorFindFile = 'rWm1',
    kDragPromisedFlavor = 'fssP'
};
```

Constants

`kDragPromisedFlavorFindFile`
The value of the `promisedFlavor` field of the `PromiseHFSFlavor` structure for Find File.

Available in Mac OS X v10.0 and later.

Declared in `Drag.h`.

`kDragPromisedFlavor`
The value of the `promisedFlavor` field of the `PromiseHFSFlavor` structure for all other file system objects.

Available in Mac OS X v10.0 and later.

Declared in `Drag.h`.

Type and Creator Constants for Volumes and Directories

Define a creator code and file types for flavor data referring to a volume or directory.

```
enum {
    kDragPseudoCreatorVolumeOrDirectory = 'MACS',
    kDragPseudoFileTypeVolume = 'disk',
    kDragPseudoFileTypeDirectory = 'fold'
};
```

Constants

`kDragPseudoCreatorVolumeOrDirectory`
The "creator type" for volumes and directories. If the data in a drag containing `kDragFlavorTypeHFS` data refers to a folder or volume, the `fileCreator` field of the `HFSFlavor` structure should be set to this value.

Available in Mac OS X v10.0 and later.

Declared in `Drag.h`.

`kDragPseudoFileTypeVolume`
The value of the `fileType` field of the `HFSFlavor` structure for a volume.

Available in Mac OS X v10.0 and later.

Declared in `Drag.h`.

`kDragPseudoFileTypeDirectory`
The value of the `fileType` field of the `HFSFlavor` structure for a directory.

Available in Mac OS X v10.0 and later.

Declared in `Drag.h`.

Standard Drop Locations

Define common drop locations.

```
enum {
    kDragStandardDropLocationTrash = 'trsh',
    kDragStandardDropLocationUnknown = 'unkn'
};
typedef OSType StandardDropLocation;
```

Constants

`kDragStandardDropLocationTrash`

Set when a drag is dropped on the trash icon. Setting this standard drop location automatically sets the traditional drop location to an alias to the trash folder.

Available in Mac OS X v10.2 and later.

Declared in `Drag.h`.

`kDragStandardDropLocationUnknown`

The receiver did not specify a drop location. This is the default.

Available in Mac OS X v10.2 and later.

Declared in `Drag.h`.

Discussion

These values are used in conjunction with the `GetStandardDropLocation` (page 939) and `SetStandardDropLocation` (page 956) functions.

Drag Image Flags

Specify the appearance of a translucent drag.

```
typedef UInt32 DragImageFlags;
enum {
    kDragRegionAndImage = (1L << 4)
    kDragStandardTranslucency = 0,
    kDragDarkTranslucency = 1,
    kDragDarkerTranslucency = 2,
    kDragOpaqueTranslucency = 3
};
```

Constants

`kDragRegionAndImage`

Add this constant to the transparency levels represented by the following constants to specify that the outline region passed to `TrackDrag` should be drawn on screen, in addition to the translucent drag image.

Available in Mac OS X v10.0 and later.

Declared in `Drag.h`.

`kDragStandardTranslucency`

Use the standard translucency level for the drag image. Currently, this is 65%.

Available in Mac OS X v10.0 and later.

Declared in `Drag.h`.

`kDragDarkTranslucency`
Use 50% translucency for the drag image.

Available in Mac OS X v10.0 and later.

Declared in `Drag.h`.

`kDragDarkerTranslucency`
Use 25% transparency for the drag image.

Available in Mac OS X v10.0 and later.

Declared in `Drag.h`.

`kDragOpaqueTranslucency`
Use an opaque drag image (0% translucency).

Available in Mac OS X v10.0 and later.

Declared in `Drag.h`.

Discussion
These constants are used in conjunction with the `SetDragImageWithCGImage` (page 951)and `SetDragImage` (page 950) functions to specify the appearance of the drag image.

Finder Flavor Types

Identify flavor types for the Finder.

```
enum {
    kFlavorTypeClippingName = 'clnm',
    kFlavorTypeClippingFilename = 'clfn',
    kFlavorTypeUnicodeClippingName = 'ucln',
    kFlavorTypeUnicodeClippingFilename = 'uclf',
    kFlavorTypeDragToTrashOnly = 'fdtt',
    kFlavorTypeFinderNoTrackingBehavior = 'fntb'
};
```

Constants
`kFlavorTypeClippingName`
The flavor of a name hint for a clipping file. This flavor type is preferred over the `kFlavorTypeClippingFilename` type.

Available in Mac OS X v10.0 and later.

Declared in `Drag.h`.

`kFlavorTypeClippingFilename`
The flavor of the name of a clipping file.

Available in Mac OS X v10.0 and later.

Declared in `Drag.h`.

`kFlavorTypeUnicodeClippingName`
The flavor of a hint for the unicode name of a clipping file. This flavor type is preferred over the `kFlavorTypeUnicodeClippingFilename` type.

Available in Mac OS X v10.2 and later.

Declared in `Drag.h`.

`kFlavorTypeUnicodeClippingFilename`
The flavor of the unicode name of a clipping file.

Available in Mac OS X v10.2 and later.

Declared in `Drag.h`.

`kFlavorTypeDragToTrashOnly`
Specify this flavor to allow dragging private data to the trash.

Available in Mac OS X v10.0 and later.

Declared in `Drag.h`.

`kFlavorTypeFinderNoTrackingBehavior`
A flavor type indicating that the Finder should ignore the drag.

Available in Mac OS X v10.0 and later.

Declared in `Drag.h`.

Zoom Acceleration Constants

Specify acceleration constants for the `ZoomRects` and `ZoomRegion` functions.

```
typedef SInt16 ZoomAcceleration;
enum {
    kZoomNoAcceleration = 0,
    kZoomAccelerate = 1,
    kZoomDecelerate = 2
};
```

Constants

`kZoomNoAcceleration`
Use linear interpolation for each frame of animation between the source and destination.

Available in Mac OS X v10.0 and later.

Declared in `Drag.h`.

`kZoomAccelerate`
Increment the step size for each frame of animation between the source and destination. This option produces the visual appearance of the animation speeding up as it approaches the destination.

Available in Mac OS X v10.0 and later.

Declared in `Drag.h`.

`kZoomDecelerate`
Decrement the step size for each frame of animation between the source and destination. This option produces the visual appearance of the animation slowing down as it approaches the destination.

Available in Mac OS X v10.0 and later.

Declared in `Drag.h`.

zoomNoAcceleration

Obsolete. Use "Zoom Acceleration Constants" instead.

```
enum {
    zoomNoAcceleration = kZoomNoAcceleration,
    zoomAccelerate = kZoomAccelerate,
    zoomDecelerate = kZoomDecelerate
};
```

kDragStandardImage

Obsolete. Use "Drag Image Flags" instead.

```
enum {
    kDragStandardImage = kDragStandardTranslucency,
    kDragDarkImage = kDragDarkTranslucency,
    kDragDarkerImage = kDragDarkerTranslucency,
    kDragOpaqueImage = kDragOpaqueTranslucency
};
```

dragTrackingEnterHandler

Obsolete. Use "Drag Tracking Messages" instead.

```
enum {
    dragTrackingEnterHandler = kDragTrackingEnterHandler,
    dragTrackingEnterWindow = kDragTrackingEnterWindow,
    dragTrackingInWindow = kDragTrackingInWindow,
    dragTrackingLeaveWindow = kDragTrackingLeaveWindow,
    dragTrackingLeaveHandler = kDragTrackingLeaveHandler
};
```

dragRegionBegin

Obsolete. Use "Drag Drawing Messages" instead.

```
enum {
    dragRegionBegin = kDragRegionBegin,
    dragRegionDraw = kDragRegionDraw,
    dragRegionHide = kDragRegionHide,
    dragRegionIdle = kDragRegionIdle,
    dragRegionEnd = kDragRegionEnd
};
```

dragHasLeftSenderWindow

Obsolete. Use "Drag Attributes" instead.

```
enum {
    dragHasLeftSenderWindow = kDragHasLeftSenderWindow,
    dragInsideSenderApplication = kDragInsideSenderApplication,
    dragInsideSenderWindow = kDragInsideSenderWindow
};
```

Result Codes

The table below lists the most common result codes returned by the Drag Manager.

Result Code	Value	Description
`badDragRefErr`	-1850	Unknown drag reference Available in Mac OS X v10.0 and later.
`badDragItemErr`	-1851	Unknown drag item reference Available in Mac OS X v10.0 and later.
`badDragFlavorErr`	-1852	Unknown flavor type Available in Mac OS X v10.0 and later.
`duplicateFlavorErr`	-1853	Flavor type already exists Available in Mac OS X v10.0 and later.
`cantGetFlavorErr`	-1854	Error while trying to get flavor data Available in Mac OS X v10.0 and later.
`duplicateHandlerErr`	-1855	Handler already exists Available in Mac OS X v10.0 and later.
`handlerNotFoundErr`	-1856	Handler not found Available in Mac OS X v10.0 and later.
`dragNotAcceptedErr`	-1857	Drag was not accepted by receiver Available in Mac OS X v10.0 and later.
`unsupportedForPlatformErr`	-1858	Call is for PowerPC only Available in Mac OS X v10.0 and later.
`noSuitableDisplaysErr`	-1859	No displays support translucency Available in Mac OS X v10.0 and later.
`badImageRgnErr`	-1860	Bad translucent image region Available in Mac OS X v10.0 and later.
`badImageErr`	-1861	Bad translucent image PixMap Available in Mac OS X v10.0 and later.

Result Code	Value	Description
`nonDragOriginatorErr`	-1862	Illegal attempt to access originator only data Available in Mac OS X v10.0 and later.

Gestalt Constants

You can check for version and feature availability information by using the Drag Manager selectors defined in the Gestalt Manager. For more information see *Inside Mac OS X: Gestalt Manager Reference*

Event Manager Reference (Not Recommended)

Framework: Carbon/Carbon.h

Declared in Events.h

Overview

Important: The Event Manager is a legacy System 7 technology. You should use the Mac OS X Carbon Event Manager instead. See *Carbon Event Manager Programming Guide*.

The Event Manager is a legacy System 7 technology that was created to support the cooperative, multitasking environment available on Macintosh computers at the time. This environment allowed users to switch between many open applications and allows other applications to receive background processing time.

The Carbon Event Manager, introduced in Mac OS X, offers a simple yet flexible approach to event handling that greatly reduces the amount of code needed to write a basic application. Moreover, the Carbon Event Manager's streamlined event handling enhances system performance on Mac OS X through more efficient allocation of processing time. Applications that use the Carbon Event Manager not only run better on Mac OS X, they help improve overall performance and responsiveness.

Since the introduction of the Macintosh computer, Mac applications have used the Event Manager to receive information about actions performed by the user, to receive notices of changes in their processing, and to communicate with other applications. For example, an application can retrieve information from the Event Manager about whether the user has pressed a key or the mouse button, whether one of the application's windows needs updating, or whether some other hardware-related or software-related action requires a response from the application.

Applications also used the Event Manager to support the cooperative, multitasking environment available on versions of the Mac OS that preceded Mac OS X. This environment allows users to switch between many open applications and allows other applications to receive background processing time. By using Event Manager routines, an application allowed the system software to coordinate the scheduling of processing time between it and other applications.

Carbon supports the majority of the Event Manager.

High-level events APIs (as contained in `EPPC.h`) are not supported. You should use Apple events instead.

Carbon does not support the `diskEvt` event. Support for volume mount and unmount events will be available in the Carbon Event Manager.

Carbon does not set the `convertClipboardFlag` in the `EventRecord` to indicate that the scrap has changed while the application was suspended. You should call the Scrap Manager function `GetCurrentScrap` instead.

Low-level event queue functions, such as `GetEvQHdr` and `PPostEvent`, are no longer supported.

Application-defined function-key procedures are not supported in Carbon.

Functions by Task

Accessors for Low-Memory Globals

`LMGetKeyRepThresh` (page 1000)
Returns the low-memory auto-key rate.

`LMGetKeyThresh` (page 1000)
Returns the low-memory auto-key threshold.

`LMSetKeyRepThresh` (page 1002)
Sets the low-memory auto-key rate.

`LMSetKeyThresh` (page 1002)
Sets the low-memory auto-key threshold.

`LMGetKbdType` (page 1000)
Returns a value that specifies the physical keyboard type.

`LMGetKbdLast` (page 999)
Returns a value that specifies the last physical keyboard type used.

`LMSetKbdLast` (page 1001)
Sets a value that specifies the last physical keyboard type used.

`LMSetKbdType` (page 1001)
Sets the keyboard type.

Getting Timing Information

`GetCaretTime` (page 993)
Obtains the suggested difference in ticks that should exist between blinks of the caret (usually a vertical bar marking the insertion point) in editable text.

`GetDblTime` (page 994)
Determines whether a sequence of mouse events constitutes a double click.

Making Keyboard Settings

`KeyScript` (page 997) Deprecated in Mac OS X v10.5
Changes the keyboard script (the script system used for keyboard input), changes the keyboard layout (the mapping of keys to characters) or input method within the current keyboard script (a facility for entering 2-byte characters), or makes a setting related to text input, using the supplied value.

Reading the Keyboard

`GetKeys` (page 995)
Obtains the current state of the keyboard.

`KeyTranslate` (page 998)
Converts a virtual key code to a character code based on a `'KCHR'` resource.

`GetCurrentKeyModifiers` (page 994)
Returns the current state of the keyboard modifier keys.

`IsCmdChar` (page 997)
Tests whether the Command key is pressed in conjunction with another key (or keys) that could generate the specified test character.

Receiving Events

`EventAvail` (page 992)
Retrieves the next available event from the Event Manager without removing the returned event from your application's event stream.

`FlushEvents` (page 993)
Removes low-level events from the Operating System event queue.

`GetNextEvent` (page 996)
Retrieves events one at a time from the Event Manager.

`SetEventMask` (page 1003)
Sets the system event mask of your application to the specified mask.

`WaitNextEvent` (page 1004)
Retrieves events one at a time from the Event Manager.

Sending Events

`PostEvent` (page 1002)
Posts events into the Operating System event queue.

Miscellaneous

`CheckEventQueueForUserCancel` (page 991)
Checks the event queue for an user-cancel event.

`GetGlobalMouse` (page 995)
Obtains the position of the mouse, in global coordinates.

Functions

CheckEventQueueForUserCancel

Checks the event queue for an user-cancel event.

```
Boolean CheckEventQueueForUserCancel (
   void
);
```

Return Value
Returns `true` if a user-cancel event is in the queue, `false` otherwise.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CarbonEvents.h`

EventAvail

Retrieves the next available event from the Event Manager without removing the returned event from your application's event stream.

```
Boolean EventAvail (
   EventMask eventMask,
   EventRecord *theEvent
);
```

Parameters

eventMask

A value that indicates which kinds of events are to be returned; this parameter is interpreted as a sum of event mask constants. You specify the event mask using one or more of the values defined by the "Event Mask Constants" (page 1017). If no event of any of the designated types is available, `EventAvail` returns a null event.

theEvent

A pointer to an event structure for the next available event of the specified type or types. The `EventAvail` function does not remove the returned event from the event stream, but does return the information about the event in an event structure. The event structure includes the type of event received and other information.

Return Value
`EventAvail` returns `false` as its function result if the event being returned is a null event; otherwise, `EventAvail` returns `true`.

Special Considerations

If `EventAvail` returns a low-level event from the Operating System event queue, the event will not be accessible later if, in the meantime, the event queue becomes full and the event is discarded from it; however, this is not a common occurrence.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Simple DrawSprocket

Declared In
`Events.h`

FlushEvents

Removes low-level events from the Operating System event queue.

```
void FlushEvents (
   EventMask whichMask,
   EventMask stopMask
);
```

Parameters

whichMask

A value that indicates which kinds of low-level events are to be removed from the Operating System event queue; this parameter is interpreted as a sum of event mask constants. You specify the event mask using one or more of the values defined in "Event Mask Constants" (page 1017). The `whichMask` and `stopMask` parameters together specify which events to remove.

stopMask

A value that limits which low-level events are to be removed from the Operating System event queue; this parameter is interpreted as a sum of event mask constants. You specify the event mask using one or more of the values defined in "Event Mask Constants" (page 1017). `FlushEvents` does not remove any low-level events that are specified by the `stopMask` parameter. To remove all events specified by the `whichMask` parameter, specify 0 as the `stopMask` parameter.

Discussion

`FlushEvents` removes only low-level events stored in the Operating System event queue; it does not remove activate, update, operating-system, or high-level events. `FlushEvents` does not remove any types of events not stored in the Operating System event queue.

You can choose to use the `FlushEvents` function when your application first starts to empty the Operating System event queue of any keystrokes or mouse events generated by the user while the Finder loaded your application. In general, however, your application should not empty the queue at any other time as this loses user actions and makes your application and the computer appear unresponsive to the user.

You specify which low-level events to remove using the `whichMask` and `stopMask` parameters. `FlushEvents` removes the low-level events specified by the `whichMask` parameter, up to but not including the first event of any type specified by the `stopMask` parameter.

If the event queue doesn't contain any of the events specified by the `whichMask` parameter, `FlushEvents` does not remove any events from the queue.

Availability

Available in Mac OS X v10.0 and later.

ictbSample

Declared In

`Events.h`

GetCaretTime

Obtains the suggested difference in ticks that should exist between blinks of the caret (usually a vertical bar marking the insertion point) in editable text.

```
UInt32 GetCaretTime (
   void
);
```

Return Value
The blink delay, in ticks.

Discussion
If your application supports editable text, your application should use the value returned by `GetCaretTime` to determine how often to blink the caret. If your application uses only TextEdit, you can use TextEdit functions to automatically blink the caret at the time interval that the user specifies in the General Controls panel.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Events.h`

GetCurrentKeyModifiers

Returns the current state of the keyboard modifier keys.

```
UInt32 GetCurrentKeyModifiers (
   void
);
```

Parameters

Return Value
A bit mask indicating which keyboard modifier keys are pressed. See "Event Modifier Constants" (page 1010) for a list of possible values.

Discussion
`GetCurrentKeyModifiers` provides a more convenient way to get the modifier key state than calling `GetNextEvent`. It returns a value whose individual bits indicate which keyboard modifier keys are currently being pressed. You can test for the Caps Lock, Shift, Control, Option, and Command keys.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`CarbonEventsCore.h`

GetDblTime

Determines whether a sequence of mouse events constitutes a double click.

```
UInt32 GetDblTime (
   void
);
```

Return Value
The suggested maximum elapsed time, in ticks, between a mouse-up event and a mouse-down event.

Discussion
The `GetDblTime` function returns the suggested maximum elapsed time, in ticks, between a mouse-up event and a mouse-down event. The user can adjust this value using the Mouse control panel.

If your application distinguishes a double click of the mouse from a single click, your application should use the value returned by `GetDblTime` to make this distinction. If your application uses TextEdit, the TextEdit functions automatically recognize and handle double clicks of text within a TextEdit edit structure by appropriately highlighting or unhighlighting the selection.

The ratio of ticks to value in the `DoubleTime` global variable is 1:1. However, the Finder multiplies `DoubleTime` by 2 to determine double click time because it needs to account for user problems that typically occur during icon arrangement. Therefore, the Finder uses `DoubleTime*2` whereas the rest of the system uses `DoubleTime`.

Incidentally, the Finder does not limit the `DoubleTime` to 64 ticks. In most places, it treats it like a byte although in some others it treats it like a longword. The best method would be to provide a one-second double-byte (two seconds in the Finder).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Events.h`

GetGlobalMouse

Obtains the position of the mouse, in global coordinates.

```
void GetGlobalMouse (
   Point *globalMouse
);
```

Parameters

`globalMouse`
The position of the mouse, as a global point.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`CarbonEventsCore.h`

GetKeys

Obtains the current state of the keyboard.

```
void GetKeys (
   KeyMap theKeys
);
```

Parameters

theKeys

On output, the current state of the keyboard, including the keypad, if any.

Discussion

You can use the `GetKeys` function to determine the current state of the keyboard at any time. For example, you can determine whether one of the modifier keys is down by itself or in combination with another key using the `GetKeys` function.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Events.h`

GetNextEvent

Retrieves events one at a time from the Event Manager.

```
Boolean GetNextEvent (
   EventMask eventMask,
   EventRecord *theEvent
);
```

Parameters

eventMask

A value that indicates which kinds of events are to be returned; this parameter is interpreted as a sum of event mask constants. You specify the event mask using one or more of the values defined in "Event Mask Constants" (page 1017). If no event of any of the designated types is available, `GetNextEvent` returns a null event.

theEvent

A pointer to an event structure for the next available event of the specified type or types. The `GetNextEvent` function removes the returned event from the event stream and returns the information about the event in an event structure. The event structure includes the type of event received and other information.

Return Value

Discussion

`GetNextEvent` returns `false` as its function result if the event being returned is a null event or if `GetNextEvent` has intercepted the event; otherwise, `GetNextEvent` returns `true`. The `GetNextEvent` function calls the Operating System Manager function `SystemEvent` to determine whether the event should be handled by the application or the Operating System.

The `GetNextEvent` function also intercepts Command–Shift–number key sequences and calls the corresponding `'FKEY'` resource to perform the associated action. The Event Manager's processing of Command–Shift–number key sequences with numbers 3 through 9 can be disabled by setting the `ScrDmpEnable` global variable (a byte) to 0.

Special Considerations

For greater support of the multitasking environment, your application should use `WaitNextEvent` instead of `GetNextEvent` whenever possible.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Events.h`

IsCmdChar

Tests whether the Command key is pressed in conjunction with another key (or keys) that could generate the specified test character.

```
Boolean IsCmdChar (
   const EventRecord *event,
   short test
);
```

Parameters

event

The event record for a key-down or auto-key event with the Command key down.

test

The character you want to test.

Return Value

The function returns `TRUE` if the test character is produced with the current modifier keys, or if it would be produced by changing the current modifier key bits in either or both of the following ways: (1) turning the Command bit off or (2) toggling the Shift bit.

Discussion

This function tests whether the Command key is pressed in conjunction with another key (or keys) that could generate the `test` character for some combination of Command up or down and Shift up or down. This accommodates European keyboards that may have the `test` character as a shifted character, and non-Roman keyboards that will only generate the `test` character if the Command key is pressed. It's most useful for testing for Command-period, but it can test for command-AnyCharacter.

Availability

Available in Mac OS X v10.0 and later.

Declared In

`Events.h`

KeyScript

Changes the keyboard script (the script system used for keyboard input), changes the keyboard layout (the mapping of keys to characters) or input method within the current keyboard script (a facility for entering 2-byte characters), or makes a setting related to text input, using the supplied value. (Deprecated in Mac OS X v10.5.)

```
void KeyScript (
   short code
);
```

Parameters

code

If 0 or positive, directly specifies a script system (that is, it is read as a script code). Negative values have special meanings.

The `code` parameter is a selector that can explicitly specify a keyboard script by script code. See the Script Manager for a list of script codes. If the selector specifies a script, then the current default keyboard layout (`'KCHR'` resource) for that script, as specified in the script's international bundle resource, becomes the current keyboard layout.

The selector can also implicitly specify a keyboard script (for example, the next script), a keyboard layout (for example, the previously used keyboard layout in the current script), or an input method (for example, inline input versus window-based input). It can also specify settings that enable or disable keyboard layouts and keyboard scripts, and toggle among input options or line direction.

Discussion

For the purposes of `KeyScript`, keyboard layout means a keyboard-layout (`'KCHR'`) resource, plus optionally a key-remap (`'itlk'`) resource. To change keyboard layouts means to change the current keyboard-layout resource.

If the Keyboard menu is displayed, `KeyScript` also updates the Keyboard menu.

If you call `KeyScript` and explicitly specify a script system that is not available, `KeyScript` does nothing. The current keyboard script remains unchanged.

Note that `Keyscript` also does nothing when passed a positive or zero script code if the user has Font and Keyboard Synchronization turned off. You can find the Font and Synchronization checkbox under Options in the Input Menu tab of the International System Preference in Mac OS X.

Special Considerations

`KeyScript` operates only on those keyboard-layout and key-remap resources that are present in the System file.

Your application's keyboard-menu setting is not maintained by the Process Manager if the state of the keyboard menu is changed while you are switched out, the Process Manager does not restore your setting when you are switched back in. However, the Process Manager does maintain the keyboard disable state (Script Manager variable `smKeyDisableState`) for your application. See the Script Manager for a description of the `smKeyDisableState` variable. `KeyScript` may move memory; your application should not call this function at interrupt time.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Events.h`

KeyTranslate

Converts a virtual key code to a character code based on a `'KCHR'` resource.

```
UInt32 KeyTranslate (
   const void *transData,
   UInt16 keycode,
   UInt32 *state
);
```

Parameters

transData

A pointer to the 'KCHR' resource that you want the KeyTranslate function to use when converting the key code to a character code.

keycode

A 16-bit value that your application should set so that bits 0–6 contain the virtual key code and bit 7 contains either 1 to indicate an up stroke or 0 to indicate a down stroke of the key. Bits 8–15 have the same interpretation as the high byte of the modifiers field of the event structure and should be set according to the needs of your application.

state

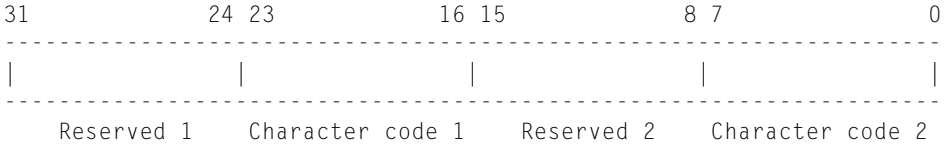
A pointer to a value that your application should set to 0 the first time it calls KeyTranslate or any time your application calls KeyTranslate with a different 'KCHR' resource. Thereafter, your application should pass the same value in the state parameter as KeyTranslate returned in the previous call.

Return Value

A 32-bit value that gives the character code for the virtual key code specified by the keycode parameter.

Discussion

The KeyTranslate function returns the values that correspond to one or possibly two characters that are generated by the specified virtual key code. The following diagram shows the structure of the 32-bit number that KeyTranslate returns.



For example, a given virtual key code might correspond to an alphabetic character with a separate accent character. When the user presses Option-E followed by E, you can map this through the KeyTranslate function using the U.S. 'KCHR' resource to produce é, which KeyTranslate returns as two characters in the bytes labeled Character code 1 and Character code 2.

If KeyTranslate returns only one character code, it is always in the byte labeled Character code 2. However, your application should always check both bytes labeled Character code 1 and Character code 2 for possible values that map to the virtual key code.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

Events.h

LMGetKbdLast

Returns a value that specifies the last physical keyboard type used.

```
UInt8 LMGetKbdLast (
   void
);
```

Return Value
The last physical keyboard type used.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Events.h`

LMGetKbdType

Returns a value that specifies the physical keyboard type.

```
UInt8 LMGetKbdType (
   void
);
```

Return Value
The physical keyboard type.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Events.h`

LMGetKeyRepThresh

Returns the low-memory auto-key rate.

```
SInt16 LMGetKeyRepThresh (
   void
);
```

Return Value
The auto-key rate, that is, the amount of time, in ticks, that must elapse before the Event Manager generates a subsequent auto-key event.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Events.h`

LMGetKeyThresh

Returns the low-memory auto-key threshold.

```
SInt16 LMGetKeyThresh (
   void
);
```

Return Value
Returns the auto-key threshold, that is, the amount of time, in ticks, that must elapse before the Event Manager generates an auto-key event.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Events.h`

LMSetKbdLast

Sets a value that specifies the last physical keyboard type used.

```
void LMSetKbdLast (
   UInt8 value
);
```

Parameters

value
The physical keyboard type you want to set.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Events.h`

LMSetKbdType

Sets the keyboard type.

```
void LMSetKbdType (
   UInt8 value
);
```

Parameters

value
The physical keyboard type you want to set.

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Declared In
`Events.h`

LMSetKeyRepThresh

Sets the low-memory auto-key rate.

```
void LMSetKeyRepThresh (
   SInt16 value
);
```

Parameters

value

The low-memory auto-key rate you want to set.

Discussion

`LMSetKeyRepThresh` sets the low-memory auto-key rate, that is, the amount of time, in ticks, that must elapse before the Event Manager generates a subsequent auto-key event.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Events.h`

LMSetKeyThresh

Sets the low-memory auto-key threshold.

```
void LMSetKeyThresh (
   SInt16 value
);
```

Parameters

value

The low-memory auto-key threshold you want to set.

Discussion

`LMSetKeyThresh` sets the low-memory auto-key threshold, that is, the amount of time, in ticks, that must elapse before the Event Manager generates an auto-key event.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Events.h`

PostEvent

Posts events into the Operating System event queue.

```
OSErr PostEvent (
   EventKind eventNum,
   UInt32 eventMsg
);
```

Parameters

eventNum

A value that indicates the type of event to post into the Operating System event queue. You specify the event kind using one or more of these values defined in "Event Mask Constants" (page 1017): `mouseDown`, `mouseUp`, `keyDown`, `keyUp`, `autoKey`, and `diskEvt`. Do not attempt to post any other type of event in the Operating System event queue.

eventMsg

An unsigned integer that contains the contents of the `message` field for the event that `PostEvent` should post in the queue.

Return Value

A result code. See "Event Manager Result Codes" (page 1023).

Discussion

In the `eventNum` and `eventMsg` parameters, you specify the value for the `what` and `message` fields of the event's event structure. The `PostEvent` function fills out the `when`, `where`, and `modifiers` fields of the event structure with the current time, current mouse location, and current state of the modifier keys and mouse button.

The `PostEvent` function posts only events that are enabled by the system event mask. If the event queue is full, `PostEvent` removes the oldest event in the queue and posts the new event.

Note that if you use `PostEvent` to repost an event, the `PostEvent` function fills out the `when`, `where`, and `modifier` fields of the event structure, giving these fields of the reposted event different values from the values contained in the original event.

Do not post any events other than mouse-down, mouse-up, key-down, key-up, auto-key, and disk-inserted events in the Operating System event queue. Attempting to post other events into the Operating System event queue interferes with the internal operation of the Event Manager.

In most cases, your application should not call the `PostEvent` function.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Events.h`

SetEventMask

Sets the system event mask of your application to the specified mask.

```
void SetEventMask (
   EventMask value
);
```

Parameters

value

A value that specifies which events should be posted in the Operating System event queue. You specify the event mask using one or more of the values defined in "Event Mask Constants" (page 1017).

Discussion

Your application should not call the `SetEventMask` function to disable any event types from being posted. Use `SetEventMask` only to enable key-up events if your application needs to respond to key-up events.

The `SetEventMask` function sets the system event mask of your application according to the parameter `value`. The Operating System Event Manager posts only low-level events (other than update or activate events) corresponding to bits in the system event mask of the current process when posting events in the Operating System event queue. The system event mask of an application is initially set to post mouse-up, mouse-down, key-down, auto-key, and disk-inserted events into the Operating System event queue.

Availability

Available in Mac OS X v10.0 and later.

Not available to 64-bit applications.

Declared In

`Events.h`

WaitNextEvent

Retrieves events one at a time from the Event Manager.

```
Boolean WaitNextEvent (
   EventMask eventMask,
   EventRecord *theEvent,
   UInt32 sleep,
   RgnHandle mouseRgn
);
```

Parameters

eventMask

A value that indicates which kinds of events are to be returned. This parameter is interpreted as a sum of event mask constants. You specify the event mask using values defined in "Event Mask Constants" (page 1017). To accept all events, you can specify the `everyEvent` constant as the event mask.

If no event of any of the designated types is available, `WaitNextEvent` returns a null event. `WaitNextEvent` determines the next available event to return based on the `eventMask` parameter and the priority of the event.

Events not designated by the event mask remain in the event stream until retrieved by an application. Low-level events in the Operating System event queue are kept in the queue until they are retrieved by your application or another application or until the queue becomes full. Once the queue becomes full, the Operating System Event Manager begins discarding the oldest events in the queue.

theEvent

A pointer to an event structure for the next available event of the specified type or types. The `WaitNextEvent` function removes the returned event from the event stream and returns the information about the event in an event structure. The event structure includes the type of event received and other information.

In addition to the event structure, high-level events can contain additional data; use the Apple Event Manager `AEProcessAppleEvent` function to get additional data associated with these events.

sleep

The number of ticks (a tick is approximately 1/60 of a second) indicating the amount of time your application is willing to relinquish the processor if no events are pending for your application. If you specify a value greater than 0 for the `sleep` parameter, your application relinquishes the processor for the specified time or until an event occurs.

You should not set the `sleep` parameter to a value greater than the number of ticks returned by `GetCaretTime` if your application provides text-editing capabilities. When the specified time expires, and if there are no pending events for your application, `WaitNextEvent` returns a `NULL` event in the parameter `theEvent`.

When running on Mac OS X, a Carbon application will block for the entire duration of the `sleep` parameter if there are no events to be delivered. This is slightly different behavior than on Mac OS 9, where the application will often receive `NULL` events before the sleep duration has elapsed.

mouseRgn

A handle to a region that specifies a region inside of which mouse movement does not cause mouse-moved events. In other words, your application receives mouse-moved events only when the cursor is outside the specified region. You should specify the region in global coordinates. If you pass an empty region or a `null` region handle, the Event Manager does not report mouse-moved events to your application. Note that your application should recalculate the `mouseRgn` parameter when it receives a mouse-moved event, or it will continue to receive mouse-moved events as long as the cursor position is outside the original `mouseRgn`.

Return Value

The `WaitNextEvent` function returns `false` as its function result if the event being returned is a null event or if `WaitNextEvent` has intercepted the event; otherwise, `WaitNextEvent` returns `true`.

Discussion

The `WaitNextEvent` function calls the Operating System Event Manager function `SystemEvent` to determine whether the event should be handled by the application or the Operating System.

If no events are pending for your application, `WaitNextEvent` waits for a specified amount of time for an event. (During this time, processing time may be allocated to background processes.) If an event occurs, it is returned through the parameter `theEvent`, and `WaitNextEvent` returns a function result of `true`. If the specified time expires and there are no pending events for your application, `WaitNextEvent` returns a null event in `theEvent` and a function result of `false`.

Before returning an event to your application, `WaitNextEvent` performs other processing and may intercept the event.

The `WaitNextEvent` function intercepts Command–Shift–number key sequences and calls the corresponding `'FKEY '` resource to perform the associated action. The Event Manager's processing of Command–Shift–number key sequences with numbers 3 through 9 can be disabled by setting the `ScrDmpEnable` global variable (a byte) to 0.

If the returned event is a high-level event and your application supports Apple events, use the Apple Event Manager function `AEProcessAppleEvent` to respond to the Apple event and to get additional information associated with the Apple event.

To retrieve an event without removing it from the event stream, use `EventAvail` (page 992).

Availability
Available in Mac OS X v10.0 and later.
Not available to 64-bit applications.

Simple DrawSprocket

Declared In
`Events.h`

Data Types

EventRecord

Contains information associated with an event.

```
struct EventRecord {
    EventKind what;
    UInt32 message;
    UInt32 when;
    Point where;
    EventModifiers modifiers;
};
typedef struct EventRecord EventRecord;
```

Fields

`what`

The kind of event received. The Event Manager specifies the kind of event with one of the values defined by the `EventKind` enumeration.

`message`

Additional information associated with the event. The interpretation of this information depends on the event type. The contents of the `message` field for each event type are summarized here:

- For a null, mouse-up, or mouse-down event, the event message is:Undefined.
- For a key-up, key-down, or auto-key event, the event message is:The low-order word contains the character code and virtual key code, which you can access with the constants `charCodeMask` and `keyCodeMask`, respectively. For Apple Desktop Bus (ADB) keyboards, the low byte of the high-order word contains the ADB address of the keyboard where the keyboard event occurred. The high byte of the high-order word is reserved.
- For an update or activate event, the event message is:A pointer to the window to update, activate, or deactivate.
- For a disk-inserted event, the event message is:The drive number in the low-order word, the File Manager result code in the high-order word.
- For a resume event, the event message is:The `suspendResumeMessage` enumerator in bits 24–31 and a 1 (the `resumeFlag` enumerator) in bit 0 indicate the event is a resume event. Bit 1 contains a 1 (the `convertClipBoardFlag` enumerator) if Clipboard conversion is required, and bits 2–23 are reserved.
- For a suspend event, the event message is:The `suspendResumeMessage` enumerator in bits 24–31 and a 0 in bit 0 to indicate the event is a suspend event. Bit 1 is undefined, and bits 2–23 are reserved.
- For a mouse-moved event, the event message is:The `mouseMovedMessage` enumerator in bits 24–31. Bits 2–23 are reserved, and bit 0 and bit 1 are undefined.
- For a high-level event, the event message is:

  The class of events to which the high-level event belongs. The `message` and `where` fields of a high-level event define the specific type of high-level event received.

`when`

The `when` field indicates the time when the event was posted (in ticks since system startup).

`where`

For low-level events and operating-system events, the `where` field contains the location of the cursor at the time the event was posted (in global coordinates).

For high-level events, the `where` field contains a second event specifier, the event ID. The event ID defines the particular type of event within the class of events defined by the `message` field of the high-level event. For high-level events, you should interpret the `where` field as having the data type `OSType`, not `Point`.

`modifiers`

The `modifiers` field contains information about the state of the modifier keys and the mouse button at the time the event was posted. For activate events, this field also indicates whether the window should be activated or deactivated. In System 7 it also indicates whether the mouse-down event caused your application to switch to the foreground.

Each of the modifier keys is represented by a specific bit in the `modifiers` field of the event structure. The modifier keys include the Option, Command, Caps Lock, Control, and Shift keys. If your application attaches special meaning to any of these keys in combination with other keys or when the mouse button is down, you can test the state of the `modifiers` field to determine the action your application should take. For example, you can use this information to determine whether the user pressed the Command key and another key to make a menu choice.

Discussion
When your application uses an Event Manager function to retrieve an event, the Event Manager returns information about the retrieved event in an event structure, which is a structure of type `EventRecord`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Events.h`

EvQEl

Defines an event queue entry.

```
struct EvQEl {
    QElemPtr qLink;
    SInt16 qType;
    EventKind evtQWhat;
    UInt32 evtQMessage;
    UInt32 evtQWhen;
    Point evtQWhere;
    EventModifiers evtQModifiers;
};
typedef struct EvQEl EvQEl;
typedef EvQEl * EvQElPtr;
```

Fields

`qLink`

Next queue entry.

`qType`

Queue type (`evType`).

`evtQWhat`

Event code.

`evtQMessage`

Event message.

`evtQWhen`

Ticks since startup.

`evtQWhere`

Mouse location.

`evtQModifiers`
Modifier flags.

Discussion
A structure of type `EvQEl` defines an entry in the Operating System event queue. Each entry in the event queue begins with 4 bytes of flags followed by a pointer to the next queue entry. The flags are maintained by and internal to the Operating System Event Manager. The queue entries are linked by pointers, and the first field of the `EvQEl` data type, which represents the structure of a queue entry, begins with a pointer to the next queue entry. Thus, you cannot directly access the flags using the `EvQEl` data type.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Events.h`

KeyMap

Contains information about the current state of the keyboard.

```
typedef BigEndianLong KeyMap[4];
```

Discussion
The type `KeyMap` is used in `GetKeys` (page 995) to return the current state of the keyboard, including the keypad, if any. The `KeyMap` type is interpreted as an array of 128 elements, each having a Boolean value. Each key on the keyboard or keypad corresponds to an element in the `KeyMap` array. A `KeyMap` element is `true` if the corresponding key is down and `false` if it isn't. The maximum number of keys that can be down simultaneously is two character keys plus any combination of the five modifier keys.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Events.h`

KeyMapByteArray

Contains information about the current state of the keyboard.

```
typedef UInt8 KeyMapByteArray[16];
```

Discussion
The type `KeyMapByteArray` is an alternate version of the type `KeyMap` (page 1009) for use on little endian platforms.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`Events.h`

Constants

Event Modifier Constants

Define modifiers for event types.

```
enum {
    activeFlagBit = 0,
    btnStateBit = 7,
    cmdKeyBit = 8,
    shiftKeyBit = 9,
    alphaLockBit = 10,
    optionKeyBit = 11,
    controlKeyBit = 12,
    rightShiftKeyBit = 13,
    rightOptionKeyBit = 14,
    rightControlKeyBit = 15
};
typedef UInt16 EventModifiers;
```

Constants

Declared in `Events.h`.

`rightControlKeyBit`
Available in Mac OS X v10.0 and later.

Declared in `Events.h`.

charCodeMask

```
enum {
    charCodeMask = 0x000000FF,
    keyCodeMask = 0x0000FF00,
    adbAddrMask = 0x00FF0000,
    osEvtMessageMask = 0xFF000000
};
```

Constants

`charCodeMask`
The enumerator indicating you want your application to receive a character-code keyboard event.

Available in Mac OS X v10.0 and later.

Declared in `Events.h`.

`keyCodeMask`
The enumerator indicating you want your application to receive a key-code keyboard event.

Available in Mac OS X v10.0 and later.

Declared in `Events.h`.

`adbAddrMask`
The enumerator indicating you want your application to receive an ADB address if there is an ADB keyboard.

Available in Mac OS X v10.0 and later.

Declared in `Events.h`.

`osEvtMessageMask`
The enumerator indicating you want your application to receive a keyboard event that can be used to extract a message code.

Available in Mac OS X v10.0 and later.

Declared in `Events.h`.

convertClipboardFlag

Obsolete in Carbon.

```
enum {
    convertClipboardFlag = 2
};
```

Constants

`convertClipboardFlag`

Available in Mac OS X v10.0 and later.

Declared in `Events.h`.

Discussion

Obsolete in Carbon. To determine if the clipboard has changed while your application was suspended, use the Scrap Manager function `GetCurrentScrap`.

Carbon Porting Notes

Unsupported. To determine if the clipboard has changed while your application was suspended, use the Scrap Manager function `GetCurrentScrap`.

Event Modifier Bits

Modifer bits for events.

```
enum {
    activeFlag = 1 << activeFlagBit,
    btnState = 1 << btnStateBit,
    cmdKey = 1 << cmdKeyBit,
    shiftKey = 1 << shiftKeyBit,
    alphaLock = 1 << alphaLockBit,
    optionKey = 1 << optionKeyBit,
    controlKey = 1 << controlKeyBit,
    rightShiftKey = 1 << rightShiftKeyBit,
    rightOptionKey = 1 << rightOptionKeyBit,
    rightControlKey = 1 << rightControlKeyBit
};
```

Constants

`activeFlag`

The enumerator that indicates a window is being activated or that a mouse-down event caused a foreground switch.

Available in Mac OS X v10.0 and later.

Declared in `Events.h`.

`btnState`

The enumerator indicating that the mouse button has been released.

Available in Mac OS X v10.0 and later.

Declared in `Events.h`.

`cmdKey`

The enumerator indicating that the Command key is being pressed.

Available in Mac OS X v10.0 and later.

Declared in `Events.h`.

`shiftKey`
The enumerator indicating that the Shift key is being pressed.
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`alphaLock`
The enumerator indicating that the Caps Lock key is being pressed.
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`optionKey`
The enumerator indicating that the Option key is being pressed.
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`controlKey`
The enumerator indicating that the Control key is being pressed.
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`rightShiftKey`
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`rightOptionKey`
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`rightControlKey`
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

HighLevelEventMsgClass

```
enum {
    HighLevelEventMsgClass = 'jaym',
    rtrnReceiptMsgID = 'rtrn'
};
```

Constants

`HighLevelEventMsgClass`
The enumerator indicating a high-level event message class for return receipt.

`rtrnReceiptMsgID`
The posting enumerator indicating the return receipt message ID.

Character Codes

Define character codes for events.

```
enum {
    kNullCharCode = 0,
    kHomeCharCode = 1,
    kEnterCharCode = 3,
    kEndCharCode = 4,
    kHelpCharCode = 5,
    kBellCharCode = 7,
    kBackspaceCharCode = 8,
    kTabCharCode = 9,
    kLineFeedCharCode = 10,
    kVerticalTabCharCode = 11,
    kPageUpCharCode = 11,
    kFormFeedCharCode = 12,
    kPageDownCharCode = 12,
    kReturnCharCode = 13,
    kFunctionKeyCharCode = 16,
    kCommandCharCode = 17,
    kCheckCharCode = 18,
    kDiamondCharCode = 19,
    kAppleLogoCharCode = 20,
    kEscapeCharCode = 27,
    kClearCharCode = 27,
    kLeftArrowCharCode = 28,
    kRightArrowCharCode = 29,
    kUpArrowCharCode = 30,
    kDownArrowCharCode = 31,
    kSpaceCharCode = 32,
    kDeleteCharCode = 127,
    kBulletCharCode = 165,
    kNonBreakingSpaceCharCode = 202
};
```

Constants

`kNullCharCode`
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`kHomeCharCode`
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`kEnterCharCode`
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`kEndCharCode`
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`kHelpCharCode`
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`kBellCharCode`
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`kBackspaceCharCode`
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`kTabCharCode`
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`kLineFeedCharCode`
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`kVerticalTabCharCode`
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`kPageUpCharCode`
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`kFormFeedCharCode`
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`kPageDownCharCode`
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`kReturnCharCode`
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`kFunctionKeyCharCode`
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`kCommandCharCode`
Available in Mac OS X v10.1 and later.
Declared in `Events.h`.

`kCheckCharCode`
Available in Mac OS X v10.1 and later.
Declared in `Events.h`.

`kDiamondCharCode`
Available in Mac OS X v10.1 and later.
Declared in `Events.h`.

`kAppleLogoCharCode`
Available in Mac OS X v10.1 and later.
Declared in `Events.h`.

`kEscapeCharCode`
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`kClearCharCode`
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`kLeftArrowCharCode`
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`kRightArrowCharCode`
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`kUpArrowCharCode`
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`kDownArrowCharCode`
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`kSpaceCharCode`
Available in Mac OS X v10.1 and later.
Declared in `Events.h`.

`kDeleteCharCode`
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`kBulletCharCode`
Available in Mac OS X v10.1 and later.
Declared in `Events.h`.

`kNonBreakingSpaceCharCode`
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

kShiftUnicode

```
enum {
    kShiftUnicode = 0x21E7,
    kControlUnicode = 0x2303,
    kOptionUnicode = 0x2325,
    kCommandUnicode = 0x2318,
    kPencilUnicode = 0x270E,
    kCheckUnicode = 0x2713,
    kDiamondUnicode = 0x25C6,
    kBulletUnicode = 0x2022,
    kAppleLogoUnicode = 0xF8FF
};
```

Constants
`kShiftUnicode`
Available in Mac OS X v10.1 and later.
Declared in `Events.h`.

`kControlUnicode`
Available in Mac OS X v10.1 and later.
Declared in `Events.h`.

`kOptionUnicode`
Available in Mac OS X v10.1 and later.
Declared in `Events.h`.

`kCommandUnicode`
Available in Mac OS X v10.1 and later.
Declared in `Events.h`.

`kPencilUnicode`
Available in Mac OS X v10.1 and later.
Declared in `Events.h`.

`kCheckUnicode`
Available in Mac OS X v10.1 and later.
Declared in `Events.h`.

`kDiamondUnicode`
Available in Mac OS X v10.1 and later.
Declared in `Events.h`.

`kBulletUnicode`
Available in Mac OS X v10.1 and later.
Declared in `Events.h`.

`kAppleLogoUnicode`
Available in Mac OS X v10.1 and later.
Declared in `Events.h`.

Event Mask Constants

Define constants you can use in the event mask.

```
enum {
    mDownMask = 1 << mouseDown,
    mUpMask = 1 << mouseUp,
    keyDownMask = 1 << keyDown,
    keyUpMask = 1 << keyUp,
    autoKeyMask = 1 << autoKey,
    updateMask = 1 << updateEvt,
    diskMask = 1 << diskEvt,
    activMask = 1 << activateEvt,
    highLevelEventMask = 0x0400,
    osMask = 1 << osEvt,
    everyEvent = 0xFFFF
};
typedef UInt16 EventMask;
```

Constants

`mDownMask`
The enumerator indicating you want your application to receive a mouse-down event.
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`mUpMask`
The enumerator indicating you want your application to receive a mouse-up event.
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`keyDownMask`
The enumerator indicating you want your application to receive a key-down event.
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`keyUpMask`
The enumerator indicating you want your application to receive a key-up event.
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`autoKeyMask`
The enumerator indicating you want your application to receive an auto-key event.
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`updateMask`
The enumerator indicating you want your application to receive an update event.
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`diskMask`
The enumerator indicating you want your application to receive a disk-inserted event.
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`activMask`
The enumerator indicating you want your application to receive an activate event.

Available in Mac OS X v10.0 and later.

Declared in `Events.h`.

`highLevelEventMask`
The enumerator indicating you want your application to receive a high-level event.

Available in Mac OS X v10.0 and later.

Declared in `Events.h`.

`osMask`
The enumerator indicating you want your application to receive an operating-system event

Available in Mac OS X v10.0 and later.

Declared in `Events.h`.

`everyEvent`
The enumerator indicating you want your application to receive every event.

Available in Mac OS X v10.0 and later.

Declared in `Events.h`.

mouseMovedMessage

```
enum {
    mouseMovedMessage = 0x00FA,
    suspendResumeMessage = 0x0001
};
```

Constants

`mouseMovedMessage`
The message code indicating the mouse-moved operating-system event.

Available in Mac OS X v10.0 and later.

Declared in `Events.h`.

`suspendResumeMessage`
The message code indicating a suspend or resume operating-system event.

Available in Mac OS X v10.0 and later.

Declared in `Events.h`.

msgWasPartiallyAccepted

```
enum {
    msgWasPartiallyAccepted = 2,
    msgWasFullyAccepted = 1,
    msgWasNotAccepted = 0
};
```

Constants

`msgWasPartiallyAccepted`
The posting enumerator value in the return receipt that indicates the message was partially accepted.

`msgWasFullyAccepted`
The posting enumerator value in the return receipt that indicates the message was fully accepted.

`msgWasNotAccepted`
The posting enumerator value in the return receipt that indicates the message was fully accepted.

networkEvt

```
enum {
    networkEvt = 10,
    driverEvt = 11,
    app1Evt = 12,
    app2Evt = 13,
    app3Evt = 14,
    app4Evt = 15,
    networkMask = 0x0400,
    driverMask = 0x0800,
    app1Mask = 0x1000,
    app2Mask = 0x2000,
    app3Mask = 0x4000,
    app4Mask = 0x8000
};
```

Constants

`networkEvt`
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`driverEvt`
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`app1Evt`
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`app2Evt`
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`app3Evt`
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`app4Evt`
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`networkMask`
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`driverMask`
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`app1Mask`
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`app2Mask`
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`app3Mask`
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`app4Mask`
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

Event Kind Constants

Define event kinds.

```
enum {
    nullEvent = 0,
    mouseDown = 1,
    mouseUp = 2,
    keyDown = 3,
    keyUp = 4,
    autoKey = 5,
    updateEvt = 6,
    diskEvt = 7,
    activateEvt = 8,
    osEvt = 15,
    kHighLevelEvent = 23
};
typedef UInt16 EventKind;
```

Constants

`nullEvent`
The event code indicating that there are no other pending events.
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`mouseDown`
The event code indicating that the mouse button has been pressed.
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`mouseUp`
The event code indicating that the mouse button has been released.
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`keyDown`
The event code indicating that a key has been pressed.
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`keyUp`
The event code indicating that a key has been released.
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`autoKey`
The event code indicating that a key has been repeatedly held down.
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`updateEvt`
The event code indicating that a window needs updating.
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`diskEvt`
The event code indicating that a disk has been inserted.
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`activateEvt`
The event code indicating that a window has been activated or deactivated.
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`osEvt`
The event code indicating a suspend, resume, or mouse-moved operating-system event.
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

`kHighLevelEvent`
A high-level event.
Available in Mac OS X v10.0 and later.
Declared in `Events.h`.

resumeFlag

Indicates a resume event.

```
enum {
    resumeFlag = 1
};
```

Constants

`resumeFlag`

Flag for a resume event.

Available in Mac OS X v10.0 and later.

Declared in `Events.h`.

Result Codes

Result codes defined for the Event Manager are listed below.

Result Code	Value	Description
`evtNotEnb`	1	Event not enabled for `PostEvent`. Available in Mac OS X v10.0 and later.

Ink Services Reference

Framework: Carbon/Carbon.h

Declared in Ink.h

Overview

Ink is a technology that allows users to enter text by writing with a stylus on a graphics tablet without requiring any modifications to the application that receives the text. As text is written on a tablet, it is automatically recognized and entered as a stream of key-down events into a document or text field.

The Ink Services application programming interface provides a set of functions that enables you to customize Ink input for your application. Using the Ink Services API, you can:

- Programmatically turn handwriting recognition on or off for your application
- Access Ink data at multiple levels (as points and recognized text)
- Support gestures that allow the user to manipulate text directly
- Set up deferred recognition or use on-demand recognition
- Access alternate text interpretations
- Manage options for drawing Ink
- Create and terminate an Ink phrase

Ink Services provides Ink input data (text interpretations, gestures, and so forth) through the Carbon Event Manager. Your application must set up one or more handlers to receive Ink-related events and to extract the relevant parameters from the events of interest to your application.

Functions by Task

Customizing Ink Services

`InkSetApplicationWritingMode` (page 1029)
Controls where the user is allowed to write in the current application.

`InkSetApplicationRecognitionMode` (page 1028)
Specifies whether Ink input should be interpreted as text, gestures, both, or neither.

`InkSetPhraseTerminationMode` (page 1030)
Sets the conditions that define a phrase termination.

`InkSetDrawingMode` (page 1030)
Controls what is drawn when the user writes.

Obtaining Information About Ink Services

`InkUserWritingMode` (page 1042)
Returns the Ink writing mode set by the user in the Ink preferences pane.

`InkIsPhraseInProgress` (page 1028)
Returns whether Ink Services has initiated and is currently maintaining an Ink phrase whose source is user input.

Handling Ink Phrases

`InkAddStrokeToCurrentPhrase` (page 1027)
Adds a stroke to the current Ink phrase.

`InkTerminateCurrentPhrase` (page 1033)
Terminates the current phrase.

Working With Alternate Text Interpretations

`InkTextAlternatesCount` (page 1034)
Returns the number of alternate text interpretations available for an Ink phrase.

`InkTextCreateCFString` (page 1035)
Obtains the string associated with a text interpretation of an Ink phrase.

`InkTextInsertAlternatesInMenu` (page 1040)
Inserts a list of alternate text interpretations into a menu.

Working With Ink Text Objects

`InkTextKeyModifiers` (page 1042)
Returns a value that specifies the key modifiers applied to an Ink phrase.

`InkTextCopy` (page 1035)
Copies an existing Ink text object.

`InkTextBounds` (page 1034)
Returns the bounds of an Ink text object.

`InkTextDraw` (page 1036)
Rescales and draws Ink text into the specified bounds.

`InkTextGetTypeID` (page 1040)
Returns the `CFTypeID` of an `InkTextRef` object.

Flattening and Unflattening Ink Text Objects

`InkTextFlatten` (page 1037)
Flattens an Ink text object for archiving.

`InkTextCreateFromCFData` (page 1036)
Creates an Ink text object from a previously-flattened Ink text object.

Working with Ink Stroke Objects

`InkTextGetStroke` (page 1038)
Returns a reference to the specified stroke in an `InkTextRef`.

`InkTextGetStrokeCount` (page 1039)
Returns the number of strokes in the specified `InkTextRef`.

`InkStrokeGetPointCount` (page 1031)
Returns the number of points in the specified `InkStrokeRef`.

`InkStrokeGetPoints` (page 1032)
Fills an array with the points belonging to the specified `InkStrokeRef`.

`InkStrokeGetTypeID` (page 1033)
Returns the `CFTypeID` of an `InkStrokeRef` object.

Functions

InkAddStrokeToCurrentPhrase

Adds a stroke to the current Ink phrase.

```
void InkAddStrokeToCurrentPhrase (
   unsigned long iPointCount,
   InkPoint *iPointArray
);
```

Parameters

iPointCount
The number of elements in the `iPointArray` array.

iPointArray
A pointer to an array of `InkPoint` structures that specify the path of the stylus, starting with the point that defines the first stylus-down location and ending with the point that defines the last stylus-down location.

Discussion
This function operates on the Ink source from the application, and not on that from direct user input. So there is no need to specify the Ink source as `kInkSourceApplication`. See "Ink Source Types" (page 1052) for more information on sources.

You do not need to call this function unless you have raw data to process or you have turned off automatic recognition (by calling the function `InkSetApplicationWritingMode` (page 1029)) and have set up your application to handle Ink input events itself. For example, you might need to handle Ink input if your application needs to acquire pen data in a device-specific manner.

If your application handles Ink input events, it can still take advantage of the recognition service provided by Ink Services. To do so, your application should call the function `InkAddStrokeToCurrentPhase` to add one stroke at a time to the current phrase. You then terminate the phrase at the appropriate time by calling the function `InkTerminateCurrentPhrase` (page 1033). Note that calling `InkAddStrokeToCurrentPhase` adds a stroke to the current phrase, but does not draw the stroke. See *Using Ink Services in Your Application* for details on writing code that uses the function `InkAddStrokeToCurrentPhase` to implement deferred recognition.

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X v10.3 and later.

Declared In
`Ink.h`

InkIsPhraseInProgress

Returns whether Ink Services has initiated and is currently maintaining an Ink phrase whose source is user input.

```
Boolean InkIsPhraseInProgress (
   void
);
```

Return Value
Returns `TRUE` if the user is currently engaged in Ink input; `FALSE` otherwise.

Discussion
If your application manages its own phrase termination, you should use this function to make sure there is a phrase that can be terminated before you call the function `InkTerminateCurrentPhrase`. Don't call this function if the Ink data stream originates from your application rather than directly from user input. The application data stream is completely independent of the user data stream. If your application builds its own Ink phrases by calling the function `InkAddStrokeToCurrentPhrase`, it should be able track whether such a phrase is in-progress or not.

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X v10.3 and later.

Declared In
`Ink.h`

InkSetApplicationRecognitionMode

Specifies whether Ink input should be interpreted as text, gestures, both, or neither.

```
void InkSetApplicationRecognitionMode (
   InkRecognitionType iRecognitionType
);
```

Parameters

iRecognitionType

The recognition mode you want Ink Services to use. Pass `kInkRecognitionGesture` to specify gesture recognition, `kInkRecognitionText` to specify text recognition, `kInkRecognitionNone` to turn off recognition, or `kInkRecognitionDefault` (which is `kInkRecognitionGesture | kInkRecognitionText`) to specify both gesture and text recognition. See "Recognition Modes" (page 1048) for more information on the constants you can supply.

Discussion

This function only affects recognition of Ink that originates from the user. It does not affect recognition of Ink that originates from your application, and is recognized using the function `InkAddStrokeToCurrentPhrase`. Note that only text recognition (not gesture recognition) is performed on an Ink data stream that originates from your application.

Availability

Not available in CarbonLib 1.x.

Available in Mac OS X v10.3 and later.

Declared In

`Ink.h`

InkSetApplicationWritingMode

Controls where the user is allowed to write in the current application.

```
void InkSetApplicationWritingMode (
   InkApplicationWritingModeType iWriteWhere
);
```

Parameters

iWriteWhere

An "Application Modes" (page 1046) constant that specifies the Ink writing mode to use for your application. Pass `kInkWriteAnywhereInApp` if you want your application to allow Ink input and recognition and to receive Ink events when the user writing mode is set to `kInkWriteInkAwareOnly`. When you call this function with the `iWriteWhere` parameter set to `kInkWriteAnywhereInApp`, your application can receive Ink events whose screen locations lie outside the application windows. Pass `kInkWriteNowhereInApp` to disable Ink input temporarily, such as when the user is using a paint tool.

Discussion

You can call the function `InkSetApplicationWritingMode` to control when Ink input and recognition are allowed in your application. Using this function, you can turn Ink Services on or off for your application. Note that Ink input is available for your application only when your application is frontmost and when the user has turned on recognition in the Ink preferences pane.

If your application calls the function `InkSetApplicationWritingMode` with the parameter `kInkWriteNowhereInApp` to disable Ink Services management of pen events because you want to accumulate Ink data yourself, be aware that you may need to manage mouse event coalescing yourself. You can use the Carbon Event Manger function `SetMouseCoalescingEnabled` for this purpose. See *Using Ink Services in Your Application* for a discussion of mouse coalescing.

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X v10.3 and later.

Declared In
`Ink.h`

InkSetDrawingMode

Controls what is drawn when the user writes.

```
void InkSetDrawingMode (
   InkDrawingModeType iDrawingMode
);
```

Parameters

`iDrawingMode`

A "Drawing Modes" (page 1046) constant that specifies the drawing mode to use for your application. The default (`kInkDrawInkAndWritingGuides`) is for Ink Services to draw both the Ink writing guides and the Ink. Pass `kInkDrawInkOnly` if you want Ink Services to draw only the Ink. Pass `kInkDrawNothing` to turn off drawing of both the Ink writing guides and the Ink.

Discussion
Normally Ink Services draws writing guides, similar in look to the alternating solid and broken lines used on many paper writing tablets. The Ink itself is drawn anti-aliased and grayscale. Your application can call the function `InkSetDrawingMode` to request that Ink Services not draw the writing guides or not draw either Ink or the writing guides. If Ink drawing is disabled, your application must receive the points (by installing a handler for `kEventInkPoint` events) and draw the Ink.

You do not need to call the function `InkSetDrawingMode` to inhibit drawing if you called the function `InkSetApplicationWritingMode`, passing the value `kInkWriteNowhereInApp`. Also, Ink Services will not draw any point for which a `kEventInkPoint` Carbon event handler returns `noErr`.

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X v10.3 and later.

Declared In
`Ink.h`

InkSetPhraseTerminationMode

Sets the conditions that define a phrase termination.

```
void InkSetPhraseTerminationMode (
   InkSourceType iSource,
   InkTerminationType iAllowedTerminationTypes
);
```

Parameters

iSource

An "Ink Source Types" (page 1052) constant that specifies the source of the Ink data stream. You can use one of these constants to get independent control over termination of data originating with the user versus data that is passed from your application to Ink Services. To manage phrase termination for user input, pass the constant `kInkSourceUser`. To manage phrase termination for application input (that is recognized using the function `InkAddStrokeToCurrentPhrase`, pass the constant `kInkSourceApplication`.

iAllowedTerminationTypes

A constant that specifies the conditions which define a phrase termination. To turn off automatic phrase termination, pass `kInkTerminationNone`. You can restore the default phrase termination behavior by passing the constant `kInkTerminationDefault`. See "Phrase Termination Modes" (page 1047) for more information on the constants you can supply.

Discussion

The default behavior is for Ink Services to terminate a phrase when one of the following events occur:

- The user removes the stylus from the proximity of the tablet
- A specified period of time elapses in which the stylus is not pressed to the tablet (The user can control the period of time in the Ink preferences pane.)
- The user writes sufficiently far away from the previous Ink—either horizontally, or on a new line

You can use the function `InkSetPhraseTerminationMode` if your application does not want the default behavior or wants complete control over when Ink phrases are terminated. If you turn off automatic phrase termination, you must make sure you manage phrase termination appropriately for your application.

For example, if you want to force Ink drawn in a specific input window to be treated as a single phrase until the user presses a "finished-writing" button, you would call `InkSetPhraseTerminationMode` with the parameter `kInkTerminationNone` to turn off automatic phrase termination. Then you would need to install a Carbon event handler for the event `kEventInkPoint`. Your handler would examine the `kEventInkPoint` events, notice when a pen-down event occurs on the "finished-writing" button, and then terminate the phrase by calling the function `InkTerminateCurrentPhrase`. See *Using Ink Services in Your Application* for details on writing code to handle phrase termination.

Availability

Not available in CarbonLib 1.x.

Available in Mac OS X v10.3 and later.

Declared In

`Ink.h`

InkStrokeGetPointCount

Returns the number of points in the specified `InkStrokeRef`.

```
CFIndex InkStrokeGetPointCount (
   InkStrokeRef iStrokeRef
);
```

Parameters

iStrokeRef

The `InkStrokeRef` to get the point count from.

Return Value

A `CFIndex` indicating the number of points contained in the specified `InkStrokeRef`.

Discussion

Given an `InkStrokeRef`, this function returns the number of points that stroke contains. Use this function to calculate the appropriate size of the buffer passed to `InkStrokeGetPoints` (page 1032).

Availability

Not available in CarbonLib 1.x.

Available in Mac OS X v10.4 and later.

Declared In

`Ink.h`

InkStrokeGetPoints

Fills an array with the points belonging to the specified `InkStrokeRef`.

```
InkPoint * InkStrokeGetPoints (
   InkStrokeRef iStrokeRef,
   InkPoint *oPointBuffer
);
```

Parameters

iStrokeRef

The `InkStrokeRef` to get the points from.

oPointBuffer

The buffer into which the point data is to be copied.

Return Value

A pointer to the copied array of point data from the specified `InkStrokeRef`; this value is the same as the `oPointBuffer` address provided by the application.

Discussion

Given an `InkStrokeRef` and a point buffer, this function fills that buffer with the points belonging to that stroke.

The size of the point buffer must be at least the size of `InkStrokeGetPointCount( iStrokeRef ) * sizeof( InkPoint )`. For details, see `InkStrokeGetPointCount` (page 1031). The pointer to the block of memory containing the ink points is returned as the result.

Availability

Not available in CarbonLib 1.x.

Available in Mac OS X v10.4 and later.

Declared In

`Ink.h`

InkStrokeGetTypeID

Returns the `CFTypeID` of an `InkStrokeRef` object.

```
CFTypeID InkStrokeGetTypeID (
   void
);
```

Return Value
The `CFTypeID` of an `InkStrokeRef` object.

Discussion
Given an `InkStrokeRef`, this function returns its `CFTypeID`.

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X v10.4 and later.

Declared In
`Ink.h`

InkTerminateCurrentPhrase

Terminates the current phrase.

```
void InkTerminateCurrentPhrase (
   InkSourceType iSource
);
```

Parameters

iSource

An "Ink Source Types" (page 1052) constant that specifies the source of the Ink data stream.To terminate a phrase that originates from application input (that is recognized using the function `InkAddStrokeToCurrentPhrase)`, pass the constant `kInkSourceApplication`.

If you are managing phrase termination that originates from direct user input, you can pass the constant `kInkSourceUser`. Note that this function is normally not used in this fashion, as most applications can let Ink Services terminate such phrases automatically.

Discussion
You do not need to call this function unless you have turned off automatic phrase termination (by calling the function `InkSetPhraseTerminationMode` (page 1030)) and have set up your application to manage phrase termination. When you call the function `InkTerminateCurrentPhrase`, any Ink drawn by Ink Services is erased. If your application handles phrase termination, it can still take advantage of the recognition service provided by Ink Services.

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X v10.3 and later.

Declared In
`Ink.h`

InkTextAlternatesCount

Returns the number of alternate text interpretations available for an Ink phrase.

```
CFIndex InkTextAlternatesCount (
   InkTextRef iTextRef
);
```

Parameters

iTextRef

On input, a reference to the Ink text object that specifies the Ink word whose alternate count you want to obtain. You must obtain an Ink text object reference (`InkTextRef`) through your application's Ink event handler. Your handler must take care of the Carbon event class `kEventClassInk` and the event kind `kEventInkText`. The event parameter `kEventParamInkTextRef` that you obtain from this event kind is a reference to an Ink text object.

Return Value

Returns the number of interpretations available for the specified Ink phrase.

Discussion

You can obtain the string associated with a text interpretation by calling the function `InkTextCreateCFString` (page 1035). If you want to display a list of the alternate text interpretations to the user, call the function `InkTextInsertAlternatesInMenu` (page 1040).

Availability

Not available in CarbonLib 1.x.

Available in Mac OS X v10.3 and later.

Declared In

`Ink.h`

InkTextBounds

Returns the bounds of an Ink text object.

```
HIRect InkTextBounds (
   InkTextRef iTextRef
);
```

Parameters

iTextRef

On input, a reference to the Ink text object whose bounds you want to obtain. You must obtain an Ink text object reference (`InkTextRef`) through your application's Ink event handler. Your handler must take care of the Carbon event class `kEventClassInk` and the event kind `kEventInkText`. The event parameter `kEventParameterInkTextRef` that you obtain from this event kind is a reference to an Ink text object.

Return Value

An `HIRect` data structure that defines the bounds of the specified Ink text object.

Discussion

The bounds are initially global coordinates, and may extend beyond your application's windows.

Availability

Not available in CarbonLib 1.x.

Available in Mac OS X v10.3 and later.

Declared In
`Ink.h`

InkTextCopy

Copies an existing Ink text object.

```
InkTextRef InkTextCopy (
   InkTextRef iTextRef
);
```

Parameters

iTextRef

On input, a reference to the Ink text object you want to copy. You must obtain an Ink text object reference (`InkTextRef`) through your application's Ink event handler. Your handler must take care of the Carbon event class `kEventClassInk` and the event kind `kEventInkText`. The event parameter `kEventParameterInkTextRef` that you obtain from this event kind is a reference to an Ink text object.

Return Value
A reference to the newly-created Ink text object.

Discussion
You can use this function to implement copy-and-paste functions in a deferred-recognition application, or in a text application to retain Ink when text is copied and pasted. The retention count of the new `InkTextRef` is 1.

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X v10.3 and later.

Declared In
`Ink.h`

InkTextCreateCFString

Obtains the string associated with a text interpretation of an Ink phrase.

```
CFStringRef InkTextCreateCFString (
   InkTextRef iTextRef,
   CFIndex iAlternateIndex
);
```

Parameters

iTextRef

On input, a reference to the Ink text object that specifies the Ink word for which you want to create a string. You must obtain an Ink text object reference (`InkTextRef`) through your application's Ink event handler. Your handler must take care of the Carbon event class `kEventClassInk` and the event kind `kEventInkText`. The event parameter `kEventParamInkTextRef` that you obtain from this event kind is a reference to an Ink text object.

iIndex

The index that specfies the text interpretation for which you want to obtain a `CFString`. Text interpretations are stored in an array in ranked order, with the most-likely interpretation at index zero.

Return Value
A `CFStringRef` that specifies an interpretation for the given Ink text phrase. Returns `NULL` if the index you provide is invalid. Your application is responsible for releasing the returned `CFStringRef`.

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X v10.3 and later.

Declared In
`Ink.h`

InkTextCreateFromCFData

Creates an Ink text object from a previously-flattened Ink text object.

```
InkTextRef InkTextCreateFromCFData (
   CFDataRef iFlattenedInkText,
   CFIndex iIndex
);
```

Parameters

`iFlattenedInkText`
On input, a reference to a `CFData` data structure that contains data from a previously-flattened Ink text object.

`iIndex`
The index at which to start reading the data.

Return Value
Returns a reference to the newly-created Ink text object. The retention count of the newly-created Ink text object is 1.

Discussion
You can unflatten an Ink text object that was previously flattened using the function `InkTextFlatten`. If you flattened more than one Ink text object to the `CFMutableData` data type, then you must call the function `InkTextCreateFromCFData` for each Ink text object you want to unflatten, specifying the index that defines the start of the Ink text data you want to unflatten.

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X v10.3 and later.

Declared In
`Ink.h`

InkTextDraw

Rescales and draws Ink text into the specified bounds.

```
void InkTextDraw (
   InkTextRef iTextRef,
   CGContextRef iContext,
   const CGRect *iBounds,
   InkTextDrawFlagsType iFlags
);
```

Parameters

iTextRef

On input, a reference to the Ink text object whose text you want to rescale and draw. You must obtain an Ink text object reference (`InkTextRef`) through your application's Ink event handler. Your handler must take care of the Carbon event class `kEventClassInk` and the event kind `kEventInkText`. The event parameter `kEventParameterInkTextRef` that you obtain from this event kind is a reference to an Ink text object.

iContext

The `CGContext` into which you want to draw. Drawing is relative to the specified `CGContextRef`, and subject to the usual window and clipping constraints. Pass `NULL` if you want to draw to the canonical context of the current port.

iBounds

On input, a `CGRect` data structure that specifies the bounds into which you want the Ink text object to be drawn.

iFlags

A "Text Drawing Flags" (page 1052) constant that specifies drawing settings. Pass `kInkTextDrawDefault` to use the default system settings when drawing, `kInkTextDrawIgnorePressure` if you do not want to use pressure sensitive gradients, and `kInkTextDrawHonorContext` t o use the current Quartz context settings.

Discussion

The function `InkTextDraw` is useful to applications that implement deferred recognition or searchable Ink. The original points and bounds of the Ink text object are scaled and offset to fit the specified bounds, so subsequent calls to the function `InkTextBounds` return the rescaled bounds.

Availability

Not available in CarbonLib 1.x.

Available in Mac OS X v10.3 and later.

Declared In

`Ink.h`

InkTextFlatten

Flattens an Ink text object for archiving.

```
CFIndex InkTextFlatten (
   InkTextRef iTextRef,
   CFMutableDataRef ioDataRef,
   CFIndex iIndex
);
```

Parameters

iTextRef

On input, a reference to the Ink text object you want to flatten. You must obtain an Ink text object reference (`InkTextRef`) through your application's Ink event handler. Your handler must take care of the Carbon event class `kEventClassInk` and the event kind `kEventInkText`. The event parameter `kEventParameterInkTextRef` that you obtain from this event kind is a reference to an Ink text object.

ioDataRef

On input, a reference to a `CFMutableData` data type. On output, refers to the flattened data. Your application is responsible for creating and releasing the `CFMutableDataRef`.

iIndex

The index at which you want the data to be written.

Return Value

Returns the number of bytes added to the `ioDataRef`. Returns `0` if the operation is unsuccessful or `iTextRef` is `NULL` or empty.

Discussion

`CFMutableData` objects are extensible, which means you can flatten more than one Ink text object into a `CFMutableData` object. You store data in a `CFMutableData` object by specifying the index at which data is to be stored. The function `InkTextFlatten` accepts the starting index as an input parameter, writes all the Ink text object data to the specified `CFMutableData` object, and returns the byte count for the amount of data that is actually stored.

To flatten an additional Ink text object into the same `CFMutableData` object, you must supply a value for the `iIndex` parameter that specifies the byte location at which to start writing the data for the additional Ink text object. You can calculate this value by summing the byte count returned by the previous call with the value of the `iIndex` parameter you provided in the previous call.

Availability

Not available in CarbonLib 1.x.

Available in Mac OS X v10.3 and later.

Declared In

`Ink.h`

InkTextGetStroke

Returns a reference to the specified stroke in an `InkTextRef`.

```
InkStrokeRef InkTextGetStroke (
   InkTextRef iTextRef,
   CFIndex iStrokeIndex
);
```

Parameters

iTextRef

The `InkTextRef` to get the stroke from.

iStrokeIndex

The index of the stroke for which you want to get an `InkStrokeRef`.

Return Value

An `InkStrokeRef` for the specified stroke of the specified `InkTextRef`.

Discussion

Given an `InkTextRef` and a stroke index (between 0 and `InkTextGetStrokeCount( iTextRef ) - 1`), this function returns the `InkStrokeRef` corresponding to the specified stroke index. For details, see `InkTextGetStrokeCount` (page 1039).

The returned `InkStrokeRef` is guaranteed to persist only for the life of the `InkTextRef` from which it was obtained. If you want to use the `InkStrokeRef` after the `InkTextRef` has been released, you must call the function `CFRetain` and pass the `InkStrokeRef` to it.

When any Ink object reference is obtained from a Carbon event, it is guaranteed to persist only for the life of the event handler. If you want to use the object at some later time, you must call the function `CFRetain` and pass the object to it.

Availability

Not available in CarbonLib 1.x.

Available in Mac OS X v10.4 and later.

Declared In

`Ink.h`

InkTextGetStrokeCount

Returns the number of strokes in the specified `InkTextRef`.

```
CFIndex InkTextGetStrokeCount (
   InkTextRef iTextRef
);
```

Parameters

iTextRef

The `InkTextRef` to get the stroke count from.

Return Value

The number of stokes in the specified `InkTextRef`.

Discussion

Given an `InkTextRef`, this function returns the number of strokes the `InkTextRef` contains.

Availability

Not available in CarbonLib 1.x.

Available in Mac OS X v10.4 and later.

Declared In
`Ink.h`

InkTextGetTypeID

Returns the `CFTypeID` of an `InkTextRef` object.

```
CFTypeID InkTextGetTypeID (
   void
);
```

Return Value
The `CFTypeID` of an `InkStrokeRef` object.

Discussion
Given an `InkTextRef`, this function returns its `CFTypeID`.

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X v10.4 and later.

Declared In
`Ink.h`

InkTextInsertAlternatesInMenu

Inserts a list of alternate text interpretations into a menu.

```
ItemCount InkTextInsertAlternatesInMenu (
   InkTextRef iTextRef,
   MenuRef iMenuRef,
   MenuItemIndex iAfterItem
);
```

Parameters

`iTextRef`

On input, a reference to an Ink text object that specifies the Ink word for which you want to provide a list of alternate text interpretations. You must obtain an Ink text object reference (`InkTextRef`) through your application's Ink event handler. Your handler must take care of the Carbon event class `kEventClassInk` and the event kind `kEventInkText`. The event parameter `kEventParamInkTextRef` that you obtain from this event kind is a reference to an Ink text object.

`iMenuRef`

A reference to the menu into which you want to insert the list of alternate text interpretations. Ink Services attaches menu event handlers to this menu, so you should use this `MenuRef` directly, rather than copy items from the menu reference to another menu.

`iAfterItem`

A value that specifies the menu item after which you want to insert the list of alternate text interpretations. If the specified menu item is `0`, the text alternates are inserted at the head of the menu. If the specified menu item is greater than or equal to the existing number of menu items, the text alternates are appended to the end of the menu. Remember that the first item in a menu item array is numbered `1`, not `0`.

Return Value
Returns the number of menu items added to the menu. Returns `0` if the operation is not successful.

Discussion
The function `InkTextInsertAlternatesInMenu` allows your application to insert a list of text interpretations for a given Ink text phrase into an existing contextual menu. You should handle a list of alternate text interpretations as a standard contextual menu using the Menu Manager function `ContextualMenuSelect`.

When a user selects an item from the list of alternates, the list of alternates maintained by Ink Services are reordered automatically. This means that if you call the function `InkTextCreateCFString` with the parameter `iIndex` set to `0`, you obtain the newly selected item.

Thus the user's choice persists in internal system data structures without requiring your application to call additional functions. However your application must update its own internal data structures appropriately.

You must rebuild the menu to reflect the user's choice. After the user makes a choice and then reopens the menu, you must make sure the newly-selected item shows up as the first item in the menu. The items in the menu should mirror the list of alternates maintained by Ink Services.

Upon return from the function `ContextualMenuSelect`, your application can determine if the user has made a selection by checking the value of the parameter `outUserSelectionType`. The value indicates the item that the user selected from the contextual menu. If there is a selection, your application can examine the `outMenuID` and `outMenuItem` parameters of the function `ContextualMenuSelect`, and use these values to obtain the alternate text interpretation by calling the Menu Manager function `CopyMenuItemTextAsCFString`.

Menu items for a set of alternates whose first letter is an alphabetical character always include an alternate whose first letter is the opposite lettercase. Menu items for a set of alternates whose first letter is a non-alphabetical character do not include a lettercase alternate.

When the menu items are reordered automatically, the text that was first in the list moves to the second or the third position, depending upon whether the first letter is alphabetical or non-alphabetical. For example, the following list of menu items:

crash, Crash, crush, crust, wrash

If the user chooses crush, the menu items are reordered as follows:

crush, Crush, crash, crust, wrash

Notice that the list of alternates is kept to a length of five. A lettercase alternate for crush is added to the menu while the uppercase alternate Crash is dropped.

For a non-alphabetic first character, however, such as a number, the original moves to the second position. So for the following menu:

1239, 1234, 1289, 1284

If the user chooses 1234, the menu becomes:

1234, 1239, 1289, 1284

If it is important for your application to maintain the original order of alternates, then it must use its own internal data structures to keep track of the original list.

See *Using Ink Services in Your Application* for details on writing code that uses the function `InkTextInsertAlternatesInMenu` to implement a correction model.

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X v10.3 and later.
Not available to 64-bit applications.

Declared In
`Ink.h`

InkTextKeyModifiers

Returns a value that specifies the key modifiers applied to an Ink phrase.

```
UInt32 InkTextKeyModifiers (
   InkTextRef iTextRef
);
```

Parameters

`iTextRef`

On input, a reference to the Ink text object whose key modifiers you want to obtain. You must obtain an Ink text object reference (`InkTextRef`) through your application's Ink event handler. Your handler must take care of the Carbon event class `kEventClassInk` and the event kind `kEventInkText`. The event parameter `kEventParameterInkTextRef` that you obtain from this event kind is a reference to an Ink text object.

Return Value
Returns a value that indicates which modifier keys were down during input of the Ink phrase. This value is in the same form as that used by the Carbon Event Manager for the event parameter `kEventParamKeyModifiers`.

Discussion
Ink Services assigns keyboard modifier keys to a stroke if those keys are held down for more than 50% of the stroke's points. Ink Services assigns the modifier keys associated with a phrase's first stroke to the entire phrase. Ink Services assigns the modifier keys associated with a phrase to all of the text interpretations that are derived from an Ink phrase.

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X v10.3 and later.

Declared In
`Ink.h`

InkUserWritingMode

Returns the Ink writing mode set by the user in the Ink preferences pane.

```
InkUserWritingModeType InkUserWritingMode (
   void
);
```

Return Value
A value that specifies the current user preferences settings for Ink: `kInkWriteInInkAwareAppsOnly`, `kInkWriteAnywhere`, or `kInkWriteNowhere`. In general, Ink services are not available if `kInkWriteNowhere` is returned (indicating the user has turned Ink off entirely). See "User Writing Modes" (page 1045) for more information on each of these constants.

Discussion
User preferences for Ink are set by the user in the Ink pane of System Preferences. Your application can only read these values, not set them.

Availability
Not available in CarbonLib 1.x.
Available in Mac OS X v10.3 and later.

Declared In
`Ink.h`

Data Types

InkTextRef

Defines a data type for a reference to an opaque Ink text object.

```
typedef     struct OpaqueInkTextRef * InkTextRef;
```

Discussion
You must use the Core Foundation functions `CFRetain` and `CFRelease` to manage the retention and release of Ink text objects. When an Ink text reference is obtained from a Carbon event, it is guaranteed to persist only for the life of the event handler. If your application needs to use the Ink text object at some later time, you must call the function `CFRetain`, passing the object you want to retain as a parameter.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`Ink.h`

InkStrokeRef

Defines a data type for a reference to an opaque Ink stroke object.

```
typedef     struct OpaqueInkStrokeRef * InkStrokeRef;
```

Discussion
You must use the Core Foundation functions `CFRetain` and `CFRelease` to manage the retention and release of Ink stroke objects. When an Ink stroke reference is obtained from a Carbon event, it is guaranteed to persist only for the life of the event handler. If your application needs to use the Ink stroke object at some later time, you must call the function `CFRetain`, passing the object you want to retain as a parameter.

Availability
Available in Mac OS X v10.4 and later.

Declared In
`Ink.h`

InkAlternateCount

Defines a data type that specifies the number of alternate text interpretations of an Ink phrase.

```
typedef unsigned long     InkAlternateCount;
```

Discussion
Values of `type InkAlternateCount` are returned by the function `InkTextAlternatesCount` (page 1034) and passed as a parameter to the function `InkTextCreateCFString` (page 1035).

Availability
Available in Mac OS X v10.3 and later.

Declared In
`Ink.h`

InkPoint

Contains data that describes an Ink point.

```
struct InkPoint {
    HIPoint             point;
    TabletPointRec      tabletPointData;
    UInt32              keyModifiers;
};
typedef struct InkPoint      InkPoint;
typedef InkPoint *      InkPointPtr;
```

Fields

`point`

Defines a point in floating-point coordinates. These values are generally in global coordinates, with full sub-pixel accuracy. This coordinate is what you obtain for a mouse event from the Carbon event parameter `kEventParamMouseLocation`, which also contains a `typeHIPoint` value.

`tabletPointData`

A tablet point structure that contains pressure, tilt, rotation, and coordinate (in tablet space) data for a pen. The pressure value is a measure of how hard the pen is being pressed, ranging from 0 to 65535. Some tablet manufacturers allow users to adjust pen sensitivity. In these cases, the zero value always corresponds to the threshold set by the user, and the pressure value is relative to that threshold. See *Carbon Event Manager Reference* for information on the `TabletPointRec` data type.

`keyModifiers`
A value that specifies the keyboard modifier key that is pressed when the point is sampled. This value is in the same form as that used by the Carbon Event Manager for the event parameter `kEventParamKeyModifiers`.

Discussion
An `InkPoint` data structure contains an essentially complete set of per-point data. Ink Services currently only requires the point's (x,y) coordinates and pressure to perform recognition and to draw the ink, but future recognition services may require other information from the `TabletPointRec`.

Availability
Available in Mac OS X v10.3 and later.

Declared In
`Ink.h`

Constants

User Writing Modes

Specify the Ink writing mode set by the user in the Ink pane of System Preferences.

```
enum {
    kInkWriteNowhere     = 'nowh',
    kInkWriteAnywhere = 'anyw',
    kInkWriteInInkAwareAppsOnly     = 'iapp'
};
typedef FourCharCode InkUserWritingModeType;
```

Constants
`kInkWriteNowhere`
Specifies the user has disabled Ink or that Ink Services are not available (for example, a tablet is not attached).

Available in Mac OS X v10.3 and later.

Declared in `Ink.h`.

`kInkWriteAnywhere`
Specifies the user has enabled Ink to allow writing anywhere on the screen. Ink Services flows ink points and recognition results to the frontmost application. This is the default situation when the user enables Ink.

Available in Mac OS X v10.3 and later.

Declared in `Ink.h`.

`kInkWriteInInkAwareAppsOnly`
Specifies the user has enabled Ink only to allow writing in an application that has enabled Ink Services by calling the function `InkSetApplicationWritingMode` with the `kInkWriteAnywhereInApp` parameter.

Available in Mac OS X v10.3 and later.

Declared in `Ink.h`.

Discussion
These constants are returned by the function `InkUserWritingMode` (page 1042).

Application Modes

Specify an Ink input mode to use for an application.

```
enum {
    kInkWriteNowhereInApp     = 'nowa',
    kInkWriteAnywhereInApp     = 'anya'
};
typedef FourCharCode     InkApplicationModeType;
```

Constants

`kInkWriteNowhereInApp`

Specifies not to allow Ink input in your application.

Available in Mac OS X v10.3 and later.

Declared in `Ink.h`.

`kInkWriteAnywhereInApp`

Specifies to allow Ink input anywhere onscreen for your application.

Available in Mac OS X v10.3 and later.

Declared in `Ink.h`.

Discussion

You can supply these constants as parameters to the function `InkSetApplicationWritingMode` (page 1029). If the user has not enabled Ink or if there is not an Ink input device available, then calling `InkSetApplicationWritingMode` (page 1029) with the parameter `kInkWriteAnywhereInApp` has no effect.

Drawing Modes

Specify what Ink Services should draw.

```
enum {
    kInkDrawNothing = 0,
    kInkDrawInkOnly = 1,
    kInkDrawInkAndWritingGuides= 2
};
typedef unsigned long InkDrawingModeType;
```

Constants

`kInkDrawNothing`

Specifies not to draw Ink or the writing guides.

Available in Mac OS X v10.3 and later.

Declared in `Ink.h`.

`kInkDrawInkOnly`

Specifies to draw Ink but not the writing guides.

Available in Mac OS X v10.3 and later.

Declared in `Ink.h`.

`kInkDrawInkAndWritingGuides`

Specifies to draw both the Ink and the writing guides. This is the default.

Available in Mac OS X v10.3 and later.

Declared in `Ink.h`.

Discussion
You can pass these constants as parameters to the function `InkSetDrawingMode` (page 1030).

Phrase Termination Modes

Defines the conditions under which an Ink phrase should be terminated.

```
enum InkTerminationType{
    kInkTerminationNone = 0,
    kInkTerminationTimeOut = 1,
    kInkTerminationOutOfProximity = 1 << 1,
    kInkTerminationRecognizerHorizontalBreak = 1 << 2,
    kInkTerminationRecognizerVerticalBreak = 1 << 3,
    kInkTerminationStroke = 1 << 4,
    kInkTerminationAll = (unsigned long) 0xFFFFFFFF,
    kInkTerminationDefault = 0x0F
};
typedef unsigned long         InkTerminationType;
```

Constants

`kInkTerminationNone`
Specifies to inhibit automatic phrase termination by Ink Services.

Available in Mac OS X v10.3 and later.

Declared in `Ink.h`.

`kInkTerminationTimeOut`
Specifies to terminate a phrase when all of the following are true:

- The user stops writing and lifts the stylus
- The user keeps the stylus within the proximity range of the tablet
- The user does not resume writing within the period of time defined by the user in the Ink pane of System Preferences

Available in Mac OS X v10.3 and later.

Declared in `Ink.h`.

`kInkTerminationOutOfProximity`
Specifies to terminate a phrase when the user stops writing and lifts the stylus entirely out of the proximity range of the tablet. This is on by default. However, users can turn off proximity termination in the Ink pane of System Preferences if they find it interferes with their writing style.

If the user turns off proximity termination, your application can't turn it on even if you call the function `InkSetPhraseTerminationMode` (page 1030) with the parameter `kInkTerminationOutOfProximity`.

Available in Mac OS X v10.3 and later.

Declared in `Ink.h`.

`kInkTerminationRecognizerHorizontalBreak`
Specifies to terminate a phrase when the user leaves a large horizontal space between words (approximately two character widths or more).

Available in Mac OS X v10.3 and later.

Declared in `Ink.h`.

`kInkTerminationRecognizerVerticalBreak`
Specifies to terminate a phrase when the user finishes one line and begins writing on the next.

Available in Mac OS X v10.3 and later.

Declared in `Ink.h`.

`kInkTerminationStroke`
Causes phrases to be terminated at the end of every stroke (whenever the pen is lifted from the tablet while writing). Only useful for single-stroke gesture input, not for text.

Available in Mac OS X v10.4 and later.

Declared in `Ink.h`.

`kInkTerminationAll`
Specifies to restore automatic phrase termination by Ink Services. In this case, Ink Services uses all of the termination modes (except `kInkTerminationNone`) described previously. Deprecated in Mac OS X v10.4. As of Mac OS X v10.4, this value is overridden to behave like `kInkTerminationDefault`.

Available in Mac OS X v10.3 and later.

Declared in `Ink.h`.

`kInkTerminationDefault`
Restores default phrase termination matching the current user settings (`kInkTerminationTimeOut | kInkTerminationOutOfProximity | kInkTerminationRecognizerHorizontalBreak | kInkTerminationRecognizerVerticalBreak`). See also `kInkTerminationOutOfProximity`.

Declared in `Ink.h`.

Available in Mac OS X v10.4 and later.

Discussion
An Ink phrase (represented as an `InkTextRef` in your application) is typically a word in a Roman language. Ink Services uses phrases to determine when to erase onscreen Ink and initiate recognition. You can pass Ink phrase termination constants as arguments to the function `InkSetPhraseTerminationMode` (page 1030). You can combine two or more constants to obtain precise control over phrase termination.

Recognition Modes

Specify how to interpret Ink input for an application.

```
enum InkRecognitionType{
    kInkRecognitionNone     = 0,
    kInkRecognitionText     = 1,
    kInkRecognitionGesture     = 1 << 1,
    kInkRecognitionDefault     = 3
};
typedef unsigned long     InkRecognitionType;
```

Constants
`kInkRecognitionNone`
Specifies to turn off Ink recognition.

Available in Mac OS X v10.3 and later.

Declared in `Ink.h`.

`kInkRecognitionText`
Specifies to allow interpretation of Ink input as text.

Available in Mac OS X v10.3 and later.

Declared in `Ink.h`.

`kInkRecognitionGesture`
Specifies to allow interpretation of Ink input as gestures.

Available in Mac OS X v10.3 and later.

Declared in `Ink.h`.

`kInkRecognitionDefault`
Specifies the default setting, which is to interpret Ink input as text or gestures.

Available in Mac OS X v10.3 and later.

Declared in `Ink.h`.

Discussion
The recognition type constants are used as arguments for the function `InkSetApplicationRecognitionMode` (page 1028). You can use these constants to specify that Ink Services interprets input as both text and gestures or as either type individually.

Editing Gestures

Define editing actions.

```
enum InkGestureKind {
    kInkGestureUndo     = 'undo',
    kInkGestureCut     = 'cut ',
    kInkGestureCopy     = 'copy',
    kInkGesturePaste     = 'past',
    kInkGestureClear     = 'cler',
    kInkGestureSelectAll     = 'sall',
    kInkGestureLeftSpace     = 'lspc',
    kInkGestureRightSpace     = 'rspc',
    kInkGestureTab     = 'tab ',
    kInkGestureLeftReturn     = 'lrtn',
    kInkGestureRightReturn     = 'rrtn',
    kInkGestureDelete     = 'del ',
    kInkGestureEscape     = 'esc ',
    kInkGestureJoin     = 'join'
    };
typedef FourCharCode     InkGestureKind;
```

Constants
`kInkGestureUndo`
Specifies to undo the last action.

Available in Mac OS X v10.3 and later.

Declared in `Ink.h`.

`kInkGestureCut`
Specifies to cut.

Available in Mac OS X v10.3 and later.

Declared in `Ink.h`.

`kInkGestureCopy`
Specifies to copy.

Available in Mac OS X v10.3 and later.

Declared in `Ink.h`.

`kInkGesturePaste`
Specifies to paste.

Available in Mac OS X v10.3 and later.

Declared in `Ink.h`.

`kInkGestureClear`
Specifies to clear.

Available in Mac OS X v10.3 and later.

Declared in `Ink.h`.

`kInkGestureSelectAll`
Specifies to select all items in the area that has user focus.

Available in Mac OS X v10.3 and later.

Declared in `Ink.h`.

`kInkGestureLeftSpace`
Specifies to insert a single space character. The “left” distinction indicates that the gesture is drawn with the long, horizontal tail is on the left side.

Available in Mac OS X v10.3 and later.

Declared in `Ink.h`.

`kInkGestureRightSpace`
Specifies to insert a single space character. The “right” distinction indicates that the gesture is drawn with the long, horizontal tail is on the right side.

Available in Mac OS X v10.3 and later.

Declared in `Ink.h`.

`kInkGestureTab`
Specifies to insert a tab character.

Available in Mac OS X v10.3 and later.

Declared in `Ink.h`.

`kInkGestureLeftReturn`
Specifies to insert a return (new line) character. The “left” distinction indicates that the gesture is drawn with the small angle-bracket pointing to the left side.

Available in Mac OS X v10.3 and later.

Declared in `Ink.h`.

`kInkGestureRightReturn`
Specifies to insert a return (new line) character. The “right” distinction indicates that the gesture is drawn with the small angle-bracket pointing to the right side.

Available in Mac OS X v10.3 and later.

Declared in `Ink.h`.

`kInkGestureDelete`
Specifies to delete. This corresponds to pressing the Delete key.

Available in Mac OS X v10.3 and later.

Declared in `Ink.h`.

`kInkGestureEscape`
This corresponds to pressing the Escape key.

Available in Mac OS X v10.3 and later.

Declared in `Ink.h`.

`kInkGestureJoin`
Specifies to join two words into a single word, eliding the space between them, and may be applied to editable objects other than text. The gesture is similar in shape to the letter "v". The joined words are the ones closest to the top-most points of the gesture. This is a tentative, always targeted, gesture, meaning that the system treats the associated Ink tentatively as a gesture until your application either confirms the Ink is indeed a gesture or returns `eventNotHandledErr`, informing the system the Ink is not a gesture.

Available in Mac OS X v10.3 and later.

Declared in `Ink.h`.

Discussion
These constants are returned in the Carbon event parameter `kEventParamInkGestureKind`. The Carbon event class for this parameter is `kEventClassInk` and the event kind is `kEventInkGesture`. The constants define the complete set of gestures recognized by Ink Services. When a gesture event is received by your application, your application should determine the gesture kind and then take appropriate action. For more details, see *Using Ink Services in Your Application*.

Alternates Menu Command IDs

Specify the menu command IDs assigned to items inserted in the alternates menu.

```
enum {
    kInkAlternateCommand = 'inka',
    kInkSeparatorCommand         = 'inks',
    kInkDrawingCommand             = 'inkd'
};
```

Constants
`kInkAlternateCommand`
Specifies the menu command ID assigned to menu items inserted by the function `InkTextInsertAlternatesInMenu` (page 1040). You can use this constant to determine which menu items in a menu are supplied by Ink Services.

Available in Mac OS X v10.3 and later.

Declared in `Ink.h`.

`kInkSeparatorCommand`
Specifies the menu command ID assigned to the separator item between the alternates and the Ink drawing.

Available in Mac OS X v10.3 and later.

Declared in `Ink.h`.

`kInkDrawingCommand`
Specifies the menu command ID assigned to the menu item containing the ink drawing.

Available in Mac OS X v10.3 and later.

Declared in `Ink.h`.

Text Drawing Flags

Specify settings to use when drawing Ink text.

```
enum unsigned long InkTextDrawFlagsType{
kInkTextDrawDefault         = 0,
kInkTextDrawIgnorePressure     = 1,
kInkTextDrawHonorContext     = 1 << 1
};
```

Constants

`kInkTextDrawDefault`
Specifies to use the default system settings when drawing. By default, Ink is drawn with pressure sensitive gradients, and the Quartz context settings are overridden for line color and width.

Available in Mac OS X v10.3 and later.

Declared in `Ink.h`.

`kInkTextDrawIgnorePressure`
Specifies not to use pressure sensitive gradients when drawing.

Available in Mac OS X v10.3 and later.

Declared in `Ink.h`.

`kInkTextDrawHonorContext`
Specifies to use the current Quartz context settings for line color and width.

Available in Mac OS X v10.3 and later.

Declared in `Ink.h`.

Ink Source Types

Specify sources for an Ink data stream.

```
enum unsigned long InkSourceType{
    kInkSourceUser                    = 1,
    kInkSourceApplication                        = 2
};
```

Constants

`kInkSourceUser`
Specifies the Ink source from direct user input.

Available in Mac OS X v10.3 and later.

Declared in `Ink.h`.

`kInkSourceApplication`
Specifies the Ink source from the application.

Available in Mac OS X v10.3 and later.

Declared in `Ink.h`.

Discussion
You can use these constants to specify which data stream is currently being controlled by calls to the functions `InkTerminateCurrentPhrase` and `InkSetPhraseTerminationMode`. You can control phrase termination for both the user-input data stream (`kInkSourceUser`) and an application-input data stream (`kInkSourceApplication`) independently.

Ink Pen Constants

Specify ink pen constants.

```
enum {
    kInkPenTipButtonMask = NX_TABLET_BUTTON_PENTIPMASK + 0,
    kInkPenLowerSideButtonMask = NX_TABLET_BUTTON_PENLOWERSIDEMASK
+ 0,
    kInkPenUpperSideButtonMask = NX_TABLET_BUTTON_PENUPPERSIDEMASK
+ 0
};
```

Constants
`kInkPenTipButtonMask`
The writing or eraser tip.

Available in Mac OS X v10.4 and later.

Declared in `Ink.h`.

`kInkPenLowerSideButtonMask`
The lower pen barrel button.

Available in Mac OS X v10.4 and later.

Declared in `Ink.h`.

`kInkPenUpperSideButtonMask`
The upper pen barrel button.

Available in Mac OS X v10.4 and later.

Declared in `Ink.h`.

Discussion
Pens used with modern graphics tablets often have multiple barrel buttons that can be assigned special meaning by the tablet driver or by an application. In addition, the writing or eraser tip may be engaged at any given moment. By performing an AND operation of these contsants with that of a `buttons` member of a `TabletPointRec` in Carbon or the value returned by the `buttonMask` message sent to tablet events (or mouse events containing tablet data) in Cocoa, you can determine which (if any) pen tip or barrel buttons are currently being held down. These buttons and `buttonMask` data are only available for tablet-point events (not tablet-proximity events).

To ensure consistency between the values used by driver writers and the values used by applications, these constants are defined in terms of `NX_` constants from `IOKit/hidsystem/IOLLEvent.h`.

Availability
Available in Mac OS X v10.4 and later.

Ink Tablet Constants

Specify ink tablet constants.

```
enum {
    kInkTabletPointerUnknown = NX_TABLET_POINTER_UNKNOWN + 0,
    kInkTabletPointerPen = NX_TABLET_POINTER_PEN + 0,
    kInkTabletPointerCursor = NX_TABLET_POINTER_CURSOR + 0,
    kInkTabletPointerEraser = NX_TABLET_POINTER_ERASER + 0
};
```

Constants

`kInkTabletPointerUnknown`

The type of tablet pointer is unknown; having an unknown type of tablet pointer should not happen.

Available in Mac OS X v10.4 and later.

Declared in `Ink.h`.

`kInkTabletPointerPen`

The writing end of a stylus-like device.

Available in Mac OS X v10.4 and later.

Declared in `Ink.h`.

`kInkTabletPointerCursor`

Any puck-like device.

Available in Mac OS X v10.4 and later.

Declared in `Ink.h`.

`kInktabletPointerEraser`

The eraser end of a stylus-like device.

Discussion

Pens used with modern graphics tablets often have a writing tip and an eraser tip. Some tablets also support pucks in addition to, or instead of, stylus-like devices. By comparing these constants to the contents of the `pointerType` element of a `TabletProximityRec` in Carbon or to the value returned by the `pointerType` message to tablet events (or mouse events with tablet data in them) in Cocoa, you can determine what kind of pointer device and which tip of a stylus-like device is being used with a graphics tablet. These `pointerType` data are only available in tablet-proximity events (not tablet-point events).

To ensure consistency between the values used by driver writers and the values used by applications, these constants are defined in terms of `NX_` constants from `IOKit/hidsystem/IOLLEvent.h`.

Availability

Available in Mac OS X v10.4 and later.

Result Codes

There are no results codes specific to Ink Services. Rather than returning `OSStatus` values, functions return `NULL` or specific, predetermined invalid responses when you pass invalid parameters to them. Designing the API in this way allows you to chain function calls and write code that is more compact.

Interface Builder Services Reference

Framework: Carbon/Carbon.h
Declared in IBCarbonRuntime.h

Overview

This reference describes the functions you use to unarchive interface objects you create using Interface Builder.

Carbon supports the Interface Builder APIs.

Functions by Task

Creating and Disposing of Nib References

`CreateNibReference` (page 1057)
Creates a reference to a nib file in the current bundle.

`CreateNibReferenceWithCFBundle` (page 1058)
Creates a reference to a nib file in the specified bundle.

`DisposeNibReference` (page 1060)
Disposes of a nib reference.

Unarchiving Menu Bars and Menus

`CreateMenuBarFromNib` (page 1056)
Unarchives a menu bar from a nib file.

`SetMenuBarFromNib` (page 1060)
Unarchives a menu bar from a nib file, then makes the menu bar available in your application.

`CreateMenuFromNib` (page 1056)
Unarchives a menu from a nib file.

Unarchiving Windows

`CreateWindowFromNib` (page 1059)
Unarchives a window from a nib file.

Functions

CreateMenuBarFromNib

Unarchives a menu bar from a nib file.

```
OSStatus CreateMenuBarFromNib (
   IBNibRef inNibRef,
   CFStringRef inName,
   Handle *outMenuBar
);
```

Parameters

inNibRef

A reference to the nib file that contains the menu bar you want to unarchive. You obtain this reference by calling the function `CreateNibReference` (page 1057) or `CreateNibReferenceWithCFBundle` (page 1058).

inName

A `CFStringRef` that denotes the menu bar you want to unarchive. This is the name you supplied to the menu bar in the Instances pane of Interface Builder. See the Base Services documentation for a description of the `CFStringRef` data type. You can use the Core Foundation function `CFSTR` to convert a string to a `CFString`.

outMenuBar

On output, points to a handle to the menu bar.

Return Value

A result code. See Runtime Errors (page 1061).

Discussion

You need to call the Menu Manager function `SetMenuBarFromNib` to make the unarchived menu bar available in your application.

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X 10.0 and later.

Not available to 64-bit applications.

Related Sample Code

BSDLLCTest

Declared In

`IBCarbonRuntime.h`

CreateMenuFromNib

Unarchives a menu from a nib file.

```
OSStatus CreateMenuFromNib (
   IBNibRef inNibRef,
   CFStringRef inName,
   MenuRef *outMenuRef
);
```

Parameters

inNibRef

A reference to the nib file that contains the menu you want to unarchive. You obtain this reference by calling the function `CreateNibReference` (page 1057) or `CreateNibReferenceWithCFBundle` (page 1058).

inName

A `CFStringRef` that denotes the menu you want to unarchive. This is the name you supplied to the menu in the Instance pane of Interface Builder. See the Base Services documentation for a description of the `CFStringRef` data type. You can use the Core Foundation function `CFSTR` to convert a string to a `CFString`.

outMenuRef

On output, points to a menu reference.

Return Value

A result code. See Runtime Errors (page 1061).

Discussion

After you call the function `CreateMenuFromNib` you need to call the Menu Manager function `InsertMenu` to make the unarchived menu available in your application.

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X 10.0 and later.

Not available to 64-bit applications.

Related Sample Code

QTCarbonShell

Declared In

`IBCarbonRuntime.h`

CreateNibReference

Creates a reference to a nib file in the current bundle.

```
OSStatus CreateNibReference (
   CFStringRef inNibName,
   IBNibRef *outNibRef
);
```

Parameters

inNibName

A `CFStringRef` that represents the name of a nib file you created for your application, but without the nib extension. See the Base Services documentation for a description of the `CFStringRef` data type. You can use the Core Foundation function `CFSTR` to convert a string to a `CFString`.

outNibRef

On output, points to a nib reference. You pass the nib reference to Interface Builder Services functions that unarchive objects from a nib file.

Return Value
A result code. See Runtime Errors (page 1061).

Discussion
Use this function if the nib file is located in the current bundle. Use the function `CreateNibReferenceWithCFBundle` (page 1058) if the nib file is located in a framework or other bundle that is not the current bundle.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Related Sample Code
BSDLLCTest
HID Config Save

QTCarbonShell
QTMetaData

Declared In
`IBCarbonRuntime.h`

CreateNibReferenceWithCFBundle

Creates a reference to a nib file in the specified bundle.

```
OSStatus CreateNibReferenceWithCFBundle (
   CFBundleRef inBundle,
   CFStringRef inNibName,
   IBNibRef *outNibRef
);
```

Parameters

inBundle

A `CFBundleRef` to your application's bundle. See the Bundle Services documentation for a description of the `CFBundleRef` data type. You can get this reference by calling the appropriate Core Foundation Bundle Services functions.

inNibName

A `CFStringRef` that represents the name of a nib file you created for your application, but without the nib extension. See the Base Services documentation for a description of the `CFStringRef` data type. You can use the Core Foundation function `CFSTR` to convert a string to a `CFString`.

outNibRef

On output, points to a nib reference. You pass the nib reference to Interface Builder Services functions that unarchive objects from a nib file.

Return Value
A result code. See Runtime Errors (page 1061).

Discussion
Use this function if the nib file is located in a framework or other bundle that is not the current bundle. Use the function `CreateNibReference` (page 1057) if the nib file is located in the current bundle.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
`IBCarbonRuntime.h`

CreateWindowFromNib

Unarchives a window from a nib file.

```
OSStatus CreateWindowFromNib (
   IBNibRef inNibRef,
   CFStringRef inName,
   WindowRef *outWindow
);
```

Parameters

inNibRef
A reference to the nib file that contains the window you want to unarchive. You obtain this reference by calling the function `CreateNibReference` (page 1057) or `CreateNibReferenceWithCFBundle` (page 1058).

inName
A `CFStringRef` that denotes the window you want to unarchive. This is the name you supplied to the window in the Instances pane of Interface Builder. See the Base Services documentation for a description of the `CFStringRef` data type. You can use the Core Foundation function `CFSTR` to convert a string to a `CFString`.

outWindow
On output, points to the window unarchived from the nib file.

Return Value
A result code. See Runtime Errors (page 1061).

Discussion
You need to call the Window Manager function `ShowWindow` to make the unarchived window visible.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

BSDLLCTest
CarbonSketch
HID Config Save
HID Explorer
QTCarbonShell

Declared In
IBCarbonRuntime.h

DisposeNibReference

Disposes of a nib reference.

```
void DisposeNibReference (
   IBNibRef inNibRef
);
```

Parameters

inNibRef

A nib reference you created by calling the function `CreateNibReference` (page 1057) or `CreateNibReferenceWithCFBundle` (page 1058).

Return Value

Discussion
You should call the function `DisposeNibReference` immediately after you have finished unarchiving objects (windows, menus, menu bar, and so forth) from the nib file associated with the nib reference.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

Declared In
IBCarbonRuntime.h

SetMenuBarFromNib

Unarchives a menu bar from a nib file, then makes the menu bar available in your application.

```
OSStatus SetMenuBarFromNib (
   IBNibRef inNibRef,
   CFStringRef inName
);
```

Parameters

inNibRef

A reference to the nib file that contains the menu bar you want to unarchive. You obtain this reference by calling the function `CreateNibReference` (page 1057) or `CreateNibReferenceWithCFBundle` (page 1058).

inName

A `CFStringRef` that denotes the menu bar you want to unarchive. This is the name you supplied to the menu bar in the Instances pane of Interface Builder. (The default name is "`MainMenu`".) See the Base Services documentation for a description of the `CFStringRef` data type. You can use the Core Foundation function `CFSTR` to convert a string to a `CFString`.

Return Value
A result code. See Runtime Errors (page 1061).

Discussion
The function `SetMenuBarFromNib` makes the menu bar visible and selectable by the user when your application opens. If you don't want the menu bar to be visible and selectable when it is unarchived, use the function `CreateMenuBarFromNib` (page 1056).

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X 10.0 and later.
Not available to 64-bit applications.

`IBCarbonRuntime.h`

Data Types

IBNibRef

A reference to a nib file.

```
typedef struct OpaqueIBNibRef * IBNibRef;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`IBCarbonRuntime.h`

Constants

Runtime Errors

Specify a problem that occurs when Interface Builder Services tries to load nib files or objects.

```
enum {
    kIBCarbonRuntimeCantFindNibFile = -10960,
    kIBCarbonRuntimeObjectNotOfRequestedType = -10961,
    kIBCarbonRuntimeCantFindObject = -10962
};
```

Constants

`kIBCarbonRuntimeCantFindNibFile`

Indicates the `CFStringRef` supplied for a nib file does not match the name of a nib file.

Available in Mac OS X v10.0 and later.

Declared in `IBCarbonRuntime.h`.

`kIBCarbonRuntimeObjectNotOfRequestedType`

Indicates the window, menu, or menu bar you want to unarchive isn't what you specified.

Available in Mac OS X v10.0 and later.

Declared in `IBCarbonRuntime.h`.

`kIBCarbonRuntimeCantFindObject`

Indicates the window, menu, or menu bar wasn't found.

Available in Mac OS X v10.0 and later.

Declared in `IBCarbonRuntime.h`.

Keyboard Layout Services Reference

Framework: Carbon/Carbon.h

Declared in Keyboards.h

Overview

Keyboard Layout Services is the programming interface that lets you obtain information about available keyboard layouts, set a keyboard layout, and access a keyboard layout property list. Keyboard Layout Services fully supports Unicode (`'uchr'`) as well as old style (`'KCHR'`) keyboard layouts.

Functions by Task

Working With Keyboard Layouts

`KBGetLayoutType` (page 1064)
Obtains the type of keyboard attached to the computer.

`KLGetCurrentKeyboardLayout` (page 1064) Deprecated in Mac OS X v10.5
Obtains the keyboard layout for the layout currently selected in the Keyboards menu.

`KLGetKeyboardLayoutAtIndex` (page 1065) Deprecated in Mac OS X v10.5
Obtains the keyboard layout reference associated with the specified index.

`KLGetKeyboardLayoutCount` (page 1066) Deprecated in Mac OS X v10.5
Returns the number of keyboard layouts.

`KLGetKeyboardLayoutProperty` (page 1066) Deprecated in Mac OS X v10.5
Obtains the value associated with the specified property tag for a keyboard layout.

`KLGetKeyboardLayoutWithIdentifier` (page 1067) Deprecated in Mac OS X v10.5
Obtains the keyboard layout reference associated with the specified identifier.

`KLGetKeyboardLayoutWithName` (page 1068) Deprecated in Mac OS X v10.5
Obtains the keyboard layout associated with the specified name.

`KLSetCurrentKeyboardLayout` (page 1068) Deprecated in Mac OS X v10.5
Sets the keyboard layout.

Unsupported Functions

`KLGetIndexedKeyboardLayout` (page 1065)
Obtains the keyboard layout reference associated with the specified index.

Functions

KBGetLayoutType

Obtains the type of keyboard attached to the computer.

```
PhysicalKeyboardLayoutType KBGetLayoutType (
   SInt16 iKeyboardType
);
```

Parameters

keyboardType

The keyboard type ID of the keyboard whose type you want to obtain. You can obtain the keyboard type ID by calling the Event Manager function `LMGetKbdType`.

Return Value

The type of the keyboard attached to the computer. See "Physical Keyboard Layout Types" (page 1072) for the values that can be returned.

Discussion

You can call the function `KBGetLayoutType` to determine whether the keyboard attached to the computer is ANSI, ISO, or JIS. You should call this function in Mac OS 9 only if the Gestalt selector `gestaltKeyboardLib` is present.

Availability

Not available in CarbonLib.

Available in Mac OS X version 10.0 and later.

Declared In

`Keyboards.h`

KLGetCurrentKeyboardLayout

Obtains the keyboard layout for the layout currently selected in the Keyboards menu. (Deprecated in Mac OS X v10.5.)

```
OSStatus KLGetCurrentKeyboardLayout (
   KeyboardLayoutRef *oKeyboardLayout
);
```

Parameters

oKeyboardLayout

On output, a pointer to the keyboard layout reference for keyboard layout currently selected in the Keyboard menu.

Return Value

A result code.

Availability

Not available in CarbonLib.

Available in Mac OS X version 10.2 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In
Keyboards.h

KLGetIndexedKeyboardLayout

Obtains the keyboard layout reference associated with the specified index.

Not supported.

```
OSStatus KLGetIndexedKeyboardLayout (
    CFIndex iIndex,
    KeyboardLayoutRef * oKeyboardLayout
);
```

Availability
Unsupported. Not available in CarbonLib. Not available in Mac OS X version 10.2 and later.

Carbon Porting Notes

You should use the function KLGetKeyboardLayoutAtIndex (page 1065) instead.

Declared In
Keyboards.h

KLGetKeyboardLayoutAtIndex

Obtains the keyboard layout reference associated with the specified index. (Deprecated in Mac OS X v10.5.)

```
OSStatus KLGetKeyboardLayoutAtIndex (
   CFIndex iIndex,
   KeyboardLayoutRef *oKeyboardLayout
);
```

Parameters

iIndex

The index of the keyboard layout whose keyboard layout reference you want to retrieve. The index must be a value from 0 through N-1, where N is the value returned in the oCount parameter by the function KLGetKeyboardLayoutCount (page 1066).

oKeyboardLayout

On output, a pointer to the keyboard layout reference associated with the index specified by the iIndex parameter.

Return Value
A result code.

Discussion
You can call this function from within an iteration to access all of the available keyboard layouts.

Availability
Not available in CarbonLib.
Available in Mac OS X version 10.2 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
Keyboards.h

KLGetKeyboardLayoutCount

Returns the number of keyboard layouts. (Deprecated in Mac OS X v10.5.)

```
OSStatus KLGetKeyboardLayoutCount (
   CFIndex *oCount
);
```

Parameters

oCount

On output, a pointer to a variable that specifies the number of keyboard layouts.

Return Value
A result code.

Discussion
You can call the function `KLGetKeyboardLayoutCount` when you want to obtain the number of keyboard layouts available to the user. Once you know the number of keyboard layouts, you can iterate through them by setting up a loop and calling the function `KLGetKeyboardLayoutAtIndex` (page 1065).

Availability
Not available in CarbonLib.
Available in Mac OS X version 10.2 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
Keyboards.h

KLGetKeyboardLayoutProperty

Obtains the value associated with the specified property tag for a keyboard layout. (Deprecated in Mac OS X v10.5.)

```
OSStatus KLGetKeyboardLayoutProperty (
   KeyboardLayoutRef iKeyboardLayout,
   KeyboardLayoutPropertyTag iPropertyTag,
   const void **oValue
);
```

Parameters

iKeyboardLayout

A keyboard layout reference for the keyboard layout whose property value you want to retrieve. You must pass a valid keyboard layout reference. You can obtain a keyboard layout reference by calling the functions `KLGetKeyboardLayoutAtIndex` (page 1065), `KLGetKeyboardLayoutWithIdentifier` (page 1067), `KLGetKeyboardLayoutWithName` (page 1068),or `KLGetCurrentKeyboardLayout` (page 1064).

iPropertyTag

A keyboard layout property tag that specifies the property whose value you want to retrieve. See "Keyboard Layout Property Tag" (page 1070) for a list of the property tag constants you can supply.

oValue

On output, a pointer to the variable associated with the tag specified by the `iPropertyTag` parameter.

Return Value
A result code.

Discussion
You can use this function to obtain keyboard layout data, the keyboard identifier, the icon used for the keyboard menu, the keyboard layout name (including its localized name), the group identifier, and the keyboard layout kind. See "Keyboard Layout Property Tag" (page 1070) for a complete list of the available property tags.

Availability
Not available in CarbonLib.
Available in Mac OS X version 10.2 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Keyboards.h`

KLGetKeyboardLayoutWithIdentifier

Obtains the keyboard layout reference associated with the specified identifier. (Deprecated in Mac OS X v10.5.)

```
OSStatus KLGetKeyboardLayoutWithIdentifier (
   KeyboardLayoutIdentifier iIdentifier,
   KeyboardLayoutRef *oKeyboardLayout
);
```

Parameters

iIdentifier

The keyboard layout identifier for which you want to obtain a keyboard layout reference. See "Keyboard Layout Identifier" (page 1069) for a list of the constants you can supply.

oKeyboardLayout

On output, a pointer to the keyboard layout reference associated with the identifier specified by the `iIdentifer` parameter.

Return Value
A result code.

Availability
Not available in CarbonLib.
Available in Mac OS X version 10.2 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Keyboards.h`

KLGetKeyboardLayoutWithName

Obtains the keyboard layout associated with the specified name. (Deprecated in Mac OS X v10.5.)

```
OSStatus KLGetKeyboardLayoutWithName (
   CFStringRef iName,
   KeyboardLayoutRef *oKeyboardLayout
);
```

Parameters

iName

A `CFStringRef` that specifies the name of the keyboard layout whose keyboard layout reference you want to obtain. This name is the nonlocalized keyboard layout name.

oKeyboardLayout

On output, a pointer to the keyboard layout reference associated with the name specified by the `iName` parameter.

Return Value

A result code.

Discussion

You can call this function when you want to obtain the keyboard layout reference for a keyboard layout other than the active keyboard layout. If you want to obtain the keyboard layout reference for the active keyboard layout, call the function `KLGetCurrentKeyboardLayout` (page 1064).

Availability

Not available in CarbonLib.

Available in Mac OS X version 10.2 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Keyboards.h`

KLSetCurrentKeyboardLayout

Sets the keyboard layout. (Deprecated in Mac OS X v10.5.)

```
OSStatus KLSetCurrentKeyboardLayout (
   KeyboardLayoutRef iKeyboardLayout
);
```

Parameters

iKeyboardLayout

A keyboard layout reference for the keyboard layout you want to set. You must pass a valid keyboard layout reference. You can obtain a keyboard layout reference by calling the functions `KLGetKeyboardLayoutAtIndex` (page 1065), `KLGetKeyboardLayoutWithIdentifier` (page 1067), `KLGetKeyboardLayoutWithName` (page 1068),or `KLGetCurrentKeyboardLayout` (page 1064).

Return Value

A result code.

Availability

Not available in CarbonLib.

Available in Mac OS X version 10.2 and later.

Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Keyboards.h`

Data Types

KeyboardLayoutRef

Specifies a reference to an opaque keyboard layout data structure.

```
typedef struct OpaqueKeyboardLayoutRef * KeyboardLayoutRef;
```

Discussion
You can use the Keyboard Layout Services functions `KLGetKeyboardLayoutAtIndex` (page 1065), `KLGetKeyboardLayoutWithIdentifier` (page 1067), `KLGetKeyboardLayoutWithName` (page 1068),or `KLGetCurrentKeyboardLayout` (page 1064) to obtain a keyboard layout reference. If you want to obtain keyboard layout data, use the function `KLGetKeyboardLayoutProperty` (page 1066).

Availability
Available in Mac OS X v10.2 and later.

Declared In
`Keyboards.h`

Constants

Keyboard Layout Constants

Keyboard Layout Identifier

Specifies a layout identifier for a keyboard.

```
typedef SInt32 KeyboardLayoutIdentifier;
enum {
    kKLUSKeyboard = 0
};
```

Constants
`kKLUSKeyboard`
Specifies a US keyboard layout. All systems support this keyboard layout.
Available in Mac OS X v10.2 and later.
Declared in `Keyboards.h`.

Discussion
You can supply this constant as the `iIdentifier` parameter to the function `KLGetKeyboardLayoutWithIdentifier` (page 1067). This constant is the property value associated with the keyboard layout property tag `kKLIdentifier`.

Keyboard Layout Formats

Specify the layout format used for a keyboard.

```
typedef SInt32 KeyboardLayoutKind;
enum {
    kKLKCHRuchrKind = 0,
    kKLKCHRKind = 1,
    kKLuchrKind = 2
};
```

Constants

`kKLKCHRuchrKind`
Specifies that both `'KCHR'` and `'uchr'` formats are available.
Available in Mac OS X v10.2 and later.
Declared in `Keyboards.h`.

`kKLKCHRKind`
Specifies that only the `'KCHR'` format is available.
Available in Mac OS X v10.2 and later.
Declared in `Keyboards.h`.

`kKLuchrKind`
Specifies that only the `'uchr'` format is available.
Available in Mac OS X v10.2 and later.
Declared in `Keyboards.h`.

Discussion
These values are associated with the keyboard layout property tag `kKLKind`.

Keyboard Layout Property Tag

Specify the property tag for a keyboard layout.

```
typedef UInt32 KeyboardLayoutPropertyTag;
enum {
    kKLKCHRData = 0,
    kKLuchrData = 1,
    kKLIdentifier = 2,
    kKLIcon = 3,
    kKLLocalizedName = 4,
    kKLName = 5,
    kKLGroupIdentifier = 6,
    kKLKind = 7
};
```

Constants

`kKLKCHRData`
Specifies `'KCHR'` layout format. The data associated with this tag is a pointer (`const void *`) to keyboard layout data formatted as `'KCHR'` data. You can use `'KCHR'` data with the Event Manager function `KeyTranslate`.

Available in Mac OS X v10.2 and later.

Declared in `Keyboards.h`.

`kKLuchrData`
Specifies `'uchr'` layout format. The data associated with this tag is a pointer (`const void *`) to keyboard layout data formatted as `'uchr'` data. You can use `'uchr'` data with the Unicode Utilities function `UCKeyTranslate`.

Available in Mac OS X v10.2 and later.

Declared in `Keyboards.h`.

`kKLIdentifier`
Specifies a keyboard layout identifier. The data associated with this tag a "Keyboard Layout Identifier" (page 1069) constant.

Available in Mac OS X v10.2 and later.

Declared in `Keyboards.h`.

`kKLIcon`
Specifies a keyboard layout icon. The data associated with this tag is an icon reference (`IconRef`) that specifies the icon that appears in the Keyboard menu.

Available in Mac OS X v10.2 and later.

Declared in `Keyboards.h`.

`kKLLocalizedName`
Specifies the localized keyboard layout name. The data associated with this tag is a `CFStringRef` that specifies the localized name for the keyboard layout.

Available in Mac OS X v10.2 and later.

Declared in `Keyboards.h`.

`kKLName`
Specifies the keyboard layout name. The data associated with this tag is a `CFStringRef` that specifies the name for the keyboard layout.

Available in Mac OS X v10.2 and later.

Declared in `Keyboards.h`.

`kKLGroupIdentifier`
Specifies the keyboard layout group identifier. The data associated with this tag is an `SInt32` value that specifies the grouping of a keyboard layout in the Keyboard menu.

Available in Mac OS X v10.2 and later.

Declared in `Keyboards.h`.

`kKLKind`
Specifies the keyboard layout format. The data associated with this tag is a "Keyboard Layout Formats" (page 1070) constant.

Available in Mac OS X v10.2 and later.

Declared in `Keyboards.h`.

Discussion
You can supply any of these constants as the `iPropertyTag` parameter to the function `KLGetKeyboardLayoutProperty` (page 1066) to retrieve the data associated with the property tag.

Physical Keyboard Layout Types

Specify the layout type associated with a physical keyboard.

```
typedef UInt32 PhysicalKeyboardLayoutType;
enum {
    kKeyboardJIS = 'JIS ',
    kKeyboardANSI = 'ANSI',
    kKeyboardISO = 'ISO ',
    kKeyboardUnknown = kUnknownType
};
```

Constants
`kKeyboardJIS`
Specifies a JIS keyboard.

Available in Mac OS X v10.0 and later.

Declared in `Keyboards.h`.

`kKeyboardANSI`
Specifies an ANSI keyboard layout.

Available in Mac OS X v10.0 and later.

Declared in `Keyboards.h`.

`kKeyboardISO`
Specifies an ISO keyboard layout.

Available in Mac OS X v10.0 and later.

Declared in `Keyboards.h`.

`kKeyboardUnknown`
Specifies the keyboard layout type is unknown.

Available in Mac OS X v10.0 and later.

Declared in `Keyboards.h`.

Discussion
These constants are returned by the function `KBGetLayoutType` (page 1064).

Unsupported Constants

Trap Value

Specifies a trap value for Keyboard Layout Services.

```
enum {
    _KeyboardDispatch = 0xAA7A
};
```

Discussion
This constant is not needed in Mac OS X.

PS2 Error Codes

Specify an error returned by unsupported PS2 keyboard functions.

```
enum {
    errKBPS2KeyboardNotAvailable = -30850,
    errKBIlligalParameters = -30851,
    errKBFailSettingID = -30852,
    errKBFailTranslationTable = -30853
    errKBFailWritePreference = -30854
};
```

Discussion
These constants are returned as error codes by the unsupported PS2 keyboard functions. They are not relevant to the functions whose prefix is 'KL'.

Keychain Manager Reference

Framework:	CoreServices/CoreServices.h, Carbon/Carbon.h
Declared in	KeychainCore.h KeychainHI.h

Overview

The Keychain Manager is an API that provides a uniform way for your application to handle passwords for multiple users, multiple databases, or any situation in which a user must enter single or multiple passwords. You can use the Keychain Manager to provide secure storage for a user's passwords, cryptographic keys, and digital certificates.

This document, which describes KeychainLib 2.0, is relevant to you if your application needs to create and manage passwords and other secure data.

Important: Keychain Manager is being phased out and replaced by Keychain Services. Any new development should use Keychain Services. See Keychain Services Reference.

Carbon fully supports the Keychain Manager.

Functions by Task

Getting Information About the Keychain Manager

`KCGetKeychainManagerVersion` (page 1114)
Determines the version of the Keychain Manager installed on the user's system.

Creating and Disposing of Keychain References

`KCMakeKCRefFromAlias` (page 1119)
Creates a keychain reference from a keychain alias.

`KCMakeAliasFromKCRef` (page 1118)
Creates an alias to a keychain reference.

`KCReleaseKeychain` (page 1122)
Disposes of the memory associated with a keychain reference.

KCMakeKCRefFromFSSpec (page 1119) Deprecated in Mac OS X v10.5
Creates a keychain reference from a file specification record.

Managing Keychains

KCCreateKeychain (page 1094)
Creates an empty keychain.

kccreatekeychain (page 1095)

KCSetDefaultKeychain (page 1126)
Sets the default keychain.

KCGetDefaultKeychain (page 1112)
Obtains the default keychain.

KCGetStatus (page 1116)
Determines the permissions that are set in a keychain.

KCGetKeychainName (page 1115)
Determines the name of a keychain.

kcgetkeychainname (page 1115)

KCCountKeychains (page 1093)
Determines the number of available keychains.

KCGetIndKeychain (page 1112)
Obtains the reference to an indexed keychain.

Storing and Retrieving Passwords

KCAddAppleSharePassword (page 1080)
Adds a new AppleShare server password to the default keychain.

kcaddapplesharepassword (page 1082)

KCFindAppleSharePassword (page 1096)
Finds the first AppleShare password in the default keychain that matches the specified parameters.

kcfindapplesharepassword (page 1098)

KCAddInternetPassword (page 1086)
Adds a new Internet server password to the default keychain.

kcaddinternetpassword (page 1087)

KCAddInternetPasswordWithPath (page 1088)
Adds a new Internet server password with a specified path to the default keychain.

kcaddinternetpasswordwithpath (page 1089)

`KCFindInternetPassword` (page 1102)
Finds the first Internet password in the default keychain that matches the specified parameters.

`kcfindinternetpassword` (page 1104)

`KCFindInternetPasswordWithPath` (page 1105)
Finds the first Internet password in the default keychain that matches the specified parameters, including path information.

`kcfindinternetpasswordwithpath` (page 1107)

`KCAddGenericPassword` (page 1084)
Adds a new generic password to the default keychain.

`kcaddgenericpassword` (page 1085)

`KCFindGenericPassword` (page 1100)
Finds the first generic password in the default keychain matching the specified parameters.

`kcfindgenericpassword` (page 1102)

Creating and Disposing of Keychain Item References

`KCNewItem` (page 1120)
Creates a reference to a keychain item.

`KCReleaseItem` (page 1121)
Disposes of the memory occupied by a keychain item reference.

Manipulating Keychain Items

`KCAddItem` (page 1090)
Adds a password or other keychain item to the default keychain.

`KCDeleteItem` (page 1096)
Deletes a password or other keychain item from the default keychain.

`KCUpdateItem` (page 1129)
Updates a password or other keychain item.

`KCCopyItem` (page 1092)
Copies a password or other keychain item from one keychain to another.

`KCGetKeychain` (page 1113)
Determines the location of a password or other keychain item.

Setting and Obtaining Keychain Item Data

`KCSetAttribute` (page 1124)
Sets or edits keychain item data using a keychain item attribute structure.

`KCGetAttribute` (page 1109)
Determines keychain item data using a keychain item attribute structure.

`KCSetData` (page 1125)
Sets or edits keychain item data.

`KCGetData` (page 1111)
Determines keychain item data.

Searching for Keychain Items

`KCFindFirstItem` (page 1099)
Finds the first keychain item in a specified keychain that matches specified attributes.

`KCFindNextItem` (page 1108)
Finds the next keychain item matching the previously specified search criteria.

`KCReleaseSearch` (page 1122)
Disposes of the memory occupied by a search criteria reference.

Managing User Interaction

`KCLock` (page 1117)
Locks a keychain.

`KCUnlock` (page 1127)
Displays a dialog box that prompts the user for a password before unlocking a keychain.

`kcunlock` (page 1129)

`KCChangeSettings` (page 1091)
Displays a dialog box enabling the user to change the name, password, or settings of a keychain.

`KCSetInteractionAllowed` (page 1127)
Enables or disables Keychain Manager functions that display a user interface.

`KCIsInteractionAllowed` (page 1117)
Indicates whether Keychain Manager functions that display a user interaction will do so.

Registering Your Keychain Event Callback Function

`KCAddCallback` (page 1083)
Registers your keychain event callback function.

`KCRemoveCallback` (page 1123)
Unregisters your keychain event callback function.

Working With Your Keychain Manager Callback Function

`NewKCCallbackUPP` (page 1130)
Creates a UPP to your keychain event callback.

`InvokeKCCallbackUPP` (page 1079)
Invokes your keychain event callback.

`DisposeKCCallbackUPP` (page 1079)
Disposes of a UPP to your keychain event callback.

Unsupported Functions

`KCChooseCertificate` (page 1092)
Displays a list of certificates that the user can choose from.

`KCFindX509Certificates` (page 1109)
Finds the certificates in a keychain that match specified search criteria.

Functions

DisposeKCCallbackUPP

Disposes of a UPP to your keychain event callback.

Not recommended

```
void DisposeKCCallbackUPP (
   KCCallbackUPP userUPP
);
```

Parameters

userUPP
A Universal Procedure Pointer (UPP) to your keychain event callback function.

Return Value
A result code. See "Keychain Manager Result Codes" (page 1154).

Discussion
When you are finished with a UPP to your keychain event callback function, you should dispose of it by calling the `DisposeKCCallbackUPP` function.

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

There is no replacement function available.

Declared In
`KeychainCore.h`

InvokeKCCallbackUPP

Invokes your keychain event callback.

Not recommended

```
OSStatus InvokeKCCallbackUPP (
   KCEvent keychainEvent,
   KCCallbackInfo *info,
   void *userContext,
   KCCallbackUPP userUPP
);
```

Parameters

keychainEvent

The keychain events you want your application to receive. See "Keychain Events Constants" (page 1140) for a description of possible values. The Keychain Manager tests the bitmask you pass in the `eventMask` parameter of the function `KCAddCallback` (page 1083) to determine which events to pass to your callback function. See "Keychain Events Mask" (page 1142) for a description of this bitmask.

info

A pointer to a structure of type `KCCallbackInfo` (page 1133) that provides information about the keychain event to your callback function. The Keychain Manager passes a pointer to this structure in the `info` parameter of your callback function.

userContext

A pointer to application-defined storage. The Keychain Manager passes this value in the `userContext` parameter of your callback function. Your application can use this to associate any particular call of the `InvokeKCCallbackUPP` function with any particular call of the keychain event callback function.

userUPP

A Universal Procedure Pointer to your keychain event callback function. For information on how to create a keychain event callback function, see `KCCallbackProcPtr` (page 1131).

Return Value

A result code. See "Keychain Manager Result Codes" (page 1154).

Discussion

You should not need to use the function `InvokeKCCallbackUPP`, as the system calls your `KCAddCallback` (page 1083) callback function for you.

Availability

Available in CarbonLib 1.1 and later.

Available in Mac OS X 10.0 and later.

Carbon Porting Notes

There is no replacement function available.

Declared In

`KeychainCore.h`

KCAddAppleSharePassword

Adds a new AppleShare server password to the default keychain.

Not recommended

```
OSStatus KCAddAppleSharePassword (
   AFPServerSignature *serverSignature,
   StringPtr serverAddress,
   StringPtr serverName,
   StringPtr volumeName,
   StringPtr accountName,
   UInt32 passwordLength,
   const void *passwordData,
   KCItemRef *item
);
```

Parameters

serverSignature

A pointer to a 16-byte Apple File Protocol server signature block. Pass a value of type `AFPServerSignature` (page 1132). Pass `NULL` to match any server signature. The Keychain Manager identifies the location for the password by the information passed in the `serverAddress` and `serverSignature` parameters. You must pass a valid value in at least one of these parameters.

serverAddress

A pointer to a Pascal string containing the server address, which may be specified as an AppleTalk zone name, a DNS domain name (in the format "xxx.yyy.zzz"), or an IP address (in the format "111.222.333.444"). The Keychain Manager identifies the location for the password by the information passed in the `serverAddress` and `serverSignature` parameters. You must pass a valid value in at least one of these parameters.

serverName

A pointer to a Pascal string containing the server name.

volumeName

A pointer to a Pascal string containing the volume name.

accountName

A pointer to a Pascal string containing the account name.

passwordLength

The length of the buffer pointed to by `passwordData`.

passwordData

A pointer to a buffer which will hold the returned password data. Before calling `KCAddAppleSharePassword`, allocate enough memory for the buffer to hold the data you want to store.

item

On return, a pointer to a reference to the added item. Pass `NULL` if you don't want to obtain this reference.

Return Value

A result code. See "Keychain Manager Result Codes" (page 1154). The result code `errKCNoDefaultKeychain` indicates that no default keychain could be found. The result code `errKCDuplicateItem` indicates that you tried to add a password that already exists in the keychain. The result code `errKCDataTooLarge` indicates that you tried to add more data than is allowed for a record of this type.

Discussion

The `KCAddAppleSharePassword` function adds a new AppleShare server password to the default keychain that is uniquely identified by the `serverName`, `volumeName`, and `accountName` parameters, and a location specified either by the `serverAddress` or `serverSignature` parameters. The `KCAddAppleSharePassword` function optionally returns a reference to the newly added item.

Most applications do not need to store AppleShare password data, as this is handled transparently by the AppleShare client software. To be compatible with the AppleShare client, you should store a fully-specified File Manager structure `AFPXVolMountInfo` as the password data.

The `KCAddAppleSharePassword` function automatically calls the function `KCUnlock` (page 1127) to display the Unlock Keychain dialog box if the keychain containing the password is currently locked.

You can also call the function `kcaddapplesharepassword` to add an AppleShare server password to the default keychain. `kcaddapplesharepassword` requires that you pass a pointer to a C string instead of a pointer to a Pascal string for the `serverAddress`, `serverName`, `volumeName`, `accountName`, and `passwordData` parameters.

Version Notes
Available beginning with KeychainLib 1.0. In KeychainLib 1.0, the `kcaddapplesharepassword` function provides the same functionality as `KCAddAppleSharePassword`, except that it accepts C strings rather than Pascal strings as arguments. In KeychainLib 2.0, you should use `KCAddAppleSharePassword`, since `kcaddapplesharepassword` is provided for convenience only and may be removed from the header file at some point in the future.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

It is recommended that you use internet passwords instead of AppleShare passwords. Use the `SecKeychainAddInternetPassword` function in Keychain Services instead.

Declared In
`KeychainHI.h`

kcaddapplesharepassword

Not recommended

```
OSStatus kcaddapplesharepassword (
   AFPServerSignature *serverSignature,
   const char *serverAddress,
   const char *serverName,
   const char *volumeName,
   const char *accountName,
   UInt32 passwordLength,
   const void *passwordData,
   KCItemRef *item
);
```

Discussion
This function is available for convenience only and may be removed. Use the function `KCAddAppleSharePassword` (page 1080) instead.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

It is recommended that you use internet passwords instead of AppleShare passwords. Use the `SecKeychainAddInternetPassword` function in Keychain Services instead.

Declared In
`KeychainHI.h`

KCAddCallback

Registers your keychain event callback function.

Not recommended

```
OSStatus KCAddCallback (
   KCCallbackUPP callbackProc,
   KCEventMask eventMask,
   void *userContext
);
```

Parameters

callbackProc

A Universal Procedure Pointer (UPP) to your keychain event callback function, described in `KCCallbackProcPtr` (page 1131). You indicate the type of keychain events you want to receive by passing a bitmask of the desired events in the `eventMask` parameter. To create a UPP to your callback function, call the function `NewKCCallbackUPP` (page 1130).

eventMask

A bitmask indicating the keychain events that your application wishes to be notified of. See "Keychain Events Mask" (page 1142) for a description of this bitmask. The Keychain Manager tests this mask to determine the keychain events that you wish to receive, and passes these events in the `keychainEvent` parameter of your callback function. See "Keychain Events Constants" (page 1140) for a description of these events.

userContext

A pointer to application-defined storage that will be passed to your callback function. Your application can use this to associate any particular call of the `KCAddCallback` function with any particular call of your keychain event callback function.

Return Value
A result code. See "Keychain Manager Result Codes" (page 1154). The result code `errKCDuplicateCallback` indicates that your callback function is already registered.

Discussion
You can register your callback function by passing a UPP to it in the `callbackProc` parameter of the `KCAddCallback` function. Once you have done so, the Keychain Manager calls the function `InvokeKCCallbackUPP` (page 1079) when the keychain event specified in the `eventMask` parameter occurs. In turn, the function `InvokeKCCallbackUPP` (page 1079) passes the keychain event, information about the event, and application-defined storage to your keychain event callback function.

Version Notes
Available beginning with KeychainLib 1.0.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainAddCallback` function in Keychain Services instead.

Declared In
`KeychainCore.h`

KCAddGenericPassword

Adds a new generic password to the default keychain.

Not recommended

```
OSStatus KCAddGenericPassword (
   StringPtr serviceName,
   StringPtr accountName,
   UInt32 passwordLength,
   const void *passwordData,
   KCItemRef *item
);
```

Parameters

serviceName
: A pointer to a Pascal string containing an application-defined service name.

accountName
: A pointer to a Pascal string containing an application-defined account name.

passwordLength
: The length of the password data to be stored

passwordData
: A pointer to the buffer that holds the returned password data. Before calling the `KCAddGenericPassword` function, allocate enough memory for the buffer to hold the data you want to store.

item
: On return, a pointer to a reference to the added item. Pass `NULL` if you don't want to obtain this reference.

Return Value
A result code. See "Keychain Manager Result Codes" (page 1154). The result code `errKCNoDefaultKeychain` indicates that no default keychain could be found. The result code `errKCDuplicateItem` indicates that you tried to add a password that already exists in the keychain. The result code `errKCDataTooLarge` indicates that you tried to add more data than is allowed for a record of this type.

Discussion
The `KCAddGenericPassword` function adds a new generic password to the default keychain. Required parameters to identify the password are `serviceName` and `accountName`, which are application-defined strings. The `KCAddGenericPassword` function optionally returns a reference to the newly added item.

You can use the `KCAddGenericPassword` function to add passwords for accounts other than Internet or AppleShare. For example, you might add passwords for your database or scheduling programs.

You can also call the function `kcaddgenericpassword` to add a new generic password to the default keychain. The difference between the two functions is that the `kcaddgenericpassword` function takes a pointer to a C string instead of a Pascal string in the `serverAddress`, `serverName`, `volumeName`, `accountName`, and `passwordData` parameters.

The `KCAddGenericPassword` function automatically calls the function `KCUnlock` (page 1127) to display the Unlock Keychain dialog box if the keychain containing the password is currently locked.

Version Notes
Available beginning with KeychainLib 1.0. In KeychainLib 1.0, the `kcaddgenericpassword` function provides the same functionality as the function `KCAddGenericPassword`, except that it accepts C strings rather than Pascal strings as arguments. In KeychainLib 2.0, you should use the `KCAddGenericPassword` function, since the `kcaddgenericpassword` function is provided for convenience only and may be removed from the header file at some point in the future.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainAddGenericPassword` function in Keychain Services instead.

Declared In
`KeychainHI.h`

kcaddgenericpassword

Not recommended

```
OSStatus kcaddgenericpassword (
   const char *serviceName,
   const char *accountName,
   UInt32 passwordLength,
   const void *passwordData,
   KCItemRef *item
);
```

Discussion
This function is available for convenience only and may be removed. Use the function `KCAddGenericPassword` (page 1084) instead.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainAddGenericPassword` function in Keychain Services instead.

Declared In
`KeychainHI.h`

KCAddInternetPassword

Adds a new Internet server password to the default keychain.

Not recommended

```
OSStatus KCAddInternetPassword (
   StringPtr serverName,
   StringPtr securityDomain,
   StringPtr accountName,
   UInt16 port,
   OSType protocol,
   OSType authType,
   UInt32 passwordLength,
   const void *passwordData,
   KCItemRef *item
);
```

Parameters

serverName

A pointer to a Pascal string containing the server name.

securityDomain

A pointer to a Pascal string containing the security domain. This parameter is optional, as not all protocols will require it.

accountName

A pointer to a Pascal string containing the account name.

port

The TCP/IP port number. Pass the constant `kAnyPort`, described in "Default Internet Port Constant" (page 1140), to specify any port.

protocol

The protocol associated with this password. See "Keychain Protocol Type Constants" (page 1151) for a description of possible values. Pass the constant `kAnyProtocol`, described in "Default Internet Protocol And Authentication Type Constants" (page 1140), to specify any protocol.

authType

The authentication scheme used. See "Authentication Type Constants" (page 1136) for a description of possible values. Pass the constant `kAnyAuthType`, described in "Default Internet Protocol And Authentication Type Constants" (page 1140), to specify any authentication scheme.

passwordLength

The length of the buffer pointed to by `passwordData`.

passwordData

A pointer to a buffer that holds the returned password data. Before calling the `KCAddInternetPasswordWithPath` function, allocate enough memory for the buffer to hold the data you want to store.

item

On return, a pointer to a reference to the added item. Pass `NULL` if you don't want to obtain this reference.

Return Value

A result code. See "Keychain Manager Result Codes" (page 1154). The result code `errKCNoDefaultKeychain` indicates that no default keychain could be found. The result code `errKCDuplicateItem` indicates that you tried to add a password that already exists in the keychain. The result code `errKCDataTooLarge` indicates that you tried to add more data than is allowed for a record of this type.

Discussion

The `KCAddInternetPassword` function adds a new Internet server password to the default keychain. Required parameters to identify the password are `serviceName` and `accountName` (you cannot pass `NULL` for both parameters). In addition, some protocols may require an optional value in the `securityDomain` parameter when authentication is requested. `KCAddInternetPassword` optionally returns a reference to the newly added item.

The `KCAddInternetPassword` function automatically calls the function `KCUnlock` (page 1127) to display the Unlock Keychain dialog box if the keychain containing the password is currently locked.

You can also call the function `kcaddinternetpassword` to add a new Internet server password to the default keychain. The `kcaddinternetpassword` function requires that you pass a pointer to a C string instead of a pointer to a Pascal string for the `serverAddress`, `serverName`, `volumeName`, `accountName`, and `passwordData` parameters.

Version Notes

Available beginning with KeychainLib 1.0. In KeychainLib 1.0, the `kcaddinternetpassword` function provides the same functionality as `KCAddInternetPassword`, except that it accepts C strings rather than Pascal strings as arguments. In KeychainLib 2.0, you should use `KCAddInternetPassword`, since `kcaddinternetpassword` is provided for convenience only and may be removed from the header file at some point in the future.

Availability

Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainAddInternetPassword` function in Keychain Services instead.

Declared In

`KeychainHI.h`

kcaddinternetpassword

Not recommended

```
OSStatus kcaddinternetpassword (
   const char *serverName,
   const char *securityDomain,
   const char *accountName,
   UInt16 port,
   OSType protocol,
   OSType authType,
   UInt32 passwordLength,
   const void *passwordData,
   KCItemRef *item
);
```

Discussion

This function is available for convenience only and may be removed. Use the function `KCAddInternetPassword` (page 1086) instead.

Availability

Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainAddInternetPassword` function in Keychain Services instead.

Declared In

`KeychainHI.h`

KCAddInternetPasswordWithPath

Adds a new Internet server password with a specified path to the default keychain.

Not recommended

```
OSStatus KCAddInternetPasswordWithPath (
   StringPtr serverName,
   StringPtr securityDomain,
   StringPtr accountName,
   StringPtr path,
   UInt16 port,
   OSType protocol,
   OSType authType,
   UInt32 passwordLength,
   const void *passwordData,
   KCItemRef *item
);
```

Parameters

serverName

A pointer to a Pascal string containing the server name.

securityDomain

A pointer to a Pascal string containing the security domain. This parameter is optional, as not all protocols will require it.

accountName

A pointer to a Pascal string containing the account name.

path

A pointer to a Pascal string containing additional information that specifies a file or directory on the server specified by the `serverName` parameter. In a typical URL, path information begins directly after the first slash ("/") character following the server name. This parameter is optional.

port

The TCP/IP port number. Pass the constant `kAnyPort`, described in "Default Internet Port Constant" (page 1140), to specify any port.

protocol

The protocol associated with this password. See "Keychain Protocol Type Constants" (page 1151) for a description of possible values. Pass the constant `kAnyProtocol`, described in "Default Internet Protocol And Authentication Type Constants" (page 1140), to specify any protocol.

authType

The authentication scheme used. See "Authentication Type Constants" (page 1136) for a description of possible values. Pass the constant `kAnyAuthType`, described in "Default Internet Protocol And Authentication Type Constants" (page 1140), to specify any authentication scheme.

passwordLength

The length of the buffer pointed to by `passwordData`.

passwordData

A pointer to a buffer which will hold the returned password data. Before calling `KCAddInternetPasswordWithPath`, allocate enough memory for the buffer to hold the data you want to store.

item

On return, a pointer to a reference to the added item. Pass `NULL` if you don't want to obtain this reference.

Return Value

A result code. See "Keychain Manager Result Codes" (page 1154). The result code `errKCNoDefaultKeychain` indicates that no default keychain could be found. The result code `errKCDuplicateItem` indicates that you tried to add a password that already exists in the keychain. The result code `errKCDataTooLarge` indicates that you tried to add more data than is allowed for a record of this type.

Discussion

The `KCAddInternetPasswordWithPath` function enables you to specify path information when adding a new Internet server password to the default keychain. Required parameters to identify the password are `serviceName` and `accountName` (you cannot pass `NULL` for both parameters). In addition, some protocols may require an optional `securityDomain` when authentication is requested. `KCAddInternetPasswordWithPath` optionally returns a reference to the newly added item.

The `KCAddInternetPasswordWithPath` function automatically calls the function `KCUnlock` (page 1127) to display the Unlock Keychain dialog box if the keychain containing the password is currently locked.

You can also call the function `kcaddinternetpasswordwithpath` to add a new Internet server password to the default keychain. The function `kcaddinternetpasswordwithpath` requires that you pass a pointer to a C string instead of a pointer to a Pascal string for the `serverAddress`, `serverName`, `volumeName`, `accountName`, and `passwordData` parameters.

Version Notes

Available beginning with KeychainLib 2.0. In KeychainLib 1.0, the `kcaddinternetpasswordwithpath` function provides the same functionality as the `KCAddInternetPasswordWithPath` function, except that it accepts C strings rather than Pascal strings as arguments. In KeychainLib 2.0, you should use the `KCAddInternetPasswordWithPath` function, since the function `kcaddinternetpasswordwithpath` is provided for convenience only and may be removed from the header file at some point in the future.

Availability

Available in CarbonLib 1.1 and later when KeychainLib 2.0 or later is present.

Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainAddInternetPassword` function in Keychain Services instead.

Declared In

`KeychainHI.h`

kcaddinternetpasswordwithpath

Not recommended

```
OSStatus kcaddinternetpasswordwithpath (
   const char *serverName,
   const char *securityDomain,
   const char *accountName,
   const char *path,
   UInt16 port,
   OSType protocol,
   OSType authType,
   UInt32 passwordLength,
   const void *passwordData,
   KCItemRef *item
);
```

Discussion
This function is available for convenience only and may be removed. Use the function `KCAddInternetPasswordWithPath` (page 1088) instead.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainAddInternetPassword` function in Keychain Services instead.

Declared In
`KeychainHI.h`

KCAddItem

Adds a password or other keychain item to the default keychain.

Not recommended

```
OSStatus KCAddItem (
   KCItemRef item
);
```

Parameters

item

A reference to the keychain item you wish to add. If you pass an existing item in the keychain, the item is updated. If you pass an item that has not been previously added to the keychain and an identical item already exists in the keychain, `KCAddItem` returns the result code `errKCDuplicateItem`.

Return Value
A result code. See "Keychain Manager Result Codes" (page 1154). The result code `errKCNoDefaultKeychain` indicates that no default keychain could be found. The result code `errKCInvalidItemRef` indicates that the specified keychain item reference was invalid. The result code `errKCDuplicateItem` indicates that you tried to add a new item that already exists in the keychain.

Discussion
You can use the `KCAddItem` function to add a password or other keychain item to the permanent data store of the default keychain. If you want to add a password to a keychain other than the default, call the function `KCSetDefaultKeychain` (page 1126) to change the default keychain. The `KCAddItem` function automatically calls the function `KCUnlock` (page 1127) to display the Unlock Keychain dialog box if the keychain containing the item is currently locked.

Version Notes
Available beginning with KeychainLib 1.0.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

When you use Keychain Services to create an item, it is always added to the specified keychain at creation time.

Declared In
`KeychainHI.h`

KCChangeSettings

Displays a dialog box enabling the user to change the name, password, or settings of a keychain.

Not recommended

```
OSStatus KCChangeSettings (
   KCRef keychain
);
```

Parameters

keychain
A reference to an unlocked keychain. Pass in `NULL` to specify the default keychain.

Return Value
A result code. See "Keychain Manager Result Codes" (page 1154). The result code `errUserCanceled` indicates that the user pressed the Cancel button in the Change Settings dialog box. The result code `errKCNoDefaultKeychain` indicates that the default keychain could not be found. The result code `errKCInvalidKeychain` indicates that the specified keychain is invalid.

Discussion
Typically, your application should not call the `KCChangeSettings` function. You would only call the `KCChangeSettings` function in response to a user's request to change keychain settings, name, or password. Note that you cannot change a keychain passphrase directly. You must call the `KCChangeSettings` function and allow the user to change it.

Version Notes
Available beginning with KeychainLib 2.0.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainSetSettings` function in Keychain Services instead.

Declared In
`KeychainHI.h`

KCChooseCertificate

Displays a list of certificates that the user can choose from.

Unsupported

```
OSStatus KCChooseCertificate (
    CFArrayRef items,
    KCItemRef *certificate,
    CFArrayRef policyOIDs,
    KCVerifyStopOn stopOn
);
```

Parameters

items

An array of certificate references.

certificate

If the `items` array only contains one certificate, on return, a pointer to that certificate. In this case, no user interface is displayed.

policyOIDs

An array of trust policy options used for Macintosh file signing. To obtain a pointer to this array, call the function `SecMacGetDefaultPolicyOIDs`.

stopOn

The criteria to use in selecting the certificates to display. See "Certificate Verification Criteria" (page 1139) for a description of this mask.

Return Value

A result code. See "Keychain Manager Result Codes" (page 1154). The result code `userCanceledErr` indicates that the user pressed the Cancel button in the user interface.

Discussion

The `KCChooseCertificate` function displays a list of the certificates from which the user can choose. If only one certificate matches the criteria, the reference is passed back in the `certificate` parameter and no user interface is presented.

Version Notes

Available beginning with KeychainLib 2.0.

Carbon Porting Notes

This function is obsolete. There is currently no replacement.

Declared In

`KeychainHI.h`

KCCopyItem

Copies a password or other keychain item from one keychain to another.

Not recommended

```
OSStatus KCCopyItem (
   KCItemRef item,
   KCRef destKeychain,
   KCItemRef *copy
);
```

Parameters

item

A reference to the keychain item you wish to copy.

destKeychain

A reference to the keychain into which the item is to be copied.

copy

A pointer to a reference to the new copied keychain item.

Return Value

A result code. See "Keychain Manager Result Codes" (page 1154). The result code `errKCReadOnly` indicates that the destination keychain is read only. The result code `errKCNoSuchClass` indicates that the item has an invalid keychain item class. The result code `errKCInvalidItemRef` indicates that the specified keychain item reference was invalid.

Discussion

You can use the `KCCopyItem` function to copy a keychain item from one keychain to another. The `KCCopyItem` function automatically calls the function `KCUnlock` (page 1127) to display the Unlock Keychain dialog box if the keychain containing the item to be copied is currently locked.

Version Notes

Available beginning with KeychainLib 2.0.

Availability

Available in CarbonLib 1.1 and later when KeychainLib 2.0 or later is present.

Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainItemCopyContent` function in Keychain Services instead.

Declared In

`KeychainCore.h`

KCCountKeychains

Determines the number of available keychains.

Not recommended

```
UInt16 KCCountKeychains (
   void
);
```

Parameters

Return Value

The number of available keychains. This includes all keychains in the Keychains folder, as well as any other keychains known to the Keychain Manager.

Discussion
This function reports the number of keychains known to the Keychain Manager. These keychains are created by the function `KCCreateKeychain` (page 1094).

Version Notes
Available beginning with KeychainLib 1.0.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainCopySearchList` function in Keychain Services followed by a call to `CFArrayGetCount` instead.

Declared In
`KeychainCore.h`

KCCreateKeychain

Creates an empty keychain.

Not recommended

```
OSStatus KCCreateKeychain (
   StringPtr password,
   KCRef *keychain
);
```

Parameters

password

A pointer to a Pascal string representing the password string which will be used to protect the new keychain. If you pass `NULL`, the Keychain Setup dialog box will be displayed to obtain it.

keychain

A pointer to a reference to the keychain you wish to create. You create a keychain reference by calling the function `KCMakeKCRefFromFSSpec` (page 1119) or `KCMakeKCRefFromAlias` (page 1119). If you pass a pointer to a keychain reference, the user will not need to be prompted for a name and location; in all other cases, `KCCreateKeychain` will interactively request this information from the user. If you pass a pointer to a `NULL` keychain reference, the Keychain Manager allocates the memory for the keychain reference and returns it in this parameter. Pass a `NULL` pointer if you do not need a reference returned.

Return Value
A result code. See "Keychain Manager Result Codes" (page 1154). The result code `userCanceledErr` indicates that the user pressed the Cancel button in the create keychain. The result code `errKCDuplicateKeychain` indicates that the user tried to create a keychain which already exists. The result code `errKCInvalidKeychain` indicates that the specified keychain is invalid. Additional errors may be returned if the keychain could not be created (for example, a file system or network error may be returned if there is no write access to the storage media).

Discussion
The `KCCreateKeychain` function creates an empty keychain. The `keychain` and `password` parameters are optional. If user interaction to create a keychain is posted, the newly-created keychain is automatically unlocked after creation.

You can also call the function `kccreatekeychain` to create an empty keychain. The function `kccreatekeychain` requires that you pass a pointer to a C string instead of a pointer to a Pascal string in the `password` parameter.

Special Considerations

It is recommended that the `KCCreateKeychain` function not be explicitly called by applications. Instead, you should call one of the add functions in "Storing and Retrieving Passwords" (page 1076) to add a password to the default keychain. If a default keychain does not exist, it is created automatically.

When you are finished with a keychain, you must deallocate its memory by calling the function `KCReleaseKeychain` (page 1122).

Version Notes

Available beginning with KeychainLib 1.0. In KeychainLib 1.0, the `kccreatekeychain` function provides the same functionality as `KCCreateKeychain`. In KeychainLib 2.0, you should use `KCCreateKeychain`, since `kccreatekeychain` is provided for convenience only and may be removed from the header file at some point in the future.

Availability

Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainCreate` function in Keychain Services instead.

Declared In

`KeychainHI.h`

kccreatekeychain

Not recommended

```
OSStatus kccreatekeychain (
   const char *password,
   KCRef *keychain
);
```

Discussion

This function is available for convenience only and may be removed. Use the function `KCCreateKeychain` (page 1094) instead.

Availability

Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainCreate` function in Keychain Services instead.

Declared In

`KeychainHI.h`

KCDeleteItem

Deletes a password or other keychain item from the default keychain.

Not recommended

```
OSStatus KCDeleteItem (
   KCItemRef item
);
```

Parameters

item

A reference to the keychain item you wish to delete. If you pass an item that has not been previously added to the keychain, the function `KCDeleteItem` does nothing and returns `noErr`.

Return Value

A result code. See "Keychain Manager Result Codes" (page 1154). The result code `errKCNoDefaultKeychain` indicates that no default keychain could be found. The result code `errKCInvalidItemRef` indicates that the specified keychain item reference was invalid.

Discussion

You can use the `KCDeleteItem` function to delete a keychain item from the permanent data store of the default keychain. The `KCDeleteItem` function automatically calls the function `KCUnlock` (page 1127) to display the Unlock Keychain dialog box if the keychain containing the item is currently locked.

Special Considerations

The `KCDeleteItem` function does not dispose the memory occupied by the item reference. To do so, call the function `KCReleaseItem` (page 1121) when you are finished with an item.

Version Notes

Available beginning with KeychainLib 1.0.

Availability

Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainItemDelete` function in Keychain Services instead.

Declared In

`KeychainCore.h`

KCFindAppleSharePassword

Finds the first AppleShare password in the default keychain that matches the specified parameters.

Not recommended

```
OSStatus KCFindAppleSharePassword (
   AFPServerSignature *serverSignature,
   ConstStringPtr serverAddress,
   ConstStringPtr serverName,
   ConstStringPtr volumeName,
   ConstStringPtr accountName,
   UInt32 maxLength,
   void *passwordData,
   UInt32 *actualLength,
   KCItemRef *item
);
```

Parameters

serverSignature

A pointer to a 16-byte Apple File Protocol server signature block. Pass a value of type `AFPServerSignature` (page 1132). Pass `NULL` to match any server signature. The Keychain Manager identifies the location for the password by the information passed in the `serverAddress` and `serverSignature` parameters. You must pass a valid value in at least one of these parameters.

serverAddress

A pointer to a Pascal string containing the server address, which may be specified as an AppleTalk zone name, a DNS domain name (in the format "xxx.yyy.zzz"), or an IP address (in the format "111.222.333.444"). The Keychain Manager identifies the location for the password by the information passed in the `serverAddress` and `serverSignature` parameters. You must pass a valid value in at least one of these parameters.

serverName

A pointer to a Pascal string containing the server name. Pass `NULL` to match any server name.

volumeName

A pointer to a Pascal string containing the volume name. Pass `NULL` to match any volume name.

accountName

A pointer to a Pascal string containing the account name. Pass `NULL` to match any account name.

maxLength

The length of the buffer pointed to by `passwordData`.

passwordData

A pointer to a buffer which will hold the returned password data. Before calling `KCFindAppleSharePassword`, allocate enough memory for the buffer to hold the data you want to store. Pass `NULL` if you want to obtain the item reference but not the password data. In this case, you must also pass `NULL` in the `actualLength` parameter. On return, a pointer to the returned password data.

actualLength

On return, the actual length of the password data that was retrieved. If the buffer pointed to by `passwordData` is smaller than the actual length of the data, `KCFindAppleSharePassword` returns the result code `errKCBufferTooSmall`. In this case, your application must allocate a new buffer of sufficient size before calling `KCFindAppleSharePassword` again.

item

On return, a pointer to a reference to the found item. Pass `NULL` if you don't want to obtain this reference.

Return Value
A result code. See "Keychain Manager Result Codes" (page 1154). The result code `errKCNoDefaultKeychain` indicates that no default keychain was found. The result code `errKCItemNotFound` indicates that no matching password item was found. The result code `errKCBufferTooSmall` indicates that your application must allocate a new buffer of sufficient size before calling `KCFindAppleSharePassword` again.

Discussion
The `KCFindAppleSharePassword` function finds the first AppleShare password item which matches the attributes you provide. The buffer specified in the `passwordData` parameter must be large enough to hold the password data, otherwise `KCFindAppleSharePassword` returns the result code `errKCBufferTooSmall`. In this case, your application must allocate a new buffer of sufficient size before calling the `KCFindAppleSharePassword` function again. The `KCFindAppleSharePassword` function optionally returns a reference to the found item.

The `KCFindAppleSharePassword` function automatically calls the function `KCUnlock` (page 1127) to display the Unlock Keychain dialog box if the keychain containing the password is currently locked.

You can also call the function `kcfindapplesharepassword` to find the first AppleShare server password matching specified attributes. `kcfindapplesharepassword` requires that you pass a pointer to a C string instead of a pointer to a Pascal string for the `serverAddress`, `serverName`, `volumeName`, `accountName`, and `passwordData` parameters.

Version Notes
Available beginning with KeychainLib 1.0. In KeychainLib 1.0, the `kcfindapplesharepassword` function provides the same functionality as `KCFindAppleSharePassword`, except that it accepts C strings rather than Pascal strings as arguments. In KeychainLib 2.0, you should use `KCFindAppleSharePassword`, since `kcfindapplesharepassword` is provided for convenience only and may be removed from the header file at some point in the future.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the Keychain Services function `SecKeychainSearchCreateFromAttributes` followed by the `SecKeychainSearchCopyNext` function instead.

Declared In
`KeychainCore.h`

kcfindapplesharepassword
Not recommended

```
OSStatus kcfindapplesharepassword (
   AFPServerSignature *serverSignature,
   const char *serverAddress,
   const char *serverName,
   const char *volumeName,
   const char *accountName,
   UInt32 maxLength,
   void *passwordData,
   UInt32 *actualLength,
   KCItemRef *item
);
```

Discussion
This function is available for convenience only and may be removed. Use the function `KCFindAppleSharePassword` (page 1096) instead.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the Keychain Services function `SecKeychainSearchCreateFromAttributes` followed by the `SecKeychainSearchCopyNext` function instead.

Declared In
`KeychainCore.h`

KCFindFirstItem

Finds the first keychain item in a specified keychain that matches specified attributes.

Not recommended

```
OSStatus KCFindFirstItem (
   KCRef keychain,
   const KCAttributeList *attrList,
   KCSearchRef *search,
   KCItemRef *item
);
```

Parameters

keychain
A reference to the keychain that you wish to search. If you pass a locked keychain, the Unlock Keychain dialog box is displayed. If you pass `NULL`, the `KCFindFirstItem` function searches all unlocked keychains.

attrList
A pointer to a list of 0 or more structures containing information about the keychain item attributes to be matched. Pass `NULL` to match any attribute.

search
On return, a pointer to a reference to the current search criteria.

item
On return, a pointer to the first matching keychain item.

Return Value
A result code. See "Keychain Manager Result Codes" (page 1154). The result code `errKCNoDefaultKeychain` indicates that no default keychain could be found. The result code `errKCItemNotFound` indicates that no matching keychain item was found. The result code `errKCNoSuchAttr` indicates that the specified attribute is undefined for this item class.

Discussion
The `KCFindFirstItem` function returns a reference to the first keychain item in a keychain that matches a list of attributes. The `KCFindFirstItem` function also returns a reference to the search criteria used. You should pass the returned search criteria in the `searchRef` parameter of the function `KCFindNextItem` (page 1108).

The `KCFindFirstItem` function automatically calls the function `KCUnlock` (page 1127) to display the Unlock Keychain dialog box if the keychain containing the item you are searching for is currently locked.

Special Considerations

When you are completely finished with a search, you should the functions `KCReleaseItem` (page 1121) and `KCReleaseSearch` (page 1122) to release the memory occupied by the keychain item and search criteria reference.

Version Notes
Available beginning with KeychainLib 1.0.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the Keychain Services function `SecKeychainSearchCreateFromAttributes` followed by a call to `SecKeychainSearchCopyNext` instead.

Declared In
`KeychainCore.h`

KCFindGenericPassword

Finds the first generic password in the default keychain matching the specified parameters.

Not recommended

```
OSStatus KCFindGenericPassword (
   ConstStringPtr serviceName,
   ConstStringPtr accountName,
   UInt32 maxLength,
   void *passwordData,
   UInt32 *actualLength,
   KCItemRef *item
);
```

Parameters

`serviceName`

A pointer to a Pascal string containing an application-defined service name. Pass `NULL` to match any service name.

accountName

A pointer to a Pascal string containing an application-defined account name. Pass `NULL` to match any account name.

maxLength

The length of the buffer pointed to by `passwordData`.

passwordData

A pointer to the buffer that holds the returned password data. Before calling the `KCFindGenericPassword` function, allocate enough memory for the buffer to hold the data you want to store. Pass `NULL` if you want to obtain the item reference but not the password data. In this case, you must also pass `NULL` in the `actualLength` parameter. On return, a pointer to the returned password data.

actualLength

On return, the actual length of the password data that was retrieved. If the buffer pointed to by the `passwordData` parameter is smaller than the actual length of the data, the `KCFindGenericPassword` function returns the result code `errKCBufferTooSmall`. In this case, your application must allocate a new buffer of sufficient size before calling the `KCFindGenericPassword` function again.

item

On return, a pointer to a reference to the found item. Pass `NULL` if you don't want to obtain this reference.

Return Value

A result code. See "Keychain Manager Result Codes" (page 1154). The result code `errKCNoDefaultKeychain` indicates that no default keychain was found. The result code `errKCItemNotFound` indicates that no matching password item was found. The result code `errKCBufferTooSmall` indicates that your application must allocate a new buffer of sufficient size before calling the function `KCFindGenericPassword` again.

Discussion

The `KCFindGenericPassword` function finds the first generic password item which matches the attributes you provide. The buffer specified in the `passwordData` parameter must be large enough to hold the password data, otherwise the function `KCFindGenericPassword` returns the result code `errKCBufferTooSmall`. In this case, your application must allocate a new buffer of sufficient size before calling the function `KCFindGenericPassword` again. The `KCFindGenericPassword` function optionally returns a reference to the found item.

The `KCFindGenericPassword` function automatically calls the function `KCUnlock` (page 1127) to display the Unlock Keychain dialog box if the keychain containing the password is currently locked.

You can also call the function `kcfindgenericpassword` to find the first generic password matching specified attributes. The `kcfindgenericpassword` function requires that you pass a pointer to a C string instead of a pointer to a Pascal string for the `serverAddress`, `serverName`, `volumeName`, `accountName`, and `passwordData` parameters.

Version Notes

Available beginning with KeychainLib 1.0. In KeychainLib 1.0, the `kcfindgenericpassword` function provides the same functionality as the function `KCFindGenericPassword`, except that it accepts C strings rather than Pascal strings as arguments. In KeychainLib 2.0, you should use the `KCFindGenericPassword` function, since the `kcfindgenericpassword` function is provided for convenience only and may be removed from the header file at some point in the future.

Availability

Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainFindGenericPassword` function in Keychain Services instead.

Declared In

`KeychainCore.h`

kcfindgenericpassword

Not recommended

```
OSStatus kcfindgenericpassword (
   const char *serviceName,
   const char *accountName,
   UInt32 maxLength,
   void *passwordData,
   UInt32 *actualLength,
   KCItemRef *item
);
```

Discussion

This function is available for convenience only and may be removed. Use the function `KCFindGenericPassword` (page 1100) instead.

Availability

Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainFindGenericPassword` function in Keychain Services instead.

Declared In

`KeychainCore.h`

KCFindInternetPassword

Finds the first Internet password in the default keychain that matches the specified parameters.

Not recommended

```
OSStatus KCFindInternetPassword (
   ConstStringPtr serverName,
   ConstStringPtr securityDomain,
   ConstStringPtr accountName,
   UInt16 port,
   OSType protocol,
   OSType authType,
   UInt32 maxLength,
   void *passwordData,
   UInt32 *actualLength,
   KCItemRef *item
);
```

Parameters

serverName

A pointer to a Pascal string containing the server name. Pass `NULL` to match any server name.

securityDomain

A pointer to a Pascal string containing the security domain. Pass `NULL` to match any domain.

accountName

A pointer to a Pascal string containing the account name. Pass `NULL` to match any account name.

port

The TCP/IP port number. Pass the constant `kAnyPort`, described in "Default Internet Port Constant" (page 1140), to match any port.

protocol

The protocol associated with this password. See "Keychain Protocol Type Constants" (page 1151) for a description of possible values. Pass the constant `kAnyProtocol`, described in "Default Internet Protocol And Authentication Type Constants" (page 1140), to match any protocol.

authType

The authentication scheme used. See "Authentication Type Constants" (page 1136) for a description of possible values. Pass the constant `kAnyAuthType`, described in "Default Internet Protocol And Authentication Type Constants" (page 1140), to match any authentication scheme.

maxLength

The length of the buffer pointed to by `passwordData`.

passwordData

A pointer to the buffer that holds the returned password data. Before calling the `KCFindInternetPassword` function, allocate enough memory for the buffer to hold the data you want to store. Pass `NULL` if you want to obtain the item reference but not the password data. In this case, you must also pass `NULL` in the `actualLength` parameter. On return, a pointer to the returned password data.

actualLength

On return, the actual length of the password data that was retrieved. If the buffer pointed to by the `passwordData` parameter is smaller than the actual length of the data, the `KCFindInternetPassword` function returns the result code `errKCBufferTooSmall`. In this case, your application must allocate a new buffer of sufficient size before calling the `KCFindInternetPassword` function again.

item

On return, a pointer to a reference to the found item. Pass `NULL` if you don't want to obtain this reference.

Return Value
A result code. See "Keychain Manager Result Codes" (page 1154). The result code `errKCNoDefaultKeychain` indicates that no default keychain was found. The result code `errKCItemNotFound` indicates that no matching password item was found. The result code `errKCBufferTooSmall` indicates that your application must allocate a new buffer of sufficient size before calling the function `KCFindInternetPassword` again.

Discussion
The `KCFindInternetPassword` function finds the first Internet password item that matches the attributes you provide. The buffer specified in the `passwordData` parameter must be large enough to hold the password data, otherwise the function `KCFindInternetPassword` returns the result code `errKCBufferTooSmall`. In this case, your application must allocate a new buffer of sufficient size before calling the function `KCFindInternetPassword` again. The `KCFindInternetPassword` function optionally returns a reference to the found item.

The `KCFindInternetPassword` function automatically calls the function `KCUnlock` (page 1127) to display the Unlock Keychain dialog box if the keychain containing the password is currently locked.

You can also call the function `kcfindinternetpassword` to find the first Internet password item matching specified attributes. The `kcfindinternetpassword` function requires that you pass a pointer to a C string instead of a Pascal string for the `serverAddress`, `serverName`, `volumeName`, `accountName`, and `passwordData` parameters.

Version Notes
Available beginning with KeychainLib 1.0. In KeychainLib 1.0, the `kcfindinternetpassword` function provides the same functionality as the function `KCFindInternetPassword`, except that it accepts C strings rather than Pascal strings as arguments. In KeychainLib 2.0, you should use the `KCFindInternetPassword` function, since `kcfindinternetpassword` is provided for convenience only and may be removed from the header file at some point in the future.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes
Use the `SecKeychainFindInternetPassword` function in Keychain Services instead.

Declared In
`KeychainCore.h`

kcfindinternetpassword
Not recommended

```
OSStatus kcfindinternetpassword (
   const char *serverName,
   const char *securityDomain,
   const char *accountName,
   UInt16 port,
   OSType protocol,
   OSType authType,
   UInt32 maxLength,
   void *passwordData,
   UInt32 *actualLength,
   KCItemRef *item
);
```

Discussion
This function is available for convenience only and may be removed. Use the function `KCFindInternetPassword` (page 1102) instead.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainFindInternetPassword` function in Keychain Services instead.

Declared In
`KeychainCore.h`

KCFindInternetPasswordWithPath

Finds the first Internet password in the default keychain that matches the specified parameters, including path information.

Not recommended

```
OSStatus KCFindInternetPasswordWithPath (
   ConstStringPtr serverName,
   ConstStringPtr securityDomain,
   ConstStringPtr accountName,
   ConstStringPtr path,
   UInt16 port,
   OSType protocol,
   OSType authType,
   UInt32 maxLength,
   void *passwordData,
   UInt32 *actualLength,
   KCItemRef *item
);
```

Parameters

serverName
A pointer to a Pascal string containing the server name. Pass `NULL` to match any server name.

securityDomain
A pointer to a Pascal string containing the security domain. Pass `NULL` to match any domain.

accountName

A pointer to a Pascal string containing the account name. Pass `NULL` to match any account name.

path

A pointer to a Pascal string containing additional information that specifies a file or directory on the server specified by the `serverName` parameter. In a typical URL, path information begins directly after the first slash ("/") character following the server name. This parameter is optional.

port

The TCP/IP port number. Pass the constant `kAnyPort`, described in "Default Internet Port Constant" (page 1140), to match any port.

protocol

The protocol associated with this password. See "Keychain Protocol Type Constants" (page 1151) for a description of possible values. Pass the constant `kAnyProtocol`, described in "Default Internet Protocol And Authentication Type Constants" (page 1140), to match any protocol.

authType

The authentication scheme used. See "Authentication Type Constants" (page 1136) for a description of possible values. Pass the constant `kAnyAuthType`, described in "Default Internet Protocol And Authentication Type Constants" (page 1140), to match any authentication scheme.

maxLength

The length of the buffer pointed to by `passwordData`.

passwordData

A pointer to a buffer which will hold the returned password data. Before calling the `KCFindInternetPasswordWithPath` function, allocate enough memory for the buffer to hold the data you want to store. Pass `NULL` if you want to obtain the item reference but not the password data. In this case, you must also pass `NULL` in the `actualLength` parameter. On return, a pointer to the returned password data.

actualLength

On return, the actual length of the password data that was retrieved. If the buffer pointed to by the `passwordData` parameter is smaller than the actual length of the data, the function `KCFindInternetPasswordWithPath` returns the result code `errKCBufferTooSmall`. In this case, your application must allocate a new buffer of sufficient size before calling the function `KCFindInternetPasswordWithPath` again.

item

On return, a pointer to a reference to the found item. Pass `NULL` if you don't want to obtain this reference.

Return Value

A result code. See "Keychain Manager Result Codes" (page 1154). The result code `errKCNoDefaultKeychain` indicates that no default keychain was found. The result code `errKCItemNotFound` indicates that no matching password item was found. The result code `errKCBufferTooSmall` indicates that your application must allocate a new buffer of sufficient size before calling the function `KCFindInternetPasswordWithPath` again.

Discussion

The `KCFindInternetPasswordWithPath` function finds the first Internet password item which matches the attributes you provide, including path information. The buffer specified in the `passwordData` parameter must be large enough to hold the password data, otherwise the function `KCFindInternetPasswordWithPath` returns the result code `errKCBufferTooSmall`. In this case, your application must allocate a new buffer of sufficient size before calling the `KCFindInternetPasswordWithPath` function again. The `KCFindInternetPasswordWithPath` function optionally returns a reference to the found item.

The KCFindInternetPasswordWithPath function automatically calls the function KCUnlock (page 1127) to display the Unlock Keychain dialog box if the keychain containing the password is currently locked.

You can also call the function kcfindinternetpasswordwithpath to find the first Internet password item matching specified attributes. The function kcfindinternetpasswordwithpath requires that you pass a pointer to a C string instead of a pointer to a Pascal string for the serverAddress, serverName, volumeName, accountName, and passwordData parameters.

Version Notes
Available beginning with KeychainLib 2.0. In KeychainLib 1.0, the kcfindinternetpassword function provides the same functionality as the function KCFindInternetPassword, except that it accepts C strings rather than Pascal strings as arguments. In KeychainLib 2.0, you should use KCFindInternetPassword, since kcfindinternetpassword is provided for convenience only and may be removed from the header file at some point in the future.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the SecKeychainFindInternetPassword function in Keychain Services instead.

Declared In
KeychainCore.h

kcfindinternetpasswordwithpath

Not recommended

```
OSStatus kcfindinternetpasswordwithpath (
   const char *serverName,
   const char *securityDomain,
   const char *accountName,
   const char *path,
   UInt16 port,
   OSType protocol,
   OSType authType,
   UInt32 maxLength,
   void *passwordData,
   UInt32 *actualLength,
   KCItemRef *item
);
```

Discussion
This function is available for convenience only and may be removed. Use the function KCFindInternetPasswordWithPath (page 1105) instead.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the SecKeychainFindInternetPassword function in Keychain Services instead.

Declared In
KeychainCore.h

KCFindNextItem

Finds the next keychain item matching the previously specified search criteria.

Not recommended

```
OSStatus KCFindNextItem (
   KCSearchRef search,
   KCItemRef *item
);
```

Parameters

search

A reference to the previously-specified search criteria. Pass the reference passed back in the searchRef parameter of the function KCFindFirstItem (page 1099).

item

On return, a pointer to the next matching keychain item, if any.

Return Value

A result code. See "Keychain Manager Result Codes" (page 1154). The result code errKCNoDefaultKeychain indicates that no default keychain could be found. The result code errKCItemNotFound indicates that no matching keychain item was found. The result code errKCInvalidSearchRef indicates that the specified search reference was invalid.

Discussion

The KCFindNextItem function finds the next keychain item matching the search criteria previously specified by a call to the function KCFindFirstItem (page 1099). The KCFindNextItem function returns a reference to the matching item, if any. The KCFindNextItem function automatically calls the function KCUnlock (page 1127) to display the Unlock Keychain dialog box if the keychain containing the item you are searching for is currently locked.

Special Considerations

When you are completely finished with a search, you should use the functions KCReleaseItem (page 1121) and KCReleaseSearch (page 1122) to release the keychain item and search criteria reference.

Version Notes

Available beginning with KeychainLib 1.0.

Availability

Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the SecKeychainSearchCopyNext function in Keychain Services instead.

Declared In

KeychainCore.h

KCFindX509Certificates

Finds the certificates in a keychain that match specified search criteria.

Unsupported

```
OSStatus KCFindX509Certificates (
    KCRef keychain,
    CFStringRef name,
    CFStringRef emailAddress,
    KCCertSearchOptions options,
    CFMutableArrayRef *certificateItems
);
```

Parameters

keychain
A reference to the keychain you want to search. If the keychain is locked, the Unlock Keychain dialog box is automatically displayed.

name
A pointer to a C string containing the certificate owner's common name.

emailAddress
A pointer to a C string containing the certificate owner's email address.

options
The search criteria you wish to use. See "Certificate Search Options" (page 1137) for a description of this mask.

certificateItems
On return, a pointer to a list of the matching certificates. Pass `NULL` if you don't want to obtain these references.

Return Value

A result code. See "Keychain Manager Result Codes" (page 1154). The result code `errKCNoDefaultKeychain` indicates that a default keychain was not found. The result code `errKCBufferTooSmall` indicates that the certificate data was too large for the supplied buffer. In this case, you should allocate a new buffer of sufficient size before calling `KCFindX509Certificates` again. The result code `errKCItemNotFound` indicates that no matching certificate was found.

Version Notes

Available beginning with KeychainLib 2.0.

Carbon Porting Notes

This function is obsolete. There is currently no replacement.

Declared In

`KeychainHI.h`

KCGetAttribute

Determines keychain item data using a keychain item attribute structure.

Not recommended

```
OSStatus KCGetAttribute (
   KCItemRef item,
   KCAttribute *attr,
   UInt32 *actualLength
);
```

Parameters

item

A reference to the keychain item whose attribute data you wish to determine.

attr

A pointer to a structure of type `KCAttribute` (page 1132). Before calling the `KCGetAttribute` function, fill in the `tag`, `length`, and `data` fields (the `data` field should contain a pointer to a buffer of sufficient length for the type of data to be returned). On return, the `KCGetAttribute` function passes back the requested data in the `data` field.

actualLength

On return, a pointer to the actual length of the attribute data. This may be more than the length you allocated in the length field of the attribute structure.

Return Value

A result code. See "Keychain Manager Result Codes" (page 1154). The result code `errKCInvalidItemRef` indicates that the specified keychain item reference was invalid. The result code `errKCNoSuchAttr` indicates that you tried to set an attribute which is undefined for this item class. The result code `errKCBufferTooSmall` indicates that your application must allocate a new buffer of sufficient size before calling `KCGetAttribute` again.

Discussion

You can call the function `KCGetAttribute` or the function `KCGetData` (page 1111) to obtain keychain item data. The difference between the functions is that the function `KCGetData` (page 1111) requires that you pass the length of the data and a pointer to that data as separate parameters rather than fields in a keychain item attribute structure.

If the keychain that contains the item is locked, before calling the `KCGetAttribute` function you should call the function `KCUnlock` (page 1127) to prompt the user to unlock the keychain.

You can determine any of the standard item attributes identified by the following tag constants: `kClassKCItemAttr`, `kCreationDateKCItemAttr`, `kModDateKCItemAttr`, `kDescriptionKCItemAttr`, `kCommentKCItemAttr`, `kLabelKCItemAttr`, `kCreatorKCItemAttr`, `kScriptCodeKCItemAttr`, and `kCustomIconKCItemAttr`. There is additional data you can determine, depending upon the type of keychain item whose data you wish to obtain. See "Keychain Item Attribute Tag Constants" (page 1144) for more information.

Version Notes

Available beginning with KeychainLib 1.0.

Availability

Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainItemCopyAttributesAndData` function in Keychain Services instead.

Declared In

`KeychainCore.h`

KCGetData

Determines keychain item data.

Not recommended

```
OSStatus KCGetData (
   KCItemRef item,
   UInt32 maxLength,
   void *data,
   UInt32 *actualLength
);
```

Parameters

item

A reference to the keychain item whose data you wish to determine.

maxLength

The length of the data buffer pointed to by the `data` parameter.

data

A pointer to the buffer that holds the returned data. Before calling the `KCGetData` function, allocate enough memory for the buffer to hold the data you want to store. On return, a pointer to the attribute data you requested.

actualLength

On return, a pointer to the actual length of the data being retrieved. If the buffer pointed to by the `data` parameter is smaller than the actual length of the data, the `KCGetData` function returns the result code `errKCBufferTooSmall`. In this case, your application must allocate a new buffer of sufficient size before calling `KCGetData` again.

Return Value

A result code. See "Keychain Manager Result Codes" (page 1154). The result code `errKCInvalidItemRef` indicates that the specified keychain item reference was invalid. The result code `errKCBufferTooSmall` indicates that your application must allocate a new buffer of sufficient size before calling `KCGetData` again. The result code `errKCDataNotModifiable` indicates that the data is not available for this item.

Discussion

You can call the function `KCGetData` or the function `KCGetAttribute` (page 1109) to obtain keychain item data. The difference between the functions is that the function `KCGetAttribute` (page 1109) requires that you pass the length of the data and a pointer to that data as fields in a keychain item attribute structure rather than as separate parameters.

If the keychain that contains the item is locked, before calling the function `KCGetData` you should call the function `KCUnlock` (page 1127) to prompt the user to unlock the keychain. You cannot call the `KCGetData` function for a private key.

You can determine any of the standard item attributes identified by the following tag constants: `kClassKCItemAttr`, `kCreationDateKCItemAttr`, `kModDateKCItemAttr`, `kDescriptionKCItemAttr`, `kCommentKCItemAttr`, `kLabelKCItemAttr`, `kCreatorKCItemAttr`, `kScriptCodeKCItemAttr`, and `kCustomIconKCItemAttr`. There is additional data you can determine, depending upon the type of keychain item whose data you wish to obtain. See "Keychain Item Attribute Tag Constants" (page 1144) for more information.

Version Notes

Available beginning with KeychainLib 1.0.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainItemCopyContent` function in Keychain Services instead.

Declared In
`KeychainCore.h`

KCGetDefaultKeychain

Obtains the default keychain.

Not recommended

```
OSStatus KCGetDefaultKeychain (
   KCRef *keychain
);
```

Parameters

keychain

On return, a pointer to default keychain reference.

Return Value
A result code. See "Keychain Manager Result Codes" (page 1154). The result code `errKCNoDefaultKeychain` indicates that there is no default keychain.

Discussion
You can determine the name of the default keychain by passing the returned keychain reference to the function `KCGetKeychainName` (page 1115).

Version Notes
Available beginning with KeychainLib 2.0.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainCopyDefault` function in Keychain Services instead.

Declared In
`KeychainCore.h`

KCGetIndKeychain

Obtains the reference to an indexed keychain.

Not recommended

```
OSStatus KCGetIndKeychain (
   UInt16 index,
   KCRef *keychain
);
```

Parameters

index

An index of the list of available keychains. Pass a value between 1 and the number returned by the function `KCCountKeychains` (page 1093).

keychain

On return, pointer to the keychain reference corresponding to the index in the `index` parameter.

Return Value

A result code. See "Keychain Manager Result Codes" (page 1154). The result code `errKCNoSuchKeychain` indicates that the index value is out of range.

Discussion

To guarantee correct operation, you should call the function `KCCountKeychains` (page 1093) once before calling `KCGetIndKeychain`.

Special Considerations

The memory that the keychain reference occupies must be released by calling the function `KCReleaseKeychain` (page 1122) when you are finished with it.

Version Notes

Available beginning with KeychainLib 1.0.

Availability

Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainCopySearchList` function in Keychain Services followed by a call to `CFArrayGetValueAtIndex` instead.

Declared In

`KeychainCore.h`

KCGetKeychain

Determines the location of a password or other keychain item.

Not recommended

```
OSStatus KCGetKeychain (
   KCItemRef item,
   KCRef *keychain
);
```

Parameters

item

A reference to the keychain item whose keychain location you wish to determine. If you pass a reference to a keychain item whose keychain is locked, the `KCGetKeychain` function returns the result code `errKCInvalidItemRef`.

keychain
On return, a pointer to the keychain containing the specified item.

Return Value
A result code. See "Keychain Manager Result Codes" (page 1154). The result code `errKCInvalidItemRef` indicates that the keychain item reference was invalid.

Discussion
The `KCGetKeychain` function determines the location of a keychain item in an unlocked keychain. It does not search locked keychains. Calling the `KCGetKeychain` function displays the Unlock Keychain dialog box if the keychain containing the item is currently locked.

Special Considerations

The keychain reference returned by `KCGetKeychain` should be released by calling the function `KCReleaseItem` (page 1121).

Version Notes
Available beginning with KeychainLib 1.0.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainItemCopyKeychain` function in Keychain Services instead.

Declared In
`KeychainCore.h`

KCGetKeychainManagerVersion

Determines the version of the Keychain Manager installed on the user's system.

Not Recommended

```
OSStatus KCGetKeychainManagerVersion (
   UInt32 *returnVers
);
```

Parameters
returnVers
On return, a pointer to the version number of the Keychain Manager installed on the current system.

Return Value
A result code. See "Keychain Manager Result Codes" (page 1154).

Discussion
Your application can call the `KCGetKeychainManagerVersion` function to find out which version of the Keychain Manager is installed on the user's system.

Version Notes
Available beginning with KeychainLib 1.0.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainGetVersion` function in Keychain Services instead.

Declared In

`KeychainCore.h`

KCGetKeychainName

Determines the name of a keychain.

Not recommended

```
OSStatus KCGetKeychainName (
   KCRef keychain,
   StringPtr keychainName
);
```

Parameters

keychain

A reference to the keychain whose name you wish to obtain.

keychainName

A pointer to a Pascal string. On return, this string contains the name of the keychain.

Return Value

A result code. See "Keychain Manager Result Codes" (page 1154). The result code `errKCInvalidKeychain` indicates that the keychain is invalid.

Discussion

You can also call the function `kcgetkeychainname` to obtain the name of a keychain. `kcgetkeychainname` requires that you pass a pointer to a C string instead of a pointer to a Pascal string in the `keychainName` parameter.

Version Notes

Available beginning with KeychainLib 2.0.

Availability

Available in CarbonLib 1.1 and later when KeychainLib 2.0 or later is present.

Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainGetPath` function in Keychain Services instead.

Declared In

`KeychainCore.h`

kcgetkeychainname

Not recommended

```
OSStatus kcgetkeychainname (
   KCRef keychain,
   char *keychainName
);
```

Discussion
This function is available for convenience only and may be removed. Use the function `KCGetKeychainName` (page 1115) instead.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainGetPath` function in Keychain Services instead.

Declared In
`KeychainCore.h`

KCGetStatus

Determines the permissions that are set in a keychain.

Not recommended

```
OSStatus KCGetStatus (
   KCRef keychain,
   UInt32 *keychainStatus
);
```

Parameters

keychain

A pointer to the keychain reference whose permissions you wish to determine. Pass `NULL` to obtain the status of the default keychain.

keychainStatus

On return, a pointer to a bitmask that you can test to determine the permissions that are set in a keychain. See "Keychain Status Constants" (page 1153) for a description of this mask.

Return Value
A result code. See "Keychain Manager Result Codes" (page 1154). The result code `errKCNoSuchKeychain` indicates that the specified keychain could not be found. The result code `errKCInvalidKeychain` indicates that the specified keychain is invalid.

Version Notes
Available beginning with KeychainLib 1.0.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainGetStatus` function in Keychain Services instead.

Declared In
KeychainCore.h

KCIsInteractionAllowed

Indicates whether Keychain Manager functions that display a user interaction will do so.

Not recommended

```
Boolean KCIsInteractionAllowed (
   void
);
```

Parameters

Return Value
A Boolean value indicating whether user interaction is permitted. If true, user interaction is allowed, and Keychain Manager functions that display a user interface can do so as appropriate.

Version Notes
Available beginning with KeychainLib 2.0.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the SecKeychainGetUserInteractionAllowed function in Keychain Services instead.

Declared In
KeychainCore.h

KCLock

Locks a keychain.

Not recommended

```
OSStatus KCLock (
   KCRef keychain
);
```

Parameters

keychain

A reference to the keychain to lock. Pass NULL to lock all unlocked keychains.

Return Value
A result code. See "Keychain Manager Result Codes" (page 1154). The result code errKCNoSuchKeychain indicates that specified keychain could not be found. The result code errKCInvalidKeychain indicates that the specified keychain is invalid.

Discussion
Your application should not call the KCLock function unless you are responding to a user's request to lock a keychain. In general, you should leave the keychain unlocked so that the user does not have to unlock it again in another application.

Version Notes
The function `KCLock` replaces the function `KCLockKeychain`, which was available in KeychainLib 1.0.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainLock` function in Keychain Services instead.

Declared In
`KeychainCore.h`

KCMakeAliasFromKCRef

Creates an alias to a keychain reference.

Not Recommended

```
OSStatus KCMakeAliasFromKCRef (
   KCRef keychain,
   AliasHandle *keychainAlias
);
```

Parameters

keychain

A reference to the keychain for which you want to create an alias.

keychainAlias

On return, a pointer to an alias handle to the file referred to by the keychain reference.

Return Value
A result code. See "Keychain Manager Result Codes" (page 1154).

Discussion
You may wish to call the `KCMakeAliasFromKCRef` function to determine the location of a keychain.

Special Considerations

When you are finished with a keychain, you should call the function `KCReleaseKeychain` (page 1122) to deallocate its memory. You should not use the keychain after its memory has been deallocated.

Version Notes
Available beginning with KeychainLib 2.0.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainGetPath` function in Keychain Services followed by calls to the function `FSPathMakeRef` and `FSNewAlias` instead.

Declared In
`KeychainCore.h`

KCMakeKCRefFromAlias

Creates a keychain reference from a keychain alias.

Not Recommended

```
OSStatus KCMakeKCRefFromAlias (
   AliasHandle keychainAlias,
   KCRef *keychain
);
```

Parameters

keychainAlias

A handle to an alias record of the keychain file. Since the keychain is a file, an alias can be made to the keychain file.

keychain

On return, a pointer to a reference to the keychain specified by the alias in the `keychainAlias` parameter.

Return Value

A result code. See "Keychain Manager Result Codes" (page 1154).

Special Considerations

When you are finished with a keychain, you should call the function `KCReleaseKeychain` (page 1122) to deallocate its memory. You should not use the keychain after its memory has been deallocated.

Version Notes

Available beginning with KeychainLib 2.0.

Availability

Available in CarbonLib 1.1 and later when KeychainLib 2.0 or later is present.

Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainOpen` function in Keychain Services instead. If the keychain doesn't exist, use the `SecKeychainCreate` function in Keychain Services.

Declared In

`KeychainCore.h`

KCMakeKCRefFromFSSpec

Creates a keychain reference from a file specification record. (Deprecated in Mac OS X v10.5.)

Not Recommended

```
OSStatus KCMakeKCRefFromFSSpec (
   FSSpec *keychainFSSpec,
   KCRef *keychain
);
```

Parameters

keychainFSSpec

A pointer to a keychain file specification record.

keychain

On return, a pointer to a reference to the keychain specified by the file in the `keychainFSSpec` parameter.

Return Value
A result code. See "Keychain Manager Result Codes" (page 1154).

Special Considerations

When you are finished with a keychain, you should call the function `KCReleaseKeychain` (page 1122) to deallocate its memory. You should not use the keychain after its memory has been deallocated.

Version Notes
Available beginning with KeychainLib 2.0.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 2.0 or later is present.
Available in Mac OS X 10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Carbon Porting Notes

Use the `SecKeychainOpen` function in Keychain Services instead. If the keychain doesn't exist, use the `SecKeychainCreate` function in Keychain Services.

Declared In
`KeychainCore.h`

KCNewItem

Creates a reference to a keychain item.

Not recommended

```
OSStatus KCNewItem (
   KCItemClass itemClass,
   OSType itemCreator,
   UInt32 length,
   const void *data,
   KCItemRef *item
);
```

Parameters

itemClass

The type of keychain item that you wish to create. See "Keychain Item Type Constants" (page 1150) for a description of possible values and a description of the `KCItemClass` data type.

itemCreator

The creator code of the application that owns this item.

length

The length of the data to be stored in this item.

data

A pointer to a buffer containing the data to be stored in this item. Before calling `KCNewItem`, allocate enough memory for the buffer to hold the data you want to store.

item

On return, a pointer to a reference to the newly-created item.

Return Value
A result code. See "Keychain Manager Result Codes" (page 1154). The Memory Manager result code `memFullErr` indicates that you did not allocate enough memory in the current heap to create the item.

Discussion
After calling the `KCNewItem` function, you should call the function `KCAddItem` (page 1090) if you wish to permanently store a password or other keychain item. Note that a copy of the data buffer pointed to by the `data` parameter is stored in the newly-created item.

Special Considerations

When you are done with a keychain item, you should call the function `KCReleaseItem` (page 1121) to release its memory. You should not use the item after its memory has been deallocated.

Version Notes
Available beginning with KeychainLib 1.0.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainItemCreateFromContent` function in Keychain Services instead.

Declared In
`KeychainCore.h`

KCReleaseItem

Disposes of the memory occupied by a keychain item reference.

Not recommended

```
OSStatus KCReleaseItem (
   KCItemRef *item
);
```

Parameters

item

A pointer to a keychain item reference. Pass the keychain item reference whose memory you want to release. On return, the reference is set to `NULL` and should not be used again.

Return Value
A result code. See "Keychain Manager Result Codes" (page 1154).

Discussion
You should call the `KCReleaseItem` function to release the memory occupied by a keychain item reference when you are finished with it.

Version Notes
Available beginning with KeychainLib 1.0

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `CFRelease` function instead.

Declared In
`KeychainCore.h`

KCReleaseKeychain

Disposes of the memory associated with a keychain reference.

Not recommended

```
OSStatus KCReleaseKeychain (
   KCRef *keychain
);
```

Parameters

keychain

A pointer to a keychain reference. Pass the keychain reference whose memory you want to release. On return, the reference is set to `NULL` and should not be used again.

Return Value
A result code. See "Keychain Manager Result Codes" (page 1154).

Discussion
You should call the `KCReleaseKeychain` function to release the memory occupied by a keychain reference when you are finished with it. You should not use the reference after it has been released.

Version Notes
Available beginning with KeychainLib 2.0.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `CFRelease` function instead.

Declared In
`KeychainCore.h`

KCReleaseSearch

Disposes of the memory occupied by a search criteria reference.

Not recommended

```
OSStatus KCReleaseSearch (
   KCSearchRef *search
);
```

Parameters

search

A pointer to a search criteria reference. Pass the search criteria reference whose memory you want to release. On return, the reference is set to `NULL` and should not be used again.

Return Value

A result code. See "Keychain Manager Result Codes" (page 1154). The result code `errKCInvalidSearchRef` indicates that the specified search reference was invalid.

Discussion

You should call the `KCReleaseSearch` function to release the memory occupied by a search criteria reference when you are completely finished with a search performed by calling the functions `KCFindFirstItem` (page 1099) or `KCFindNextItem` (page 1108).

Version Notes

Available beginning with KeychainLib 1.0

Availability

Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `CFRelease` function instead.

Declared In

`KeychainCore.h`

KCRemoveCallback

Unregisters your keychain event callback function.

Not recommended

```
OSStatus KCRemoveCallback (
   KCCallbackUPP callbackProc
);
```

Parameters

callbackProc

A Universal Procedure Pointer (UPP) to your keychain event callback function that was previously registered with the function `KCAddCallback` (page 1083).

Return Value

A result code. See "Keychain Manager Result Codes" (page 1154). The result code `errKCInvalidCallback` indicates that the callback function was not previously registered.

Discussion

After you pass a UPP to your keychain event callback function to the `KCRemoveCallback` function, it will no longer be called by the Keychain Manager.

Special Considerations

After calling `KCRemoveCallback`, you should call the function `DisposeKCCallbackUPP` (page 1079) to dispose of the UPP to your callback function.

Version Notes

Available beginning with KeychainLib 1.0.

Availability

Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainRemoveCalllback` function in Keychain Services instead.

Declared In

`KeychainCore.h`

KCSetAttribute

Sets or edits keychain item data using a keychain item attribute structure.

Not recommended

```
OSStatus KCSetAttribute (
   KCItemRef item,
   KCAttribute *attr
);
```

Parameters

item

A reference to the keychain item whose data you wish to set or edit.

attr

A pointer to a structure of type `KCAttribute` (page 1132) containing keychain item data you want to set. Before calling the function `KCSetAttribute`, fill in the `tag`, `length`, and `data` fields of this structure with the tag identifying the attribute you wish to modify or set, the length of the attribute data you wish to set, and a pointer to that data, respectively.

Return Value

A result code. See "Keychain Manager Result Codes" (page 1154). The result code `errKCInvalidItemRef` indicates that the keychain item reference was invalid. The result code `errKCNoSuchAttr` indicates that the item attribute you wish to set is undefined for the specified item. The result code `errKCDataTooLarge` indicates that more data was supplied than is allowed for this attribute.

Discussion

You can call the `KCSetAttribute` function or the function `KCSetData` (page 1125) to set or modify keychain item data. The difference between the functions is that the `KCSetData` (page 1125) function requires that you pass the length of the data and a pointer to that data as separate parameters rather than fields in a keychain item attribute structure.

If the keychain that contains the item is locked, before calling the `KCSetAttribute` function you should call the function `KCUnlock` (page 1127) to prompt the user to unlock the keychain. The keychain must permit read/write access in order to modify keychain item data.

You can only set or modify standard item attributes identified by the tag constants `kDescriptionKCItemAttr`, `kCommentKCItemAttr`, `kLabelKCItemAttr`, `kCreatorKCItemAttr`, `kTypeKCItemAttr`, and `kCustomIconKCItemAttr`. In addition, each class of keychain item has attributes specific to that class which may be set or modified. See "Keychain Item Attribute Tag Constants" (page 1144) for more information.

Version Notes
Available beginning with KeychainLib 1.0.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainItemModifyAttributesAndData` function in Keychain Services instead.

Declared In
`KeychainCore.h`

KCSetData

Sets or edits keychain item data.

Not recommended

```
OSStatus KCSetData (
   KCItemRef item,
   UInt32 length,
   const void *data
);
```

Parameters

item
A reference to the keychain item whose data you wish to set.

length
The length of the data buffer pointed to by the `data` parameter.

data
A pointer to a buffer containing the data to be stored in this item. Before calling the `KCSetData` function, allocate enough memory for the buffer to hold the data you want to store.

Return Value
A result code. See "Keychain Manager Result Codes" (page 1154). The result code `errKCInvalidItemRef` indicates that the specified keychain item reference was invalid. The result code `errKCDataTooLarge` indicates that the data was too large for the supplied buffer. The result code `errKCDataNotModifiable` indicates that the data cannot be set for this item.

Discussion
You can call the function `KCSetData` or the function `KCSetAttribute` (page 1124) to set or modify keychain item data. The difference between the functions is that the function `KCSetAttribute` (page 1124) requires that you pass the length of the data buffer as a field in a keychain item attribute structure rather than as a separate parameter.

If the keychain that contains the item is locked, before calling the `KCSetData` function you should call the function `KCUnlock` (page 1127) to prompt the user to unlock the keychain. The keychain must permit read/write access in order to modify keychain item data.

You can set or edit any of the standard item attributes identified by the following tag constants: `kDescriptionKCItemAttr`, `kCommentKCItemAttr`, `kLabelKCItemAttr`, `kCreatorKCItemAttr`, `kTypeKCItemAttr`, and `kCustomIconKCItemAttr`. There is additional data you can set, depending upon the type of keychain item whose data you are manipulating. See "Keychain Item Attribute Tag Constants" (page 1144) for more information.

Version Notes
Available beginning with KeychainLib 1.0.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainItemModifyContent` function in Keychain Services instead.

Declared In
`KeychainCore.h`

KCSetDefaultKeychain

Sets the default keychain.

Not recommended

```
OSStatus KCSetDefaultKeychain (
   KCRef keychain
);
```

Parameters

keychain

A reference to the keychain you wish to make the default.

Return Value
A result code. See "Keychain Manager Result Codes" (page 1154). The result code `errKCNoSuchKeychain` indicates that the specified keychain could not be found. The result code `errKCInvalidKeychain` indicates that the specified keychain is invalid.

Discussion
In most cases, your application should not need to set the default keychain, because this is a choice normally made by the user. You should call the `KCSetDefaultKeychain` function to change where a password or other keychain items are added.

The `KCSetDefaultKeychain` function sets the default keychain regardless of whether the keychain is currently locked.

Version Notes
Available beginning with KeychainLib 2.0.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 2.0 or later is present.

Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainSetDefault` function in Keychain Services instead.

Declared In

`KeychainCore.h`

KCSetInteractionAllowed

Enables or disables Keychain Manager functions that display a user interface.

Not recommended

```
OSStatus KCSetInteractionAllowed (
   Boolean state
);
```

Parameters

state

A flag that indicates whether the Keychain Manager will display a user interface. If you pass `true`, user interaction is allowed. This is the default value. If `false`, Keychain Manager functions that normally display a user interface will instead return an error.

Return Value

A result code. See "Keychain Manager Result Codes" (page 1154).

Discussion

The `KCSetInteractionAllowed` function enables you to control whether the functions `KCLock` (page 1117), `KCUnlock` (page 1127), and `KCChangeSettings` (page 1091) display a user interface. Note that failure to re-enable user interaction will affect other clients of the Keychain Manager. By default, user interaction is permitted.

Version Notes

Available beginning with KeychainLib 2.0.

Availability

Available in CarbonLib 1.1 and later when KeychainLib 2.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainSetUserInteractionAllowed` function in Keychain Services instead.

Declared In

`KeychainCore.h`

KCUnlock

Displays a dialog box that prompts the user for a password before unlocking a keychain.

Not recommended

```
OSStatus KCUnlock (
   KCRef keychain,
   StringPtr password
);
```

Parameters

keychain

A reference to the keychain to unlock. Pass `NULL` to specify the default keychain. If you pass `NULL` and the default keychain is currently locked, the keychain will appear as the default choice. If you pass a locked keychain, the function `KCUnlock` displays the Unlock Keychain dialog box and the keychain appears as the chosen menu item in the keychain popup menu. If the default keychain is currently unlocked, the Unlock Keychain dialog box is not displayed and the `KCUnlock` function returns `noErr`.

password

A pointer to a Pascal string representing the password string for this keychain. Pass `NULL` if the user password is unknown. In this case, The `KCUnlock` function displays the Unlock Keychain dialog box, and the authentication user interface associated with the keychain about to be unlocked. If you specify an invalid password, you will not be able to unlock the keychain with a specified password until the machine is rebooted. In this case, the `KCUnlock` function returns `errKCInteractionRequired`.

Return Value

A result code. See "Keychain Manager Result Codes" (page 1154). The result code `noErr` does not guarantee that the specified keychain is unlocked, because the user can select any available keychain and unlock it. The result code `userCanceledErr` indicates that the user pressed the Cancel button in the Unlock Keychain dialog box. The result code `errKCAuthFailed` indicates that authentication failed because of too many unsuccessful retries. The result code `errKCInteractionRequired` indicates that user interaction is required to unlock the keychain. In this case, you will not be able to unlock the keychain with that password until the machine is rebooted.

Discussion

In most cases, your application does not need to call the `KCUnlock` function directly, since most Keychain Manager functions that require an unlocked keychain call `KCUnlock` automatically. If your application needs to verify that a keychain is unlocked, call the function `KCGetStatus` (page 1116).

You can also call the function `kcunlock` to display a user interface prompting the user to unlock a keychain. The `kcunlock` function requires that you pass a pointer to a C string instead of a pointer to a Pascal string in the `password` parameter.

Special Considerations

It is recommended that the `KCUnlock` function not be explicitly called by applications. Most functions that require an unlocked keychain call the `KCUnlock` function for you.

The memory that the keychain reference occupies must be released by calling the function `KCReleaseKeychain` (page 1122) when you are finished with it.

Version Notes

The `KCUnlock` function replaces the function `KCUnlockKeychain`, which was available in KeychainLib 1.0.

Availability

Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.

Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainUnlock` function in Keychain Services instead.

Declared In
KeychainHI.h

kcunlock

Not recommended

```
OSStatus kcunlock (
   KCRef keychain,
   const char *password
);
```

Discussion
This function is available for convenience only and may be removed. Use the function KCUnlock (page 1127) instead.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the SecKeychainUnlock function in Keychain Services instead.

Declared In
KeychainHI.h

KCUpdateItem

Updates a password or other keychain item.

Not recommended

```
OSStatus KCUpdateItem (
   KCItemRef item
);
```

Parameters

item

A reference to the keychain item whose data you wish to update. If you pass an item that has not been previously added to the keychain, the KCUpdateItem function does nothing and returns noErr.

Return Value
A result code. See "Keychain Manager Result Codes" (page 1154). The result code errKCNoDefaultKeychain indicates that no default keychain could be found. The result code errKCInvalidItemRef indicates that the specified keychain item reference was invalid.

Discussion
You can use the KCUpdateItem function to update a password or other keychain item in a keychain's permanent data store after changing its data. The function KCUpdateItem automatically calls the function KCUnlock (page 1127) to display the Unlock Keychain dialog box if the keychain containing the item is currently locked.

Version Notes
Available beginning with KeychainLib 1.0.

Availability
Available in CarbonLib 1.1 and later when KeychainLib 1.0 or later is present.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

Use the `SecKeychainItemModifyContent` function in Keychain Services instead.

Declared In
`KeychainCore.h`

NewKCCallbackUPP

Creates a UPP to your keychain event callback.

Not recommended

```
KCCallbackUPP NewKCCallbackUPP (
   KCCallbackProcPtr userRoutine
);
```

Parameters

`userRoutine`

A pointer to your keychain event callback function. For information on how to create a keychain event callback, see `KCCallbackProcPtr` (page 1131).

Return Value
A UPP to your callback function. You can register your callback function by passing this UPP in the `callbackProc` parameter of the function `KCAddCallback` (page 1083). See the description of the `KCCallbackUPP` data type.

Discussion
The `NewKCCallbackUPP` function creates a pointer to your keychain event callback function. You pass a pointer to your callback function in the `callbackProc` parameter of the function `KCAddCallback` (page 1083) if you want your application to receive data transfer events.

Special Considerations

When you are finished with a UPP to your keychain event callback function, you should dispose of it by calling the function `DisposeKCCallbackUPP` (page 1079).

Availability
Available in CarbonLib 1.1 and later.
Available in Mac OS X 10.0 and later.

Carbon Porting Notes

There is no replacement function available.

Declared In
`KeychainCore.h`

Callbacks

KCCallbackProcPtr

Defines a pointer to your keychain event callback that handles user keychain access events.

```
typedef OSStatus (*KCCallbackProcPtr)
(
        KCEvent keychainEvent,
        KCCallbackInfo * info,
        void * userContext
);
```

If you name your function `MyKCCallbackProc`, you would declare it like this:

```
OSStatus MyKCCallbackProc (
        KCEvent keychainEvent,
        KCCallbackInfo * info,
        void * userContext
);
```

Parameters

keychainEvent

The keychain event that your application wishes to be notified of. See "Keychain Events Constants" (page 1140) for a description of possible values. The type of event that can trigger your callback depends on the bitmask you passed in the `eventMask` parameter of the function `KCAddCallback` (page 1083). For more information, see the discussion.

info

A pointer to a structure of type `KCCallbackInfo` (page 1133). On return, the structure contains information about the keychain event that occurred. The Keychain Manager passes this information to your callback function via the `info` parameter of the function `InvokeKCCallbackUPP` (page 1079).

userContext

A pointer to application-defined storage that your application previously passed to the function `KCAddCallback` (page 1083). You can use this value to perform operations such as tracking which instance of a function is operating.

Return Value

A result code. See "Keychain Manager Result Codes" (page 1154). Your keychain event callback function should process the keychain event and return `noErr`.

Discussion

Your keychain event callback function handles those keychain events that you indicate. In order to be notified of these events, you must pass a UPP to your notification callback function in the `callbackProc` parameter of `KCAddCallback` (page 1083). You indicate the type of data transfer events you want to receive via a bitmask in the `eventMask` parameter. When you no longer wish to receive notification of keychain events, you should call the function `KCRemoveCallback` (page 1123) to dispose of the UPP to your keychain event callback function.

Carbon Porting Notes

Use the `SecKeychainCallback` function in Keychain Services instead.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`KeychainCore.h`

Data Types

AFPServerSignature

Represents a 16-byte Apple File Protocol server signature block.

```
typedef UInt8 AFPServerSignature[16];
```

Discussion
The `AFPServerSignature` type represents a 16-byte Apple File Protocol server signature block. You can pass a value of this type in the serverSignature parameter of the functions `KCAddAppleSharePassword` (page 1080) and `KCFindAppleSharePassword` (page 1096) to represent an Apple File Protocol server signature. You can use a value of this type with the keychain item attribute constant `kSignatureKCItemAttr` to specify an Apple File Protocol server signature.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`KeychainCore.h`

KCAttribute

Contains information about a keychain item attribute.

```
typedef SecKeychainAttribute KCAttribute;
```

Discussion
The `KCAttribute` type represents a structure containing information about the attribute of a keychain item. It contains a tag that identifies a particular keychain item attribute value, the length of the attribute value, and a pointer to the attribute value. You can modify attribute data for a keychain item attribute by passing a pointer to this structure in the `attr` parameter of the function `KCSetAttribute` (page 1124). The function `KCGetAttribute` (page 1109) passes back a pointer to this structure in the `attr` parameter.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`KeychainCore.h`

KCAttributeList

Lists attributes in a keychain item.

```
typedef SecKeychainAttributeList KCAttributeList;
```

Discussion
The `KCAttributeList` type represents a list of structures containing information about the attributes in a keychain item. You pass a pointer to this list of 0 or more structures in the `attrList` parameter of the function `KCFindFirstItem` (page 1099) to indicate the attributes to be matched.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`KeychainCore.h`

KCAttrType

Identifies a keychain item attribute value.

```
typedef SecKeychainAttrType KCAttrType;
```

Discussion
The `KCAttrType` type represents a tag that identifies a keychain item attribute value. You can use this value in the `tag` field of the structure `KCAttribute` (page 1132) to identify the keychain item attribute value you wish to set or obtain. See `Keychain Item Attribute Tag Constants` (page 1144) for a description of the Apple-defined tag constants and the data types of the values they identify. Your application can create application-defined tags of type `KCAttrType`.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`KeychainCore.h`

KCCallbackInfo

Contains information about a keychain event.

```
struct KCCallbackInfo {
    UInt32 version;
    KCItemRef item;
    long processID[2];
    long event[4];
    KCRef keychain;
};
typedef struct KCCallbackInfo KCCallbackInfo;
```

Fields

`version`
The version of this structure.

`item`
A reference to the keychain item in which the event occurred. If the event did not involve an item, this field is not valid.

`processID`
: A 64-bit quantity containing the process serial number of the process in which the event occurred. This is not available on Mac OS X.

`event`
: The keychain event that occurred. If the event is a system event as indicated by the constant `kSystemKCEvent`, the Keychain client can process events. If the event is not a system event, this field is not valid. This is not available on Mac OS X.

`keychain`
: A reference to the keychain in which the event occurred. If the event did not involve a keychain, this field is not valid.

Discussion
The `KCCallbackInfo` type represents a structure that contains information about the keychain event of which your application wants to be notified. The Keychain Manager passes a pointer to this structure in the `info` parameter of your callback function via the function `InvokeKCCallbackUPP` (page 1079), which invokes your callback function. For information on how to write a keychain event callback function, see `KCCallbackProcPtr` (page 1131).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`KeychainCore.h`

KCCallbackUPP

Defines a data type for the `KCCallbackProcPtr` callback pointer.

```
typedef KCCallbackProcPtr KCCallbackUPP;
```

Availability
Available in Mac OS X v10.0 and later.

Declared In
`KeychainCore.h`

KCItemRef

Represents a reference to a keychain item.

```
typedef SecKeychainItemRef KCItemRef;
```

Discussion
The `KCItemRef` type represents a reference to an opaque structure that identifies a keychain item. You should call the function `KCNewItem` (page 1120) to create a keychain item reference. The function `KCReleaseItem` (page 1121) disposes of a keychain item reference when no longer needed.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`KeychainCore.h`

KCPublicKeyHash

Represents a 20-byte public key hash.

```
typedef UInt8 KCPublicKeyHash[20];
```

Discussion
The `KCPublicKeyHash` type represents a hash of a public key. You can use the constant `kPublicKeyHashKCItemAttr`, described in `Keychain Item Attribute Tag Constants` (page 1144), to set or retrieve a certificate attribute value of this type.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`KeychainCore.h`

KCRef

Represents a reference to a keychain.

```
typedef SecKeychainRef KCRef;
```

Discussion
The `KCRef` type represents a reference to an opaque structure that identifies a keychain. You should call the function `KCMakeKCRefFromFSSpec` (page 1119) or `KCMakeKCRefFromAlias` (page 1119) to create a keychain reference. The function `KCReleaseKeychain` (page 1122) disposes of a keychain reference when no longer needed. You pass a reference of this type to Keychain Manager functions that operate on a keychain in some way.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`KeychainCore.h`

KCSearchRef

Represents a reference to the current search criteria.

```
typedef SecKeychainSearchRef KCSearchRef;
```

Discussion
The `KCSearchRef` type represents a reference to an opaque structure that identifies the current search criteria. The function `KCFindFirstItem` (page 1099) passes back a reference of this type in the `search` parameter for subsequent calls to the function `KCFindNextItem` (page 1108). You must release this reference when you are finished with a search by calling the function `KCReleaseSearch` (page 1122).

Availability
Available in Mac OS X v10.0 and later.

Declared In
`KeychainCore.h`

KCStatus

Identifies a mask that you can use in determining the permissions that are set in a keychain.

```
typedef SecKeychainStatus KCStatus;
```

Discussion
The `KCStatus` enumeration defines masks your application can use to determine the read and write permissions for a keychain. The function `KCGetStatus` (page 1116) passes back this mask in the `status` parameter.

Availability
Available in Mac OS X v10.0 and later.

Declared In
`KeychainCore.h`

Constants

Authentication Type Constants

Represent the type of authentication to use in storing and retrieving Internet passwords.

```
enum {
    kKCAuthTypeNTLM = 'ntlm',
    kKCAuthTypeMSN = 'msna',
    kKCAuthTypeDPA = 'dpaa',
    kKCAuthTypeRPA = 'rpaa',
    kKCAuthTypeHTTPDigest = 'httd',
    kKCAuthTypeDefault = 'dflt'
};
typedef FourCharCode KCAuthType;
```

Constants

`kKCAuthTypeNTLM`
Specifies Windows NT LAN Manager authentication.
Available in Mac OS X v10.0 and later.
Declared in `KeychainCore.h`.

`kKCAuthTypeMSN`
Specifies Microsoft Network authentication.
Available in Mac OS X v10.0 and later.
Declared in `KeychainCore.h`.

`kKCAuthTypeDPA`
Specifies Distributed Password authentication.
Available in Mac OS X v10.0 and later.
Declared in `KeychainCore.h`.

`kKCAuthTypeRPA`
Specifies Remote Password authentication.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kKCAuthTypeHTTPDigest`
Specifies HTTP Digest Access authentication.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kKCAuthTypeDefault`
Specifies default authentication.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

Discussion
The `KCAuthType` enumeration defines constants you can use to identify the type of authentication to use in storing and retrieving Internet passwords. You can pass a constant of this type in the `authType` parameter of the functions `KCAddInternetPassword` (page 1086), `KCAddInternetPasswordWithPath` (page 1088), `KCFindInternetPassword` (page 1102), and `KCFindInternetPasswordWithPath` (page 1105).

Certificate Search Options

Represent a mask that specifies the search criteria to use when finding certificates.

```
typedef UInt32 KCCertSearchOptions;
enum {
    kCertSearchShift = 0,
    kCertSearchSigningIgnored = 0,
    kCertSearchSigningAllowed = 1 << (kCertSearchShift + 0),
    kCertSearchSigningDisallowed = 1 << (kCertSearchShift + 1),
    kCertSearchSigningMask = ((kCertSearchSigningAllowed) |
        (kCertSearchSigningDisallowed)),
    kCertSearchVerifyIgnored = 0,
    kCertSearchVerifyAllowed = 1 << (kCertSearchShift + 2),
    kCertSearchVerifyDisallowed = 1 << (kCertSearchShift + 3),
    kCertSearchVerifyMask = ((kCertSearchVerifyAllowed) |
        (kCertSearchVerifyDisallowed)),
    kCertSearchEncryptIgnored = 0,
    kCertSearchEncryptAllowed = 1 << (kCertSearchShift + 4),
    kCertSearchEncryptDisallowed = 1 << (kCertSearchShift + 5),
    kCertSearchEncryptMask = ((kCertSearchEncryptAllowed) |
        (kCertSearchEncryptDisallowed)),
    kCertSearchDecryptIgnored = 0,
    kCertSearchDecryptAllowed = 1 << (kCertSearchShift + 6),
    kCertSearchDecryptDisallowed = 1 << (kCertSearchShift + 7),
    kCertSearchDecryptMask = ((kCertSearchDecryptAllowed) |
        (kCertSearchDecryptDisallowed)),
    kCertSearchWrapIgnored = 0,
    kCertSearchWrapAllowed = 1 << (kCertSearchShift + 8),
    kCertSearchWrapDisallowed = 1 << (kCertSearchShift + 9),
    kCertSearchWrapMask = ((kCertSearchWrapAllowed) |
        (kCertSearchWrapDisallowed)),
    kCertSearchUnwrapIgnored = 0,
    kCertSearchUnwrapAllowed = 1 << (kCertSearchShift + 10),
    kCertSearchUnwrapDisallowed = 1 << (kCertSearchShift + 11),
    kCertSearchUnwrapMask = ((kCertSearchUnwrapAllowed) |
        (kCertSearchUnwrapDisallowed)),
    kCertSearchPrivKeyRequired = 1 << (kCertSearchShift + 12),
    kCertSearchAny = 0
};
```

Discussion
The `KCCertSearchOptions` enumeration defines masks that you can use in the `options` parameter of the function `KCFindX509Certificates` (page 1109).

Certificate Usage Options

Represent a mask that specifies the usage options when adding certificates.

```
typedef UInt32 KCCertAddOptions;
enum {
    kSecOptionReserved = 0x000000FF,
    kCertUsageShift = 8,
    kCertUsageSigningAdd         = 1 << (kCertUsageShift + 0),
    kCertUsageSigningAskAndAdd = 1 << (kCertUsageShift + 1),
```

```
    kCertUsageVerifyAdd = 1 << (kCertUsageShift + 2),
    kCertUsageVerifyAskAndAdd = 1 << (kCertUsageShift + 3),
    kCertUsageEncryptAdd = 1 <<(kCertUsageShift + 4),
    kCertUsageEncryptAskAndAdd = 1 << (kCertUsageShift + 5),
    kCertUsageDecryptAdd = 1 << (kCertUsageShift + 6),
    kCertUsageDecryptAskAndAdd = 1 << (kCertUsageShift + 7),
    kCertUsageKeyExchAdd = 1 << (kCertUsageShift + 8),
    kCertUsageKeyExchAskAndAdd = 1 << (kCertUsageShift + 9),
    kCertUsageRootAdd = 1 << (kCertUsageShift + 10),
    kCertUsageRootAskAndAdd = 1 << (kCertUsageShift + 11),
    kCertUsageSSLAdd = 1 << (kCertUsageShift + 12),
    kCertUsageSSLAskAndAdd = 1 << (kCertUsageShift + 13),
    kCertUsageAllAdd = 0x7FFFFF00
};
```

Certificate Verification Criteria

Identify the verification criteria for use when displaying certificates to the user.

```
typedef UInt16 KCVerifyStopOn;
enum {
    kPolicyKCStopOn = 0,
    kNoneKCStopOn = 1,
    kFirstPassKCStopOn = 2,
    kFirstFailKCStopOn = 3
};
```

Constants

`kPolicyKCStopOn`
Indicates that the function `KCChooseCertificate` (page 1092) should use the trust policy options currently in effect.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kNoneKCStopOn`
Indicates that the function `KCChooseCertificate` (page 1092) completes after examining all available certificates.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kFirstPassKCStopOn`
Indicates that the function `KCChooseCertificate` (page 1092) when one certificate meeting the verification criteria is found.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kFirstFailKCStopOn`
Specifies that the function `KCChooseCertificate` (page 1092) completes when one certificate that fails to meet the verification criteria is found.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

Discussion
The `KCVerifyStopOn` enumeration defines constants your application can use to identify the verification criteria to use in selecting certificates. You can pass a constant of this type in the `stopOn` parameter of the function `KCChooseCertificate` (page 1092).

Default Internet Port Constant

Represent the internet ports available.

```
enum {
    kAnyPort = 0
};
```

Constants
`kAnyPort`
Indicates that any Internet port can be used.
Available in Mac OS X v10.1 and later.
Declared in `KeychainCore.h`.

Default Internet Protocol And Authentication Type Constants

Represent the internet protocols and authentication types available.

```
enum {
    kAnyProtocol = 0,
    kAnyAuthType = 0
};
```

Constants
`kAnyProtocol`
Indicates that any Internet protocol can be used.
Available in Mac OS X v10.1 and later.
Declared in `KeychainCore.h`.

`kAnyAuthType`
Indicates that any Internet authentication type can be used.
Available in Mac OS X v10.1 and later.
Declared in `KeychainCore.h`.

Keychain Events Constants

Identify keychain events.

```
typedef UInt16 KCEvent;
enum {
    kIdleKCEvent = 0,
    kLockKCEvent = 1,
    kUnlockKCEvent = 2,
    kAddKCEvent = 3,
    kDeleteKCEvent = 4,
    kUpdateKCEvent = 5,
    kPasswordChangedKCEvent = 6,
    kSystemKCEvent = 8,
    kDefaultChangedKCEvent = 9,
    kDataAccessKCEvent = 10,
    kKeychainListChangedKCEvent = 11
};
```

Constants

`kIdleKCEvent`
Indicates a `NULL` event.
Available in Mac OS X v10.0 and later.
Declared in `KeychainCore.h`.

`kLockKCEvent`
Indicates that the keychain was locked.
Available in Mac OS X v10.0 and later.
Declared in `KeychainCore.h`.

`kUnlockKCEvent`
Indicates that the keychain was unlocked.
Available in Mac OS X v10.0 and later.
Declared in `KeychainCore.h`.

`kAddKCEvent`
Indicates that an item was added to a keychain.
Available in Mac OS X v10.0 and later.
Declared in `KeychainCore.h`.

`kDeleteKCEvent`
Indicates that an item was deleted from a keychain.
Available in Mac OS X v10.0 and later.
Declared in `KeychainCore.h`.

`kUpdateKCEvent`
Indicates that a keychain item was updated.
Available in Mac OS X v10.0 and later.
Declared in `KeychainCore.h`.

`kPasswordChangedKCEvent`
Indicates that the identity of the keychain was changed.
Available in Mac OS X v10.0 and later.
Declared in `KeychainCore.h`.

`kSystemKCEvent`
Indicates that the keychain client can process events.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kDefaultChangedKCEvent`
Indicates that the default keychain has changed.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kDataAccessKCEvent`
Indicates that a process has called the function `KCGetData` (page 1111) to access a keychain item's data.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kKeychainListChangedKCEvent`
Indicates that the list of keychains has changed.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

Discussion
The `KCEvent` enumeration defines constants that identify the Keychain-related events your callback function wishes to receive. The Keychain Manager tests a mask that you pass in the `eventMask` parameter of the function `KCAddCallback` (page 1083) to determine the data transfer events your notification callback function wishes to receive. It passes these events in the `keychainEvent` parameter of the function `InvokeKCCallbackUPP` (page 1079). For a description of the Keychain-related event masks, see `Keychain Events Mask` (page 1142).

Keychain Events Mask

Identify a mask that you can use to set the keychain events you wish to receive.

```
typedef UInt16 KCEventMask;
enum {
    kIdleKCEventMask = 1 << kIdleKCEvent,
    kLockKCEventMask = 1 << kLockKCEvent,
    kUnlockKCEventMask = 1 << kUnlockKCEvent,
    kAddKCEventMask = 1 << kAddKCEvent,
    kDeleteKCEventMask = 1 << kDeleteKCEvent,
    kUpdateKCEventMask = 1 << kUpdateKCEvent,
    kPasswordChangedKCEventMask = 1 << kPasswordChangedKCEvent,
    kSystemEventKCEventMask = 1 << kSystemKCEvent,
    kDefaultChangedKCEventMask = 1 << kDefaultChangedKCEvent,
    kDataAccessKCEventMask = 1 << kDataAccessKCEvent,
    kEveryKCEventMask = 0xFFFF
};
```

Constants
`kIdleKCEventMask`
If the bit specified by this mask is set, your callback function will be invoked during a `NULL` event.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kLockKCEventMask`

If the bit specified by this mask is set, your callback function will be invoked when the keychain is locked.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kUnlockKCEventMask`

If the bit specified by this mask is set, your callback function will be invoked when the keychain is unlocked.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kAddKCEventMask`

If the bit specified by this mask is set, your callback function will be invoked when an item is added to the keychain.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kDeleteKCEventMask`

If the bit specified by this mask is set, your callback function will be invoked when an item is removed from the keychain.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kUpdateKCEventMask`

If the bit specified by this mask is set, your callback function will be invoked when a keychain item is updated.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kPasswordChangedKCEventMask`

If the bit specified by this mask is set, your callback function will be invoked when the keychain identity is changed.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kSystemEventKCEventMask`

If the bit specified by this mask is set, your callback function will be invoked when the keychain client processes an event.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kDefaultChangedKCEventMask`

If the bit specified by this mask is set, your callback function will be invoked when the default keychain is changed.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kDataAccessKCEventMask`

If the bit specified by this mask is set, your callback function will be invoked when a process calls the function `KCGetData` (page 1111).

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kEveryKCEventMask`

If the bit specified by this mask is set, your callback function will be invoked when any of the above Keychain-related events occur.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

Discussion

The `KCEventMask` enumeration defines masks your application can use to set Keychain event bits. You pass this mask in the `eventMask` parameter of the function `KCAddCallback` (page 1083), thereby defining the Keychain-related events to which your callback will respond. The Keychain Manager uses this mask to test which events your callback function will handle. It passes these events in the `keychainEvent` parameter of the function `InvokeKCCallbackUPP` (page 1079). For a description of Keychain-related events, see `Keychain Events Constants` (page 1140).

Keychain Item Attribute Tag Constants

Represent tags that identify keychain item attribute values.

```
enum {
    kClassKCItemAttr = 'clas',
    kCreationDateKCItemAttr = 'cdat',
    kModDateKCItemAttr = 'mdat',
    kDescriptionKCItemAttr = 'desc',
    kCommentKCItemAttr = 'icmt',
    kCreatorKCItemAttr = 'crtr',
    kTypeKCItemAttr = 'type',
    kScriptCodeKCItemAttr = 'scrp',
    kLabelKCItemAttr = 'labl',
    kInvisibleKCItemAttr = 'invi',
    kNegativeKCItemAttr = 'nega',
    kCustomIconKCItemAttr = 'cusi',
    kAccountKCItemAttr = 'acct',
    kServiceKCItemAttr = 'svce',
    kGenericKCItemAttr = 'gena',
    kSecurityDomainKCItemAttr = 'sdmn',
    kServerKCItemAttr = 'srvr',
    kAuthTypeKCItemAttr = 'atyp',
    kPortKCItemAttr = 'port',
    kPathKCItemAttr = 'path',
    kVolumeKCItemAttr = 'vlme',
    kAddressKCItemAttr = 'addr',
    kSignatureKCItemAttr = 'ssig',
    kProtocolKCItemAttr = 'ptcl',
    kSubjectKCItemAttr = 'subj',
    kCommonNameKCItemAttr = 'cn  ',
    kIssuerKCItemAttr = 'issu',
    kSerialNumberKCItemAttr = 'snbr',
    kEMailKCItemAttr = 'mail',
    kPublicKeyHashKCItemAttr = 'hpky',
    kIssuerURLKCItemAttr = 'iurl',
    kEncryptKCItemAttr = 'encr',
    kDecryptKCItemAttr = 'decr',
    kSignKCItemAttr = 'sign',
    kVerifyKCItemAttr = 'veri',
    kWrapKCItemAttr = 'wrap',
    kUnwrapKCItemAttr = 'unwr',
    kStartDateKCItemAttr = 'sdat',
    kEndDateKCItemAttr = 'edat'
};
typedef FourCharCode KCItemAttr;
```

Constants

`kClassKCItemAttr`

Identifies the class attribute. You use this tag to set or get a value of type `KCItemClass` that indicates whether the item is an AppleShare, Internet, or generic password, or a certificate. See "KCPublicKeyHash" (page 1135) for a description of possible values.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kCreationDateKCItemAttr`

Identifies the creation date attribute. You use this tag to set or get a value of type `UInt32` that indicates the date the item was created.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kModDateKCItemAttr`
Identifies the modification date attribute. You use this tag to set or get a value of type `UInt32` that indicates the last time the item was updated.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kDescriptionKCItemAttr`
Identifies the description attribute. You use this tag to set or get a value of type `string` that represents a user-visible string describing this item.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kCommentKCItemAttr`
Identifies the comment attribute. You use this tag to set or get a value of type `string` that represents a user-editable string containing comments for this item.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kCreatorKCItemAttr`
Identifies the creator attribute. You use this tag to set or get a value of type `OSType` that represents the item's creator.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kTypeKCItemAttr`
Identifies the type attribute. You use this tag to set or get a value of type `OSType` that represents the item's type.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kScriptCodeKCItemAttr`
Identifies the script code attribute. You use this tag to set or get a value of type `ScriptCode` that represents the script code for all strings.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kLabelKCItemAttr`
Identifies the label attribute. You use this tag to set or get a value of type `string` that represents a user-editable string containing the label for this item.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kInvisibleKCItemAttr`
Identifies the invisible attribute. You use this tag to set or get a value of type `Boolean` that indicates whether the item is invisible.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kNegativeKCItemAttr`

Identifies the negative attribute. You use this tag to set or get a value of type `Boolean` that indicates whether there is a valid password associated with this keychain item. This is useful if your application doesn't want a password for some particular service to be stored in the keychain, but prefers that it always be entered by the user. The item (typically invisible and with zero-length data) acts as a placeholder to say “don't use me.”

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kCustomIconKCItemAttr`

Identifies the custom icon attribute. You use this tag to set or get a value of type `Boolean` that indicates whether the item has an application-specific icon. To do this, you must also set the attribute value identified by the tag kTypeKCItemAttr to a file type for which there is a corresponding icon in the desktop database, and set the attribute value identified by the tag `kCreatorKCItemAttr` to an appropriate application creator type. If a custom icon corresponding to the item's type and creator can be found in the desktop database, it will be displayed by Keychain Access. Otherwise, default icons are used.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kAccountKCItemAttr`

Identifies the account attribute. You use this tag to set or get a value of type `Str63` that represents the user account. It also applies to generic and AppleShare passwords.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kServiceKCItemAttr`

Identifies the service attribute for a generic password. You use this tag to set or get a value of type `Str63` that represents the service.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kGenericKCItemAttr`

Identifies the generic attribute for a generic password. You use this tag to set or get a value of untyped bytes that represents a user-defined attribute.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kSecurityDomainKCItemAttr`

Identifies the security domain attribute for an internet password. You use this tag to set or get a value of type `Str63` that represents the Internet security domain.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kServerKCItemAttr`

Identifies the server attribute for an internet password. You use this tag to set or get a value of type `string` that represents the Internet server’s domain name or IP address.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kAuthTypeKCItemAttr`
Identifies the authentication type attribute for an internet password. You use this tag to set or get a value of type `KCAuthType` that represents the Internet authentication scheme.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kPortKCItemAttr`
Identifies the port attribute for an internet password. You use this tag to set or get a value of type `UInt16` that represents the Internet port.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kPathKCItemAttr`
Identifies the path attribute for an internet password. You use this tag to set or get a value of type `Str255` that represents the path.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kVolumeKCItemAttr`
Identifies the volume attribute for an AppleShare password. You use this tag to set or get a value of type `Str63` that represents the AppleShare volume.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kAddressKCItemAttr`
Identifies the address attribute for an AppleShare password. You use this tag to set or get a value of type `string` that represents the zone name, or the IP or domain name that represents the server address.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kSignatureKCItemAttr`
Identifies the server signature attribute for an AppleShare password. You use this tag to set or get a value of type `KCPublicKeyHash` (page 1135) that represents the server signature block.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kProtocolKCItemAttr`
Identifies the protocol attribute for an AppleShare or internet password. You use this tag to set or get a value of type `KCProtocolType` that represents the Internet protocol.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kSubjectKCItemAttr`
Identifies the subject attribute for a certificate. You use this tag to set or get `DER`-encoded data that represents the subject distinguished name.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kCommonNameKCItemAttr`
Identifies the common name attribute for a certificate. You use this tag to set or get a `UTF8`-encoded string that represents the common name.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kIssuerKCItemAttr`
Identifies the issuer attribute for a certificate. You use this tag to set or get a `DER`-encoded data that represents the issuer distinguished name.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kSerialNumberKCItemAttr`
Identifies the serial number attribute for a certificate. You use this tag to set or get a `DER`-encoded data that represents the serial number.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kEMailKCItemAttr`
Identifies the email attribute for a certificate. You use this tag to set or get an `ASCII`-encoded string that represents the issuer's email address.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kPublicKeyHashKCItemAttr`
Identifies the public key hash attribute for a certificate. You use this tag to set or get a value of type `KCPublicKeyHash` (page 1135) that represents the hash of the public key.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kIssuerURLKCItemAttr`
Identifies the issuer URL attribute for a certificate. You use this tag to set or get an `ASCII`-encoded string that represents the URL of the certificate issuer.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kEncryptKCItemAttr`
Identifies the encrypt attribute for a certificate or key. You use this tag to set or get a value of type `Boolean` that indicates whether the item can encrypt.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kDecryptKCItemAttr`
Identifies the decrypt attribute for a certificate or key. You use this tag to set or get a value of type `Boolean` that indicates whether the item can decrypt.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kSignKCItemAttr`
Identifies the sign attribute for a certificate or key. You use this tag to set or get a value of type `Boolean` that indicates whether the item can sign.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kVerifyKCItemAttr`
Identifies the verify attribute for a certificate or key. You use this tag to set or get a value of type `Boolean` that indicates whether the item can verify.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kWrapKCItemAttr`
Identifies the wrap attribute for a certificate or key. You use this tag to set or get a value of type `Boolean` that indicates whether the item can wrap.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kUnwrapKCItemAttr`
Identifies the unwrap attribute for a certificate or key. You use this tag to set or get a value of type `Boolean` that indicates whether the item can unwrap.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kStartDateKCItemAttr`
Identifies the start date attribute for a certificate or key. You use this tag to set or get a value of type `UInt32` that indicates the start date.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kEndDateKCItemAttr`
Identifies the end date attribute for a certificate or key. You use this tag to set or get a value of type `UInt32` that indicates the end date.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

Discussion
The `KCItemAttr` enumeration defines the Apple-defined tag constants that identify keychain item attribute values. Your application can use one of these tags in the `tag` field of the structure `KCAttribute` (page 1132) to identify the keychain item attribute value you wish to set or retrieve. Your application can create application-defined tags of type `KCAttrType` (page 1133).

Keychain Item Type Constants

Identify the type of keychain item.

```
enum {
    kCertificateKCItemClass = 'cert',
    kAppleSharePasswordKCItemClass = 'ashp',
    kInternetPasswordKCItemClass = 'inet',
    kGenericPasswordKCItemClass = 'genp'
};
typedef FourCharCode KCItemClass;
```

Constants

`kCertificateKCItemClass`
Specifies that the item is a digital certificate.
Available in Mac OS X v10.0 and later.
Declared in `KeychainCore.h`.

`kAppleSharePasswordKCItemClass`
Specifies that the item is an AppleShare password.
Available in Mac OS X v10.0 and later.
Declared in `KeychainCore.h`.

`kInternetPasswordKCItemClass`
Specifies that the item is an Internet password.
Available in Mac OS X v10.0 and later.
Declared in `KeychainCore.h`.

`kGenericPasswordKCItemClass`
Specifies that the item is a generic password.
Available in Mac OS X v10.0 and later.
Declared in `KeychainCore.h`.

Discussion

The `KCItemClass` enumeration defines constants your application can use to specify the type of the keychain item you wish to create, dispose, add, delete, update, copy, or locate. You pass a constant of this type to the functions `KCNewItem` (page 1120), `KCReleaseItem` (page 1121), `KCAddItem` (page 1090), `KCDeleteItem` (page 1096), `KCUpdateItem` (page 1129), `KCCopyItem` (page 1092), and `KCGetKeychain` (page 1113). You can also use these constants with the tag constant `kClassKCItemAttr`, described in `Keychain Item Attribute Tag Constants` (page 1144).

Keychain Protocol Type Constants

Identify the protocol to use in storing and retrieving Internet passwords.

```
enum {
    kKCProtocolTypeFTP = 'ftp ',
    kKCProtocolTypeFTPAccount = 'ftpa',
    kKCProtocolTypeHTTP = 'http',
    kKCProtocolTypeIRC = 'irc ',
    kKCProtocolTypeNNTP = 'nntp',
    kKCProtocolTypePOP3 = 'pop3',
    kKCProtocolTypeSMTP = 'smtp',
    kKCProtocolTypeSOCKS = 'sox ',
    kKCProtocolTypeIMAP = 'imap',
    kKCProtocolTypeLDAP = 'ldap',
    kKCProtocolTypeAppleTalk = 'atlk',
    kKCProtocolTypeAFP = 'afp ',
    kKCProtocolTypeTelnet = 'teln'
};
typedef FourCharCode KCProtocolType;
```

Constants

`kKCProtocolTypeFTP`
Specifies the File Transfer Protocol.
Available in Mac OS X v10.0 and later.
Declared in `KeychainCore.h`.

`kKCProtocolTypeFTPAccount`
Specifies the File Transfer Protocol Account.
Available in Mac OS X v10.0 and later.
Declared in `KeychainCore.h`.

`kKCProtocolTypeHTTP`
Specifies the HyperText Transfer Protocol.
Available in Mac OS X v10.0 and later.
Declared in `KeychainCore.h`.

`kKCProtocolTypeIRC`
Specifies the Internet Relay Channel Protocol.
Available in Mac OS X v10.0 and later.
Declared in `KeychainCore.h`.

`kKCProtocolTypeNNTP`
Specifies the Network News Transfer Protocol.
Available in Mac OS X v10.0 and later.
Declared in `KeychainCore.h`.

`kKCProtocolTypePOP3`
Specifies the Post Office 3 Protocol.
Available in Mac OS X v10.0 and later.
Declared in `KeychainCore.h`.

`kKCProtocolTypeSMTP`
Specifies the Simple Mail Transfer Protocol.
Available in Mac OS X v10.0 and later.
Declared in `KeychainCore.h`.

`kKCProtocolTypeSOCKS`
Specifies the Secure Proxy Server Protocol.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kKCProtocolTypeIMAP`
Specifies the Internet Message Access Protocol.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kKCProtocolTypeLDAP`
Specifies the Lightweight Directory Access Protocol.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kKCProtocolTypeAppleTalk`
Specifies the AppleTalk Protocol.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kKCProtocolTypeAFP`
Specifies the AppleTalk File Protocol.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kKCProtocolTypeTelnet`
Specifies the Telnet Protocol.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

Discussion
The `KCProtocolType` enumeration defines constants you can use to identify the type of authentication to use in storing and retrieving Internet passwords. You can pass a constant of this type in the `protocol` parameter of the functions `KCAddInternetPassword` (page 1086), `KCAddInternetPasswordWithPath` (page 1088), `KCFindInternetPassword` (page 1102), and `KCFindInternetPasswordWithPath` (page 1105).

Keychain Status Constants

Identify the keychain status.

```
enum {
    kUnlockStateKCStatus = 1,
    kRdPermKCStatus = 2,
    kWrPermKCStatus = 4
};
```

Constants
`kUnlockStateKCStatus`
If the bit specified by this mask is set (bit 0), the keychain is unlocked.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kRdPermKCStatus`

If the bit specified by this mask is set (bit 1), the keychain is unlocked with read permission.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

`kWrPermKCStatus`

If the bit specified by this mask is set (bit 2), the keychain is unlocked with write permission.

Available in Mac OS X v10.0 and later.

Declared in `KeychainCore.h`.

Result Codes

The most common result codes returned by Keychain Manager are listed below.

Result Code	Value	Description
`errKCNotAvailable`	-25291	Indicates that the Keychain Manager was not loaded. Available in Mac OS X v10.0 and later.
`errKCReadOnly`	-25292	Returned by the function `KCCopyItem` to indicate that the keychain file is read-only and cannot be edited. Available in Mac OS X v10.0 and later.
`errKCAuthFailed`	-25293	Returned by the function `KCUnlock` to indicate that the authentication failed (too many unsuccessful retries). Available in Mac OS X v10.0 and later.
`errKCNoSuchKeychain`	-25294	Returned by the functions `KCUnlock`, `KCSetDefaultKeychain`, `KCGetStatus`, and `KCGetIndKeychain` to indicate that the specified keychain was not found. Available in Mac OS X v10.0 and later.
`errKCInvalidKeychain`	-25295	Returned by the functions `KCUnlock`, `KCSetDefaultKeychain`, `KCGetStatus`, `KCGetKeychainName`, `KCChangeSettings`, and `KCCreateKeychain` to indicate that the keychain is not valid. Available in Mac OS X v10.0 and later.
`errKCDuplicateKeychain`	-25296	Returned by the function `KCCreateKeychain` to indicate that your application tried to create a keychain that already exists. Available in Mac OS X v10.0 and later.
`errKCDuplicateCallback`	-25297	Returned by the function `KCAddCallback` to indicate that your callback function was already registered. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
errKCInvalidCallback	-25298	Returned by the function KCRemoveCallback to indicate that the callback function was not previously registered. Available in Mac OS X v10.0 and later.
errKCDuplicateItem	-25299	Returned by the functions KCAddAppleSharePassword, KCAddInternetPassword, KCAddInternetPasswordWithPath, KCAddGenericPassword, and KCAddItem to indicate that you tried to add an existing keychain item to the keychain. Available in Mac OS X v10.0 and later.
errKCItemNotFound	-25300	Returned by the functions KCFindAppleSharePassword, KCFindInternetPassword, KCFindInternetPasswordWithPath, KCFindGenericPassword, KCFindNextItem, and KCFindFirstItem to indicate that no matching item was found. Available in Mac OS X v10.0 and later.
errKCBufferTooSmall	-25301	Returned by the functions KCFindAppleSharePassword, KCFindInternetPassword, KCFindInternetPasswordWithPath, KCFindGenericPassword, KCGetAttribute, KCGetData, and KCFindX509Certificates to indicate that the buffer was not large enough to contain the password data. Available in Mac OS X v10.0 and later.
errKCDataTooLarge	-25302	Returned by the functions KCAddAppleSharePassword, KCAddInternetPassword, KCAddInternetPasswordWithPath, KCAddGenericPassword, KCSetAttribute, and KCSetData to indicate that the data is too large. Available in Mac OS X v10.0 and later.
errKCNoSuchAttr	-25303	Returned by the functions KCSetAttribute, KCGetAttribute, and KCFindFirstItem to indicate that no such attribute exists. Available in Mac OS X v10.0 and later.
errKCInvalidItemRef	-25304	Returned by the functions KCSetAttribute, KCGetAttribute, KCSetData, KCGetData, KCAddItem, KCDeleteItem, KCUpdateItem, KCCopyItem, and KCGetKeychain to indicate that the keychain item reference is invalid. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
errKCInvalidSearchRef	-25305	Returned by the functions KCFindNextItem and KCReleaseSearch to indicate that the specified search reference is invalid. Available in Mac OS X v10.0 and later.
errKCNoSuchClass	-25306	Returned by the function KCCopyItem to indicate that the item class does not exist. Available in Mac OS X v10.0 and later.
errKCNoDefaultKeychain	-25307	Returned by the functions KCChangeSettings, KCSetDefaultKeychain, KCGetDefaultKeychain, KCAddAppleSharePassword, KCAddInternetPassword, KCAddInternetPasswordWithPath, KCAddGenericPassword, KCFindAppleSharePassword, KCFindInternetPassword, KCFindInternetPasswordWithPath, KCFindGenericPassword, KCCopyItem, KCAddItem, KCDeleteItem, KCUpdateItem, KCFindNextItem, KCFindFirstItem, and KCFindX509Certificates to indicate that there is no default keychain. Available in Mac OS X v10.0 and later.
errKCInteractionNotAllowed	-25308	Returned by the functions KCCreateKeychain, KCChangeSettings, KCUnlock, and KCGetData (the latter two only when the Unlock Dialog and Allow Access dialog boxes are needed) to indicate that there is no start-up keychain. Available in Mac OS X v10.0 and later.
errKCReadOnlyAttr	-25309	Returned by the function KCSetAttribute to indicate that the keychain item attribute is read-only. Available in Mac OS X v10.0 and later.
errKCWrongKCVersion	-25310	Indicates that the wrong version of Keychain Manager is installed to perform this operation. Available in Mac OS X v10.0 and later.
errKCKeySizeNotAllowed	-25311	Indicates that the key size is illegal. Available in Mac OS X v10.0 and later.
errKCNoStorageModule	-25312	Returned by functions that prompts the loading of the Keychain Manager to indicate that the storage module is not found. Available in Mac OS X v10.0 and later.
errKCNoCertificateModule	-25313	Returned when a function is required for a certificate and the certificate module is not found. Available in Mac OS X v10.0 and later.

Result Code	Value	Description
`errKCNoPolicyModule`	-25314	Returned when a function is required for a trust policy and the policy module is not found. Available in Mac OS X v10.0 and later.
`errKCInteractionRequired`	-25315	Returned by the function `KCUnlock` to indicate that user interaction is required for this operation. Available in Mac OS X v10.0 and later.
`errKCDataNotAvailable`	-25316	Indicates that the requested data is not available. Available in Mac OS X v10.0 and later.
`errKCDataNotModifiable`	-25317	Returned by the functions `KCSetData` and `KCGetData` to indicate that the data cannot be modified. Available in Mac OS X v10.0 and later.
`errKCCreateChainFailed`	-25318	Returned by the functions `KCChooseCertificate` and `KCFindX509Certificates` to indicate that the attempt to create a new keychain failed. Available in Mac OS X v10.0 and later.

List Manager Reference (Not Recommended)

Framework: Carbon/Carbon.h
Declared in Lists.h

Overview

Important: The List Manager is deprecated in Mac OS X version 10.5 and later. The replacement API is the Data Browser. For more information, see *Data Browser Programming Guide*.

In Mac OS 9 and earlier, the List Manager allowed applications to create, manipulate, and display scrolling lists of data items in a window. The List Manager was included in Carbon to facilitate the porting of legacy applications to Mac OS X. For Carbon applications, the Data Browser provides a more convenient way to present data for browsing and to create easily customized lists whose columns can be sorted, moved, and resized.

You should not use the List Manager in new application development.

Functions by Task

Accessing and Manipulating Cell Data

`LAddToCell` (page 1177) Deprecated in Mac OS X v10.5
Appends data to the data already contained in a cell.

`LClrCell` (page 1179) Deprecated in Mac OS X v10.5
Clears the data contained in a cell.

`LGetCell` (page 1183) Deprecated in Mac OS X v10.5
Copies a cell's data.

`LGetCellDataLocation` (page 1183) Deprecated in Mac OS X v10.5
Finds the memory location of cell data.

`LSetCell` (page 1190) Deprecated in Mac OS X v10.5
Changes the data contained in a cell.

Adding and Deleting Columns and Rows To and From a List

`LAddColumn` (page 1175) Deprecated in Mac OS X v10.5
Adds one or more columns to a list.

`LAddRow` (page 1176) Deprecated in Mac OS X v10.5
Adds one or more rows to a list.

`LDelColumn` (page 1180) Deprecated in Mac OS X v10.5
Deletes one or more columns from a list.

`LDelRow` (page 1181) Deprecated in Mac OS X v10.5
Deletes one or more rows from a list.

Changing the Size of Cells and Lists

`LCellSize` (page 1178) Deprecated in Mac OS X v10.5
Changes the size of cells in a list.

`LSize` (page 1193) Deprecated in Mac OS X v10.5
Changes the size of a list.

Creating and Disposing of Lists

`LDispose` (page 1181) Deprecated in Mac OS X v10.5
Disposes of the memory associated with a list.

`LNew` (page 1186) Deprecated in Mac OS X v10.5
Creates a new list in a window.

Creating and Managing Universal Procedure Pointers

`DisposeListClickLoopUPP` (page 1164) Deprecated in Mac OS X v10.5
Disposes of the universal procedure pointer (UPP) to a list click loop callback function.

`DisposeListDefUPP` (page 1165) Deprecated in Mac OS X v10.5
Disposes of the universal procedure pointer (UPP) to a list definition callback function.

`DisposeListSearchUPP` (page 1165) Deprecated in Mac OS X v10.5
Disposes of the universal procedure pointer (UPP) to a list search callback function.

`InvokeListClickLoopUPP` (page 1173) Deprecated in Mac OS X v10.5
Calls your list click loop callback function.

`InvokeListDefUPP` (page 1173) Deprecated in Mac OS X v10.5
Calls your list definition callback function.

`InvokeListSearchUPP` (page 1174) Deprecated in Mac OS X v10.5
Calls your list search callback function

`NewListClickLoopUPP` (page 1194) Deprecated in Mac OS X v10.5
Creates a new universal procedure pointer (UPP) to a list click loop callback function.

`NewListDefUPP` (page 1194) Deprecated in Mac OS X v10.5
Creates a new universal procedure pointer (UPP) to a list definition callback function.

`NewListSearchUPP` (page 1195) Deprecated in Mac OS X v10.5
Creates a new universal procedure pointer (UPP) to a list search callback function.

Determining or Changing the Selection

`LGetSelect` (page 1184) Deprecated in Mac OS X v10.5
Gets information about which cells are selected.

`LSetSelect` (page 1192) Deprecated in Mac OS X v10.5
Selects or deselects a cell.

Getting Information About Cells

`LLastClick` (page 1185) Deprecated in Mac OS X v10.5
Determines the coordinates of the last cell clicked in a particular list.

`LNextCell` (page 1187) Deprecated in Mac OS X v10.5
Finds the next cell in a given row, in a given column, or in an entire list.

`LRect` (page 1188) Deprecated in Mac OS X v10.5
Finds a rectangle that encloses a cell.

Modifying a List's Appearance

`LAutoScroll` (page 1178) Deprecated in Mac OS X v10.5
Scrolls a list so that the first selected cell is in the upper-left corner of the list's visible rectangle.

`LDraw` (page 1182) Deprecated in Mac OS X v10.5
Draws a cell in a list.

`LScroll` (page 1189) Deprecated in Mac OS X v10.5
Scrolls a list a specified number of rows and columns.

`LSetDrawingMode` (page 1191) Deprecated in Mac OS X v10.5
Changes the automatic drawing mode specified when creating a list.

Responding to Events Affecting Lists

`LActivate` (page 1175) Deprecated in Mac OS X v10.5
Activates or deactivates a list.

`LClick` (page 1179) Deprecated in Mac OS X v10.5
Processes a mouse-down event in a list.

`LUpdate` (page 1193) Deprecated in Mac OS X v10.5
Responds to an update event.

Searching a List for a Particular Item

`LSearch` (page 1190) Deprecated in Mac OS X v10.5
Finds a cell whose data matches data that you specify.

Miscellaneous

`CreateCustomList` (page 1163) Deprecated in Mac OS X v10.5

`GetListActive` (page 1165) Deprecated in Mac OS X v10.5

`GetListCellIndent` (page 1166) Deprecated in Mac OS X v10.5

`GetListCellSize` (page 1166) Deprecated in Mac OS X v10.5

`GetListClickLocation` (page 1167) Deprecated in Mac OS X v10.5

`GetListClickLoop` (page 1167) Deprecated in Mac OS X v10.5

`GetListClickTime` (page 1167) Deprecated in Mac OS X v10.5

`GetListDataBounds` (page 1168) Deprecated in Mac OS X v10.5

`GetListDataHandle` (page 1168) Deprecated in Mac OS X v10.5

`GetListDefinition` (page 1169) Deprecated in Mac OS X v10.5

`GetListFlags` (page 1169) Deprecated in Mac OS X v10.5

`GetListHorizontalScrollBar` (page 1169) Deprecated in Mac OS X v10.5

`GetListMouseLocation` (page 1170) Deprecated in Mac OS X v10.5

`GetListPort` (page 1170) Deprecated in Mac OS X v10.5

`GetListRefCon` (page 1171) Deprecated in Mac OS X v10.5

`GetListSelectionFlags` (page 1171) Deprecated in Mac OS X v10.5

`GetListUserHandle` (page 1171) Deprecated in Mac OS X v10.5

`GetListVerticalScrollBar` (page 1172) Deprecated in Mac OS X v10.5

GetListViewBounds (page 1172) Deprecated in Mac OS X v10.5

GetListVisibleCells (page 1173) Deprecated in Mac OS X v10.5

RegisterListDefinition (page 1195) Deprecated in Mac OS X v10.5

SetListCellIndent (page 1196) Deprecated in Mac OS X v10.5

SetListClickLoop (page 1196) Deprecated in Mac OS X v10.5

SetListClickTime (page 1197) Deprecated in Mac OS X v10.5

SetListFlags (page 1197) Deprecated in Mac OS X v10.5

SetListLastClick (page 1198) Deprecated in Mac OS X v10.5

SetListPort (page 1198) Deprecated in Mac OS X v10.5

SetListRefCon (page 1198) Deprecated in Mac OS X v10.5

SetListSelectionFlags (page 1199) Deprecated in Mac OS X v10.5

SetListUserHandle (page 1199) Deprecated in Mac OS X v10.5

SetListViewBounds (page 1200) Deprecated in Mac OS X v10.5

Functions

CreateCustomList

(Deprecated in Mac OS X v10.5.)

```
OSStatus CreateCustomList (
   const Rect *rView,
   const ListBounds *dataBounds,
   Point cellSize,
   const ListDefSpec *theSpec,
   WindowRef theWindow,
   Boolean drawIt,
   Boolean hasGrow,
   Boolean scrollHoriz,
   Boolean scrollVert,
   ListHandle *outList
);
```

Parameters

rView

dataBounds

cellSize

theSpec

theWindow

drawIt

hasGrow

scrollHoriz

scrollVert

outList

Return Value
A result code.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Lists.h`

DisposeListClickLoopUPP

Disposes of the universal procedure pointer (UPP) to a list click loop callback function. (Deprecated in Mac OS X v10.5.)

```
void DisposeListClickLoopUPP (
   ListClickLoopUPP userUPP
);
```

Parameters

userUPP

Discussion
See the `ListClickLoopProcPtr` (page 1200) callback for more information.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In
Lists.h

DisposeListDefUPP

Disposes of the universal procedure pointer (UPP) to a list definition callback function. (Deprecated in Mac OS X v10.5.)

```
void DisposeListDefUPP (
   ListDefUPP userUPP
);
```

Parameters
userUPP

Discussion
See the ListDefProcPtr (page 1201) callback for more information.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In
Lists.h

DisposeListSearchUPP

Disposes of the universal procedure pointer (UPP) to a list search callback function. (Deprecated in Mac OS X v10.5.)

```
void DisposeListSearchUPP (
   ListSearchUPP userUPP
);
```

Parameters
userUPP

Discussion
See the ListSearchProcPtr (page 1204) callback for more information.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In
Lists.h

GetListActive

(Deprecated in Mac OS X v10.5.)

```
Boolean GetListActive (
   ListHandle list
);
```

Parameters

list

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
Lists.h

GetListCellIndent

(Deprecated in Mac OS X v10.5.)

```
Point * GetListCellIndent (
   ListHandle list,
   Point *indent
);
```

Parameters

list

indent

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
Lists.h

GetListCellSize

(Deprecated in Mac OS X v10.5.)

```
Point * GetListCellSize (
   ListHandle list,
   Point *size
);
```

Parameters

list

size

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Lists.h`

GetListClickLocation

(Deprecated in Mac OS X v10.5.)

```
Point * GetListClickLocation (
   ListHandle list,
   Point *click
);
```

Parameters

list

click

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Lists.h`

GetListClickLoop

(Deprecated in Mac OS X v10.5.)

```
ListClickLoopUPP GetListClickLoop (
   ListHandle list
);
```

Parameters

list

Return Value
See the description of the `ListClickLoopUPP` data type.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Lists.h`

GetListClickTime

(Deprecated in Mac OS X v10.5.)

```
SInt32 GetListClickTime (
   ListHandle list
);
```

Parameters

list

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Lists.h`

GetListDataBounds

(Deprecated in Mac OS X v10.5.)

```
ListBounds * GetListDataBounds (
   ListHandle list,
   ListBounds *bounds
);
```

Parameters

list

bounds

Return Value
See the description of the `ListBounds` data type.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Lists.h`

GetListDataHandle

(Deprecated in Mac OS X v10.5.)

```
DataHandle GetListDataHandle (
   ListHandle list
);
```

Parameters

list

Return Value
See the description of the `DataHandle` data type.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Lists.h`

GetListDefinition

(Deprecated in Mac OS X v10.5.)

```
Handle GetListDefinition (
   ListHandle list
);
```

Parameters
list

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Lists.h`

GetListFlags

(Deprecated in Mac OS X v10.5.)

```
OptionBits GetListFlags (
   ListHandle list
);
```

Parameters
list

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Lists.h`

GetListHorizontalScrollBar

(Deprecated in Mac OS X v10.5.)

```
ControlRef GetListHorizontalScrollBar (
   ListHandle list
);
```

Parameters

list

Return Value
See the Control Manager documentation for a description of the `ControlRef` data type.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Lists.h`

GetListMouseLocation

(Deprecated in Mac OS X v10.5.)

```
Point * GetListMouseLocation (
   ListHandle list,
   Point *mouse
);
```

Parameters

list

mouse

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Lists.h`

GetListPort

(Deprecated in Mac OS X v10.5.)

```
CGrafPtr GetListPort (
   ListHandle list
);
```

Parameters

list

Return Value
See the QuickDraw Manager documentation for a description of the `CGrafPtr` data type.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Lists.h`

GetListRefCon

(Deprecated in Mac OS X v10.5.)

```
SInt32 GetListRefCon (
   ListHandle list
);
```

Parameters
list

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Lists.h`

GetListSelectionFlags

(Deprecated in Mac OS X v10.5.)

```
OptionBits GetListSelectionFlags (
   ListHandle list
);
```

Parameters
list

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Lists.h`

GetListUserHandle

(Deprecated in Mac OS X v10.5.)

```
Handle GetListUserHandle (
   ListHandle list
);
```

Parameters

list

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Lists.h`

GetListVerticalScrollBar

(Deprecated in Mac OS X v10.5.)

```
ControlRef GetListVerticalScrollBar (
   ListHandle list
);
```

Parameters

list

Return Value
See the Control Manager documentation for a description of the `ControlRef` data type.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Lists.h`

GetListViewBounds

(Deprecated in Mac OS X v10.5.)

```
Rect * GetListViewBounds (
   ListHandle list,
   Rect *view
);
```

Parameters

list

view

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Lists.h`

GetListVisibleCells

(Deprecated in Mac OS X v10.5.)

```
ListBounds * GetListVisibleCells (
   ListHandle list,
   ListBounds *visible
);
```

Parameters

list

visible

Return Value
See the description of the `ListBounds` data type.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Lists.h`

InvokeListClickLoopUPP

Calls your list click loop callback function. (Deprecated in Mac OS X v10.5.)

```
Boolean InvokeListClickLoopUPP (
   ListClickLoopUPP userUPP
);
```

Parameters

userUPP

Discussion
See the `ListClickLoopProcPtr` (page 1200) callback for more information.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In
`Lists.h`

InvokeListDefUPP

Calls your list definition callback function. (Deprecated in Mac OS X v10.5.)

```
void InvokeListDefUPP (
   short lMessage,
   Boolean lSelect,
   Rect *lRect,
   Cell lCell,
   short lDataOffset,
   short lDataLen,
   ListHandle lHandle,
   ListDefUPP userUPP
);
```

Parameters

lMessage

lSelect

lRect

lCell

lDataOffset

lDataLen

lHandle

userUPP

Discussion
See the `ListDefProcPtr` (page 1201) callback for more information.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In
`Lists.h`

InvokeListSearchUPP

Calls your list search callback function (Deprecated in Mac OS X v10.5.)

```
short InvokeListSearchUPP (
   Ptr aPtr,
   Ptr bPtr,
   short aLen,
   short bLen,
   ListSearchUPP userUPP
);
```

Parameters

aPtr

bPtr

aLen

bLen

userUPP

Return Value

Discussion
See the `ListSearchProcPtr` (page 1204) callback for more information.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.

Declared In
`Lists.h`

LActivate

Activates or deactivates a list. (Deprecated in Mac OS X v10.5.)

```
void LActivate (
   Boolean act,
   ListHandle lHandle
);
```

Parameters

act

Indicates whether the list should be activated. Specify `TRUE` to activate the list. Specify `FALSE` to deactivate the list.

lHandle

The list to be activated or deactivated.

Discussion
If a list is being deactivated, this function removes highlighting from selected cells and hides the scroll bars. If a list is being activated, the function highlights selected cells and shows the scroll bars.

This function has no effect on a list's size box, if one exists.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Lists.h`

LAddColumn

Adds one or more columns to a list. (Deprecated in Mac OS X v10.5.)

```
short LAddColumn (
   short count,
   short colNum,
   ListHandle lHandle
);
```

Parameters

count

The number of columns to add.

colNum

The column number of the first column to add.

lHandle
The list to which to add the columns.

Return Value
The column number of the first column added, which is equal to the value specified by the `colNum` parameter if that value is a valid column number. If the column number specified by `colNum` is not already in the list, then new last columns are added. The value returned by this function thus has significance only in this case.

Discussion
This function inserts columns starting at the column specified by the `colNum` parameter. If there is insufficient memory in the heap to add the new columns, this function may fail to add the new columns although it returns a positive function result. Be sure there is enough memory in the heap to allocate the new columns before calling `LAddColumn`.

Columns whose column numbers are initially greater than `colNum` have their column numbers increased by `count`.

If the automatic drawing mode is enabled and the columns added by the function are visible, then the list (including its scroll bars) is updated. New cells created by a call to this function are initially empty.

You may add columns to a list that does not yet have rows. The `dataBounds` field of the list record reflects that the list has columns, but you can only access cells when both rows and columns have been added.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Lists.h`

LAddRow

Adds one or more rows to a list. (Deprecated in Mac OS X v10.5.)

```
short LAddRow (
   short count,
   short rowNum,
   ListHandle lHandle
);
```

Parameters
count
The number of rows to add.

rowNum
The row number of the first row to add.

lHandle
The list to add the rows to.

Return Value
The row number of the first row added, which is equal to the value specified by the `rowNum` parameter if that value is a valid row number. If the row number specified by `rowNum` is not already in the list, then new last rows are added. The value returned by this function thus has significance only in this case.

Discussion
This function inserts rows starting at the row specified by the `rowNum` parameter. If there is insufficient memory in the heap to add the new rows, the function may fail to add the new rows although it returns a positive function result. Be sure there is enough memory in the heap to allocate the new rows before calling this function.

Rows whose row numbers are initially greater than `rowNum` have their row numbers increased by `count`.

If the automatic drawing mode is enabled and the rows added by this function are visible, then the list (including its scroll bars) is updated. New cells created by a call to this function are initially empty.

You may add rows to a list that does not yet have columns. The `dataBounds` field of the list record reflects that the list has rows, but you can only access cells when both rows and columns have been added.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Lists.h`

LAddToCell

Appends data to the data already contained in a cell. (Deprecated in Mac OS X v10.5.)

```
void LAddToCell (
   const void *dataPtr,
   short dataLen,
   Cell theCell,
   ListHandle lHandle
);
```

Parameters

`dataPtr`
A pointer to the data to be appended.

`dataLen`
The length in bytes of the data to be appended.

`theCell`
The coordinates of the cell to which the data should be appended.

`lHandle`
The list containing the cell given in the `theCell` parameter.

Discussion
If the cell coordinates specified by the parameter `theCell` are invalid, then this function does nothing.

If the data of a visible cell is changed and the automatic drawing mode is enabled, the function updates the list.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Lists.h`

LAutoScroll

Scrolls a list so that the first selected cell is in the upper-left corner of the list's visible rectangle. (Deprecated in Mac OS X v10.5.)

```
void LAutoScroll (
   ListHandle lHandle
);
```

Parameters

`lHandle`

The list to be scrolled.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Lists.h`

LCellSize

Changes the size of cells in a list. (Deprecated in Mac OS X v10.5.)

```
void LCellSize (
   Point cSize,
   ListHandle lHandle
);
```

Parameters

`cSize`

The new size of each cell in the list. This function sets the `cellSize` field of the list record of the list to the value of the `cSize` parameter. That is, the list's new cells will be of width `cSize.h` and of height `cSize.v`.

All cells in a list must be the same size.

`lHandle`

The list whose cells' size is being changed.

Discussion
The function updates the list's visible rectangle to contain cells of the specified size. However, it does not redraw any cells.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Lists.h`

LClick

Processes a mouse-down event in a list. (Deprecated in Mac OS X v10.5.)

```
Boolean LClick (
   Point pt,
   EventModifiers modifiers,
   ListHandle lHandle
);
```

Parameters

pt

The location in local coordinates of the mouse-down event. Your application can simply call `GlobalToLocal(myEvent.where)` and then pass `myEvent.where` in this parameter.

If the `pt` parameter specifies a portion of the list's visible rectangle, then cells are selected with an algorithm that depends on the list's selection flags and on the `modifiers` parameter. If the user drags the cursor above or below the list's visible rectangle and vertical autoscrolling is enabled, then the List Manager vertically autoscrolls the list. If the user drags the cursor to the right or the left of the list's visible rectangle and horizontal autoscrolling is enabled, then the List Manager horizontally autoscrolls the list.

If the `pt` parameter specifies a point within the list's scroll bar, then the List Manager calls the scroll bar's control definition function to track the cursor and it scrolls the list appropriately.

modifiers

An integer value corresponding to the `modifiers` field of the event record.

lHandle

The list in which the mouse-down event occurred.

Return Value

`TRUE` if the click was a double-click, or `FALSE` otherwise.

Discussion

The `LClick` function handles all user interaction until the user releases the mouse button.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Lists.h`

LClrCell

Clears the data contained in a cell. (Deprecated in Mac OS X v10.5.)

```
void LClrCell (
   Cell theCell,
   ListHandle lHandle
);
```

Parameters

theCell

The coordinates of the cell to be cleared.

lHandle
The list containing the cell given in the `theCell` parameter.

Discussion
If the cell coordinates specified by the `theCell` parameter are invalid, then the function does nothing.

If the data of a visible cell is cleared and the automatic drawing mode is enabled, the function updates the list.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Lists.h`

LDelColumn

Deletes one or more columns from a list. (Deprecated in Mac OS X v10.5.)

```
void LDelColumn (
   short count,
   short colNum,
   ListHandle lHandle
);
```

Parameters
count
The number of columns to delete, or 0 to delete all columns.
colNum
The column number of the first column to delete.
lHandle
The list from which to delete the columns.

Discussion
This function deletes columns starting at the column specified by the `colNum` parameter. If the column specified by `colNum` is invalid, then nothing is done.

Your application can quickly delete all columns from a list (and thus delete all cell data) simply by setting the `count` parameter to 0. The number of rows is left unchanged. Your application can achieve the same effect by setting the `colNum` parameter to `(**lHandle).dataBounds.left` and setting the `count` parameter to a value greater than `(**lHandle).dataBounds.right - (**lHandle).dataBounds.left`.

Columns whose column numbers are initially greater than `colNum` have their column numbers decreased by `count`.

If the automatic drawing mode is enabled and one or more of the columns deleted by this function are visible, then the list (including its scroll bars) is updated.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Lists.h`

LDelRow

Deletes one or more rows from a list. (Deprecated in Mac OS X v10.5.)

```
void LDelRow (
   short count,
   short rowNum,
   ListHandle lHandle
);
```

Parameters

`count`
The number of rows to delete, or 0 to delete all rows.

`rowNum`
The row number of the first row to delete.

`lHandle`
The list from which to delete the rows.

Discussion
This function deletes rows starting at the row specified by the `rowNum` parameter. If the row specified by `rowNum` is invalid, then nothing is done.

Your application can quickly delete all rows from a list (and thus delete all cell data) simply by setting the `count` parameter to 0. The number of columns is left unchanged. Your application can achieve the same effect by setting the `rowNum` parameter to `(**lHandle).dataBounds.top` and setting the `count` parameter to a value greater than `(**lHandle).dataBounds.bottom - (**lHandle).dataBounds.top`.

Rows whose row numbers are initially greater than `rowNum` have their row numbers decreased by `count`.

If the automatic drawing mode is enabled and one or more of the rows deleted by the function are visible, then the list (including its scroll bars) is updated.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Lists.h`

LDispose

Disposes of the memory associated with a list. (Deprecated in Mac OS X v10.5.)

```
void LDispose (
   ListHandle lHandle
);
```

Parameters

lHandle

The list to be disposed of.

Discussion

This function releases all memory allocated by the List Manager in creating a list. First, it issues a close request to the list definition function and calls the Control Manager function `DisposeControl` for the list's scroll bars (if any). The function then uses the Memory Manager to free the memory referenced by the cells field, then disposes of the list record itself.

Because it disposes of data associated with cells in your list, there is no need to clear the data from list cells or to delete individual rows and columns before calling this function.

This function does not dispose of any memory associated with a list that the List Manager has not allocated. In particular, it does not dispose of any memory referenced by the `userHandle` field of the list record. Your application is responsible for deallocating any memory it has allocated through the `userHandle` field before calling this function.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Lists.h`

LDraw

Draws a cell in a list. (Deprecated in Mac OS X v10.5.)

```
void LDraw (
   Cell theCell,
   ListHandle lHandle
);
```

Parameters

theCell

The cell to draw.

lHandle

The list containing the cell identified by the parameter `theCell`.

Discussion

The List Manager makes the list's graphics port the current port, sets the clipping region to the cell's rectangle, and calls the list definition function to draw the cell. It restores the clipping region and port before exiting.

Ordinarily, you should only need to use this function when the automatic drawing mode has been disabled.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In
`Lists.h`

LGetCell

Copies a cell's data. (Deprecated in Mac OS X v10.5.)

```
void LGetCell (
   void *dataPtr,
   short *dataLen,
   Cell theCell,
   ListHandle lHandle
);
```

Parameters

dataPtr
A pointer to the location to which to copy the cell's data.

dataLen
On input, a pointer to the maximum number of bytes to copy. On return, a pointer to the number of bytes actually copied.

theCell
The cell whose data is to be copied.

lHandle
The list containing the cell specified by the parameter `theCell`.

Discussion
If the cell data is longer than `dataLen`, only `dataLen` bytes are copied and the `dataLen` parameter is unchanged. If the cell data is shorter than `dataLen`, then the function sets `dataLen` to the length in bytes of the cell's data.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Lists.h`

LGetCellDataLocation

Finds the memory location of cell data. (Deprecated in Mac OS X v10.5.)

```
void LGetCellDataLocation (
   short *offset,
   short *len,
   Cell theCell,
   ListHandle lHandle
);
```

Parameters

offset

On return, a pointer to the offset of the cell's data, specified from the beginning of the data handle referenced by the `cells` field of the list record.

len

On return, a pointer to the length of the cell's data in bytes.

theCell

The cell whose data's location is sought.

lHandle

The list containing the cell specified by the parameter `theCell`.

Discussion

Your application can use this function to read cell data. The `cells` field of the list record contains a handle to a relocatable block used to store all cell data. When this function returns, the `offset` parameter contains the offset of the specified cell's data in this relocatable block, and the `len` parameter specifies the length in bytes of the cell's data. In other words, the first byte of cell data is located at `Ptr(ORD4(lHandle^^.cells^) + offset)`, and the last byte of cell data is located at `Ptr(ORD4(lHandle^^.cells^) + offset + len)`. Your application should not modify the contents of the `cells` field directly. To change a cell's data, use the `LSetCell` (page 1190) function or the `LAddToCell` (page 1177) function.

If the cell coordinates specified by the parameter `theCell` are invalid, then the function sets the `offset` and `len` parameters to –1.

This function is also available as the `LFind` function.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Lists.h`

LGetSelect

Gets information about which cells are selected. (Deprecated in Mac OS X v10.5.)

```
Boolean LGetSelect (
   Boolean next,
   Cell *theCell,
   ListHandle lHandle
);
```

Parameters

next

Indicates whether the function should check only the cell specified by the parameter `theCell`, or whether it should try to find the next selected cell. If `next` is `TRUE`, then the function searches the list for the first selected cell beginning at the cell specified by `theCell`. (In particular, it first checks cells in row `theCell.v`, and then cells in the next row, and so on.)

If `next` is `FALSE`, then the function checks only the cell specified by the parameter `theCell`.

theCell

On input, a pointer to the first cell whose selection status should be checked. If `next` is `TRUE`, then, on return this parameter is a pointer to the next selected cell greater than or equal to the cell specified on input. Otherwise, this parameter remains unchanged.

lHandle

The list in which the selection is being checked.

Return Value

`TRUE` if `next` is `TRUE` and the function finds a selected cell, or if `next` is `FALSE` and the cell specified by `theCell` is selected. If this function does not find a selected cell, `FALSE`.

Special Considerations

This function is contained in a resource of resource type `'PACK'`. Calling it could result in the loading of the package resource and the allocation of memory. Thus, your application should not call this function from within an interrupt, such as in a completion function or VBL task.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Lists.h`

LLastClick

Determines the coordinates of the last cell clicked in a particular list. (Deprecated in Mac OS X v10.5.)

```
Cell LLastClick (
   ListHandle lHandle
);
```

Parameters

lHandle

The list to be checked for the last cell clicked.

Return Value

The cell coordinates of the last cell clicked. If the user has not clicked a cell since the creation of the list, then both the `h` and `v` fields of the cell returned contain negative numbers. See the description of the `Cell` data type.

Discussion
Note that the last cell clicked is not necessarily the last cell selected. The user could Shift-click in one cell and then drag the cursor to select other cells.

Availability
Available in Mac OS X v10.0 and later.
Deprecated in Mac OS X v10.5.
Not available to 64-bit applications.

Declared In
`Lists.h`

LNew

Creates a new list in a window. (Deprecated in Mac OS X v10.5.)

```
ListHandle LNew (
   const Rect *rView,
   const ListBounds *dataBounds,
   Point cSize,
   short theProc,
   WindowRef theWindow,
   Boolean drawIt,
   Boolean hasGrow,
   Boolean scrollHoriz,
   Boolean scrollVert
);
```

Parameters

rView
A pointer to the rectangle in which to display the list, in local coordinates of the window specified by the `theWindow` parameter. This rectangle does not include the area to be taken up by the list's scroll bars.

dataBounds
A pointer to the initial data bounds for the list. By setting the `left` and `top` fields of this rectangle to (0,0) and the `right` and `bottom` fields to (`kMyInitialColumns`, `kMyInitialRows`), your application can create a list that has `kMyInitialColumns` columns and `kMyInitialRows` rows.

cSize
The size of each cell in the list. If your application specifies (0,0) and is using the default list definition function, the List Manager sets the `v` coordinate of this parameter to the sum of the ascent, descent, and leading of the current font, and it sets the `h` coordinate using the following formula:

```
cSize.h = (rView.right - rView.left) / (dataBounds.right - dataBounds.left).
```

theProc
The resource ID of the list definition function to use for the list. To use the default list definition function, which supports the display of unstyled text, specify a resource ID of 0.

theWindow
A pointer to the window in which to install the list.

drawIt

Indicates whether the List Manager should initially enable the automatic drawing mode. When the automatic drawing mode is enabled, the List Manager automatically redraws the list whenever a change is made to it. You can later change this setting using the `LSetDrawingMode` (page 1191) function. Your application should leave the automatic drawing mode disabled only for short periods of time when making changes to a list (by, for example, adding rows and columns).

hasGrow

Indicates whether the List Manager should leave room for a size box. The List Manager does not actually draw the grow icon. Usually, your application can draw it with the Window Manager's `DrawGrowIcon` function.

scrollHoriz

Indicates whether the list should contain a horizontal scroll bar. Specify `TRUE` if your list requires a horizontal scroll bar; specify `FALSE` otherwise.

scrollVert

Indicates whether the list should contain a vertical scroll bar. Specify `TRUE` if your list requires a vertical scroll bar; specify `FALSE` otherwise.

Return Value

A handle to the newly created list, or if the function cannot allocate the list, `NULL`. This might happen if there is not enough memory available or if the function cannot load the resource specified by the `theProc` parameter. If it returns successfully, then all of the fields of the list record referenced by the returned handle are correctly set. See the description of the `ListHandle` data type.

Discussion

If the list contains a horizontal or vertical scroll bar and the window specified by the parameter `theWindow` is visible, this function draws the scroll bar for the new list in the window just outside the list's visible rectangle specified by the `rView` parameter. This function does not, however, draw a 1-pixel border around the list's visible rectangle.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Lists.h`

LNextCell

Finds the next cell in a given row, in a given column, or in an entire list. (Deprecated in Mac OS X v10.5.)

```
Boolean LNextCell (
   Boolean hNext,
   Boolean vNext,
   Cell *theCell,
   ListHandle lHandle
);
```

Parameters

hNext

Indicates whether the function should check columns other than the current column. To get the next cell in a row, set this parameter to `TRUE` and set `vNext` to `FALSE`. The function then tries to find a cell whose coordinates are greater than those of the cell specified in `theCell` parameter but that is in the same row as `theCell`.

To get the next cell in a column, set this parameter to `FALSE` and set `vNext` to `TRUE`. The function then tries to find a cell whose coordinates are greater than those of the cell specified in `theCell` but that is in the same column as `theCell`.

To get the next cell in a list, set both this parameter and `vNext` to `TRUE`. This function then tries to find a cell whose coordinates are greater than those of the cell specified in the parameter `theCell`.

vNext

Indicates whether the function should check rows other than the current row. To get the next cell in a row, set this parameter to `FALSE` and set `hNext` to `TRUE`. The function then tries to find a cell whose coordinates are greater than those of the cell specified in `theCell` parameter but that is in the same row as `theCell`.

To get the next cell in a column, set this parameter to `TRUE` and set `hNext` to `FALSE`. The function then tries to find a cell whose coordinates are greater than those of the cell specified in `theCell` but that is in the same column as `theCell`.

To get the next cell in a list, set both this parameter and `hNext` to `TRUE`. This function then tries to find a cell whose coordinates are greater than those of the cell specified in the parameter `theCell`.

theCell

A pointer to the coordinates of the current cell. On return, a pointer to the next cell in the list, column or row being searched. If there are no more cells in the list, column or row, this parameter remains unchanged.

lHandle

The list in which to find the next cell.

Return Value

`TRUE`, if the function finds the next cell in the list, column or row being searched. `FALSE`, if the cell initially specified by `theCell` is the last in the row, column or list being searched. Also `FALSE` when both `hNext` and `vNext` are `FALSE`.

Availability

Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

Declared In

`Lists.h`

LRect

Finds a rectangle that encloses a cell. (Deprecated in Mac OS X v10.5.)

```
void LRect (
   Rect *cellRect,
   Cell theCell,
   ListHandle lHandle
);
```

Parameters

cellRect

On return, a pointer to the rectangle enclosing the cell, specified in local coordinates of the list's graphics port. This rectangle is not necessarily within the list's rectangle.

theCell

The cell for which an enclosing rectangle is sought. This function does not check whether the cell is actually contained within the list's visible rectangle.

If this parameter specifies cell coordinates not contained within the list, this function sets the `cellRect` parameter to (0,0,0,0).

lHandle

The list containing the cell specified by the parameter `theCell`.

Discussion
Because the List Manager automatically draws cells, few applications need to call this function directly.

Availability
Available in Mac OS X v10.0 and later.

Deprecated in Mac OS X v10.5.

Not available to 64-bit applications.

`Lists.h`

LScroll

Scrolls a list a specified number of rows and columns. (Deprecated in Mac OS X v10.5.)

```
void LScroll (
   short dCols,
   short dRows,
   ListHandle lHandle
);
```

Parameters

dCols

The number of columns to scroll. Specify a positive number to scroll down (that is, each cell moves up), and a negative number to scroll up.

dRows

The number of rows to scroll. Specify a positive number to scroll right (that is, each cell moves left), and a negative number to scroll left.

lHandle

The list to be scrolled.
